**15481.** Schneider, T.; Schneider, E.; Schneider, J.; Vierstraete, A.; Dumont, H.J. (2015): *Aeshna vercanica* sp. nov. from Iran with a new insight into the *Aeshna cyanea*-group (Odonata: Aeshnidae). *Odonatologica* 44(1/2): 81-106. (in English) ["*Aeshna vercanica* sp. nov. is described and illustrated. The male holotype and four male paratypes were collected on 15-vii-2013 in the Hyrcanian forest of the Alborz Mountains, Mazandaran province, northwestern Iran. A specimen collected on 29-vi-2002 in the Talysh Hills, Lankoran area, Azerbaijan, also belongs to the new species. In July 2014 the species, including females, was recorded again at the type locality and additionally ca 400 km further east in Golestan province. Males are similar to *Aeshna cyanea* in the structure of genitalia and terminalia but differ in head morphology, pterostigma length, colour pattern, and behaviour. Females have small abdominal blue or turquoise postero-median dorsal spots which are absent on S9 and S10, thin green antehumeral stripes, a less robust appearance than females of *A. cyanea*, and are more slender and longer. The range of *A. vercanica* sp. nov. covers the Hyrcanian forest along the southern margin of the Caspian

Sea. Analysis of the barcoding COI sequence of DNA confirmed that *A. vercanica* sp. nov. is separated from *A. cyanea* by a genetic distance of more than 4 %. The ITS gave a similar result. A haplotype map could not derive *A. vercanica* sp. nov. directly from *A. cyanea*. They are thus related but different species, and we suggest the common ancestor lived in pre-Pleistocene times. Analysis of *A. cyanea* specimens from across its range revealed two infraspecific clades. The western one extends from the Maghreb to Central Europe; the eastern one from the Caucasus to Eastern Europe, a common scenario for post-glacial invaders. A molecular comparison of the species pair *A. juncea* and *A. subarctica* showed these to be even more closely related than *A. cyanea* and *A. vercanica* sp. nov." **15483.** Schröter, A.; Seehausen, M.; Kunz, B.; Günther, A.; Schneider, T.; Jödicke, R. (2015): Update of the Odonata fauna of Georgia, southern Caucasus ecoregion. *Odonatologica* 44(3): 279-342. (in English) ["A total of 63 odonate taxa were recorded in Georgia during nationwide surveys in June–July 2014, and June and July–August 2015, corresponding to at least 85 % of the country's Odonata fauna. For the majority of species information from Georgia is provided in English language for the first time. *Selysiothemis nigra* is a new addition to the country's list. The occurrence of *Chalcolestes parvidens* is confirmed and previous records from Georgia listed as *Lestes viridis* are doubted and believed to pertain to *parvidens*. The second and third records only for *L. macrostigma* are presented. Individuals intermediate between *Enallagma cyathigerum* and *E. c. risi* are reported from Georgia for the first time. As to Georgian *Lestes virens*, the infraspecific taxonomy is critically discussed, with special reference to Central Asian forms described as ssp. *marikovskii*. It is recommended to avoid any further splitting into inadequately defined subspecies, as the variability of eastern forms from Central Europe towards Central Asia can be better described as clinal variation within the ssp. *vestalis*. In consequence, the name *marikovskii* is regarded as a junior synonym of *vestalis*: *Lestes virens vestalis* Rambur, 1842 = *L. virens marikovskii* Belyshev, 1961, syn. nov. The diversity of taxa within the *Calopteryx splendens* complex in the Caucasus region is considered to comprise in fact three subspecies in Georgia: ssp. *intermedia*, ssp. *tschaldirica*, and ssp. *mingrelica*. Despite of transition zones and hybridisation each subspecies represents in toto a spatially clearly delimited unit. In ssp.

*intermedia* androchrome females frequently occurred in the Kakheti region in the east of Georgia. The distinct female colour form 'feminalis' of *Calopteryx virgo* is illustrated for the first time and the availability of the name *Calopteryx virgo* var. *feminalis* Bartenev, 1910 is critically discussed. For a number of species the first information from Georgia is provided since their discovery over a century ago, such as *Coenagrion armatum*, *Aeshna serrata*, and *Onychogomphus assimilis*; for *Coenagrion lunulatum* and *C. scitulum* the first data since over 75 years are presented. *Coenagrion ponticum* was recorded throughout the country and at least at two sites found to reproduce syntopically with *C. puella*. New information is provided for the little known *Coenagrion vanbrinkae*, including a formerly unknown pink colour morph of reproductive females. The infraspecific taxonomy of *Ischnura elegans* is critically discussed, with special reference to the taxa *pontica* Schmidt, 1938 and *ebneri* Schmidt, 1938. In addition, new records of *Pyrrhosoma nymphula* and *Coenagrion pulchellum*, both being rare in the Caucasus region, are given. The presence of distinct *Gomphus schneiderii* in Georgia is confirmed as well as the continuous presence of *Gomphus ubadschii* at the Rioni River over 80 years after its description under the homonym »*Gomphus flavipes* var. *lineatus* var. n.«. *Onychogomphus assimilis* and *O. flexuosus* were found to be abundant in the eastern half of the country suggesting that Georgia is an important global stronghold for both threatened species. Males of *Caliaeschna microstigma* exhibited a distinctive tendency for reduced ante-humeral stripes, leaving only a small bluish patch at the posterior part in some males. Vital populations of *Libellula pontica*, endemic to the East Mediterranean, were found and the species is assumed to be well established in the Kakheti region in the East of the country." **15484.** Schütte, C.; Müller, O. (2015): Dorsolateral cuticular outgrowths in second stadium larvae of *Gomphus flavipes* (Odonata: Gomphidae). *International Journal of Odonatology* 18(1): 65-69. (in English) ["Second and third stadium larvae of *Gomphus flavipes* have dorsolateral cuticular outgrowths in the form of small basal tubercles bearing fan-shaped setae. These sensilla are aligned in two rows on each side of the thorax and abdomen. European species of *Gomphus*, *Onychogomphus* and *Ophiogomphus* that we examined lack these structures, having instead, at most, short hairlike setae in double rows. The fan-shaped setae of *G. flavipes* are present only in second and third stadia, apparently being lost later in larval development. We speculate that this loss might be due to changes in microhabitat or might be some kind of phylogenetic constraint." (Authors)] Address: Schütte, C., Bindestr. 16, D-38162 Weddel, Germany. **15485.** Segev, O.; Rodríguez, A.; Hauswaldt, S.; Hagemann, K.; Vences, M. (2015): Flatworms (*Schmidtea nova*) prey upon embryos of the common frog (*Rana temporaria*) and induce minor developmental acceleration. *Amphibia-Reptilia* 36(2): 155-163. (in English) ["Amphibians vary in

the degree of pre-metamorphic developmental plasticity in response to risk of predation. Changes in hatching time and development rate can increase egg or tadpole survival respectively by shortening the duration of the more vulnerable stages. The intensity of predator induced developmental response and its direction, i.e. delayed, accelerated, or none, varies considerably between amphibian and predator species. We surveyed freshly deposited clutches of the European common frog *Rana temporaria* in a population in Braunschweig, Germany and found that 62% (N = 20) of the clutches contained planarians (*Schmidtea nova*), with an average of  $3.94 \pm 0.79$  and a maximum of 13 planarians per clutch. A laboratory predation experiment confirmed that this planaria preys on *R. temporaria* eggs and early embryos. We further exposed freshly laid egg masses to either free, caged, or no planarians treatments using floating containers within a breeding pond where the two species co-occur. After 10 days exposure, embryos showed developmental stages 14-25 along the Gosner scale with statistically significant positive effects of both predator treatments. The observed effect was rather slight as predator-exposed individuals showed an increase by a single Gosner stage relative to those raised without planarians. The detected trend suggests that direct and indirect cues from flatworms, rarely considered as anuran predators, might induce a developmental response in *R. temporaria* early developmental stages." (Authors) The paper includes many references to Odonata.] Address: 1Institute of Evolution, University of Haifa, Mt. Carmel, Haifa 31905, Israel; 2Zoologisches Institut, Technische Universität Braunschweig, Mendelssohnstr. 4, D-38106 Braunschweig, Germany

**15486.** Seifert, N.; Koschkar, S.; Schmitz-Ornés, A. (2015): Diet of Baillon's Crakes *Zapornia pusilla*: Assessing differences in prey availability and consumption during the breeding season in the Senegal River Delta, West Africa. *Acta Ornithologica* 50(1): 69-84. (in English) ["The Baillon's Crake *Zapornia* (*Porzana*) *pusilla* is considered as one of the least known Rallidae species of the Palaearctic. Very little information exists about its ecological requirements and knowledge on diet refers to very few observations. Based on the analysis of faecal samples (N = 59) from two study sites in Djoudj National Park (NW Senegal), we describe the major diet components and examine how seasonal and environmental factors influence its dietary composition. All faeces contained remains of invertebrates. Coleopterans were the most frequent prey items with an occurrence in 95% of the samples. Other important food items were: Odonata (82%), Araneae (78%), Nematocera (59%), and Brachycera (44%). Remains of gecko skin were the only evidence for vertebrate prey. 75% of the faeces contained plant matter, especially seeds of *Eleocharis mutata* which constituted in some individuals > 90% of the sample content. Generalized linear models (GLMs) were used to assess whether occurrence of prey items was an effect of selection or environmental variation, considering both consumed items as well as prey availability. Sweep netting was used to provide an estimate of relative abundance of poten-

tial invertebrate prey. Despite pronounced seasonal changes in temperature and humidity, models revealed a lower influence of meteorological variables on prey composition and availability. Rather we found water level, date and site having the highest impact in the models. In contrast to decreasing diversity of available food items in the course of the season, diversity in the faeces remained constant indicating Baillon's Crakes prey less selectively when resources diminish. Furthermore, diversity of Baillon's Crakes' diet was lower at higher water levels, suggesting stronger selectivity when prey abundances are high as implied by positive relationships of several invertebrate groups with water level. Despite the rapidly declining water levels and decreasing abundances of e.g. Nematocera, Odonata and Mollusca in the course of the season, we found no clear shift from aquatic to a more terrestrial dominated composition of taxa in the birds' diet. This might be due to the selection of profitable prey such as araneans or molluscs but could also be explained by better accessibility due to physical changes in the habitats e.g. in the case of consumed Odonata and Saltatoria. High disintegration of invertebrates in the faeces rendered quantification of prey items impossible. Biomass estimates could support the assessment of specialization of the Baillon's Crakes as well as the detection of seasonal succession of the wetlands' biotic communities." **15489.** Shaffery, H.M.; Relyea, R.A. (2015): Predator-induced defenses in five species of larval *Ambystoma*. *Copeia* 103(3): 552-562. (in English) ["While predator-induced plasticity has been demonstrated in a wide range of organisms, relatively few data exist to compare differences among species. In studies of predator-induced plasticity in amphibians, larval anurans have been widely examined, but there are fewer data for larval salamanders. We sought to examine morphological and behavioural defenses in larvae of five species of *Ambystoma* salamanders. We raised five species of larval mole salamanders (*A. barbouri*, *A. gracile*, *A. laterale*, *A. maculatum*, *A. tigrinum*) in separate lab experiments and exposed them to predator cues from larval dragonflies (*Anax junius*). Salamanders did not vary in their refuge use during the experiment, but *A. gracile*, *A. laterale*, and *A. tigrinum* reduced their activity in the presence of predators early in development. Dragonfly (*Anax junius*) cues induced relatively few morphological changes across species: *A. barbouri* developed relatively large heads and deep tails, *A. gracile* and *A. laterale* developed relatively shorter heads, and *A. maculatum* developed relatively wider heads and shorter tails. Our results suggest that behavioural and morphological defenses in *Ambystoma* are highly variable among species and they appear to be less plastic than tadpoles and other salamander species." **15490.** Sharkey, C.R.; Partridge, J.C.; Roberts, N.W. (2015): Polarization sensitivity as a visual contrast enhancer in the Emperor dragonfly larva, *Anax imperator* (Leach, 1815). *Journal of Experimental Biology* 218: 3399-3405. (in English) ["Polarization sensitivity (PS) is a common feature of invertebrate visual systems. In insects, PS is well known for its use in several different visually guided behaviours, particularly navigation and habitat search. Adult dragonflies use the polarization of light to find water but a role for PS in aquatic dragonfly larvae, a stage that inhabits a very different photic environment to the adults, has not been investigated. The optomotor response of the larvae of the Emperor dragonfly, *Anax imperator*, was used to determine whether these larvae use PS to enhance visual contrast underwater. Two different light scattering conditions were used to surround the larval animals: a naturalistic horizontally polarized light field and non-naturalistic weakly polarized light field. In both cases these scattering light fields obscured moving intensity stimuli that provoke an optokinetic response in the

larvae. Animals were shown to track the movement of a square-wave grating more closely when it was viewed through the horizontally polarized light field, equivalent to a similar increase in tracking ability observed in response to an 8% increase in the intensity contrast of the stimuli. Our results suggest that larval PS enhances the intensity contrast of a visual scene under partially polarized lighting conditions that occur naturally in freshwater environments." **15491.** Sigutova, H.; Sigut, M.; Dolny, A. (2015): Intensive fish ponds as ecological traps for dragonflies: an imminent threat to the endangered species *Sympetrum depressiusculum* (Odonata: Libellulidae). *Journal of Insect Conservation* 19: 961-974. (in English) ["The concept of ecological traps, in which animals settle in low-quality habitats, is well-established. Dragonflies are a good model for investigating the effects of ecological traps because their habitat selection process can be directly observed. Unfortunately, most such studies focus on oviposition on artificial materials, such as car surfaces, gravestones, and plastic foils, which results in complete mortality of the clutch. It remains unclear to what extent intensive fish ponds, ubiquitous in the European agricultural landscape, act as ecological traps for some dragonfly species and how they influence their vulnerability. We investigated the effects of putative ecological traps on the threatened dragonfly *S. depressiusculum* and the common closely related species *S. sanguineum* in a Central European agricultural landscape. Observations of adult behaviour were used to parameterize GLMs examining the attractiveness of five fish ponds (three fish breeding and two intensive) to each species. We also counted exuviae at each pond as a measure of each species' survival. We used GLMMs to determine which factors affected selection of oviposition sites and the environmental factors resulting in ecological traps for each species. All five ponds were attractive to ovipositing pairs of both species, although they were largely unsuitable for subsequent development (four for *S. depressiusculum* and two for *S. sanguineum*). Our results provide evidence that intensive fish ponds act as ecological traps for both species. We believe that cutting of the vegetation surrounding trap habitats could be an effective way to decrease their attractiveness to a wide range of dragonfly species." (Authors)] Address: Šigutová, Hana, Department of Biology and Ecology/Institute of Environmental Technologies, Faculty of Science, University of Ostrava, Chittussiho 10, 710 00 Ostrava, Czech Republic, E-mail: sigutova.hanka@gmail.com

**15492.** Simaika, J.P.; Samways, M.J. (2015): Predicted range shifts of dragonflies over a wide elevation gradient in the southern hemisphere. *Freshwater Science* 34(83): 1133-1143. (in English) ["Human-induced climate change is among the greatest threats to biodiversity, especially when coupled with habitat destruction. For an already water-stressed country like South Africa, changes in temperature

and precipitation regimes, coupled with increasing water demands, are likely to lead to losses in biodiversity. Dragonflies are a well-studied surrogate taxon for aspects of freshwater biodiversity. We created species distribution models for 14 dragonfly species, and predicted the changes in species richness, extent of occurrence, and habitat suitability for the years 2050 and 2080 in South Africa, a poorly studied area for range-change predictions for insects. Model predictions for 2 different emissions scenarios suggest that at least 2 species will be lost from the area by 2050, and 3 by 2080. All are widespread Afrotropical species, but with narrow elevation ranges in South Africa. Only 1 species is predicted to benefit greatly from climate change. The remaining species are predicted to persist with reduced extents of occurrences at higher elevations. Most species we studied (12 of 14) thrive in artificial environments. Therefore, to a certain extent, loss in connectivity is unlikely to play a role for these species. However, the 2 stream specialists that occur in the area are particularly vulnerable because of loss of habitat. Species that currently occur farther north in southern Africa and South Africa also are likely to move southward in the future. Thus, species richness may not necessarily decrease, but replacement of species within communities will be significant." **15498.** Sniegula, S.; Golab, M.J.; Johansson, F. (2015): Time constraint effects on phenology and life history synchrony in a damselfly along a latitudinal gradient. *Oikos* 125: 414-423. (in English) ["In organisms with complex life cycles living in seasonal environments, the synchronisation of phenological events is important from the ecological and evolutionary perspectives. Life history transitions should be synchronised to a greater degree at northern latitudes. We quantified hatching and emergence timing and synchrony in the obligate univoltine damselfly *Lestes sponsa* along a latitudinal gradient covering its entire north-south range in Europe. In our first experiment, populations from different latitudes were grown in separate climate chambers simulating temperature and photoperiod conditions occurring at their sites of origin. Northern populations expressed early and high synchronous hatching and emergence, central populations intermediate, and southern populations late and low synchronous hatching and emergence. This pattern was expressed at both population and full-sibling family levels, indicating stronger selection for timing and synchronisation in the north compared to the south. In our second experiment, populations from all latitudes were reared in conditions simulating an average temperature and photoperiod over the latitudinal gradient. Interestingly, the pattern of timing and synchronisation was reversed with respect to latitude when compared to the pattern shown in the first experiment, indicating the importance of environmental factors in shaping phenological events. Our results indicate strong selection for timing and synchronisation of life history events at northern latitudes, caused by time constraints.

Our results also show that it is important to use as natural conditions as possible in experiments on life history shifts in organisms with complex life cycles in order to achieve a correct understanding of these shifts." **15499.** Soares, J.A.C.; Batista-Silva, V.F.; Boneto, D.D.; Bailly, D.; Abelha, M.C.F.; Oliveira, I.A. (2015): Assemblage of immature Odonata (Insecta, Anisoptera) in streams of the Mato Grosso do Sul State: spatial and temporal implications. *Iheringia Série Zoologia* 105(3): 325-332. (in English, with Portuguese summary) ["This study investigated the spatial and temporal distribution of Odonata, Anisoptera assemblages in two streams of the Iguatemi River basin, Água Boa and Perobão, which are under strong anthropogenic pressure. Samplings were carried out in both streams during the rainy (March to December 2008) and dry (June and September 2008) periods. The Mantel test was used to check the influence of spatial autocorrelation on the Odonata composition. Spatial and temporal variations in the composition were summarized by the Principal Coordinates Analysis (PCoA), using Mantel test residuals. Odonata assemblages were further evaluated for abundance, richness, diversity and evenness. The most representative genera in each stream and hydrological period were identified by the Indicator Value Method. The spatial-temporal variations in the attributes of the assemblages were assessed using two-factor analysis of variance. We collected 500 immature individuals of 23 genera and three families. Only the composition and abundance showed significant spatial differences, with the highest mean abundance found in the Perobão Stream. As for the temporal variation, abundance, richness and diversity were significantly higher in the dry period for the two streams. *Miathyria* and *Zenithoptera*, were the indicator genera of the Água Boa Stream and *Erythrodiplax*, *Libellula*, *Macrothemis*, *Progomphus* and *Tramea*, were the indicator genera of the Perobão Stream. The Odonata fauna was mainly influenced by the temporal dynamics of the rainfall regime, and the composition responded only to spatial variations represented by the streams." **15501.** Souza, A.M.; Fogaça, F.N.O.; Cunico, A.M.; Higuti, J. (2015): Does the habitat structure control the distribution

and diversity of the Odonatofauna? *Brazilian Journal of Biology* 75(3): 598-606. (in English, with Portuguese summary) ["The statement that the habitat complexity and structure govern the abundance and diversity of biological communities has been widely investigated. In this context, we assumed the hypothesis of habitat heterogeneity, that is, the higher habitat complexity leads to greater diversity of Odonata. In addition, we analyzed the influence of habitat structure on the distribution of this community, and evaluated the effects of abiotic variables. Odonata larvae were collected with sieves and by electrofishing in ten Neotropical streams belonging to the Pirapó River basin. Forty species of Odonata were registered, which were distributed in eight families, Libellulidae stood out with the highest richness. The high gamma diversity and distribution of Odonata were associated with habitat heterogeneity in these streams. However, the abiotic variables also seem to affect the distribution of Odonata species, in view of the impact of the land use in the vicinity of streams." **15502.** Staats, E.G. (2015): Emergent non-consumptive predator effects alter habitat colonization by dipteran prey. MSc thesis, Virginia Commonwealth University, Richmond, Virginia: IV + 22 pp. (in English) ["When ovipositing, prey organisms avoid habitat patches containing predator cues because predators consume, and negatively affect the fitness of their prey. Richness of predator species often enhances the strength of consumptive predator effects, but little is known about how multiple predators combined affect prey non-consumptively. We quantified dipteran colonization in aquatic mesocosms in response to varied predator richness. Multiple predator species combined reduced oviposition by *Culex* mosquitoes, chironomid midges, and the general colonizing dipteran community more than predicted by the effects of the independent predator species. Previous research which quantifies effects of multiple predators on prey as prey abundance, but does not measure consumption by predators, may be underestimating or overestimating the strength of effect by assuming equal colonization. Our findings enhance understanding of the ways predators influence abundances and distributions of their prey, and yields insight into the ways predators may non-consumptively affect prey by changing prey behaviour. Oviposition by the dipteran community was reduced 37% by *Celithemis eponina* ( $Z = 3.037$ ,  $df = 18$ ,  $P = 0.0024$ ), 31% by *Enallagma* spp. ( $Z = 2.570$ ,  $df = 18$ ,  $P = 0.0102$ ), and 27% by crayfish ( $Z = -2.189$ ,  $df = 18$ ,  $P = 0.0286$ ), relative to the predator-free control." *avian fauna*. Springer New York: 379-451. (in English) ["Prague, which is the capital of the Czech Republic, occupies 496 km<sup>2</sup> and has a population of 1.2 million people. This chapter describes six of the major invertebrate groups that occur in the city: Arachnida (spiders and related species)—504 species or 58 % of the national species; Coleoptera—Carabidae (ground beetles)—362 species found between 1790 and 2013 or 70 % of the national list of ground beetles; Lepidoptera (diurnal butterflies)—119 species or c. 74 % of the 161 species recorded in the country; Mollusca (molluscs)—146 species or 65 % of the national species; Odonata (dragonflies and damselflies) 41 species or > 50 % of the national species; and Orthoptera (grasshoppers and crickets)—44 species or 53 % of the national species. Prague is one of the European cities where mollusc fauna has been studied in detail. Altogether, 146 species of gastropods and bivalves were recorded here, which is 60 % of the Czech Republic's mollusc fauna. This surprisingly high species diversity reflects the geological and geomorphological diversity of the city that is crucial for molluscs. The gradient from eusynanthropic species over common assemblages of catholic species to the scattered network of nature reserves inhabited by rare and protected species is described. The highest concentration of non-native mollusc species in the Czech Republic was recorded only in Prague." **15505.** Stigge, H.A.; Bolek, M.G. (2015): The alteration of life history traits and increased success of *Halipegus eccentricus* through the use of a paratenic host: A comparative study. *Journal of Parasitology* 101(6): 658-665. (in English) [Oklahoma, USA; "Complex life cycles are a hallmark characteristic of many parasites; however, little is known about the process by which life cycles become more complex

through the addition of hosts. Paratenic hosts are present in the life cycles of several phylogenetically distinct groups of helminths; this suggests that they may play a key role during this process. This study examined the development of metacercariae of *Halipegus eccentricus* within intermediate microcrustacean and odonate (*Ischnura* sp.) paratenic hosts. Then a comparative approach was used to evaluate how life history traits of *H. eccentricus* within the anuran definitive hosts differ between metacercariae of the same age that developed within an intermediate ostracod host or a paratenic odonate host. The results of this study indicate that metacercariae of *H. eccentricus* do not grow at the same rate in different intermediate hosts, and significant differences exist in growth within intermediate and paratenic hosts. Individuals from odonate paratenic hosts always had larger bodies and suckers than those of metacercariae of the same age that develop within microcrustacean intermediate hosts. Furthermore, metacercariae from odonates were more successful in establishing and migrating in definitive anuran hosts. Last, individuals from paratenic hosts began reproducing earlier within anuran definitive hosts than age-matched worms that develop within the intermediate hosts. Collectively these results suggest that the variation in body and sucker sizes within odonate and microcrustacean hosts may carry over to the definitive host and in the case of *H. eccentricus* using the paratenic host increases transmission and alters other life history traits within definitive hosts. These results indicate that using a paratenic host can affect the success of parasites in subsequent hosts, and therefore these hosts may provide benefits other than just increasing transmission by bridging an ecological gap." **15506.** Stoks, R.; Debecker, S.; Dinh Van, K.; Janssens, L. (2015): Integrating ecology and evolution in aquatic toxicology: insights from damselflies. *Freshwater Science* 34(3): 1032-1039. (in English) ["Current legislation and ecological risk assessment fails to protect aquatic biodiversity at low levels of contaminants. We addressed 3 topics embedded in general stress ecology and evolutionary ecology that are relevant to arrive at a better evaluation of the risk of low contaminant levels in aquatic systems: 1) delayed effects of contaminants, 2) interactions between contaminants and biotic interactors, and 3) vulnerability to contaminants under global warming. We developed these topics by capitalizing on the key insights obtained using damselflies as model organisms. First, delayed contaminant effects on important fitness-related effects exist during the larval stage and after metamorphosis in the adult stage. Second, synergistic interactions of contaminants with bacteria and predation risk have been demonstrated, and we present advances in the mechanistic understanding of these synergisms with biotic interactors. Third, we illustrate the strength of assessing the effect of contaminants under global warming using a space-for-time substitution approach and the need to consider temperature extremes. These studies using damselflies as model organisms highlight the relevance of considering

contaminant effects after the exposure period and in the presence of natural stressors, such as predation risk and higher temperatures. They further highlight the need for spatially explicit risk-assessment and conservation tools. These insights are relevant for most aquatic taxa. Indeed most aquatic taxa have a complex life cycle, are strongly affected by predation risk and by warming, and show latitudinal gradients. Better integration of these topics in ecological risk assessment will be a major challenge for both scientists and policy makers, but of crucial importance to preserve aquatic biodiversity." **15507.** Suhling, F.; Suhling, I.; Richter, O. (2015): Temperature response of growth of larval dragonflies – an overview. *International Journal of Odonatology* 18(1): 15-20. (in English) ["We review the knowledge about the thermal reaction norms of larval growth in Odonata with a focus on the temperature response function. We re-analyze literature data and present our own results on growth rates of larvae of 14 species of Libellulidae reared at different temperatures. Temperature response curves (TRC) were fitted in order to estimate two relevant components of the thermal reaction, namely the optimum temperature for growth ( $T_{opt}$ ) and the increase of growth rate with temperature ( $Q_{10}$ ). We also examined what is known about the thermal minimum ( $T_{min}$ ) and the thermal maximum ( $T_{max}$ ) for growth to delimit the thermal ranges of odonates. All information indicates that larval growth is generally warm adapted, with species-specific variation of  $T_{opt}$  of 21–31°C,  $T_{min}$  of 8–12°C, and  $T_{max}$  of up to 44°C (the latter being the upper lethal limit, the true  $T_{max}$  for growth remains unknown). The values of  $Q_{10}$  distinguish some more specialized species, mostly with high  $T_{opt}$  and of tropical origin, and others being more thermal generalists, often being temperate species and/or from lotic habitats. We examine some biotic and abiotic factors affecting the temperature response of growth and we discuss the temperature response in the light of global warming." (Authors)] Address: Suhling F., Inst. **15508.** Swaegers, J.; Mergeay, J.; St-Martin, A.; De Knijf, G.; Larmuseau, M.; Stoks, R. (2015): Genetic signature of the colonisation dynamics along a coastal expansion front in the damselfly *Coenagrion scitulum*. *Ecological Entomology* 40(4): 353-361. (in English) ["1. Many insects are expanding their distribution range polewards as a result of climate change, which has been shown to be associated with founder effects leading to a reduction in genetic diversity and an increase in genetic differentiation. These spatial genetic patterns may arise from colonisation from a broad expansion front or a limited neighbourhood after a stepping stone model of dispersal. The temporal persistence of such founder effects are poorly understood, mainly because studies looking at the fine-scale initial temporal dynamics of the genetic signature of a range expansion are rare. 2. Us-

ing microsatellite markers, we performed a detailed spatio-temporal genetic analysis of the range expanding damselfly *Coenagrion scitulum* (Rambur) along a coastal axis during the first years after colonisation. 3. A decrease was in (private) allelic richness when going northwards along the coastline, which is consistent with a scenario of cumulative founder events. In spite of the spatiotemporal dynamics in the observation records of the species along the coastline, the spatial genetic data indicated a major contribution from the broad expansion front during the colonisation of the coastline rather than a stepping-stone colonisation process. 4. The fine-scale temporal dynamics of the range expansion indicated the absence of persistent founder effects and instead showed considerable temporal instability in genetic indices at the more northern edge populations. This may be explained by genetic immigration and admixture from the broad expansion front in this active disperser." (Authors)] Address: Swaegers, J., Deberiotstr. 32, 3000 Leuven, Belgium. **15509.** Swaegers, J.; Mergeay, J.; Van Geystelen, A.; Thery, L.; Larmuseau, M.; Stoks, R. (2015): Neutral and adaptive genomic signatures of rapid poleward range expansion. *Molecular Ecology* 24(24): 6163-6176. (in English) ["Many species are expanding their range polewards and this has been associated with rapid phenotypic change. Yet, it is unclear to what extent this reflects rapid genetic adaptation or neutral processes associated with range expansion, or selection linked to the new thermal conditions encountered. To disentangle these alternatives, we studied the genomic signature of range expansion in the damselfly *Coenagrion scitulum* using 4950 newly developed genomic SNPs and linked this to the rapidly evolved phenotypic differences between core and (newly established) edge populations. Most edge populations were genetically clearly differentiated from the core populations and all were differentiated from each other indicating independent range expansion events. In addition, evidence for genetic drift in the edge populations, and strong evidence for adaptive genetic variation in association with the range expansion was detected. We identified one SNP under consistent selection in four of the five edge populations and showed that the allele increasing in frequency is associated with increased flight performance. This indicates collateral, non-neutral evolutionary changes in independent edge populations driven by the range expansion process. We also detected a genomic signature of adaptation to the newly encountered thermal regimes, reflecting a pattern of countergradient variation. The latter signature was identified at a single SNP as well as in a set of covarying SNPs using a polygenic multilocus approach to detect selection. Overall, this study highlights how a strategic geographic sampling design and the integration of genomic, phenotypic and environmental data can identify and disentangle the neutral and adaptive processes that are simultaneously operating during range expansions." **15510.** Tabugo, S. R.; Casas, P.A.; Pareño, M.T.; Peñaredondo, M.A. (2015): Fluctuating asymmetry and developmental instability in the wings of *Neurothemis terminata* as bioindicator of stress. *Advances in Environmental Biology* 9(19): 10-17. (in English) [Background: Fluctuating asymmetry (FA) is a measure of differences between the right and the left half of bilaterally symmetrical organisms and is a useful trait to monitor developmental instability and ecological stress. Dragonflies are often used for biomonitoring purposes. In this study, analysis was done on eurytopic species *Neurothemis terminata*, since they are widely distributed and adapted to different environment. Analysis was based on the Procrustes method and makes comparison of FA indices of homologous points. Using landmark method for shape asymmetry, anatomical landmarks were used and analyzed using Symmetry and Asymmetry in Geometric Data (SAGE) program. Twenty-nine landmarks on the forewing and thirty five landmarks on the hind wing were tested for samples for all populations. Objective: This study assessed developmental stability in three populations of *Neurothemis terminata* using FA analysis on wings from different barangays (Tibanga, Tominobo and Tipanoy) in Iligan City, Mindanao, Philippines. Results: Procrustes ANOVA results showed variation and significant evidence of FA for all populations with relatively high FA for Tibanga population and no indication of Directional asymmetry (DA). Possible explanation for significant FA for populations mean varying level of stress as experienced by populations, suggesting that there is a significant variation between the left and right side of each individual induced by the genes and the environment. Conclusion: Significant FA and increase FA present inability of species to buffer stress in its developmental pathways hence, would mean developmental instability and have implications on species fitness, adaptation, quality of individuals and the level of endogenous and exogenous stress experienced by individuals or populations during development.] Address: Tabugo, Sharon, Dept Biol. Sciences, Mindanao State Univ. - Iligan Institute of Techonlogy, Iligan City, Philippines. E-mail: sharonrose0297@gmail.com

**15511.** Tajima, Y. (2015): Evolution of sperm displacement mechanism and genital morphology in the damselfly, *Ischnura asiatica*. Dissertation, Graduate School of Life and Environmental Sciences, the University of Tsukuba, Japan: 32 pp. (in English) ["In most species of Odonata, males physically displace rivals' sperm stored in the female sperm storage organs. During copulation, appendages on the male secondary genitalia enter the female sperm storage organs, and trap and remove sperm masses from previous matings. Considerable variations of male and female genitalia among species has been clarified, indicating that males of some species are able to displace all sperm in female sperm storage organs, while males of other species displace not all sperm stored in female sperm storage organs. The *Ischnura asiatica* male has a pair of appendages at the tip of his genitalia that are shorter than the length of the narrow duct from the bursa copulatrix to the spermatheca in the female. Although the males remove bursal sperm during the copulation, the males have no appendages that can remove

spermathecal sperm directly. However, reduction of the number of spermatozoa occurs both in the bursa copulatrix and in the spermatheca during copulation. An alternative mechanism for the reduction of the spermathecal sperm by the male was previously suggested. Females have mechano-receptive sensilla that communicate the presence of an egg to the muscles covering the sperm storage organs for the purpose of fertilization. Then, it is hypothesized that the penis head might mimic the movement of the egg, thus stimulating the sensilla to induce spermathecal sperm ejection by the female. In the present study, in order to clarify the mechanism of sperm removal by stimulating females' sensory system, an interrupted copulation experiment was conducted in the fields in order to examine the relationship between sperm reduction and the morphology of the male's genitalia. The extent of sperm reduction in the spermatheca increased with the width of the penis head. Thus, the hypothesis of the indirect sperm removal mechanism by stimulating females' sensory system was supported. The females might suffer costs such as a loss of genetic variety of their offspring when the sperm displacement is complete. Thus, a counter-adaptation might have evolved in the females to prevent complete sperm displacement. In order to clarify females' adaptation for spermathecal sperm removal, the inter-population and seasonal variation of morphological factors affecting sperm removal, such as the width of the penis head and the number of vaginal sensilla, were examined, and counter-adaptations with which to prevent sperm ejection such as a decrease in the number of vaginal sensilla and an increase in the size of the spermatheca were found in females. Thus, the genital morphology of females and the indirect sperm removal mechanism that makes use of females' sensory system in the reproductive organs were shaped by sexual conflict. Proposing this co-evolutionary scenario for male-female genitalia in *I. asiatica* made it possible to reveal the role of females in genital coevolution." (Author)] Address: not stated

**15512.** Takahashi, Y. (2015): Mechanisms and tests for geographic clines in genetic polymorphisms. *Population Ecology* 57(2): 355-362. (in English) ["A continuous spatial gradient in visible traits, which is called a cline, is a natural model system for quantifying the effects of selection and stochastic factors and their relative importance. Geographic clines in phenotypic traits also provide key insights into the evolutionary forces that lead to allopatric speciation in nature. Thus, the underlying mechanisms for establishing clines and their evolutionary consequences remain key topics in evolutionary biology. However, few experimental studies have confirmed the underlying mechanisms of geographic clines in morph/allele frequencies, probably because of the lack of understanding of the theoretical basis of geographic clines in polymorphisms and/or suitable comprehensive tests. Thus, I present a general review of the underlying mechanisms for establishing geographic clines in polymorphisms. I also provide a case study using the female dimorphic damselfly *Ischnura senegalensis* to illustrate a strategy that confirms the underlying mechanisms of geographic clines in morph frequencies. This review may

help to address geographic clines in other polymorphic systems, as well as contribute to a comprehensive understanding of geographic clines in quantitative traits, and thus, their evolutionary consequences in nature." **15514.** Tamm, J. (2015): Zur Verbreitung und Ökologie von *Cordulegaster bidentata* in Nordhessen mit besonderer Berücksichtigung ihrer Vorkommen auf Buntsandstein (Odonata: Cordulegastridae). *Libellula* 34(1/2): 27-58. (in German, with English summary) ["On distribution and ecology of *Cordulegaster bidentata* in Northern Hesse, Germany, with emphasis on its occurrence on Bunter Sandstone (Odonata: Cordulegastridae) – The distribution of *C. bidentata* (imagines) has been mapped in eight mountain areas of northern Hesse and in parts of the Rhön Mountains in Thüringen, Germany. It is evident that the species occurs very patchily within some of the geological formations studied. *C. bidentata* was rare in the Bunter sandstone areas mainly mapped, but quite common in adjacent Bunter sandstone areas mapped in former studies. Analysis shows that the species' rarity mainly is the result of both the most important natural habitat structures and man-made impact. The main factors are insufficient slope inclines and long stream drainages, and on the other hand, coniferous plantations and ponds dammed close to the springs. But it was remarkable that even habitats suitable for *C. bidentata* were in many cases not populated by the species. This suggests

that the subpopulations recently may live too far from each other to be able to regenerate locally extinct subpopulations from outside. The species is also distributed patchily on palaeozoic greywacke and limestone. Here again both natural and man-made factors are responsible. *C. bidentata* has not been found in the high Rhön and Rothaar mountains. This suggests that there are climate effects as well, like rainy cool summers or freezing of spring outflows in times of severe frost without snow cover. At least in Hesse, *C. bidentata* should be classified as "highly endangered species" because of its regional rarity and several negative impacts which are strong and increasing." **15517.** Termaat, T.; van Grunsven, R.A.H.; Plate, C.L.; van Strien, A.J. (2015): Strong recovery of dragonflies in recent decades in The Netherlands. *Freshwater Science* 34(3): 1094-1104. (in English) ["Many dragonfly species in The Netherlands declined in the 20th century because of acidification, eutrophication, and desiccation of lotic and lentic habitats and canalization of streams and rivers. These pressures peaked in the 1970s, when 26 of 65 native species had an unfavourable conservation status on the 1997 Dutch Red List. Since the 1980s, environmental regulations have led to improved water quality, and many habitat restoration

projects have been carried out. We used standardized monitoring data (1999-2013) and unstandardized observations (1991-2013) to investigate how dragonflies have changed in the last 20 y on a national scale. We compared trends of dragonfly species from different habitat types and with southern vs northern distribution in Europe. Dragonflies recovered strongly in The Netherlands in a period of ~20 y, probably because of recent habitat improvements. Lotic species have benefitted more than lentic species, and southern species have more positive trends than northern species, suggesting that climate change has contributed to the recovery. Dragonflies were resilient and able to quickly recover when their habitats were restored. Recovery has led to a better conservation status for many species. Unstandardized data delivered results consistent with those from monitoring data and had greater statistical power to detect trends because many more unstandardized data than standardized data were available. Thus, when the goal is to provide a general overview of changes in dragonflies, unstandardized data can outperform standardized abundance data. However, abundance data may deliver complementary information for individual species. Our results support the suitability of dragonflies as indicators of freshwater habitat condition, but they recover more strongly in The Netherlands than many other insects, possibly because of their higher dispersal abilities or different habitat requirements." **15518.** Theischinger, G.; Richards, S.J. (2015): The genus *Nososticta* Hagen (Odonata: Platynemididae) from the Papuan region with descriptions of ten new species group taxa. *Odonatologica* 44(1/2): 153-224. (in English) ["The males and, when available, females of ten new species and subspecies of *Nososticta* are described from the Papuan region. They are: *Nososticta caerulea* sp. nov. (♂ holotype: Papua New Guinea, Upper Sepik Basin, 09-vi-2010, ♀ described), *Nososticta finisterrae satisbona* ssp. nov. (♂ holotype: Papua New Guinea, Goodenough Island, 26-X-1953), *Nososticta interrupta* sp. nov. (♂ holotype: Indonesia, Papua Province, Kabupaten Asmat, Vriendschap R., 21-25-vii-2009), *Nososticta kaizei* sp. nov. (♂ holotype: Indonesia, Papua Province, Yapen Island, Ambaidiru village, 15-vii-2006, female described), *Nososticta azurosignata* sp. nov. (♂ holotype: Papua New Guinea, Survey Site 2, Sepik Basin, 25-ii-2010), *Nososticta longicauda* (male holotype: Papua New Guinea, Darai Plateau, 24-vii-2003), *Nososticta manuscola* sp. nov. (♂ holotype: Papua New Guinea, Manus Island, 23-ix-2011, female described), *Nososticta parafonticola* sp. nov. (♂ holotype: Papua New Guinea, Upper Sepik Basin, 10-ii-xii-2009, female described), *Nososticta tricolorata* sp. nov. (♂ holotype: Papua New Guinea, Upper Sepik Basin, 01-xii-2009) and *N. truncata* sp. nov. (♂ holotype: Papua New Guinea, Ivimka camp, Lakekamu, 15-xi-1996). In addition females of *N. africana* Schmidt, 1944, *N. aurantiaca* (Lieftinck, 1938) and *N. hiroakii* Sasamoto, 2007 are described and the morphology and variability of a number of additional species is discussed. Diagnostic charac-

ters of the available genders are illustrated, habitat conditions are given and their affinities are discussed. Live photos of selected species are presented. Keys to the males of all *Nososticta* species known from New Guinea and the Solomon Islands, and to the described females from this region are included. *Nososticta lorentzi* Lieftinck, 1938 is considered a synonym of *N. nigrifrons* (Ris, 1913) (syn. nov.)." **15520.** Therry, L., Bonte, D., Stoks, R. (2015): Higher investment in flight morphology does not trade off with fecundity estimates in a poleward range-expanding damselfly. *Ecological Entomology* 40(2): 133-142. (in English) ["(1.) Evolutionary increases in dispersal-related traits are frequently documented during range expansions. Investment in flight-related traits is energetically costly and a trade-off with fecundity may be expected during range expansion. (2.) However, in contrast to wing-dimorphic species, this trade-off is not general in wing-monomorphic species. In the absence of a dispersal-fecundity trade-off, an increased investment in clutch size at the expansion front is expected possibly at a cost of reduced offspring size. (3.) The study evaluated investment in female flight morphology and fecundity-related traits (clutch size, hatchling size) and potential trade-offs among these traits in replicated populations of the poleward range-expanding damselfly *Coenagrion scitulum*. (4.) Females at the expansion front had a higher relative thorax length, indicating an increased investment in flight; this can be explained by spatial sorting of dispersal ability or in situ natural selection at the expansion front. Edge females produced larger hatchlings, however, this pattern was totally driven by the population-specific thermal larval regimes and could not be attributed to the range expansion per se. By contrast, clutch sizes did not differ between core and edge populations. There was no signal of a dispersal-fecundity trade-off either for a trade-off between clutch size and hatchling size. (5.) These results indicate that evolution of a higher dispersal ability at the expansion front of *C. scitulum* does not trade off with investment in fecundity, hence a dispersal-fecundity trade-off is unlikely to

slow down range expansion of this species." (Authors)] Address: Therry, L., Laboratory of Aquatic Ecology, Evolution and Conservation, KU Leuven, Deberiotstraat 32, 3000 Leuven, Belgium. E-mail: Lieven.Therry@bio.kuleuven.be

**15521.** Tichanek, F.; Tropek, R. (2015): Conservation value of post-mining headwaters: drainage channels at a lignite spoil heap harbour threatened stream dragonflies. *Journal of Insect Conservation* 19: 975-985. (in English) ["Headwaters and small streams are crucial components of riverine systems, harbouring many highly specialized and unique invertebrate species. Unfortunately, the overwhelming majority of the Central European lowland headwaters are channeled, eutrophicated and/or polluted, and many related species have become critically endangered. Artificial streams established to drain some post-mining sites supplement a network of headwaters and generally do not suffer from agricultural pollution. Nevertheless, the biodiversity and conservation potential of the streams at post-mining sites has never been evaluated. We studied the biodiversity of Odonata at 53 sections (30 m) of an extraordinarily dense system of drainage ditches at a large lignite spoil heap in the Czech Republic. We recorded 22 dragonfly species, of which eight are threatened according to the national Red List. Moreover, four of them are closely associated with the endangered environment of small streams. Overall diversity was generally low at very tiny and/or narrowed streams and was also strongly reduced by high water velocity, high bankside inclination and dominance of expansive common reeds. Sufficient cover of rather shallow sediment layers strongly supports the studied diversity indicators. We thus conclude that post-mining streams in drainage ditches could have a strong potential to offer secondary habitats for threatened headwater biodiversity. However, intermittent reed suppression and the establishment of gently sloping banks and a structured stream bottom are necessary measures for maximizing post-mining stream conservation." (2015): Fourier transform infrared spectroscopy and imaging of dragonfly, damselfly and cicada wing membranes. *Spectroscopy Europe* 27(4): 15-18. (in English) ["Conclusion: Insect wings possess some remarkable properties, enabling them to thrive in challenging environments. Often, a combination of nano- and micro-structured topography, with chemical heterogeneity on the micron scale, provides these structures with efficient superhydrophobic, self-cleaning and antibacterial capabilities. Their complex surfaces are providing inspiration for the design of novel coatings and surface structures that can mimic these beneficial properties. High spatial resolution FT-IR spectroscopy and imaging, when combined with other techniques such as SEM and GC-MS, provide unique insights into the complex

chemical patterning that contributes to this functionality. Further developments in FT-IR imaging, such as 3D infrared tomography and scanning near-field nano spectroscopy have the potential to add a further dimension to the chemical and physical information that is enabling us to obtain a greater understanding of these natural surfaces. These techniques can also continue to be applied to the study of manmade material surfaces that attempt to emulate the properties of their biological templates." (2015): Nanoindentation mechanical properties and structural biomimetic models of three species of insects wings. *Journal of Wuhan University of Technology-Mater. Sci. Ed.* 30(4): 831-839. (in English) ["Mimicking insect flights were used to design and develop new engineering materials. Although extensive research was done to study various aspects of flying insects. Because the detailed mechanics and underlying principles involved in insect flights remain largely unknown. A systematic study was carried on insect flights by using a combination of several advanced techniques to develop new models for the simulation and analysis of the wing membrane and veins of three types of insect wings, namely dragonfly (*Pantala flavescens* Fabricius), honeybee (*Apis cerana cerana* Fabricius) and fly (*Sarcophaga carnaria* Linnaeus). In order to gain insights into the flight mechanics of insects, reverse engineering methods were used to establish three-dimensional geometrical models of the membranous wings, so we can make a comparative analysis. Then nano-mechanical test of the three insect wing membranes was performed to provide experimental parameter values for mechanical models in terms of nano-hardness and elastic modulus. Finally, a computational model was established by using the finite element analysis (ANSYS) to analyze and compare the wings under a variety of simplified load regimes that are concentrated force, uniform line-load and a torque. This work opened up the possibility towards developing an engineering basis for the biomimetic design of thin solid films and 2D advanced engineering composite materials." **15524.** Torres-Cambas, Y.; Lorenzo-Carballa, M.O.; Ferreira, S.; Cordero-Rivera, A. (2015): *Hypolestes hatuey* sp. nov.: a new species of the enigmatic genus *Hypolestes* (Odonata, Hypolestidae) from Hispaniola. *Zootaxa* 4000(2): 207-226. (in English) ["Both sexes of *Hypolestes hatuey* Torres-Cambas, sp. nov. (Odonata: Zygoptera: Hypolestidae) from Hispaniola are described and illustrated here. This newly described species differs from *H. trinitatis* and *H. clara*, the other two species within the genus, by the morphology of the genital ligula and male cerci. Females of *H.*

*hatuey* sp. nov. differ from *H. clara* by the shape of the female antehumeral stripe and wing venation. Morphological distinctiveness in males is supported by genetic differences in the 16S mitochondrial gene. Following the categories and criteria of the IUCN Red List of Threatened Species, we suggest this species should be listed as Data Deficient (DD), given that available data on its distribution are too limited to assess its risk of extinction." (Authors)] Address: Torres-Cambas, Y., Depto Biol., Fac. Cien. Nat., Univ. de Oriente. Patricio Lumumba s/n, Santiago de Cuba, Cuba. E-mail: ytorres@cnt.uo.edu.cu, yusdiel.torres@gmail.com

**15525.** Torres-Cambas, Y.; Trapero-Quintana, A.D.; Lorenzo-Carballa, M.O.; Newell, D.; Suriel, C.; Cordero-Rivera, A. (2015): An update on the distribution of threatened odonate species from the Greater Antilles. *International Journal of Odonatology* 18(2): 89-104. (in English) ["The Antilles harbour several island endemic odonate species, including some palaeoendemics, within a relatively small and anthropized area. Such attributes give this archipelago a special significance for the conservation of Odonata in the Neotropics. However, despite the importance of these islands, inadequately surveyed regions persist, mainly in the Greater Antilles, and there is not enough information to set IUCN threat categories for eight species supposed to be at risk, which are currently classified as data deficient (DD). To update the distribution of endangered (EN), vulnerable (VU) and DD species, we conducted a series of field surveys in Dominican Republic, Jamaica and Cuba, and compiled data from literature, museum collections as well as personal communications. We sampled a total of 37 species, including *Microneura caligata*, *Phyllestes ethelae* and *Hypolestes clara* (EN); *H. trinitatis* (VU); and *Diceratobasis macrogaster*, *Neoneura maria* and *Protoneura capillaris* (DD). We provide new locality records for *M. caligata*, *N. carnatica* (DD), *N. maria* (DD), *P. capillaris*, *H. clara*, *H. trinitatis* and *Erythrodiplax bromeliicola* (DD). According to our results, we suggest changing the category of *D. macrogaster*, *D. melanogaster*, *N. carnatica*, *N. maria* and *P. capillaris* to VU." **15527.** Toth, Z. (2015): Context-dependent plastic response during egg-laying in a widespread newt species. *PLoS ONE*

10(8): e0136044. doi:10.1371/journal.pone.0136044: 18 pp. (in English) ["Previous research on predator-induced phenotypic plasticity mostly focused on responses in morphology, developmental time and/or behaviour during early life stages, but the potential significance of anticipatory parental responses has been investigated less often. In this study I examined behavioural and maternal responses of gravid female smooth newts, *Lissotriton vulgaris*, in the presence of chemical cues originating from invertebrate predators, *Acilius sulcatus* water beetles and *Aeshna cyanea* dragonfly larvae. More specifically, I tested the extent of oviposition preference, plasticity in egg-wrapping behaviour and plasticity in egg size when females had the possibility to lay eggs at oviposition sites with and without predator cues during overnight trials. I found that individuals did not avoid laying eggs in the environment with predator cues; however, individuals that deposited eggs into both environments adjusted the size of the laid eggs to the perceived environment. Females deposited larger eggs earlier in the season but egg size decreased with time in the absence of predator cues, whereas individuals laid eggs of average size throughout the investigated reproductive period when such cues were present. Also, egg size was found to be positively related to hatching success. Individuals did not adjust their wrapping behaviour to the presence of predator cues, but females differed in the extent of egg-wrapping between ponds. Females' body mass and tail depth were also different between ponds, whereas their body size was positively associated with egg size. According to these results, female smooth newts have the potential to exhibit activational plasticity and invest differently into eggs depending on temporal and environmental factors. Such an anticipatory response may contribute to the success of this caudate species under a wide range of predator regimes at its natural breeding habitats." **15528.** Touchon, J.C.; Vonesh, J.R. (2015): Variation in abundance and efficacy of tadpole predators in a Neotropical pond community. *Journal of Herpetology* 50(1): 113-119. (in English, with Spanish summary) ["Variation in predation risk plays an important role in shaping prey behaviour, morphology, life history, population dynamics, and community structure in freshwater systems. Anuran larvae are important prey in freshwater communities and spatiotemporal variation in risk can arise from changes in the number and identity of predators; however, our understanding of variation in abundance, identity, and foraging rates for natural predator assemblages in tropical pond communities is limited. We surveyed ponds near Gamboa, Panama in 2004 and 2010 to estimate variation in predator communities of tadpoles over space and time. We also conducted short-term predation trials with the 10 most common predators using hatchling tadpoles of two widespread Neotropical frog species, Red-Eyed Treefrogs (*Agalychnis callidryas*) and Pantless Treefrogs (*Dendropsophus ebraccatus*). Predator abundance varied nearly threefold across ponds within a single year and as much as 19-fold within a pond across

years. Dominant taxa also varied, with backswimmers (Notonectidae), poeciliid fish, or libellulid dragonfly naiads being the most common depending upon pond and year. Predation trials revealed that prey-specific predation rates differed among predator taxa. Some presumed predators did not consume hatchlings, whereas others consumed >90% of prey. The smaller *D. ebraccatus* hatchlings generally experienced higher predation rates; however, large invertebrate predators like aeshnid dragonfly naiads, giant water bugs, and fishing spiders consumed more *A. callidryas*. These results suggest that strong but variable larval-stage risk may be an important selective factor shaping tadpole communities and phenotypes in Neotropical ponds." **15529.** Trockur, B.; Lingenfelder, U. (2015): Die FFH-Libellenarten im Saarland (Insecta: Odonata). *Abh. DELATTINIA* 40: 77-136. (in German, with English and French summaries) ["There are four dragonfly species in the Saarland listed in annex II and/or IV of the EU Habitats Directive. An overall view for each of the species is given concerning distribution and status, based on new data from the years 2012 until 2014. Changes in population size and threatening factors for the species and their occurrence are discussed. The situation for *Coenagrion mercuriale* is critical. Actually only three populations are known, all with low abundances. Both populations in the floodplain of the river Blies are severely threatened by intensive use and inappropriate measures of preservation applied. The third population of the species near Heinitz seems to be stable, but the core of the population depends on right preservation and is therefore indirectly and latently endangered. *Ophiogomphus cecilia* occurs especially in the southeast of the Saarland and clearly shows positive trends. The river Blies is the most important locality for recording. It contains in the meantime a stable population. But the situation at other actual or former localities is not clear. The number of localities of *Leucorrhinia caudalis* is more or less almost constantly increasing in the last years, and thus a positive trend can be attested. The species has an abundant and stable population near Heinitz with increasing abundance, while all other localities in the Saarland show instable conditions in population size. Trends are even negative in some places. *Leucorrhinia pectoralis* has been recorded only twice in the Saarland in 2012 and 2014 and is of unclear status here. Conservation measures for *C. mercuriale* are absolutely required at present to preserve, protect and/or support the populations, and they would be for *Leucorrhinia caudalis* at least in some localities helpful. Species specific requirements on the habitat have to be respected for *O. cecilia* also because of actual or potential threats not only in the areas of the Habitats Directive." **15530.** Troyer, R.R.; Turner, A.M. (2015): Chemosensory perception of predators by larval amphibians depends on water quality. *PLoS ONE* 10(6): e0131516. doi:10.1371/

journal.pone.0131516: 10 pp. (in English) ["The acquisition of sensory information by animals is central to species interactions. In aquatic environments, most taxa use chemical cues to assess predation risk and other key ecological factors. A number of laboratory studies suggest that anthropogenic pollutants can disrupt chemoreception, even when at low, non-toxic concentrations, but there are few tests of whether real-world variation in water quality affects chemoreception. Here we investigate whether chemosensory perception of predators (*Anax* sp.) by the gray treefrog, *Hyla versicolor*, depends on water quality. We evaluated the anti-predator response of anuran tadpoles housed in water collected from three sites that represent strong contrasts in the concentration and types of dissolved solids: de-chlorinated tap water, water from an impaired stream, and treated wastewater effluent. Behavioural assays were conducted in laboratory aquaria. Chemical cues associated with predation were generated by feeding tadpoles to dragonfly predators held in containers, and then transferring aliquots of water from dragonfly containers to experimental aquaria. Tadpoles housed in tap water responded to predator cues with an activity reduction of 49%. Tadpoles housed in stream water and wastewater effluent responded to predator cues by reducing activity by 29% and 24% respectively. The results of factorial ANOVA support the hypothesis that the response to predator cues depended on water type. These results show that alteration of the chemical environment can mediate chemical perception of predators in aquatic ecosystems. Because most aquatic species rely on chemoreception to gather information on the location of food and predators, any impairment of sensory perception likely has important ecological consequences." (Authors)] Address: Turner, A.M., Department of Biology, Clarion University, Clarion, PA, USA. E-mail: aturner@clarion.edu

**15531.** Valdivia, F.G.A. (2015): Territoriality of Zenithoptera *lanei* (Anisoptera: Libellulidae) in an area of Brazilian savana. Master's Dissertation, Faculdade de Filosofia, Ciências e Letras de Ribeirão Preto, Univ. Sao Paulo: V + 53 pp. (in Portuguese, with English summary) ["Animal behaviour associated with morphological characteristics supplies evidence for a better understanding of how sexual behaviour has evolved, and how organisms can maximize their reproductive success. Factors such as size, fat reserves and other sexual characters such as coloration are essential to individual better performance in relation to conspecifics. These factors can bring information of the male quality to other conspecifics and females. This quality keeps relation with the physical condition (energy reserves) that they have which is required to succeed in breeding, as reproduction is one of the most expensive activity in energy cost in relation to other activities. The reproductive behaviour is related to the individual fat reserves that influences, among other factors, in the condition that they adopt and to the duration in time of the related interactions to reproduction. Therefore, individuals with more developed characteristics or with better physical conditions will have an advantage in the reproduction comparing with other individuals of the community. The dragonfly Zenithoptera *lanei* is a Neotropical species

present in Brazil, only studied so far by Guillermo-Ferreira in 2015, when structures that conform this pruinosity and his function in the intraspecific communication were described. In this study, describe the sexual behaviour of *Z. lanei*. Was hypothesized that in this species males present territorial behaviour, and that the coloration of wings, body size and the energy reserves (fat) may play an important role in territorial condition and reproductive success. Thus, males with higher quantity of energy and larger size should win more disputes, defend territories and, therefore, maintain the territorial condition. In addition, was also assessed whether this condition of territoriality may influence the duration of the copulation and oviposition by females. The results showed that males are territorial, and its territoriality keeps relation with size and the physical condition. In other words, males with larger body and higher energy reserves have won more disputes and maintained a territory. Although males were territorial, there was no difference between the duration of reproductive interactions, winning males and losers, thus indicating that the reproductive interactions are not influenced by the condition of territoriality of the male." **15533.** Van Schandevyl, D.; Vercruyssen, W. (2015): Yellow-spotted Emerald (*Somatochlora flavomaculata*) looking for new reproduction sites. *Brachytron* 17(2): 100-106. (in Dutch, with English summary) ["*S. flavomaculata* is a rare species in Belgium. Its distribution is restricted to swampy areas in the eastern part of Flanders and the southernmost part of Wallonia. Sightings of vagrant individuals are exceptional. This article describes the discovery (2013-2014) of the species in East Flanders. Until recently the species was unknown from the western part of Flanders. At the two newly discovered localities (the Wellemerssen in Denderleeuw and the Damvallei, east of Ghent), a small population may be present. In the Netherlands the range of the Yellow-spotted Emerald has greatly increased in the last ten years

and a number of new populations were discovered. Similarly, an expansion of *S. flavomaculata* can be expected in Belgium." (Authors)] Address: Danny Van Schandevyl. E-mail: danny.van.schandevyl@telenet.be

**15534.** Vannini, L.; Bowen, J.H.; Reed, T.W.; Willis, J.H. (2015): The CPCFC cuticular protein family: anatomical and cuticular locations in *Anopheles gambiae* and distribution throughout Pancrustacea. *Insect Biochemistry and Molecular Biology* 65: 57-67. (in English) ["Highlights: •New cuticular protein family described, characterized by a 16 amino acid motif ending C-X(5)-C. •In *Anopheles gambiae*, transcripts localized primarily in epidermis underlying hard cuticle. •Proteins localized primarily in endocuticle. •Family members identified in 14 orders of Hexapoda and 4 classes of Crustacea. Abstract: Arthropod cuticles have, in addition to chitin, many structural proteins belonging to diverse families. Information is sparse about how these different cuticular proteins contribute to the cuticle. Most cuticular proteins lack cysteine with the exception of two families (CPAP1 and CPAP3), recently described, and the one other that we now report on that has a motif of 16 amino acids first identified in a protein, Bc-NCP1, from the cuticle of nymphs of the cockroach, *Blaberus craniifer* (Jensen et al., 1997). This motif turns out to be present as two or three copies in one or two proteins in species from many orders of Hexapoda. We have named the family of cuticular proteins with this motif CPCFC, based on its unique feature of having two cysteines interrupted by five amino acids (C-X(5)-C). Analysis of the single member of the family in *Anopheles gambiae* (*AgamCPCFC1*) revealed that its mRNA is most abundant immediately following ecdysis in larvae, pupae and adults. The mRNA is localized primarily in epidermis that secretes hard cuticle, sclerites, setae, head capsules, appendages and spermatheca. EM immunolocalization revealed the presence of the protein, generally in endocuticle of legs and antennae. A phylogenetic analysis found proteins bearing this motif in 14 orders of Hexapoda, but not in some species for which there are complete genomic data. Proteins were much longer in Coleoptera and Diptera than in other orders. In contrast to the 1 and occasionally 2 copies in other species, a dragonfly, *Ladona fulva*, has at least 14 genes coding for family members. CPCFC proteins were present in four classes of Crustacea with 5 repeats in one species, and motifs that ended C-X(7)-C in Malacostraca. They were not detected, except as obvious contaminants, in any other arthropod subphyla or in any other phylum. The conservation of CPCFC proteins throughout the Pancrustacea and the small number of copies in individual species indicate that, when present, these proteins are serving important functions worthy of further study." **15535.** Varshini, R.A.; Kanagappan, M. (2015): Effect of space on the feeding efficiency of dragonfly nymph *Bradinopyga geminata*. *European Journal of Biotechnology and Bioscience* 3(12): 6-10. (in English) ["Among various predators of mosquito larvae, dragonfly nymphs are efficient,

found naturally, safe for human beings, and are also economical in their application. There are many physical, chemical and biological factors like prey species, prey size, prey stage, predator species, predator size, predator stage, aquatic vegetation, quality and quantity of water, illumination, and space affect the feeding efficiency of dragonfly nymphs. These factors serve as a basis for the richness or otherwise biological productivity of any aquatic environment. The present study shows negative correlation where with the increasing space of the basins the feeding efficiency of the nymph decreased. The maximum prey consumption  $34.91 \pm 3.96$  was recorded when the circumference of the basin was 4 cm and the water level was 3 cm height and minimum predation  $16 \pm 2.72$  was recorded when the circumference of the basin was 64 cm and the water level was 3 cm height." **15536.** Venkatesh, A.; Tyagi, B.K. (2015): *Bradinopyga geminata* (Anisoptera: Libellulidae) as a predator of *Aedes aegypti* immatures (Diptera: Culicidae). *International Journal of Mosquito Research* 2(2): 98-105. (in English) ["Predatory potential of 12th instar larvae of *Bradinopyga geminata* on *Aedes* mosquito immatures was observed, by exposing two different prey-predator combinations (Prey: Predator; 200:1 and 1000:5). One and five 12th instar larvae of *B. geminata* were provided with 200 (SET A) and 1000 (SET B) I, II, III & IV instars of *Aedes aegypti* larvae as prey, for a period of 24 hr in plastic containers containing 1 and 5 litres of water respectively. The number of *Ae. aegypti* larvae consumed by *B. geminata* larvae were noted through one day, at an interval of 3 hours. To maintain the prey density, same number of larvae was replenished. In the daily feeding rate experiment the consumption showed a peak during the 9th hour, irrespective of the instar stages. Predation rate of *B. geminata* was more for I instar. The predatory impact values for I instar in both Set A and B were  $4.12 \pm 0.05$  and  $3.6 \pm 0.02$  respectively, and were significant ( $P < 0.01$ ). The comparative clearance rate for Set A and B was highly significant for the first instar ( $P < 0.01$ ). This study revealed that *B. geminata* larvae is an efficient predator of mosquito larvae. The rate of consumption was dependent on the size of the prey and the density of the predator. The predatory impact of *B. geminata* was more for the first instar *Ae. aegypti*, owing to its size and energy requirements. To conclude, *B. geminata* is an efficient bio-control agent for container breeding *Ae. aegypti* and can be an effective tool in the integrated vector control programme." English ) ["Helsinki is located on a peninsula projecting into the Baltic Sea from the south coast of Finland. The country lies in the Boreal region, which is typified by the mixed coniferous forests, although Helsinki itself is located in a narrow strip of the hemiboreal zone, which also has noble deciduous forest, similar to those of the temperate region. The region is also characterized by a variety of wetland habitats. Descriptions are provided of the following invertebrate taxa: Arachnida, Carabidae, Syrphidae, Apidae sensu lato, Formicidae, Isopoda, Lepidoptera and Odonata, as well as some of the habitats they occupy. The information provided is rather patchy, as the amount of data varies considerably between different taxa and habitats. The urban region contains some sites that are valuable for invertebrate diversity, regardless of their location. The characteristic features of the urban environment, such as mild climate and longer growing season, may be beneficial for some taxa." (in English) ["Biomimetic air vehicles (BAV) are a class of unmanned aircraft that mimic the flapping wing kinematics of flying organisms (e.g. birds, bats, and insects [including dragonflies]). Research into BAV has rapidly expanded over the last 30 years. In this paper, we present a comprehensive bibliometric review of engineering and biology journal articles that were published on this subject between 1984 and 2014. These articles are organized into five topical categories: aerodynamics, guidance and control, mechanisms, structures and materials, and system design. All of the articles are compartmented into one of these categories based on their primary focus. Several aspects of these articles are examined: publication year, number of citations, journal, authoring organization and country, non-academic funding sources, and the flying organism focused upon for bio-mimicry. This review provides useful information on the state of the art of BAV research and insight on potential future directions. Our intention is that this will serve as a resource for those already engaged in BAV research and enable insight that promotes further research interest." (in Dutch, with English summary) ["The importance of Selys for the Dutch study of dragonflies is described, using articles, his published diaries and his scientific correspondence present in RBINS (Brussels) and Naturalis (Leiden). Selys visited the RMNH collection (now NCB Naturalis) in Leiden six times and the collection of *Natura Artis Magistra* in Amsterdam five times. For the RMNH he carried out identifications, they exchanged dragonflies and with some curators he conducted a regular correspondence. The summarizing catalogue which Selys made in 1879 of the RMNH dragonfly collection has unfortunately not yet been found. Selys had a warm friendship with Adrien Maurissen from Maastricht, for whom he wrote a necrology, and with Herman Albarda from Friesland, after whom he named *Sieboldius albardae*. The three publications concerning dragonflies in the Netherlands which appeared in 1852, 1866, and 1889 are clearly influenced by Selys. With that and his regular contact with the RMNH Selys has sown the seeds for the current flourishing study of dragonflies in the Netherlands.] Address: Wasscher, M., Minstraat 15bis, NL-3582 CA Utrecht, The Netherlands, E-mail: marcel.hilair@12move.nl

**15541.** Watanabe, M. (2015): Larval community dynamics in an artificial habitat created for conservation of a local population of the endangered brackish water damselfly *Mortonagrion hirosei* (Odonata: Coenagrionidae). *Odonatologica* 44(1/2): 45-62. (in English) ["Brackish water ecosystems in estuaries are highly threatened due to land development, the improvement of embankments, and reclamation. Several threatened species of dragonflies and damselflies inhabit these ecosystems. The brackish water damselfly, *M. hirosei*, has been an important focus of conservation studies. Here, we describe a conservation project for *M. hirosei* begun in 2003, and review the data collected in order to quantify details of the species' life cycle, especially larvae and larval environment. An artificially established reed community was created as a habitat for this damselfly, and water depth, salinity, and water temperature in the reed bed were continuously monitored thereafter. Because this damselfly is univoltine, the number and distribution of the odonate larvae in the experimental habitat in May, or presence of last-instar larvae of *M. hirosei*, were considered suitable indices of colonisation success. Since many odonate adults, including *M. hirosei*, visited the habitat in the first year and laid eggs, high larval diversity was found in the second year. Although the salinity of water in the reed bed varied because cyclical tidal fluctuations, the saline water gradually excluded odonate larvae that inhabit freshwater only. However, *M. hirosei* survived, and the larval population increased year by year. Consequently, the odonate larval diversity in the artificial habitat decreased, while the population of *M. hirosei* was maintained." (Author)] Address: Watanabe, M., Dept Biol., Fac. Education, Mie Univ., Tsu, Mie 514-8507, Japan. E-mail: watanabe@edu.mie-u.ac.jp

**15543.** Wesner, J.S.; Meyers, P.; Billman, E.J.; Belk, M.C. (2015): Habitat selection and consumption across a landscape of multiple predators. *Ecology and Evolution* 5(1): 121-129. (in English) ["Predator community composition can alter habitat quality for prey by changing the strength and direction of consumptive effects. Whether predator community composition also alters prey density via nonconsumptive effects during habitat selection is not well known, but is important for understanding how changes to predator communities will alter prey populations. We tested the hypothesis that predator community composition (presence of caged trout, caged dragonflies [*Ophiogomphus severus*], or caged trout + dragonflies) alters colonization of aquatic mesocosms by ovipositing aquatic insects. In a previous experiment in this system, we found a spatial contagion effect, in which insects avoided pools with predators, but only when predator-free pools were isolated (~5 m away from predator pools). Here, we removed the isolated predator-free pools, allowing us to test whether insects would make fine-scale (~1 m) oviposition decisions in the absence of preferred isolated pools. We also estimated consumptive effects by allowing predators to feed on colonists for 5 days following colonization. All insects collected after 21 days were dipterans, dominated by Chironomidae. Total colonization, measured as the number of developing larvae after 21 days, was not affected by either predator presence or composition. Consumption was significant in the trout only treatment, reducing larval insect density by  $46 \pm 37\%$  (mean  $\pm$  SE). No other predator treatment significantly reduced prey density, although the proportion of chironomid larvae in protective cases increased in response to direct predation from dragonflies, indicating an antipredatory behavioural response. Taken together, these results reveal that predator community composition altered larval survival and behaviour, but colonizing females either did not or could not assess these risks across small scales during oviposition." **15544.** White, E.L.; Hunt, P.D.; Schlesinger, M.D.; Corser, J.D.; deMaynadier, P.G. (2015): Prioritizing Odonata for conservation action in the northeastern USA. *Freshwater Science* 34(3): 1079-1093. (in English) ["Odonata are valuable biological indicators of freshwater ecosystem integrity and climate change, and the northeastern USA (Virginia to Maine) is a hotspot of odonate diversity and a region of historical and growing threats to freshwater ecosystems. This duality highlights the urgency of developing a comprehensive conservation assessment of the region's 228 resident

odonate species. We offer a prioritization framework modified from NatureServe's method for assessing conservation status ranks by assigning a single regional vulnerability metric (R-rank) reflecting each species' degree of relative extinction risk in the northeastern USA. We calculated the R-rank based on 3 rarity factors (range extent, area of occupancy, and habitat specificity), 1 threat factor (vulnerability of occupied habitats), and 1 trend factor (relative change in range size). We combine this R-rank with the degree of endemism (% of the species' USA and Canadian range that falls within the region) as a proxy for regional responsibility, thereby deriving a list of species of combined vulnerability and regional management responsibility. Overall, 18% of the region's odonate fauna is imperiled (R1 and R2), and peatlands, low-gradient streams and seeps, high-gradient headwaters, and larger rivers that harbour a disproportionate number of these species should be considered as priority habitat types for conservation. We anticipate that our analysis might serve as a model for guiding and standardizing conservation assessments at multiple scales for Odonata and other diverse taxa that have not yet received attention to prioritization." **15545.** Wildermuth, H.; Roland, H.-J.; Hein, A.T. (2015): Landmilben als Libellenparasiten – bisher bekanntes Wirtsspektrum in Europa (Acari: Prostigmata; Odonata). *Libellula* 34(1/2): 103-115. (in German, with English summary) ["Terrestrial mites as parasites of dragonflies – updated host spectrum in Europe (Acari: Prostigmata; Odonata) – In contrast to aquatic mites as parasites of Odonata few studies of terrestrial mites exist. In order to obtain more information on their distribution and their relation to their odonate hosts, an appeal to odonatologists was made via various photo- and dragonfly platforms on the internet to submit photos of odonates infested by mites. Besides a great amount of images with aquatic mites, 24 photo documents with terrestrial mites came in. Among the host species five have been unknown up to now: *Calopteryx xanthostoma*, *Libellula quadrimaculata*, *Leucorrhinia dubia*, *Sympetrum flaveolum*, and *S. sanguineum*. The parasite load was 1.7 mites per host individual on average. Most mite larvae clung to the host's legs, some also to the abdomen and the thorax, only one to the head. The records of the terrestrial mites originated from eleven localities, most of them from Germany, two from Georgia and one from France. All hitherto published records of terrestrial mites on Odonata are summarized and reviewed. The host spectrum, the distribution in Europe, the prevalence and parasite load as well as the problem of parasitization and/or phoresy of terrestrial mites on Odonata are discussed." (Authors)] Address: Hein, A.T., Ackerstr. 109, 13355 Berlin, Germany. E-mail: post@libellenwissen.de

**15546.** Williams, A.T. (2015): The dragonflies of Reigersbroek and Schrevenhofsbroekje. The effect of nature development on dragonfly fauna. *Natuurhistorisch maandblad*

104(6): 103-109. (in Dutch, with English summary) ["The natural landscape of Reigersbroek and Schrevenhofsbroekje in the province of Limburg is being redeveloped in order to restore its original marshy character. Topsoil removal, the scattering of wet heathland vegetation clippings and the raising of water levels have created different habitats for dragonflies. This restoration work has led to various inventories being carried out of the flora and fauna in the area, and by extension the monitoring of the dragonfly population. The restoration work has resulted in sparsely-planted shallow pools and ponds in Reigersbroek, which is still in a pioneer phase, and two large ponds with structure-rich banks in Schrevenhofsbroekje. The habitats in Reigersbroek currently appear to attract predominantly pioneer species such as *Ischnura pumilio* and *Sympetrum fonscolombii*, but are also visited by fenland dragonflies and vagrants from southern regions such as *Anax parthenope*. A number of ditches in the area have been colonised by *Orthetrum coerulescens* and *Sympetrum pedemontanum*. Given the growth in species and populations since the beginning of the restoration work, it is expected that the variety and quantities of species will continue to develop as the area evolves into a mature, contiguous wetland reserve with management focused on the on the preservation of present populations.] Address: Williams, A.T., Julianastraat 5, 6067 EV Linne, The Netherlands

**15547.** Willkommen, J.; Michels, J.; Gorb, S.N. (2015): Functional morphology of the male caudal appendages of the damselfly *Ischnura elegans* (Zygoptera: Coenagrionidae). *Arthropod Structure & Development* 44(4): 289-300. (in English) ["Highlights: The clasping of the dragonfly *Ischnura elegans* represents an energy-efficient process. •The closing of the male claspers is a mainly passive process. •Surface microstructures and the female thoracic morphology secure the clamping. Odonata are usually regarded as one of the most ancient extant lineages of winged insects. Their copulatory apparatus and mating behaviour are unique among insects. Male damselflies use their caudal appendages to clasp the female's prothorax during both copulation and egg-laying and have a secondary copulatory apparatus for sperm transfer. Knowledge of the functional morphology of the male caudal appendages is the basis for understanding the evolution of these structures in Odonata and respective organs in other insects. However, it is still not exactly known how the zygopteran claspers work. In this study, we applied micro-computed tomography and a variety of microscopy techniques to examine the morphology, surface microstructure, cuticle material composition and muscle topography of the male caudal appendages of *Ischnura elegans*. The results indicate that the closing of the paraproctal claspers is mainly passive. This indirect closing mechanism is very likely supported by high proportions of the elastic protein resilin present in the cuticle of the paraproctal bases. In addition, the prothoracic morphology of the female plays an important role in the indirect closing of the male claspers. Our data indicate that both structures – the male claspers and the female prothoracic hump – function together like a snap-fastener." (Authors)] Address:

**15548.** Worthen, W.B.; Turner, L.H. (2015): The effects of odonate species abundance and diversity on parasitism by water mites (*Arrenurus* spp.): testing the dilution effect. *International Journal of Odonatology* 18(3): 233-248. (in English) ["Water mites (*Arrenurus* spp.) parasitize adult dragonflies. We collected dragonflies weekly at 11 waterbodies in Greenville Co. and Pickens Co., SC, USA, to: (1) compare parasitism prevalence across species, sites, and sampling periods; (2) test the hypothesis that prevalence correlates with host abundance; (3) test the hypothesis that prevalence is inversely related to host diversity (the "dilution effect"); and (4) test the hypothesis that prevalence and intensity vary with ecological conditions. Parasitism prevalence varied among well-sampled ( $N > 30$ ) hosts; *Perithemis tenera*, *Plathemis lydia*, and *Celithemis ornata* had no mites, whereas prevalence exceeded 20% for *Argia fumipennis*, *Celithemis elisa*, and *C. fasciata*. Differences among species, however, varied across sites and through time, suggesting patchy or species-specific relationships not captured by our diffuse analysis at the generic level. Prevalence was positively correlated with species abundance and host site occupancy, as expected for generalist parasites. There was no evidence of a dilution effect: there were no significant negative relationships between prevalence and three measures of species richness (observed richness, extrapolated Sest, or CHAO2 estimated richness), considering all odonate species, parasitized species, or only species in the parasitized families Libellulidae or Coenagrionidae. Odonate communities in more pristine sites had higher mean prevalence ( $18.4 \pm 6.0$ ) and median intensity (4.5) than those in disturbed sites ( $13.1 \pm 7.0$ ; 3.0), but only intensities were marginally significantly different. Parasitism by *Arrenurus* spp. met the criteria for a dilution effect, but did not exhibit this effect as a diffuse community-level response." **15555.** Yuen, E.Y.L.; Dudgeon, D. (2015): Dietary dependence of predatory arthropods on volant aquatic insects in tropical stream riparia. *Biotropica* 48(2): 218-228. (in English) ["The dietary dependence on volant aquatic insects of eight species of predatory arthropods from three different orders was determined by stable isotope analyses in combination with three-source, two-isotope (C and N) Bayesian mixing models. The predators were collected from riparian zones along three streams in tropical Hong Kong during both the wet and dry seasons. Dietary importance of aquatic insects varied according to predator hunting modes, and showed a consistent pattern across all sites during the wet season. The web-building tetragnathid spider (*Orsinome diporusa*) had the greatest reliance (~40–55%) on this water-to-land subsidy, followed by two species of damselflies (40–50%) (*Rhinocypha perforata*, *Euphaea decorata*), three cursorial spiders (*Lycosidae*, *Pisauridae*, and *Sparassidae*: 32–51%) and two neustic Gerrids (17–36%). Such reliance also varied according to the microhabitat preferences of different cursorial spiders. Four species of predators (Gerrids and cursorial spiders) that were active year-round showed generally consistent reliance on aquatic insects between seasons, which probably reflected the observed lack of seasonal variability in the relative proportions of aquatic and terrestrial prey. There was a marked overlap in isotopic signatures of aquatic and terrestrial prey at all sites which, com-

bined with the absence of data on the extent to which isotopic fractionations may vary among individual species of prey and predators, contributes some uncertainty to the estimates of dietary compositions derived by mixing models. The findings of the present study are thus likely to be indicative rather than definitive. **15556.** Yuto, C.M.M.; Nuneza, O.M.; Villanueva, J.T. (2015): Species diversity of the odonatofauna of Mts. Pinukis and Gimamaw, Zamboanga del Sur, Philippines. *Journal of Biodiversity and Environmental Sciences* 7(4): 135-146. (in English) ["Odonata is highly sensitive to various changes in the environment which makes it an excellent bioindicator of environmental health. This study was conducted to assess the species richness of Odonata in Mts. Pinukis and Gimamaw, Zamboanga del Sur, Philippines. Eleven sampling sites were surveyed comprising six sites in Mt. Pinukis and five sites in Mt. Gimamaw. Opportunistic sampling using sweep nets was conducted for a total of 192 man-hours. Biodiversity indices, cluster analysis, and detrended correspondence analysis were determined using Paleontological Statistics Software Package (PAST) version 2.17b. Thirty-five species were recorded belonging to 25 genera and 10 families with relatively low endemism of 40%. There was a more or less even species distribution. High relative abundance of 18.83% was observed in site 1. Site11 was observed to have the most number of endemic species. High species diversity was recorded in both Mts. Pinukis and Gimamaw. Detrended correspondence analysis showed that vegetation structure greatly influences habitat preferences of Odonata. It appears that human-induced disturbances limit the occurrence and abundance of the Odonata, especially the endemic species." **15557.** Zebsa, R.; Khelifa, R.; Kahalerras, A. (2015): Emergence pattern, microhabitat choice, and population structure of the Maghribian endemic *Gomphus lucasii* Selys, 1849 (Odonata: Gomphidae) in northeastern Algeria. *Aquatic Insects* 36(3-4) (2014): 245-255. (in English) ["Emergence of *Gomphus lucasii* Selys, 1849, an unstudied Maghreb endemic, was synchronised by overwintering in the final stadium in the Seybouse River in northeastern Algeria. Regular collections revealed that half of the annual population emerged during 10 days, showing a typical 'spring species' emergence pattern. Sex ratio was slightly male biased (51%). Males and females did not differ in vertical stratification. Emergence support choice was not random, but rather depended on support height, body size, and daily population density. Mortality was caused mainly by ants, although deformity of teneral and bird predation were also important factors. *Gomphus lucasii* has been assessed as vulnerable (International Union for Conservation of Nature (IUCN) Red List), and the information provided in our

study will be helpful in future conservation efforts." (Authors)] Address: Zebsa, R., Département d'écologie et du génie de l'environnement, Faculté des Sciences de la Nature et de la Vie et des Sciences de la Terre et de l'Univers, Université 08 Mai 1945, Guelma 24000, Algérie

**15558.** Zebsa, R.; Khelifa, R.; Kahalerras, A. (2015): Adult movement pattern and habitat preferences of the Maghribian endemic *Gomphus lucasii* (Odonata: Gomphidae). *J. Insect Sci.* (2015) 15(1): 151; DOI: 10.1093/jisesa/iev128: 8 pp. (in English) ["The Algerian Cudtail (*Gomphus lucasii* Selys) (Odonata: Gomphidae) is a river-dwelling dragonfly and one of the least known gomphid in the Palearctic. A survey of the movement patterns and habitat requirements of adults was conducted in the largest currently known population, located in the Seybouse River (Northeast Algeria). Daily mark-release-resighting surveys along a 2.5 km stretch of the watercourse and within plots in terrestrial habitats were carried out; a total of 1,316 individuals were marked. The resighting rate along the watercourse was 8.13% and did not significantly vary with sex and age. Adult spatial distribution differed according to sex and age. Mature females were significantly further from the water than males. Mature males were observed not only along the watercourse but also far from the water, up to 450m where reproductive pairs in copula were recorded. Preferred maturation and foraging sites were open grasslands and dense wheat fields. Philopatry to reproductive sites had a mean of 1.11%, while philopatry to emergence site was lower (0.4%) and noted only in males. The mean distance of natal dispersal (from emergence to reproductive areas) was 596.564.94 m. The mean dispersal distance from one reproductive site to another was 180.976238.54 m. Both mature males and females preferred fast flowing water, but females were observed to oviposit in relatively small watercourses." **15564.** Akram, W.; Ali-Khan, H.A. (2016): Odonate nymphs: Generalist predators and their potential in the management of dengue mosquito, *Aedes aegypti* (Diptera: Culicidae). *Journal of Arthropod-Borne Diseases* 10(2): 253-258. (in English) ["Background: Dengue is amongst the most serious mosquito-borne infectious disease with hot spots in tropical and subtropical parts of the world. Unfortunately, no licensed vaccine for the disease is currently available in medicine markets. The only option available is the management of dengue vector mosquito, *Aedes aegypti* (Diptera: Culicidae). Method: Predatory potential of five odonate nymphs namely *Anax parthenope*, *Bradinopyga geminate*, *Ischnura forcipata*, *Rhinocypha quadrimaculata*, and *Orthetrum sabina* were evaluated against the 4th instar larvae of the dengue vector mosquito, *Aedes aegypti*, under laboratory conditions. The consumption of the mosquito larvae was evaluated at three water volume levels viz., 1 liter, 2 liter and 3 liter. Results: The number of *Ae. aegypti* larvae consumed varied significantly among the five species, and at different levels of water volume ( $P < 0.01$ ). However, the interaction between odonate nymphs and the water volumes was statistically non-significant ( $P > 0.05$ ). *Ischnura forcipata* consumed the highest number of *Ae. aegypti* larvae ( $n=56$ ) followed by *A. parthenope* ( $n=47$ ) and *B. geminate* ( $n=46$ ). The number of larvae consumed was decreased with increasing search area or water volume, and the highest predation was observed at 1-liter water volume. Conclusion: The odonate nymphs could be a good source of biological agents for the management of the mosquitoes at larval stages." **15565.** Allen, A.M.; Singh, N.J. (2016): Linking movement ecology with wildlife management and conservation. *Front. Ecol. Evol.* 3:155.doi: 10.3389/fevo.2015.00155: 13 pp. (in English) ["A common challenge in species conservation and management is how to incorporate species movements into management objectives. There often is a lack of knowledge of where, when, and why species move. The field of movement ecology has grown rapidly in the last decade and is now providing the knowledge needed to incorporate movements of species into management planning. This knowledge can also be used to develop management strategies that are flexible in time and space and may improve the effectiveness of management actions. Therefore, wildlife management and conservation may benefit by strengthening the link with movement ecology. We present a framework that illustrates how animal movement can be used to enhance conservation planning and identify management actions that are complementary to existing strategies. The framework contains five steps that identify (1) the

movement attributes of a species, (2) their impacts on ecosystems, (3) how this knowledge can be used to guide the scale and type of management, (4) the implementation, and (5) the evaluation of management actions. We discuss these five steps in detail, highlighting why the step is important and how the information can be obtained. We illustrate the framework through a case study of managing a highly mobile species, the Atlantic salmon (*Salmo salar*), a harvested species of conservation concern. We believe that the movement-management framework provides an important, and timely, link between movement ecology and wildlife management and conservation, and highlights the potential for complementary, dynamic solutions for managing wildlife." **15567.** Arbeiter, S.; Schulze, M.; Tamm, P.; Hahn, S. (2016): Strong cascading effect of weather conditions on prey availability and annual breeding performance in European bee-eaters *Merops apiaster*. Journal of Ornithology 157(1): 155-163. (in English, with German summary) ["Aerial insectivorous birds depend highly on favourable weather conditions for successful foraging because flight activity of insects is constrained by daily weather. Thus, the variation in weather conditions during reproduction, mediated by prey limitations, should be mirrored in annual reproduction performance, and finally in annual breeding success. We analysed the effect of local weather conditions on the availability of airborne insects and on the variation in brood size and nestling condition of European bee-eaters *Merops apiaster* at the northern edge of their range where years with adverse weather frequently occur. The availability of large flying insects, the common prey of bee-eaters, increased with

air temperatures and duration of daily sunshine. As predicted, local weather conditions affected reproductive performance with annual breeding success (mean 3.7 nestlings per breeding pair, range 1.7–4.9 nestlings) being up to 32 % higher in extraordinary dry and hot summers. Additionally, a nestling's body condition (residual mass) was also affected by sunshine duration during their growth period and internally was co-affected by the number of siblings and the individual rank within the sibling hierarchy. Thus, a prolonged duration of daily sunshine causes a cascade from higher insect flight activity, and, thus, higher food availability for chick-rearing bee-eaters, which finally translates into better chick body conditions and higher annual breeding success. Consequently reproduction and population development of European bee-eaters might be especially susceptible to regional changes in weather and climatic conditions."(Authors) The paper includes references to Odonata.] Address: Arbeiter, Susanne, Zool. Inst. & Museum, Univ. Greifswald, Johann-Sebastian-Bach-Str.11/12, 17489, Greifswald, Germany. E-mail: [susanne.arbeiter@uni-greifswald.de](mailto:susanne.arbeiter@uni-greifswald.de)

**15568.** Aschonitis, V.G.; Feld, C.K.; Castaldelli, G.; Turin, P.; Visonà, E.; Fano, E.A. (2016): Environmental stressor gradients hierarchically regulate macrozoobenthic community turnover in lotic systems of Northern Italy. Hydrobiologia 765: 131-147. (in English) ["Environmental stressors present a hierarchical influence on freshwater organisms. This study investigates the hierarchy of environmental stressor gradients, which regulate the composition of instream macroinvertebrate communities of northern Italy (Po Valley and the south-eastern Alps). Species and environmental data were derived from 585 monitoring sites. Environmental parameters were split into three groups, describing (i) ecoregional, (ii) hydromorphological, and (iii) water quality attributes. Partial Redundancy Analysis (partial RDA) was used to hierarchically rank the group effects, which were expressed as unique (group specific) and joint effects (of two groups together). Overall, ecoregion explained more variance (30.2%) than hydromorphology (24.8%) and water quality (22.3%). Unique effects were generally low, but ecoregional unique effects were twice as high as those of the other groups. The analysis of single environmental variables highlighted significant effects of anthropogenic impact related to the substrate size composition, riparian vegetation, flow conditions, and *Escherichia coli* (surrogate descriptor of organic fecal pollution). Such stressor hierarchies can support biodiversity conservation plans, while the high joint effects of stressor groups suggested the need for combined management activities, addressing the respective stressors and stressor groups in concert. Management measures addressing only one stressor group isolated from others are likely to be less effective, or even ineffective." (Authors) Taxa including Odonata are treated at genus level.] Address: Aschonitis, V.G., Department of Life Sciences and Biotechnology, University of Ferrara, Ferrara, Italy. **15569.** Berquier, C.; Antoine Orsini, A.; Ferrat, L.; Andrei-Ruiz, M.-C. (2016): Odonata Community Index – Corsica"

(OCIC): A new biological index based on adult odonate populations for assessment of the ecological status of watercourses in Corsica. *Ecological Indicators* 66: 163-172. (in English) ["Corsica is a French island in the western Mediterranean with numerous distinct geomorphological, landscape, and biological characteristics. These specific attributes, mostly related to insularity, are hardly taken into account by the biological indices currently recommended in the framework of the European Union Water Framework Directive "WFD" for assessing the ecological status of watercourses. Thus, this work has focused on developing an innovative biological index adapted to the specific context of territories such as Corsica, based on the Odonata group. In this context, imago sampling of Odonata was performed at 40 representative stations to assess the 33 major permanent rivers of the island. In parallel, various biological, hydrological, and physicochemical parameters affecting the ecological status of these organisms were recorded. The data collected on nearly 30 species of Odonata allowed for the accurate description of the typical populations of Corsican watercourses, highlighting this group's potential as a biological indicator. An indicator value was assigned to the 12 species identified as the most representative of these environments. The results were used to develop 5 biological indices based on simple statistical descriptors. The index that was found to be the best for assessing the ecological status of the watercourses, as indicated by correlation tests, was named "Odonata Community Index – Corsica" (OCIC), and was finally confronted with the 5 biological indices recommended by the WFD and currently used in Corsica. The results of this study confirm the significant potential of the OCIC index compared to other "official" indicators, that are limited in they do not accurately assess all territories. The results of our tests indicate that this new index using Odonata group appears to be a credible method that could potentially improve the evaluation system currently used for monitoring the ecological quality of watercourses in Corsica." **15570.** Blecher, M. (2016): Hebrew names for insects toward environmental education and nature conservation: dragonflies and damselflies as a case study. *Negev, Dead Sea and Arava Studies* 7(3): 58-65. (in Hebrew, with English summary) ["The issue of the report is interdisciplinary: linking biological knowledge and environmental education, connecting zoological taxonomy with the Hebrew language. The necessity of Hebrew names for Israeli dragonflies and damselflies is explained and discussed, and the practice of creating those names is analyzed. The vernacular names were proposed for the taxonomical insect order (Odonata) comprehensively. A methodical consistent approach, as the base for suggesting the names, is briefly described. The complete and clarified names proposal (the first for an arthropods group of the country) was submitted to the Academy of the Hebrew Language. After lengthy process of detailed discussions in the Zoological Terminology Committee,

the Hebrew common names of dragonflies and damselflies have been approved by the Plenary Session of the Academy. The accepted names should be an important tool in education for biodiversity conservation and in promotion for fresh-water habitats protection. Additionally, an up-dated Odonata faunistic list of Israel is given. The list is a concise literature summary for practical conservation purposes." **15571.** Boonsoong, B. (2016): Phoretic associations between *Nanocladius asiaticus* (Diptera, Chironomidae) and its hosts *Gestroiella* (Heteroptera, Naucoridae) and *Euphaea masoni* (Odonata, Euphaeidae) in streams in Western Thailand. *Annales de Limnologie - International Journal of Limnology* 52: 163-169. ["Phoretic associations between larvae of *Nanocladius* (Plecopteracoluthus) *asiaticus* (Diptera, Chironomidae) and two species in the genus *Gestroiella* (Heteroptera, Naucoridae) were studied in Kanchanaburi and Ratchaburi Provinces (Western Thailand). *Gestroiella siamensis* was used by chironomid larvae as a host more frequently than was *Gestroiella limnocoroides*. Moreover, *N. asiaticus* larvae were associated symphoretically with nymphs of *Euphaea masoni*. This is the first report of a symphoretic association involving *E. masoni*. Approximately 44% of the population of naucorids harboured symphoretic chironomids, whereas only 13% of damselfly nymphs were hosts of the chironomid larvae. Most of the brachypterous male (59%) naucorids hosted chironomid larvae. The attachment site of the chironomids was frequently along the mesofemur and mesosternum of the naucorid hosts. The chironomids were attached to the ventral sides of abdominal segments of *E. masoni* nymphs. There was a positive correlation in body length between chironomids and naucorids ( $r=0.389$ ,  $P<0.01$ ). There are many benefits of symphoresis in the Chironomidae, such as improved feeding opportunities, increased mobility, suitable pupation sites and decreased predation risks." **15572.** Braun, A.P.; Phelps, Q.E. (2016): Channel Catfish habitat use and diet in the Middle Mississippi River. *The American Midland Naturalist* 175(1): 47-54. (in English) [Overall, vegetation, fish, and Cambaridae (freshwater crayfishes) made up the highest mean proportion of stomach contents by weight (27.5%, 20.6%, and 19.9% respectively). Trichoptera constituted the next highest proportion (4.6%), while Collembola, Coleoptera, Odonata, and Bivalvia were minor proportions "River modifications have had detrimental effects on biota that depend on river systems; therefore, information is needed to understand these effects and direct management efforts. Channel catfish (*Ictalurus punctatus*) are important recreationally, commercially, and ecologically in the Middle Mississippi River (MMR), but few studies have examined their habitat requirements, and food

habits have not been evaluated in the MMR. Information about habitat use and food habits could help direct management efforts for channel catfish. To more thoroughly understand the synergistic relation between channel catfish and the associated habitat, we used data from the United States Army Corps of Engineer's Long-Term Resource Monitoring Program to evaluate channel catfish use of large-scale river features (i.e., macrohabitats) and more fine scale mesohabitats (i.e., substrate type, depth, and velocity). Stomach contents from channel catfish were identified and quantified to determine the relative importance of specific prey items in diets. Channel catfish presence was positively affected by current but negatively affected by depth. Off-channel habitats appeared more suitable for channel catfish. In terms of food habits, Cambaridae, fish, and vegetation were most frequently found in the diet, but a variety of other food items were consumed. Conserving premodification habitat characteristics, such as open side channels, shallow sandbars, and seasonally inundated floodplains, as well as habitats with high forage productivity, should help to sustain a stable population of channel catfish in the MMR. Future studies could examine the tenets of the optimal foraging theory within these habitats to determine the mechanisms regulating channel catfish habitat use and prey selection." **15573.** Brown, A.L.; Robinson, B.W. (2016): Variation in behavioural plasticity regulates consistent individual differences in *Enallagma* damselfly larvae. *Animal Behaviour* 112: 63-73. (in English) ["Highlights: •Larvae of different *Enallagma* species experience constant or variable predation risk. •Larvae predictably vary in plastic behaviour in response to fish predator cues. •More plasticity is associated with reduced variation in plasticity among individuals. •Less variation in plasticity enhances consistent individual differences in behaviour. •Variation in behavioural plasticity and in mean behaviour regulates behaviour types. Plastic behavioural responses by individuals to different conditions and consistent individual differences in mean behaviour across situations both contribute to variation in a population. The relationship between behavioural plasticity and consistent individual differences is not clearly understood but may help predict personality variation in animals. High variation in mean behaviour and low variation in individual plastic responses will tend to maintain the rank order of individuals across situations and so permit consistent individual differences. Conversely, low variation in mean behaviour and high variation in plastic responses, by changing the rank orders of individuals, will erode consistent individual differences. Thus, selection that reduces variation in individual plastic responses should increase the opportunity for consistent individual differences in a population. We tested for relationships between heterogeneous predation regimes, the mean and variance of behavioural plasticity and consistent individual differences among three species groups of larval damselflies. Larvae of *Enallagma signatum*

probably face consistent predation from fish over successive generations, whereas *Enallagma ebrium/hageni* and *Enallagma annexum/boreale* face a changing predation regime over generations either from fish or larval dragonflies. The behavioural reaction norms of larvae in repeated exposure trials to cues from a predatory fish, dragonfly larvae or no predator differed between species groups. *Enallagma ebrium/hageni* expressed the most consistent plastic response to predator cues, less variability in plasticity and greater consistent individual differences across cues compared to more variable plastic responses and low consistent individual differences in *E. signatum*. Selection on behavioural plasticity may enhance consistent individual differences in *E. ebrium/hageni* whereas relaxing selection on plasticity may reduce consistent individual differences in *E. signatum*. More generally, selection on plastic behaviour may enhance behavioural types while selection on mean behaviour may reduce behavioural types in animal populations." (Authors)] Address: Robinson, Beren, Department of Integrative Biology, University of Guelph, Guelph, ON, N1G 2W1, Canada. E-mail: berenrob@uoguelph.ca

**15574.** Bruni, G.; Ricciardi, G.; Vannini, A. (2016): Effectiveness of artificial amphibian breeding sites against non-native species in a public protected area in Tuscany, Italy. *Conservation Evidence* (2016) 13, 12-16: 12-13. (in English) ["The spread of non-native invasive species is among the factors thought to be responsible for the recent global declines in amphibian populations. In a Protected Natural Area of Local Interest in Tuscany, Italy, we tested approaches for preserving the local amphibian populations threatened by the presence of the red swamp crayfish *Procambarus clarkii*. The construction of artificial breeding ponds, with suitable vertical barriers, was initially effective in preventing the spread of the red swamp crayfish and created a source site for amphibians, in particular newt species. Unfortunately, five years after construction, the breeding sites were colonized by fish and crayfish, possibly due to the actions of members of the public.... In addition to the target species, many aquatic insects, such as dragonflies and damselflies (Odonata) (e.g. *Anax imperator*, *Crocothemis erythraea*, *Libellula quadrimaculata*) successfully colonized the reconstructed habitats." **15575.** Callahan, M.S.; McPeck, M.A. (2016): Multi-locus phylogeny and divergence time estimates of *Enallagma* damselflies (Odonata: Coenagrionidae). *Molecular Phylogenetics and Evolution* 94, Part A: 182-195. (in English) ["Highlights: •*Enallagma* damselflies show complex diversification across North America and Eurasia. •Four subclades radiated in the Pleistocene to produce 28 extant species. •Both speciation and extinction rates increased over the last 1.5 million years. Reconstructing evolutionary patterns of species and populations provides a framework for asking questions about the impacts of climate change. Here we

use a multilocus dataset to estimate gene trees under maximum likelihood and Bayesian models to obtain a robust estimate of relationships for a genus of North American damselflies, *Enallagma*. Using a relaxed molecular clock, we estimate the divergence times for this group. Furthermore, to account for the fact that gene tree analyses can overestimate ages of population divergences, we use a multi-population coalescent model to gain a more accurate estimate of divergence times. We also infer diversification rates using a method that allows for variation in diversification rate through time and among lineages. Our results reveal a complex evolutionary history of *Enallagma*, in which divergence events both predate and occur during Pleistocene climate fluctuations. There is also evidence of diversification rate heterogeneity across the tree. These divergence time estimates provide a foundation for addressing the relative significance of historical climatic events in the diversification of this genus." (Authors)] Address: Callahan, Melissa, Department of Biological Sciences, Dartmouth College, 78 College Street, Hanover, NH 03755, USA. E-mail: callahan.ms@gmail.com

**15576.** Campos, F.; Velasco, T.; Sanz, G.; Casanueva, P.; Albuquerque, M.T.D.; Antunes, M.H.R. (2016): *Ischnura graellsii* (Insecta: Odonata): a water pollution biovulnerable indicator-probability mapping using spatial uncertainty. *River Research and Applications* 32: 483-489. (in English) ["Monitoring changes of anthropogenic impacts from a broad scope of species in biodiversity research require practical, easy-to-use and efficient assessment as well as monitoring methods. Odonates are a valuable tool for assessing freshwater systems' quality and have been used as bioindicators of environmental variety. The Águeda watershed, located in the central west of the Iberian Peninsula, shows an exponential increase in the last 60 years of natural resource exploitation coupled with alterations in consumer habits, causing significant environmental changes and deferred direct effects on the natural habitats. Fourteen river sites, selected a priori, were sampled. Adult odonates were collected using standardized methods. Selected environmental variables and water quality parameters were evaluated in situ. Precipitation and altitude were the most important physical, environmental variables in explaining the assemblage structure. Meaningful abiotic-biotic as well as biotic-biotic relationships were set up. Furthermore, situations in the urbanized watershed area showed to be highly impacted and closely related with damselfly *Ischnura graellsii*, which should be targeted as a possible vulnerability indicator for polluted fresh waters. A probability map for *Ischnura graellsii* distribution was performed using indicator kriging with external drift and spatial uncertainty obtain through the calculation of two categorical maps (binary), corresponding to the mean (0.485) and the trimmed mean by discharging the 10% lower distribution tail (0.533). The subsequent overlapping of both categorical maps (binary) allowed the definition of the higher spatial uncertainty map for surface water contamination." **15577.** Casillas-Barragán, I.; Costa-Pereira, P.; Cardoso Peixoto, P.E. (2016): Perceived predation risk decreases movement and increases aggregation of Amazon milk frog (*Anura*, *Hylidae*) tadpoles throughout ontogeny. *Hydrobiologia* 765: 379-386. (in English) ["In order to maximize escaping success, prey may change their predator avoidance behaviours according to their susceptibility. Morphological development during ontogeny may lead to different susceptibility to predators. Consequently, prey may exhibit different predator avoidance strategies according to the ontogenetic state. In this study, we used tadpoles of the Amazon milk frog *Trachycephalus resinifictrix* to evaluate how variation in the ability to actively escape owed to the mobility acquired through ontogeny affects the adoption of predator avoidance strategies. We sampled tadpoles (N = 384) in temporary ponds and divided them in four consecutive developmental stages according to body size and mobility capacity. Subsequently, we measured their movement and spatial distribution when subjected to chemical cues of predators or control solutions. We found that they spent less time moving and increased spatial aggregation after receiving solutions with predator cues, independent of their developmental stage. These results indicate that the variation in escape capacity through larval ontogeny does not determine their antipredator strategy. Since tadpoles of *T. resinifictrix* typically grow in environments with reduced space for active escaping, such as tree holes and bromeliads, it may be that the ability to flee from predators is absent, even when this behaviour increases the survival chances." (2016): Sex-specific functional responses of dragonfly naiads *Rhodothemis rufa* on *Culex quinquefasciatus* larvae in laboratory bioassay. International Journal of Pest Management 62(2): 135-139. (in English) ["Laboratory bioassay was conducted to establish the biocontrol potentiality of naiads (aquatic nymphal stage) of *Rhodothemis rufa* (Rambur, 1842) against larvae of *Culex quinquefasciatus*, a common vector of filariasis in Tropical countries. From the study, it was noticed that in laboratory condition, the rate of predation of males of *R. rufa* was higher than that of females of almost same size and same species. The results of the present study revealed that both sexes displayed a density-dependent decelerating type-II functional response as the logistic regression estimated a significant negative linear parameter (P1 value of -0.330 and -0.151 for males and females, respectively). Attack rate was almost similar for both sexes (0.082); however, handling time is less in males (0.62 min) than in females (0.852 min). The predator species usually coexist in the same aquatic habitat to that of mosquito larvae and can be effectively used in field condition to reduce the larval densities of mosquitoes in temporary or permanent aquatic water bodies." **15581.** Chen, Y.H.; Skote, M. (2016): Gliding performance of 3-D corrugated dragonfly wing with spanwise variation. Journal of Fluids and Structures 62: 1-13. (in English) ["Computational fluid dynamics (CFD) analyses are conducted to evaluate the gliding performance of a three-dimensional (3-D) corrugated wing while considering variations in the corrugation pattern across the wing span. Comparisons with the smoothly profiled counterpart assess the overall effect of wing corrugation on the gliding performance of the 3-D dragonfly wing, with primary focus on the effect of three-dimensionality as compared to the 2-D model. Earlier simulations of both 2-D and 3-D gliding corrugated wings showed oscillations on lift and drag, while in nature, such force fluctuation would be undesirable and unrealistic. In contrast, no non-realistic fluctuations are present in this simulation. The feature included here, which has been neglected in the earlier studies, namely the variation of leading edge orientation along the wing span, is the crucial detail for

preventing such non-realistic oscillations. Furthermore, strong spanwise flow occurs in the 3-D corrugated wing used in this study, which earlier models have been incapable to capture." (in English) ["The diets of the Intermediate Egret *Egretta intermedia*, Little Egret *E. garzetta*, and Cattle Egret *Bubulcus ibis* were examined by analyzing nestling regurgitations collected during the breeding season in 2005 at a colony in Asan, South Korea. Intermediate Egret nestlings mainly fed on insects (86.7% of total prey items), but fish were the most important group by biomass (64.3% of total biomass). Little Egret nestlings fed mainly on insects and fishes (43.4% and 33.2% of total items, respectively), and fish contributed 64.2% to the total biomass consumed. Cattle Egret chicks were mainly fed invertebrate prey (96.5% of total items), such as insects and spiders, which comprised just 64.3% of the total biomass of their diet. Loaches and aquatic insect larvae (mainly Odonata and Coleoptera) comprised a large proportion of the nestling diet of the three egret species. This suggests that all species forage primarily in rice fields, which represented the most extensive habitat surrounding the breeding colony." **15583.** Cooper, I.A.; Brown, J.M.; Getty, T. (2016): A role for ecology in the evolution of colour variation and sexual dimorphism in Hawaiian damselflies. Journal of Evolutionary Biology 29(2): 418-427. (in English) ["Variation in traits that are sexually dimorphic is usually attributed to sexual selection, in part because the influence of ecological differences between sexes can be difficult to identify. Sex-limited dimorphisms, however, provide an opportunity to test ecological selection disentangled from reproductive differences between the sexes. Here, we test the hypothesis that ecological differences play a role in the evolution of body colour variation within and between sexes in a radiation of endemic Hawaiian damselflies. We analyzed 17 *Megalagrion* damselflies species in a phylogenetic linear regression, including three newly-discovered cases of species with female-limited dimorphism. We find that rapid colour evolution during the radiation has resulted in no phylogenetic signal for most colour and habitat traits. However, a single ecological variable, exposure to solar radiation (as measured by canopy cover) significantly predicts body colour variation within sexes (female-limited dimorphism), between sexes (sexual dimorphism), and among populations and species. Surprisingly, the degree of sexual dimorphism in body colour is also positively correlated with the degree of habitat differences between sexes. Specifically, redder colouration

is associated with more exposure to solar radiation, both within and between species. We discuss potential functions of the pigmentation, including antioxidant properties that would explain the association with light (specifically UV) exposure, and consider alternative mechanisms that may drive these patterns of sexual dimorphism and colour variation." **15585.** Cordero-Rivera, A. (2016): Demographics and adult activity of *Hemiphlebia mirabilis*: a short-lived species with a huge population size (Odonata: Hemiphlebiidae). *Insect Conservation and Diversity* 9: 108-117. (in English) ["(1.) Rare species are expected to be more susceptible to extinction, particularly if rarity can be used to describe several characteristics for a particular species. *Hemiphlebia mirabilis*, an endemic damselfly known from a few sites in the South of Australia and Tasmania, has been considered at risk of imminent global extinction, given its small population size, its localised distribution, and the fact that it is a 'living fossil', described as the oldest extant damselfly. (2.) One population found in a protected wetland in Victoria, was studied by behavioural observations of marked animals,

during Nov-Dec 2013. Results indicate that *H. mirabilis* is a short-lived species, with a mature lifespan of about 1 week in males and 4 days in females. (3.) Population size estimates and field observations indicate that this population is huge, likely over one million individuals per generation. Adults show little mobility and fly for short distances, being inactive most of the time, particularly at temperatures below 17 °C or over 35 °C. (4.) The low mobility and cryptic coloration, and the inaccessibility of its preferred habitat might explain why huge populations like the one studied here have remained unnoticed until recently. Nevertheless, both sexes show frequent abdominal flicking displays, and fast rotations over the perching support, both behaviours apparently unique to this species, making them highly conspicuous to human observers. It is concluded that *H. mirabilis* should not be regarded as critically endangered." (Authors)] Address: Cordero Rivera, A., Depto de Ecología e Biología Animal, Universidade de Vigo, E.U.E.T. **15586.** Cordero-Rivera, A. (2016): Sperm removal during copulation confirmed in the oldest extant damselfly, *Hemiphlebia mirabilis*. *PeerJ Preprints* 4:e1810v1 <https://doi.org/10.7287/peerj.preprints.1810v1>: (in English) ["Post-copulatory sexual selection may favour mechanisms to reduce sperm competition, like physical sperm removal by males. To investigate the origin of sperm removal, I studied the reproductive behaviour and mechanisms of sperm competition in the only living member of the oldest damselfly family, *Hemiphlebia mirabilis*, one species that was considered extinct in the 1980s. This species displays scramble competition behaviour, whose males search for females with short flights and both sexes exhibit a conspicuous "abdominal flicking". This behaviour is used by males during an elaborate precopulatory courtship, unique among the Odonata. Females use a similar display to reject male attempts to form tandem, but eventually signal receptivity by a particular body position. Males immobilise females during courtship using their legs, which, contrarily to other damselflies, never autotomize. Copulation is short (range 4.1-18.7 min), and has two stages. In the first stage, males remove part of the stored sperm, and inseminate during the second stage, at the end of mating. The examination of genitalia indicates that males have two horns covered by back-oriented spines, which match the size and form of female genitalia. The volume of sperm in females after copulation was 2.8 times larger than the volume stored in females whose copulation was interrupted at the end of stage I, indicative of a significant sperm removal. These results point out that sperm removal is an old character in the evolution of odonates, probably dating back to the Permian." N. (2016): The status of *Rhionaeschna galapagoensis* (Currie, 1901) with notes on its biology and a description of its ultimate instar larva (Odonata, Aeshnidae). *Animal Biodiversity and Conservation* 39(1): 45-63. (in English, with Spanish summary) ["A morphological, molecular, and behavioural characterization of *R. galapagoensis* is presented, based on a series of specimens and observations from San Cristóbal Island, Galápagos, including both adults and larvae. Several of the characters proposed earlier to distinguish between the adults of this species and its closest relative, *R. elsia*, are found to be variable, but the presence of a black band over the fronto-clypeal suture is confirmed as a good diagnostic character. The ultimate instar larvae of *R. galapagoensis* is described for the first time, and diagnosed from its closest relatives by a combination of characters, including the acute angle between the prothoracic apophyses, absence of lateral spines on abdominal segment 6, and length of cerci relative to paraprocts. Molecular analysis confirmed that *R. galapagoensis* and *R. elsia* are sister species, and showed that their genetic distance is the closest among the analyzed species, which is to be expected given the young age of the Galápagos Islands. The larvae of *R. galapagoensis* were very common and widespread in the mountain streams and a pond in the southwest of San Cristóbal. Swarms of tens of individuals formed at sunrise in the coastal vegetation, together with adults of *Tramea cf. cophysa*, feeding on small flying insects. Males showed patrolling behaviour on small sections of the streams and at a pond. Only one copulation was observed, lasting 10 minutes. Females oviposited alone on floating vegetation in running and standing waters. Our observations corroborate that *R. galapagoensis* and *R. elsia* are two parapatric species, morphologically and genetically close. In San Cristóbal, *R. galapagoensis* had large populations, apparently not threatened." (2016): Landscape complexity and farmland biodiversity: Evaluating the CAP target on natural elements. *Journal for Nature Conservation* 30(1): 19-26. (in English) ["Increasing pressures on natural areas and limited conservation budgets require, particularly in rural landscapes in the Western world, an immediate answer to the question how much natural area is required to provide a sustainable future for wild plant and animal species on farmland. The European Union proposed in its Common Agricultural Policy that 3–7% of EU farmland should be managed as ecological focus area (EFA) in order to halt biodiversity loss. For the first time, we empirically assessed the implications of this policy by evaluating the effects of the density of natural elements in agricultural landscapes on multi-taxon species richness, including vascular plants, breeding birds, butterflies, hoverflies, dragonflies, and grasshoppers for an entire European country. We found that species richness increased either as

linear or as a logarithmic function of the proportion of natural elements in the landscape, but not with a sigmoid function as predicted by the 'intermediate landscape complexity' hypothesis. Even landscapes with 3–7% of natural elements harboured generally 37–75% of maximum species richness, indicating good potential of implementing the CAP target to preserve farmland biodiversity. However, differences between the 3 and 7% limits were considerable for butterflies, birds, and hoverflies. Also, the shape of the species richness response was shown to differ between landscape types for butterflies. Thus, it may be necessary to develop tailor-made guidelines at regional levels." (2016): Diverse circular replication-associated protein encoding viruses circulating in invertebrates within a lake ecosystem. *Infection, Genetics and Evolution* 39: 304-316. (in English) ["Highlights: •Sampled molluscs, insect larvae, water and benthic sediments for CRESS DNA viruses. •Recover 169 circular molecules (160 CRESS DNA molecules, nine circular molecules). •Identification of a new RNA–DNA hybrid virus. •Strong association between viral sequences between water and browser organisms. •Strong association between viral sequences between sediments and undefended prey species. Abstract: Over the last five years next-generation sequencing has become a cost effective and efficient method for identifying known and unknown microorganisms. Access to this technique has dramatically changed the field of virology, enabling a wide range of environmental viral metagenome studies to be undertaken of organisms and environmental samples from polar to tropical regions. These studies have led to the discovery of hundreds of highly divergent single stranded DNA (ssDNA) virus-like sequences encoding replication-associated proteins. Yet, few studies have explored how viruses might be shared in an ecosystem through feeding relationships. Here we identify 169 circular molecules (160 CRESS DNA molecules, nine circular molecules) recovered from a New Zealand freshwater lake, that we have tentatively classified into 51 putatively novel species and five previously described species (*DflaCV-3*, -5, -6, -8, -10). The CRESS DNA viruses identified in this study were recovered from molluscs (*Echydrella menzeisii*, *Musculium novaezelandiae*, *Potamopyrgus antipodarum* and *Physella acuta*) and

insect larvae (*Procordulia grayi*, *Xanthocnemis zealandica*, and *Chironomus zealandicus*) collected from Lake Sarah, as well as from the lake water and benthic sediments. Extensive diversity was observed across most CRESS DNA molecules recovered. The putative capsid protein of one viral species was found to be most similar to those of members of the Tombusviridae family, thus expanding the number of known RNA–DNA hybrid viruses in nature. We noted a strong association between the CRESS DNA viruses and circular molecules identified in the water and browser organisms (*C. zealandicus*, *P. antipodarum* and *P. acuta*), and between water sediments and undefended prey species (*C. zealandicus*). However, we were unable to find any significant correlation of viral assemblages to the potential feeding relationships of the host aquatic invertebrates." **15593.** Dickens, C.W.S.; Graham, P.M. (2016): The South African Scoring System (SASS) Version 5 Rapid Bioassessment Method for Rivers. *African Journal of Aquatic Science* 27: 1-10. (in English) ["The assessment of biota in rivers is a widely recognized means of determining the condition or 'health' of rivers. Benthic macroinvertebrates, in particular, are recognized as valuable organisms for bioassessments, due largely to their visibility to the naked eye, ease of identification, rapid life cycle often based on the seasons and their largely sedentary habits. Numerous bioassessment techniques have been developed over the last three decades, varying in complexity and region of implementation. South Africa has an exemplary history in this field, culminating in the refinement of invertebrate and other techniques and their application in a National River Health Programme. The method presented here is a refinement of the highly successful SASS (South African Scoring System) method developed by Chutter (1994), which forms the backbone of this programme. This paper takes the method to a level where it can, and has been, accredited to ISO standards. The principal changes made include the tighter definition of the technique and the sampling and analytical methods, as well as the introduction of quality control procedures. Some changes have also been made to the list of invertebrates used in this method. Field trials were conducted to test the variability of the method. Of the various indices available to the method, the ASPT is the most consistent over all biotopes (lowest CV%). On the other hand, of the biotopes examined the Gravel/Sand/Mud (GSM) combination is the most variable with respect to the SASS Score and number of taxa encountered. The spatial variability on a reach of river with similar water quality characteristics was found to be statistically negligible. However, one generally finds that statistically significant differences occur between the SASS Scores and the number of taxa counted by different operators. The ASPT, on the other hand, is a more consistent and repeatable measure of river health assessment and, within a given reach of river and considering all biotopes, the differences in results produced by different operators were statistically negligible. The results highlight the need for appropriate competency-based training and consistent application of the method." **15594.** Dorrington, G.E. (2016): Heavily loaded flight and limits to the maximum size of dragonflies (Anisoptera) and griffenflies (Meganisoptera). *Lethaia* 49(2): 261-274. (in English) ["An original hypothesis is presented that the maximum mass and size of living anisopteran dragonflies are constrained by a physiological performance limit: the wing muscle power required to permit reproductively successful males to carry heavier females in the so-called 'wheel position' in flight. It is proposed that the same limit cannot have applied to all fossil Odonatoptera. As the physiology of the giant Carboniferous griffenfly *Namurotypus sippeli* precludes flight in the wheel position, it did not need to carry any substantial load aside from exogenous aerial prey. Based

on its thorax dimensions, it is argued that *Namurotypus* flew with a relatively low maximum specific muscle power output in comparison with living Anisoptera. The extinction of some families of large Mesozoic Odonoptera may have been exacerbated by competition with smaller (stem-) Anisoptera that evolved higher specific power outputs and superior flight performance similar to living Anisoptera. To investigate the credibility of this flight-performance size-limit hypothesis and its consequences, an analysis of the scaling of the required flight power and available muscle power is presented using allometric relations. It is found that for living Anisoptera and fossil Odonoptera, there are different limiting sizes, above which the required specific flight power would exceed the available muscle specific power. These limits are directly related to maximum load-carrying capacity and the atmospheric air density at the habitual altitude. It is suggested that the largest living species of Petaluridae, *Petalura ingentissima*, is close to the proposed Anisoptera size limit at current near-sea-level air density conditions." **15599.** Espanha, J.; de Vasconcelos, M.F.; Eterovick, P.C. (2016): The role of tadpole coloration against visually oriented predators. *Behavioral Ecology and Sociobiology* 70(2): 255-267. (in English) ["An animal's vulnerability to predators can be influenced by its behaviour, morphology, body size, coloration, habitat preferences, and palatability. We tested whether the coloration of *Bokermannohyla saxicola* and *Scinax machadoi* tadpoles affects their survival when exposed to local visually oriented predators at a site in southeastern Brazil. We tested three aquatic invertebrates (*Aeshnidae*, *Belostoma* sp., *Lethocerus* sp.) and birds as tadpole predators. We predicted that predation rates would differ depending on the substrate where the tadpoles positioned themselves (light or dark), hypothesizing that each tadpole would use preferentially a background that conferred camouflage and that predation levels would be lower on such backgrounds compared to others. *B. saxicola* had higher survivorship than *S. machadoi* on light backgrounds at some instances, in accordance with its crypsis hypothesis. However, *B. saxicola* tadpoles did not use light backgrounds more often than dark ones. *S. machadoi* coloration looked disruptive on both light and dark backgrounds, and tadpoles showed no preference or differences in survival rates between these backgrounds. Predation rates did not differ between the two species in a way that could confirm a previous hypothesis of aposematic/mimetic coloration for *S. machadoi* tadpoles. Our results show that colorations that appear to function to impair visual detection may play this role at some circumstances but not others. Tadpole colorations may have evolved in another context, in which avoiding visual detection by predators was a stronger selective pressure. In a context with lower predation pressure from visually oriented predators, the expected background choice behaviour for increased camouflage

may not be strongly selected for." (Authors)] Address: Eterovick, Paula, Programa de Pós Graduação em Biologia de Vertebrados, Pontifícia Universidade Católica de Minas Gerais, Belo Horizonte, 30535-610, Brazil. E-mail: pcterovick@gmail.com

**15600.** Fauziyah, S.; Soesilohadi, R.C.H.; Retnoaji, B.; Alam, P. (2016): Dragonfly wing venous cross-joints inspire the design of higher-performance bolted timber truss joints. *Composites Part B: Engineering* 87: 274-280. (in English) ["This communication concerns the design and development of high performance biomimetic timber joints as inspired by the venous cross-joints of dragonfly wings. A special cross-joint configuration in *Crocothemis servilia* is identified. Between the veins of this cross-joint is a resilin envelope. Finite element modelling reveals that the presence of this resilin envelope reduces the levels of localised stress in the jointing region. By gaining an understanding of the structure and function of this dragonfly wing joint, dragonfly-joint inspired timber trusses are developed by integrating low-modulus adhesives around bolted connectors. We find that not only are the properties of strength, stiffness, toughness and deformability of bolted truss joints vastly improved on applying dragonfly-mimicking technology, but that the fatigue resistance is also enhanced. This preliminary work is an important step forward in the design and development of high-performance biomimetic joints for timber construction." **15602.** Finley, M.L.D.; Kidd, K.A.; Curry, R.A.; Lescord, G.L.; Clayden, M.G.; O'Driscoll, N.J. (2016): A comparison of mercury biomagnification through lacustrine food webs supporting Brook Trout (*Salvelinus fontinalis*) and other salmonid fishes. *Frontiers in Environmental Science* 4 (Article23): 13 pp. (in English) ["Methylmercury (MeHg) bioaccumulation in lower-trophic-level organisms and its subsequent biomagnification through food webs differs in magnitude among lakes and results in intraspecific variability of

MeHg in top predator fishes. Understanding these differences is critical given the reproductive and neurotoxic effects of MeHg on fishes and their predators, including humans. In this study we characterized the food webs of five lakes in New Brunswick, Canada, supporting Brook Trout (*Salvelinus fontinalis*) using measures of relative trophic position (d15N) and carbon sources (d13C), determined the concentrations of MeHg in invertebrates and total Hg (THg) in fishes, and quantified MeHg biomagnification from primary to tertiary consumers. Methyl Hg and THg concentrations were highest in biota from lakes with lower pH. The trophic magnification slopes (TMS; log Hg vs. d15N) varied significantly among lakes (0.13–0.20; ANCOVA,  $p = 0.031$ ). When combined with data from other salmonid lakes in temperate and Arctic Canada ( $n = 36$ ), among-system variability in TMS was best, but weakly, positively predicted by aqueous total phosphorous ( $p = 0.028, 0.109$ ). These results suggest that lake productivity directly or indirectly influences the biomagnification of MeHg through diverse food webs supporting salmonids." **15603.** Freeland-Riggert, B.T.; Cairns, S.H.; Poulton, B.C.; Riggert, C.M. (2016): Differences found in the macroinvertebrate community composition in the presence or absence of the invasive alien crayfish, *Orconectes hylas*. *PLoS ONE* 11(3): e0150199. doi:10.1371/journal.pone.0150199: 27 pp. (in English) ["Introductions of alien species into aquatic ecosystems have been well documented, including invasions of crayfish species; however, little is known about the effects of these introductions on macroinvertebrate communities. The woodland crayfish (*Orconectes hylas* (Faxon)) has been introduced into the St. Francis River watershed in southeast Missouri and has displaced populations of native crayfish. The effects of *O. hylas* on macroinvertebrate community composition were investigated in a fourth-order Ozark stream at two locations, one with the presence of *O. hylas* and one without. Significant differences between sites and across four sampling periods and two habitats were found in five categories of benthic macroinvertebrate metrics: species richness, percent/composition, dominance/diversity, functional feeding groups, and biotic indices. In most seasons and habitat combinations, the invaded site had significantly higher relative abundance of riffle beetles (Coleoptera: Elmidae), and significantly lower Missouri biotic index values, total taxa richness, and both richness and relative abundance of midges (Diptera: Chironomidae). Overall study results indicate that some macroinvertebrate community differences due to the *O. hylas* invasion were not consistent between seasons and habitats, suggesting that further research on spatial and temporal habitat use and feeding ecology of Ozark crayfish species is needed to improve our understanding of the effects of these invasions on aquatic communities." **15604.** Fujimoto, M.S.; Suvorov, A.; Jensen, N.O.; Clement, M.J.; Bybee, S.M. (2016): Detecting false positive sequence homology: a machine learning approach. *BMC Bioinformatics* (2016) 17:101. DOI 10.1186/s12859-016-0955-3: 11 pp. (in English) ["Background: Accurate detection of homologous relationships of biological sequences (DNA or amino acid) amongst organisms is an important and often difficult task that is essential to various evolutionary studies, ranging from building phylogenies to predicting functional gene annotations. There are many existing heuristic tools, most commonly based on bidirectional BLAST searches that are used to identify homologous genes and combine them into two fundamentally distinct classes: orthologs and paralogs. Due to only using heuristic filtering based on significance score cutoffs and having no cluster post-processing tools available, these methods can often produce multiple clusters constituting unrelated (non-homologous) sequences. Therefore sequencing data extracted from incomplete genome/transcriptome assemblies originated from low coverage sequencing or produced by de novo processes without a reference genome are susceptible to high false positive rates of homology detection. Results: In this paper we develop biologically informative features that can be extracted from multiple sequence alignments of putative homologous genes (orthologs and paralogs) and further utilized in context of guided experimentation to verify false positive outcomes. We demonstrate that our machine learning method trained on both known homology clusters obtained from OrthoDB and randomly generated sequence alignments (non-homologs), successfully determines apparent false positives inferred by heuristic algorithms especially among proteomes recovered from low-coverage RNA-seq data. Almost ~42 % and ~25 % of predicted putative homologies by InParanoid and HaMStR respectively were classified as false positives on experimental data set (For the experimental data set (OD\_S) we used 18 Odonata (dragonflies and damselflies) and 2 Ephemeroptera (mayflies) species.). Conclusions: Our process increases the quality of output from other clustering algorithms by providing a novel post-processing method that is both fast and efficient at removing low quality clusters of putative homologous genes recovered by heuristic-based approaches." **15605.** Golfieri, B.; Hardersen, S.; Maiolini, B.; Surian, N. (2016): Odonates as indicators of the ecological integrity of the river corridor: Development and application of the Odonate River Index (ORI) in northern Italy. *Ecological Indicators* 61(2): 234-247. (in English) ["The assessment of the ecological conditions of rivers is crucial for their appropriate management and restoration. Bioindicators commonly used to evaluate the river status (i.e. diatoms, aquatic macrophytes, benthic macroinvertebrates and fish) detect alterations of water quality, but are not particularly sensitive to hydromorphological degradation, which is another relevant pressure in river systems. Furthermore, those bioindicators are usually applied only to flowing channels. We developed

a new multimetric index, the Odonate River Index (ORI), to assess the conditions of the whole corridor in alluvial rivers. The ORI is a development of an evaluation system proposed in Austria, and based on the Odonate Habitat Index (OHI). Odonates were chosen as bioindicators for the ecological integrity of the river corridor, since this taxon provides information on the conditions of their aquatic breeding sites, as well as on the surrounding terrestrial areas, due to its amphibiotic life cycle. We used a case study of 18 reaches from six Italian Alpine rivers, characterized by different morphological conditions and level of human impact. Within each study reach, we selected four sites, both lotic and lentic sites. Dragonfly surveys consisted in field observation of adults, and collection of larvae and exuviae. To define the best sampling strategy, we compared the results of the ORI metrics obtained varying the input data by combining different sampling methods: the best compromise between effort and exhaustiveness was obtained coupling the observation of adults with the collection of exuviae. We found the ORI to be a robust and reliable tool to assess the status of the river corridor in a wide range of environmental conditions and river morphology, being particularly suitable to detect hydromorphological degradation and alterations of the structure of aquatic and riparian vegetation. We identified two limiting factors for the applicability of this index: low water temperatures of the main channel (i.e. mean annual value below 10 °C) and river reaches with no or scarce aquatic and riparian vegetation. In addition to the assessment of river conditions, the ORI could also be applied for monitoring the effects of river restoration actions." **15608.** Harabis, F. (2016): High diversity of odonates in post-mining areas: Meta-analysis uncovers potential pitfalls associated with the formation and management of valuable habitats. *Ecological Engineering* 90: 438-446. (in English) ["A growing number of studies indicate high conservation potential of freshwater habitats occurring in post-mining areas. The overall diversity of these habitats depends on many factors, however, even a high diversity may diminish significantly over time. Therefore, it is difficult to identify and understand the importance of key habitat properties for diversity. Here I present analysis of three studies comparing the diversity of dragonflies and damselflies (Odonata). Each study was performed in different coal mining basins within the Czech Republic (a total of 94 sites). In this analysis, I used generalized linear mixed models and several multivariate methods to analyze the effects of a number of environmental characteristics such as depth, bottom substrate or bank slope, reflecting not only the current quality but also the succession and formation of individual pools. The occurrence of overall 14 nationally red listed species indicates the high conservation value of these habitats, while the 40 species found indicate that these areas contribute significantly to regional diversity. Species richness of individual pools was associated with habitat type (spoil heap vs. mine subsidence) and with several habitat variables, in particular the character of vegetation around aquatic habitats. In conclusion, the results indicate that diversity and species composition are significantly influenced by factors reflecting the formation and subsequent succession of pools. Effective conservation management should concentrate primarily on modifying pools' initial properties such as bottom substrate. Subsequent management should then sustain landscape dynamics, which means in particular to sustain minor disturbances that subsequently affect vegetation succession and prevent excessive overgrowing of expansive vegetation, as doing so is promoting the habitat heterogeneity which is essential to high biodiversity in these areas." (Author)] Address: Harabiš, F., Department of Ecology, Faculty of Environmental Sciences, Czech University of Life Sciences Prague, CZ-165 21 Prague 6, Czech Republic. E-mail: harabis.f@gmail.com

**15609.** Hasenbein, S.; Lawler, S.P.; Geist, J.; Connon, R.E. (2016): A long-term assessment of pesticide mixture effects on aquatic invertebrate communities. *Environmental Toxi-*

*cology and Chemistry* 35(1): 218-232. (in English) ["To understand the potential effects of pesticide mixtures on aquatic ecosystems, studies that incorporate increased ecological relevance are crucial. Using outdoor mesocosms, the authors examined long-term effects on aquatic invertebrate communities of tertiary mixtures of commonly used pesticides: 2 pyrethroids (permethrin, I-cyhalothrin) and an organophosphate (chlorpyrifos). Application scenarios were based on environmentally relevant concentrations and stepwise increases of lethal concentrations from 10% (LC10) to 50% (LC50) based on laboratory tests on *Hyalella azteca* and *Chironomus dilutus*; repeated applications were meant to generally reflect runoff events in a multiple-grower or homeowner watershed. Pyrethroids rapidly dissipated from the water column, whereas chlorpyrifos was detectable even 6wk after application. Twelve of 15 macroinvertebrate and 10 of 16 zooplankton taxa responded to contaminant exposures. The most sensitive taxa were the snail *Radix* sp., the amphipod *H. azteca*, the water flea *Daphnia magna*, and copepods. Environmentally relevant concentrations had acute effects on *D. magna* and *H. azteca* (occurring 24 h after application), whereas lag times were more pronounced in *Radix* sp. snails and copepods, indicating chronic sublethal responses. Greatest effects on zooplankton communities were observed in environmentally relevant concentration treatments. The results indicate that insecticide mixtures continue to impact natural systems over multiple weeks, even when no longer detectable in water and bound to particles. Combinations of indirect and direct effects caused consequences across multiple trophic levels. ... Summed over the present study period, Zygoptera represented the largest portion of macroinvertebrate abundance (20.9%), followed by the pulmonate snail *Radix* sp. (14.8%) and the amphipod *H. azteca* (13.2%). ... Between the 2 Odonata suborders, the chemical exposure had a greater effect on Anisoptera (positive trend) than Zygoptera. ... Zygoptera was the third most sensitive taxon and displayed a decreased abundance in LC-Chiro in week 2. ... Anisoptera abundance did not significantly deviate from the control over the course of the present study period but displayed a positive trend in all treatments from week 2 to week 5. This trend was not visible in the Odonata abundance, possibly because Anisoptera and Zygoptera responded in opposite directions. ... Zygoptera was the only taxon for which a decrease in emergence was detected." (Authors)] Address: Hasenbein, Simone, Dept of Anatomy, Physiology & Cell Biology, School of Veterinary Medicine, Univ. of California, Davis, California, USA. E-mail: shasenbein@ucdavis.edu

**15610.** Haug, J.T.; Haug, C.; Garwood, R.J. (2016): Evolution of insect wings and development – new details from Palaeozoic nymphs. *Biological Reviews* 91(1): 53-69. (in English) ["The nymphal stages of Palaeozoic insects differ significantly in morphology from those of their modern counterparts. Morphological details for some previously reported species have recently been called into question. Palaeozoic insect nymphs are important, however – their study could

provide key insights into the evolution of wings, and complete metamorphosis. Here we review past work on these topics and juvenile insects in the fossil record, and then present both novel and previously described nymphs, documented using new imaging methods. Our results demonstrate that some Carboniferous nymphs – those of Palaeodictyopteroidea – possessed movable wing pads and appear to have been able to perform simple flapping flight. It remains unclear whether this feature is ancestral for Pterygota or an autapomorphy of Palaeodictyopteroidea. Further characters of nymphal development which were probably in the ground pattern of Pterygota can be reconstructed. Wing development was very gradual (archimeta-boly). Wing pads did not protrude from the tergum posterolaterally as in most modern nymphs, but laterally, and had well-developed venation. The modern orientation of wing pads and the delay of wing development into later developmental stages (condensation) appears to have evolved several times independently within Pterygota: in Ephemeroptera, Odonoptera, Eumetabola, and probably several times within Polyneoptera. Selective pressure appears to have favoured a more pronounced metamorphosis between the last nymphal and adult stage, ultimately reducing exploitation competition between the two. We caution, however, that the results presented herein remain preliminary, and the reconstructed evolutionary scenario contains gaps and uncertainties. Additional comparative data need to be collected. The present study is thus seen as a starting point for this enterprise." **15611.** Hill, M.J.; Sayer, C.D.; Wood, P.J. (2016): When is the best time to sample aquatic macroinvertebrates in ponds for biodiversity assessment? *Environmental Monitoring and Assessment* 188:194: 11 pp. (in English) ["Ponds are sites of high biodiversity and conservation value, yet there is little or no statutory monitoring of them across most of Europe. There are clear and standardised protocols for sampling aquatic macroinvertebrate communities in ponds, but the most suitable time(s) to undertake the survey(s) remains poorly specified. This paper examined the aquatic macroinvertebrate communities from 95 ponds within different land use types over three seasons (spring, summer and autumn) to determine the most appropriate time to undertake sampling to characterise biodiversity. The combined samples from all three seasons provided the most comprehensive record of the aquatic macroinvertebrate taxa recorded within ponds (alpha and gamma diversity). Samples collected during the autumn survey yielded significantly greater macroinvertebrate richness (76 % of the total diversity) than either spring or summer surveys. Macroinvertebrate diversity was greatest during autumn in meadow and agricultural ponds, but taxon richness among forest and urban ponds did not differ significantly temporally. The autumn survey provided the highest measures of richness for Coleoptera, Hemiptera and Odonata. However, richness of the aquatic insect order Trichoptera was highest in spring and

lowest in autumn. The results illustrate that multiple surveys, covering more than one season, provide the most comprehensive representation of macroinvertebrate biodiversity. When sampling can only be undertaken on one occasion, the most appropriate time to undertake surveys to characterise the macroinvertebrate community biodiversity is during autumn, although this may need to be modified if other floral and faunal groups need to be incorporated into the sampling programme." **15613.** Hossie, T.J.; Murray, D.L. (2016): Spatial arrangement of prey affects the shape of ratio-dependent functional response in strongly antagonistic predators. *Ecology* 97(4): 834-841. (in English) ["Predators play a key role in shaping natural ecosystems, and understanding the factors that influence a predator's kill rate is central to predicting predator-prey dynamics. While prey density has a well-established effect on predation, it is increasingly apparent that predator density also can critically influence predator kill rates. The effects of both prey and predator density on the functional response will, however, be determined in part by their distribution on the landscape. To examine this complex relationship we experimentally manipulated prey density, predator density, and prey distribution using a tadpole (prey) - dragonfly nymph (predator) system. Predation was strongly ratio-dependent irrespective of prey distribution, but the shape of the functional response changed from hyperbolic to sigmoidal when prey were clumped in space. This sigmoidal functional response reflected a relatively strong negative effect of predator interference on kill rates at low prey: predator ratios when prey were clumped. Prey aggregation also appeared to promote stabilizing density-dependent intra-guild predation in our system. We conclude that systems with highly antagonistic predators and patchily distributed prey are more likely to experience stable dynamics, and that our understanding of the functional response will be improved by research that examines directly the mechanisms generating interference." (Authors)] Address: Hossie, T., Department of Biology, Trent University, Peterborough, Ontario, Canada. E-mail: thossie@trentu.ca

**15614.** Ilvonen, J.J.; Kaunisto, K.M.; Suhonen, J. (2016): Are sexes equally parasitized in damselflies and dragonflies? *Oikos* 125: 315-325. (in English) ["Parasitism plays an essential part in ecology and evolution of host species and understanding the reasons for differential parasitism within and among hosts species is therefore important. Among the very important factors potentially affecting parasitism is the gender of the host. Here, we studied whether either females

or males are more likely to harbour parasites among odonatan insects, by relying on an extensive literature review and new field data. We collected data on numerous dragonfly and damselfly species and their ectoparasites (water mites) and endoparasites (gregarines) to examine the generality of similarities and differences in prevalence, intensity and maximum number of parasites of male and female hosts. We found three main results. Firstly, most of the odonate host species showed no differences between sexes in either gregarine or water mite prevalence and intensity. The only exception was female damselflies' higher gregarine prevalence and intensity compared to conspecific males. These inequalities in gregarine parasitism may be due to behavioural and physiological differences between conspecific males and females. In comparison, there were no differences in dragonflies between sexes in water mite or gregarine prevalence and intensity. Secondly, damselflies had higher prevalence and intensity levels of both gregarine and water mite parasites compared to dragonflies. Finally, we found a strong species level pattern between female and male parasitism: a certain level of gregarine or water mite parasitism in one sex was matched with a similar parasitism level for the other. This indicates similar exposure and susceptibility to parasites on both sexes. Even though significant differences of parasite levels between the sexes were observed within certain host species, our results strongly suggest that on a general level a more parasitized sex does not exist in the order, Odonata." **15615.** Jakob, C.; Poulin, B. (2016): Indirect effects of mosquito control using Bti on dragonflies and damselflies (Odonata) in the Camargue. *Insect Conservation and Diversity* 9: 161-169. (in English) ["(1.) *Bacillus thuringiensis* var. *israelensis* (Bti) has become the most commonly used larvicide to control mosquitoes worldwide. Bti is considered non-toxic to most organisms, except some Diptera such as chironomids, which are a major prey in wetland food webs. (2.) Although Odonata are important predators of mosquitoes and chironomids at the larval and adult stages, no study has ever considered the potential indirect effects of Bti on Odonata abundance through trophic interactions. We addressed this topic in the Camargue where 2500 of the 25 000 ha of mosquito larval biotopes are Bti-sprayed (aqueous solution of VectoBac 12AS at 2.5 L ha<sup>-1</sup>) whenever mosquito larvae appear in water bodies (i.e. 30–50 aerial treatments overall annually). (3.) Adult Odonata were surveyed along a 100-m line transect in spring, summer and autumn at three control and three treated sites over a 5-year period. (4.) Mean number of species (9.9 vs. 5.2) and of individuals (100 vs. 50) detected per year were significantly higher in control areas compared to Bti-sprayed areas. Bti treatment contributed to 87.3% of the explained variance in Odonata richness, compared to 2.9% for site, 6.8% for year and 3.0% for salinity effects. (5.) These results are coherent with other studies carried out in the same area and time period highlighting a lower abundance of chironomids, and a lower intake of odonates by breeding birds in treated areas.

(6.) We conclude that mosquito control using Bti should be acknowledged as a potential threat to Odonata." (Authors)] Address: Poulin, Brigitte, Tour du Valat, Le Sambuc, 13200 Arles, France. E-mail: [poulin@tourduvalat.org](mailto:poulin@tourduvalat.org)

**15616.** Jeremiason, J.D.; Reiser, T.K.; Weitz, R.A.; Berndt, M.E.; Aiken, G.R. (2016): Aeshnid dragonfly larvae as bio-indicators of methylmercury contamination in aquatic systems impacted by elevated sulfate loading. *Ecotoxicology* 25(3): 456-468. (in English) ["Methylmercury (MeHg) levels in dragonfly larvae and water were measured over two years in aquatic systems impacted to varying degrees by sulfate releases related to iron mining activity. This study examined the impact of elevated sulfate loads on MeHg concentrations and tested the use of MeHg in dragonfly larvae as an indicator of MeHg levels in a range of aquatic systems including 16 river/stream sites and two lakes. MeHg concentrations in aeshnid dragonfly larvae were positively correlated ( $R^2 = 0.46$ ,  $p < 0.01$ ) to peak MeHg concentrations in the dissolved phase for the combined years of 2012 and 2013. This relation was strong in 2012 ( $R^2 = 0.85$ ,  $p < 0.01$ ), but showed no correlation in 2013 ( $R^2 = 0.02$ ,  $p > 0.05$ ). MeHg in dragonfly larvae were not elevated at the highest sulfate sites, but rather the reverse was generally observed. Record rainfall events in 2012 and above average rainfall in 2013 likely delivered the majority of Hg and MeHg to these systems via interflow and activated groundwater flow through reduced sediments. As a result, the impacts of elevated sulfate releases due to mining activities were not apparent in these systems where little of the sulfate is reduced. Lower bioaccumulation factors for MeHg in aeshnid dragonfly larvae were observed with increasing dissolved organic carbon (DOC) concentrations. This finding is consistent with previous studies showing that MeHg in high DOC systems is less bioavailable; an equilibrium model shows that more MeHg being associated with DOC rather than algae at the base of the food chain readily explains the lower bioaccumulation factors." **15617.** Jisha Krishnan, E. K.; Sebastian, C. D. (2016): Analysis of phylogenetic status of different *Neurothemis* (Odonata:libellulidae) species using Cytochrome Oxidase I gene sequence. *Global Journal For Research Analysis* 5(3): 85-87. (in English) ["Here we have analysed the phylogenetic relationships of three different species of *Neurothemis* (*tullia*, *intermedia*, *fulvia*) by the partial sequencing of mitochondrial cytochrome oxidase subunit I (COI) gene. Phylogenetic tree constructed by Neighbour joining method proved that *Neurothemis tullia* and *Neurothemis intermedia* are taxonomically more closer and they together formed a single clade in the tree. *Neurothemis fulvia* is sister to this clade but it represents the most diverged species in terms of branch length and nucleotide substitution. Comparison with the retrieved sequences confirmed that it strictly belong to Libellulidae family. The tree also depicted that *Neurothemis* genus is more close to *Orthetrum sabina* than *Diplacodes trivialis*. Hence the study concluded that DNA

barcoding is an invaluable tool for confirming the species identification and to assess the proper phylogenetic relationships." (Authors)] Address: Sebastian, C. D., Molecular Biology Lab., Dept of Zoology, Univ. Calicut, Kerala, India

**15618.** Jones, D.K.; Hua, J.; Relyea, R.A. (2016): Effects of endosulfan in freshwater pond communities. *Freshwater Science* 35(1): 152-163. (in English) ["Pesticide use has led to ubiquitous contamination of natural habitats that can cause direct and indirect effects on nontarget organisms. Laboratory toxicity tests are valuable for evaluating the direct lethal effects of pesticides, but whether species differences in sensitivity identified from such tests are representative of more natural conditions is unknown. Studies of pesticide effects on communities are needed to understand the indirect effects of pesticides, but many such studies are focused on simplified communities and overlook the contribution of higher trophic levels (i.e., lethal predators), which can have interactive effects with pesticides and may play a large role in influencing community dynamics in contaminated habitats. Much of the research investigating pesticides in communities has focused on organophosphates, carbamates, and pyrethroids, whereas organochlorines are understudied, despite the fact that they can be highly toxic and persist in the environment. We investigated the effect of the organochlorine insecticide endosulfan on aquatic food webs composed of 3 tadpole species, vertebrate and invertebrate predators, zooplankton, and algae. We manipulated endosulfan concentrations (0, 0.2, 3.1, and 27.3 µg/L) and free-ranging predators (adult red-spotted newts [*Notophthalmus viridescens*] and dragonfly larvae [*Anax junius*]). Endosulfan caused direct lethal effects on tadpoles, red-spotted newts, and copepods. Patterns of species sensitivity were consistent with past laboratory experiments. Free-ranging predators caused additive, negative effects on tadpole survival, and affected anuran time to and size at metamorphosis. Our study demonstrated that endosulfan can initiate a wide range of direct and indirect effects on nontarget organisms and interacts additively with lethal predators." (2016): Spatial distribution of benthic macroinvertebrate assemblages in relation to environmental variables in Korean nationwide streams. *Water* 2016, 8(1), 27; doi:10.3390/w8010027: 20 pp. (in English) ["Conserving and enhancing freshwater biodiversity are global issues to ensure ecosystem integrity and sustainability. To meet this, it is critical to understand how the biological assemblages are determined by environmental gradients in different spatial scales. Nevertheless, information on their large-scale environmental relationships remains scarce in Korea. We aimed to understand nationwide spatial distribution patterns of benthic macroinvertebrates and important environmental factors affecting their distribution in 388 streams and rivers across Korea. A total of 340 taxa, be-

longing to 113 families in 23 orders of five phyla, were identified. Assemblage composition in most Korean streams included a few predominant colonizers and a majority of rare taxa. Cluster analysis based on benthic macroinvertebrates classified a total of 720 sampling sites into five clusters according to the pollution levels from fast-flowing less polluted streams with low electrical conductivity to moderately or severely polluted streams with high electrical conductivity and slow water velocity. Canonical correspondence analysis revealed that altitude, water velocity and streambed composition were the most important determinants, rather than watershed and water chemistry variables, for explaining the variation in macroinvertebrate assemblage patterns. The results provide basic information for establishing the conservation and restoration strategies of macroinvertebrate biodiversity against anthropogenic disturbances and developing more confident bio-assessment tools for diagnosing stream ecosystem integrity." (Authors) Odonata are treated at the order level.] Address: Hwang, S.-J., Department of Environmental Health Science, Konkuk University, Seoul 143-701, Korea

**15621.** Kassner, Z.; Dafni, E.; Ribak, G. (2016): Kinematic compensation for wing loss in flying damselflies. *Journal of Insect Physiology* 85(1): 1-9. (in English) ["Highlights: •*Ischnura elegans* can fly using only three of their wings. •We compare the wingbeat kinematics of four-winged flight with three-winged flight. •In three-winged flight the insects increased wingbeat frequency. •The increase was sufficient to explain compensation for loss in total wing area. •The flapping of the remaining wings changed to allow steady flight. Abstract: Flying insects can tolerate substantial wing wear before their ability to fly is entirely compromised. In order to keep flying with damaged wings, the entire flight apparatus needs to adjust its action to compensate for the reduced aerodynamic force and to balance the asymmetries in area and shape of the damaged wings. While several studies have shown that damaged wings change their flapping kinematics in response to partial loss of wing area, it is unclear how, in insects with four separate wings, the remaining three wings compensate for the loss of a fourth

wing. We used high-speed video of flying *I. elegans* to identify the wingbeat kinematics of the two wing pairs and compared it to the flapping kinematics after one of the hindwings was artificially removed. The insects remained capable of flying and precise maneuvering using only three wings. To compensate for the reduction in lift, they increased flapping frequency by  $18\% \pm 15.4\%$  on average. To achieve steady straight flight, the remaining intact hindwing reduced its flapping amplitude while the forewings changed their stroke plane angle so that the forewing of the manipulated side flapped at a shallower stroke plane angle. In addition, the angular position of the stroke reversal points became asymmetrical. When the wingbeat amplitude and frequency of the three wings were used as input in a simple aerodynamic model, the estimation of total aerodynamic force was not significantly different (paired t-test,  $p=0.73$ ) from the force produced by the four wings during normal flight. Thus, the removal of one wing resulted in adjustments of the motions of the remaining three wings, exemplifying the precision and plasticity of coordination between the operational wings. Such coordination is vital for precise maneuvering during normal flight but it also provides the means to maintain flight when some of the wings are severely damaged." **15622.** Kastner, F.; Buchwald, R.; Kömer, F.; Marxmeier, U.; Steffens, P.; Winkler, C.-; Jödicke, K.; Mauschering, I. (2016): Wiederansiedlungen als Maßnahmen des Artenschutzes. Die Grüne Mosaikjungfer (*Aeshna viridis*, Odonata) in Niedersachsen und Schleswig-Holstein – ein Beitrag zum Habitatverbund. *Naturschutz und Landschaftsplanung* 48(3): 87-96. (in German, with English summary) ["Reintroduction as a method of species conservation for the Green Hawker (*Aeshna viridis*) – Contribution to habitat networking in Lower Saxony and Schleswig-Holstein - Habitat loss results in a continuous species decline. Options to stop the decline include the improvement of habitat quality or habitat connectivity and in this context also the reintroduction of species to their former range. This paper presents three species conservation projects in Northern Germany aiming to reintroduce and stabilize the rare and protected dragonfly species Green Hawker (*Aeshna viridis*). The dragonfly *A. viridis* is strongly associated with the Water Soldier (*Stratiotes aloides*) as highly specified plant species for oviposition. In two of the projects *S. aloides* was reintroduced in ponds and ditches in order to establish suitable habitats for *A. viridis*. The results showed that the reintroduction of *S. aloides* can be successfully implemented but does not always succeed. Beside the plants the dragonfly species could also be reintroduced indirectly, either as egg or larvae, by transferring it together with the plants. In the third project larvae of *A. viridis* were reintroduced in a second phase after an efficient resettlement of *S. aloides* some years earlier, since the dragonfly had not been successfully transferred together with the plant." **15623.** Kautza, A.R.; Sullivan, S.M.P. (2016): The energetic contributions of aquatic primary producers to terrestrial food webs in a mid-size river system. *Ecology* 97(3): 694-705. (in English) ["Rivers are increasingly recognized as providing nutritional subsidies (i.e., energy and nutrients) to adjacent terrestrial food webs via depredation of aquatic organisms (e.g., emergent aquatic insects, crayfish, fish) by terrestrial consumers. However, because these prey organisms assimilate energy from both aquatic (e.g., benthic algae, phytoplankton, aquatic macrophytes) and terrestrial (e.g., riparian leaf detritus) primary producers, river subsidies to terrestrial consumers represent a combination of aquatically- and terrestrially-derived energy. To date, the explicit contribution of energy derived from aquatic primary producers to terrestrial consumers has not been fully explored yet might be expected to be quantitatively important to terrestrial food webs. At 12 reaches along a 185-km segment of the 6th-order Scioto River system (Ohio, USA), we quantified the relative contribution of energy derived from aquatic primary producers to a suite of terrestrial riparian consumers that integrate the adjacent landscape across multiple spatial scales through their foraging activities (tetragnathid spiders, rove beetles, adult coenagrionid damselflies, riparian swallows, and raccoons). We used naturally-abundant stable isotopes ( $^{13}\text{C}$  and  $^{15}\text{N}$ ) of periphyton, phytoplankton, macrophytes, and terrestrial vegetation to evaluate the energetic contribution of aquatic primary producers to terrestrial food webs. Shoreline tetragnathid spiders were most reliant on aquatic primary producers (50%), followed by wider-ranging raccoons (48%), damselflies (44%), and riparian swallows (41%). Of the primary producers, phytoplankton (19%) provisioned the greatest nutritional contribution to terrestrial consumers (considered collectively), followed by periphyton (14%) and macrophytes (11%). Our findings provide empirical evidence that aquatic primary producers of large streams and rivers can be a critical nutritional resource for terrestrial food webs. We also show that aquatically-derived nutrition contributes to both shoreline and broader-ranging terrestrial consumers and thus may be an important landscape-scale energetic linkage between rivers and upland habitats." **15626.** Kubohara, T.; Ii, H. (2016): Cu, Co and Ni Contamination index for river using river insects and river plants. *International Journal of GEOMATE* 11(26): 2651-2658. (in English) ["Useful species as an index of metal contamination needs a high metal concentration in a contaminated area and low metal concentration in a non-contaminated area. Moreover, it needs a high metal concentration factor. Metal concentrations of moss were high in the Cu mine area (31 to 21,000 and 2 to 200 mg/kg-dry for Cu and Co) and were low in the other areas (2 to 87 and 2 to 33 mg/kg-dry for Cu and Co). Ni concentrations of caddice-worm were high in the serpentinite area (9 to 590 mg/kg-dry) and were low in the other areas (2 to 74 mg/kg-dry). Moss had the highest concentration factor (160,000, 4,600 and 59,000 for Cu, Co and Ni) among river plants. Therefore, it was clarified that moss was useful species for an index of Cu, Co and Ni contamination among river plants based upon its metal concentration and concentration factor. In river insects, metal concentrations of crane fly larva were high in the Cu mine area (50 to 1,400 and 1 to 82 mg/kg-dry for Cu and Co) and were low in the other areas (11 to 130 and 0.7 to 10 mg/kg-dry for Cu and Co). Crane fly larva had the highest concentration factor for Cu (46,000) and also kept high concentration factor for Co (2,700) among river insects. Ni concentrations of caddice-worm were high in the serpentinite area (52 to 220 mg/kg-dry) and were low in the other areas (0.3 to 20 mg/kg-dry). Caddice-worm had the highest Ni concentration factor (22,000) among river insects. Therefore, it was clarified that crane fly larva was useful species for an index of Cu and Co contamination and caddice-worm was useful species for an index of Ni contamination based upon their metal concentrations and concentration factors." (2016): Distribution of benthic macroinvertebrates in a tropical reservoir cascade. *Hydrobiologia* 765: 265-275. (in English) ["The functioning of systems arranged in cascades of reservoirs can be explained by the Cascading Reservoir Continuum

Concept, providing a theoretical framework for addressing ecological processes. In this context, this study tested the following hypotheses: (i) the benthic macroinvertebrate assemblage shows a nested distribution along a reservoir cascade; and (ii) local factors explain the structure of the benthic assemblage in every reservoir along the cascade. Macroinvertebrates play essential role in aquatic systems, especially due to recycling and, in reservoirs, as important links in every food chain. Sampling was conducted quarterly between October 2006 and September 2010 in six reservoirs located in the São Francisco River, Brazil. The benthic macroinvertebrate assemblage showed nested distribution in the reservoirs, indicating that a loss of species occurs along the cascade. Each reservoir presented a different set of variables that explained the distribution of macroinvertebrates, showing the importance of local factors determining the composition and distribution of benthic assemblages in the reservoirs. Therefore, there is a clear interaction between the position of a reservoir along a cascade and the macroinvertebrate assemblages, which indicate the importance of considering this pattern during the decision-making process of constructing new dams on rivers already regulated." (Authors) The list of taxa includes 'Coenagrionidae' and 'Gomphidae'.] Address: Lacerda dos Santos, Natália Carneiro Núcleo de Pesquisas em Limnologia, Ictiologia e Aquicultura – Programa de Pós-graduação em Ecologia de Ambientes Aquáticos Continentais, Univ. **15628.** Lee, H.-J.; Johansson, F. (2016): Compensating for a bad start: compensatory growth across life stages in an organism with a complex life cycle. *Canadian Journal of Zoology* 94(1): 41-47. (in English) ["Organisms with a complex life cycle are characterized by a life history shift through metamorphosis, and include organisms such as insects and amphibians. They must optimize their use of resources and behaviour across different life stages in order to maximize their fitness. An interesting question with regard to such life history shifts is whether growth in the juvenile stage can be compensated for in the adult stage. Here we ask whether damselflies are able to compensate for depressed growth during the juvenile aquatic stage in their terrestrial adult stage. Damselflies emerge at a fixed adult body size, but feed during the adult stage and are thus able to gain mass as adults. We performed a mark recapture study in order to answer whether individuals that emerge from metamorphosis with a low mass are able to compensate by subsequent mass gain during the adult stage. Results showed that compensatory mass gain occurred in the adult stage such that small individuals gained more mass than large individuals. We also found that females gained more mass than males. However, individuals that emerged at a low mass still had lower mass as mature adults than individuals that emerged at a high mass, suggesting that compensation was not complete. This suggests that larval ecology and adult fitness are tightly linked and future research should focus more on elucidating the nature of this relationship." **15629.** Letsch, H.; Gottsberger, B.; Ware, J.L. (2016): Not going with the flow: a comprehensive time-calibrated phylogeny of dragonflies (Anisoptera: Odonata: Insecta) provides evidence for the role of lentic habitats on diversification. *Molecular Ecology* 25(6): 1340-1353. (in English) ["Ecological diversification of aquatic insects has long been suspected to have been driven by differences in freshwater habitats, which can be classified into flowing (lotic) waters, and standing (lentic) waters. The contrasting characteristics of lotic and lentic freshwater systems imply different ecological constraints on their inhabitants. The ephemeral and discontinuous character of most lentic water bodies may encourage dispersal by lentic species in turn reducing geographical isolation among populations. Hence, speciation probability would be lower in lentic species. Here, we assess the impact of habitat use on diversification patterns in dragonflies (Anisoptera: Odonata). Based on eight nuclear and mitochondrial genes, we inferred species diversification with a model-based evolutionary framework, to account for rate variation through time and among lineages, and to estimate the impact of larval habitat on the potentially non-random diversification among anisopteran groups. Ancestral state reconstruction revealed lotic fresh water systems as their original primary habitat, while lentic waters have been colonised independently in Aeshnidae, Corduliidae and Libellulidae. Furthermore, our results indicate a positive correlation of speciation and lentic habitat colonisation by dragonflies: speciation rates increased in lentic Aeshnidae and Libellulidae, whereas they remain mostly uniform among lotic groups. This contradicts the hypothesis of inherently lower speciation in lentic groups and suggests species with larger ranges are more likely to diversify, perhaps due to higher probability of larger areas being dissected by geographical barriers. Furthermore, larger range sizes may comprise more habitat types, which could also promote speciation by providing additional niches, allowing the coexistence of emerging species." (2016): Development of a benthic macroinvertebrate multimetric index (MMI) for Neotropical Savanna headwater streams. *Ecological Indicators* 64: 132-141. (in English) ["Highlights: •We tested four macroinvertebrate multimetric indices (MMIs) for the Cerrado biome. •We used a statistical criterion for identifying least- and most-disturbed sites. •The best-performing MMI had landscape-adjusted and PCA-selected metrics. •Our MMI is sensitive to anthropogenic pressures at local- and catchment-scales. Abstract: Assessing the ecological impacts of anthropogenic pressures is a key task in environmental management. Multimetric indices (MMIs), based on aquatic assemblage responses to anthropogenic pressures, have been used increasingly throughout the world. The MMI approach is a low-cost, rapid field method that produces an aquatic condition index that responds precisely to anthropogenic pressures, making it useful for conservation and environmental management. We developed four candidate MMIs based on benthic macroinvertebrate assemblages sampled at 40 randomly selected sites to assess the environmental condition of streams upstream of a hydroelectric power plant in the Brazilian Neotropical Savanna biome. Those MMIs were built from landscape-adjusted and unadjusted biological metrics as well as two alternative ways of choosing metrics. The alternative MMIs performances were tested by comparing their precision to distinguish least-disturbed areas, responsiveness to discriminate least- and most-disturbed areas, and sensitivity to anthropogenic pressures at catchment and local scales. The best performing MMI had landscape-adjusted metrics and was produced through use of principal component analysis for metric selection. It included 4 metrics: Ephemeroptera richness, average tolerance score per taxon, percentage of predator individuals, and percentage of Odonata individuals adjusted by elevation. This index discriminated well the anthropogenic pressures at local- and catchment-scales, and at both scales simultaneously, as indicated by an integrated disturbance index. Our methodological development included statistical criteria for identifying least- and most-disturbed sites, calibrating for natural landscape variability, and use of non-redundant metrics. Therefore, we expect it will provide a model for environmental assessment of water resources elsewhere in Brazil and in other nations." ford R.J.; Ivanova, E.P. (2016): The nature of inherent bactericidal activity: insights from the nanotopology of three species of dragonfly. *Nanoscale* 8: 6527-6534. (in English) ["While insect wings are widely recognised as multi-functional, recent work showed that this extends to extensive bactericidal activity brought about by cell deformation and lysis on the wing nanotopology. We now quantitatively show that subtle changes to this topography result in substantial changes in bactericidal activity able span an order of magnitude. Notably, the chemical composition of the lipid nanopillars was seen by XPS and synchrotron FTIR microspectroscopy to be similar across these activity differences. Modelling the interaction between bacterial cells and the wing surface lipids of 3 species of dragonflies (*Hemianax papuensis*, *Austroaeschna multipunctata*, *Diplacodes bipunctata*), that inhabit similar environments but with distinctly different behavioural repertoires, provided the relationship between surface structure and antibacterial functionality. In doing so, these principal behavioural patterns correlated with the demands for antimicrobial efficiency dictated by differences in their foraging strategies. This work now reveals a new feature in the design elegance of natural multi-functional surfaces as well providing insights into bactericidal mechanism underlying inherently antimicrobial materials, while suggesting that nanotopology is related to evolutionary development of a species through the demands of its behavioural repertoire. The underlying relationship between the processes of wetting, adhesion and capillarity of the lipid nanopillars and bactericidal efficiency suggests new prospects for purely mechano-responsive antibacterial surfaces." **15633.** Mair, L.; Ruete, A. (2016): Explaining spatial variation in the recording effort of citizen science data across multiple taxa. *PLoS ONE* 11(1): e0147796. doi:10.1371/journal.pone.0147796: 13 pp. (in English) ["The collation of citizen science data in open-access biodiversity databases makes temporally and spatially extensive species' observation data available to a wide range of users. Such data are an invaluable resource but contain inherent limitations, such as sampling bias in favour of recorder distribution, lack of survey effort assessment, and lack of coverage of the distribution of all organisms. Any technical assessment, monitoring program or scientific research applying citizen science data should therefore include an evaluation of the uncertainty of its results. We use 'ignorance' scores, i.e. spatially explicit indices of sampling bias across a study region, to further understand spatial patterns of observation behaviour for 13 reference taxonomic groups. The data is based on voluntary observations made in Sweden between 2000 and 2014. We compared the effect of six geographical variables (elevation, steepness, population density, log population density, road density and footpath density) on the ignorance scores of each group. We found substantial variation among taxonomic groups in the relative importance of different geographic variables for explaining ignorance scores.

In general, road access and logged population density were consistently important variables explaining bias in sampling effort, indicating that access at a landscape-scale facilitates voluntary reporting by citizen scientists. Also, small increases in population density can produce a substantial reduction in ignorance score. However the between-taxa variation in the importance of geographic variables for explaining ignorance scores demonstrated that different taxa suffer from different spatial biases. We suggest that conservationists and researchers should use ignorance scores to acknowledge uncertainty in their analyses and conclusions, because they may simultaneously include many correlated variables that are difficult to disentangle." (Authors) The data set includes Odonata.] Address: Mair, Louise, Species Information Centre, Swedish University of Agricultural Sciences (SLU), P.O. 7007, 750 07 Uppsala, Sweden. **15634.** Marinov, M.; Amaya-Perilla, C.; Holwell, G.I.; Varsani, A.; Van Bysterveldt, K.; Kraberger, S.; Stainton, D.; Dayaram, A.; Curtis, N.; Cruickshank, R.H.; Paterson, A. (2016): Geometric morphometrics and molecular systematics of *Xanthocnemis sobrina* (McLachlan, 1873) (Odonata: Coenagrionidae) and comparison to its congeners. *Zootaxa* 4078(1): 84-120. (in English) ["The taxonomy of the damselfly genus *Xanthocnemis* is revised, with particular focus on populations inhabiting the North Island of New Zealand. Earlier studies revealed two species: *X. sobrina*, restricted to cool, shaded streams in kauri forests and other forested areas, and *X. zealandica*, a common species throughout New Zealand except the Chatham and subantarctic islands. A field study encompassing aquatic habitats throughout the whole North Island was carried out to establish the relationship between morphological variation (body size and various morphological traits over the entire body) observed by previous researchers with ecological conditions and/or geographical location. The main aim was to propose reliable diagnostic features that could be used in future studies. Morphological and molecular variation was assessed. Morphological examination included assigning landmarks for all body parts corresponding to the external morphological features that are usually used in Odonata taxonomy. Molecular analysis targeted fragments of the 28S and 16S rRNA genes. Congruence was sought between both types of data, statistical support for two morphological types previously described as different species and a maximum likelihood phylogenetic tree in conjunction with a pairwise genetic distance matrix constructed from the DNA sequences obtained from the sampled specimens. Geometric morphometrics revealed statistically significant differentiation between specimens identified as *X. zealandica* and *X. sobrina* for four traits: (1) dorsal view of the head for both sexes as well as male appendages from (2) dorsal, (3) ventral and (4) lateral views. Wings appeared different when analysed for males only. Molecular analysis, however, grouped all specimens into a single undifferentiated cluster with very low mean pairwise distance (<0.01) between them showing almost no variation at the molecular level among the sampled populations on the North Island. Therefore, an additional

analysis of the mitochondrial cytochrome c-oxidase I gene was carried out comparing randomly selected North Island specimens to *Xanthocnemis* specimens targeted in other molecular studies (Nolan et al. 2007, Amaya-Perilla et al. 2014). The analysis of the COI gene confirmed that all North and South Island isolates of *Xanthocnemis* cluster together in a well-supported clade with pairwise identity >96% and ~93% pairwise identity with *X. tuanuii* sequences obtained from the Chatham Island specimens. A careful investigation of the thin plate spline deformations generated for the geometric morphometric landmarks showed that the significant variations in the appendages of the *Xanthocnemis* specimens appeared to be the result of size, rather than shape, differences. Therefore, *X. sobrina* is proposed as a synonym of *X. zealandica*. Recently Amaya-Perilla et al. (2014) synonymised *X. sinclairi* with *X. zealandica* and confirmed the status of the Chatham Island *X. tuanuii* as a distinct species. It is therefore proposed that the genus *Xanthocnemis* consists of two species only: *zealandica* occurring all over the North, South and Stewart Islands, and *tuanuii*, endemic to Chatham and Pitt islands. Considering several statistical tests involving body measurements and ecological variables recorded during the field study, as well as various discussion points from similar studies of other species of Odonata, two alternative hypotheses are proposed for future testing. The first hypothesis synonymises *X. sobrina* with *X. zealandica* and suggests a possible explanation for the evolution of the two morphological traits that have previously been considered diagnostic for these species. The second hypothesis suggests that as typical *X. sobrina* were not sampled during this study this could represent a species that is now extinct, unless future studies prove it otherwise." **15635.** Martínez, A.; Larrañaga, A.; Miguélez, A.; Yvon-Durocher, G.; Pozo, J. (2016): Land use change affects macroinvertebrate community size spectrum in streams: the case of *Pinus radiata* plantations. *Freshwater Biology* 61: 69-79. (in English) ["(1.) In low-order forested streams, catchment-scale land-use modifications to vegetation can affect energy inputs into streams and trophic interactions within these donor-controlled food webs. (2.) We examined the effects of *Pinus radiata* plantations on the intercept and slope of the size spectrum (the relationship between log-mass and log-density) of macroinvertebrate communities in low-order forested streams. We compared three streams draining pine plantations with three draining native deciduous forests, all without significant differences in water physicochemical characteristics. (3.) While size spectrum intercept was similar between the two stream types, the slope of the size spectrum was shallower in pine than in deciduous streams based on a decline in the density of the smaller individuals. (4.) The shredder feeding guild showed the largest changes, with a significant reduction in their total density and, specifically, in the density of the smaller individuals from the deciduous to the pine streams. This alteration is

explained by the change in very specialist shredders, such as plecopterans and trichopterans, but not in those with highly mobile crustaceans or more generalist dipterans. (5.) The effect detected for shredders might have scaled up to higher trophic levels as the density of invertebrate predators (small and big) was lower in streams under pine, suggesting a response to prey limitation. 6. These results indicate that the change of in-stream resource quality arising from the replacement of deciduous vegetation by pine plantations can trigger size-specific responses of macroinvertebrates and target specialised feeding guilds such as shredders, and can elicit a bottom-up reaction in the organisation of food webs." (Authors) Boyeria, Calopteryx and Gomphus settled only in deciduous streams, while Cordulegaster inhabitate deciduous as pine streams as well.] Address: Martínez, A., Laboratory of Stream Ecology, Department of Plant Biology and Ecology, University of the Basque Country, P.O. **15636.** Melfi, J.; Leonardo, A.; Wang, J. (2016): Recovery methods of the dragonfly from irregular initial conditions. *Bulletin of the American Physical Society*. Abstract: R41.00013: (in English) [Verbatim: We release dragonflies from a magnetic tether in a wide range of initial orientations, which results in them utilizing multiple methods to regain their typical flight orientation. Special focus is placed on dropping them while upside down, as the recovery method used is a purely rolling motion. Filming this stereotypical motion with a trio of high speed cameras at 4000 fps, we capture detailed body and wing kinematics data to determine how the dragonfly generates this motion. By replaying the flights within a computer simulation, we can isolate the significant changes to wing kinematics, and find that it is an asymmetry in the wing pitch which generates the roll. Further investigation demonstrates that this choice is highly dependent upon the state of the dragonfly, and as such our results indicate the dragonfly both tracks its current state, and changes its mid-flight control mechanisms accordingly.] Address: Wang, Z. **15640.** Moskowitz, D.P. (2016): The life history, behavior and conservation of the Tiger Spiketail dragonfly (*Cordulegaster erronea* Hagen) in New Jersey. Ph.D. thesis, Graduate School - New Brunswick, Rutgers, The State University of New Jersey: VIII + 128 pp. (in English) ["This dissertation explores the life history and behaviour of *C. erronea* and provides recommendations for the conservation of the species. Like most species in the genus *Cordulegaster* and the family *Cordulegastridae*, the Tiger Spiketail is geographically restricted, patchily distributed with its range, and a habitat specialist in habitats susceptible to disturbance. Most *Cordulegastridae* species are also of conservation concern and *C. erronea* is no exception. However, many aspects of the life history of *C. erronea* and many other *Cordulegastridae* are poorly understood, complicating conservation strategies. In this dissertation, I report the results of my research on *C. erronea* in New Jersey. The research to investigate life history and behaviour included: larval and

exuvial sampling; radio-telemetry studies; marking-resighting studies; habitat analyses; observations of ovipositing females and patrolling males, and the presentation of models and insects to patrolling males. The research reports: the first use of radio-telemetry for the species; the first observations of mating; the first comprehensive report and analysis of larval site emergence site selection; the triggering mechanisms for male recognition of females; adult and larval habitat use, and many other life history and behavioural aspects of the species. The dissertation also provides recommendations for conservation strategies that maybe useful for protecting the Tiger Spiketail and other *Cordulegastridae* species." (Author)] Address: not stated

**15641.** Munguía-Steyer, R.; Córdoba-Aguilar, A.; Maya-García, J.S. (2016): Rubyspot territorial damselflies behave as "Nasty Neighbors". *Journal of Insect Behavior* 29(2): 143-152. (in English) ["Two mutually-excluding hypotheses explain the intensity of aggression between neighbours and their non-neighbours in territorial animals. On one hand, the "dear enemy" hypothesis predicts that territorial animals should be more tolerant towards their neighbours than towards non-neighbours. Conversely, the "nasty neighbor" hypothesis predicts increased aggression towards neighbours than non-neighbours. These different situations depend on who is more likely to be a real competitor, either a neighbour or a non-neighbour, and the intensity of resource competition. Male damselfly of *Hetaerina vulnerata* defend riverine, mating territories that is the main way to have access to females. These territories are not fixed and so males continuously defend them especially against neighbours. Given this, we tested whether the nasty neighbour principle operates in this species. We monitored a population during an entire mating season, and recorded duration of aggressive behaviours. As a key prediction of the nasty neighbour hypothesis, we expected that such behaviours last for longer when encountering a conspecific neighbour than a conspecific non-neighbour. We also predicted that such duration should be date-dependent as territorial competition could increase in the middle of the season when male density is at its highest. Our results corroborated that aggressive behaviours lasted longer against a neighbour male than a non-neighbour male but there was not effect of date. Thus, neighbours may pose a greater risk and may be a strong selective force than non-neighbours in terms of resource competition. Since neighbour males are continuously trying to widen their territory boundaries (a situation that has been also found in other study systems), an owner male may not even need to recognize his neighbours to fight back." **15642.** Mutlu, O.; Gumuslu, E.; Kokturk, S.; Ulak, G.; Akar, F.; Erden, F.; Kaya, H.; Tanyeri, P. (2016): Effects of chronic administration of adipokinetic and hypertrehalosemic hormone on animal behavior, BDNF, and CREB expression in

the hippocampus and neurogenesis in mice. *Fundamental & Clinical Pharmacology* 30(1): 4-13. (in English) ["Neurosecretory cells in corpus cardiacum of insects synthesize a set of hormones that are called adipokinetic, hypertrehalosaemic or hyperprolinaemic, depending on insect in question. This study investigated effects of chronic administration of *Anax imperator* adipokinetic hormone (Ani-AKH), *Libellula auripennis* adipokinetic hormone (Lia-AKH), and *Phormia-Terra* hypertrehalosaemic hormone (Pht-HrTH) on depression, anxiety, analgesy, locomotion in forced swimming (FST), elevated plus-maze (EPM), hot plate, and locomotor activity tests. Ani-AKH (1 and 2 mg/kg), Lia-AKH (1 and 2 mg/kg), and Pht-HrTH (1 and 2 mg/kg) had antidepressant effects in forced swimming test. Lia-AKH (2 mg/kg) and Pht-HrTH (1 and 2 mg/kg) had anxiolytic effects when given chronically in elevated plus-maze test. Ani-AKH (1 and 2 mg/kg) and Pht-HrTH (2 mg/kg) had antinociceptive effects in hot plate test in male balb-c mice. Ani-AKH (2 mg/kg), Lia-AKH (1 and 2 mg/kg), and Pht-HrTH had locomotion-enhancing effects in locomotor activity test in male balb-c mice. Drug treatment significantly increased brain-derived neurotrophic factor (BDNF) and cyclic adenosine monophosphate (cAMP) response element binding protein (CREB) gene expression levels compared to control levels. Pht-HrTH and Ani-AKH groups had significantly increased numbers of BrdU-labeled cells, while neurodegeneration was lower in the Pht-HrTH group. Our study showed that AKH/RPCH family peptides may be used in treatment of psychiatric illness such as depression and anxiety, in treatment of pain and in diseases related to locomotion system. AKH/RPCH family peptides increase neurotrophic factors in brain and have potential proliferative and neuroprotective effects in hippocampal neurogenesis and neurodegeneration." **15643.** Naka, H.; Hashimoto, H. (2016): The effect of passive deformation of dragonfly wing on aerodynamic characteristics. *Transactions of the JSME* 82(833): 14 pp. (in Japanese, with English summary) ["Dragonflies can perform both of gliding and flapping flight and have high maneuverability in spite of small-size. The aim of this study is to develop Micro Air Vehicle (MAV) based on the flight of dragonfly. The characteristics of wings are very important for development of MAV. Dragonfly wing is easy to be passively deformed in the tip side from the nodus in flapping flight, and thereby, aerodynamic force is generated effectively. In this study, the effect of passive deformation of wing on aerodynamic force was investigated using fluid-structure interaction analysis to develop the artificial wing suitable for dragonfly-like MAV. In this study, aerodynamic characteristics of wings in the gliding flight and aerodynamic force generated in flapping flight are numerically analyzed. In this analysis, nodus wing models, which can deform passively, and rigid wing model, which cannot deform, are used. Nodus wing model imitates the nodus structure; the tip side of this model is free to rotate around leading edge. As a result of gliding flight, the lift coefficient of the nodus wing was lower in low-

angle of attack and was higher in high-angle of attack, compared to rigid wing. Moreover, the more flexible wings are, the more change. The gliding flight is low-angle of attack usually. Therefore, flexible wing is less suitable for the gliding flight than inflexible wing. As a result of flapping flight, the nodus wing made drag force generated during down stroke lower compared with the rigid wing. However, thrust forces generated during up stroke in both wings were the same. Therefore, flexible wings are more suitable for the flapping flight than inflexible wing. The wings of dragonfly-like MAV need to appropriate level of flexibility to upgrade the performance in both case of gliding and flapping flight." **15644.** Nayak, A.K.; Roy, U.S. (2016): An observation on the Odonata fauna of the Asansol-Durgapur Industrial Area, Burdwan, West Bengal, India. *Journal of Threatened Taxa* 8(2): 8503-8517. (in English) ["The present investigation was undertaken as a pilot study to examine the diversity, occurrence and distribution pattern of Odonata from the selected study sites of the Asansol-Durgapur industrial area of Burdwan District of West Bengal, India from January 2012 to December 2015. A combination of direct search and opportunistic sighting methods were applied to record 57 different Odonata species (38 dragonflies and 19 damselflies). Among the dragonflies the most diverse family was Libellulidae represented by 36 species while among damselflies Coenagrionidae was the most diverse family represented by 16 species. In spite of the Asansol-Durgapur region being an industrial urban area, the present study revealed a handsome diversity of odonates. A suitable geographic location, favourable climatic conditions, heterogeneous habitat types that included ponds, wetlands, riverbeds, grasslands and agricultural lands along with the presence of appropriate vegetation provided a comfortable shelter for Odonata species to flourish in this ecoregion. All the odonates noted in the present study belong to the Least Concerned category as designated by IUCN." **15654.** Pinto, A.P.; Almeida, M.V.O. (2016): A taxonomic synopsis of South American Cyanogomphini Carle with description of *Cyanogomphus angelomachadoi* sp. nov. from the Cerrado of Brazil (Odonata: Gomphidae). *Zootaxa* 4078(1): 38-69. (in English) ["A synopsis of Cyanogomphini Carle, 1986 (sensu Belle 1996), including all species currently under the genera *Cyanogomphus* Selys, 1873, and *Tibiagomphus* Belle, 1992, is provided. *Cyanogomphus angelomachadoi* sp. nov. (Holotype male deposited in DZRJ: Brazil, Minas Gerais State, Jaboticatubas municipality, Parque Nacional da Serra do Cipó, collecting site Corrego das Pedras 19.22.17S, 43.36.03W, 76 m a.s.l., 12.XII.2011, A.P.M. Santos & D.M. Takiya leg.) is described and illustrated based on four males and two females from Minas Gerais and Sao Paulo States, southeastern Brazil. The new species is most similar to *C. waltheri* Selys, 1873, from which it can be distinguished by its smaller size; larger pale areas on mesepisternum; pale dorsal surface of metathoracic tibia; larger distal concavity on epiproct, with latero-distal projection, in lateral view forefinger-shaped; and occurrence in Cerrado province. Five species are recognized in Cyanogomphini, and for each one a synonymy, diagnoses, identification key and maps of distribution are presented. The status of sibling taxa *Tibiagomphus uncatus* (Fraser, 1947) and *T. noval* (Rodrigues Capitulo, 1985), as well as the *Agriogomphus*-complex of genera are also discussed." **15655.** Piria, M.; Jakšić, G.; Jakovlic, I.; Treer, T. (2016): Dietary habits of invasive Ponto-Caspian gobies in the Croatian part of the Danube River basin and their potential impact on benthic fish communities. *Science of The Total Environment* 540: 386-395. (in English) ["Highlights: •Dietary habits and impacts of invasive P-C gobies on other fish were studied. •Monkey and round goby preferred Trichoptera, Megaloptera and Coleoptera. •Bighead goby preferred Trichoptera, Gammarus and Pisces. •No negative impacts of the most abundant, monkey goby, on native fish populations. •Round goby negatively impacts native zingel, and bighead goby - chub populations. Abstract: Invasive Ponto-Caspian (P-C1) gobies have recently caused dramatic changes in fish assemblage structures throughout the Danube basin. While their presence in the Croatian part of the basin has been noted and distribution studied, their dietary habits and impacts on native fish communities have, until now, been unknown. In 2011, 17 locations in the Sava River Basin were sampled for fish and 15 for benthic invertebrates. Fish population monitoring data, available for nine

seasons (2003–2006 and 2010–2014) and 12 locations, were used to analyse the impacts of P-C gobies on benthic fish abundance. Gut content analysis indicates that the monkey goby *Neogobius fluviatilis* diet is very diverse, but dominated by Trichoptera, Chironomidae, Bivalvia and Odonata. The diet overlaps considerably with the round goby *Neogobius melanostomus* diet, although Gastropoda are dominant in the latter's diet. Small fish and *Gammarus* sp. dominate the bighead goby *Ponticola kessleri* diet. Comparison of gut content with the prey available in the environment indicates that monkey and round gobies exhibit preference for Trichoptera, Megaloptera and Coleoptera, and bighead goby for Trichoptera, *Gammarus* sp. and Pisces. P-C gobies in the Sava River are spreading upstream, towards the reaches with lower fish diversity. Analyses indicate potentially positive impacts of P-C gobies' presence on some fish populations: round and bighead goby on Balkan golden loach *Sabanejewia balcanica* and monkey goby on common carp *Cyprinus carpio*, crucian carp *Carassius carassius*, burbot *Lota lota* and Balkan loach *Cobitis elongata*. However, there are also indications that bighead and round goby could adversely impact the native chub *Squalius cephalus* and zingel *Zingel zingel* populations, respectively. As P-C gobies are still in the expansionary period of invasion and the ecosystem still adapting to new circumstances, continued monitoring of fish population dynamics in the Sava basin is needed to determine the outcome and impacts of this invasion." **15656.** Polo-Cavia, N.; Burraco, P.; Gomez-Mestre, I. (2016): Low levels of chemical anthropogenic pollution may threaten amphibians by impairing predator recognition. *Aquatic Toxicology* 172: 30-35. (in English) ["Highlights: •Humic acid and ammonium nitrate impair responses of tadpoles to predator cues. •Even low concentrations of pollutants increase predation risk of tadpoles. •Sublethal pollution may contribute to amphibian declines by disrupting predator recognition. Abstract: Recent studies suggest that direct mortality and physiological effects caused by pollutants are major contributing factors to global amphibian decline. However, even sublethal concentrations of pollutants could be harmful if they combined with other factors to cause high mortality in amphibians. Here we show that sublethal concentrations of pollutants can disrupt the ability of amphibian larvae to recognize predators, hence increasing their risk of predation. This effect is indeed much more important since very low amounts of pollutants are ubiquitous, and environmental efforts are mostly directed towards preventing lethal spills. We analyzed the effects of two common contaminants (humic acid and ammonium nitrate) on the ability of tadpoles of the western spadefoot toad (*Pelobates cultripes*) to recognize chemical cues from a common predator, nymphs of the dragonfly *Anax imperator*. We compared the swimming activity of tadpoles in the presence and absence of water-borne chemical cues from dragonflies at

different concentrations of humic acid and ammonium nitrate. Tadpoles reduced swimming activity in response to predator cues in the absence of pollutants, whereas they remained unresponsive to these cues when either humic acid or ammonium nitrate was added to the water, even at low concentrations. Moreover, changes in tadpole activity associated with the pollutants themselves were non-significant, indicating no toxic effect. Alteration of the natural chemical environment of aquatic systems by pollutants may be an important contributing cause for declines in amphibian populations, even at sublethal concentrations." (2016): Cyclicity of long-term population dynamics in damselflies of the genus *Coenagrion* (Odonata, Zygoptera) in the Lake Chany basin. *Russian Journal of Ecology* 47(1): 74-81. (in English) ["The cyclicity of population dynamics of abundance has been analyzed in sympatric adult populations of three odonate species monitored for long time (1980–2010) in the Lake Chany basin (Western Siberia). The spectra of odonate population dynamics have been constructed for the first time and shown to be species-specific: each species has its own population cycles, and if the cycles are similar, interspecific differences manifest themselves in the relative power of these cycles. These differences provide for separation of species in time, reducing the stress of competition between them. The population rhythms of all studied species show synchronicity with natural rhythms that are important to them, such as fluctuations of climatic parameters (2–3 year cycles) and hydrological parameters of Lake Chany (2–4-year cycles)."] (Authors)] Address: Popova, Olga, Institute of Systematics and Ecology of Animals, Siberian Branch, Russian Academy of Sciences, ul. **15658.** Rajabi, H.; Rezasefat, M.; Darvizeh, A.; Dirks, J.-H.; Eshghi, S.; Shafiei, A.; Mirzababaie Mostofi, T.; Gorb, S.N. (2016): A comparative study of the effects of constructional elements on the mechanical behaviour of dragonfly wings. *Applied Physics A* 122:19: 13 pp. (in English) ["Although wings of insects show a large variation in morphology, they are all made from a network of irregular veins interconnected through membranous areas. Depending on their shape, size, and position, wing veins are usually divided into three different groups: longitudinal veins, cross-veins and ambient veins. The veins together with the membrane and some other elements such as spines, nodus and pterostigma can be considered as the wing's "constructional elements". In spite of rather extensive literature on dragonfly wing structure, the role of each of these elements in determining the wing's function remains mostly unknown. As this question is difficult to answer in vivo using biomechanical experiments on actual wings, this study was undertaken to reveal the effects of the constructional elements on the me-

chanical behaviour of dragonfly wings by applying numerical simulations. An image processing technique was used to develop 12 finite element models of the insect wings with different constructional elements. The mechanical behaviour of these models was then simulated under normal and shear stresses due to tension, bending and torsion. A free vibration analysis was also performed to determine the resonant frequencies and the mode shapes of the models. For the first time, a quantitative comparison was carried out between the mechanical effects selectively caused by different elements. Our results suggest that the complex interactions of veins, membranes and corrugations may considerably affect the dynamic deformation of the insect wings during flight." **15659.** Rajabi, H.; Ghoroubi, N.; Darvizeh, A.; Appel, E.; Gorb, S.N. (2016): Effects of multiple vein microjoints on the mechanical behaviour of dragonfly wings: numerical modelling. *R. Soc. open sci.* 3: 150610. <http://dx.doi.org/10.1098/rsos.150610>: 16 pp. (in English) ["Dragonfly wings are known as biological composites with high morphological complexity. They mainly consist of a network of rigid veins and flexible membranes, and enable insects to perform various flight manoeuvres. Although several studies have been done on the aerodynamic performance of Odonata wings and the mechanisms involved in their deformations, little is known about the influence of vein joints on the passive deformability of the wings in flight. In this article, we present the first three-dimensional finite-element models of five different vein joint combinations observed in Odonata wings. The results from the analysis of the models subjected to uniform pressures on their dorsal and ventral surfaces indicate the influence of spike-associated vein joints on the dorso-ventral asymmetry of wing deformation. Our study also supports the idea that a single vein joint may result in different angular deformations when it is surrounded by different joint types. The developed numerical models also enabled us to simulate the camber formation and stress distribution in the models. The computational data further provide deeper insights into the functional role of resilin patches and spikes in vein joint structures. This study might help to more realistically model the complex structure of insect wings in order to design more efficient bioinspired micro-air vehicles in future." **15660.** Rajabi, H.; Shafiei, A.; Darvizeh, A.; Dirks, J.-H.; Appel, E.; Gorb, S.N. (2016): Effect of microstructure on the mechanical and damping behaviour of dragonfly wing veins. *Royal Society Open Science* 3: 160006. <http://dx.doi.org/10.1098/rsos.160006>: 12 pp. (in English) ["Insect wing veins are biological composites of chitin and protein arranged in a complex lamellar configuration. Although these hierarchical structures are found in many 'venous wings' of insects, very

little is known about their physical and mechanical characteristics. For the first time, we carried out a systematic comparative study to gain a better understanding of the influence of microstructure on the mechanical characteristics and damping behaviour of the veins. Morphological data have been used to develop a series of three-dimensional numerical models with different material properties and geometries. Finite-element analysis has been employed to simulate the mechanical response of the models under different loading conditions. The modelling strategy used in this study enabled us to determine the effects selectively induced by resilin, friction between layers, shape of the cross section, material composition and layered structure on the stiffness and damping characteristics of wing veins. Numerical simulations suggest that although the presence of the resilin-dominated endocuticle layer results in a much higher flexibility of wing veins, the dumbbell-shaped cross section increases their bending rigidity. Our study further shows that the rubber-like cuticle, friction between layers and material gradient-based design contribute to the higher damping capacity of veins. The results of this study can serve as a reference for the design of novel bioinspired composite structures." **15661.** Razeng, E.; Moran-Ordóñez, A.; Brim Box, J.; Thompson, R.; Davies, J.; Sunnucks, P. (2016): A potential role for overland dispersal in shaping aquatic invertebrate communities in arid regions. *Freshwater Biology* 61: 745-757. (in English) [Australia, "(1.) Traditionally, dispersal of aquatic invertebrates has been thought to be very closely associated with river network structure, despite many species being capable of active or passive dispersal across the terrestrial matrix. However, recent studies of both population genetics and community structure from dryland regions indicate that aquatic species commonly disperse across catchments, implying that movement away from streams is more common than originally thought. This study investigated how aquatic invertebrate metacommunity structure in central Australia is influenced by interactions between species' dispersal traits, dispersal routes and local environmental conditions. (2.) We sampled community composition in 16 perennial and long-term inundated freshwater habitats in central Australia. Aquatic invertebrate taxa were allocated to one of four dispersal trait groups: obligate aquatic, passive aerial, weak flying and strong flying. We then used Mantel tests to examine correlations between trait group community dissimilarities, and four isolation models representing (i) local environmental conditions, (ii) geographical distances, (iii) landscape resistances restricted to river networks and (iv) landscape resistances incorporating overland dispersal 'conduits'. (3.) We found that the community composition of aquatic invertebrates in three of four dispersal trait groups, and all traits combined, was influenced primarily by topographic connectivity via overland dispersal conduits. (4.) Our results suggest that rainfall events and their effect on the landscape as a whole, rather than river flow during these

events, shape aquatic invertebrate metacommunity structure in central Australia. This study provides further support for the importance of overland dispersal conduits to aquatic invertebrates, particularly in arid environments with irregular rainfall." **15663.** Rodrigues, M.E.; Roque, F.; Ochoa Quintero, J.M.; Penad, J.C.; Caribé de Sousa, D.; De Marco Junior, P. (2016): Nonlinear responses in damselfly community along a gradient of habitat loss in a savanna landscape. *Biological Conservation* 194: 113-120. (in English) ["Highlights: •We evaluated thresholds for damselflies in riparian zones in a savanna landscape. •We sampled 98 streams located in the Pantanal plateau, Brazil. •We used Threshold Indicator Taxa Analysis — TITAN and segmented regression analysis. •We found weak evidence of a threshold between 40 and 60% native vegetation loss. •Maintaining habitat loss above the "zone of increasing risk of impact" should be priority for conservation planners. Abstract: Riparian zones are among the most threatened natural ecosystems, being greatly affected by land use changes across the world. Working in a savanna landscape in the Central-West region of Brazil, we assessed the responses of damselfly communities to changes on native vegetation extent in riparian zones. We sampled damselflies around 98 streams in a continuous gradient of native vegetation loss (0 to 100%). We used the Threshold Indicator Taxa Analysis (TITAN) to test whether the damselfly community showed nonlinear responses related to native vegetation loss within buffers of 250 m radius. We collected 1245 individuals of damselflies, representing 31 species. The TITAN identified 16 species with a significant response: 11 species with negative indicators (Z<sup>-</sup>) and five as positive indicators (Z<sup>+</sup>) in relation to native vegetation loss. Six species showed evidence of nonlinear response (Z<sup>-</sup>), at sites with native vegetation loss between 40% and 60%. We also used segmented regression analysis with species richness, which showed weak evidence of a threshold located at 54% of native vegetation loss. Differently of previous studies with other taxonomic groups in forested environments, our results indicate that the variability around the threshold is higher. Under a precaution perspective and given current levels of vegetation loss around streams where the risk of losing species is higher, we reinforce the importance of appropriate landscape management strategies. In order to effectively conserve biodiversity in aquatic-and-terrestrial environments, the native vegetation loss within pastures and agriculture landscapes, should be above the "zone of increasing risk of impact" level. According to the current Brazilian Forest Act, riparian forest of at least 30 m wide must

be preserved along both sides of each watercourse. In our study 30 m vegetation wide represents only 10% of the 250 m buffer area. It implies that the current Brazilian Forest Act does not preserve the Cerrado's riparian vegetation and its associated aquatic biodiversity, since the amount of native vegetation loss is below the "zone of increasing risk of impact" we detected for damselflies in evaluated landscapes." (2016): Feeding behaviour, predatory functional responses and trophic interactions of the invasive Chinese mitten crab (*Eriocheir sinensis*) and signal crayfish (*Pacifastacus leniusculus*). *Freshwater Biology* 61(4): 426-443. (in English) ["(1.) Freshwaters are subject to particularly high rates of species introductions; hence, invaders increasingly co-occur and may interact to enhance impacts on ecosystem structure and function. As trophic interactions are a key mechanism by which invaders influence communities, we used a combination of approaches to investigate the feeding preferences and community impacts of two globally invasive large benthic decapods that co-occur in freshwaters: the signal crayfish (*Pacifastacus leniusculus*) and Chinese mitten crab (*Eriocheir sinensis*). (2.) In laboratory preference tests, both consumed similar food items, including chironomids, isopods and the eggs of two coarse fish species. In a comparison of predatory functional responses with a native crayfish (*Austropotamobius pallipes*), juvenile *E. sinensis* had a greater predatory intensity than the native *A. pallipes* on the keystone shredder *Gammarus pulex*, and also displayed a greater preference than *P. leniusculus* for this prey item. (3.) In outdoor mesocosms ( $n = 16$ ) used to investigate community impacts, the abundance of amphipods, isopods, chironomids and gastropods declined in the presence of decapods, and a decapod >gastropod >periphyton trophic cascade was detected when both species were present. *Eriocheir sinensis* affected a wider range of animal taxa than *P. leniusculus*. (4.) Stable-isotope and gut-content analysis of wild-caught adult specimens of both invaders revealed a wide and overlapping range of diet items including macrophytes, algae, terrestrial detritus, macroinvertebrates and fish. Both decapods were similarly enriched in  $^{15}\text{N}$  and occupied the same trophic level as Ephemeroptera, Odonata and Notonecta. *Eriocheir sinensis*  $\delta^{13}\text{C}$  values were closely aligned with macrophytes indicating a reliance on energy from this basal resource, supported by evidence of

direct consumption from gut contents. *Pacifastacus leniusculus*  $\delta^{13}\text{C}$  values were intermediate between those of terrestrial leaf litter and macrophytes, suggesting reliance on both allochthonous and autochthonous energy pathways. (5.) Our results suggest that *E. sinensis* is likely to exert a greater per capita impact on the macroinvertebrate communities in invaded systems than *P. leniusculus*, with potential indirect effects on productivity and energy flow through the community." **15667.** Sanchez, S.; Wilson, D.E. (2016): Food items of *Macrotus waterhousii* (Chiroptera: Phyllostomidae) in central Mexico. *Therya* 7(1): 161-177. (in English, with Spanish summary) ["*Macrotus waterhousii* is a phyllostomid bat whose diet is poorly known, particularly in semiarid and temperate central Mexico. In this work additional information is reported from food remains discarded by this bat, including taxonomic composition, frequencies and size range of consumed insects; the assessment of a prediction on prey hardness of food insects, at the ordinal level; relative energy reward of insect prey in the sample; a comparison of the composition of the food sample from the arid study locality against one from a subtropical-temperate site; and brief comments on the known ecological importance of particular prey in the arid site. A sample of insect food remains discarded by *Macrotus waterhousii bulleri*, was recovered from under a roost in semiarid northern Querétaro, Mexico. The taxonomic identity, estimated relative abundance, size, hardness, and ecological relations of prey species in the sample were studied and results were compared with reference to feeding ecology. A comparison of the data with available information on food taken by *Macrotus waterhousii mexicanus* in temperate-subtropical central Mexico was made. Information on the importance of the most relevant identified insects was extracted from literature and analyzed. In Querétaro, Lepidoptera, Hymenoptera, and Coleoptera were frequent; moths dominated but, as a single species, the (winged) ant, *Atta mexicana* was most frequent. Nocturnal insects were frequent; diurnal ones may have been gleaned at night. A sample from Estado de México featured Orthoptera, Coleoptera, and Lepidoptera. Wingspan range of frequent prey in Querétaro was 25-80 mm, but moths over 70 mm were over one fifth of the sample. Prey hardness estimation was similar to that for *Macrotus californicus*. Some insects identified are of ecologic and agricultural relevance. Insects known to be seasonally abundant in the environment were also abundant in the sample, presumably captured according to that availability. However this bat, aside from eating insects of moderate size in proportion to its jaw size, is also capable of capturing

large moths and these may represent a significant energy intake. Most insects are nocturnal species. The taxonomic composition of the food samples from both areas suggests that *M. waterhousii* (sensu lato) may be mostly an opportunistic predator. Local insect fauna composition and dynamics may be hypothesized to influence food taken by *M. waterhousii*. Several insect species consumed by this bat in semiarid Querétaro have crucial roles in the ecology of arid land vegetation, as well as some economic importance for agriculture as pests." (Authors) *Odonata Anax* sp., *Erpetogomphus* sp., *Paltothemis* sp.) account less than 1% of diet items. ]Address: Sánchez, S., Las Flores, San Lorenzo Tepaltitlán 50018, Estado de México, México. **15668.** Scales, J.A.; Butler, M.A. (2016): The relationship between microhabitat use, allometry, and functional variation in the eyes of Hawaiian *Megalagrion* damselflies. *Functional Ecology* 30(3): 356-368. (in English) ["(1.) The evolution of visual systems is guided by the interaction of visual requirements imposed by habitat light heterogeneity, eye size, and physical limitations imposed by the resolution-sensitivity tradeoff. The physical constraints related to eye surface area result in a tradeoff between resolution, the ability of the eye to detect detail, and sensitivity, the ability to capture photons, so that both cannot be simultaneously maximized without increases to eye size. How this constraint interacts with ecology and whether it allows the fine tuning of the visual system to smaller scale habitat heterogeneity remains an understudied question in visual ecology. (2.) Here we use closely related species of damselflies in the Hawaiian genus *Megalagrion* which differ in ecology to test whether variation about the resolution-sensitivity tradeoff is the evolutionary result of scaling or differences in microhabitat use. We use regression analyses and phylogenetic comparative methods to examine the effects of size and microhabitat use on traits related to light sensitivity and visual resolution. (3.) We find that eye size is tightly associated with body size in these damselflies, but morphological traits related to light sensitivity and resolution are associated with microhabitat type. Furthermore, size and morphology relationships vary across microhabitats, and resolution tends to be more conserved than variation in light sensitivity. (4.) Additionally, smaller species in visually challenging microhabitats have more regionalized eyes than species with larger eyes in open, well-lit areas. Thus, regionalization of the eye allows a decoupling of size and morphology/performance so that even small insect species can exploit visually challenging habitats. (5.) These results suggest that variation in visual performance results from changes in eye geometry as well as size. These morphological changes are likely adaptive to differences in microhabitat indicating that variation in microhabitat use, even at small scales, can play an important role in the evolution of visual systems." SMP-NRVA: 45 pp. + 8pp app.. (in French, with English summary) ["Irish Damselfly (*Coenagrion lunulatum*) is a rare and endangered dragonfly found only in the French Massif Central and especially in the Volcans d'Auvergne Natural Regional Park (PNRVA). After two years of studies about inventory and larval habitat characterisation, 2015 is about moving capacities of this species. On the one hand, Mark-Release-Recapture method enables to understand the population dynamic of the species. On the other hand, recapture shows that *C. lunulatum* can moving punctually on distance longer than 4km. With the current knowledge about the species' ecology, the potential distribution of *C. lunulatum* on the PNRVA has been modelled. This map shows

some population cores well connected, and two isolated areas, in the North and in the South of PNRVA territory, due to small populations, relief, and woodland. Now, it must allow to define priority area where actions will be suggest to preserve this dragonfly." (Authors)] Address: not stated.

**15672.** Segura-Trujillo, C.A.; Lidicker, W.Z.; Álvarez-Castañeda, S.T. (2016): New perspectives on trophic guilds of arthropodivorous bats in North and Central America. *Journal of Mammalogy* 97(2): 644-654. (in English, with Spanish summary) ["Trophic guilds are useful concepts for advancing our knowledge of trophic structure of communities, dynamics of species interactions, redundancy in ecosystem services, resilience to disturbances, response to climate change, conservation strategies, etc. For insectivorous bats, current literature suggests 8 trophic-related guilds. These include 3 guilds based on the openness of foraging areas, 3 based on the style of feeding, and 2 recently proposed subguilds among gleaners. Some gleaners are "passive," using densely cluttered vegetation in which echolocation is ineffective, and others are "actively" gleaning, using echolocation to procure prey. None of these guilds is based on the actual diets of bats. We analyzed 33 reports of diet composition representing 51 species of arthropod-feeding bats inhabiting North and Central America. We wanted to determine if the classical guild structure was concordant with the actual diets of bats and to compare guild structure in the Nearctic with that in the Neotropics. Discriminant function and principle component analyses generated 5 groups of genera based on the proportion of various arthropod taxa (mainly orders) in their diets. These groups were very different from classical guilds and showed almost no overlap among bat genera between the 2 continental regions. A similar analysis based on prey flying ability and hardness of their exoskeletons suggested 4 guilds that were more consistent with classical guild concepts, had higher rates of unambiguous guild assignment, and also showed major continental differences. Our results suggest a new arrangement of 4 guilds for arthropod-feeding bats in North and Central America that are based primarily on 2 features of their prey. New molecular techniques should allow us to build on this arrangement by significantly improving the taxonomic level of prey identification." **15673.** Shaffery, H.M.; Relyea, R.A. (2016): Dissecting the smell of fear from conspecific and heterospecific prey: investigating the processes that induce anti-predator defenses. *Oecologia* 180(1): 55-65. (in English) ["Prey use chemical cues from predation events to obtain information about predation risk to alter their phenotypes. Though we know how many prey respond to predators, we still have a poor understanding of the processes and chemical cues involved during a predation event. We examined how gray treefrog tadpoles (*Hyla versicolor*) altered their behaviour and morphology when raised with cues from different

stages of predator (*Anax junius*) attack, predators fed different amounts of prey, and predators consuming different combinations of treefrog tadpoles or snails (*Helisoma trivolvis*). We found that starved predators and predators fed snails induced no defensive responses whereas tadpoles exposed to a predator consuming gray treefrogs induced greater hiding, lower activity, and relatively deeper tails. We also found that the tadpoles did not respond to crushed, chewed, or digested conspecifics, but they did respond to consumed (i.e., chewed plus digested) conspecifics. When we increased the treefrog biomass consumed by predators, tadpoles frequently increased their defenses when only tadpoles were consumed and always increased their defenses when the total diet biomass was held constant via the inclusion of snails. When predators experienced temporal variation in diet composition, including cues from snails to cause additional digestive cues or chemical noise, there was no effect on tadpole phenotypes. Our results suggest that amphibian prey rely on cues from both chewing and digestion of conspecifics and that the presence of cues from digested heterospecifics play little or no role in adding chemical noise or increased digestive enzymes and by-products that could potentially interfere with induced defenses." A* 472: 20150712. <http://dx.doi.org/10.1098/rspa.2015.0712>: 37 pp. (in English) ["There are nearly a million known species of flying insects and 13000 species of flying warm-blooded vertebrates, including mammals, birds and bats. While in flight, their wings not only move forward relative to the air, they also flap up and down, plunge and sweep, so that both lift and thrust can be generated and balanced, accommodate uncertain surrounding environment, with superior flight stability and dynamics with highly varied speeds and missions. As the size of a flyer is reduced, the wing-to-body mass ratio tends to decrease as well. Furthermore, these flyers use integrated system consisting of wings to generate aerodynamic forces, muscles to move the wings, and sensing and

control systems to guide and manoeuvre. In this article, recent advances in insect-scale flapping-wing aerodynamics, flexible wing structures, unsteady flight environment, sensing, stability and control are reviewed with perspective offered. In particular, the special features of the low Reynolds number flyers associated with small sizes, thin and light structures, slow flight with comparable wind gust speeds, bioinspired fabrication of wing structures, neuron-based sensing and adaptive control are highlighted." **15676.** Siepielski, A.M.; Fallon, E.; Boersma, K. (2016): Predator olfactory cues generate a foraging–predation trade-off through prey apprehension. *R. Soc. open sci.* 3: 150537. <http://dx.doi.org/10.1098/rsos.150537>: 7 pp. (in English) ["Most animals are faced with the challenge of securing food under the risk of predation. This frequently generates a trade off whereby animals respond to predator cues with reduced movement to avoid predation at the direct cost of reduced foraging success. However, predators may also cause prey to be apprehensive in their foraging activities, which would generate an indirect 'apprehension cost'. Apprehension arises when a forager redirects attention from foraging tasks to predator detection and incurs a cost from such multi-tasking, because the forager ends up making more mistakes in its foraging tasks as a result. Here, we test this apprehension cost hypothesis and show that damselflies (*Ischnura cervula*) miss a greater proportion of their prey during foraging bouts in response to both olfactory cues produced by conspecifics that have only viewed a fish predator and olfactory cues produced directly by fish (*Gambusia affinis*). This reduced feeding efficiency is in addition to the stereotypical antipredator response of reduced activity, which we also observed. These results show that costs associated with anti-predator responses not only arise through behavioural alterations that reduce the risk of predation, but also from the indirect costs of apprehension and multi-tasking that can reduce feeding efficiency under the threat of predation." *Technology* 49: 259-268. (in English) ["A procedure for designing a simplified, dragonfly-like wing model that is suitable for use in a Biomimetic Micro Air Vehicle (BMAV) is presented. BMAV are a relatively new class of micro-scaled unmanned air systems that mimic the flapping wing propulsion system of flying biological organisms (like insects). Many insects (e.g. dragonflies) have complex wing vein and membrane patterns that are too small to fabricate using many types of machine cutting tools (e.g. micro laser cutting). Structural dynamic modification using the spatial network analysis approach is used to create a simplified model. Our objective was to minimize the wing vein patterns so that they were within our fabrication tolerances. Simulations were performed for both the detailed and simplified models. The natural frequency and corresponding mode shapes, modal assurance criterion (MAC) and static bend-twist coupling results were very similar. This analysis shows that a simplified model can be designed and fabricated to closely biomimic a real dragonfly wing." (2016): Seasonal time constraints reduce genetic variation in life-history traits along a latitudinal gradient. *Journal of Animal Ecology* 85(1): 187-198. (in English) ["(1.) Time constraints cause strong selection on life-history traits, because populations need to complete their life cycles within a shorter time. We therefore expect lower genetic variation in these traits in high- than in low-latitude populations, since the former are more time-constrained. (2.) The aim was to estimate life-history traits and their genetic variation in an obligately univoltine *Lestes sponsa* along a latitudinal gradient of 2730 km. (3.) Populations were grown in the laboratory at temperatures and photoperiods simulating those at their place of origin. In a complementary experiment, individuals from the same families were grown in constant temperature and photoperiod that mimicked average conditions across the latitude. (4.) Development time and size was faster and smaller, respectively, and growth rate was higher at northern latitudes. Additive genetic variance was very low for life-history traits, and estimates for egg development time and larval growth rate showed significant decreases towards northern latitudes. The expression of genetic effects in life-history traits differed considerably when individuals were grown in constant rather than simulated and naturally variable conditions. (5.) Our results support strong selection by time constraints. They also highlight the importance of growing organisms in their native environment for correct estimates of genetic variance at their place of origin. Our results also suggest that the evolutionary potential of life-history traits is very low at northern compared to southern latitudes, but that changes in climate could alter this pattern." (2016): Impacts of introduced species on the biota of an oceanic archipelago: the relative importance of competitive and trophic interactions. *Ecological Research* 31(2): 155-164. (in English) ["Introduced species negatively impact native species through competitive and trophic interactions, particularly on oceanic islands that have never been connected to any continental landmass. However, there are few studies on the relative importance of competitive interactions (resource competition with introduced species) and trophic interactions (predation or herbivory by introduced species) with respect to the negative impacts on native organisms on oceanic islands. A literature review on introduced and native species of the oceanic Ogasawara (Bonin) Islands in the western Pacific Ocean indicated that many native species (e.g., bees, beetles, damselflies, butterflies, land snails, birds, and plants) have been negatively impacted by introduced predators and herbivores (e.g., lizards, rats, flatworms, and goats). Several native plants and bees have been negatively affected by introduced competitors. However, the native species that have competed with introduced species have also suffered from either intense herbivory or predation by other introduced species. Thus, introduced predators and herbivores have had greater impacts on native species than introduced competitors in the Ogasawara Islands." (2016): A global population genetic study of *Pantala flavescens*. *PLoS ONE* 11(3): e0148949. doi:10.1371/journal.pone.0148949: 13 pp. (in English) ["Among terrestrial arthropods, the dragonfly species *Pantala flavescens* is remarkable due to their nearly global distribution and extensive migratory ranges; the largest of any known insect. Capable of migrating across oceans, the potential for high rates of gene flow among geographically distant populations is significant. It has been hypothesized that *P. flavescens* may be a global panmictic population but no sufficient genetic evidence has been collected thus far. Through a population genetic analysis of *P. flavescens* samples from North America, South America, and Asia, the current study aimed to examine the extent at which gene flow is occurring on a global scale and discusses the implications of the genetic patterns we uncovered on population structure and genetic diversity of the species. This was accomplished using PCR-amplified cytochrome oxidase one (CO1) mitochondrial DNA data to reconstruct phylogenetic trees, a haplotype network, and perform molecular variance analyses. Our results suggested high rates of gene flow are occurring among all included geographic regions; providing the first significant evidence that *Pantala flavescens* should be considered a global panmictic population." **15684.** Valente-Neto, F.; Roque, F.; Rodrigues, M.E.; Juen, L.; Swan, C.M. (2016): Toward a practical use of Neotropical odonates as bioindicators: Testing congruence across taxonomic resolution and life stages. *Ecological Indicators* 61(2): 952-959. (in English) ["Highlights: •We assessed environmental factors driving larvae and adults of odonates. •We evaluated the congruency between and within life-history stages. •Larvae vs. adult and adult genera vs. species were congruent. •Environmental variables were important to explain the congruence pattern. •For operational reasons, adult genera are recommended in biomonitoring programs. Abstract: Odonates are suggested as bioindicators of human impact. However, their complex life cycles add additional challenges in the practical use as bioindicators, because the level of taxonomic identification could be dependent on life-history stage and, during their ontogeny, dramatic changes occur in their niche (ontogenetic niche shifts). Considering that larvae and adults have different biological characteristics, which could interfere in their performance as bioindicators, we first sought to understand how similar or different environmental factors affect larval and adult life stages in the Odonata. Second, we assessed the level of congruence between (larvae and adult) and within (adult genera and species) life-history stages, considering the taxonomic and numerical resolution. We sampled larvae and adults in 44 streams distributed along a riverine

network in southwest Brazil. Larvae samples constituted 20 sampling units of 1 m length each, using the kick sampling method; adults were collected for 1 h at each site with a hand net along a 100-m transect parallel to the stream/river banks. The influence of environmental factors on larvae and adult was assessed by redundancy analysis coupled with forward selection. The congruence level between response matrices was determined by Procrustes analysis. Our results revealed that a set of environmental variables explained a portion of larvae and adults distribution and some environmental factors affect both between (larvae and adults) and within (adult genera and species) life-history stages. Larvae and adult were about 54% congruent, regardless of taxonomic level of adults. Abundance of adult genera and species were 94% congruent, but numerical resolution (abundance vs. incidence) decreased the congruency by 10%. Environmental variables could influence larvae and adults individually or via carry-over effects, i.e., larval environmental conditions that could affect adult fitness components or vice versa. In addition, some odonate behaviours, such as female selection of more appropriate habitats for laying their eggs, could also help us to explain our results, because it could determine larvae distribution. In a biomonitoring perspective, considering the cost-benefit of taxonomic level and sampling of larvae and adults, our results suggest that abundance of adult genera could be used in biomonitoring programs since they capture, respectively, 94% and 54% of the information carried by adult species and larvae." **15685.** Van Dinh, K.; Janssens, L.; Therry, L.; Gyulavári, H.A.; Bervoets, L.; Stoks, R. (2016): Rapid evolution of increased vulnerability to an insecticide at the expansion front in a poleward moving damselfly. *Evolutionary Applications* 9(3): 450-461. (in English) ["Many species are too slow to track their poleward moving climate niche under global warming. Pesticide exposure may contribute to this by reducing population growth and impairing flight ability. Moreover, edge populations at the moving range front may be more vulnerable to pesticides because of the rapid evolution of traits to enhance their rate of spread that shunt energy away from detoxification and repair. We exposed replicated edge and core populations of the poleward moving damselfly *Coenagrion scitulum* to the pesticide esfenvalerate at low and high densities. Exposure to esfenvalerate had strong negative effects on survival, growth rate and development time in the larval stage and negatively affected flight-related adult traits (mass at emergence, flight muscle mass and fat content) across metamorphosis. Pesticide effects did not differ between edge and core populations, except that at the high concentration the pesticide-induced mortality was 17% stronger in edge populations. Pesticide exposure may therefore slow down the range expansion by lowering population growth rates, especially because edge populations suffered a higher mortality, and by

negatively affecting dispersal ability by impairing flight-related traits. These results emphasize the need for direct conservation efforts toward leading-edge populations for facilitating future range shifts under global warming." J., Uberlândia* 32(2): 486-495. (in English, with Spanish summary) ["Studies concerning the occurrence of species and seasonality are of great importance for both the elucidation of species distribution and conservation of natural habitats. We performed a survey of Odonata species and studied their seasonality in an endemic endangered palm swamp (i.e. Veredas) environment of the Ecological Reserve of Clube de Caça e Pesca Itororó de Uberlândia, Southeastern Brazil. Between July 2010 and June 2011, we recorded 31 species of five different families and 21 genera. The community was strongly seasonal, since 24 species occurred in the wet season, while ten occurred in both dry and wet season, and only two species occurred only in the dry season. All Anisoptera species preferred lentic habitats, whereas seven of the 18 Zygoptera species preferred lentic habitats and 11 species preferred lotic sites. The five Calopterygidae and Protoneuridae species preferred lotic habitats. The study site exhibits a great diversity of dragonflies and damselflies, which are important elements of the trophic chain in the Cerrado aquatic and neighbouring land environments. This justifies the development of conservation actions in palm swamp areas, which are poorly known and threatened by the constant advance of urban, monoculture and pasture areas in Cerrado." **15687.** Villalobos-Jimenez, G.; Dunn, A.M.; Hassall, C. (2016): Dragonflies and damselflies (Odonata) in urban ecosystems: A review. *Eur. J. Entomol.* 113: 217-232. (in English) ["The expansion of urban areas is one of the most significant anthropogenic impacts on the natural landscape. Due to their sensitivity to stressors in both aquatic and terrestrial habitats, dragonflies and damselflies (the Odonata) may provide insights into the effects of urbanisation on biodiversity. However, while knowledge about the impacts of urbanisation on odonates is growing, there has not been a comprehensive review of this body of literature until now. This is the first systematic literature review conducted to evaluate both the quantity and topics of research conducted on odonates in urban ecosystems. From this research, 79 peer-reviewed papers were identified, the vast majority (89.87%) of which related to studies of changing patterns of biodiversity in urban odonate communities. From the papers regarding biodiversity changes, 31 were performed in an urban-rural gradient and 21 of these reported lower diversity towards built up city cores. Twelve of the cases of

biodiversity loss were directly related to the concentrations of pollutants in the water. Other studies found higher concentrations of pollutants in odonates from built-up catchments and suggested that odonates such as *Aeshna juncea* and *Platycnemis pennipes* may be candidate indicators for particular contaminants. We conclude by identifying current research needs, which include the need for more studies regarding behavioural ecology and life-history traits in response to urbanisation, and a need to investigate the mechanisms behind diversity trends beyond pollution." **15688.** Vinatier, F.; Lagacherie, P.; Voltz, M.; Petit, S.; Lavigne, C.; Brunet, Y.; Lescourret, F. (2016): An unified framework to integrate biotic, abiotic processes and human activities in spatially explicit models of agricultural landscapes. *Front. Environ. Sci.*, 02 February 2016 | <http://dx.doi.org/10.3389/fenvs.2016.00006> : 7 pp. (in English) ["Recent concern over possible ways to sustain ecosystem services has triggered important research worldwide on ecosystem processes at the landscape scale. Understanding this complexity of landscape functioning calls for coupled and spatially-explicit modelling approaches. However, disciplinary boundaries have limited the number of multi-process studies at the landscape scale, and current progress in coupling processes at this scale often reveals strong imbalance between biotic and abiotic processes, depending on the core discipline of the modellers. We propose a spatially-explicit, unified conceptual framework that allows researchers from different fields to develop a shared view of agricultural landscapes. In particular, we distinguish landscape elements that are mobile in space and represent biotic or abiotic objects (for example water, fauna or flora populations), and elements that are immobile and represent fixed landscape elements with a given geometry (for example ditch section or plot). The shared representation of these elements allows setting common objects and spatio-temporal process boundaries that may otherwise differ between disciplines. We present guidelines and an assessment of the applicability of this framework to a virtual landscape system with realistic properties. This framework allows the complex system to be represented with a limited set of concepts but leaves the possibility to include current modelling strategies specific to biotic or abiotic disciplines. Future operational challenges include model design, space and time discretization, and the availability of both landscape modelling platforms and data." **15689.** Wellenreuther, M.; Sánchez-Guillén, R.A. (2016): Non-adaptive radiation in damselflies. *Evolutionary Applications* 9(1): 103-118. (in English) ["Adaptive radiations have long served as living libraries to study the build-up of species richness, however, they do not provide good models for radiations that exhibit negligible adaptive disparity. Here we

review work on damselflies to argue that non-adaptive mechanisms were predominant in the radiation of this group and have driven species divergence through sexual selection arising from male–female mating interactions. Three damselfly genera (*Calopteryx*, *Enallagma* and *Ischnura*) are highlighted and the extent of (i) adaptive ecological divergence in niche use and (ii) non-adaptive differentiation in characters associated with reproduction (e.g. sexual morphology and behaviours) evaluated. We demonstrate that species diversification in the genus *Calopteryx* is caused by non-adaptive divergence in colouration and behaviour affecting premating isolation, and structural differentiation in reproductive morphology affecting postmating isolation. Similarly, the vast majority of diversification events in the sister genera *Enallagma* and *Ischnura* are entirely driven by differentiation in genital structures used in species recognition. The finding that closely related species can show negligible ecological differences yet are completely reproductively isolated suggests that the evolution of reproductive isolation can be uncoupled from niche-based divergent natural selection, challenging traditional niche models of species coexistence." host. *Journal of Insect Science* 16(1)(37): 6 pp. (in English) ["Some adult odonates resist parasitism by larval water mites (*Arrenurus* spp.) with melanotic encapsulation, in which the mite's styletome is clogged and the mite starves. In summer 2014, we counted the engorged and resisted mites on 2,729 adult odonates sampled by aerial net at 11 water bodies in Greenville Co. and Pickens Co., SC, and tested the hypothesis that the frequency and intensity of resistance correlates with parasite prevalence (the percentage of parasitized hosts). Resistance prevalence (the percentage of parasitized hosts that resisted at least one mite) varied significantly among host species, exceeding 60% for *Argia fumipennis* and *Celithemis fasciata* but less than 20% for other species. However, neither resistance prevalence nor mean resistance intensity (mean percentage of resisted mites on resisting hosts) correlated with parasite prevalence. We described potential effects of parasitism on host development of *A. fumipennis* and *Pachydiplax longipennis* by comparing the percent asymmetry of forewing lengths between parasitized and unparasitized individuals. There was no significant difference in asymmetry for either males or females of *A. fumipennis*, or males of *Pa. longipennis* (females were not sampled). We also evaluated differences in melanotic encapsulation between *A. fumipennis*, which readily encapsulates mites in nature, and *Pa. longipennis*. We inserted a 2.0-mm piece of sterile monofilament line into the thorax of captured individuals for 24h and compared mean gray value scores of inserted and emergent ends using Image-J software. There was no difference in melanotic encapsulation between species." (Authors)] Address: Hart, T.M., Biology Department, Furman University, Greenville, SC 29613, USA. E-mail: Thomasmhart0@gmail.com

**15692.** Xu, Q.; Lin, W.; Zhuang, F.; Shen, C.; Lin, X. (2016): Acute toxicity of three pesticides to *Orthetrum* larvae. *Chinese Agricultural Science Bulletin* 32(2): 73-76. (in Chinese, with English summary) ["To select efficient and safe pesticides and control dragonfly larvae in fishing ponds, acute toxicity tests of three pesticides (trichlorfon, bifenthrin and clothianidin) to last-stadium larvae of *Orthetrum* were performed respectively. The results showed that LC50 (96 h) values of trichlorfon, bifenthrin and clothianidin to last-stadium larvae of *Orthetrum* were 0.2506, 0.0012 and 0.0517 mg a.i./L, respectively. Comparing LC50 (96 h) values of the three pesticides to the last-stadium larvae of *Orthetrum*, freshwater fishes and the tadpole of *Rana grylio*, and the aquatic ecological characteristics of the three pesticides, clothianidin was recommended as the suitable pesticide for controlling dragonfly larvae in fishing ponds." **15694.** Yapac, L.A.; Villanueva, R.J.T.; Nuñez, O.M. (2016): Species richness of Odonata in the agricultural area of Sultan Naga Dimaporo, Lanao del Norte, Philippines. *Bulletin of Environment, Pharmacology and Life Sciences* 5(3): 60-67. (in English) ["This study was conducted to determine the species richness of Odonata in the agricultural areas of Sultan Naga Dimaporo, Lanao del Norte. Eight sampling sites were assessed comprising heavily disturbed and slightly disturbed agricultural areas. Sampling was done by sweep netting. Thirteen species composed of 10 Anisoptera and three Zygoptera were documented belonging to 10 genera and three families. Only two endemic species were found (*Diplacina bolivari*, *Coeliccia dinoceras*). *Orthetrum sabina sabina*, an Oriental species, was the most abundant species found in all areas. The agroforestry sites which are slightly disturbed areas had higher species richness, abundance, endemism, and diversity. Results indicate that agricultural land use has adverse impact on species richness of Odonata." **15695.** Yeates, D.K.; Meusemann, K.; Trautwein, M.; Wiegmann, B.; Zwick, A. (2016): Power, resolution and bias: recent advances in insect phylogeny driven by the genomic revolution. *Current Opinion in Insect Science* 13: 16-23. (in English) ["Our understanding on the phylogenetic relationships of insects has been revolutionised in the last decade by the proliferation of next generation sequencing technologies (NGS). NGS has allowed insect systematists to assemble very large molecular datasets that include both model and non-model organisms. Such datasets often include a large proportion of the total number of protein coding sequences available for phylogenetic comparison. We review some early entomological phylogenomic studies that employ a range of different data sampling protocols and analyses strategies, illustrating a fundamental renaissance

in our understanding of insect evolution all driven by the genomic revolution. The analysis of phylogenomic datasets is challenging because of their size and complexity, and it is obvious that the increasing size alone does not ensure that phylogenetic signal overcomes systematic biases in the data. Biases can be due to various factors such as the method of data generation and assembly, or intrinsic biological feature of the data per se, such as similarities due to saturation or compositional heterogeneity. Such biases often cause violations in the underlying assumptions of phylogenetic models. We review some of the bioinformatics tools available and being developed to detect and minimise systematic biases in phylogenomic datasets. Phylogenomic-scale data coupled with sophisticated analyses will revolutionise our understanding of insect functional genomics. This will illuminate the relationship between the vast range of insect phenotypic diversity and underlying genetic diversity. In combination with rapidly developing methods to estimate divergence times, these analyses will also provide a compelling view of the rates and patterns of lineagenesis (birth of lineages) over the half billion years of insect evolution." **15696.** Yu, P.; Cheng, X.; Ma, Y.; Yu, D.; Zhang, J. (2016): The complete mitochondrial genome of *Brachythemis contaminata* (Odonata: Libellulidae). *Mitochondrial DNA* 27(3): 2272-2273. (in English) ["In this study, we reported the complete mitochondrial genome of the dragonfly *Brachythemis contaminata* (Odonata: Libellulidae). The entire circular genome is 15,056 bp in length and represents the smallest in presently known odonatan mitogenomes. The DNA molecule contains 13 protein-coding genes, 2 rRNA genes, 22 tRNA genes and a non-coding control region of 323 bp. There were a total of 137 bp short intergenic spacers and 89 bp overlaps in the genome. The gene arrangement is similar to other dragonflies. The base composition of the genome is A (40.2%), T (32.8%), C (15.6%) and G (11.4%) with an AT content of 73.0%. Four start codons (ATA, ATT, ATC and ATG) and two stop codons (TAG and TAA/TA) were found in 13 protein-coding genes. The length of 22 tRNA genes ranged from 63 (trnP) to 72 bp (trnK)."] (Authors)] Address: Zhang, J., Institute of Ecology, Zhejiang Normal University, Jinhua 321004, Zhejiang Province, P. R. China. **15697.** Yuto, C.M.M.; Lumogdang, L.; Tabugo, S.R.M. (2016): Fluctuating asymmetry as an indicator of ecological stress in *Rhinocypha colorata* (Odonata: Chlorocyphidae) in Iligan city, Mindanao, Philippines. *Entomology and Applied Science Letters* 3(1): 13-20. (in English) ["Odonata species are known to be successful biological indicators because they are particularly sensitive to human disturbances due to their habitat selection which makes them vulnerable to changes. A useful trait to monitor developmental instability (DI) and ecological stress is fluctuating asymmetry (FA),

which is a measure of the differences between the left and right side of bilateral symmetrical organisms. It refers to a slight number and nondirectional deviations from strict bilateral symmetry of biological objects that occur as a result of stochastic microscopic processes. In this study, fore-wing variation of *Rhinocypha colorata*, a Philippine endemic species was investigated. It assessed developmental stability via fluctuating asymmetry in the fore-wings of *R. colorata*, in three populations from three areas: Buruun, Dituclalan, Dalipuga, Iligan City, Mindanao, Philippines. Analysis was based on Procrustes method that makes comparison of FA indices of homologous points. Using landmark method for shape asymmetry, anatomical landmarks were used and analyzed using Symmetry and Asymmetry in Geometric Data (SAGE) program. Twenty landmarks on the fore-wings were tested on samples for all populations. Results obtained showed variation and significantly high FA for all populations with relatively higher FA for Dalipuga. Principal component analysis (PCA) showed that barangay Dalipuga exhibited more variations (74.93%) than that of Dituclalan (72.19%) and Buru-un (67.97%). Possible reasons behind high FA values were anthropogenic activities in the area. FA has been considered as a good indicator of DI and thus acts as a biomarker for environmental stress. Hence, results may reflect inability of the organism to cope with stressing factors and any perturbations during development. Here-with, understanding the relationship between the species and its environment would help determine the health of a given ecosystem. Nonetheless, Odonata, as bioindicator species, can play an important role for biomonitoring purposes." **15698.** Zaliyati, A.M.; Shariff, S.M. (2016): Diversity of dragonfly communities at two habitats in Negeri Sembilan. *Regional conference on science, technology and social sciences (RCSTSS 2014)*: 557-564. (in English) ["Kuala Pilah and Batu kikir are located in Negeri Sembilan, Malaysia. The changes of flora and fauna community have always been related with the anthropogenic activities. This study was conducted in order to determine the species diversity of dragonfly within two different habitats in Negeri Sembilan. The sampling was carried out from August 2013 to October 2013 at two habitats comprising of UiTM Forest Reserve (Kuala Pilah) and Kampung Lonek Paddy Field (Batu Kikir). A total of 164 individuals of dragonflies were collected, which comprise of 14 species. For Kuala Pilah, a total of 11 species with 62 individuals were collected while for Batu kikir, a total of 9 species with 102 individuals were collected. Family Libellulidae was the dominant family that indicates 99 % of the total collected followed by one percent of total collected by Family Gomphidae. The highest total number of dragonfly individuals was shown by *Potamarcha congener* with 52 individuals that indicate 32 % of total collected while the least number of individuals was shown by the species of *Orthetrum chrysis*, *Tholymis tillarga*, and *Ictinogomphus decoratus* with one individual that indicate only one

percent, respectively. Thus, there was high species diversity ( $H' = 1.9$ ), high species richness ( $R = 2.423$ ), and high species evenness of dragonfly ( $E = 0.792$ ) in UiTM Forest Reserve as compared to Kampung Lonek Paddy Field." Project number: 21410-I 130-2N19: 17 pp. (in English) ["Reintroduction of the northern aplomado falcon (*Falco femoralis septentrionalis*) into its former range in Texas began in 1985, and continued with a full scale release of captive-bred falcons in 1993 on Laguna Atascosa National Wildlife Refuge (NWR). A study was conducted in 1994 to determine whether contaminants in falcon prey posed a threat to the successful recovery of the species. Meadowlark (*Stumella* sp.), mourning dove (*Zenaidura macroura*), cicadas, and dragonflies were collected from two areas on the Laguna Atascosa NWR and from two tracts on the Lower Rio Grande Valley NWR where falcons may disperse. Organophosphate pesticides and PAH's were below detection levels in all samples. With the exception of DDE, all other organochlorine pesticides were also below detection. Mercury concentrations in meadowlark were above levels in prey that have been associated with reproductive anomalies in sensitive aquatic birds, so there may be some concern about reproductive or chronic effects in the aplomado falcon from this heavy metal.] Address: U.S Fish and Wildlife Service, Corpus Christi Ecological Services Field Office, Campus Box 338, 6300 Ocean Drive, Corpus Christi, Texas 78412, USA

**15706.** Naylor, G. (1998): The Banded Demoiselle (*Calopteryx splendens* (Harris)) in north Cumbria in 1998. *Carlisle Naturalist* 6(2): 31-32. (in English) ["*C. splendens* was, until recently, restricted in its northern outpost to a few sites along the lower reaches of the river Waver occupying the 10 km grid squares NY15 and NY25. In 1996, as was reported in this newsletter (Clarke and Garner 1996), there were sightings at some places along the river Wampool and close to the river Eden, which expanded its range into squares NY24 and NY35. The records from the Wampool were the first known from that river and those for the Eden were the first there for almost 40 years. The expected continuation of this expansion in 1997 did not come about, but there was one additional record near Rockcliffe, which was also reported in this newsletter (Naylor 1997). This was in another new square, NY36. The expected resurgence seems to have arrived in 1998. Firstly, the Environment Agency reported very large numbers in the usual Waver sites (this also happened in 1996). On 16th July Stephen Hewitt and I observed a female *Calopteryx* in Rickerby Park, Carlisle and although we could not be certain which species, *splendens* or *virgo*, it is very unlikely to have been the latter. This again was a new square (NY45). Two weeks later I found a male and female *splendens* on the banks of the Eden at Cargo. David Clarke followed up this report and saw at least 7 (males and females) at the same site on the next day. During this visit, a local fisherman reported having seen them there in 1997. DC saw another one there on 15th August. At around this time I made an unsuccessful search of the area at Rockcliffe, where I had seen one in 1997. It would appear from these observations that there may now be an established population along the river Eden from at least Carlisle down to Rockcliffe and that searches of other parts of this stretch of river and possibly upstream from Rickerby Park may produce

more sightings. The flight period is from late May to mid-August so make a note of those dates in your diary for 1999. Clarke, D.J. & Garner, S., 1996, A dispersal of the *C. splendens* in the Solway area in 1996, *Carlisle Naturalist* 4 (2): 38. Naylor, G.R., 1997, A further record of the *C. splendens* on the River Eden, *Carlisle Naturalist* 5(2): 35.]" Address: Naylor, G., 2 Fell Cottages, Milton, Brampton, Carlisle, UK

Usually the eye-controlled vertebrate looks for success with a sudden mighty leap. After failing an extra-intelligent frog was speculated that got its prey by an underwater attack! The egg-laying female dragonfly was not able to compete with this tactic." (Author)] Address: Brünner-Garten, K., Kellerstraße 9 d , 90530 Wendelstein, Germany

**15708.** de Jong, T. (2000): Poelen vol libellen. *De levende Natuur* 101(4): 127-132. (in Dutch, with English summary) ["Ponds with dragonflies. Since 1990 a few hundred ponds have either been restored or newly created in the eastern part of the province of Utrecht. These ponds are important breeding places for amphibians, but also fish, dragonflies and plants use these ponds. In this article the effects of the creation and restoration of ponds on the presence of dragonflies are discussed. Sixty ponds were investigated. In these ponds 29 species of dragonflies were found. There are large differences in the presence of species of dragonflies in the different ponds. Therefore data on the abiotic and biotic characteristics of all ponds were collected to obtain some insight in how an 'ideal' pond for dragonflies can be created. Analysis of these data shows that the most important features of a good pond for dragonflies are a surface of at least 100 m<sup>2</sup>, a minimum depth of 50 cm of water, a sloping bank and plenty of sunlight. The requirements for a good pond for dragonflies are largely the same as for ponds for amphibians. If properly managed, ponds can play an important role as stepping stones in a rural landscape." (in German, with English summary) ["Between 1995 and 1997 on 20 all-day field trips a total of 9025 individuals of 32 dragonfly species were recorded at a dynamic floodplain of the River Danube near Regelsbrunn. The most abundant species was *Platycnemis pennipes* with 52 % of the total catch, followed by *E. viridulum* with 20 %. In 1995 and 1996 the four most widely distributed species were *P. pennipes*, *Calopteryx splendens*, *Ischnura elegans* and *Orthetrum cancellatum*. The paper discusses species composition and the expected effects of hydrological connectivity."] Address: Raab, R., Quadenstr. 13, 2232 Deutsch-Wagram, Austria. E-mail: rainer.raab@gmx.at

## 2001

**15714.** Glotzhofer, R.C.; Chapman, E. (2001): Second location for two rare Odonata in Ohio, *Nannothemis bella* and *Ladona julia*, (Odonata: Libellulidae) discovered at Singer Lake Bog, Summit County, Ohio. *The Great Lakes Entomologist* 34(2): 63-66. (in English) ["Previously the

dragonflies (Odonata, Libellulidae) *Ladona julia* and *Nanothemis bella* were known in Ohio from only one extant population each: *L. julia* from extreme northwest Ohio in Williams County and *N. bella* from west-central Ohio in Champaign County. During the summer of 2000 populations of each of these species were found in close proximity to each other at Singer Lake, a wetlands complex in southern Summit County in northeastern Ohio. This new location is also home to a population of another rare Ohio dragonfly, *Dorocordulia libera* (Odonata, Corduliidae) that was discovered during 1999. The Singer Lake wetlands are proving to be a very significant habitat for Ohio Odonata." (Authors)]

**15715.** Booker, J.S. (2002): *Enallagma civile* (Odonata: Coenagrionidae) life history and production in a west Texas playa. M.Sc. thesis, University of North Texas: IV + 46 pp. (in English) ["Conclusions: This study was conducted to describe the life history of *Enallagma civile* and the other Odonates that inhabit playa habitats in the Southern High Plains of Texas. It was learned that *Enallagma civile* has a low secondary production estimate of 66.8 mg/m<sup>2</sup>. It was also determined that this species, *Enallagma civile*, had a developmental time of approximately 21 days in a playa setting. Another important fact was that *E. civile* was the earliest colonizer of all of the Odonate species studied. It was recorded in the playa at least one week earlier than all of the other Odonates. Odonate populations in the playa continued to increase in size throughout the study. Some populations grew more quickly than others. For instance, the damselfly, *Lestes disjunctus*, had the population that grew the slowest. Its average population estimate per m<sup>2</sup> changed from 0 to approximately 3 in an eight-week time period. On the opposite end of the spectrum, the damselfly, *Enallagma civile*, had an average population estimate per m<sup>2</sup> which increased in size from 2 to approximately 670 naiads in the same eight-week time period. When the playa began to lose water and thus dwindled in size, the Odonate populations all had significant decreases in size. The naiads either became prey for another organism, emerged or died due to lack of water or lack of food. None of the species in this study were able to continue increases in their population sizes during this time. The period after this drought is what is unique. Some of the species continued to have numbers that dwindled, while others maintained relatively similar amounts of naiads. One species, *Anax junius*, actually had a population explosion after the drought when the playa began to refill close to the beginning of September. During the course of this study, much was learned about the niches that Odonates occupy in a playa. The populations of some prominent dragonfly species were studied and their quantities were estimated for different periods during one season. Sizes of head capsules were studied in an effort to determine the development of Odonate populations over a period of time. In addition, field sampling showed high points in population sizes and trends in growth. Research was conducted of the life histories of Odonates and a lot of information was gained about the productivity of dragonflies. This study was a valuable proponent to the collection of information available about playa habitats." (Author)] Address: not stated

**15716.** Kirti, J.S., Singh, A. (2002): Studies on the male secondary genitalia of two species of genus *Sympetrum* Newman (Libellulidae: Anisoptera). *Fraseria* (N.S.) 7: 9-12. **15717.** MacKenzie, R.A.; Kaster, J.L. (2002): A preservative-free emergent trap for the isotopic and elemental analysis of emergent insects from a wetland system. *The Great Lakes Entomologist* 35: 47-51. (in English) ["This study reports a cost-effective, live emergent trap designed for the preservative-free use in both biogeochemical and ecological analyses of emerging insects. The trap proved to be advantageous in several ways. First, the simple design made the trap time-efficient since it was easy to set-up, change, and maintain. Second, live sampling not only provided uncontaminated organisms for elemental and stable isotopic analyses, it minimized disfigurement. This resulted in rapid and easy handling, as well as identification, of adult insects. Finally, trap avoidance by ephemeropterans and odonates, a common problem encountered in the literature, was minimal and organisms from both insect orders were successfully collected." **15721.** Hatakeyama, S.; Sugaya, Y.; Ogamino, Y. (2005): The acute toxicity of fenthion, an organophosphorus insecticide on damselfly and freshwater shrimp through fenthion-accumulated midge larvae. Jpn. J. Environ. Toxicol. 8(1): 13-22. (in Japanese, with English summary) ["Effects of dietary fenthion (hereafter MPP), an organophosphorus insecticide, on mortality of damselfly larvae, *Ischnura senegalensis*, and freshwater shrimp, *Macrobrachium rdpense*, were assessed using an insecticide-tolerant strain of *Chironomus yoshimatsui* (Chironomid) as a prey organism. Midge larvae had been exposed to MPP of 125, 250, 500 and 1000/ig/L, respectively, for 24-hrs, and resultant, accumulated MPP at 0.9, 2.1, 11.8 and 68 ng/g (wet wt.). In addition, fenthion sulfoxide (FSO) was detected in the midge larvae at higher levels rather than MPP itself. Individual shrimp and damselfly larva (each, ten replicates) were daily fed on MPP accumulated midge larvae (3 or 4 individuals/d) in a flowthrough aquarium. All damselfly larvae died within 3 days by ingesting the midge larvae accumulated 2.1 (2.8) or 11.8 (17.7) ng/g of MPP (FSO in parentheses). While, mortality of the shrimp fed on the midge larvae accumulated 0.9 or 2.1 ng/g MPP increased slowly to 40 and 80%, respectively, until 24 days after start of the experiment. Both predators continued to eat the MPP-accumulated midge larvae without showing hesitation, suggesting that they lack ability to keep away from toxic prey. We estimated the exposure levels of MPP and FSO in the live midge larvae that brought 50% mortality of predators used for the tests." **15722.** Jakab, T.; Müller, Z.; Devai, G.; Miskolczi, M. (2005): Adatok a Tisza-tó és környéke szitakötőfaunájához (Odonata) az 1998-1999. évi gyűjtések és megfigyelések alapján. Studia Odonatologica Hungarica 9: 5-31. (in Hungarian, with English summary) ["The paper presents faunistic data on dragonflies collected (larvae, exuviae and adults) and observed (adults) from the shallow lake type reservoir Tisza-tó and its surrounding (in- and outflows, leaking canals). Initially the authors present the methods employed in the field work and in data processing, and introduce the literature they have considered in the identification of species and in reporting faunistic data. Thereafter they provide a detailed survey of collection and observation results from the area. Finally they summarize and evaluate the data on the dragonfly fauna. Collections and observations were made in two years

(1998 and 1999), with the participation of 3 specialists on 58 days and 60 localities in the seven cells (DT65, DT66, DT76, DT77, DT78, DT87 and DT88) of the UTM grid map. In the faunistic report data on 459 larvae (241 males and 218 females), 244 exuviae (122 males and 122 females) and 916 adults (595 males and 321 females) are given in detail, representing 959 data (186 larvae, 107 exuviae and 666 adults). The number of observational data without the number of individuals is 154, thus the total number of data is 1113. By this study 39 species (13 Zygoptera and 26 Anisoptera) were found to occur in the area, out of which 1 comes from the very frequent, 16 from the frequent, 12 from the less frequent, 5 from the rare and 5 from the sporadic class of country-wide occurrence frequency." **15723.** Landwer, B.H.P.; Sites, R.W. (2005): Diagnostic efficacy of morphological characters of larval *Tamea lacerata* Hagen and *Tamea onusta* Hagen (Odonata: Libellulidae) in the Prairie region of Missouri. The Great Lakes Entomologist 38(3/4): 155-163. (in English) ["Distinguishing among species of larvae of the dragonfly genus *Tamea* historically has been problematic, largely due to conflicting characterizations of the larvae of *T. lacerata* Hagen and *T. onusta* Hagen (Odonata: Libellulidae) in the literature. The various systematic treatments usually focused on relative lengths of morphological characters to distinguish the species, but often contradicted one another and themselves as to what the diagnostic values actually were. We traced much of the confusion back to errors in the original larval description of *T. onusta*. We used morphometric analyses to determine the efficacy of previously published characterizations to distinguish between the larvae of *T. lacerata* and *T. onusta*. Previous characterizations, especially those involving relative lengths of the caudal appendages, were generally found to be inadequate for distinguishing larvae of the two species. The most reliable characteristic for distinguishing the two species was found to be the length of the epiproct relative to the length of the paraproct." **15724.** Marzouq, M.K. (2005): Relative growth and morphological variability in *Ischnura evansi* (Morton) (Odonata: Coenagrionidae). Marina Mesopotamica 20(1): 27-38. (in English) ["Morphological variability was studied in a laboratory reared adults of *I. evansi*. Total body length, head width, thorax length, abdomen length and width length were measured in 44 ♂♂ and 69 ♀♀ phenotype (23 blue, 28 orange and 18 orange-brown females). Result indicated that males were smaller than females in all character, females phenotypes were significant difference, linear regression equation for relationship between body length and abdomen length as well as wing length for males and females are significant. Gynochrome 2 females were larger than androchromes, as body size is related to larval nourishment, this suggest an effect of maintenance of polymorphism. The difference of the mean body mass between sexes is significant, head width and wing length increased with body

length." (Author)] Address: Marzoq, M.K., Dept. Biology, College of Education, Univ. Basrah, Iraq

**15725.** McWilliams, L.A. (2005): Variation in diet of the Mexican Free-Tailed Bat (*Tadarida brasiliensis mexicana*). *Journal of Mammalogy* 86(3): 599-605. (in English) ["This study documents the diet of Mexican free-tailed bats (*Tadarida brasiliensis mexicana*) at Carlsbad Cavern, Carlsbad Caverns National Park, Eddy County, New Mexico, and provides information on seasonal variation in food habits of this species throughout its summer residence. Diet was determined from 1,303 fecal samples. 11 orders and 38 families of insects, unidentified insects, 2 orders of Arachnida (Araneae and Acari), bat hair, and mist net were consumed, with Lepidoptera and Coleoptera occurring at greatest percentage volumes and percentage frequencies in the diet. Diet varied significantly throughout the season. 22 food categories exhibited statistically significant variation among sampling sessions. Amounts of Coleoptera, Lepidoptera, Formicidae, Psyllidae, Hymenoptera, and Diptera consumed showed the greatest differences among sampling sessions." (Author)] Address: McWilliams, Lisa, Dept Biol. Sciences, 101 Cary Hall, Auburn Univ., AL 36849, USA. E-mail: mcwilla@auburn.edu

**15726.** Osborn, R. (2005): Odonata as indicators of habitat quality at lakes in Louisiana, United States. *Odonatologica* 34(3): 259-270. (in English) ["Larval Odonata were sampled at 3 lakes. Environmental variables such as chemical composition, water current, turbidity, and vegetation cover were measured. Cross Lake had the most species and greater diversity of species than Chaplin's and Sibley lakes. Most Zygoptera species were found at Cross Lake where carbon availability was highest. Classification and ordination analysis produced similar species groups, providing strong evidence for species assemblages being determined by the measured environmental variables. Tolerant species included *Enallagma civile*, *Erythemis simplicicollis* and *Plathemis lydia*. Species only present at Cross Lake (incl. *Argia sedula*, *Enallagma basidens*, *Ischnura hastata*, *I. kellicotti*, *Celithemis eponina*, *Erpetogomphus designatus*, *Libellula luctuosa*, *L. pulchella*, *Nasiaeschna pentacantha*) were associated with lower levels of ammonia, conductivity, pH, and higher levels of oxygen and increased vegetation. Cross Lake provided habitat that could support more species and was important for species that were less tolerant of ammonia and anoxia. This study provides baseline data for future monitoring and conservation management of these lakes." (Author)] Address: Osborn, R., Dept Biol. Sci., Box 19498, Northwestern State Univ., Natchitoches, LA 71497, USA

**15731.** Iwata, T.; Fujioka, M. (2006): Effects of winter flooding on aquatic fauna in lotus and rice fields during the growing season. *Japanese Journal of Conservation Ecology* 11: 94-104. (in Japanese, with English summary) ["We compared the aquatic fauna in ordinary rice fields, which are dry in winter, with those in lotus fields, which are flooded in winter. We carried out biweekly sampling of zooplankton and small aquatic animals at 15 pairs of adjacent rice and lotus fields in Ibaraki Prefecture, Japan, during the crop-growing season, when both types of paddy arc flooded. Zooplankton were more abundant in the lotus fields than in the rice fields. The total number and biomass of small aquatic animals peaked in early June in the rice fields, but continued to increase in July in the lotus fields. In the rice fields, crayfish (*Procambarus clarkii*) dominated

in May and tadpoles and insects dominated in June. In the lotus fields, *Rana japonica* tadpoles dominated from April to May and fish dominated from June to July. Some insects (*Rhantus pulverosus* and *Berosus signaticollis*), fish (*Carassius* spp., *Pseudorasbora parva*), and *R. japonica* tadpoles were more abundant in the lotus fields than in the rice fields, while dragonfly larva (*Sympetrum* spp.) and *Hyla japonica* tadpoles were more abundant in the rice fields than in the lotus fields. The observed differences in fauna may be the result not only of winter flooding but also of differences in water management and in the application of fertilizer and pesticides." (Authors)] Address: Iwata, T., College of Agrobiological Resources, University of Tsukuba, Japan

**15732.** Tushabe, H.; Kalema, J.; Byaruhanga, A.; Asasira, J.; Ssegawa, P.; Balmford, A.; Davenport, T.; Fjeldsa, J.; Friis, I.; Pain, D.; Pomeroy, D.; Williams P.; Williams, C. (2006): A nationwide assessment of the biodiversity value of Uganda's Important Bird Areas network. *Conservation Biology* 20(1): 85-99. (in English) ["BirdLife International's Important Bird Areas (IBA) program is the most developed global system for identifying sites of conservation priority. There have been few assessments, however, of the conservation value of IBAs for nonavian taxa. We combined past data with extensive new survey results for Uganda's IBAs in the most comprehensive assessment to date of the wider biodiversity value of a tropical country's IBA network. The combined data set included more than 35,000 site × species records for birds, butterflies, and woody plants at 86 Ugandan sites (23,400 km<sup>2</sup>), including 29 of the country's 30 IBAs, with data on additional taxa for many sites. Uganda's IBAs contained at least 70% of the country's butterfly and woody plant species, 86% of its dragonflies and 97% of its birds. They also included 21 of Uganda's 22 major vegetation types. For butterflies, dragonflies, and some families of plants assessed, species of high conservation concern were well represented (less so for the latter). The IBAs successfully represented wider biodiversity largely because many have distinctive avifaunas and, as shown by high cross-taxon congruence in complementarity, such sites tended to be distinctive for other groups too. Cross-taxon congruence in overall species richness was weaker and mainly associated with differences in site size. When compared with alternative sets of sites selected using complementarity-based, area-based, or random site-selection algorithms, the IBA network was efficient in terms of the number of sites required to represent species but inefficient in terms of total area. This was mainly because IBA selection considers factors other than area, however, which probably improves both the cost-effectiveness of the network and the persistence of represented species. ... Nevertheless, for dragonflies, grasses, and sedges, the data gaps were small enough to make a provisional assessment worthwhile. Although dragonfly species lists were lacking for six IBAs, 86% of the 231 species on the national list have already been recorded from IBAs (Table 1), including 11 of the 13 Ugandan species recently assessed as threatened or near threatened in a provisional red list of East African dragonflies (assessment by V. Clausnitzer, K. D. B. Dijkstra, and F. Suhling, personal communication)." (Authors)] Address:

**15733.** Bauer, U. (2007): Beobachtungen am Rettenberger Weiher (Landkreis Augsburg). *Berichte des Naturwissenschaftlichen Vereins für Schwaben e.V.* 111: 45-45. (in German) [Bavaria, Germany; records of *Libellula quadrimaculata*, *Calopteryx splendens*, *Anax imperator*, and *Somatochlora spec* are listed.] Address: Bauer, W., Schrofenstraße 33, 86163 Augsburg, Germany

**15734.** Bienek, R.; Hickner, S. (2007): The effects of colonization by Zebra Mussels, *Dreissena polymorpha* on fitness in two anisopteran species: *Hagenius brevistylus* and *Didymops transversa*. *University of Michigan Biological Station, Pellston, MI Ola Fincke, University of Oklahoma, Mentor Biology 390: Evolution: 14 pp.* (in English) ["The colonization of two Anisopteran larvae (*Hagenius brevistylus* and *Didymops transversa*) by *Dreissena polymorpha* was studied in Douglas Lake after the recent mussel invasion from the Lake Huron watershed. Our objectives included measuring the frequency of the zebra mussels on larvae and exuviae, and measuring fitness indirectly by means of "righting" tests, or how long it took the *D. transversa* larvae to "right" itself after being placed upside down. We hypothesized that larvae with zebra mussels attached would show a decrease in fitness because of the increased energy costs. Because we found a low frequency of larvae with mussels, colonization was induced. Our results indicated that as the number of zebra mussels per larva increased, so did "righting" time. "Righting" time also increased as the ratio of mussel weight to larva weight increases. None of the *H. brevistylus* were able to right themselves when observed. There was a significant difference between the average "righting" time for *D. transversa* larvae before after colonization. The larvae with mussels had a higher "righting" time than larvae without mussel attachment, supporting our hypothesis. Because the majority of our larvae were induced with zebra mussels, they had a higher ratio of mussel weight to larval weight than is found in naturally occurring populations in Douglas Lake from previous studies. This indicates that although a large load of zebra mussels may decrease fitness, the occurrence is unusual and may not have an effect on large populations in Lakes."] Address: Bienek, Rosalie, University of Michigan Biological Station, Pellston, MI; Ola Fincke, University of Oklahoma, Mentor, Biology 390: Evolution, August 13, 2007

**15735.** DuBois, R.B.; Stettner, C.R. (2007): *Gomphus spicatus* (Odonata: Gomphidae) rediscovered in Illinois and *Libellula semifasciata* (Odonata: Libellulidae) recorded near Wisconsin. *The Great Lakes Entomologist* 40(1/2): 99-100. (in English) ["We collected one adult male of *G. spicatus* and observed several other males during the mid-afternoon of 10 June 2007 near the Dead River in Illinois Beach State Park (South Unit), Lake County, Illinois. The specimen is deposited in the Odonata Collection of the Wisconsin Department of Natural Resources (WDNR),

which is housed at the WDNR Superior Service Center. The males of *G. spicatus* were perched on a gravel access road where it intersected a hiking trail immediately adjacent to the river, less than 1 km from its mouth at Lake Michigan. The Dead River at the site is a slowly flowing stream that is blocked by a sand bar much of the year, forming an elongated pond. On 22 June 2007, one of us (CRS) returned to the South Unit and observed several *G. spicatus* at each of two interdunal wetlands (pannes) on the calcareous moist sands of the lake plain, about 800 m north of the mouth of the Dead River (about 600 m from the original *G. spicatus* site). Our findings suggest that these sites, which are located less than 30 km from the three lakes where *G. spicatus* was found over 100 years ago, likely provided breeding habitat for *G. spicatus* in 2007. Further surveys of Odonata at the Dead River and the nearby pannes are recommended to determine if populations of *G. spicatus* are persisting in those areas, and surveys of the odonate faunas of Clear, Fox, and Sand lakes would be helpful as well. A single adult female *Libellula semifasciata* Burmeister (Odonata: Libellulidae), commonly called painted skimmer, was also collected on the hiking trail along the Dead River on 10 June 2007 and is deposited in the WDNR Odonata Collection. A number of adult *L. semifasciata* had been observed by CRS along the same hiking trail on several previous occasions and several individuals were again present along that trail on 22 June 2007. The finding of *L. semifasciata* evidently breeding at the Dead River site, which is within 8 km of the Wisconsin state line, is noteworthy because that species has not been found in Wisconsin since Muttkowski (1908) reported it from Milwaukee County in 1903 (Smith et al. 2003; Wisconsin Odonata Survey 2008). Populations of *L. semifasciata* may persist, and should be looked for, in the southern tier of counties of Wisconsin, especially in Kenosha County near Lake Michigan." **15736.** Eijk, J.-L. van (2007): Large population of *Orthetrum coerulescens* in the northeastern part of the Achterhoek, province of Gelderland. *Brachytron* 10(2): 205-211. (in Dutch, with English summary) ["In 2005, a large population of *Orthetrum coerulescens* was discovered near Eibergen, in the province of Gelderland. On 16 locations, 75 individuals were seen. Mating and deposition of eggs was noticed at several locations. The nearest known populations are at a distance of 25 kilometers. The habitat is described as ditches and artificial brooks which are partly fed by local groundwater. It is argued that the role of this ground water is of vital importance. It prevents the brooks from desiccation during summer and prevents the water to freeze in winter. The author states that more populations are to be discovered since the type of habitat is poorly visited by odonatologists." (Author)] Address: van Eijk, J.-L., Bruno Walterstraat 7, 7556 DV Hengelo, Netherlands

**15738.** George, J. (2007): Lundy's lentic waters: Their biology and ecology. Extract from J George, 'Lundy Studies' (2007). Copyright Lundy Field Society and the authors: 103-128. (in English) ["Research on the Lundy freshwater ecosystems in the late 1970s, 1980s and early 1990s showed that the major standing water bodies (lentic waters) supported different populations of organisms, particularly in the planktonic and macroinvertebrate groups. Recent research in the autumn of 2003, spring 2005 and winter 2006 not only demonstrated that these differences still are present, but also gained information on seasonal changes occurring in these waters. Four water bodies, Pondsby, the Rocket Pole Pond, Quarry Pool and the larger pond at Quarter Wall have been studied at all seasons. Differences can be related to the position of the pond on the island and hence degree of exposure, the amount of plant cover and the input of decaying material and nutrients. At various times during the last 27 years smaller, often temporary, bodies of water have been surveyed e.g. pools in North Quarry, smaller pond at Quarter Wall, pond in Barton Field. Brief descriptions of these small ecosystems are given here." **15740.** Krakowiak, P.J.; Pennuto, C.M. (2008): Fish and macroinvertebrate communities in tributary streams of Eastern Lake Erie with and without Round Gobies (*Neogobius melanostomus*, Pallas 1814). *J. Great Lakes Res.* 34: 675-689. (in English) ["Round gobies have had significant impacts on benthic fish and invertebrate communities in nearshore habitats of the Great Lakes. As round gobies have become more abundant in lake habitats, there has been an expansion of their populations into tributary streams and rivers. We compared stream invertebrate and fish communities in New York tributaries to Lake Erie with round gobies present and absent. Four of six benthic invertebrate metrics differed between streams with and without round gobies. Streams with round gobies present

had reduced Shannon diversity, EPT richness, and EPT/chironomid ratios, and increased macroinvertebrate density relative to streams without round gobies, but there was no difference in non-Diptera density, or total taxa richness. None of the four fish metrics examined differed between streams with and without round gobies. However, darters occurred in all streams lacking round gobies, but did not occur in any streams with round gobies. Comparisons with historical fish and macroinvertebrate distributional data support our suspicion of goby-induced community changes. In these New York streams, round gobies seem to have had significant impacts on invertebrate communities via their consumptive behavior, whereas the impacts on fish communities are less evident. If round gobies continue to expand their distribution inland, the resultant alterations in macroinvertebrate communities may impact the suitability of tributary streams as spawning and nursery habitat for several sport fish species and for energy dynamics in tributary streams." (Authors)] Address: Pennuto, C.M., Dept of Biology, Buffalo State College, 1300 Elmwood Avenue Buffalo, New York 14222, USA.

## 2009

**15745.** Clarke, D. (2009): Keeled Skimmers at Glasson Moss NNR. *The Carlisle Naturalist* 17(2): 47. (in English) [Verbatim: Before 2005, *Orthetrum coerulescens* was not known in Cumbria north of their regular site near Grange-in-Borrowdale (NY21). In that year I found them, for the first time but evidently well-established, on runnels just below Carrock Fell (NY33) –see *Carlisle Naturalist* 13:2, p.9. The species is a specialist in slow-moving boggy runnels and in Cumbria at least is never associated with static water. The finding of two males of the species on a dragonfly walk at Glasson Moss led by Mike and Anne Abbs on Saturday 25th July this year was completely unexpected and by far the most northerly record for the county. The insects were evidently showing interest in water trickling over the firebreak at the corner of a pool not far from the Kirkbride-Bowness road. Photographs were obtained, including a fine one by Darren Robson taken on 27th. As there is little flowing water at Glasson Moss, it is perhaps doubtful whether the species could establish there, but this is at least further indication of its relative mobility and therefore of the potential for range extension. Given the amount of apparently suitable habitat at moderate altitudes in Cumbria, the species might well be expected to colonise sites above its

present altitudinal limits of c. 250 m a.s.l. – as well as just spreading further afield.] Address: Clarke, D., Burnfoot, Cumwhitton, Brampton, Cumbria CA8 9EX, UK

**15746.** Faúndez, E.I. **15749.** Matsui, A. (2009): Growth of several fish and dragonfly species in the drainage system of a consolidated paddy field. *Japanese Journal of Conservation Ecology* 14: 3-11. (in Japanese, with English summary) ["This study examined the growth of aquatic animals in the canal system constituting the main, lateral, and farm drains in a consolidated paddy field, with emphasis on canal structure and year-round water flow in the canals. A field survey at six sites, which involved three different canal levels, was carried out in Chikusei, Ibaraki Prefecture, Japan (36°21'N, 139°59'E). Sampling was conducted at monthly intervals from April 2001 to March 2002. Of the freshwater fish, young-of-the-year (YOY) *Zacco platypus* appeared in September, while YOY *Misgurnus anguillicaudatus* appeared in May.

Last instars of *Calopteryx atrata* were collected only in June, suggesting emergence about this time, while those of *Orthetrum albistylum speciosum* were collected in May and July, suggesting a longer duration of emergence. Since populations of the four species decreased during the non-irrigation season when the water level was low, I propose that a marsh be developed as a wintering site in the lower reaches of the canal system in consolidated paddy fields." (Author)] Address: not stated

**15750.** Mishra, S.K. (2009): Insecta: Odonata. Zoological Survey. India, Fauna of Bandhavgarh Tiger Reserve, Conservation Area Series 40: 25-38. (in English) ["Bandhavgarh lies on the extreme north-eastern border of the state of Madhya Pradesh in district Umaria (which was earlier a part of Sahadol district) and the northern flanks of the eastern Satpura mountain range. It is located on the coordinates 23 °30' 12" to 23° 46' 30" N and 80° 47' 15" to 81°11' 45" E at altitudes between 410 m and 810 m. Presently the Reserve's area falls in the two districts Umaria and Katri." "The identification of Odonata collections made from Bandhavgarh Tiger Reserve has revealed 32 species belonging to 24 genera under 7 families. These include 8 species of damselflies (Zygoptera) and 24 species of dragonflies (Anisoptera)." (Author)] Address: Mishra, S.K., Zoological Survey of India, Central Regional Station, Lalapur-482002, India

**15751.** Nakanishi, K.; Taiwa, K.; Kanbara, B.; Noma, N.; Sawada, H. (2009): Comparisons of macro-aquatic animal communities among paddy fields under different cultivation management systems. *Jpn. J. Environment. Entomol. Zool.* 20(3): 103-114. (in Japanese, with English summary) ["To examine the effects of differences in cultivation management, we conducted censuses of macro-aquatic animal communities in paddy fields in Takashima, Shiga prefecture, during April-September, 2008. Among a number of species we selected the following three orders of aquatic insects (Odonata, Hemiptera, and Coleoptera) and fish such as loach, *Misgurnus anguillicaudatus* as target organisms. Four types of paddy fields were set up under different cultivation management systems with two replicates for each treatment: 1) conventional management with an application of standard amounts of agrochemicals and kept dry during winter, 2) reduced-agrochemical management and kept dry during winter, 3) no agrochemical management and kept dry during winter, and 4) no agrochemical management and flooded year round. In paddy fields under the conventional and reduced-agrochemical management systems, aquatic insects were fewer in terms of the number of species and individuals. This was largely to the result: enhanced mortality of aquatic insects, which were assumed to have been killed by agrochemicals used in the early season. In the winter-flooded paddies aquatic insects were most abundant, both in the number of species and individuals throughout the census period. This suggested the critical importance of paddies as units of conservation of aquatic insects. By contrast, loach were less abundant in the winter-flooded paddies, indicating their low suitability as a spawning site and habitat for young fish. To account for this phenomenon, the persistent presence of aquatic insects that act as fish food, and the low availability of plank-

ton as a food resource were suggested and discussed." (Authors)] Address: Nakanishi, K., School of Environmental Science, Univ. of Shiga Prefecture. Hikone, Shiga 522-8533, Japan. E-mail: k\_mw\_newt@hotmail.com

**15752.** Neves dos Santos, A.; Racca-Filho, F.; Neves dos Santos, L.; Gerson Araújo, F. (2009): El pez *Trachelyopterus striatulus* (Siluriformes: Auchenipteridae) como herramienta de muestreo de la entomofauna en un embalse tropical. *Revista de Biología Tropical* 57(4): 1081-1091. ["The fish *T. striatulus* used to sample insects in a tropical reservoir. ... Insectivorous fishes represent good users of these ecosystems and analyzing the aquatic organisms present in fish stomachs, is an alternative way to determine resource abundance and utilization. In this paper, the potential of *Trachelyopterus striatulus* as an insect sampler was examined through dietary analyses of 383 individuals caught between April 1999 and March 2000 in Lajes Reservoir, a 30 km<sup>2</sup> oligotrophic impoundment in Southeast Brazil. We estimated frequency of occurrence and Schoener's index of similarity. Diet changes among seasons and reservoir zones were addressed with DCA and ANOVA analyses. Its diet was 92.1% insects (ten orders and nine families). Hymenoptera (57.90%), Odonata (39.76%) [Aeshnidae (immatures) \*37.74 \*34.32 \*44.27; Aeshnidae (adultes) 3.77 1.35 3.05], Trichoptera (27.41%), Ephemeroptera (26.25%) and Coleoptera (28.96%) were the most common groups. Highest insect occurrence and richness were recorded in autumn-summer, a period of greater rainfall and insect activity. Formicidae, the dominant prey item in all seasons, appeared to be especially important in spring, a season marked by shortness of food resources. Trichoptera and Ephemeroptera were the most consumed prey items in the other seasons. Highest insect occurrence and richness were recorded in the middle and upper reservoir zones, respectively. Trichoptera and Ephemeroptera prevailed in the upper zone, where small pristine rivers and tributaries are abundant, whereas Formicidae and Belostomatidae predominated in the lower and middle zones. Because of its abundance in many freshwater ecosystems of Brazil, the ubiquity of insects in its digestive tract and the low level of prey degradation, *T. striatulus* has potential as an insect sampler of Neotropical reservoirs. However, conventional sampling in Lajes Reservoir is necessary to compare the effectiveness of *T. striatulus* with other insect sampling methods." **15757.** Copp, G.H.; Tarkan, S.; Godard, M.J.; Edmonds, N.J.; Wesley, K.J. (2010): Preliminary assessment of feral goldfish impacts on ponds, with particular reference to native crucian carp. *Aquatic Invasions* 5(4): 413-422. (in English) ["Introductions of an Asian cyprinid, goldfish *Carassius auratus*, are known to pose a genetic threat to crucian carp *Carassius carassius*, which is native to northern parts of central and western Europe, including southeast England. However, there are no known studies in Europe of goldfish impacts on crucian carp growth and life-history traits, nor on the recipient ecosystems. The present study is the first such attempt, and compares the plants, invertebrates and fish biology (growth, condition, reproduction) in six ponds, two containing crucian carp only (allopatry), two containing goldfish only (allopatry), and two with both species (sympatry). Feral goldfish growth was greatest in sympatry with native crucian carp, whereas crucian carp growth was similar regardless of goldfish presence or absence. However, body condition (LK) and relative fecundity (per unit of body weight) of crucian carp was greatest in sympatry with feral goldfish. LK increased significantly with increasing water conductivity in goldfish but not in crucian carp, and LK was not related to pond invertebrate densities in either fish species. Differences in the plant and aquatic invertebrate communities observed in the study ponds could not be attributed to the introduction and establishment of goldfish, however non-native plant and invertebrate species were observed only in ponds containing goldfish. Differences in growth and condition between the two *Carassius* species does not appear to be due to differences in available food, so elevated somatic growth and reproductive output in crucian carp and faster growth in goldfish in sympatry may be due to non-dietary competitive interactions. The present preliminary study highlights the difficulties of assessing 'real world' impacts of non-native species on native species and ecosystems as well as the need for further study of feral goldfish impacts on European pond ecosystems in general and on native congener crucian carp in particular." ## 2011

**15762.** Arndt, E; Domdei, J. (2011): Influence of beaver ponds on the macroinvertebrate benthic community in lowland brooks. *Polish Journal of Ecology* 59(4): 799-811. (in English) [Sachsen-Anhalt, Germany; "Beavers (*Castor fiber*) alter stream ecosystems by dam building resulting in a lower stream velocity, retention of sediments and organic matter as well as modifying physical, chemical and geomorphological conditions in these streams. the effects of

beaver dams on invertebrate benthic communities were examined in two semi-natural lowland brooks. For this purpose, beaver ponds and reference sections upstream and downstream of each pond were sampled. Mollusca, Crustacea and five orders of aquatic insects were analyzed according to taxa richness, abundances, micro-habitat preferences and feeding types to characterize the macroinvertebrate communities. Detailed data in downstream sections and taxa-related parameters of insects (upstream and downstream sections) were analyzed first time. - the abundance of Trichoptera, Plecoptera and Crustacea as well as taxa numbers of ePt taxa decreased significantly in the ponds compared to the free-flowing sections. Odonata and Ephemeroptera did not respond in abundance but in a change of the species composition, because lentic species replaced the lotic species in the impoundment section. - only the number of molluscs increased in the ponds. - regarding the microhabitat preferences, lithal dwellers dominated in all free-flowing sections, whereas its proportion decreased in the ponds. - on the opposite, pelal dwellers increased in the impounded area. - significant differences were also found in proportions of shredders and passive filter feeders (decreasing in ponds), whereas predators increased in the ponds compared to the downstream section of the brooks. ... There occur 10 critical endangered and further 12 endangered species of aquatic insects in the brook system. *Ophiogomphus cecilia* is listed in Annex II of the European Habitats Directive. ... *Calopteryx virgo* is the only of these endangered species which could be recorded also in one of the beaver dams. ... *Cordulegaster boltonii* (Endangered) were limited to brook sections upstream of the ponds." (Authors) ] Address: Arndt, E., Department 1, Anhalt University of Applied Sciences, Strenzfelder Allee 28, D-06406 Bernburg, Germany. E-mail: e.arndt@loel.hs-anhalt.de

**15763.** Chiba, W.A.C.; Passerini, M.D.; Tundisi, J.G. (2011): Metal contamination in benthic macroinvertebrates in a sub-basin in the southeast of Brazil. *Brazilian Journal of Biology* 71(2): 391-399. ["Benthic macroinvertebrates have many useful properties that make possible the use of these organisms as sentinel in biomonitoring programmes in freshwater. Combined with the characteristics of the water and sediment, benthic macroinvertebrates are potential indicators of environmental quality. Thus, the spatial occurrence of potentially toxic metals (Al, Zn, Cr, Co, Cu, Fe, Mn and Ni) in the water, sediment and benthic macroinvertebrates samples were investigated in a sub-basin in the southeast of Brazil in the city of São Carlos, São Paulo state, with the aim of verifying the metals and environment interaction with benthic communities regarding bioaccumulation. Hypothetically, there can be contamination by metals in the aquatic environment in the city due to lack of industrial effluent treatment. All samples were analysed by the USEPA adapted method and processed in an atomic absorption spectrophotometer. The sub-basin studied is contaminated by toxic metals in superficial water, sediment and benthic macroinvertebrates. The Bioaccumulation Factor showed a tendency for metal bioaccumulation by the benthic organisms for almost all the metal species. The results show a potential human and ecosystem health risk, contributing to metal contamination studies in aquatic en-

vironments in urban areas." (Authors)] Address: Chiba, WAC, Programa de Pós-graduação em Ecologia e Recursos Naturais, Centro de Ciências Biológicas e da Saúde, Universidade Federal de São Carlos – UFSCar, Rod. Washington Luís, Km 235, CP 676, CEP 13565-905, São Carlos, SP, Brazil

**15764.** Conze, K.-J. (2011): Die Libellenfauna in Nordrhein-Westfalen – aktueller Stand und Aktivitäten des AK Libellen NRW. *Entomologie heute* 24: 287-295. (in German, with English summary) ["Since 1996 the working group for the conservation and faunistic mapping of the dragonflies in North Rhine-Westphalia has comprehensively collected all country specific data of these insects. For that all available faunistic literature was evaluated; in addition, in the last 15 years about 250 collaborators reported more than 180,000 data sets of field observations. Up to now 81 of the 140 dragonfly species known from Europe have been also reported from Germany. In North Rhine-Westphalia 73 species have been observed so far; 66 species appear to be established, i.e. they are constantly found and are reproducing. While southern species are spreading and populations of streaming water species are increasing, species typically for fens and specialists for nutrient-poor water bodies are remarkably decreasing above average. Altogether the dragonfly fauna in North Rhine-Westphalia shows great dynamics, driven by the geographical situation being the transient area between low- and highland and the atlantic and the continental biogeographical regions as well as by the effects of climate change and the effects of the accelerated anthropogenic change of landscape in the most densely populated federal state of Germany." **15765.** Devai, G.; Miskolczi, M. (2011): Adatok a Báb-tava és a Nyíres-tó szitakötő-faunájához (Odonata) [Data on the dragonfly (Odonata) fauna from the bogs Báb-tava and Nyíres-tó (NE-Hungary)]. *Studia odonotol. hung.* 13: 63-70. (in Hungarian, with English summary) ["This is the 21th paper of a series directed at communicating faunistical data of Hungary which had been unpublished until December 31, 1987 (cf. DÉVAI, GY. et al. 1993). The authors present faunistical data from two bogs (Báb-tava and Nyíres-tó) in the geographical microregion Beregi-sík in NE-Hungary, over the administrative area of the settlement Csaroda and Beregdaróc. Collections were made in 4 years between 1983 and 1987, with the participation of 4 specialists on 15 days, in one 10×10 km UTM grid map cell (FU 13). In the report information on 487 adults (339 males and 148 females) is given in detail, representing 110 faunistical data. In this study 26 species (9 Zygoptera and 17 Anisoptera) were found to occur in the area, out of which 1 belongs to the very frequent, 16 to the frequent, 7 to the less frequent, 1 to the rare and 1 to the sporadic class of countryside occurrence frequency." **15770.** Klimsa, E. (2011): Exuvienfunde der Schabrackenlibelle *Hemianax ephippiger* (BURMEISTER, 1838) in den Jahren 2008 und 2009 in der "Grube Auhofweiher" bei Schwandorf (Odonata). *Galathea* 27(1): 43-47. (in German, with English summary) ["A compilation of rare dragonflies could be found in 2008 and 2009 in a pond within a clay ditch near the city of Schwandorf, Upper Palatinate, Northern Bavaria. Thorough investigations led to 66 exuvias of *H. ephippiger*. The natural area of this species expands from Africa to Southern Asia. In Southern Europe it reproduces irregularly and migrates into Bavaria from time to time. This paper deals with precise features to identify exuvias from *Hemianax* with certainty. Differences to other dragonfly species are shown in pictures. Unsolved questions remain: what caused *Hemianax* to accept this pond for breeding - despite the high risk that the larvae will not survive our winter temperatures? Is it a certain similarity of our native waterplant *Biysmus compressus* with the favoured rice plants from the reproducing area in Southern Europe, that let the female imago lay the eggs and that guided later on the grown-up larvae towards their last mould into the air? Is the new generation able to find their way back to the South? - More information is needed." (Author)] Address: Klimsa, K., Zeisigstr. 2, 92421 Schwandorf, Germany. **15771.** Lenssen, J.P.M.; Klutman, A.G.M.; Nijboer, R.C.; Boedeltje, G. (2011): Changes in stream macro-invertebrate communities due to water quality improvements. *Levende Nat.* 112(6): 213-218. (in Dutch, with English summary) ["The last decades have shown a tremendous decrease of organic and nutrient load in streams in The Netherlands. During the last 23 years, macro invertebrates have been monitored in a consistent manner in most of the streams in the Dutch region Oost-Gelderland. The data allow us to assess the effect of improved water quality on macro invertebrate communities during the last 23 years. This effect strongly depends on the stream type. In highly regulated streams, i.e. canalized, enlarged in profile and barraged, we noticed a shift from species with high tolerance against low oxygen concentrations in the water towards species with a slightly higher oxygen demand. However, the resulting community was still dominated by limnophilic species. Different shifts were noticed in unregulated streams, where stream velocities tend to be higher and morphological variation offers a wide variety of substrates. Here we noticed a clear shift towards species with high oxygen demand. Moreover, the number of rare spe-

cies (indicative of undisturbed stream environments) also significantly increased in unregulated waters, whereas no increase occurred in regulated waters. These results clearly demonstrate the interaction between water quality and stream morphology and hydrology. Improvement of water quality is not sufficient if stream hydrology and morphology is not restored. On the other hand, natural stream communities are highly susceptible for changes in water quality." **15773.** Phommexay, P.; Satasook, C.; Bates, P.; Pearch, M.; Bumrungsri, S. (2011): The impact of rubber plantations on the diversity and activity of understorey insectivorous bats in southern Thailand. *Biodivers. Conserv.* 20: 1441-1456. (in English) ["Although a large proportion of tropical rain-forest in South-east Asia has been replaced by rubber plantations, there is very little information about the impact of such forest conversion on bat diversity. To address this deficiency, trapping and acoustic monitoring programmes were carried out in Ton Nga Chang and Khao Ban That wildlife sanctuaries in southern Thailand with the purpose of comparing species diversity and activity of understorey insectivorous bats at sites in forest and in nearby monoculture rubber plantations. Insect biomass in both habitats was assessed. Bat species diversity and activity were found to be much lower in rubber plantations than in forested areas and mean insect biomass was determined to be more than twice as high in the latter habitat than in the former. Bats utilising forest were shown to have significantly higher call frequencies but marginally lower wing loadings and aspect ratios than bats found in both habitats. Management strategies to increase biodiversity in rubber plantations are discussed." **15774.** Reiss, M. (2011): Substratpräferenz und Mikrohabitat-Fauna-Beziehung im Eukrenal von Quellgewässern. Dissertation Fachbereich Geographie der Philipps-Universität Marburg: 245 pp, Anhang. (in German) ["The function and the ecological significance of the substratum as a hydromorphological element and as a microhabitat for in-

vertebrates of springs are poorly investigated. In eco-faunistic studies which interpret the fauna-microhabitat-relationship of springheads (eucrenal), quantitative and qualitative investigations and analysis of the substrate preferences of invertebrate taxa regarding the eucrenal as an ecotone are still missing. Thereby faunistic research focuses mostly on the aquatic taxa only, rarely on terrestrial organisms. The main objectives of this study are formulated in three questions: 1. Is there a substrate preference for specific taxa considering the ecotone characteristics of springs? 2. What kind of microhabitat functions offers the substrate type for the fauna? 3. Is there a faunistic relevance of substrate specific habitat types that can be ascertained? The results of this study show a significant relevance of the substrate as a microhabitat for the aquatic and terrestrial invertebrate fauna in springs. Therefore only forest springs of the low mountain range were investigated in regions of Hesse and Thuringia. For some taxa a specific substrate preference was found. Microhabitat functions are mostly characterized as food basis, refuge, protection and reproduction area. A first quantitative method to identify fauna-microhabitat-relationship is given with a new approach of a multihabitat-sampling as an integrated method for collecting and recording faunistic data. For the most commonly substrate specific microhabitat types the faunistic evidence and relevance was found. Some results are leading to new hypotheses, which show the importance of further research in the topic of substrate preferences of fauna and fauna-microhabitat-relationships of springs." **15779.** Batema, D.L.; Bellian, A.; Landowski, L. (2012): A survey of Odonata of the Patoka River National Wildlife Refuge and Management Area. *Proceedings of the Indiana Academy of Science* 121(1): 54-61. (in English) ["The Patoka River National Wildlife Refuge and Management Area (hereafter Patoka River Refuge or the Refuge) represents one of the largest intact bottomland hardwood forests in southern Indiana, with meandering oxbows, marshes, ponds, managed moist-soil units, and constructed wetlands that provide diverse and suitable habitat for wildlife. Refuge personnel strive to protect, restore, and manage this bottomland hardwood ecosystem and associated habitats for a variety of wildlife. The Patoka River National Wildlife Refuge Comprehensive Conservation Plan (CCP) lists many species of management priority (McCoy 2008), but Odonata are not included, even though they are known to occur on the Refuge. The absence of Odonata from the CCP is the result of lack of information about this ecologically important group of organisms. Therefore, we

conducted a survey, from May to October 2009, to document their presence, with special attention being paid to rare, threatened, and endangered species. A total of 43 Odonata species were collected and identified. No threatened or endangered species were found on the Refuge, but three species were found that are considered imperiled in Indiana based on Nature Serve Ranks (Stein 2002). Additionally, 19 new odonate records were documented for Pike County, Indiana. The results of this survey will be used by Refuge personnel to assist in management decisions and to help establish priorities for the Patoka River Refuge activities and land acquisition goals." (2012): Understanding invasion success: life-history traits and feeding habits of the alien crayfish *Orconectes immunis* (Decapoda, Astacida, Cambaridae). *Knowledge and Management of Aquatic Ecosystems* 404, 04: 22 pp. (in English) ["In the present study, the life history and diet of the highly successful North American invader *Orconectes immunis* was assessed for the first time in its introduced European range. In 2007, *O. immunis* population dynamics were monitored in a typical backwater habitat using unbaited funnel traps, and its life history was analysed using Von Bertalanffy's growth function. Juveniles hatched as early as March and may attain sexual maturity at the end of their first summer. The adult population moulted up to four times during the summer months, with the non-breeding form (II) lasting for a remarkably short time period. The high growth rate of *O. immunis* was combined with a short longevity, which was estimated at 2.5 years. The fecundity ranged from 119 to 495 pleopodal eggs. The stomach contents were dominated by

detritus, followed by macroinvertebrates and macrophytes, and no ontogenetic shift in diet was observed. The ability to prey on a wide array of invertebrate taxa presumably supports the sustained high growth rate of *O. immunis*. The presented data provide evidence that *O. immunis* exhibits a strongly r-selected life history and omnivorous feeding habits. These ecological properties have often been linked to successful invaders and enhance the invasiveness of *O. immunis*." (Author)] Address: Chucholl, C., Dept. **15785.** Grether, G.F. (2012): The neuroecology of competitor recognition. *Integr. Comp. Biol.* 51(5): 807-818. (in English) ["Territorial animals can be expected to distinguish among the types of competitors and noncompetitors that they encounter on a regular basis, including prospective mates and rivals of their own species, but they may not correctly classify individuals of other species. Closely related species often have similar phenotypes and this can cause confusion when formerly allopatric populations first come into contact. Errors in recognizing competitors can have important ecological and evolutionary effects. I review what is known about the mechanisms of competitor recognition in animals generally, focusing on cases in which the targets of recognition include other species. Case studies include damselflies, ants, skinks, salamanders, reef fishes, and birds. In general, recognition systems consist of a phenotypic cue (e.g., chemical, colour, song), a neural template against which cues are compared, a motor response (e.g., aggression), and sensory integration circuits for context dependency of the response (if any). Little is known about how competitor recognition systems work at the neural level, but inferences about specificity of cues and about sensory integration can be drawn from the responses of territory residents to simulated intruders. Competitor recognition often involves multiple cues in the same, or different, sensory modalities. The same cues and templates are often, but not always, used for intraspecific and interspecific recognition. Experiments have shown that imprinting on local cues is common, which may enable templates to track evolved changes in cues automatically. The dependence of aggression and tolerance on context is important even in the simplest systems. Species in which mechanisms of competitor recognition are best known offer untapped opportunities to examine how competitor-recognition systems evolve (e.g., by comparing allo-

patric and sympatric populations). Cues that are gene products (peptides, proteins) may provide insights into rates of evolution. There are many avenues for further research on the important but understudied question of how animals recognize competitors." (Author) Hetaerina occisa, H. americana, H. cruentata, H. titia] Address: Grether, G.F., Dept of Ecology & Evolutionary Biology, University of California, Los Angeles, CA 90095-1606, USA. **15786.** Grözinger, F.; Wertz, A.; Thein, J.; Feldhaar, H.; Rödel, M.O. (2012): Environmental factors fail to explain oviposition site use in the European common frog. *Journal of Zoology* 288(2): 103-111. (in English) ["A 7-year monitoring of potential oviposition ponds of the European common frog *Rana temporaria*, in northern Bavaria, Germany, indicated that breeding ponds were not randomly used. Site fidelity could not consistently explain this pattern. Because amphibians are known to select oviposition sites according to certain habitat characteristics, we investigated pond parameters that may drive breeding site selection in that area. We recorded 44 abiotic and biotic parameters, including variables within-ponds, predator presence, as well as habitat characteristics of the terrestrial area surrounding the ponds. However, multifactorial statistics such as non-metric multidimensional scaling, hierarchical clustering and random forest algorithm as well as single-factor comparisons could not highlight common habitat features of chosen ponds. The results of this study indicate that breeding site choice is more than a pure function of habitat characteristics, and that understanding the reproductive biology, even of such a widespread species as *R. temporaria*, needs more research effort." **15787.** Hernandez-Manrique, O.L.; Numa, C.; Verdu, J.R.; Galante, E.; Lobo, J.M. (2012): Current protected sites do not allow the representation of endangered invertebrates: the Spanish case. *Insect Conservation and Diversity* 5: 414-421. (in English) ["1. Using a recently created database representing the joint effort of around 100 invertebrate taxonomists, this study uses the information on 52 arthropoda and 27 mollusca species that are endangered and critically endangered to examine to what extent invertebrate species are represented in existing Spanish protected areas. 2. As distribution information is available at a 100 km<sup>2</sup> resolution, we consider different area thresholds to judge cells as being protected. 3. Approximately 19% of the area represented by the grid cells with observed occurrences rates as extant protected reserves, and 36% is included within the Natura 2000 network. 4. If having 50% of the cell area as a Natura 2000 reserve is considered as sufficient to have effective protection, almost 68% of species and 32% of probable populations (contiguous cell groups) would be represented. 5. However, 77% of species and 94% of probable populations are not represented in the current protected reserves if we establish that at least 95% of each cell area should belong to a reserve to provide effective protection. 6. Thus, existing conservation strategies, which are based primarily on the

protection of certain areas and vertebrate species, may be insufficient to ensure the conservation of invertebrate species." (Authors)] Address: Lobo, J.M., Museo Nacional de Ciencias Naturales, CSIC, José Gutiérrez Abascal 2, Madrid 28006, Spain. E-mail: mcnj117@mncn.csic.es

**15789.** Jones, J.I.; Murphy, J.F.; Collins, A.L.; Sear, D.A.; Naden, P.S.; Armitage, P.D. (2012): The impact of fine sediment on macro-invertebrates. Rivers Research and Applications 28(8): 1055-1071. (in English) ["The sustainable use of water resources requires clear guidelines for the management of diffuse pollution inputs to rivers. Without informed guidelines, management decisions are unlikely to deliver cost-effective improvements in the quality of rivers as required by current water policy. Here, we review the evidence available for deriving improved guidelines on the loading of fine sediment to rivers based on the impact on macro-invertebrates. The relationship between macro-invertebrates and fine sediments is poorly defined. Studies of the impacts of fine sediment on macro-invertebrates have been undertaken at various scales, which has an influence on the range of responses displayed and the reliability of the results obtained; results obtained from investigations at smaller scales may not manifest at the scale required to manage rivers and vice versa. Many of the identified effects of increased loading of fine sediment on macro-invertebrates occur as a consequence of deposition on the river bed, yet many current management guidelines are based on suspended sediment targets. On this basis, existing water quality guidelines for sediment management are unlikely to be appropriate." **15791.** Michels, J.; Gorb, S.N. (2012): Detailed three-dimensional visualization of resilin in the exoskeleton of arthropods using confocal laser scanning microscopy. Journal of Microscopy 245(1): 1-16. (in English) ["Resilin is a rubber-like protein found in the exoskeleton of arthropods. It often contributes large proportions to the material of certain structures in movement systems. Accordingly, the knowledge of the presence and distribution of resilin is essential for the understanding of the functional morphology of these systems. Because of its specific autofluorescence, resilin can be effectively visualized using fluorescence microscopy. However, the respective excitation maximum is in the UV range, which is not covered by the lasers available in most of the modern commercial confocal laser scanning microscopes. The goal of this study was to test the potential of confocal laser scanning microscopy (CLSM) in combination with a 405 nm laser to visualize and analyse the presence and distribution of resilin in arthropod exoskeletons. The results clearly show that all resilin-dominated structures, which were visualized successfully using wide-field fluorescence microscopy (WFM) and a 'classical' UV excitation, could also be visualized efficiently with the proposed CLSM method. Furthermore, with the application of additional laser lines CLSM turned out to be very appropriate for studying differences in the material composition within arthropod exoskeletons in great detail. As CLSM has several advantages over WFM with respect to detailed morphological imaging, the application of the proposed CLSM method may reveal new information about the micromorphology and material composition of resilin-dominated exoskeleton structures leading to new insights into the functional morphology and biomechanics of arthropods."... CLSM, known resilin-dominated structures including the wing hinge and the prealar arm of the locust *Locusta migratoria* (Insecta, Caelifera, Acrididae; see Weis-Fogh, 1960), a vein joint in the hind wing of *Sympetrum striolatum* (Authors)] Address: Gorb, S.N., Functional Morphology & Biomechanics, Zoological Institute, Christian-Albrecht University of Kiel, 24098 Kiel, Germany. **15792.** Morrill, A.; Forbes, M.R. (2012): Random parasite encounters coupled with condition-linked immunity of hosts generate parasite aggregation. International Journal for Parasitology 42(7): 701-706. (in English) ["Parasite aggregation is viewed as a natural law in parasite-host ecology but is a paradox insofar as parasites should follow the Poisson distribution if hosts are encountered randomly. Much research has focused on whether parasite aggregation in or on hosts is explained by aggregation of infective parasite stages in the environment, or by heterogeneity within host samples in terms of host responses to infection (e.g., through representation of different age classes of hosts). In this paper, we argue that the typically aggregated distributions of parasites may be explained simply. We propose that aggregated distributions can be derived from parasites encountering hosts randomly, but subsequently by parasites being 'lost' from hosts based on condition-linked escape or immunity of hosts. Host condition should be a normally distributed trait even among otherwise homogeneous sets of hosts. Our model shows that mean host condition and variation in host condition have different effects

on the different metrics of parasite aggregation. Our model further predicts that as host condition increases, parasites become more aggregated but numbers of attending parasites are reduced overall and this is important for parasite population dynamics. The effects of deviation from random encounter are discussed with respect to the relationship between host condition and final parasite numbers." **15793.** Rozner, G.; Ferincz, A.; Miokovics, E. (2012): Data to the distribution of Golden Ringed Dragonfly (*Cordulegaster bidentata* Selys, 1843) and Large Golden Ringed Dragonfly (*Cordulegaster heros* Theischinger, 1979) in Bakony Mountains. *Természeti Kéziratok* 18: 447-455. (in Hungarian, with English summary) ["According to earlier data, *C. bidentata* occurs in the Koszeg Mountains, the Bakony and the North Central Mountains, while *C. heros* is found in the Sopron Mountains, the Ország, the Mecsek and, according to more recent data, in the Zselic. Our studies in 2008-2009 confirmed the occurrence of *C. heros* syntopic *C. bidentata* in several watercourses of the Koszeg Mountains, which was an important new finding for the occurrence of the species, and also confirmed the occurrence of both species in the same water system. On this basis, it was reasonable to assume that *C. heros* could occur in other areas previously considered to be the habitat of *C. bidentata*. In 2010-2011, we extended our studies to the Bakony area and were able to detect *C. heros* in several watercourses and recorded the occurrence of both species in different sections of the same watercourse. **15794.** Soldan, T.; Bojková, J.; Vrba, J.; Bitušík, P.; Chvojka, P.; Papáček, M.; Peltanová, J.; Sychra, J.; Tátosová, J. (2012): Aquatic insects of the Bohemian Forest glacial lakes: Diversity, long-term changes, and influence of acidification. *Silva Gabreta* 18(3): 123-283. ["Aquatic insects have been studied in five Czech (Ěrné, Ěrtovo, Prášílské, Plešné, and Laka) and three German (Großer Arbersee, Kleiner Arbersee, and Rachelsee) lakes and their inlets and outlets in the Bohemian Forest. All available historical and present records, as well as many unpublished data were summarised. Of nine insect orders, 70 families, 214 genera, and 373 species/taxa were found in total (Ephemeroptera 20, Odonata 22, Plecoptera 37, Heteroptera 35, Megaloptera and aquatic Neuroptera 3, Trichoptera 46, Coleoptera 58, Chironomidae 113, other Diptera 39). All aquatic insect groups are discussed from the point of view of species richness, influence of acidification, ecological requirements, distributional ranges of species, and species protection. Altogether 215 species/ taxa were found in the lakes, where Heteroptera, Coleoptera, and Chironomidae were the most species-rich groups (135 taxa). The lowest number of taxa was recorded in strongly acidified Ěrtovo Lake and Rachelsee (55 and 56 taxa, respectively); the highest number of species/taxa was recorded in Laka, Plešné and Prášílské lakes (95, 91 and 89 taxa, respect-

ively). Altogether 237 taxa were found in inlets and outlets; Chironomidae, Trichoptera, and Plecoptera prevailed (151 taxa). Based on the cluster analysis of recent species data, the lakes were classified into four groups which primarily reflect characteristics of the lake littoral and water chemistry. Available data on Ephemeroptera, Plecoptera, Trichoptera, and Heteroptera from the past two decades were analysed in order to reveal possible biological recovery from acid stress. A certain degree of recovery has been documented by the increase in species richness of Ephemeroptera and Heteroptera. Yet the lakes have not been colonised by any acid-sensitive species." **15795.** Thomas, H.H.; Moosman, P.R.; Veilleux, J.P.; Holt, J. (2012): Foods of bats (Family Vespertilionidae) at five locations in New Hampshire and Massachusetts. *Canadian Field-Naturalist* 126(2): 117-124. (in English) ["Diet and feeding relations of six species of bats at five locations in New Hampshire and Massachusetts were studied to improve understanding of foraging niche differentiation. Fecal samples were collected from 100 Big Brown Bats (*Eptesicus fuscus*), 154 Little Brown Myotis (*Myotis lucifugus*), 49 Northern Myotis (*M. septentrionalis*), 54 Eastern Small-footed Myotis (*M. leibii*), 9 Eastern Red Bats (*Lasiurus borealis*), and 1 Hoary Bat (*L. cinereus*) netted during non-hibernation periods from 2004 to 2008 at four locations in southern New Hampshire and one in north-central Massachusetts. Beetles (Order Coleoptera) were the major food of *E. fuscus* (mean percentage volume = 81.6%, 97% occurrence) followed by moths (Order Lepidoptera), with scarabaeid and carabid beetles the most abundant consumed families by volume and frequency. Moths were the most important item by volume and frequency preyed on by the remaining species (*M. lucifugus*, mean percentage volume 30.7%, 82% occurrence; *M. septentrionalis*, mean percentage volume 42.7%, 82% occurrence; *M. leibii*, mean percentage volume 49.4%, 81% occurrence; *L. borealis*, mean percentage volume 62.8%, 100% occurrence; *L. cinereus*, mean percentage volume 82%, 100% occurrence). Little Brown Myotis consumed the largest variety of prey (40); Northern Myotis consumed the highest volume of spiders (8.1%). Community similarity index values indicated diets of the three species of *Myotis* were more similar to each other (similarity = 0.71) than to those of non-*Myotis*. The diet of *E. fuscus* was more similar to that of the *Myotis* cluster (0.58) than to either species of *Lasiurus*. Results suggest that, despite faunal differences between the U.S. Northeast and other parts of North America, foraging relationships among guild members follows a similar pattern." (2013): Food and feeding habits of *Synodontis nigrita*, Valenciennes, 1840 (Pisces: Mochokidae) in Asejire Lake, Nigeria. *International Journal of Lakes and Rivers* 6(1): 1-8. (in English) ["Food and feeding habits of *Synodontis nigrita* were examined in Asejire Lake, South-western, Nigeria between January 2002 and December 2003. A total of 517 specimens of *S. nigrita* were collected bi-monthly from the catches of local fishermen using cast nets, gill nets and bamboo-made traps. The stomach contents were analyzed using frequency of occurrence, numerical and volumetric methods. Two hundred and sixty one (50.48%) had empty stomachs, with the highest recorded in wet season (April-October) and lowest in dry season (November-March). The fish fed mainly on insects from seven taxa. The most frequently consumed insects were the isoptera which occurred in 49.27% of the stomachs, and accounted for 43.85% by number and 37.12% by volume; while dictyoptera were the least consumed insects occurring in 6.86% of stomachs, accounting for 2.84% by number and 8.30% by volume. Feeding habits varied with size, suggesting an age-specific food preference in order to avoid intra-specific competition for available food items in the lake. This coupled with the ability to feed on highly nutritious food probably accounted for the survival of the fish in the lake system." **15800.** Alvial, I.E.; Orth, K.; Durán, B.C.; Álvarez, E.; Squeo, F.A. (2013): Importance of geochemical factors in determining distribution patterns of aquatic invertebrates in mountain streams south of the Atacama Desert, Chile. *Hydrobiologia* 709: 11-25. (in English) ["The ecology of macroinvertebrate communities in arid regions is still poorly understood. Here we examined how the community structure varied at spatial and temporal scales in streams and tributaries of the Huasco River in semi-arid region of Northern Chile. We expected that macroinvertebrate distribution may be responding to natural processes of mineralization described for Chilean semiarid basins. The relationships among biotic and abiotic variables were assessed through multivariate techniques (principal component analysis, non-metric multidimensional scaling, canonical correspondence analysis), and a two-way analysis of similarity was used to evaluate differences between basins and years (2007, 2008, and 2009). Significant differences in community structure and physical-chemical variables between basins (Del Carmen and Del Tránsito) were found, but not between years. Altitude, Mn, Al, Ca, Na, HCO<sub>3</sub>, and dissolved oxygen were the variables that best accounted for the communities distribution. In particular, high metals concentration in El Tránsito basin should determine low density and diversity of macroinvertebrates. Chironomidae, Ephydriidae, and Glossiphoniidae were associated to waters with high metals content and acidic pH, whereas Baetidae, Hydroptilidae, and Blephariceridae were associated to sites with more favorable physical-chemical conditions. These results contribute to under-

stand the ecological patterns of macroinvertebrates in arid regions and should lead to conservation and monitoring plans for this remote place." (Authors)] Address: Alvial, Ingrid, Center for Advanced Studies in Arid Zones (CEAZA), Casilla 599, La Serena, Chile. E-mail: ingrid.alvial@ceaza.cl

Journal of Applied Sciences in Environmental Sanitation 8(3): 151-160. (in English) ["Biological monitoring assessing pollution levels and water quality. The objective of this study was to determine the composition and abundance of benthic macroinvertebrate in a tropical urban river over five consecutive months (No communities from three sampling stations located in the middle section of the Mengkibol River, Kluang were monitored. Biotic, water quality, diversity and evenness indices as well as statistical analysis were applied that the river did not support much macroinvertebrate diversity. Moderately intolerant pollution species such as dragonfly (Insecta: Odonata) were observed to be dominant in each site. However, the occurwater quality of the Mengkibol River. Indices such as the Biological Monitoring Working Party (BMWP), Lincoln Quality Index (LQI), and Water Quality Index (WQI) were also used to assess the level of impact on the Mengkibol River. The relationship between the physicochemical and benthic macroinvertebrate data were investigated by one ANOVA and Pearson's correlation of coefficient analysis. These statistical methods indicate that temperature had addition, the LQI value was generally affected by the BMWP score ( $P < 0.01$ ), while the Pielou Evenness Index (J) was strongly correlated with the BMWP, LQI and Shannon Weiner Diversity Index ( $H'$ ) ( $P$  uniformly.)] Address: Arman, N.Z., Institute of Environmental & Water Resource Management, Univ. (2013): Use of the ABC curve as a method to detect the effect of anthropogenic change on the Odonata (Insecta) assembly. Interciencia 38(7): 516-522. (in Portuguese, with English summary) ["The insects of the order Odonata are organisms commonly used in biomonitoring studies, since they have some species with very specific requirements and high sensitivity to environmental changes. The aim of this study is to evaluate whether the effects of environmental changes lead to a change in patterns of abundance and biomass of the Odonata assembly, testing the hypothesis that, because of the demands ecophysiological order, with the removal of riparian vegetation took place an increase the in abundance of Anisoptera and a decrease in Zygoptera. Ten streams were sampled, five being altered and five preserved. A comparison of biomass and abundance was done using the W statistic. The hypothesis was supported in part since for Zygoptera the biomass curve for both preserved and altered environments was above the abundance curve, despite the fact that difference in altered environments was very small. For Anisoptera in degraded environments there was a predominance of fast growing and larger body size species, and therefore, the biomass curve extends above the abundance curve. This pattern can be explained by the thermoregulation demands of the suborder. Even considering that Zygoptera did not show a re-

versal of the curves, the technique proved effective in assessing environmental impact and can be employed in biomonitoring programs that use this group." (2013): Observations on egg parasitism of *Aeshna tuberculifera* (Odonata: Aeshnidae) by Eulophidae, Trichogrammatidae and Mymaridae (Hymenoptera) in Alger county, Michigan. *The Great Lakes Entomologist* 46: 145-153. (in English) ["Egg parasitoids were reared from a population of *Aeshna tuberculifera* in the Kingston Lake area of Alger County, Michigan, from 1983-2005. Leaves of *Iris versicolor* were repeatedly used for oviposition during the period of observation, with the result that just a few leaves were targeted by different females. Seven species of parasitic Hymenoptera were reared from 1688 eggs. The cumulative rate of parasitization over the course of the study was 18.4%. Three species of parasitoids were responsible for approximately 96% of the parasitized eggs: *Aprostocetus (Ootetrastichus) mymaridis* Girault (Eulophidae) (41%); and the Mymaridae *Polynema* nr. *needhami* (34%) and *Anagrus subfuscus* Förster (21%)."] (Authors)] Address: Cebulski, B.C., 122 White Bear Drive, Negaunee, MI 49866, USA

**15808.** Chakravorty, J.; Ghosh, S.; Meyer-Rochow, V.B. (2013): Comparative survey of entomophagy and entomotherapeutic practices in six tribes of eastern Arunachal Pradesh (India). *Journal of Ethnobiology and Ethnomedicine* 9:50 doi:10.1186/1746-4269-9-50: 12 pp. (in English) ["A consolidated list of edible insects used in the eastern part of Arunachal Pradesh (N.E. India) by Wangcho (Wancho) and Nocte tribes of the Tirap District and the Shingpo, Tangsa, Deori and Chakma of the Changlang District has been prepared. The list is based on thorough, semi-structured field-interviews with 20 informants of each tribal group. At least 51 insect species, belonging to 9 orders were considered edible. The largest number of the edible species belonged to the Coleoptera (14), followed by 10 each of the Orthoptera and Hymenoptera, 9 of the Hemiptera, 3 Lepidoptera, 2 Isoptera and one each of Ephemeroptera, Odonata and Mantodea. As far as therapeutic uses of insects are concerned, 4 species (Hemiptera) were mentioned by the Wangcho (Wancho). Food insects are chosen by members of the various tribes according to traditional beliefs, taste, regional and seasonal availability of the insects. Depending on the species, only certain, but sometimes all, developmental stages are consumed. Preparation of the food insects for consumption involves mainly roasting or boiling. With the degradation of natural resources, habitat loss, rapid population growth, and increasing 'westernization', the traditional wisdom of North-East Indian tribals related to insect uses is at risk of being lost. ] Address: Chakravorty, J., Biochemical Nutrition Laboratory, Dept of Zoology, Rajiv Gandhi Univ., Arunachal Pradesh 791112, India. E-mail: jharnaau@yahoo.com

**15809.** Chen, Jia-Huei (2013): Comparative food habits of two closely-related insectivorous bats and their eco-mor-

phological correlates. MSc. thesis, Dept of Life Sciences, School of Biological Science & Technology, National Cheng Kung University: 46 pp. (in Chinese, with English summary) ["... The diet of *H. terasensis* comprised of 9 insect orders, and that of *H. turpis* additionally included Araneae, Odonata, and Trichoptera and contained a total of 12 orders of arthropods. Both species fed primarily on Coleoptera that accounted for more than 20% in frequency of occurrence and about 40% in volume percentage, while the rest prey orders accounted for different proportions in their respective diets. Hemiptera and Hymenoptera accounted for 53.8% of the total frequency of occurrence and contributed to 50.8% of the volume in the diets of *H. terasensis*. In contrast, Orthoptera, Hemiptera, and Blattodea were more prevalent in the diet of *H. turpis*, but Orthoptera and Lepidoptera were more abundant in volumes. Below the level of order, I found 21 and 13 prey taxon, mostly families, in the diets of *H. terasensis* and *H. turpis*, respectively. Within hemipterans, *H. terasensis* consumed higher proportions of cicadas than *H. turpis*. Overall, *H. terasensis* displayed a more even and thus a more heterogeneous diet than that of *H. turpis*, with a medium dietary overlap between the two species at 0.67, based on Horn's index of similarity. Most wing parameters measured were higher in *H. terasensis* than those of *H. turpis*. A higher wing loading and aspect ratio indicate a faster but less maneuverable flight for *H. terasensis*. In contrast, the flight of *H. turpis* is expected to be more maneuverable and adapted to near vegetation and the ground. In addition, *H. turpis* with higher call frequency would be more tolerant to cluttered environments. Incorporating the general flight potentials of insects, dietary results showed that *H. terasensis*, with higher wing loading and aspect ratio, consumed a higher proportion of faster-flying insects, such as Hymenoptera. The larger body and skull size of *H. terasensis* suggest a more powerful bite force, and the estimated hardness index of prey eaten by *H. terasensis* (3.75) was slightly higher than that of *H. turpis* (3.67). The food habits differed between *H. terasensis* and *H. turpis* in several aspects, and various factors might have contributed to these differences. The dietary results were consistent with the predictions from eco-morphological traits, including body size, wing parameters, and echolocation. Since *H. terasensis* ate more evenly among each insect order, it ate less number of insect orders but had a more heterogeneity diet. This study did not measure food availability on site, thus can't rule out the possibility of dietary differences affected by prey availability. The dietary compositions of *H. terasensis* among sites across Taiwan, however, indicate little dietary variation in space and substantiate our conclusions. Eco-morphological traits constrain animals to explore resources and to a certain extent that have contributed to the different patterns of resource use, thus eco-morphological traits can be a good indicator for resource use patterns of animals with caution." **15811.** Cuello, J.A.G. (2013): Entomofauna bioindicadora del Río Algodonal, La Ermita, norte de Santander. *Revista ingenio* 6(1): 112-117. ["The river Algodonal is one of the most important bodies of water in the department of North of Santander, Colombia. Could a study of biodiversity of insects associated to the basin of the River Algodonal to determine the quality of the water that is being you dilute below in the municipality of Ocana? For this study it took three sampling stations in the basin of the River. It took samples in transeptos of 100m x 20m, an area of 2000 m<sup>2</sup> for station. The collection was carried out with hand net, manual, aquatic net and pitfall traps. It was collected on the average seven orders for station: Hymenoptera, Coleóptera, Hemipterous, Homoptera, Dipteral, Ortoptera and Odonata, with a total abundance of 431 individuals. They were seven families bioindicadoras: Curculionidae, Veliidae, Libellulidae, Coenagrionidae, Gelastocoridae, Muscidae and Culicidae whose values of importance inside the methodology BMWP/Col added 40 classifying the water in class IV or of doubtful quality what indicates that it is polluted. Physicochemical parameters were evaluated in situ like oxygenate dissolved 5,23 - 7,57 mg/L, PH 7 - 8 and Conductivity 31,8 - 55,4  $\mu$ S-cm, those which leaning with tests of total hardness (mg/L), Chlorides (mg/L), total Alkalinity (mg/L) and Turbidity NTU, determined that the quality of the water is doubtful and that it stops its consumption it should be treated." **15812.** Curtis, L.R.; Morgans, D.L.; Thoms, B.; Villeneuve, D. (2013): Extreme precipitation appears a key driver of mercury transport from the watershed to Cottage Grove Reservoir, Oregon. *Environmental Pollution* 176: 178-184. (in English) ["An abandoned cinnabar mining and roasting site is in the major sub-basin of the watershed for Cottage Grove Reservoir, Oregon. Average surface sediment total mercury concentration in the river draining this sub-basin ( $0.61 \pm 0.52 \mu\text{g/g}$ ) was about ten-fold higher than three smaller tributaries to the reservoir. Total mercury in reservoir surface sediments averaged  $1.66 \pm 0.70 \mu\text{g/g}$ . Stratigraphy for two sediment cores indicated generally decreased reservoir mercury loading from 1963 to 2002 but two pronounced peaks in mercury deposition. Years of extreme precipitation immediately prior to these peaks at least partially explained them. Epaxial muscle total mercury concentrations of largemouth bass increased with body weight up to  $2.5 \mu\text{g/g}$ . A gradient of mercury concentrations in soils from a 3.3 km diameter grid indicated condensation of mercury vapors from the mine site polluted the sub-basin. Highlights: Pollution of the watershed with

mercury yields a highly persistent human health risk. \*Watershed level events profoundly influence mercury transport into aquatic ecosystems. \*Soil and sediment mercury concentration gradients are a source identification tool." (Authors) Fingerling brown bullhead catfish (*Ameiurus nebulosus*), snails (*Physidae*), bullfrog tadpoles (*Rana*), and Anisoptera and Zygoptera larvae were collected from the reservoir shoreline using a sweepnet. ... **15813.** De Nadaï-Monoury, E.; Lecerf, A.; Canal, J.; Buisson, L.; Laffaille, P.; Gilbert, F. (2013): A cost-effective method to quantify biological surface sediment reworking. *Hydrobiologia* 713: 115-125. (in English) ["We propose a simple and inexpensive method to determine the rate and pattern of surface sediment reworking by benthic organisms. Unlike many existing methods commonly used in bioturbation studies, which usually require sediment sampling, our approach is fully non-destructive and is well suited for investigating non-cohesive fine sediments in streams and rivers. Optical tracer (e.g. luminophores or coloured sand) disappearance or appearance is assessed through time based on optical quantification of surfaces occupied by tracers. Data are used to calculate surface sediment reworking (SSR) coefficients depicting bioturbation intensities. Using this method, we evaluated reworking activity of stream organisms (three benthic invertebrates and a fish) in laboratory microcosms mimicking pool habitats or directly in the field within arenas set in depositional zones. Our method was sensitive enough to measure SSR as low as  $0.2 \text{ cm}^2 \text{ day}^{-1}$ , such as triggered by intermediate density ( $774 \text{ m}^2$  of *Gammarus fossarum* (Amphipoda) in microcosms. In contrast, complex invertebrate community in the field and a fish (*Barbatula barbatula*) in laboratory microcosms were found to yield to excessively high SSR ( $>60 \text{ cm}^2 \text{ day}^{-1}$ ). Lastly, we suggest that images acquired during experiments can be used for qualitative evaluation of species-specific effects on sediment distribution." **15815.** di Lascio, A.; Rossi, L.; Carlino, P.; Calizza, E.; Rossi, D.; Costantini, M.L. (2013): Stable isotope variation in macroinvertebrates indicates anthropogenic disturbance along an urban stretch of the river Tiber (Rome, Italy). *Ecological Indicators* 28: 107-114. (in English) ["Running waters in urbanized areas are large-scale systems of anthropogenic energy dissipation that receive effluents from point and diffuse sources, potentially inducing changes in organic matter decomposition and deposition and thus modifying river metabolism and the feeding patterns of inhabiting populations. Based on the hypothesis that anthropogenic disturbance provides important trophic constraints that influence the trophic niches of local communities, stable isotopes analysis was used to evaluate possible alterations in resource assimilation by aquatic species in response to diffuse and point sources of pollution from the city of Rome. For this purpose, the isotopic signature ( $\delta^{15}\text{N}$  and  $\delta^{13}\text{C}$ ) of detritus-based benthic communities and fish was determined upstream and downstream of two wastewater treatment plants (WWTPs) located before and after the urban stretch of the river Tiber. Community-wide metrics as the carbon range and convex hull area encompassing all taxa in a  $\delta^{15}\text{N}$  and  $\delta^{13}\text{C}$  bi-plot were used to measure the species' niche width and overlap. Differences were found between the upstream and downstream signatures, regarding the  $\delta^{15}\text{N}$  and  $\delta^{13}\text{C}$  of both detritivores and predators. The differences were found to be more pronounced at the southern WWTP, located downstream of the city. The lower  $\delta^{15}\text{N}$  in macroinvertebrates at the WWTP-impacted sites reflected the lower  $\delta^{15}\text{N}$  of suspended particulate organic matter and was associated with higher inorganic and organic loads. The decreasing range of  $\delta^{13}\text{C}$  values in macroinvertebrates and fish indicated a narrowing of the niche width downstream of the treatment plants, particularly downstream of the urban area itself. The effects were stronger on detritivores than predators due to direct incorporation of the sewage-derived material that dominated the locally available food sources. These data suggest that isotopic signals coupled with community-wide metrics can be used as functional indicators of treated and untreated sewage impacts on aquatic communities even when the primary targets (species abundance and community structure) appear to be largely unaffected." *Soc. B* 7 March 2013 vol. 280 no. 1754: 8 pp. (in English) ["Gleaning insectivorous bats that forage by using echolocation within dense forest vegetation face the sensorial challenge of acoustic masking effects. Active perception of silent and motionless prey in acoustically cluttered environments by echolocation alone has thus been regarded impossible. The gleaner insectivorous bat *M. microtis* however, forages in dense understory vegetation and preys on insects, including dragonflies, which rest silent and motionless on vegetation. From behavioural experiments, we show that *M. microtis* uses echolocation as the sole sensorial modality for successful prey perception within a complex acoustic environment. All individuals performed a stereotypical three-dimensional hovering flight in front of prey items, while continuously emitting short, multi-harmonic, broadband echolocation calls. We observed a high precision in target localization which suggests that *M. microtis* perceives a detailed acoustic image of the prey based on shape, surface structure and material. Our experiments provide, to our knowledge, the first evidence that a gleaner bat uses echolocation alone for successful detection, classification and precise localization of silent and motionless prey in acoustic clutter. Overall, we conclude that the three-dimensional hovering flight of *M. microtis* in combination with a frequent emission of short, high-frequency echolocation calls is the key for active prey perception in acoustically highly cluttered environments." **15819.** Harris, S.; Karlsson Green, K.; Pettersson, L.B. (2013): Predator faunas past and present: quantifying the influence of waterborne cues in divergent ecotypes of the isopod *Asellus aquaticus*. *Oecologia* 173(3): 791-799. (in English) ["Waterborne chemical cues are an important source of information for many aquatic organisms, in particular when assessing the current risk of predation. The ability to use chemical cues to detect and respond to potential predators before an actual encounter can improve prey chances of survival. We investigated predator recognition and the impact of chemical cues on predator avoidance in the freshwater isopod *Asellus aquaticus*. This isopod has recently colonised a novel habitat and diverged into two distinct ecotypes, which encounter different predator communities. Using laboratory-based choice experiments, we have quantified behavioural responses to chemical cues

from predators typical of the two predator communities (larval dragonflies in the ancestral habitat, perch in the newly colonised habitat) in wild-caught and lab-reared *Asellus* of the two ecotypes. Individuals with prior experience of predators showed strong predator avoidance to cues from both predator types. Both ecotypes showed similar antipredator responses, but sexes differed in terms of threat-sensitive responses with males avoiding areas containing predator cues to a larger extent than females. Overall, chemical cues from fish elicited stronger predator avoidance than cues from larval dragonflies. Our results indicate that in these isopods, prior exposure to predators is needed to develop antipredator behaviour based on waterborne cues. Furthermore, the results emphasise the need to analyse predator avoidance in relation to waterborne cues in a sex-specific context, because of potential differences between males and females in terms of vulnerability and life history strategies." **15820.** Hellmund, M.; Hellmund, W. (2013): Fossile Kleinlibellen (Odonata, Zygoptera) und ihr endophytischer Fortpflanzungsmodus - Erfolgreiche Strategie seit mindestens 100 Millionen Jahren. *Entomologische Nachrichten und Berichte* 57(1/2): 31-44. (in German, with English summary) ["Fossil damselflies (Odonata, Zygoptera) and their endophytic reproductive behaviour -successful strategy since at least 100 Million years. - For 20 years, we have intensely researched the reproductive behaviour of fossil as well as contemporary damselflies (Zygoptera). Meanwhile we are able to distinguish and differentiate four different modes of ovipositing. To simplify and clarify communication, we created new descriptive labels, e. g. „Coenagrioniden-Typ“ („Zickzack-Modus“ and „Bogen-Modus“) respectively Lestiden-Typ („Einzelreihen-Modus“ and „Doppelreihen-Modus“), which are now fundamentally accepted and adopted by the current junior authors, searching in this field. Based on numerous Contemporary studies it became clear that the fossil egg-sets amazingly agree, both in size and morphology, with egg-sets of taxa belonging to the extant zygopteran families Coenagrionidae and Lestidae. The above-mentioned actualistic studies and observations are the key for understanding and interpreting the processes of the past Earth history, in particular in paleoethology. Zygoptera (damselflies) other than Anisoptera (dragonflies) practice a „balanced strategy“, by producing only a restricted number of eggs each of which is by the female carefully and thoroughly inserted into plant tissue (fresh leaves, leaf litter or small twigs). The egg is this individually protected while developing to a prolarva. This is called „endophytic ovipositioning“. In contrast, most Anisoptera produce a large number of eggs which are dropped freely into wet substratum like mosses or comparable plant material and onto pond water surfaces, practicing a mode of „opportunistic strategy“, despite the drawback that the majority of these eggs may not be able to develop successfully to a prolarva. The latter method is called „Freileger“ or random scattering of eggs." (Authors)] Address: Hellmund, M., Zentralmagazin Naturwissen. Sammlungen Martin-Luther-Univ. Halle-Wittenberg Kustos

**15823.** Khelifa, R.; Zebba, R.; Sakrane, N.E.; Youcefi, A.; Bensouilah, S.; Amari, H. (2013): Long-range movements of an endangered endemic damselfly *Calopteryx exul* Selys, 1853 (Calopterygidae: Odonata). *African Journal of Ecology* 52: 375-377. (in English) ["The study was carried out in Salah Salah (36°27'41.37"N 7°20'22.07"E located upstream Seybouse River (north-east Algeria). It is a 20-m width watercourse with a mean depth of 70 cm and bank vegetation consisted of dense *Typha angustifolia* and *Nerium oleander*. This part of the river was affected by human activities like water pumping and throwing tons of rocks and gravelly soil coming from nearby building constructions into the river bed. We conducted capture-mark-resightings on imagos during five days (20, 22, 25, 28 May and 01 June 2010) in the morning within a stretch of 200 m. The short sampling period was due to conflicts with local people. The current study stretch was isolated from other potential suitable ones by a distance of about 4 km. Adults were individually marked on the left and right wing, thorax and the abdomen using paint spots of different colours. SPSS 17.0 (SPSS Inc, Chicago, IL, USA) was used to perform Mann-Whitney U-test. The species flight period started in early May, and the first reproductive pair was observed on 25 May. A total of 141 imagos (64 males and 77 females) were marked, among which 33 (14 males and 19 females) were subsequently resighted giving a mean resighting rate of 23.40% (21.18% for males and 24.67% for females). All of the latter individuals were resighted only once. Almost all resighted individuals (94%) displayed movements of less than 50 m with a

mean of  $9.35 \pm 8.49$  m ( $9.35 \pm 8.49$  for males and  $9.56 \pm 10.20$  m for females). There was no significant difference in short-scale movements (<50 m) between males and females ( $U = 94.5$ ,  $P = 0.35$ ). However, 6% of resighted individuals carried out long-range movements. An individual male marked on 22 May was resighted two days after in a subpopulation 5.3 km downstream in a site where the species reproductive behaviour and biology were daily studied by our colleagues. Similarly, a female marked on 25 May noted dead during the next day in another subpopulation 4.9 km downstream" (Authors)] Address: Khelifa, R., Institute of Evolutionary Biology and Environmental Studies, University of Zürich, Winterthurerstr. 190, CH-8057, Zürich, Switzerland. **15824.** Kim, J.S.; Kwak, J.I.; Noh, T.H. (2013): Characteristics of Odonata communities based on habitat types of superb biotope in Wonju city, Korea. *Korea Journal of Environment and Ecology* 27(2): 209-218. (in Korean, with English summary) ["This study was conducted to analyze the characteristics of odonata communities as habitat types in Wonju City, Korea. The 33 plots were installed at 4 types of biotope like abandoned paddy fields, natural type reservoir, natural type river and forest valley in Wonju city. From the survey, the 9 family and 38 species were identified. As the result of comparative investigation of the species composition of each habitat through TWINSpan analyzing, the difference of species composition was definite in abandoned paddy field, natural type reservoir and forest valley, however, it was uncertain in natural type river. The dominant species and the subdominant species of each habitat were mainly *Sympetrum frequens* and *S. infuscatum* but the distributions of *Paracercion hieroglyphicum*, *Epophthalmia elegans*, and *Anax parthenope julius* were different as habitat types. The order of the index of species diversity was not different between abandoned paddy fields, natural type reservoir and natural type river, but forest valley was low. The abandoned paddy field was shown the most diverse spawning type of odonata, it is considered that hydrophytes play an important role in the abundant of odonata since the sorts of odonata spawning in plants are majority. As the result of analyzing interspecies relationship, *Crocothemis servilia mariannae* and *Orthetrum albistylum*, *C. servilia mariannae*-*Platycnemis phyllopora*, *Lyriothemis pachygastra*-*Sympetrum parvulum* are shown the positive correlation, however, they have a difference in preferred habitat between high correlation species." **15827.** Lou, Y.-G.; Zhang, G.-R.; Zhang, W.-Q.; Hu, Y.; Zhang, J. (2013): Biological control of rice insect pests in China. *Biological Control* 67(1): 8-20. (in English) ["Highlights: •Rice is one of the most important food crops in the world. •Damage by insect pests is a serious challenge to rice production in China. •Biological control is an effective method for pest control but not extensively adopted. •Integration of new strategies in biological control should be explored. Abstract: Rice is one of the most important food crops in the world. China has the second largest area of the rice growing in the world and the highest yield of rice

produced. Infestation by insect pests, especially rice planthoppers, stem borers and leaf folders, is always a serious challenge to rice production in China. Current methods for controlling insect pests in China mainly include good farming practices, biological control, breeding and growing resistant varieties, and the use of chemical insecticides. However, for farmers, the favorite method for insect pest control is still the application of chemical insecticide, which not only causes severe environmental pollution and the resurgence of herbivores but also reduces populations of the natural enemies of herbivores. To control insect pests safely, effectively and sustainably, strategies encouraging biological control are currently demanded. Here we review the progress that has been made in the development and implementation of biological controls for rice in China since the 1970s. Such progress includes the species identification of the natural enemies of rice insect pests, the characterization of their biology, and the integration of biological controls in integrated pest management. To develop effective ecological engineering programs whose aim is to implement conservation biological controls, further research, including the evaluation of the roles of plants in non-crop habitats in conservation biological controls, volatiles in enhancing efficiency of natural enemies and natural enemies in manipulating insect pests, and education to increase farmers' knowledge of biological controls, is proposed." (Authors) Address: Lou, Y.-G., State Key Laboratory of Rice Biology, Institute of Insect Science, Zhejiang University, Hangzhou 310058, China

**15828.** Md Rawi, C.S.; Al-Shami, S.A.; Madrus, M.R.; Ahmad, A.H. (2013): Biological and ecological diversity of aquatic macroinvertebrates in response to hydrological and physicochemical parameters in tropical forest streams of Gunung Tebu, Malaysia: implications for ecohydrological assessment. *Ecohydrology* 7(2): 496-507. (in English) ["In this study, we have investigated the effects of some hydrological and physicochemical parameters such as water quality, velocity, water depth, river width, water pH, water temperature, ammonia-N, biochemical oxygen demand (BOD), chemical oxygen demand (COD) and dissolved oxygen (DO) on diversity of aquatic macroinvertebrates in forest streams of Gunung Tebu (GT), Malaysia. The results of canonical correspondence analysis identified three groups of the aquatic macroinvertebrates according to their relationships with hydrological and physicochemical parameters. The stream velocity, water quality (i.e. DO, BOD and ammonia-N) in addition to canopy cover, total habitat score and substrate quality were the determinant factors controlling the diversity pattern of the aquatic macroinvertebrates in GT streams. Alteration in the hydrological and physicochemical parameters showed to influence the ecological diversity of the aquatic macroinvertebrates in GT streams. The predators were found to be highly associated with the elevated concentrations of BOD and COD. Shredders were positively correlated with pH, stream velocity, DO and habitat quality indicators (total habitat score, embeddedness, epifaunal and canopy cover). However, the collector-gatherers correlated negatively with all of these parameters. It was concluded that stream velocity, substrate structure and water quality were strong attributes for variation in aquatic macroinvertebrate

assemblage structure in tropical forest streams of GT." (Authors) Address: Salman Abdo Al-Shami, School of Biological Sciences, Universiti Sains Malaysia (USM), 11800 Penang, Malaysia. E-mail: alshami200@gmail.com; salshami@usm.my

**15829.** Meyer, M.D.; Davis, C.A.; Bidwell, J.R. (2013): Assessment of two methods for sampling invertebrates in shallow vegetated wetlands. *Wetlands* 33(6): 1063-1073. (in English) ["Invertebrates are often used as indicators of wetland health and habitat quality for species such as waterbirds. However, the sampling method may influence the characterization of wetland invertebrate populations. The objective of this study was to compare the effectiveness of two sampling methods, the aquatic D-frame net and Quadrat-Column-Core (QCC) method, in determining invertebrate population metrics in vegetated depressional wetlands of north central Oklahoma. As compared to the D-frame net, use of the QCC method resulted in higher estimates of both total microcrustacean and nonmicrocrustacean density and biomass. Additionally, the QCC method had higher estimates of density and biomass for seven of the eight functional feeding groups and nearly half of the 49 taxa collected from the wetlands. The D-frame net method produced higher estimates of taxa richness and the Shannon index as well as higher densities and biomasses than the QCC method for five taxa. Overall, invertebrate community structure was different between the two sampling methods. In light of differences in the metrics determined for the two sampling methods, the ultimate choice of a sampling method for wetland invertebrates should be based on study objectives." **15830.** Morrill, A.; Mlynarek, J.J.; Forbes, M.R. (2013): Explaining covariation between endo- and ecto-parasites in spreadwing damselflies (Zygoptera: Lestidae). *Canadian Journal of Zoology* 91(10): 761-765. ["Host individuals and populations are commonly infected by more than one type of parasite, yet studies examining parasite effects on host fitness often limit observations or experiments to only a single parasite taxon or to a narrow subset of potential parasite taxa. Addressing covariation between parasite taxa is important for determining the potential for misattributing effects caused by one parasite species to another parasite species, and also for testing more broadly whether host attributes relate to exposure or susceptibility to infection. In this study, parasitism by ectoparasitic water mites (Arrenuridae) and endoparasitic gregarines (Eugregarinidae) of two spreadwing damselfly species, *Lestes disjunctus* Selys, 1862 and *Lestes forcipatus* Rambur, 1842, was measured and analyzed for covariance. No significant correlations between the intensities of the two types of infecting parasites were found when both live and resisted mites were considered. However, significant negative correlations between live mites and gregarines were consistently found in *L. forcipatus* host samples, but never in *L. disjunctus* samples. These results show some species-specific patterns of covariation between mite and gregarine infections in damselflies. We propose potential

underlying causes for this correlation related to parasite–host ecology and to changes in host behaviour resulting from water mite infection of *L. forcipatus*." **15832.** Nurulain, B.S. (2013): Morphological variation of selected species in the genus *Orthetrum* (Odonata: Anisoptera) in Sarawak. B.Sc. thesis, Universiti Malaysia Sarawak: VII + ? pp ["Dragonflies are widely distributed in the tropical rainforests of the island of Borneo. Dragonflies can be differentiated morphologically at the species level. Study on the morphological variations of four selected species in the genus *Orthetrum* (i.e. *O. glaucum*, *O. testaceum*, *O. chrysis*, and *Orthetrum sabina*) from the suborder Anisoptera in Sarawak was conducted by using voucher specimens deposited in UNIMAS Zoological Museum, Sarawak Forestry Research Centre, and Sarawak Biodiversity Centre. This study was done to determine the morphological variations among dragonflies species based on morphometric characters and to identify the important characters that differentiate the individuals at the species level. A total number of 89 adult individuals were morphologically analysed with 15 morphometric measurements. Cluster Analysis (CA) and Discriminant Function Analysis (DFA) showed that *O. sabina* can be discriminated from *O. glaucum*, *O. testaceum*, and *O. chrysis* mainly based on four major diagnostic characters; length of abdomen, length of thorax, width of thorax, and length of tarsus (hind leg). However, none of the canonical coefficients estimated from the measured characters are suitable to distinguish *O. glaucum*, *O. testaceum*, and *O. chrysis* from each other. The knowledge from this morphometric analysis will assist researchers to choose the best characters to discriminate between the *Orthetrum* species for future research." (in Spanish, with English summary) ["*T. kirbyi* is recorded for the first time, from Ciudad Real (first record from Castilla La Mancha) and Huelva (Andalusia). The presence in the province of Badajoz (Extremadura) is also confirmed. The increment of its distribution range to inland and

the Atlantic coast is shown with this new data." (Authors)] Address: Obregón-Romero, R., Dpto. Botánica, Ecología y Fisiología Vegetal. Área de Ecología. Campus de Rabanales. Universidad de Córdoba, Spain. E-mail: rafaobregonr@gmail.com

**15834.** Oliveira, E.; Takeuchi, S.S.; Cerutti, V.E. (2013): Assembly of Odonata (Insecta) Larvae in limnic environments in the Parque Estadual de Vila Velha, Brazil. *Estud. Biol.* 35(85): 163-176. (in Portuguese, with English summary) ["To analyze the composition, distribution and ecological indices for the assembly of Odonata larvae in 15 sampling points (six lentic and nine lotic) Parque Estadual de Vila Velha, were executed four sampling programs. At the end of each season, between March and December/2011. At each point five samples were extracted, each one obtained at an interval of 15 minutes using sieve (diameter 25 cm, mesh opening of 0,2 mm). A total of 3.061 larvae were collected, these 2.419 recorded in lentic systems and 642 in lotic. Lentic systems in the largest absolute (538) occurs in the Baixo do Coqueiro. In lotic systems (166) occur in Rio Guabirola. Among the seven families registered Coenagrionidae – 40.48% Te Libellulidae – 39.36% are the most abundant and Megapodagrionidae – 0.52%, the smallest representation. Of the 21 genera occurred: *Acanthagrion*, *Aeshna*, *Hetaerina*, *Lestes*, *Macrothemis* and *Telebasis* represent about 88%. The genus richness was close: lentic (10) and lotic (9). The greatest of richness Margalef (17.4) occurs in Rio Guabirola, higher values of Shannon diversity (0.83) occur in rivers Barrozinho and Quebra Perna. The Berger Parker dominance was attended by *Hetaerina* Rio Barrozinho and evenness was more pronounced in Rio Guabirola. The estimator Jackknife 2nd order indicated maximum value (23.4) for genera. The results reflect the importance of this conservation unit with respect to the maintenance of wetlands preserved for biodiversity of this assembly of larvae." **15835.** Patten, M.A.; Smith-Patten, B.D. (2013): Odonata species of special concern for Oklahoma, USA. *International Journal of Odonatology* 16(4): 327-350. (in English) ["Assessment of conservation status is a necessary step before management plans can be formulated. Historically such assessments have a strong bias toward vertebrates, particularly endothermic terrestrial vertebrates (i.e. birds and mammals). Invertebrates, by contrast, tend to be ignored, and many insect groups, despite being species rich and reasonably well studied, such as the Odonata (damselflies and dragonflies), have not been assessed or have been assessed only at a broad geographic level (e.g. internationally or continentally). Assessment at a state level recognizes that states often are at the front of regional and local conservation and management planning and implementation. On the basis of our extensive surveys across the Great Plains state of Oklahoma in the central USA, as well as our compilation of thousands of museum specimens dating back to 1877, we were able to discern the status and distribution of each of the 161 species of odonates recorded in the state. In doing so we were able to assess a conservation rank, using

NatureServe criteria, for each species. We conclude that nine species are critically imperiled (S1) in the state. These species require immediate conservation attention, initially at the level of intensive surveys to delineate the full extent of the geographic range in the state and to determine the population size and habitat needs. We categorized an additional 13 species as imperiled (S2) and placed 18 species on a "watch list" (S3). Species on these two lists will require field surveys as well, and regions of high occurrence of listed species ought to be targeted for such efforts and considered as set-asides for preservation of key members of the odonate fauna in the state." **15837.** Polo-Cavia, N.; Gomez-Mestre, I. (2013): Learned recognition of introduced predators determines survival of tadpole prey. *Functional Ecology* 28(2): 432-439. ["Alien predators are one of the major causes for rapid decline and extinction of native species, because they often create novel ecological contexts in which the antipredatory responses of native organisms are no longer fit. Although larval amphibians are often capable of innately responding to chemical cues from local predators through changes in morphology and behaviour, naïve tadpoles generally cannot recognise introduced predators with which they have not shared an evolutionary past. However, in a few documented cases, aquatic organisms have been observed to alter morphology or behaviour in response to alien predators. Such a response may have evolved as adaptive recognition, increasing their repertoire of innate responses to include the novel predator, or may have evolved as the prey's ability to learn new threats by association with conspecific alarm cues. The red swamp crayfish, *Procambarus clarkii*, is a harmful invasive species in aquatic systems worldwide, causing great ecological impact on native amphibian populations during the last decades through intense predation of eggs and tadpoles. We demonstrate that naïve tadpoles of the western spadefoot toad, *Pelobates cultripes*, are not capable of innately recognising waterborne predator cues from the red swamp crayfish. Nevertheless, we demonstrate that *P. cultripes* tadpoles can learn to recognise the cues of the invasive predatory crayfish as a threat when they are exposed to predator cues combined with conspecific alarm cues. Finally, we show that tadpoles conditioned by joint exposure to crayfish and alarm cues enjoy higher survival during predation trials with invasive crayfish. Learning to recognise a newly introduced predator through association with conspecific alarm cues may allow successful generalisation of antipredatory responses by tadpoles. This cognitive ability of tadpoles may contrib-

ute to reduce their vulnerability to alien predators and soothe the impact of invasions in natural populations ... either an invasive predator (*P. clarkii*) or a native one (nymphs of *Anax imperator*). ... We also dip-netted ten dragonfly nymphs (*A. imperator*), and used fyke-nets to ..." (Authors)] Address: Polo-Cavia, Nuria, Dept of Biology, Univ. Autónoma de Madrid, 28049 Madrid, Spain,

**15838.** Rueda, J.; Mesquita-Joanes, F.; Valentín, A.; Dies, B. (2013): Inventario de los macroinvertebrados acuáticos del "Ullal de Baldoví" (Sueca, Valencia, España) tras un programa de restauración. Check-list of the aquatic macroinvertebrates of "Ullal de Baldoví" spring pond (Sueca, Valencia, Spain) after a restoration program. *Bol. R. Soc. Esp. Hist. Nat. Sec. Biol.*, 107: 57-65. (in Spanish, with English summary) [The water body Ullal de Baldoví (Sueca, Valencia) is a priority habitat (Calcareous fens with *Cladium mariscus*, code 7210 of EU priority habitats) system located inside the Albufera Natural Park, composed of reduced surface but deep ponds, associated with subterranean springs. Its progressive reduction and degradation forced the regional government (Consellería de Infraestructuras, Territorio y Medio Ambiente) and the local council of the city of Sueca to start a restoration action that lasted until 2008. This restoration plan was concluded in the framework of a LIFE-Nature development project, "Recovering of a priority habitat in the Albufera Natural Park", known as "Proyecto Ullals" ("Spring pond project"). In the present study we provide a list of the aquatic invertebrates collected in Ullal de Baldoví (Sueca, Valencia) during 2007. This is an emblematic spring system with oligohaline waters, located inside the l'Albufera Natural Park. In total, 81 taxa were found distributed in 6 phyla, 24 orders and 57 families. These results were obtained from six sampling stations accounting for different environments in the Ullal, including a restored area. Three endemisms were found: *Melanopsis tricarinata* (Bruguière, 1789), an species endemic to the Iberian Peninsula, plus *Dugastella valentina* (Ferrer Galdiano, 1924) and *Palaemonetes zariquieyi* Sollaud, 1939 both with even more restricted distributions in the Valencian region. *Leptocheirus pilosus* Zaddach, 1844, an amphipod species belonging to the family Aoridae is reported for the first time in the region. Fifteen taxa belong to the class Ostracoda, two of which are considered invasive alien species (IAS): *Fabaeformiscandona subacuta* (Yang, 1982) and *Stenocypris major* (Baird, 1859). In the study carried out by Poquet et al. (2008) on the ostracods of shallow lakes in the Valencian Community, 6 species were found in the Ullal de Baldoví system during 2000. In comparison, just one of them, *Candonopsis scourfieldi* Brady, 1910, was not collected during the present survey. The limnological results indicate low variability in conductivity, salinity, chlorides and alkalinity in the Ullal (Tab. I). The recent restored part of the system has allowed the colonization of several new taxa into Ullal de Baldoví. When aiming at estimating the maximum biodiversity of an ecosystem, it is essential to carefully select a wide array of habitat types to be sampled, in order to maximize the expected number of taxa. In comparison to a previous survey carried out in 2000 (Sahuquillo et al., 2007) in the same system, the present survey is remarkable with regards to the notably higher number of taxa collected in the Ullal de Baldoví wa-

ter body. The importance of seasonal sampling campaigns is made clear to thoroughly characterise epicontinental aquatic systems, even when studying such a stable water body. Indeed, a monthly monitoring survey for one year would most probably uncover a higher faunistic richness of the system and would maximise its environmental value, a reason to remark the necessity for a preservation of this environment for the future generations." **15839.** Simon, S.; Hadrys, H. (2013): A comparative analysis of complete mitochondrial genomes among Hexapoda. *Molecular Phylogenetics and Evolution* 69(2): 393-403. (in English) ["With respect to bauplan radiation, species and taxa richness, hexapods have an unassailable lead. But still, the phylogenetic relationships among the orders and infraorders remain a matter of discussion. The rapidly increasing mitochondrial genome sequences from diverse insect species provide the opportunity to explore miscellaneous evolutionary questions in the superclass Hexapoda. A combined primary sequence analyses of the complete available data set has not yet been performed. Until now phylogenetic analyses of subsets of selected taxa resulted to strong supported topologies showing in some instances discrepancies between morphological and nuclear data. This circumstance started the discussion about the limits of complete mitochondrial genomes for inferring deep hexapod relationships. By using the hitherto densest taxon sampling of Hexapoda our analyses resulted in discrepancies to the current phylogenetic hypotheses based on morphological and nuclear data, e.g. monophyly of hexapods and some hexapods orders, e.g. Diptera, Hemiptera and Orthoptera. Nonetheless, compared to previously published studies that strongly support systematically erroneous groups using a sparse taxon sampling, our analyses had no support for these discrepancies. Consequently, we highly recommend interpreting mt-genome based phylogenies with reduced datasets particularly for hexapods with cautions although the inferred relationships are highly supported." (Authors)] Address: Hadrys, Heike, ITZ, Ecology & Evolution, TiHo Hannover, Bünteweg 17d, 30559, Hannover, Germany. E-mail: [heike.hadrys@ecolevol.de](mailto:heike.hadrys@ecolevol.de)

**15840.** Torralba Burrial, A.; Nores Quesada, C.I.; Armendariz, C. (2013): Evaluando la situación de la libélula amenazada *Oxygastra curtisii* (Odonata: Corduliidae) en Navarra (N Península Ibérica). *Biodiversidad florística vegetación Tamega IV Congreso de Biodiversidad: Pósters*: 190. (in Spanish) [Verbatim: About 23% of Iberian dragonflies are regionally threatened in Spain according to the Atlas and Red Book of Threatened Invertebrates in Spain. One of the few dragonflies that, in addition to being threatened, is included in the Habitats Directive and the Spanish Catalogue of Threatened Species is *Oxygastra curtisii*. Generally associated with rivers with backwater areas and alder groves (although it can be found in certain reservoirs and ponds), it has a fragmented distribution in the Iberian Peninsula. It has recently been found in Navarre, far from its main Iberian population centres. In this work, funded by the Government of Navarra through the

public company GANASA, we analyse the biodiversity of the fluvial communities of odonates in the Navarran part of the Bidasoa River, especially the distribution of *O. curtisii*. During the summer of 2012, three sampling campaigns were carried out, covering 20 stretches (about 200 m long), selected according to vegetation and hydromorphological criteria, in order to be able to extrapolate the situation of their populations to the entire Navarrese part of the river. The samplings also recorded the adult odonates found, but given the influence of the meteorological conditions on their detection, the exuviae samplings (almost 1,700 specimens identified) allowed a more accurate evaluation of the odonate communities. These consisted of *Onychogomphus uncatatus*, *O. forcipatus*, *Cordulegaster boltonii*, *Boyeria irene* and *O. curtisii*, for which quantitative data on population size and sex ratio were obtained, and ten other species, mostly Zygoptera, for which only qualitative or adult-based data could be obtained. *O. curtisii* maintains high populations in numerous stretches of the Bidasoa River, having identified the characteristics of the most favourable habitats for the species and those in which it is lacking. **15842.** Wesner, J.S. (2013): Fish predation alters benthic, but not emerging, insects across whole pools of an intermittent stream. *Freshwater Science* 32(2): 438-449. (in English) ["Predation effects in streams can cascade to terrestrial food webs through the flux of organisms that develop in the stream and emerge as adults to the terrestrial system. This emergence subsidizes some terrestrial predators, an effect that generally varies based on the magnitude of the subsidy. Factors regulating this magnitude are relatively well known, but factors regulating the trophic structure of the subsidy are not. I tested the hypothesis that predatory fish in natural stream pools alter the biomass and trophic structure (proportion of predatory adults) of emerging aquatic insects. I created a 13× gradient of predatory fish biomass (4 species of *Lepomis* sunfish and the minnow *Notropis boops*; within the range of natural variation) across 10 pools in Brier Creek, Oklahoma (USA). Pool area and substrate composition varied naturally, so I also measured their effect on insects. At the end of the experiment after the stream became intermittent, fish reduced benthic insect biomass but not emergence to the terrestrial habitat. The proportion of predatory insects emerging from pools was positively associated with pool area, but was unaffected by fish density. The best predictor of emergence biomass among pools on any date was the standing crop of benthic insects before fish manipulation, a result suggesting a time lag between measured benthic

standing crop in the stream and subsequent emergence. Fish manipulations occurred during the end of peak summer insect emergence, which may have limited my ability to detect fish effects on emergence. My study demonstrates that variation in the timing of predation may constrain the spatial scale of fish effects in aquatic and terrestrial food webs and suggests that pool size can influence the trophic structure of emerging aquatic insects." **15843.** Yu, J.; Wang, T.; Han, S.; Wang, P.; Zhang, Q.; Jiang, G. (2013): Distribution of polychlorinated biphenyls in an urban riparian zone affected by wastewater treatment plant effluent and the transfer to terrestrial compartment by invertebrates. *Science of The Total Environment* 463–464: 252–257. (in English) ["Highlights: •The distribution of PCBs in an urban riparian zone around a wastewater effluent affected river was investigated. •Relatively high abundances of PCB-11 and PCB-28 were found for most samples. •Mid-chlorinated congeners (PCB-153 and PCB-138) were more accumulated in chironomids and dragonflies as well as soil dwelling invertebrates. •Emerging invertebrates can carry waterborne PCBs to the terrestrial compartment. •The estimated annual flux of PCBs from emerging chironomids ranged from 0.66 to 265 ng m<sup>-2</sup> y<sup>-1</sup>. Abstract: In this study, we investigated the distribution of polychlorinated biphenyls (PCBs) in a riparian zone affected by the effluent from a wastewater treatment plant (WWTP). River water, sediment, aquatic invertebrates and samples from the surrounding terrestrial compartment such as soil, reed plants and several land based invertebrates were collected. A relatively narrow range of d13C values was found among most invertebrates (except butterflies, grasshoppers), indicating a similar energy source. The highest concentration of total PCBs was observed in zooplankton (151.1 ng/g lipid weight), and soil dwelling invertebrates showed higher concentrations than phytophagous insects at the riparian zone. The endobenthic oligochaete *Tubifex tubifex* (54.28 ng/g lw) might be a useful bioindicator of WWTP derived PCBs contamination. High bioaccumulation factors (BAFs) were observed in collected aquatic invertebrates, although the biota-sediment/soil accumulation factors (BSAF) remained relatively low. Emerging aquatic insects such as chironomids could carry waterborne PCBs to the terrestrial compartment via their lifecycles. The estimated annual flux of PCBs for chironomids ranged from 0.66 to 265 ng-m<sup>-2</sup> y<sup>-1</sup>. Although a high prevalence of PCB-11 and PCB-28 was found for most aquatic based samples in this riparian zone, the mid-chlorinated congeners (e.g. PCB-153 and PCB-138) became predominant among chironomids and dragonflies as well as soil dwelling invertebrates, which might suggest a selective biodriven transfer of different PCB congeners." **15849.** Clarke, D. (2014): The White-faced Darter (*Leucorrhinia dubia* Vander Linden) re-introduction project in Cumbria. *Journal of the British Dragonfly Society* 30(2): 54-78. (in English) ["*L. dubia* is a small dragonfly especially associated with bog-pools in peatlands. In England, there are only three areas (including one in Cumbria) where it has strong populations, most of its former sites having been lost due to habitat changes, mainly human-induced. A project in Cumbria aims to restore a population that once existed and was lost through afforestation in the mid 20th century. Approved by landowners and conservation bodies in 2008, an annual programme based on IUCN guidelines has been implemented from 2010 onwards to restore a colony at Cumbria Wildlife Trust's Foulshaw Moss Reserve near Morecambe Bay. The donor population, Scaleby Moss, is in north Cumbria. Translocation of larvae has been the main methodology, though experimentation with obtaining eggs began in 2013. Monitoring the populations at both sites, mainly by collecting exuviae at the breeding pools, has been the main measure for ensuring that the population at Scaleby Moss has not been adversely affected and for judging the efficacy of the translocations to Foulshaw Moss. Early years of the project were marred by poor summers but good numbers emerged at Foulshaw Moss in both 2013 and 2014, with clear evidence of on-site breeding. However, it is too soon to say

whether a sustainable colony has been established. The genetic diversity of the new population has yet to be assessed and a current University-based research study on the genetics of the species in the UK may prove helpful in this regard. The long-term management of the donor site remains a concern and reinforces the need for the current project, which will continue for several more seasons. A parallel re-introduction project in Cheshire commenced translocations in 2013." (Author)] Address: Clarke, D., Burnfoot, Cumwhitton, Brampton, Cumbria CA8 9EX, UK

(2014): Nouvelles observations de *Macromia splendens* en région Midi-Pyrénées (Odonata: Macromiidae). *Martinia* 30(2): 47-58. (in French, with English summary) ["*M. splendens* is an iconic dragonfly species of the European fauna. Endemic to South-West of the continent and recognized as vulnerable in its range, it is one of the species taken into account by the French national action plan for Odonata. In the Midi-Pyrénées administrative region (South-Western France), this species was known to reproduce on several rivers: Tarn, Aveyron, Lot and Célé. To improve knowledge of the geographical distribution of this species, targeted surveys were conducted by the Office pour les insectes et leur environnement de Midi-Pyrénées (Opie-MP) in 2012 and 2013, in partnership with the Ligue pour la protection des oiseaux du Tarn (LPO81). 140 exuviae and at least 15 adults were observed during these two years, which demonstrates the presence of the species on several portions of the Lot and Célé rivers and on a significant part of the Aveyron River and its main tributary, the Viaur. The species was found in its classical substitution habitats (dams, including those linked to old mills), but also in a surprising anthropogenic habitat (fishing pond). However, *M. splendens* could not be found on the Tarn River, between Saint-Rome-de-Tarn and Ambialet, where it was known until 2009." (Author)] Address: Delphon,

Gaël, 17 route de Foix, F-09400 Amplaing, France. E-mail: gael.delpon@yahoo.fr

**15854.** Döler, H.-P.; Ehret, S. (2014): Zur Verbreitung der Speer-Azurjungfer (*Coenagrion hastulatum*) auf der östlichen Schwäbischen Alb (Odonata: Coenagrionidae). *Mercuriale* 14: 13-26. (in German, with English summary) ["In contrast to the negative population trend on the national scale records of *C. hastulatum* on the Eastern Swabian Alb (Germany) have increased since 1986. In the investigation area, in 27 sites records of *C. hastulatum* have currently been confirmed (evidence 2010 to 2014). The standing waters in this area are so-called Hülben (pools of anthropogenic origin) and smaller ponds. Most have an acidic and dystrophic character on account of the specific soil conditions (decalcified loam). The accompanying odonate fauna shows 31 species. Among them are 9 species, which are on the Red List of Baden-Württemberg. The significant increase of records of *C. hastulatum* at waters that are monitored since 1986 suggests a possible link between this trend and both the creation of new small ponds (regionally specific waters called 'Hülben') and periodic maintenance measures for existing waters already begun in the early 1980s and still continued so far. In addition, it is very likely that the increase in search intensity since 2010 has contributed to this positive result." (Authors)] Address: Ehret, S., Seligerstr. 45, 89537 Giengen/ Brenz, Germany. **15855.** Dorji, T.; Thinley, K.; Jamstsho, S. (2014): Macroinvertebrate diversity in Threlpang and Kawajangsa freshwater streams in Bhutan. *BeBIO* 5(1): 1-5. ["... Despite the importance of freshwater biodiversity and macroinvertebrates as natural resources, the conservation threat assessment for macroinvertebrate in particular is limited throughout the world, and its study is at early stage in Bhutan. The current study describes the macroinvertebrate composition and diversity in two freshwater streams, viz., Threlpang and Kawajangsa streams located respectively in Trongsa and Thimphu districts of Bhutan. Macroinvertebrates were sampled in December 2011 (Threlpang) and 2012 (Kawajangsa) at two sampling reaches, upper less impaired and lower more impaired by human activities in both the streams. The study revealed total of 9 taxa within the study streams with 8 in Threlpang and 7 in Kawajangsa stream. Threlpang stream was dominated by Ephemero-

ptera (22.1%, n=19), followed by Plecoptera (20.9%, n=18), while Kawajangsa stream was dominated by Trichoptera (57.8%, n=122) followed by Diptera (15.6%, n=33). In both the streams macroinvertebrate composition changed from that of more pollution sensitive taxa in upper reaches to that of less pollution sensitive taxa in lower reaches." **15858.** Gauci, C. (2014): A review of the Odonata of the Maltese Islands. *Journal of the British Dragonfly Society* 30(2): 79-109. (in English) ["This paper is the result of five years of detailed observations of Odonata at several sites in the Maltese Islands. It updates the status and relative abundance of the various species. There is currently only one zygopteran *Ischnura genei* established on the Islands. *Calopteryx virgo* is considered a vagrant, while the occurrence of *C. haemorroidalis*, is considered to be highly doubtful. There are nine species of anisopterans which are established in the Islands, these being *Anax imperator*, *A. parthenope*, *Orthetrum cancellatum*, *O. coerulescens*, *O. trinacria*, *Sympetrum fonscolombii*, *Crocothemis erythraea*, *Trithemis annulata* and *Selysiothemis nigra*. Three more: *O. nitidinerve*, *O. chrysostigma* and *Pantala flavescens*, have recently been added to the Islands' list, while two – *O. brunneum* and *S. striolatum* – which were formerly considered common, are now very rare. *A. ephipigiger* is a fairly regular migrant, appearing in considerable numbers in some

years. *Aeshna mixta* is rare but might be on the verge of establishing itself on the Islands, following a recent spate of records, including ovipositing females. Various inaccuracies and conflicting statements appearing in previous contributions are corrected. Observations on behaviour are included where these are of special interest as well as where they are in contradiction of what has been stated in the literature." **15859.** Gerecke, R.; Marrone, F.; sorgi, G.; Dossena, M.; Stoch, F. (2014): The water mites (Acari: Hydrachnidia) of the standing waters of Corsica, Sardinia and Sicily: review and new data. *Italian Journal of Zoology* 81(3): 389-408. (in English) ["A compilation of our present knowledge of the water mites (Acari: Hydrachnidia) adapted to life in standing waters on the three large islands in the western Mediterranean (Corsica, Sardinia and Sicily) is provided. In addition to published data, this study deals with a rich volume of new material from recent field work, mostly deriving from intermittent ponds and pools, an extremely poorly investigated yet peculiar habitat type in the Mediterranean area. Species richness of water mites reported for the standing waters of the three islands amounts to 91 species. Out of the 47 species for which we present new distributional data, *Hydrachna incisa* Halbert, 1903, *Hydrachna leegei* Koenike, 1895, *Piersigia limophila* Protz, 1896, *Hydryphantes crassipalpis* Koenike, 1914 and *Piona laminata* (Thor, 1900) have not been recorded previously from the Mediterranean area. Most of these species were believed to have typical North European distributions. In addition to these, a further 13 species are recorded for the first time from the area covered. In total, 11 species are new for Italy, seven more are new for Sicily, three for Sardinia and seven for Corsica. Redescriptions are given of *Axonopsis complanata* (Müller, 1776) (*A. graeca*, nov. syn), *Brachypoda baderi* (reported for the first time after the original description from Abruzzo, Italy, synonymization with *B. mutila* rejected) and *B. mutila* (recorded for the first time outside Algeria with certainty). For each species, information is given on habitat preference and geographical distribution; the significance of the data is discussed under perspectives of zoogeography and nature protection. The completeness of our knowledge for the three investigated island is assessed using rarefaction curves and non-parametric estimators of species richness; while Sicily can be considered fairly well known, Corsica and Sardinia require further sampling to assess their water mite diversity." **15862.** Haro, R.J. (2014): All along the watchtower: Larval dragonflies are promising biological sentinels for monitoring methylmercury contamination. *Park Science* 31(1): 70-73. (in English) ["Humans have used other organisms to detect environmental danger for centuries (e.g., the canary in the coal mine). The use of "biosentinels" has developed and expanded to become a mainstay for monitoring environmental contaminants like methylmercury, a pervasive and largely anthropogenic neurotoxin. Biosentinels provide insights on how and where contaminants are entering and moving through aquatic food webs. Many water bodies in the Great Lakes region, including those in national park units, have fish-consumption advisories because of the atmospheric deposition of mercury and its conversion into methylmercury, which can biomagnify. For many years young yellow perch served as the principal biosentinel for monitoring methylmercury. Recent research shows that the diverse assemblage of dragonflies in this region can provide an additional suite of biosentinels, complementing the use of perch among water bodies with fish and expanding the reach of methylmercury monitoring to include fishless ecosystems (e.g., small ponds and wetlands)." **15863.** Kirby, D.; Kirby, M. (2014): Mixed pairing between Emerald Damselfly *Lestes sponsa* and Small Red Damselfly *Ceriagrion tenellum*. *Atropos* 52: 75. (in English) [Verbatim: Further to the observations of mixed pairings in *L. sponsa* reported by Pickess (2012) we wish to report another unusual pairing of damselflies. On 11-VII-2014 we visited Cors Caron, Ceredigion, on a sunny and warm day with a moderate breeze. At around 13.00hrs we noticed a

female *C. tenellum* f. *typica* paired with a male *L. sponsa*. We watched them for a few minutes as they remained in tandem but stayed low in the vegetation without any attempt to fly off or *L. sponsa* (♂) paired with *C. tenellum* (♀). I do not get the chance to see *C. tenellum* very often and had been hoping to see the species as Cors Caron is a known breeding site. To see one in these circumstances was particularly memorable, however. Reference: Pickess, B.P., 2012. Mixed pairings: are male Emerald Damselfly *Lestes sponsa* short-sighted or desperate? *Atropos* 12: 76-77.] Address: David & Meg Kirby, Hafodwen, Cae Melyn, Aberystwyth, Ceredigion, SY23 2HA, UK

**15864.** Klecka, J. (2014): The role of a water bug, *Sigara striata*, in freshwater food webs. *PeerJ* 2:e389; DOI 10.7717/peerj.389: 16 pp. (in English) ["Freshwater food webs are dominated by aquatic invertebrates whose trophic relationships are often poorly known. Here, I used laboratory experiments to study the role of a water bug, *Sigara striata*, as a potential predator and prey in food webs of stagnant waters. Multiple-choice predation experiment revealed that *Sigara*, which had been considered mostly herbivorous, also consumed larvae of *Chironomus* midges. Because they often occur in high densities and are among the most ubiquitous aquatic insects, *Sigara* water bugs may be important predators in fresh waters. A second experiment tested the role of *Sigara* as a potential prey for 13 common invertebrate predators. Mortality of *Sigara* inflicted by different predators varied widely, especially depending on body mass, foraging mode (ambush/searching) and feeding mode (chewing/suctorial) of the predators. *Sigara* was highly vulnerable to ambush predators, while searching predators caused on average 8.1 times lower mortality of *Sigara*. Additionally, suctorial predators consumed on average 6.6 times more *Sigara* individuals than chewing predators, which supports previous results hinting on potentially different predation pressures of these two types of predators on prey populations. The importance of these two foraging-related traits demonstrates the need to move from body mass based to multiple trait based descriptions of food web structure. Overall, the results suggests that detailed experimental studies of common but insufficiently known species can significantly enhance our understanding of food web structure." **15865.** Kok, J.M.; Chahl, J.S. (2014): Optimisation of a dragonfly-inspired flapping wing-actuation system. *International Journal of Mechanical, Aerospace, Industrial and Mechatronics Engineering* 8(9): 1459-1466. (in English) ["An optimisation method using both global and local optimisation is implemented to determine the flapping profile which will produce the most lift for an experimental wing-actuation system. The optimisation method is tested using a numerical quasi-steady analysis. Results of an optimised flapping profile show a 20% increase in lift generated as compared to flapping profiles obtained by high speed cinematography of a *Sympetrum frequens* dragonfly. Initial optimisation procedures showed 3166 objective function evalu-

ations. The global optimisation parameters - initial sample size and stage one sample size, were altered to reduce the number of function evaluations. Altering the stage one sample size had no significant effect. It was found that reducing the initial sample size to 400 would allow a reduction in computational effort to approximately 1500 function evaluations without compromising the global solvers ability to locate potential minima. To further reduce the optimisation effort required, we increase the local solver's convergence tolerance criterion. An increase in the tolerance from 0.02N to 0.05N decreased the number of function evaluations by another 20%. However, this potentially reduces the maximum obtainable lift by up to 0.025N." (Authors)] Address: Kok, J.M., School Engineering, Univ. South Australia, Mawson Lakes, South Australia, 5095, Australia

**15866.** Korkeamäki, E. (2014): Newly formed wetland pools for *Leucorrhinia pectoralis*: Monitoring results 2013. 13 pp. (in Finnish, with English summary) ["This article examines the factors that affect the colonization of Odonata in new habitats, especially newly formed wetland pools. Wetland pools were dug in Lintulahdet Life project to the shore areas to provide a suitable living environment for odonates. The special target species was *L. pectoralis*. The persistence of Odonata populations was studied by the monitoring with exuviae and adults. The monitoring in the years 2005-2008 and 2013 showed that *L. pectoralis* and many other dragonfly species inhabited the newly formed pools. Potential restoration managements are briefly discussed." (Author)] Address: Korkeamäki, E., Karkunkatu 18 a 4 b, 48600 Karhula, Finland.

**15867.** Kottawa-Arachchi, J.D.; Gamage, R.N.; Jayathilake, G.G. (2014): The role of different ecosystems to maintain odonate and butterfly diversity in Mattakelle Tea Estate, Sri Lanka. *Proceedings of the International Forestry and Environment Symposium 2014 of the Department of Forestry and Environmental Science, University of Sri Jayawardenepura, Sri Lanka*: 133-134. (in English) [Verbatim: A survey on dragonfly and butterfly was conducted at Mattakelle Tea Estate with the objective of assessing the significance of a given tea plantation ecosystem in maintaining dragonfly and butterfly diversity. Odonate and butterfly communities of selected different habitats (seasonal stream, home gardens, small reservoir, Eucalyptus plantation, tea field, marshy land and secondary forest) assessed using line transect method. Dragonfly and butterfly counts were made along two 100 m x 10 m line transects and 30 minutes were spent at each habitat starting from 6.30 – 7.00 am in the morning and same methodology was repeated in all habitats. Other ecological parameters such as air and water temperatures, %RH, pH and EC were also recorded. The intensity of observations was 8 days per month. During two months sampling, 13 species of Odonata and 46 species of butterflies were recorded. Interestingly, 7 dragonfly and 8 butterfly species are in the national threatened category. Present study indicated that small scale reservoir and marshy land habitats maintain the highest dragonfly diversity recording 10 and 8 species where Shannon index (H) = 2.17 and 2.01, respectively. Conversely, home garden and secondary forest habitats recorded significant butterfly diversity with 33 and 32 species

where (H) = 3.31 and 3.28, respectively. This can be explain, as the home garden and secondary forest habitats are well-structured with more plant species that provide feeding and nectarine plants for butterflies. Continuous water supply and water quality may support to maintain highest dragonfly diversity in small reservoir and marshy land habitats. Water sources in home garden and secondary forest have been dried in study period therefore dragonfly diversity was relatively low. Some of the recorded odonate taxa can be used as reliable indicators of ecosystem health. Vegetation structure and the complexity of the ecosystem in tea plantations play a vital role in sustaining odonate and butterfly fauna. Several conservation measures such as increasing plant diversity, introduction of shade trees, feeding and nectarine plants and conduct of good agricultural practices are recommended to protect and conserve odonate and butterfly diversity.] Address: Kottawa-Arachchi, J.D., Hill-Country Environment Association, Tea Research Institute, Talawakelle, Sri Lanka. **15873.** Nicolai, B.; Mammen, K. (2014): Zum Vorkommen der Libellen bei Halberstadt (Nordharzvorland) und die Phänologie von *Coenagrion mercuriale* und *Orthetrum coerulescens* (Odonata). *Abhandlungen und Berichte aus dem Museum Heineanum* 10: 93-112. (in German, with English summary) ["From 2008 to 2014, the dragonfly fauna was observed in a small area near Halberstadt (Sauteichsgraben/ Goldbach/retention basins). A total of 35 species were recorded, with 21 species can be considered as indigenous (at least once mating flights, egg oviposition or newly emerged odonates were found). For the species *C. mercuriale*, *O. coerulescens* and *O. brunneum* data for phenology and biology are given. The presence was noted in detail in *C. mercuriale* (19.05.-10.08.), *O. coerulescens* ([27.05.]02.06.-28.08.) and *O. brunneum* (02.06.-10.08.). Species richness, occurrence of some species mentioned in the Red List of endangered odonates and the outstanding occurrence of the FFH-spe-

cies *C. mercuriale* show the large nature conservation importance of the area. Measures for protection and management of the area were already proposed by NICOLAI & MAMMEN (2009). On their necessity and consistent implementation are explicitly stated." (Authors)] Address: Nicolai, B., Museum Heineanum, Domplatz 36, 38820 Halberstadt, Germany. E-mail: nicolai@halberstadt.de

**15874.** Nieoczym, M.; Kloskowski, J. (2014): Responses of epibenthic and nektonic macroinvertebrate communities to a gradient of fish size in ponds. *Journal of limnology* 74(1): 50-62. (in English) ["Size relationships between fish and organisms from adjacent trophic levels are crucial for predicting the structure and dynamics of aquatic ecosystems. We compared macroinvertebrate communities along a fish-size gradient created by separate stocking of three age cohorts of common carp *Cyprinus carpio* in semi-natural ponds. The specific size range of fish (small, medium and large) corresponding to fish age in ponds was the factor most strongly associated with macroinvertebrate composition. The other significant habitat variables were dissolved oxygen concentration in the water and submerged vegetation abundance in the open-water zone. Among the most numerous taxa in the ponds, relative abundances of Hirudinea, Gastropoda, Odonata and Coleoptera were larger in the presence of small-sized than of larger-sized carp. However, fish size effect was not linear, in that macroinvertebrate assemblages were less similar between ponds containing medium- vs large-sized fish than between ponds with small- vs. large-sized fish. The dissimilarity patterns were mainly determined by disparities in abundance of Corixidae, which unlike other taxa common in the ponds occurred in the greatest numbers in the presence of large-sized carp. Macroinvertebrate diversity was greatest in ponds with small-sized fish and was positively related to emergent macrophyte cover. Enhancement of emergent vegetation is recommended as the most effective management strategy to buffer adverse impacts of fish on macroinvertebrates. If fish are present in the system, assessment of the size structure of fish populations can be advantageous in unravelling the essential processes driving the variation in pond communities." **15875.** Ohtaka, A.; Uenishi, M.; Wulandari, L.; Liwat, Y.; Ardianor; Gumiri, S.; Nagasaka, M.; Fukuhara, H. (2014): Structure and abundance of "interrhizon" invertebrates in an oxbow lake in the peat swamp area of Central Kalimantan, Indonesia. *Limnology* 15(2): 191-197. (in English) ["The faunal composition of "interrhizon" invertebrate communities associated with submerged parts of three kinds of macrophytes, *Eichhornia crassipes*, Gramineae spp. and *Polygonum tomentosum*, were studied in an oxbow lake, Lake Tundai, with acidic water (pH 3.9-4.4) in the peat swamp area of Central Kalimantan. The pH, turbidity, and chlorophyll-a concentration in the surface waters tended to be higher in macrophyte stands than in open waters near the stands. Thirty-one taxa belonging to three groups of invertebrates, Arachnida, Insecta, especially chironomids, and Isopoda, were found from the root systems, of which

insects were the most abundant in every macrophyte stand. The interrhizon invertebrates accounted for 0.16-8.7 g wet wt m<sup>-2</sup> among three vegetational stands. The diversity and abundance of interrhizon invertebrates are low in Lake Tundai; this could be due to low pH and/or low productivity in the lake water ... Odonata. Coenagrionidae gen. sp. - ... Libellulidae gen. sp.]" (Authors): Address: Ohtaka, A., Faculty of Education, Hirosaki University, Hirosaki, Aomori, 036-8560, Japan. E-mail: ohtaka@cc.hirosaki-u.ac.jp

**15876.** Parr, A.J. (2014): Migrant and dispersive dragonflies in Britain during 2012 and 2013. *Journal of the British Dragonfly Society* 30(2): 110-124. (in English) ["The years 2012 and 2013 were quite eventful for migrant and dispersive species in Britain. *Sympetrum fonscolombii* in particular appeared in good numbers during both years, though local breeding was more noticeable during 2012. After record-breaking appearances of *Anax ephippiger* during 2011, another major influx was also noted during autumn 2013. *A. parthenope*, by contrast, had a poor year in 2013, though appearances in the preceding year had been at above-average levels. Species such as *S. danae* and *Ischnura pumilio* showed some notable migratory movements during the period, and rarer migrants similarly produced a number of highlights. The second and third British records of *Leucorrhinia pectoralis* were, for instance, made in coastal Suffolk during late spring 2012, whilst a single *Sympetrum vulgatum* was noted in Kent during autumn 2013. Recent colonist species also fared well during the reporting period, with *Lestes barbarus*, *Coenagrion scitulum* and *Aeshna affinis* all holding their own. Populations of *Chalcolestes viridis* continued to strengthen, and some range expansion was noted, particularly in East Anglia. In addition to these newcomers, regular records of *Anaciaeschna isocetes* from the Westbere region of East Kent hint at the presence of a newly-established population of the species that might well be of immigrant origin (another, confirmed, new population at Paxton Pits, Cambridgeshire, is more likely to be of local derivation)." **15877.** Rafay, M.; Hussain, T.; Ruby, T.; Rehman, F.; Ahmad, I.; Abdullah, M. (2014): Role of weeds in creating Agro Ecological stability. *Pak. J. Agri. Sci.* 51(3): 531-538. (in English) ["We devised a study to ascertain the role of weeds in agro-ecosystem. Therefore, we made seasonal cataloguing of the line data on multiple crops i.e., sugarcane, fodder, wheat and mustard to see crops' viability and role of weeds' diversity in preventing insect outbreaks by reducing crop productivity losses. We found that out of fifteen weed species, 11 weed species were of broad-leaved category while four were of pointed-leaves. The arthropod-fauna included insect pest-species from Orthoptera, Hemiptera and Lepidoptera that used weeds as priority food. Besides that, some specific zoophagous insect-predators belonging to orders Odonata (*Lestes* sp.), Coleoptera, Hymenoptera and Araneae were documented on similar weeds, for food, shelter and egg-laying. In the light of our observations, we concluded that there is a significant role of weeds in a crop-system that may support other essential life forms in creating ecological balance." (Authors)] Ad-

**15878.** Rees, H.C.; Maddisonm, B.C.; Middleditch, D.J.; Patmore, J.R.M.; Gough, K.C. (2014): The detection of aquatic animal species using environmental DNA – a review of eDNA as a survey tool in ecology. *Journal of Applied Ecology* 51(5): 1450-1459. (in English) ["(1) Knowledge of species distribution is critical to ecological management and conservation biology. Effective management requires the detection of populations, which can sometimes be at low densities and is usually based on visual detection and counting. Recently, there has been considerable interest in the detection of short species-specific environmental DNA (eDNA) fragments to allow aquatic species monitoring within different environments due to the potential of greater sensitivity over traditional survey methods which can be time-consuming and costly. (2) Environmental DNA analysis is increasingly being used in the detection of rare or invasive species and has also been applied to eDNA persistence studies and estimations of species biomass and distribution. When combined with next-generation sequencing methods, it has been demonstrated that entire faunas can be identified. (3) Different environments require different sampling methodologies, but there remain areas where laboratory methodologies could be standardized to allow results to be compared across studies. (4) Synthesis and applications. We review recently published studies that use eDNA to monitor aquatic populations, discuss the methodologies used and the application of eDNA analysis as a survey tool in ecology. We include innovative ideas for how eDNA can be used for conservation and management citing test cases, for instance, the potential for on-site analyses, including the application of eDNA analysis to carbon nanotube platforms or laser transmission spectroscopy to facilitate rapid on-site detections. The use of eDNA monitoring is already being adopted in the UK for ecological surveys." (Authors)] Address: Rees, Helen, ADAS UK Ltd, School of Veterinary Medicine & Science, Univ. Most of the cases which concern an accidental capture refer to plants. Here, we are dealing with a male of *E. viridulum* who had a

leg accidentally trapped by a sticky batch of eggs of *L. depressa*. The male finally got free and flew off. To our knowledge, this kind of capture is published for the first time.] Address: Ruffoni, A., Maison du Parc, 58230 Saint-Brisson, France. E-mail: shna.ruffoni@orange.fr

**15881.** Saha, N.; Aditya, G.; Saha, G.K. (2014): Prey preferences of aquatic insects: potential implications for the regulation of wetland mosquitoes. *Medical and Veterinary Entomology* 28(1): 1-9. (in English) ["Wetlands are potential sites for mosquito breeding and are thus important in the context of public health. The use of chemical and microbial controls is constrained in wetlands in view of their potential impact on the diverse biota. Biological control using generalist aquatic insects can be effective, provided a preference for mosquito larvae is exhibited. The mosquito prey preferences of water bugs and larvae of odonate species were evaluated using chironomid larvae, fish fingerlings and tadpoles as alternative prey. Manly's selectivity ( $a_i$ ) values with 95% confidence intervals (CIs) were estimated to judge prey preference patterns. Multivariate analysis of variance (manova) and standardized canonical coefficients were used to test the effects of density on prey selectivity. The  $a_i$  values indicated a significant preference ( $P < 0.05$ ) in all of the insect predators tested for mosquito larvae over the alternative prey as a density-dependent function. On a comparative scale, chironomid larvae had the highest impact as alternative prey. In a multiple-prey experiment, predators showed a similar pattern of preference for mosquito larvae over alternative prey, reflecting a significant ( $P < 0.05$ ) niche overlap. The results suggest that, in a laboratory setting, these insect predators can effectively reduce mosquito density in the presence of multiple alternative prey... and the larvae of the odonate species *Brachydiplax chalybea chalybea*..."] (Authors) Address: Saha, Nabaneeta, Dept of Zoology, University of Calcutta, 35 Ballygunge Circular Road, Kolkata 700019, India. **15885.** Tsubaki, Y. (2014): Forest light environment as the cradle or forest biodiversity: thermal ecology of *Mnais* damselflies. *Tombo* 56: 49-56. (in Japanese, with English summary) ["Forests have a complex mosaic of light environments that differ in color and brightness as well as a mosaic of thermal environments that differ between shade and light. In this paper, I review studies on habitat selection and reproductive behavior of forest-dwelling damselflies (*Mnais costalis* and *M. pruinosa*) in response to forest light environments. Measurement of canopy openness in a forest habitat in Kinki district, where two species coexist, revealed that *M. costalis* preferred sunny habitats while *M. pruinosa* preferred shady habitats. Species-specific differences in physiological responses to abiotic factors of habitats have been suggested to cause habitat segregation. Our observations on reproductive behavior suggests that habitat thermal condition is an important factor for habitat selection in *Mnais* damselflies, because thermal conditions strongly influence the degree to which *Mnais* can perform physiological and behavioral activities, and this will therefore influence fitness. Copulation success of males in relation to insolation conditions of territorial sites was shown that *M. costalis* males were successful at sunny territorial sites. This was partly because males at sunny sites have higher body temperatures and are able to perform intensive courtship displays toward females. In contrast, mating success of *M. pruinosa* males was not influenced by the insolation condition at territorial sites, probably because males of this species do not show any courtship display. Human-induced forest disturbance alters the geometry of forests, and will significantly affect all the components of fitness that depend on light for both animals and plants. We need detailed knowledge of forest-dwelling species in its natural light environment in order to understand what goes wrong when its habitat is disturbed." (Author)] Address: E-mail: mnais.pruinosa@me.com

**15886.** Van Buskirk, J. (2014): Incipient habitat race formation in an amphibian. *Journal of Evolutionary Biology* 27(3): 585-592. (in English) ["Theory defines conditions under which sympatric speciation may occur, and several possible examples of the process in action have been identified. In most cases, organisms specialize onto habitats that fall into discrete categories, such as host species used by herbivores and parasites. Ecological specialization within a continuous habitat gradient is theoretically possible, but becomes less likely with increasing gene flow among clinal habitat types. Here, I show that habitat race formation is underway in a frog, *Rana temporaria*, along a continuous and spatially mosaic habitat gradient. Tadpoles from 23 populations raised in an outdoor mesocosm experiment showed adaptive phenotypic variation correlated with the predator density in their pond of origin. A survey of microsatellite markers in 48 populations found that neutral genetic divergence was enhanced between ponds with very different densities of predators. This represents a new example of habitat specialization along a continuous habitat gradient with no spatial autocorrelation in habitat." **15888.** Vince, A.; Bodor, T.; Jakab, T.; Miskolczi, M.; Devai, G. (2014): Data on the dragonfly (Odonata) fauna of the small water courses in the landscape Dél-Nyírség (NE-Hungary). *Studia odonatol. hung.* 16: 67-79. (in Hungarian, with English summary) ["The authors present faunistic data on dragonflies collected (larvae, exuviae and adults) and observed (adults) from the small water courses in the lowland area of the geographical region Dél-Nyírség (NE-Hungary). Firstly the authors offer a brief survey of the faunistic results of the odonatological researches carried out up till now in the ET 56 UTM grid map cell. Secondly they present the methods employed in the collection of specimens and in data processing, and introduce the literature they have considered in the identification of species and in reporting faunistic data. Finally they provide a detailed survey of the collection and observation results from the area and summarize and evaluate the data on the dragonfly fauna. Collections were made in one year (2013), with the participation of four specialists on 25 days and six localities altogether, in one cell (ET 56) of the 10×10 km UTM grid map. In the report, information on 336 specimens (220 males, 112 females, 4 specimens with undecided sex) are given in detail [19 larvae (8 males, 9 females, 2 with undecided sex), 103 exuviae (61 males, 40

females, 2 with undecided sex), 214 adults (151 males, 63 females)], with the observed adults representing altogether 224 faunistical data (16 larvae, 30 exuviae, 171 collected and 7 observed adults). In this study 29 species (14 Zygoptera and 15 Anisoptera) were found to occur in the area, out of which 1 belongs to the very frequent, 14 to the frequent, 9 to the less frequent, 3 to the rare and 2 to the sporadic class of country-wide occurrence frequency." **15890.** Wong, W.H.; Tay, Y.C.; Puniamoorthy, J.; Balke, M.; Cranston, P.S.; Meier, R. (2014): "Direct PCR" optimization yields a rapid, cost-effective, non-destructive, and efficient method for obtaining DNA barcodes without DNA extraction. *Molecular Ecology Resources* 14(6): 1271-1280. (in English) ["Macroinvertebrates that are collected in large numbers pose major problems in basic and applied biodiversity research: identification to species via morphology is often difficult, slow and/or expensive. DNA barcodes are an attractive alternative or complementary source of information. Unfortunately, obtaining DNA barcodes from specimens requires many steps and thus time and money. Here, we promote a short cut to DNA barcoding, that is, a nondestructive PCR method that skips DNA extraction ('direct PCR') and that can be used for a broad range of invertebrate taxa. We demonstrate how direct PCR can be optimized for the larvae and adults of nonbiting midges (Diptera: Chironomidae), a typical invertebrate group that is abundant, contains important bioindicator species, but is difficult to identify based on morphological features. After optimization, direct PCR yields high PCR success rates (>90%), preserves delicate morphological features (e.g. details of genitalia, and larval head capsules) while allowing for the recovery of genomic DNA. We also document that direct PCR can be successfully optimized for a wide range of other invertebrate taxa that need routine barcoding (flies: Culicidae, Drosophilidae, Dolichopodidae, Sepsidae; sea stars: Oreasteridae). Key for obtaining high PCR success rates is optimizing (i) tissue quantity, (ii) body part, (iii) primer pair and (iv) type of Taq polymerase. Unfortunately, not all invertebrates appear suitable because direct PCR has low success rates for other taxa that were tested (e.g. Coleoptera: Dytiscidae, Copepoda, Hymenoptera: Formicidae and Odonata). It appears that the technique is less successful for heavily sclerotized insects and/or those with many exocrine glands." (Authors)] Address: Wong, W.H., Dept of Biological Sciences, National Univ. of Singapore, 14 Science Drive 4, Singapore, 117543, Singapore

**15891.** Xu, M.; Wang, Z.; Pan, B.; Yu, G. (2014): The assemblage characteristics of benthic macroinvertebrates in the Yalutsangpo River, the highest major river in the world. *Frontiers of Earth Science* 8(3): 351-361. (in English) ["Aquatic ecosystems of highland rivers are different from those of low altitude rivers because of the specific topography and environmental parameters associated with high altitudes. Yalutsangpo, the upper course of the Brahmaputra River, is the highest major river in the world, flowing from west to east across Tibet, China and pouring into India. Macroinvertebrates were sampled from Yalutsangpo and its tributaries, the Lhasa, Niyang, and Parlong Tsangpo Rivers, from October 2009 to June 2010, to study characters of the highland aquatic ecosystem. Altogether, 110 macroinvertebrate taxa belonging to 57 families and 102 genera were identified from the basin. The biodiversity and composition of macroinvertebrate assemblages were strongly affected by altitude gradients. Local diversity represented by taxa richness and the improved Shannon-Wiener index were high at altitudes of 3,300–3,700 m, among which suitability of habitat was higher due to the better integrated environmental conditions of water temperature, dissolved oxygen, and aquatic vegetation, etc.

Macroinvertebrates were grouped into shredders, scrapers, predators, collector-filterers, and collector-gatherers according to their feeding behaviors. It was found that the distributions of the functional feeding groups varied with habitat altitudes. Shredders were present at altitudes of 2,900–4,400 m, while scrapers mainly inhabited altitudes of 3,500–4,500 m, and collector-filterers preferred 3,500–4,000 m. Even though the local taxa richness was not high at each site, the taxonomic composition and density of the assemblages varied greatly among the different sites, resulting in much higher regional diversity compared to the lowland river with similar flow and substrate conditions. The regional cumulative taxa richness of Yalutsangpo decreased and more families were lost as the altitude increased. However, some families that were newly present as the altitude increased were essential for sustaining the high regional biodiversity. The ordination diagram obtained from Detrended Correspondence Analysis indicated that altitude, river pattern, riverbed structures, bank structures, and flow conditions were the main factors that influenced the macroinvertebrate assemblages in the Yalutsangpo basin." **15893.** Zhao, Y.; Wang, D.; Tong, J.; Sun, Ji Y.; Zhang, J. (2014): Statics analysis of dragonfly wing based on finite element model. *Journal of Agricultural Engineering* 30(15): 33-38. (in Chinese, with English summary) ["A dragonfly can hover, flap its wings for flight and fly vertically for a short distance. The membranous wings of a dragonfly have a high load-bearing capacity for static and dynamic load during flight. The mass of the wings of a dragonfly is only 1%-2% of its whole body but the wings can stabilize its body. The statics properties of biomimetic models were researched. The finite element software ANSYS was used to simulate the dragonfly wing. The veins were simulated by pipe20 with two nodes and the membranes by shell43 with four nodes. The influence of geometrical nonlinearity was taken into account but material nonlinearity. The models

were assumed in the elastic range. The three-dimensional model of the dragonfly wing was reconstructed using reverse engineering software Imageware. The veins of dragonfly wing were drawn with AutoCAD and the membranes were added with ANSYS. The finite element models imitating the dragonfly wing were established by using free meshing. The finite element models of the dragonfly wing were simulated with structural statics. The deformation, the stress and the strain of the models under loads were analyzed respectively. The loads include the uniform load, the bending moment and the torque. Under the uniform load, the deformation of the finite element model imitating a dragonfly wing is very small, and increases gradually from the base to the wing tip. The base of the model bears heavy stress, the middle parts smaller, and the wing tip the least. The strain shows a radial pattern along the longitudinal veins, and reduces gradually from the base to the wing tip of the model. Under the bending moment, the deformation and the rotation angle around y axis increase gradually from the base to the wing tip of the model. The heavy stress and strain are mainly concentrated on the base of the model. The small stress and strain are acted on the middle parts and the wing tip. The distribution trend of the stress and strain is in substantial agreement. Under the torque, the finite element model imitating a dragonfly wing deforms only a little as a whole. The heavy deformation is mainly concentrated on the leading edges and the rear edges of the model. The smaller deformation is acted on the middle parts and the least deformation on the base. The maximum stress and strain occur at the middle parts of the model. The minimum stress and strain occur at the base of the model. The dragonfly wing is a two-dimensional truss structure with excellent rigidity. The dragonfly wing deforms only a little under loads. It is shown that the grid structures of the dragonfly wing deforming together at the boundaries of veins and membranes have excellent integrity. The understanding of dragonfly wings' characteristics provides some reference for improving the properties of two-dimensional composite materials through biomimetic designs." **15894.** Zhu, J.Y.; Zhou, C.Y. (2014): Aerodynamic performance of a two-dimensional flapping wing in asymmetric stroke. *Proceedings of the Institution of Mechanical Engineers, Part G: Journal of Aerospace Engineering* 228(5): 641-651. (in English) ["A numerical study on the aerodynamic performance of a two-dimensional flapping wing in asymmetric stroke in hovering and forward flight is carried out. The effect of the asymmetry of the stroke on aerodynamic forces and flow structures of the wing is analyzed. It is found that for hovering flight appropriate asymmetric stroke can enhance the aerodynamic performance of the wing at low Reynolds number, but it may not be functioning at moderate and high Reynolds numbers. For forward flight the asymmetric stroke does not increase the lifting efficiency and propulsive efficiency of the wing simultaneously. However, it influences the time history of the aerodynamic force significantly, which may enhance the flight maneuverability of the wing. The present results provide physical insight into the understanding of aerodynamics

and flow structures of insect flight with asymmetric stroke." (Authors)] Address: Zhou, C.Y., Dept Mechanical Engineering & Automation, Harbin Institute of Technology Shenzhen Graduate School, Shenzhen, People's Republic of China. E-mail: cyzhou@hit.edu.cn

**15896.** Azam, I.; Afsheen, S.; Zia, A.; Javed, M.; Saeed, R.; Sarwar, M.K.; Munir, B. (2015): Evaluating insects as bioindicators of heavy metal contamination and accumulation near industrial area of Gujrat, Pakistan. BioMed Research International Volume 2015, Article ID 94275: 11 pp. (in English) ["To study the accumulation and contamination of heavy metals (i.e., Cd, Cr, Cu, Ni, and Zn) in soil, air, and water, few insect species were assayed as ecological indicators. Study area comes under industrial zone of district Gujrat of Punjab, Pakistan. Insects used as bioindicators included a libellulid dragonfly (*Crocothemis servilia*), an acridid grasshopper (*Oxya hyla hyla*), and a nymphalid butterfly (*Danaus chrysippus*) near industrial zone of Gujrat. Accumulation of Cd was highest in insect species followed by Cu, Cr, Zn, and Ni. Hierarchical cluster analysis (HACA) was carried out to study metal accumulation level in all insects. Correlation and regression analysis confirmed HACA observations and declared concentration of heavy metals above permissible limits. Metal concentrations in insects were significantly higher near industries and nal-lahs in Gujrat and relatively higher concentrations of metals were found in Orthoptera than Odonata and Lepidoptera. The total metal concentrations in insects were pointed significantly higher at sites S3 (Mid of HalsiNala), S9 (End of HalsiNala), and S1 (Start of HalsiNala), whereas lowest value was detected at site S6 (Kalra Khasa) located far from industrial area. HACA indicates that these insect groups are potential indicators of metal contamination and can be used in biomonitoring." **15897.** Bailowitz, R.; Danforth, D.; Upson, S. (2015): A Field Guide to the Damselflies and Dragonflies of Arizona & Sonora. Nova Granada Publications: 459 pp. (in English) ["An identification guide for all 167 known species of Odonata of the states of Arizona (USA) and Sonora (Mexico). ... Species accounts begin with the common name approved by the Checklist Committee of the Dragonfly Society of the Americas. Species accounts are organized alphabetically by the scientific (Latin) species name which follows the common name. Each family is divided into genera listed alphabetically. An entry for each genus presents pertinent information concerning important characteristics, distribution, and genera and species numbers. General information includes the habits and habitats of the species, noteworthy or singular behaviors, and selected information of historical or biological import. Field marks are indicated in

bulleted, telegraphic style. For every species, information is presented in a set sequence beginning with the insect's total body length in millimeters. Next, characteristics are cited for the male, from the front of the insect progressing to the abdomen and appendages. Female characters follow. The most important characteristics are in bold print. Descriptions of species in this book are based on populations found in the region covered by this book. The information may or may not apply in other areas of the species' range.]

**15898.** Baltus, H. (2015): Le project LIFE Lomme contribue au developpement des populations de libellules en Haute-Lesse et Haute-Lomme. Les Naturalistes beiges 96(3-4): 37-56. (in French, with English summary) ["From 2010 to 2014, the LIFE Lomme Project has made major restorations of peatlands, meadows and forests. Among these habitats, many ponds have been created and many rivers have become favourable for dragonflies. Standardized surveys based on reliable bioindicators such as dragonflies have been started at the implementation of the project. The number of dragonfly species in the restored sites increased from 21 species in 2009 before the project to 33 species in 2014. Several common dragonflies have already significantly expanded their range and new species appeared. Some specialist species have also shown a rapid growth but others have not yet responded. This clear positive response of dragonflies is clearly due to restorations but also increasing sampling effort as a result of the project implementation." (in English) ["An Odonata survey on downstream of Sone River was conducted in the surrounding of Bansagar dam in Madhya Pradesh from December, 2014 to November, 2015. The purpose of this one year investigation was to provide information on the diversity and abundance of Odonata. The study revealed that in catchments of river Sone, 22 species of 6 families under 2 sub orders of Odonata were encountered where family Libellulidae was the most diverse with 10 species in contrast to local reference sites of river. The increase of

Odonata in the surrounding of river throughout the study period was best highlighted by the presence of biological pollution indicator species." (Authors)] Address: Bhandari, R., Dept of Zool., Govt. O.F.K. College, Jabalpur (M.P), India

**15901.** Bichuette, M.E.; Gallao, J.E.; von Schimonsky, D.M.; Trajano, E. (2015): Subterranean aquatic fauna of Tapagem Cave, a study in the touristic stretch. ANAIS do 33º Congresso Brasileiro de Espeleologia: 103-108. (in Portuguese, with English summary) ["Studies conducted since the 1970s in Brazil, involving cave fauna until some recent studies, contributed to knowledge mainly to the inventory and ecological-evolutionary categorization. However, the development of Speleological Management Plans of the Vale do Ribeira, which includes the Parque Estadual da Cavema do Diabo (PECD), it achieved a more precise level regarding the location of fauna inside the cave, including the aquatic cave fauna. During an annual cycle, a touristic stretch of Rio das Ostras was sampled inside the cave, which is extremely altered. The aquatic fauna was sampled using Surber traps. The collected fauna was analyzed in the Subterranean Studies Laboratory and 24 species was recorded in the cave, some of which are water quality indicator, exceeding the number of species in previous works (16). Using this data, we conducted an ecosystem analysis to detect weaknesses related to aquatic habitat. Therefore, this study was the basis to the Speleological Management Plan of Tapagem cave and we propose the water monitoring of this cave to assess and minimize the impacts." **15905.** Chovanec, A.; Waringer, J. (2015): Colonization of a 3rd order stream by dragonflies (Insecta: Odonata) – a best practice example of river restoration evaluated by the Dragonfly Association Index (lower Weidenbach, eastern Austria). Acta Zoo. Bot. Austria 152: 89-105. (in English, with German summary) ["Restoration measures implemented on the lower section of a third order stream (Weidenbach, eastern lowlands of Austria) were assessed by carrying out a dragonfly survey. As required under the European Water Framework Directive the assessment was based on a comparison between a river type-specific, near-pristine reference situation and the actual status quo. As a result of large-scale river regulation, there were no natural sections of the river left. Therefore, the ecological requirements of dragonfly associations were correlated with river type-specific features for deriving type-specific communities. Twenty-six breeding species belonging to all six type-specific dragonfly associations were recorded. Applying the Dragonfly Association Index, the restored river section was allocated to class I ("high ecological status"), which corresponds to the reference situation and underlines the success of the implemented restoration measures. These measures were focused on increasing the sinuosity of the river and the in-stream habitat heterogeneity (e.g. by river widening and by creating meanders) and on improving the lateral connectivity in the river system (e.g. by creating backwaters). The results of the study emphasize the necessity of implementing type-specific restoration as a basis for the colonization by a dragonfly fauna characteristic for the river." **15912.** Gallesi, M.M.; Sacchia, R.; Hardersen, S. (2015): Does wing shape of andromorph females of *Calopteryx splendens* (Harris, 1780) resemble that of males? *International Journal of Odonatology* 18(4): 305-315. (in English) ["Female limited polymorphism consists in the coexistence of two or more female morphs in the same population and is widespread among odonates. Generally, one female morph, the andromorph, resembles males in colour or, sometimes, also in morphology and behaviour, while one or more other morphs, gynomorphs, differ from males. This phenomenon is probably promoted by advantages to females which arise from reduced sexual harassment. Andromorph

females of *C. splendens* keep wing spots, like males (although these ornaments do not match exactly male wing spot colour), while gynomorphs have hyaline wings. Males and gynomorphs show a marked sexual dimorphism in wing shape, and this determines flight patterns which differ between sexes. If andromorphs mimic male wing spots to avoid harassment, they may also benefit from mimicking the male flight morphology, and consequently the male flight pattern. In this case wing shape of andromorph and gynomorph females would differ, as the wing shape of andromorphs resembles that of males. In this study we compared the wing morphology of males and of the two female morphs of *C. splendens* using geometric morphometrics. Our results revealed that andromorphs and gynomorphs of this species share the same wing shape, size, and static allometry, and this suggests that flight patterns should also be shared by the two morphs. Thus, females might avoid male harassment by mimicking exclusively male wing pigmentation (male mimicry hypothesis), or confound males through an uncommon appearance (learned mate recognition hypothesis)." **15918.** Hamidan, N.; Jackson, M.C.; Britton, J.R. (2015): Diet and trophic niche of the endangered fish *Garra ghorensis* in three Jordanian populations. *Ecology of Freshwater Fish* 25(3): 455-464. (in English) ["*G. ghorensis* is a small riverine cyprinid fish endemic to the southern Dead Sea that is endangered through habitat loss and invasive species. Here, their diet and trophic niche were assessed in three Jordanian populations: an allopatric population, a population sympatric with native *Capoeta damascina* and a population sympatric with invasive *Oreochromis aureus*. Stomach content analyses of samples collected between February 2011 and January 2012 revealed that detritus and algae were prominent food items in their diets, with low dietary contributions of animal material. The most frequent and abundant macro-invertebrates in intestines were Odonata nymphs and gastropod species. The calculation of trophic niche size from the stomach content data revealed that the niche of *G. ghorensis* (0.10) was gener-

ally smaller than sympatric *C. damascina* (0.24), with an overlap of 72%, whereas they had a larger trophic niche than sympatric *O. aureus* (0.20–0.13), with a niche overlap of 54%. These outputs were generally supported by stable isotope analyses of  $d^{13}C$  and  $d^{15}N$  completed on samples collected at the end of the 2011 growth season, although these indicated a greater contribution of animal material to assimilated diet. They also indicated that the trophic niche breadth [as standard ellipse area (SEA)] of *C. damascina* ( $4.18\%^{2}$ ) was higher than *G. ghorensis* ( $2.48\%^{2}$ ) and overlapped by 26%. For *G. ghorensis*, their SEA was slightly larger than *O. aureus* ( $4.33\text{--}4.00\%^{2}$ ), with an overlap of 27%. Although both methods indicated some sharing of food resources between sympatric fishes, there was no evidence suggesting detrimental outcomes for *G. ghorensis* and thus was not considered as a constraint on the status of their populations." **15919.** Hasan, J.; Raj, S.; Yadav, L.; Chatterjee, K. (2015): Engineering a nanostructured "super surface" with superhydrophobic and superkilling properties. *RSC Adv.*, 2015, 5: 44953–44959. (in English) ["We present a nanostructured "super surface" fabricated using a simple recipe based on deep reactive ion etching of a silicon wafer. The topography of the surface is inspired by the surface topographical features of dragonfly wings. The super surface is comprised of nanopillars 4  $\mu\text{m}$  in height and 220 nm in diameter with random inter-pillar spacing. The surface exhibited superhydrophobicity with a static water contact angle of  $154.0^{\circ}$  and contact angle hysteresis of  $8.3^{\circ}$ . Bacterial studies revealed the bactericidal property of the surface against both gram negative (*Escherichia coli*) and gram positive (*Staphylococcus aureus*) strains through mechanical rupture of the cells by the sharp nanopillars. The cell viability on these nanostructured surfaces was nearly six-fold lower than on the unmodified silicon wafer. The nanostructured surface also killed mammalian cells (mouse osteoblasts) through mechanical rupture of the cell membrane. Thus, such nanostructured super surfaces could find applications for designing self-cleaning and anti-bacterial surfaces in diverse applications such as microfluidics, surgical instruments, pipelines and food packaging." **15920.** Hayashi, F. (2015): Mechanisms of sperm displacement in *Calopteryx cornelia*: effects of sexual conflict. *Tombo* 57: 1–7. (in Japanese, with English summary) ["In this short review, the shape and function of female sperm-storage organs and male sperm-removal organs in *C. cornelia* are discussed from the viewpoint of sexual conflict. Females have two sperm-storage organs, a spherical bursa copulatrix (be) and a tubular Y-shaped spermatheca (sp), both of which function equally in sperm storage because the survival rates of stored sperm for 5 days do not differ between be and sp. Males possess a peculiar aedeagus with a recurved head to remove bursal sperm and spiny lateral processes to remove spermathecal sperm as

known generally in other calopterygid damselfly species. However, the male genitalia of *C. cornelia* are morphologically asymmetric after sexual maturation. The left lateral process is well developed (projected outwards) but the right one is positioned along the edge of the recurved head. Experiments by surgical cutting of each lateral process demonstrate that only the left process functions in removal of left spermathecal sperm. Such asymmetric male genitalia may be caused by sexual conflict in sperm displacement processes." (Author)] Address: E-mail: fhayashi@t-mu.ac.jp

**15921.** Hefler, C.; Qiu, H. (2015): Visualization and aerodynamic analysis of an escaping dragonfly. The 13th Asian Symposium on Visualization, Novosibirsk, Russia, 2015: 10 pp. (in English) ["An unsteady flow visualization and force measurement were carried out in order to investigate the effects of the reduced frequency of a dragonfly-type model. The flow visualization of the wing wake region was conducted by using a smoke-wire technique. An electronic device was mounted below the test section in order to find the exact position angle of the wing for the visualization. A load-cell was employed in measuring aerodynamic forces generated by a plunging motion of the experimental model. To find the period of the flapping motion in real time, trigger signals were also collected by passing laser beam signals through the gear hole. Experimental conditions were as follows: the incidence angles of the fore and hind-wing were  $0^{\circ}$  and  $10^{\circ}$ , respectively, and the reduced frequencies were 0.150 and 0.225. The free stream velocities of the flow visualization and force measurement were 1.0 and 1.6m/sec, respectively, which correspond to Reynolds numbers of  $3.4 \times 10^3$  and  $2.9 \times 10^3$ . The variations of the flow patterns and phase-averaged lift and the thrust coefficients during one cycle of the wing motion were presented. Results showed that the reduced frequency was closely related to the flow pattern that determined flight efficiency, and the maximum lift coefficient and lift coefficient per unit of time increased with reduced frequency." (Authors)] Address: Hefler, C., Dept of Mechanical & Aerospace Engineering, Hong Kong University of Science and Technology, Hong Kong SAR, China. E-mail: meqiu@ust.hk

**15922.** Hunt, S.K. (2015): Climate- and habitat-mediation of predator-prey interactions in an invasion context. Master of Science thesis, University of Canterbury. 82 pp. (in English) ["Ecosystems across the globe are facing a range of anthropogenically-driven changes, including biotic invasions, urbanisation and land-use alterations, which can affect ecosystem structure and stability. To manage both native species decline and invasive species spread it is imperative that we can accurately predict how current global environmental change will affect biotic communities. I examined effects of different land uses at both landscape- and habitat-scales on native (*Culex pervigilans*) and exotic (*Aedes notoscriptus*) mosquito distributions in lentic (standing water) freshwater habitats. Because of the importance of land use on habitat characteristics, I expected different land uses would contain different biotic communities, and that mosquitoes would more likely be present in simple communities with fewer predators. Moreover, because habitat disturbance and modification can signific-

antly influence community structure, I expected less diverse pond communities in habitats within highly modified urban and pasture land uses would also be more likely to contain mosquitoes. I found land use affects mosquito presence, and was likely strongly linked with land-use effects on predator presence and taxon richness. Predators were more common in habitats within native forest and tussock grassland, and mosquitoes were almost entirely restricted to urban and pasture habitats. Moreover, local habitat characteristics had a strong influence on both mosquito and predator presence, with deeper and more open habitats supporting greater predator abundance, thereby excluding mosquito larvae. To further investigate the global of climate change on predator-prey interactions involving *Ae. notoscriptus* and *Cx. pervigilans*, I conducted two experiments. Firstly, I measured effects of habitat warming and short- and long-term habitat drying on interactions between the two mosquito species and three predatory invertebrates, *Anisops wakefieldi* backswimmers, *Austrolestes colenisonis* damselflies, and *Procordulia smithii* dragonflies, which represented predators characteristic of different habitat drying regimes. A second experiment further tested interactions between *A. wakefieldi* and the two mosquito species in a wider range of temperatures. There was little evidence that short-term habitat drying affected interaction strengths of any of the predator-prey combinations, but strong evidence for the importance of temperature-mediated predation rates which depended on both predator and prey identities. Here, predators characteristic of more temporary hydroperiods showed temperature-mediated predation responses on the two mosquito species: increasing temperature resulted in greater predation on native *Cx. pervigilans* but not effect on predation on exotic *Ae. notoscriptus*. The second experiment revealed, again, that predation depended on both temperature and mosquito species with higher predation occurring at increased temperature, but also indicated life history traits could mediate the overall effect of temperature-mediated predation. Overall, I have shown that interactions between temperature, predator identity and mosquito species will be very important in determining the potential for mosquitoes to invade under a changing climate. Considering effects of both climate change and land-use-driven habitat modification on the invasion potential of mosquitoes in freshwater communities will therefore be important for managing both native species decline and spread of invaders. Moreover, research and management decisions on critical species like mosquitoes will need to encompass multiple drivers of climate change at both global and local scales." **15944.** Magalhaes, E.R.S.; Yamamoto, K.C.; Anjos, H.D.; Loebens, S.; Soares, M.G.M. (2015): Banks of aquatic macrophytes of floodplain lake: sites of alimentation of two species of the fish in the region of Manaus, Amazon, Brazil. *Actapesca* 3(1): 25-40. (in Portuguese, with English summary) ["The aquatic macrophytes banks in the floodplain lakes of the Amazon river constitute a major environments inhabited by fish. The abundance of aquatic macrophytes suggests that there is a high availability of food, autochthones and allochthones, to fish species. The diet composition of *S. marmoratus* and *C. amazonarum* was evaluated by the analysis of stomach contents of 201 specimens, by frequency of occurrence and gravimetric methods. The results of both methods were combined in the food index (IAi). In the high and low water periods, the food items most eaten by *S. marmoratus* and *C. amazonarum* were insects (Hemiptera and Odonata) and the fish (muscle and scales). The analysis of variance (one-way ANOVA) shows there are significant differences in the food types according length classes. In *S. marmoratus* differences occurring between high and low water periods. But to *C. amazonarum* was different only in high water periods. In conclusion, the aquatic macrophytes banks serve as an important feeding place for *S. marmoratus* and *C. amazonarum* in Amazon floodplain lakes." (Au-

thors)] Address: Magalhaes, E., Depto de Ciências Pesqueiras, Universidade Federal do Amazonas - UFAM, Brazil. E-mail: esnermagalhaes@gmail.com

**15945.** Maingot, M.; Motte, G.; Goffart, P. (2015): Première étude de l'émergence de la Cordulie à corps fin (*Oxygastra curtisii*) le long de l'Ourthe. *Les Naturalistes beiges* 96(3-4): 57-83. (in French, with English summary) ["Emergence is an important and highly vulnerable step in the dragonfly life. This process seemed not to have been directly observed on *O. curtisii*, a remarkable species of West-European fauna, protected by the "Natura 2000" Habitat Directive, while several studies have provided information on its larval and adult life. A preliminary study has therefore been carried out in June 2014 and 2015 on a little section of the river Ourthe (a tributary of the Meuse river), to document this step. Observations of emergence sequences occurred only at night time, between 22h00 and 5h00 in the morning, for a duration of 4 hours to 6 hours, the maiden flight taking place before dawn. This particular mode of emergence, described in some Anisoptera of our regions and more frequently in the tropics, likely allows to escape predation by birds. Given the aggregative character of this species' emergences on trees above larval breeding sites (among immersed roots), this nocturnal tempo presents an obvious selective advantage. The phenomenon of "divided" emergence, consisting of shifting the period of emergence during the day when the nocturnal temperatures are too cool, known from other European species with nocturnal emergence, has not been observed. The temporal and spatial distribution of the emergences, the sex ratio, the supports and positions chosen at the emergence are also presented and discussed." (Authors)] Address: Goffart, P., Observatoire de la Faune, de la Flore et des Habitats, Centre de Recherche de la Nature, des Forêts et du Bois, Avenue de la Faculte d'Agronomic, 22, 5030 Gembloux, Belgium. **15946.** Malikova, E.I.; Streltsov, A.N. (2015): Artificial water bodies as a base in the dispersal of dragonflies (on the sample of the Kivdinskoe reservoir, Amurskaya oblast). *A.I. Kurentsov's Annual Memorial Meetings* 26: 76-87. (in Russian, with English summary) ["The list of 44 species of dragonflies collected in Amurskaya oblast from Kivdinskoe reservoir (a technological water reservoir to the Raichikhinsk GRES) is given. A number of rare in the Amur region oriental species were abundant there. *Paracercion hieroglyphicum* and *Deiella phaon* are reported for Amurskaya oblast for the first time. Number of species of the studied reservoir is richer by 10-15 species than that of the neighbouring natural water bodies (lakes, oxbows, creeks etc.), probably due to better temperature conditions. The high abundance of the mentioned species suggests that the Kivdinskoe reservoir can serve as a base in the dispersal of southern migrants to the north and west." défenseur de la nature, membre méritant de la Société des naturalistes luxembourgeois. Bulletin de la Société des naturalistes luxembourgeois 116: 321-345. (in French, with English summary) ["Jos Hoffmann was born in Reckange (commune of Mersch) on 11-XII-1911 and died in Luxembourg-City on 16-XII-2000. He was a natural sciences teacher, first at the 'gymnase d'Echternach' (grammar school), then at the 'Lycée de garçons de Luxembourg' and the 'Cours supérieurs/Cours universitaires de Luxembourg'. The author of numerous faunistical studies of invertebrate groups such as Ephemeroptera, Hirudinea, Myriapoda, Odonata, Plecoptera, Neuropteroidea, Amphipoda, Orthoptera, Mecoptera, Dermaptera, Trichoptera, Oligochaeta and others, he was the outstanding zoologist of the second half of the 20th century in Luxembourg. Jos Hoffmann was an active member of the 'Société des naturalistes luxembourgeois' (Society of Luxembourg naturalists) and above all of the science section of the grand-ducal Institute. He was a keen angler, and a member of the executive board of the 'Fédération luxembourgeoise des pêcheurs sportifs' (Luxembourg federation of sport anglers) as well as the editorial director of 'De Lëtzeburger Sportfëschcher', the federation's bulletin, from 1956 to 1959. In 1948, he had distinguished himself by his resolute intervention during the accidental pollution of the river Eisch by the phenol factory of Steinfort. Just like so many young Luxembourgers two of his brothers had been illegally forced into the German Wehrmacht during World War II by the Nazis occupying Luxembourg, and they had been made prisoners of war on the Eastern Front. This explains why Jos Hoffmann had been a founding member and a member of the executive board of the Luxembourg association of parents of prisoners of war in 1945. In the following years he developed a short-time public activity in the Christian Social Party (Parti chrétien-social). Jos Hoffmann is the father of Jules A. Hoffmann, winner of the Nobel prize for physiology or medicine in 2011." (Author)] Address: Geimer, Gaby, 1a, rue des Romains, 6478 Echternach, Luxembourg. E-mail: gabrielle.geimer@education.lu

**15955.** Munoz, P.; Torres, F.; Megias, A. (2015): Effects of roads on insects: a review. *Biodivers. Conserv.* 24: 659-682. (in English) ["In the last few decades, mounting evidence points to a negative impact of roads on several groups of animals. Most studies on the effects of roads on animal populations concentrate on vertebrates, and only a few on insects. It is difficult to determine the real effects of roads on insects due to the variety of methods used. We review recent literature examining the ecological impact of roads on insects. The objectives of our synthesis are to gain insight into the effects of the construction and operation of a road on insect groups, and to determine the gaps of knowledge. We found that roads negatively affect the abundance and diversity of insects due to two main factors: (1) the high mortality of some groups when crossing the road, with more impact at higher traffic volumes. (2) The unwillingness of many species to cross a road or live close to it. Roads are major barriers for small or flightless species, although the response varied for flying species. Finally, both experimental and observational evidence support the idea that air pollutants and de-icing salt used for the road maintenance negatively affect insects." **15956.** Møller, A.P.; Mousseau, T.A. (2015): Biological indicators of ionizing radiation in nature. In: Armon, R.H. & O. Hänninen (eds.): *Environmental Indicators*: 871-881. (in English) ["Ionizing radiation that consists of  $\alpha$ ,  $\beta$  and  $\gamma$  rays can directly damage DNA and other molecules and as such result in somatic or germline mutations. The consequences of ionizing radiation for living beings cannot be measured with a Geiger counter because it will depend on external dose, internal dose, and the extent of DNA repair. In addition it will depend on the environmental conditions under which living organisms exist. We list environmental indicators of ionizing condition that reveal immediate and long-term consequences ranging from changes in DNA, over damaged cells and organs to altered gene function

and development, reduced fecundity and survival, and hence to negative population trends, and altered communities and ecosystems and perturbed ecosystem functioning. We test for consistency in biological indicator ability across spatial and temporal scales relying on long-term field data collected at Chernobyl and Fukushima, and we test for consistency in indicator ability among indicators. Finally, we address the direct and indirect effects of ionizing radiation and we discuss the species or taxa most susceptible to the effects of radiation ... Indeed, species richness and abundance of birds (Møller & Mousseau 2007a, b, 2009), but also spiders, dragonflies, grasshoppers, bumblebees, butterflies, amphibians, ... In contrast, there were significant interactions for butterflies, dragonflies, ...]. (Authors) Address: Mousseau, T.A., Dept of Biol. Sciences, Univ. South Carolina, Columbia, SC, 29208, USA. **15957.** Nakanishi, H.; Mori, A.; Takeda, K.; Tanaka, H.; Kobayashi, N.; Tanoi, K.; Yamakawa, T.; Mori, S. (2015): Discovery of radioactive silver (110mAg) in spiders and other fauna in the terrestrial environment after the meltdown of Fukushima Dai-ichi nuclear power plant. *Proc. Jpn. Acad., Ser. B* 91 (2015): 160-174. (in English) ["Six months after the explosion of TEPCO's Fukushima Dai-ichi nuclear power plant, radioactive silver (110mAg), was detected in concentrations of 3754 Bq/kg in *Nephila clavata* (the orb-web spider; Joro-gumo in Japanese) collected at Nimaibashi, litate village in Fukushima Prefecture, whereas 110mAg in the soil was 43.1 Bq/kg. A survey of 35 faunal species in the terrestrial environment during the 3.5 years after the accident showed that most of Arthropoda had two orders higher 110mAg in their tissues than soils, although silver is not an essential element for their life. However, tracing of the activity of 110mAg detected in spider *Atypus karschi* collected regularly at a fixed location showed that it declined much faster than the physical half-life. These results suggest that 110mAg was at once biologically concentrated by faunal species, especially Arthropoda, through food chain. The factors affecting the subsequent rapid decline of 110mAg concentration in faunal species are discussed." (Authors) Sampling includes *Sympetrum croceolum*, *S. frequens* and *Anotogaster sieboldii*.] Address: Mori, S., Graduate School of Agricultural and Life Sciences, The University of Tokyo, 1-1-1 Yayoi, Bunkyo-ku, Tokyo 113-8657, Japan. water quality indicators in the Berasau River, Johor, Malaysia. *Environmental Monitoring and Assessment* 187: 493-501. (in English) ["Influence of deforestation on biodiversity of aquatic organisms was investigated in a stream in the Ulu Sedili Forest Reserve. The stream was monitored five times from December 2011 until December 2012 with 2-month intervals. Sampling of benthic communities was carried out using rectangular dip net while water quality study using a YSI ProPlus meter and the rest were done in the laboratory. Physicochemical parameters and water quality index (WQI) calculation showed no significant difference among the investigated events. WQI classified the Berasau River between Class II (good) to III (moderate) of river water quality. In total, 603 individuals representing 25 taxa that were recorded with Decapods from genus *Macrobrachium* were widely distributed. Several intolerant taxa, especially Ephemeroptera and Odonata, were also observed in this river. According to Pearson's correlation analysis, the richness and diversity indices were generally influenced by water quality parameters represented by WQI ( $P < 0.01$ ). In conclusion, logging activities have strong attributes for variation in benthic macroinvertebrate assemblage." (Authors) To determine the Odonata, a key from North America was used.] Address: Salmiati, Centre for Environmental Sustainability and Water Security (IPASA), Research Institute for Sustainable Environment (RISE), Universiti Teknologi Malaysia, 81310, Johor Bahru, Malaysia. **15960.** Nuñezza, K.J.M.; Nuñezza, O.M.; Villanueva, R.J.T. (2015): Species diversity of Odonata in Bega watershed, Agusan del Sur, Philippines. *Journal of Biodiversity and Environmental Sciences* 7(5): 69-82. (in English) ["Odonata is dependent upon habitats with standing or flowing water. Its sensitivity to changes in water ecosystems makes it a good biological indicator. This study aimed to determine the species richness of Odonata in Bega Watershed, Prosperidad, Agusan del Sur, Philippines. A survey was conducted in 12 sites on May 8-14, 2014 using sweep netting and hand catching methods. 27 species consisting of 11 species of dragonflies and 16 species of damselflies under 10 families and 20 genera were recorded. Of the 27 species, 17 are endemic with 62.96% endemism. Bega Watershed had high species diversity with an uneven distribution of species. Among the sampled sites, sites 2 and 4 had the highest species richness ( $S=14$ ) while highest species diversity ( $H'=2.47$ ) was recorded in site 4 which is a relatively undisturbed and intact ecosystem. Highest abundance of Odonata was recorded in Site 1, the first level of Bega falls. *Rhinocypha colorata*, an endemic species, was found to be the most abundant and widespread, being found in seven out of 12 sites. Detrended correspondence analysis showed that Odonata prefers semi-forested riparian areas while Bray-Curtis cluster analysis showed that sites 2 and 4 are the most similar sites. The high level of endemism and moderate to high diversity in most of the sites indicate that Bega watershed is a relatively healthy ecosystem and is of high conservation importance." (Authors); Mindanao] Address: Nuñezza, Olga, Dept of Biological Sciences, College of Science and Mathematics, MSU-Iligan Institute of Technology, A. Bonifacio Ave., Tibanga, Iligan City, Philippines. **15961.** Olomukoro O. J.; Osuinde, G.A. (2015): Benthic macroinvertebrate in relation to pollution tolerance index of a creek flowing through an urban area in southern Nigeria. *Egerton J. Sci. & Technol.* 15: 141-156. (in English) ["Assessment of the pollution tolerance index (PTI) of Ekpan creek Delta state, Southern Nigeria was studied fortnightly from January to June, 2007. Macroinvertebrates were collected from floating macrophytes (*Eichhornia crassipes*) using the quadrant sampling method and dusted in formalin solution. Physico-chemical parameters were analyzed using test methods according to APHA, 1998 while heavy metals were analyzed with an atomic absorption spectrometer (PYE unicam SP2900) after digestion. Eleven (11) major groups were recorded comprising of 45 species that were sorted, identified and counted. Station one had a relative abundance of 41.1%, station two had 30.7% and station three had 28.2 % respectively of the total population. The dominant groups were Gastropoda (69.9%) and Crustacea (22.0%) while others were rare groups. Polychaete, Crustacea, Coleoptera, Odonata, Gastropoda, Arachnida, occurred both in the rainy and dry season with the exceptions of Collembola and Ephemeroptera which occurred only in the rainy season. Diversity of the benthos showed no significant variation between the stations. There also existed a significant correlation ( $p>0.05$ ) between most of the groups. The PTI values ranged between 11-14 in the study stations and were less than 10 in most months indicating a

compromised water quality." (Authors)] Address: Osuinde, Gloria, Dept of Animal and Environmental Biology, Faculty of Life Sciences, Univ. Benin, P.M.B 1154, Benin City, Edo State, Nigeria. E-mail: gloriaonde@gmail.com

(in German, with English summary) ["An arthropod/plant-taphocoenosis from a Pliocene crater lake at Ruppach-Goldhausen, Westerwald (Rhineland-Palatinate, SW Germany). Some plants and insects are reported from laminated sediments of an ancient lake at Ruppach-Goldhausen in the Westerwald area. This taphocoenosis is briefly discussed in terms of age, climate and palaeoecology. Preliminary results suggest that these laminites were deposited in a hydrologically isolated, probably not very large and not particularly deep crater lake. The plant association suggests an Upper Pliocene age and a Cfa-like palaeoclimate. Besides common beetles, there is a notably high share of (semi-)aquatic insects (e. g. Notonectidae, chaoborid pupae) and cladoceran ephippia, which indicate the prolonged existence of an autochthonous aquatic ecosystem within the lake. The fossil preservation hints at quiet conditions at the site of burial. Abundant pyrite framboids suggest anoxic conditions at least below the sediment/water interface." ["There is an increasing need to develop harmonised frameworks and methods for the risk assessment of combined exposure to multiple chemicals. A number of activities have already been undertaken by EFSA, notably in the fields of pesticides and contaminants. This project aims at searching for, reviewing, collecting and synthesizing the published data on combined effects of multiple chemicals in more than 50 species of veterinary and ecological relevance, using extensive literature searches. The taxonomical hierarchy for the literature searches was very wide ranging from bacteria, fungi, invertebrates and vertebrates (amphibians, ... Odonata, ...). In vivo toxicity data were extracted from 199 publications representing 3,074 individual studies on pesticides, environmental contaminants, food-related products, hormones, metals, mycotoxins and pharmaceuticals. The magnitudes of interaction following acute and chronic exposure to multiple chemicals were consolidated via meta-analysis and expressed as mean effect ratios between single and multiple chemicals. Overall, this report illustrates how systematic published data collection and synthesis can support hazard characterisation of combined toxicity of multiple chemicals. Further work is proposed to compare the toxicity datasets for which statically significant interactions have been reported with chemical-specific reference points from EFSA's chemical hazards database. These analyses will allow testing the sensitivity of the toxicological endpoints (e.g. acute versus chronic effects, mortality versus biochemical parameters etc...), the dose dependency of the toxicological interactions and the potential use of the methodology in ecological risk assessment of multiple chemicals." (in Japanese, with English summary) ["An adult female of *T. melampus* was captured at Nagatoromachi, Saitama Prefecture, Japan on October 4th, 2014. This record is unusually late, because the main flight season of this species is from May to July. Past late record of adult of this species in Saitama Prefecture was only in July recorded in 1973 and 1995." (Authors)] Address: not stated

**15973.** Sharma, S.; Shukla, A. (2015): Preliminary study of Odonates in southeast region of Narmada Valley, Jabalpur (M.P.). *International Journal of Recent Scientific Research* 6(10): 7038-7040. (in English) ["... odonates are potential bio control agents of many invertebrates. Odonate assemblage from Narmada Valley in Jabalpur has been investigated. A total of 25 species of Odonata have been distributed in 7 families were sampled. Libellulidae is most dominating family, with 10 species followed by Coenagrionidae with 7 species [...]. Mostly odonates were aggregated due to habitat specific nature and random distribution indicates availability of resource utilization to survive but, in the urban forest area high anthropogenic disturbances were observed which creates high biotic pressure on forest. A detailed list of odonates recorded from urban forest area is presented." (Authors)] Address: Sharma, S., Dept Zool., Government. Model Science College, Jabalpur (M.P.)

**15974.** Siukevicius, S.; Barekute, D.; Ivtnskis, P.; Rlinsaitė, J. (2015): Diversity and distribution of glacial origin forest lakes of Grazute regional park. 8th International Conference on Biodiversity Research. 28.-30.04.2015, Daugavpils, Latvia: 139. (in English) [Verbatim: The investigation on Odonata diversity and distribution of glacial origin forest lakes has been carried out in Grazute regional park (Igalina. Zarasai districts. Lithuania). The material was collected in 25 lakes, two times during the third decade of

May - first decade of June and second decade of July in 2008-2009. The selected lakes were located in four groups, distance in each group apart from one another about 10-20 km. The sampling sites were divided into two groups by lakes surface and water level fluctuations: lakes with small surface area (0.5-5 ha), without discharge, situated in potholes, surrounded with forest and lakes with surface area 3-20 ha without discharge or partly drained, with marshy shore of the lake. Nestedness temperature calculator (NTC) has been used for measurement of species distribution in lakes of two types. The lower temperature level shows that system operating in some rules, when temperature are higher (close 100°) the system are more chaotic. 25 species of dragonflies (Odonata) have been registering during the research period in lakes of first group. The lowest species diversity was establish in small dystrophic lakes, there were registered 4 ordinary, 9 indicator, 8 accidentally species. *Epitheca bimaculata* and *Aeshna juncea* have been found only in small dystrophic lakes. 32 species of Odonata were found in lakes of second group: 9 ordinary species, 11 indicator species and 8 accidental species. The highest number of species was established near lake Palsinis, random distribution of different Odonata species was established in lake Berzinis. Highest species diversity and individual abundance were in lakes of second group, here was established statistical significant higher temperature of matrix  $T = 31.75^\circ$  ( $p = 0.06$ ). The matrix temperature of first group lakes was lowest ( $T = 21.62^\circ$ ), it shown higher stability of species composition.] Address: Siukevicius, S., Univ. Vilnius. Faculty of Natural Sciences. **15975.** Stih, A, Koren, T.; Bobinec, A.; Matejcic, M.; Frankovic, M. (2015): The River Zrmanja - another hotspot of dragonfly diversity in the Dinaric karst, Croatia. *Entomologia Croatica* 19(1-2): 43-57. (in English, with Croatian summary) ["The Zrmanja is one of the largest rivers in Dalmatia, along with the rivers Krka and Cetina. At the same time it is one of the least surveyed larger rivers in the region, with only a few published records about its dragonfly fauna so far. Between 1984 and 2010 the authors collected data about the dragonflies around the river Zrmanja and its surroundings. Altogether 29 species were recorded at 17 localities. Of those, 12 species were recorded for the first time for the region. The most valuable record is that of *Coenagrion ornatum*, a local and rare Natura 2000 species. With the overview of the data from museum collections, private field data, published data and data collected during this survey the number of species known from the Zrmanja river increases to 31, making this river one of the best studied areas in Croatia. However, this is probably not the final number of species and new records are to be expected with further research." **15976.** Takizawa, K.; Tezduyar, T.E.; Buscher, A. (2015): Space-time computational analysis of MAV flapping-wing aerodynamics with wing clapping. *Computational Mechanics* 55(6): 1131-1141. (in English) ["Computational analysis

of flapping-wing aerodynamics with wing clapping was one of the classes of computations targeted in introducing the space-time (ST) interface-tracking method with topology change (ST-TC). The ST-TC method is a new version of the deforming-spatial-domain/stabilized ST (DSD/SST) method, enhanced with a master-slave system that maintains the connectivity of the "parent" fluid mechanics mesh when there is contact between the moving interfaces. With that enhancement and because of its ST nature, the ST-TC method can deal with an actual contact between solid surfaces in flow problems with moving interfaces. It accomplishes that while still possessing the desirable features of interface-tracking (moving-mesh) methods, such as better resolution of the boundary layers. Earlier versions of the DSD/SST method, with effective mesh update, were already able to handle moving-interface problems when the solid surfaces are in near contact or create near TC. Flapping-wing aerodynamics of an actual locust, with the forewings and hindwings crossing each other very close and creating near TC, is an example of successfully computed problems. Flapping-wing aerodynamics of a micro aerial vehicle (MAV) with the wings of an actual locust is another example. Here we show how the ST-TC method enables 3D computational analysis of flapping-wing aerodynamics of an MAV with wing clapping. In the analysis, the wings are brought into an actual contact when they clap. We present results for a model dragonfly MAV." **15984.** Trippier, R.; Brooks, S. (2015): Voltinism in Erythromma viridulum (Charpentier) (Small Red-eyed Damselfly): a newly colonised damselfly species in the UK. Journal of the British Dragonfly Society 31(2): 74-88. (in English) ["Odonates have displayed strong responses to changing climate through shifting range margins and changes in phenology and voltinism. Newly colonising species may also be competing with previously established species. This study analysed voltinism and feeding behaviour of a recent coloniser, E. viridulum. The results indicate that the populations sampled were likely to be semivoltine, and growth rates suggest that early instar larvae present in July would overwinter in that stage and emerge the following year. This implies that voltinism has not changed in British populations since the species colonised this country. Gut content analysis of larvae found that larval prey items changed through progressive instars but indicated that E. viridulum is unlikely to feed upon other odonate species in the UK." **15987.** Westermann, K. (2015): Eine Erfassungsmethode frisch geschlüpfter Schwarzer Heidelibellen (*Sympetrum danae*) an künstlichen Moorteichen im Oberen Hotzenwald (Hochschwarzwald). *Naturschutz südl. Oberrhein* 8: 127-134. (in German, with English summary) ["Freshly emerged *S. danae* whose wings had dried sufficiently to be able to fly, for a long time stayed close to their place of emergence at artificial moor ponds in the upper Hotzenwald (southern Black Forest), even during sunny and warm weather conditions. During noon and in the early afternoon, they could be counted quickly and easily, so it was possible to obtain precise daily numbers. This method was clearly superior to the previously used method of counting exuviae." (Author)] Address: Westermann, K., Buchenweg 2, 79365 Rheinhausen, Germany

**15988.** Wijeyeratne, G. (2015): *A Naturalist's Guide to the Butterflies & Dragonflies of Sri Lanka*. John Beaufoy Publishing Ltd: 176 pp. (in English) ["Increasingly the segmentation between birders, butterfly watchers, dragonfly watchers and photographers is reducing as interests overlap and there is a demand for books that cover the three popular groups of birds, butterflies and dragonflies. Having written and photographed the guide to the birds of Sri Lanka in the series, Gehan de Silva Wijeyeratne has produced a single, compact and portable photographic guide to the butterflies and dragonflies of the country. The emphasis in the 280 species featured is on the commoner species, covering around 90 per cent of the species that a visitor is likely to see. It is also an excellent book for resid-

ents to learn about the commoner butterflies and dragonflies before progressing to more advanced technical books. The guide is focused on field use to help beginners and experts identify species and provides information on their distribution and habitats. As identification of butterflies and dragonflies require a different approach, the two sections are done as two mini photographic field guides with common introductory sections to wildlife watching in Sri Lanka. The book includes information on the key wildlife sites, general introductions to the biology of dragonflies and butterflies, up-to-date checklists with local status and useful references for people who wish to progress further with their study of these charismatic and photogenic animals." **15991.** Zheng, D.; Zhang, H.; Zhang, Q.; Li, S.; Wang, H.; Fang, Y.; Liu, Q.; Jarzembowski, E.A.; Yan, E.; Wang, B. (2015): The discovery of an Early Cretaceous dragonfly *Hemeroscopus baissicus* Pritykina, 1977 (Hemeroscopidae) in Jiuquan, Northwest China, and its stratigraphic implications. *Cretaceous Research* 52: 316-322. (in English) ["The Early Cretaceous dragonfly *Hemeroscopus baissicus* Pritykina is reported for the first time from the Jiuquan Basin, Gansu Province, Northwest China based on adult wings. These wings are different from those from other localities in two aspects: the oblique crossvein 'O' is 3 or 4 cells distal of the subnodus; the wing size is much smaller (30e42 mm in length for forewings). These differences are considered to be intraspecific variations, based on which diagnoses of the genus *Hemeroscopus* and the family Hemeroscopidae are revised. The discovery of *H. baissicus* in Jiuquan suggests that the Zhonggou Formation may be correlated with the Fuxin Formation in Liaoning Province, the Lushangfen Formation in western Beijing, and the Dongmyeong Formation in southern Korea. A possible migration path of the dragonfly is indicated that it initially appeared in Transbaikalia in the Aptian, migrated southwestwards to Mongolia in the Aptian or early Albian, and then southwestwards to northwest China, southeastwards to northeast China, and southern Korea in the early Albian." (Authors)] Address: Zhang, H., State Key Lab. Palaeobiology & Stratigraphy, Nanjing inst. Geology & Palaeontology, Chinese Acad. Sciences, 39 East Beijing Rd, Nanjing 210008, China. **15994.** Abreu, F.; De la Fuente, M.F.; Schiel, N.; Souto, A. (2016): Feeding ecology and behavioral adjustments: flexibility of a small neotropical primate (*Callithrix jacchus*) to survive in a semiarid environment. *Mammal Research* 61(3): 221-229. (in English) ["Semiarid environments are known for climate extremes such as high temperatures, low humidity, irregular precipitations, and apparent resource scarcity. We aimed to investigate how a small neotropical primate (*C. jacchus*; the common marmoset) manages to survive under the harsh conditions that a semiarid environment imposes. The study was carried out in a 400-ha area of Caatinga in the northeast of Brazil. During a 6-month period (3 months of dry season and 3 months of wet season), we collected data on the diet of 19 common marmosets (distributed in five groups) and estimated their behavioral time budget during both the dry and rainy seasons. Resting significantly increased during the dry season, while playing was more frequent during the wet season. No significant differences were detected regarding other behaviors. In relation to the diet, we recorded the consumption of prey items such as insects, spiders, and small vertebrates. We also observed the consumption of plant items, including prickly cladodes, which represents a previously undescribed food item for this species. Cladode exploitation required perceptual and motor skills to safely access the food resource, which is protected by sharp spines. Our findings show that common marmosets can survive under challenging conditions in part because of adjustments in their behavior and in part because of changes in their diet." **15995.** Acevedo, V.; Amador, M.; Félix, G.; Barrera, R. (2016): Operational aspects of the centers for disease control and prevention autocidal gravid ovitrap. *Journal of the American Mosquito Control Association* 32(3): 254-257. (in English) ["Dengue viruses cause hundreds of millions of in-

fections every year in tropical and subtropical countries. Unfortunately, there is not a single universal vector control method capable of suppressing *Aedes aegypti* (L.) populations. Amongst novel control tools or approaches are various types of traps targeting gravid females or their eggs. Here, we provide details of the operational use of the Centers for Disease Control and Prevention autocidal gravid ovitrap (CDC-AGO trap) for the surveillance and control of *Ae. aegypti*. Adult mosquitoes were monitored every week in 2 isolated neighborhoods treated with 3 AGO traps per house in 85% of houses and in 2 reference neighborhoods without control traps. Between March 2013 and April 2015 we serviced the AGO traps 14 times in each community (every 2 months). Common trap problems were absent or broken trap tops (1–1.5%), flooded (0.1–0.7%) or dry (0.5–1.3%) traps, and missing (0.3–0.8%) or vandalized (0.5–1.4%) traps. Most traps kept a volume of infusion between 45% and 97% of their original volume (10 liters). Nontarget organisms captured in AGO traps were mostly small flies, and to a lesser extent ants, cockroaches, grasshoppers, butterflies, dragonflies, and lizards. Trap coverage ranged between 83% and 87% of houses in both communities throughout the study. We interpret such high levels of trap retention over time as an expression of acceptance by the community." **15998.** Alberts, J.M.; Sullivan, S.M.P. (2016): Factors influencing aquatic-to-terrestrial contaminant transport to terrestrial arthropod consumers in a multiuse river system? *Environmental Pollution* 213: 53-62. (in English) ["Highlights: •River contamination decreased with downstream longitudinal distance from a large urban center. •Recipient consumer dynamics were influenced by riparian habitat complexity. •Contaminant flux via emergent insects was not a strong predictor of terrestrial arthropod body burdens. •Terrestrial consumer body burdens were best predicted by riparian land cover. •Riparian land cover regulated aquatic-to-terrestrial contaminant transport. Abstract: Emerging aquatic insects are important vectors of contaminant transfer from aquatic to terrestrial food webs. However, the environmental factors that regulate contaminant body burdens in nearshore terrestrial consumers remain largely unexplored. We investigated the relative influences of riparian landscape composition (i.e., land use and nearshore vegetation structure) and contaminant flux via the emergent aquatic insect subsidy on selenium (Se) and mercury (Hg) body burdens of riparian ants (*Formica subsericea*) and spiders of the family Tetragnathidae along 11 river reaches spanning an urban-rural land-use gradient in Ohio, USA. Model-selection results indicated that fine-scale land cover (e.g., riparian zone width, shrub cover) in the riparian zone was positively associated with reach-wide body burdens of Se and Hg in both riparian *F. subsericea* and tetragnathid spiders (i.e., total magnitude of Hg and Se concentrations in ant and spider populations, respectively, for each reach). River distance downstream of Columbus, Ohio – where study reaches were impounded and flow through a large urban center – was also implicated as an important factor. Although stable-isotope analysis suggested that emergent aquatic insects were likely vectors of Se and Hg to tetragnathid spiders (but not to *F. subsericea*), emergent insect contaminant flux did not emerge as a significant predictor for either reach-wide body burdens of spider Hg or Se. Improved understanding of the pathways and influences that control aquatic-to-terrestrial contaminant transport will be critical for effective risk management and remediation." **16000.** Anderson, T.L. (2016): Predation risk between cannibalistic aeshnid dragonflies influences their functional response on a larval salamander prey. *Journal of Zoology* 300(3): 221-227. (in English) ["In size-structured populations of predators, the threat of cannibalism can influence behavior of prey that are attempting to avoid predation by larger conspecifics, including reducing their foraging rates. Such behavioral responses subsequently release basal prey of both cannibal and non-cannibal predators from predation risk. However, whether the non-consumptive effects of cannibalism on conspecific predators varies with basal heterospecific prey density is relatively unexplored. I conducted a laboratory study in plastic containers to test whether cannibalism risk influenced the functional response of dragonflies while foraging on three different densities of larval salamander prey. Dragonfly predators foraged with a Type II functional response, and when exposed to cannibalism cues, per capita feeding rates were lower at high prey densities. Salamander prey mortality rates declined with increasing prey densities, but the presence of cannibalism risk did not influence this pattern. Overall, this study shows that functional response curves of predators can vary in response to whether cannibalism risk is present in their environment across a small range of prey densities. Incorporating synergistic effects of multiple processes, such as non-consumptive risk factors and prey density, may help further elucidate the processes that structure both predator and prey population dynamics." **16002.** Araujo, J.P.M.; Hughes, D.P. (2016): Diversity of entomopathogenic fungi: Which groups conquered the insect body? *Advances in Genetics* 94: 1-39. (in English) ["The entomopathogenic fungi are organisms that evolved to exploit insects. They comprise a wide range of morphologically, phylogenetically, and ecologically diverse fungal species. Entomopathogenic fungi can be found distributed among five of the eight fungal phyla. Entomopathogens are also present among the ecologically similar but phylogenetically distinct Oomycota or water molds, which belong to a different kingdom, the Stramenopila. As a group of parasites, the entomopathogenic fungi and water molds infect a wide range of insect hosts, from aquatic larvae to adult insects from high canopies in tropical forests or even deserts. Their hosts are spread among 20 of the 31 orders of insects, in all developmental stages: eggs, larvae, pupae, nymphs, and adults. Such assortment of niches has resulted in these parasites evolving a considerable morphological diversity, resulting in enormous biodiversity, the majority of which remains unknown. Here we undertake a comprehensive survey of records of these entomopathogens in order to compare and contrast both their morphologies and their ecological traits. Our findings highlight a wide range of adaptations that evolved following the evolutionary transition by the fungi and water molds to infect the most diverse and widespread animals on Earth, the insects.] Address: Araujo, J.P.M., Penn State Univ., University Park, PA, USA. **16004.** Avila Varshini, R.; Kanagappan, M. (2016): A study on the diversity of odonate larvae in a permanent pond Melpalai at Melpuram in Kanyakumari district, Tamil Nadu, India. *International Journal of Applied Research* 2(3): 592-598. (in English) ["The present study gives an overview of data on the habitat diversity of odonate larvae occurring in a permanent pond Melpalai in Melpuram, Kanyakumari District (Tamil Nadu), India, during August 2013-July 2014. The survey of the permanent pond Melpalai revealed the occurrence of 21 species of Odonata. Libellulidae dominated all the other families, while the family Coenagrionidae occupied the second position. The physicochemical parameters (temperature 22-31.5 °C; pH 6.8-7.13; Total dissolved solids 110-143 ppm; Dissolved oxygen 4.1- 5.1 ml/l; Electric conductivity 58-105) of this pond were more or less ideal for the abundance and distribution of odonate larvae. Various diversity indices were calculated for premonsoon, monsoon and post monsoon seasons and the results indicated that maximum diversity and distribution were occurred during the monsoon season followed by the postmonsoon season and minimum diversity was recorded during the premonsoon season." **16005.** Baird, I.R.C.; Burgin, S. (2016): Conservation of a groundwater-dependent mire-dwelling dragonfly: implications of multiple threatening processes. *Journal of Insect Conservation* 20(2): 165-178. (in English) ["Groundwater-dependent ecosystems and their dependent species are under increasing threat globally. Petalurid dragonflies are one such group. This review highlights processes that threaten the groundwater-dependent mire habitats of *Petalura gigantea*, a dragonfly with long-lived fossorial larvae. The species is reliant for successful reproduction on areas of emergent seepage, or at least, on a water table that is sufficiently high to cause saturation of the peaty substrate. These microhabitat characteristics are critical for successful oviposition and larval burrow establishment, making the species particularly

vulnerable to any lowering of water tables. The effect of any lowering of water tables, due to groundwater abstraction or longwall coal mining, for example, will be compounded by the effects of more intense fire regimes in these mires and by projected climate change. These threatening processes act in conjunction with a range of other anthropogenic threats and are mirrored globally in threats to other groundwater-dependent mire ecosystems and their dependent species, including other petalurid dragonflies." **16006.** Baumann, K. (2016): Veränderungen von Höhenverbreitung und Abundanz von *Somatochlora alpestris* und *Somatochlora arctica* im Harz unter dem Einfluss des Klimawandels (Odonata: Corduliidae). *Libellula* 35(1/2): 43-64. (in German, with English summary) ["Shifts of the altitudinal range and abundance of *S. alpestris* and *S. arctica* in the Harz within the impact of climate change (Odonata: Corduliidae) – From 2000–2015, the abundances of *S. alpestris* and *S. arctica* have been researched on the bogs of the Harz Mountains based on collected exuviae. In raised bogs below 850 m a.s.l. the number of *S. alpestris* has noticeably decreased recently, whereas in the highest locations of about 1,000 m a.s.l. their abundance has increased. On the whole, the proportion of the abundances of *S. alpestris* and *S. arctica* has shifted in favour of *S. arctica* in the raised bogs. In slope located soligenous bogs (which are microclimatically cooler) the abundance of *S. alpestris* has not decreased, not even in the lowest elevations of 650–700 m a.s.l. Meanwhile *S. arctica* has spread its area into the highest located bogs, though its frequency there is still smaller than that of *S. alpestris*. Most probably these processes are caused by the global climate change. Limiting factors for the cryophilic *S. alpestris* are assumed to be too high temperatures or too much fluctuation of the temperatures in the pools (increased larval mortality) and perhaps too high air temperatures (inhibition of the adults' activity). In the case of progressing global warming, very unfavourable conditions for *S. alpestris* in the raised bogs in the Harz Mountains must be forecast. By contrast, the less cold resistant *S. arctica* profits by global warming

and will predictably become the dominant dragonfly in the raised bogs at all elevations in the medium term." (Authors)] Address: Baumann, Katrin, ALNUS GbR, Lärchenweg 15a, 38667 Bad Harzburg, Germany. E-mail: alnus-k.baumann-@t-online.de

(2016): Acute changes in whole body corticosterone in response to perceived predation risk: A mechanism for anti-predator behavior in anurans? Gen. Comp. Endocrinol. 229: 62-66. (in English) ["Anuran larvae exhibit behavioral and morphological plasticity in response to perceived predation risk, although response type and magnitude varies through ontogeny. Increased baseline corticosterone is related to morphological response to predation risk, whereas the mechanism behind behavioral plasticity remains enigmatic. Since tadpoles alter behavioral responses to risk immediately upon exposure to predator cues, we characterized changes in whole body corticosterone at an acute (<1h post-exposure) timescale. Tadpoles (*Lithobates sylvaticus*) at Gosner stage (GS) 25 (free-swimming, feeding larvae) increased corticosterone levels to a peak at 10-20min post-exposure to predator cues, paralleling the acute stress response observed among other taxa. Tadpoles reared for 3 weeks (mean GS29) with predation risk (caged, fed Aeshnid dragonfly nymph) had lower corticosterone levels at 10-20min post-exposure to dragonfly cues than predator-naïve controls, suggesting habituation, although the magnitude of increase was markedly diminished when compared to younger tadpoles (GS25). These experiments represent the first assessment of tadpole hormonal responses to predation risk at the acute timescale. Further research is required to establish causality between hormonal responses and behavioral changes, and to examine how and why responsiveness changes over ontogeny and with chronic exposure to risk." **16012.** Borkenstein, A.; Schröter, A.; Jödicke, R. (2016): *Aeshna viridis* is an early bird – matutinal matings in a crepuscular species (Odonata: Aeshnidae). Odonatologica 45(1/2): 37-56. (in English) ["The hitherto unknown mating activities of *Aeshna viridis* at dawn are described and photographically documented. At first morning light both sexes arrived at the breeding pond flying over dense stands of *Stratiotes aloides*. Their flight style was of two types: the well-known feeding flight and a slow, low, linear and non-aggressive cruising flight. Cruising individuals sometimes formed mating wheels and the couples left the pond. Shortly before sunrise numerous males started to search for receptive females in the tall herbaceous vegetation near the pond. This non-aggressive flight mode was slow and at knee-height, characterised by intrusion into dense thickets; we term it searching flight. It ceased within a period of 45–70 min after sunrise. We assume that the terrestrial vegetation represents the main rendezvous site and that searching flight leads to the majority of matings. One male was recorded grasping a resting female. Wheel formation was completed while perching without further flight, resulting in a distinctive twisted wheel position. Further observations confirmed that such twisted wheels found in the morning are typical. There are also records of occasional matings during the period from noon until late afternoon. The restriction of most mating activities to the period around sunrise rejects the myth of *A. viridis* being a late riser. The mating behaviour of this species with its combination of mainly sunrise-limited searching flight and wheel formation with resting mates seems to be unique in Odonata. In referring

to twilight activities – at dawn and dusk – we use the term ‘crepuscular’ in the general sense and eschew the term ‘eocrepuscular’, making a distinction between morning and evening with the terms ‘matutinal’ (at dawn) and ‘vespertine’ (at dusk).” (Authors)] Address: Borkenstein, Angelika, Lebensborner Weg 5, 26419 Schortens, Germany. **16013.** Borkenstein, A.; Jödicke, R. (2016): Crepuscular collective flight of *Aeshna viridis* in Central Europe (Odonata: Aeshnidae). *Not. Odonat.* 8(8): 297-307. (in English) [“Crepuscular flight activity was studied in *A. viridis* at a woodland pond in NW Germany that harboured an isolated, relatively small breeding population. We observed twilight behaviour in 2014 and 2015 during 14 evenings and four mornings from early July until early September. In twilight, under a clear sky always before sunrise and after sunset, a substantial part of the population gathered at the breeding pond and performed a collective flight over Water Soldier *Stratiotes aloides*, the plant species which also served as habitat for diurnal oviposition and patrol flight. The collective flight usually started with hunting mosquitoes (feeding flight) but within few minutes it gradually changed to a linear and slow flight style performed densely above *Stratiotes* (cruising flight). Only feeding individuals in a higher abundance at dusk gave the impression of swarming. Cruising individuals occasionally formed mating wheels but exclusively at dawn. Generally, males prevailed during the collective flight. We attempt to offer first answers to the question why *A. viridis* regularly performs collective flight and discuss its relation to the vespertine mass swarms reported from Finland and western Siberia.” (Authors)] Address: Borkenstein, A., Lebensborner Weg 5, 26419 Schortens, Germany. (in Dutch, with English summary) [“*C. armatum* was rediscovered in the Netherlands in 1999. The Dutch population is located at the Weerribben and is one of the very few populations of this species in North-West Europe. Since its rediscovery *C. armatum* has been studied intensively in the Netherlands but also in Scandinavia and Germany. Although other nature reserves were intensively investigated, the species was not found outside the Weerribben, even where suitable habitat seems to be present. The habitat where the *C. armatum* is found in the Netherlands and in countries nearby is very specific with an open helophyte vegetation in shallow water. The structure of the vegetation appears to be more important than the plant species that form it. The situation in the Netherlands is fragile with only one large population. Specific management is required, aimed at maintaining current habitat locations and creating new ones.” (Authors)] Address: Bouwman, J.H.. E-mail: j.bouwman@bosgroepen.nl

**16015.** Brouwer, P. (2016): *Trithemis kirbyi* near the Spanish-French border. *Boletín Rola* 8: 5-8. (in English, with Spanish summary) [“Two sightings of *T. kirbyi* are reported from the province of Huesca and located south of the Pirenees. Those

records are the most northernmost for the species so far.” (Author)] Address: Brouwer, P. E-mail: p.brouwer4@upcmail.nl

**16016.** Burbach, K.; Schiel, F.-J. (2016): Verbreitung und Bestandssituation von *Sympetrum depressiusculum* im Südteil des Regierungsbezirks Schwaben, Südwestbayern. *Mercuriale* 16: 9-23. (in German, with English summary) [“Distribution and population size of *S. depressiusculum* in the southwestern prealpine area of Bavaria (Suevia) - In 2012, we recorded *S. depressiusculum* at 20 out of 24 investigated sites in the western part of the prealpine area of Bavaria between Lake Constance and the river Lech (district of Schwaben = Suevia). At 8 sites successful reproduction was evident, at another 4 sites very probable. At 8 sites we observed only single or few individuals and we assume *S. depressiusculum* not to have reproduced there due to a lack of suitable waterbodies. Because of the high water levels during summer, we suppose that 2012 was a very suitable year for successful development of this highly endangered species. At five sites we recorded more than 100 specimens per visit. We estimated population sizes of several hundred individuals per site. We consider the populations of the reed zones of Lake Constance and the Forggensee, a reservoir filled with water of the river Lech and two smaller rivers during the summer, to be essential for the continued existence of *S. depressiusculum* in this part of the Bavarian prealpine region. For conservation purposes, the typical water regime with low water levels during winter and high levels from late spring/early summer to late summer/autumn is to be preserved. Furthermore, annual mowing of reed vegetation is important to keep vegetation density low and to prevent succession of high growing reed plants such as *Phragmites australis*, woody succession of willows (*Salix* spp.) and neophytes.” (Authors)] Address: Burbach, K., Am Bachwinkel 3, 85417 Marzling, Germany. **16017.** Butler, S.G.; Steinhoff, P.O.M.; Dow, R.A. (2016): Description of the final instar larva of *Acrogomphus jubilaris* Lieftinck, 1964 (Odonata, Gomphidae), with information on the distribution of *Acrogomphus* in Borneo. *Zootaxa* 4184(2): 367-375. (in English) [“The final instar larva of *A. jubilaris*, is described and figured for the first time based on exuviae from four male and one female larvae collected in Sarawak, Malaysian Borneo. The adults of *A. jubilaris* are very rarely encountered. The larvae, however, are surprisingly common in forest streams in Borneo. It is compared with *A. malayanus* Laidlaw, 1925 and *A. walshae* Lieftinck, 1935, and notes on behaviour, distribution and habitat are included. A map including all known records of *A. jubilaris* is provided.” (Authors)] Address: Butler, S.G., Red Willow, All Stretton, SY6 6HN Shropshire, UK. E-Mail: sgbutler15@btopenworld.com

**16018.** Campos, V.C. de (2016): Estudo comparativo sobre a dieta do *Galbula ruficauda* (Aves, Galbulidae) no Brasil central. Dissertação (Mestrado em Zoologia), Universidade de Brasília, Instituto de Ciências Biológicas, Departamento de Zoologia, Programa de Pós Graduação em Zoologia: 31 pp. (in Portuguese, with English summary) [“This study compares the diet of the *Galbula ruficauda* between sexes, seasons (rainy season and dry season) and two locations relatively

close to each other along a gallery forest of the Maranhão River and one of its tributaries in central Brazil. Additional comparisons involving the results obtained in this study with data on the diet of this bird in another site in Central Brazil and a forest site in Costa Rica were also carried out. Insects attacked and consumed by wild birds in central Brazil belong to seven orders including: Hymenoptera, Diptera, Lepidoptera, Odonata, Coleoptera, Orthoptera and Mantodea. Small insects like Diptera and micro-Hymenoptera constituted the most abundant items in the diet of this bird, followed by relatively large Hymenoptera (especially wasps), Lepidoptera, Odonata, Coleoptera, Orthoptera and Mantodea. Comparisons involving the proportion of these items in the birds' diet showed no significant differences between sexes, but showed strong differences between seasons. Comparisons involving different locations in Central Brazil showed significant differences in some cases but not in others. Comparisons involving locations in central Brazil and data obtained in Costa Rica also furnished strong significant differences between them." (Author)] Address: not stated

**16019.** Cardona-Rivera, G.A.; Ramírez, A. (2016): Predation of *Telebasis vulnerata* (Odonata: Coenagrionidae) eggs by detritivorous caddisfly larva, *Phylloicus pulchrus* (Trichoptera: Calamoceratidae). *International Journal of Odonatology* 19(4): 253-256. (in English) ["After observing the presence of *P. pulchrus* and tadpoles of *Leptodactylus albilabris* (Anura: Leptodactylidae) on submerged leaves with recently laid eggs of *T. vulnerata*, we set up an experiment to determine if they were consuming Odonata eggs. We collected leaves from the stream, where consumers were positioned over egg masses, and designed an experiment to expose *T. vulnerata* eggs for two days to consumers. Observations indicated that tadpoles did not harm *T. vulnerata* eggs. In contrast, *P. pulchrus* completely scraped eggs from leaves, with little damage to the leaf tissue itself. *P. pulchrus* is detritivorous insect that consume leaf tissue, but it is capable of consuming *T. vulnerata* eggs, potentially as a supplementary food resource." **16020.** Catling, P.M. (2016): Climate warming as an explanation for the recent northward range extension of two dragonflies, *Pachydiplax longipennis* and *Perithemis tenera*, into the Ottawa valley, Eastern Ontario. *The Canadian Fieldnaturalist* 130(2): 122-132. (in English) ["Climate warming is accepted as an explanation for the recent appearance of *P. longipennis*, and *P. tenera*, in the Ottawa region, as this range expansion meets 6 criteria: (1) the climate in the newly occupied territory has warmed sufficiently to allow colonization; (2) a new range expectation based on the amount of climate warming is met; (3) other factors potentially promoting spread are excluded; (4) the possibility that range extension is a result of difficulty of observation and/or insufficient fieldwork in earlier times is excluded; (5) there is ample evidence for establishment; and (6) spread has been in the direction of the warmer territory or within it. By 2000, the mean daily temperature in the Ottawa region had increased by about 2°C

since 1880 and about 1.1°C since 1960. This would allow new zonal boundaries and the prediction of expansion from a well-defined and long-occupied area into the Ottawa Valley. The two species entered this region in 2008–2012 and, subsequently, became well established." (Author)] Address: Catling, P.M., 170 Stanford Ave., Ottawa, Ontario K2C 0E9, Canada. **16025.** Chovanec, A.; Spira, Y. (2016): Bewertung der Renaturierungsmaßnahmen in den Unterläufen und Mündungsbereichen von Leitenbach und Sandbach sowie an der Aschach (Oberösterreich) aus libellenkundlicher Sicht (Insecta: Odonata). Beiträge zur Entomofaunistik 17: 1-29. (in German, with English summary) ["River restoration at Leitenbach, Sandbach and Aschach in Upper Austria: assessment by dragonfly surveys (Insecta: Odonata). – The ecological status (with special reference to morphological aspects) of the restored lower courses and mouths of Leitenbach and Sandbach as well as of the restored Aschach in this area was assessed by an investigation of the dragonfly fauna. The Dragonfly Association Index was used to compare rivertype-specific reference conditions with the status quo – this procedure is in line with the requirements of the EU Water Framework Directive. 25 species were recorded, which corresponds to 32 % of the species inventory of Austria; 21 species were autochthonous. At the Leitenbach 23 species were found (20 of them autochthonous), at the Sandbach 16 (14), and at the Aschach 16 (11). The three river sections were colonised by a high number of rheophilic species: *Calopteryx splendens*, *C. virgo*, *Platynemis pennipes*, *Gomphus vulgatissimus*, *Onychogomphus forcipatus*, *Ophiogomphus cecilia*, and *Orthetrum brunneum*. *G. vulgatissimus*, *O. cecilia*, and *O. forcipatus* are "endangered" according to the Austrian Red List. *O. cecilia* is listed in the Appendices II and IV of the EU Fauna-Flora-Habitat-Directive. Due to the species spectrum found, the three river sections were classified as "high ecological status." (Authors)] Address: Chovanec, A., Umweltbundesamt, Spittelauer Lände 5, 1090 Wien, Austria. **16027.** Cleary, D.F.R. (2016): Diversity and composition of plants, butterflies and odonates in an Imperata cylindrica grassland landscape in East Kalimantan, Indonesia. Journal of Tropical Ecology 32: 555-560. (in English) ["In Indonesia and elsewhere, Imperata cylindrica grassland now

covers millions of hectares of land previously covered by rain forest. In the present study, shrubs, trees and climbers were recorded in sixteen 10 × 20-m plots and herb cover (ferns, grasses and herbaceous dicots) estimated in nested 2 × 2-m subplots. Butterflies and odonates were netted along 300-m transects. All plots and transects were randomly allocated to a 450 ha, I. cylindrica-dominated landscape. A total of 43 shrub, tree and climber, 16 herb, 67 butterfly and 30 odonate species were recorded. Shrubs, trees and climbers were present throughout the study area, but basal area was very low and mainly consisted of invasive species. Imperata cylindrica covered an estimated 65% of the area with other plant species or bare soil covering the remainder. Butterfly and odonate communities mainly consisted of species with large geographic distributions, but some recorded species had more limited distributions. The latter were, however, species known to associate with perturbed forest environments. Variation in the composition of butterflies and odonates was also related to variation in habitat structure (e.g. altitude and slope) and plant composition. Plant composition in particular appeared to structure both butterfly and odonate communities." **16028.** Corbi, J.J.; Abrahão, D.P.; Mello, J.L.S.; Gorni, G.R. (2016): Record of epibiont ciliates (Ciliophora: Peritrichia) living on larvae of Odonata from Brazil. Brazilian Journal of Biology 77(2): 1-3. (in English) ["Here, we report a first record of epibiont ciliates (Ciliophora: Peritrichia) living on larvae of Coenagrionidae (Odonata) in Brazil (see Figure 1). The organisms were collected in September 2015, from the Monjolinho Reservoir, using a "D" aquatic net, during a survey of benthic macroinvertebrates. This reservoir is located in the campus of the Federal University of São Carlos (São Paulo, Brazil) in a subtropical region (47°53'W and 22°01'S). The Odonata were identified using the special identification key (Hamada et al., 2014; Mugnai et al., 2010). We recorded the occurrence of epibiont ciliates (Protozoa: Ciliophora) living on larvae of Coenagrionidae (Odonata). The epibiont ciliates were found attached to some body part of the Odonata larvae, but most usually located on the head and on the pronotum and mesonotum (thorax) (see Figure 1). The presence of epibionts mostly on the head and on the pronotum and mesonotum (thorax) of the Odonata can bring some feed difficulties for these predator aquatic organism. On the other hand, as pointed by Henebry and Ridgeway (1979) since peritrichs primarily consume bacteria, their location on the body of the host is indifferent. However, adhesion to appendages is probably inadequate because epibionts may be lost with the attrition caused by movements and, according to Green (1974), the frequent perturbation by the antenna of the host interrupts the feeding of peritrichs, causing zooid contraction. On the other hand, Regali-Selegim and Godinho (2004) consider that bigger organisms are easier targets for the epibionts than smaller ones. Consequently, our observations may be related to epibiont preference for these aquatic organisms or to the presence of a comparatively larger adhesion surface

offered by each Odonata individual." **16029.** Cuéllar-Cardozo, J.A.; Arteaga-Guzmán, E.; Bernal-Arriero, L.; Campo-Garnica, A.; Capera, D.; Ocampo, C.; Ortiz-Ruiz, M.; Rincón-Aceldas, S.; Sánchez, F. (2016): Composición y riqueza de odonatos en tres humedales artificiales suburbanos en Cajicá, Cundinamarca, Colombia. *Rev. Biodivers. Neotrop.* 6(2): 164-170. (in Spanish, with English summary) ["Odonata composition and richness in three artificial, suburban wetlands in Cajicá, Cundinamarca, Colombia. The Sabana de Bogotá landscape has been highly modified and there are artificial wetlands that have been created for different purposes. Very little is known about the biodiversity of these wetlands. Objective: To compare the composition and species richness of Odonata in three artificial wetlands on the Universidad Militar Nueva Granada campus in Cajicá, Cundinamarca, Colombia. Methodology: Adults were captured using entomological nets during March and April, 2015. Three sites were sampled: 1. A wetland near the Bogotá river, 2. A temporary wetland surrounded by grassland, and 3. A wetland bordered by buildings and grassland and with the bottom covered with geomembrane. Results: 817 individuals belonging to the following species were collected: *Rhionaeschna marchali*, *Enallagma civile*, *Ischnura cruzi*, *Ischnura* sp. *Mesamphiagrion laterale* and *Erythrodiplax fusca*. The riverine and temporary wetlands shared four species and showed greater similarity between them than with the geomembrane wetland. There was an association between the frequency of species of Odonata and each of the wetlands; for example; a species was unique to the riverine wetland (*R. marchali*) and another was exclusive to the temporary wetland (*Ischnura* sp.). There were no differences in estimated species richness between the riverine and temporary wetlands, and both had greater richness than the geomembrane wetland. Conclusion: Our results suggest that the differences between the wetlands affected the composition, frequency and richness of Odonata. Increasing the abundance and diversity of macrophytes should help to maintain the diversity of Odonata on campus." (Authors)] Address: Cuéllar-Cardozo, J.A., Programa de Biología Aplicada, Fac. Ciencias Básicas y Aplicadas, Univ. Militar Nueva Granada, Cajicá, Colombia. e-mail: josecuellar1094@gmail.com

**16030.** Cuellar-Cardozo, J.A.; Castro-Rebolledo, M.I. (2016): Biomasa de odonatos en un humedal artificial suburbano, Cajica (Cundinamarca-Colombia). *Rev. Intropica* 11: 97-103. (in English, with Spanish summary) ["The wetlands from Sabana of Bogota have ecological alterations caused by the impact of anthropogenic activities. Second productivity particularly in macroinvertebrates like the odonates, is the most important aspect that can precisely define the conservation degree of wetlands. This study aimed to characterize the Odonata assembly through taxonomic identification, density and

biomass quantification, and to evaluate an allometric relation between the growth of the cephalic amplitude and the dry weight of *Rhionaeschna marchali* (larvae), present in a suburban wetland from Nueva Granada Military University (Cajicá, Cundinamarca). In total seven weekly samplings were made in the period between August and October 2014. Data were obtained in relation to the density, biomass and a linear regression model between the dry mass and cephalic amplitude for *R. marchali* naiads ( $R^2 = 0.61$ ), the others regressions were not significant. *Mesamphiagrion laterale* showed the highest density of adult individuals (0.14 ind m<sup>2</sup>) and *R. marchali* (200 ind m<sup>2</sup>) had the highest density of larvae." (2016): Diversity of Odonata in and around the Vivekananda Kendra Vidyalaya (NEC), Baragolai, Margherita, Tinsukia district of Assam (India). *International Journal of Scientific and Research Publications* 6(8): 406-410. (in English) ["A total of 39 species of Odonates, including 28 species of Anisoptera and 11 species of Zygoptera were recorded in and around the Vivekananda Kendra Vidyalaya (NEC) Baragolai, Margherita, Tinsukia district of Assam (India) between March, 2015 to June, 2016. From the sub-order Anisoptera, Libellulidae was the richest family with 25 species and from the sub-order Zygoptera, Coenagrionidae is the richest family with 9 species. A detail list of odonates recorded from the study area is presented." (Author)] Address: Das, S.M., Department of Biology, Guru Teg Bahadur Academy, Tinsukia, Assam, India

**16032.** David, S.; Funken, J.; Potthast, W.; Blanke, A. (2016): Musculoskeletal modelling under an evolutionary perspective: deciphering the role of single muscle regions in closely related insects. *Journal of The Royal Society Interface*: 13 (123): 9 pp. (in English) ["Insects show a remarkable diversity of muscle configurations, yet the factors leading to this functional diversity are poorly understood. Here, we use musculoskeletal modelling to understand the spatio-temporal activity of an insect muscle in several dragonfly species and to reveal potential mechanical factors leading to a particular muscle configuration. Bite characteristics potentially show systematic signal, but absolute bite force is not correlated with size. Muscle configuration and inverse dynamics show that the wider relative area of muscle attachment and the higher activity of subapical muscle groups are responsible for this high bite force. This wider attachment area is, however, not an evolutionary trend within dragonflies. Our inverse dynamic data, furthermore, show that maximum bite forces most probably do not reflect maximal muscle force production capability in all studied species. The thin head capsule and the attachment areas of muscles most probably limit the maximum force output of the mandibular muscles." - 16035.** De Knijf, G.; Sparrow, D.J.; Dimitriou, A.C.; Kent, R.; Kent, H.; Siedle, K.; Lewis, J.; Crossley, L. (2016): Distribution, ecology and status of a threatened species *Ischnura intermedia* (Insecta: Odonata), new for Europe. *International Journal of Odonatology* 19(4): 257-274. (in English) ["The dragonfly genus *Ischnura* has been the subject of numerous studies and is well studied in Europe and the Middle East. Nevertheless, information on the ecology, habitat preferences and phylogenetic relationships of some species is deficient. One species lacking such data is *Ischnura intermedia*, a near endemic species of the Middle East, found for the first time in Europe on Cyprus in 2013, where it occurs in five river valleys. In this study, we monitored *I. intermedia* in Cyprus where the species has a long flight period from the end of March until mid-November. Our results show that it has two and possibly even three generations a year, with the males of the first generation having reduced blue coloration on abdominal segments 8 and 9. *Ischnura intermedia* is confined to small secondary channels adjacent to streams and rivulets where the current slows and water is retained. It appears that populations can only become established at sites that have permanent water. It is therefore anticipated that the species will be under severe pressure within its range. We suggest listing this species as "Endangered" in Europe and globally as "Vulnerable" following the IUCN Red List Categories and Criteria and to prepare a species action plan for the European population of *Ischnura intermedia* on Cyprus. Two partial DNA fragments,
- mtDNA cytochrome b (Cytb) and cytochrome oxidase subunit I (COI) were used to gain insights into the phylogenetic position within *Ischnura*, especially within the *I. pumilio* clade. We demonstrate that *I. intermedia* is clearly separated from *I. pumilio*, but closely related to *I. forcipata*." - 16037.** Debecker, S.; Sanmartin-Villar, I.; de Guinea-Luengo, M.; Cordero-Rivera, A.; Stoks, R. (2016): Integrating the pace-of-life syndrome across species, sexes and individuals: covariation of life history and personality under pesticide exposure. *Journal of Animal Ecology* 85(3): 726-738. (in English) ["(1.) The pace-of-life syndrome (POLS) hypothesis integrates covariation of life-history traits along a fast–slow continuum and covariation of behavioural traits along a proactive–reactive personality continuum. Few studies have investigated these predicted life-history/personality associations among species and between sexes. Furthermore, whether and how contaminants interfere with POLS patterns remains unexplored. (2.) We tested for covariation patterns in life history and in behaviour, and for life-history/personality covariation among species, among individuals within species and between sexes. Moreover, we investigated whether pesticide exposure affects covariation between life history and behaviour and whether species and sexes with a faster POLS strategy have a higher sensitivity to pesticides. (3.) We reared larvae of four species of *Ischnura* damselflies (*I. elegans*, *I. genei*, *I. graellsii* and *I. pumilio*) in a common garden experiment with an insecticide treatment (chlorpyrifos absent/present) in the final instar. We measured four life-history traits (larval growth rate during the pesticide treatment, larval development time, adult mass and life span) and two behavioural traits (larval feeding activity and boldness, each before and after the pesticide treatment). (4.) At the individual level, life-history traits and behavioural traits aligned along a fast–slow and a proactive–reactive continuum, respectively. Species-specific differences in life history, with fast-lived species having a faster larval growth and development, a lower mass at emergence and a shorter life span, suggested that time constraints in the larval stage were predictably driving life-history evolution both in the larval stage

and across metamorphosis in the adult stage. Across species, females were consistently more slow-lived than males, reflecting that a large body size and a long life span are generally more important for females. In contrast to the POLS hypothesis, there was only little evidence for the expected positive coupling between life-history pace and proactivity. Pesticide exposure decreased larval growth rate and affected life-history/personality covariation in the most fast-lived species. (5.) Our study supports the existence of life-history and behavioural continua with limited support for life-history/personality covariation. Variation in digestive physiology may explain this decoupling of life history and behaviour and provide valuable mechanistic insights to understand and predict the occurrence of life-history/personality covariation patterns." (2016): Study on biting bugs encountered in the aquatic environments in Kashan, Isfahan Province, Iran. *Journal of Coastal Life Medicine* 4(11): 852-855. (in English) ["Summary: Objective: To determine biting bugs of Hemiptera families presenting in the county of Kashan. Methods: For this descriptive study, samples were collected from 17 locations of lentic and lotic waters, 3 times for each. These specimens were identified by using a stereo microscope and morphological keys. Results: Out of 5 535 specimens collected in three times of samplings, 3 024 specimens (54.6%) belonged to order Diptera, 701 specimens (12.7%) belonged to Crustaceans, 691 specimens (12.5%) belonged to Trichoptera, 468 specimens (8.4%) belonged to Hemiptera, 303 specimens (5.5%) belonged to Ephemeroptera, 133 specimens (2.4%) belonged to Odonata, 104 specimens (1.9%) belonged to Coleoptera, 98 specimens (1.8%) belonged to Hydrocarina and 13 specimens (0.2%) belonged to Plecoptera. In this study, Families Corixidae, Notonectidae, Gerriidae and Nepidae from Hemiptera order were identified 45.9%, 26.9%, 25.0% and 2.2%, respectively. Conclusions: These

results lead to the conclusion that Hemiptera fauna is relatively rich in Kashan. More studies by entomologists and biologists are recommended to determine the benefits and damages of these insects on the environment." (Authors)] Address: Dehghani, R. **16041.** Denloye, A.A.; Alafia, O.A.; Ajelara, K.O.; Babalola, O.O.; Dosunmu, O.A.; Owodeinde, F.G.; Solomon, O.O. (2016): Occurrence of *Orthetrum abbotti* Calvert (1892) (Odonata, Libellulidae) and intraguild predation on *Clarias gariepinus* Burchell, 1822 (Suliformes, Clariidae) and *Oreochromis niloticus* L., 1758 (Perciformes, Cichlidae) fries in Lagos fish farms. *Int. J. Aquat. Biol.* 4(5): 325-329. (in English) ["Intraguild predation occurs when species competing for the same resource prey upon or parasitize one another. This may result in economic losses under commercial circumstances. A survey of the insect species of fish farms in Badagry and Ojo Areas of Lagos State, Nigeria was carried out followed by an evaluation of the predatory ability of *Orthetrum abbotti* nymphs on fish fries. Nymph predation was evaluated in the laboratory against fries of *Clarias gariepinus* and *Oreochromis niloticus*. Samples of insects were randomly collected from 10 earthen ponds, 10 concrete ponds and the vegetation surrounding the ponds and identified over a period of 12 weeks from three study fish farms. Six species of insects belonging to four orders namely *Notonecta unifasciata*, *Gerris remigis*, *O. abbotti*, *Aedes aegypti*, *Dysticus marginalis* and *Acentria ephemerella* syn. *niveus* were collected from the ponds. Studies on feeding preference of 5th nymphal instar of *O. abbotti* on fries of *C. gariepinus* and *O. niloticus* over other food types revealed that the dragonfly preferred to feed more on *C. gariepinus* fry than on *O. niloticus* although there was no significant difference in the number of *O. niloticus* and *C. gariepinus* fries preyed upon by *O. abbotti* nymphs." **16044.** Ding, Y.; Rong, N.; Shan, B. (2016): Impact of extreme oxygen consumption by pollutants on macroinvertebrate assemblages in plain rivers of the Ziya River Basin, north China. *Environmental Science and Pollution Research* 23(14): 14147-14156. (in English) ["The aim of the study was to estimate the impact of oxygen depletion on macroinvertebrate community structure in benthic space. Macroinvertebrate assemblages and potential of dissolved oxygen (DO) consumption were investigated simultaneously in the plain rivers of the Ziya River Basin. The degree of DO depletion was represented by sediment oxygen demand (SOD) and DO, chemical oxygen demand (CODCr), and ammonia nitrogen (NH<sub>4</sub><sup>+</sup>-N) in the overlying water. The results showed an all-around hypoxia environment formed, and the values of DO, SOD, CODCr, and NH<sub>4</sub><sup>+</sup>-N were separately 0.11–4.03 mg L<sup>-1</sup>, 0.41–2.60 g m<sup>-2</sup> day<sup>-1</sup>, 27.50–410.00 mg L<sup>-1</sup>, and 1.79–101.41 mg L<sup>-1</sup>. There was an abnormal macroinvertebrate assemblage, and only 3 classes, Insecta, Gastropoda, and Oligochaeta, were found, which included 9 orders, 30 families, and 54 genera. The biodiversity was at a low level, and Shannon-Wiener index was 0.00–1.72. SOD, and NH<sub>4</sub><sup>+</sup>-N had major impact on the macroinvertebrate community, and the former had negative effect on most taxa, for instance, Nais, Branchiura, Paraleptophlebia, etc., which were sensitive or had a moderate-high tolerance to pollution. NH<sub>4</sub><sup>+</sup>-N had both positive and negative impacts on benthic animals, for instance, Dicrotendipes, Gomphus, Cricotopus, etc., for the former, and Procladius, Limnodrilus, Hippeutis, etc., for the latter. They all had a moderate-high tolerance to pollution. It is significant to improve DO condition and macroinvertebrate diversity in river harnessing and management." **16047.** Du, C.-p.; Xu, J.-x.; Zheng, Y. (2016): Application of iterative learning tuning to a dragonfly-like flapping wing micro aerial vehicle. *Chinese Control and Decision Conference (CCDC)*, 28-30 May 2016, Yinchuan, China: 4215-4220. (in English) ["The flight control design of a dragonfly-like flapping wing micro aerial vehicle (FWMAV) is studied in this paper. The main contribution of this work is to design an appropriate flight controller by incorporating a linear-quadratic regulator (LQR) method and an iterative learning tuning (ILT). The linear model of dragonfly-like FWMAV is developed at the equilibrium point. Then a linear-quadratic regulator approach is applied to design the flight controller of FWMAV. However the flight controller performance of FWMAV is sensitive to the input weighting matrix of LQR. In order to improve the flight controller, an iterative learning tuning is developed to optimize the input weighting matrix of LQR problem due to unknown constraints and relations between the state and the control input. Numerical simulation results show that the effectiveness and convergence performance of the flight controller of FWMAV are obtained.] Address: Du, C.-p., School of Aeronautics and Astronautics, Zhejiang University, Hangzhou, 310027, China

**16048.** DuBois, R.B.; Smith, W.A. (2016): Pre-emergent movements and survival of F-0 larvae of *Ophiogomphus rupinsulensis* (Odonata: Gomphidae) in a northern Wisconsin river. *International Journal of Odonatology* 19(1-2): 83-93. (in English) ["We marked and released 276 F-0 larvae of *O. rupinsulensis* in the fall of 2008 in a 99-m riffle (marking riffle) of a small, serially discontinuous, northern Wisconsin river (USA). We then recovered marked exuviae via exhaustive collecting on the banks of a 272-m sampling reach in which the marking riffle was located during spring of 2009. We collected 6054 exuviae of *O. rupinsulensis* along the sampling reach, including 3829 exuviae along the marking riffle (19.3 exuviae m<sup>-1</sup>). Mark retention was complete and our ability to recover marked exuviae in the field was high (92%). We recovered 38 marked exuviae which provided a minimum estimate of survival (14%) for F-0 larvae from late September to the following June. The density of F-0 larvae in the marking riffle in late September was estimated at 22.6 larvae m<sup>-2</sup>. Nearly all F-0 larvae made small downstream movements (97% moved <60 m) at some time during the 36 weeks before emergence, but they did not make substantial longitudinal movements. These results affirmed the premise that locations of found exuviae of *O. rupinsulensis* along a small river are in close proximity to the habitats where the larvae developed." **16050.** Dumont, H.J. (2016): The dragonfly fauna of South Mauretania: 40 years later. *Brachytron* 18(1): 57-67. (in Dutch, with English summary) ["In February 2016, I observed 11 species of dragonflies in the Tagant plateau and Senegal valley. The Tagant area is relatively rich in permanent water, being situated at the transition of Sahara desert and Sahel. I re-visited several water points seen and sampled forty years earlier (1975 and 1976). A comparison with the current situation revealed incisive changes: in many places, new human settlements have appeared, leading to the privatization (fencing) of large parts of oases and other desert areas, a huge proliferation of cattle, and the use of detergents (and presumably, but not observed) of pesticides. *Agriocnemis zerafica*, of which one population north of the Senegal River was known from the oasis of El Houseiniye, had disappeared, and

most other species had decreased in abundance. I was also struck by some biogeographic anomalies: at least two Afro-tropical species that are currently common in Morocco and expanding into the Iberian Peninsula, are not or scarcely found in Mauretania and Senegal. Other species, common in these two countries, have relict populations in the central Sahara (mainly in Algeria and Libya) but are lacking in the western desert and do not reach the Maghreb. The reasons behind this pattern are unknown, but are likely of an ecological (species interaction?) nature. *Hemianax ephippiger* was present but not abundant and did not (yet?) migrate. *Lestes pallidus* was found to associate with *Acacia* trees, abundantly in the Senegal valley, but isolated occurrences were noted up to 100 km from the river. The dynamics of this association tree-dragonfly deserves closer attention. Possibly it is neutral, but it is not excluded that it might be a mutualistic relationship, the first to involve a dragonfly." (Author)] (Address: Dumont, H.J., Univ. Gent, Inst. Animal Ecology, K.L. **16051.** Dutmer, G. (2016): Discovery of a population of *Nehalennia speciosa* in the eastern part of the Netherlands. *Brachytron* 18(1): 16-22. (in Dutch, with English summary) ["*N. speciosa* has always been a very rare species in the Netherlands and was regarded as extinct, with only two reliable records, from 1899 and 1912. In June 2015, a population was found in the eastern part of the Netherlands. Between June 11 and July 31 a maximum of 40 individuals per day, including copulae and teneral were seen. The flight period is from the beginning of June till the end of July. The population was visited regularly and their ecology and behaviour was observed. Although the habitat corresponds with the description in the literature the individuals were only seen on land. The origin of this population is unclear. Possibly it survived the excavations in the early 20th century. The nearest known population is located 200 kilometres away in Germany. Possibly more populations are to be discovered in the border area between the Netherlands and Germany." (Author)] (Address: Gerard Dutmer. E-mail: gerarddutmer@hotmail.com

**16052.** Ehram, M.; Knutie, S.A.; Rohr, J.R. (2016): The herbicide atrazine induces hyperactivity and compromises tadpole detection of predator chemical cues. *Environmental Toxicology & Chemistry* 35(9): 2239-2244. (in English) ["The ability to detect chemical cues is often critical for freshwater organisms to avoid predation and find food and mates. In particular, reduced activity and avoidance of chemical cues signaling predation risk are generally adaptive behaviors that reduce prey encounter rates with predators. The present study examined the effects of the common herbicide atrazine on the ability of Cuban tree frog (*Osteopilus septentrionalis*) tadpoles to detect and respond to chemical cues from larval dragonfly (*Libellulidae* sp.) predators. Tadpoles exposed to an estimated environmental concentration of atrazine (calculated using US Environmental Protection Agency software; measured concentration, 178 µg/L) were significantly hyperactive relative to those exposed to solvent control. In addition, control tadpoles significantly avoided predator chemical cues, but tadpoles exposed to atrazine did not. These

results are consistent with previous studies that have demonstrated that ecologically relevant concentrations of atrazine can induce hyperactivity and impair the olfactory abilities of other freshwater vertebrates. The authors call for additional studies examining the role of chemical contaminants in disrupting chemical communication and the quantification of subsequent impacts on the fitness and population dynamics of wildlife." **16054.** Escoriza, D.; Hassine, J.B.; Sala, J.; Boix, D. (2016): Zoophagy in the larvae of Ibero-Maghrebian Spade-foot Toads. *Herpetologica* 72(4): 281-287. (in English, with French summary) ["The ecological role of anuran larvae is usually defined as a primary consumer. Recent studies have shown, however, that some grazing-rasping species consume animal matter on a regular basis. We investigated zoophagy in two species of Spade-foot Toads (*Pelobates cultripes* and *P. varaldii*). The larvae of both species showed no specific morphological adaptations for macrophagy but are very large and inhabit invertebrate-rich ponds under prolonged summer drought conditions. We hypothesized that both species would consume animals having high nutritional value, and that there would be no difference between the two species in terms of the animals consumed, because tadpoles are broad dietary generalists. We also hypothesized that the consumption of animals would vary during development based on the size limitations of the oral cavity. Examination of the intestinal contents of *P. varaldii* and *P. cultripes* indicated that they had consumed a wide range of invertebrates, as predicted. Differences in the composition of animals between the two species might be attributable to variability in the composition of invertebrate assemblages among ponds. We provide the first evidence of consumption by taxa within *Pelobates* of aquatic species of Insecta (Coleoptera, Diptera, Ephemeroptera, and Odonata), Collembola (*Sminthuridae* and *Poduridae*), large Branchiopoda (*Anostraca*, *Notostraca*, and *Spinicaudata*), and Gastropoda (*Physidae* and *Planorbidae*). We also found a correlation between the diversity of animals consumed and the ontogenetic variation in size in both *Pelobates* species. These findings support the hypothesis that grazing-rasping tadpoles have an omnivorous role in aquatic

trophic webs." (Authors)] Address: Escoriza, D., GRECO, Institute of Aquatic Ecology, Univ. of Girona, Girona 17003, Spain. E-mail: daniel\_escoriza@hotmail.com

**16057.** Farkas, A.; Danyik, T.; Móra, A. (2016): Riverine dragonflies (Odonata: Gomphidae) of the rivers of Körös-Maros National Park. *Crisicum* 9: 133-164. (in Hungarian, with English summary) ["In 2013 and 2014 systematic collections of Gomphidae exuviae were carried out at altogether 89 sampling sites in the Natura 2000 areas along the rivers of Körös-Maros National Park (Maros, Sebes-Körös, Fehér-Körös, Fekete-Körös, Kettos-Körös, Hármaskörös and Hortobágy-Berettyó). The sampling sites were visited during the emergence periods of gomphid species. Besides Gomphidae, exuviae of other species were also collected, and observational data on adult specimens were occasionally recorded. During our work 8296 exuviae (from which 7323 were exuviae of Gomphidae) were collected and 1854 adults were observed. A total of 26 species were found (18 as exuviae and 23 as adults). In the Maros, Fehér-, Fekete-, Kettos- and Sebes-Körös the co-occurrence of the four Hungarian gomphid species was detected, although only a single exuvia of *O. cecilia* and a single exuvia of *O. forcipatus* was found in the Sebes-Körös and the Maros respectively. In the Hármaskörös and the Hortobágy-Berettyó only the two Gomphus species occurred, but while larger populations exist in the Hármaskörös, their occurrence in the Hortobágy-Berettyó is very sporadic. Furthermore, our collections resulted in several new localities for gomphid species, which was especially evident for *O. cecilia* and *O. forcipatus* and therefore their

distributional areas were remarkably expanded. Comparing the studied rivers, apparently the Maros was the most favourable for gomphids: mean number of exuviae was much higher here than at the other rivers. Except the Hortobágy-Berettyó, stable and viable populations of Gomphidae exist along the studied rivers with great significance in terms of nature conservation. Accordingly, either the studied reaches of the rivers or their Gomphidae populations deserve protection." (Authors)] Address: Farkas Anna, Park u. 2., 1223 Budapest, Hungaria

**16058.** Feindt, W.; Osigus, H.-J.; Herzog, R.; Mason, C.E.; Hadrys, H. (2016): The complete mitochondrial genome of the neotropical helicopter damselfly *Megaloprepus caerulatus* (Odonata: Zygoptera) assembled from next generation sequencing data. *Mitochondrial DNA Part B: Resources* 1(1): 497-499. (in English) ["Odonata is a small order at the base of flying insects (Pterygota). Resolving family-level phylogenetic relationships within this order receives great attention. Hereby, genetic data already resulted in various changes, which are however still under discussion. Mitochondrial genomes may further enhance such phylogenies. This study presents the complete mitochondrial genome of the Neotropical damselfly *M. caerulatus* based on next generation sequencing (NGS) data on total genomic DNA. The total length comprises 16,094 bp and includes the standard metazoan set of 37 genes together with a 1376 p long A+T rich (control) region. Gene content, gene arrangement and base frequency are consistent with other odonate mitochondrial genomes. It further contains four intergenic spacer regions, indicating a possible family specific feature for the Coenagrionidae and its close relatives." **16059.** Feindt, W.; Herzog, R.; Osigus, H.-J.; Schierwater, B.; Hadrys, H. (2016): Short read sequencing assembly revealed the complete mitochondrial genome of *Ischnura elegans* Vander Linden, 1820 (Odonata: Zygoptera). *Mitochondrial DNA Part B* 1(1): 574-576. (in English) ["Damselflies of the genus *Ischnura* emerge as organisms with high potential in ecological, evolutionary and developmental research at the base of flying insects. *Ischnura elegans* and *Ischnura hastata* are for example one of the few odonate species where a complete life cycle over generations can be reared under laboratory conditions. We here report the complete mitochondrial genome of *Ischnura elegans* as a valuable genomic resource for future eco-evo-devo studies at the base of flying insects. The genome has a total length of 15,962 bp and displays all typical features of Odonata mitochondrial genomes in gene content and order as well as A + T content. Start and stop codons of all protein-coding genes are consistent. Most interestingly, we found four intergenic spacer regions and a long A + T rich (control) region of 1196 bp, which is almost double the size of the close relative *Ischnura pumilio*. We assume that the adequate insert size and iterative mapping may be more efficient in assembling this duplicated and repetitive region." (Authors)] Address:

**16061.** Feriwibisono, B.; Marsoedi; Leksono, A.S. (2016): The model of odonate diversity relationship with environmental factors based on path analysis. *El-Hayah* 6(1): 7-14. (in English) ["This study aims to analyze and describe the relationship between altitude, aerial variables (temperature, light intensity, humidity), water qualities (water temperature, pH, BOD, COD, DO, TOM, and water velocity), and vegetation with the diversity of Odonate assemblages. Odonate samplings were conducted at six survey sites based on altitude and vegetation characteristics. Measurement of altitude, aerial variables, water qualities and vegetation characteristics were replicate in the first day and third day. Analysis of correlations of all environmental factors with the odonate diversity was done through structural equation model using Partial Least Squares (PLS), Open source Smart Software and Microsoft Excel. The aerial variables and water qualities affected indirectly on odonate diversity. The aerial variables directly or with interaction to other factor affected the water qualities and vegetation characteristics. The vegetation characteristics directly influenced to odonate diversity. Water flow affected water quality, light intensity affected the aerial, while morning period observation affected the odonate diversity. Predictive relevance (Q<sup>2</sup>) for a model designed amounted to 99.95%, while the rest of 0.05% are explained by other variables." **16062.** Ferreras-Romero, M.; Márquez-Rodríguez, J.; Fernández-Delgado, C. (2016): Long-time effect of an invasive fish on the Odonata assemblage in a Mediterranean lake and

early response after rotenone treatment. *Odonatologica* 45(1/2): 7-21. (in English) ["Over a thirty year period from 1977 to 2007, 16 Odonata species were recorded in the Nature Reserve "Laguna de Zóñar", Cordova, Andalusia, Spain. Thermophilic dragonflies with wide distribution in the African continent were dominant in recent years. In 1985, Common carp *Cyprinus carpio* L., 1758 were introduced in an uncontrolled and illegal action, and aquatic macrophytes and benthonic macroinvertebrates of the lake practically disappeared within ten years. One of the most successful tools for controlling and eradicating invasive fish is the use of chemical compounds such as rotenone. This compound adversely affects aquatic organisms with gill respiration by inhibiting oxygen intake at the cell level. Here, we analyse the effect on the Odonata assemblage of this lake after treatment with rotenone intended to eradicate the carp population. During the first year after treatment, nine Odonata species were recorded, and at least six of them obviously had completed their life cycle in the lake. We also carried out the determination of the five last growth stadia in *Orthetrum cancellatum* larvae, and we propose that, in the southern Iberian Peninsula, this species has a univoltine life cycle with asynchronous emergence." **16063.** Foglini, C. (2016): Odonata next-door: an updated check-list of two parks in the Northern Milan outskirts (Lombardy, Italy). *Natural History Sciences. Atti Soc. it. Sci. nat. Museo civ. Stor. nat. Milano* 3(2): 35-40. (in English, with Italian summary) ["Odonata are usually regarded as bioindicators and model organisms in many studies and are subjected to increasing threats worldwide. Such insects populate freshwater ecosystems at both natural and urban landscapes and they are also well-known by common people. This work is aimed at summarizing and updating the current knowledge concerning Odonata species inhabiting two parks located at the northern boundary of the Milan outskirts (Italy, Lombardy). Occupancy status for odonate species were obtained merging the field data of surveys conducted during 2014 and 2015 with spare information from specialistic websites and forums, grey literature, and pictures collected at the same sites by occasional observers. The total number of species found in both parks showed an increase of species richness when compared with two previous studies. Moreover, Odonata communities of the two parks showed a common chorological composition and similarity in the species assemblages. This work had also a positive impact about the perception of urban biodiversity: some of the untrained observers, who shared their pictures for species identification, rapidly acquired sufficient knowledge to easily recognize the most common species present in both parks." **16064.** Gabela Flores, M.V. (2016): Demography and territorial behavior of three species of the genus *Hetaerina* (Odonata: Calopterygidae) along three tropical stream ecosystems. Tesis (Licenciada en Biología), Universidad San

Francisco de Quito, Colegio de Ciencias Biológicas y Ambientales; Quito, Ecuador: 52 pp. ["We studied the demography and territorial behavior of three damselfly species of the *Hetaerina* genus (*H. fuscoguttata*, *H. aurora* and *H. caja*) along three lowland stream ecosystems in western Ecuador. Throughout a Capture-Mark-Recapture (CMR) methodology, we estimated the daily survival rates, sex ratio and longevity of the most abundant species on each location, as well as the respective population size. Overall, we captured more males than females and we found male biased sex ratios in all three studied populations. Throughout focal observations, we analyzed male territorial behavior as well as male and female reproductive behavior of the three *Hetaerina* species. We registered a low number of reproductive events in all populations. Conversely, we registered a higher number of male-male interactions of this territorial genus. However, we did not find evidence that certain morphological characters are related to a male's territorial role." (Author)] Address: not stated

**16066.** Gallesi, M.M.; Mobili, S.; Cigognini, R.; Hardersen, S.; Sacchi, R. (2016): Season matters: differential variation of wing shape between sexes of *Calopteryx splendens* (Odonata: Calopterygidae). *Zoomorphology* 135(3): 313-322. (in English) ["Insects adapt commonly to seasonally changing habitats and reproductive contexts. Individuals that mature at different times during the year can show patterns of life cycle or morphological variation, possibly associated with changes in reproductive behaviour. Concerning mating strategies of flying insects, wing morphology may be related both to the outcome of male-male contests and to the ability in acquiring females. Therefore, different mating strategies (territorial vs. non-territorial) may have different flight morphology optima that increase fitness in their context. Males of *C. splendens* are mainly territorial early in the season, but with the advancing season and with increasing competition, more and more males adopt a non-territorial pursuing strategy. Given that different mating tactics have different wing morphologies, here we test whether the wing shape of males shifts from a "territorial" to a "non-territorial morphology" during the season. So, early in the season males show highly sexually dimorphic wings, which allow for high manoeuvrability and larger spots, while late in the season wing shapes of males become less sexually dimorphic and more suitable when pursuing females. Additionally, we studied the seasonal variation of other flight related traits, specifically wing lengths, abdomen length and weight. We found that these latter

traits decreased along the season in both sexes without altering sexual dimorphism. However, wing shape, which resulted sexually dimorphic, showed a seasonal variation, decreasing the level of sexual dimorphism. The most probable determinant of this change is phenotypic plasticity triggered by environmental cues, but other explanations of the observed pattern are discussed." (2016): Biomimetics for early stage biofouling prevention: Templates from insect cuticles. *Journal of Materials Chemistry B, Materials for biology and medicine* 4: 5747-5754. (in English) ["A biomimetic antifouling material study was carried out utilising superhydrophobic cicada and dragonfly wings replicated with a polymer (epoxy resin). They were tested in a marine biofouling study for up to 1 week in addition to biofouling assays of protein, carbohydrate and DNA absorption. The materials were compared against a commercial antifouling paint and a polymeric smooth surface constituting a control sample. The replicated surfaces demonstrated superior antifouling properties in comparison to the control and similar efficiency in DNA (10% reduction), protein and carbohydrate adsorption (15%) to the commercial anti-fouling paint. As the fabricated surfaces have roughness at the nano metre scale it is probable that the low adsorption properties, at least at the early stages, may be related to air trapped at the surface. Interestingly the most disordered replicated surface (dragonfly wing replicate) demonstrated the lowest values of absorption." **16071.** Geraeds, R.P.G. (2016): Hibernation Common Winter Damselflies at the Driestruik Nature Reserve. *Natuurhistorisch Maandblad* 105(1): 244-246. (in Dutch, with English summary) ["For several years, *Sympecma fusca* were observed until late autumn along the edge of a forest at the Driestruik nature reserve during surveys of Common lizards (*Zootoca vivipara*). Unlike most European dragonfly species, Common winter damselflies hibernate in the adult stage, rather than as eggs or larvae. For a long time, little was known about the hibernation of this species. Recent research in the Netherlands has shown that at least some of the animals hibernate freely suspended in the vegetation. As of the winter of 2012, the forest edge has been searched annually for hibernating damselflies. None were found during the first two winters, but in the winter of 2014-15 two hibernating animals were found, and three in the winter of 2015-16. Four of the five specimens were found in vegetation, at heights of 10 to 40 cm above the ground. The fifth animal was found in a narrow slit in a fence post. While hibernating, the animals are still active during warmer periods. They can cover short distances by crawling through the vegetation." **16072.** Gitarama, A.M.; Krisanti, M.; Agungpriyono, D.R. (2016): Macrozoobenthic Communities and Accumulation of Chromium in Cimanuk Lama River, West Java. *Jurnal Ilmu Pertanian Indonesia* 21(1): 48-55. (in Indonesian, with English summary) ["The residue of human activities and batik industrial waste water surrounding the river will be able to increase the accumulation of chromium and to disrupt macrozoobenthic communities in the river. The aims of this

study was to assess the impact of human activities surrounding the river to the macrozoobenthic communities and the accumulation of chromium in Cimanuk Lama River, Indramayu District, West-Java. The study has been conducted from April/May 2015 based on three times sampling at three different sampling stations. The result of this study shows that the chromium accumulated in the waters of all station still meet the standard quality ranging from 0,010 to 0,016 mg/l, but only station 1 fulfills the standard quality for chromium accumulated in the river sediment with the range of all stations was about 11,72 to 46,63 mg/kg. The results also show that the community index analysis describes the change of macrozoobenthic community at all stations caused by environmental pressure, especially at the station 2 which is indicated by the highest score of Family Biotic Index. The accumulation of the chromium in the waters and the change of macrozoobenthic community structure are mostly influenced by the use of the Cimanuk Lama river long for agricultural and fisheries activities, and also batik home industry." **16075.** Golfieri, B.; Surian, N.; Hardersen, S.; Maiolini, B. (2016): How to comprehensively evaluate river corridor conditions? A comparison of different biotic and morphological indices in northern Italy. EGU General Assembly 2016, held 17-22 April, 2016 in Vienna Austria: 7059. (in English) [Verbatim: The assessment of river conditions is crucial for planning appropriate management actions. The European Water Framework Directive 2000/60/EC (WFD) requires the assessment of biological, physical-chemical and hydromorphological elements to define the ecological status of rivers. The WFD suggests the use of different bioindicators (i.e. benthic macroinvertebrates, diatoms, aquatic macrophytes and fish), the so called "biological quality elements" (BQEs). However, recent studies showed that BQEs-based indices have two main limitations: (i) their standard application is limited to flowing channels and (ii) they are not sensitive to hydromorphological alteration. Hydromorphological conditions are usually evaluated applying methods for physical habitat assessment (i.e. the River Habitat Survey or derived methods) that consist in site-scale inventories of river forms and anthropic structures. The lack of consideration of wider spatial (i.e. reach or catchment scale) and temporal scales (e.g. channel evolution over the last 50-100 years) make such methods inadequate for a sound diagnosis of morphological alterations. The Morphological Quality Index (MQI) and the dragonfly-based Odonate River Index (ORI) were developed in the recent years to overcome the above-mentioned limitations and to assess the condition of the whole river corridor (i.e. the channel and its adjacent floodplain) at reach scale. In this study we correlated the assessments of MQI, ORI and two BQEs-based biotic indices (i.e. STAR\_ICMi for benthic macroinvertebrates and ICMi for diatoms) in 15 lowland river reaches in northern Italy. The selected reaches are characterized by a wide range of morphological degradation. MQI and ORI were highly correlated, probably because both methods work at reach scale and consider the integrity of the whole river corridor, either in terms of morphology or considering ecological aspects. In contrast, no significant relationships were found between MQI and ORI and the BQEs-based indices (i.e. ICMi and STAR\_ICMi). This can be probably attributed to the differences in spatial scale (i.e. site scale) at which the BQEs-based indices apply and to the human pressure that they were originally designed to detect (i.e. water quality). These results show that MQI and ORI are useful tools to evaluate the integrity of the river corridor, at reach scale. The ORI provides information on the ecological condition of the river not covered by the other biotic indices, thanks to the sampling strategy that considers also secondary channels and ponds. We underline the importance of integrating the assessment of the lateral dimension of the river corridor in the evaluation and the need to choose appropriate indicators. The choice of the indicators must also consider the spatial and temporal scale of their application, in order to detect pressures operating at various scales (e.g. water quality and hydromorphological alteration). Only the integration of reach-scale indicators, such as MQI and ORI, would allow for a comprehensive evaluation of river corridor conditions and to define sound and appropriate management actions.]

**16076.** Gordon, A.M.; Youngquist, M.B.; Boone, M.D. (2016): The effects of pond drying and predation on Blanchard's Cricket Frogs (*Acris blanchardi*). *Copeia* 104(2): 482-486. (in English) ["Pond hydroperiod and predators play a central role in structuring aquatic communities. Because of predicted changes in precipitation and temperature patterns associated with climate change, pond hydroperiods will likely be altered. Reduced hydroperiods can impact amphibian populations by restricting the amount of time available for larval growth and by altering predatory interactions via increased predator densities. We investigated how pond drying and predation singularly and interactively affected growth and survival of *A. blanchardi*. We reared recently hatched tadpoles through metamorphosis in outdoor mesocosms using a factorial design incorporating three hydroperiods (fast-drying, slow-drying, or constant) and three larval odonate predator treatments (caged, uncaged, or absent). Caged and uncaged predator treatments were implemented to evaluate both consumptive and non-consumptive effects. There were no differences in survival, time to metamorphosis, or size at metamorphosis in response to drying or predation treatments. Although pond drying rates in this study did not induce measurable responses, it is possible that more extreme conditions could impact metamorphosis. The lack of response to odonate predator presence and cues suggests tadpoles of *A. blanchardi* may rely on other behavioral and phenotypic defenses, such as the tail spot, to escape predation. Developing a more comprehensive understanding of how *A. blanchardi* responds to altered hydroperiod, predators, and their potential interactions is important to predict how this species and other amphibians that breed in diverse aquatic habitats may respond to the influence of climate change on aquatic ecosystems." (2016): Body size, reproductive behaviour, and microhabitat use of two sympatric *Trithemis* species – what might allow their sympatry? (Odonata: Libellulidae). *Odonatologica* 45(1/2): 23-36. (in English) ["Sympatric territorial species are subject to interference competition when they share the same resources. The interaction becomes stronger when the coexisting species share similar traits, which is often the case in congeners. In this study, we investigated the body size, reproductive behaviour, and microhabitat use of two congeneric dragonflies, *T. annulata* and *T. arteriosa*, in Northeast Algeria from September to November 2012 in order to assess the potential factors that allow their coexistence in the same system. Even though *T. annulata* was larger than *T. arteriosa*, mistaken recognition was often observed. The behavioural sequence of both species exhibited broadly similar patterns in reproductive behaviour but they differed in mate guarding tactics and male-male interference. Copulation duration was shorter in *T. annulata* than in *T. arteriosa*. Oviposition bouts lasted longer in *T. arteriosa* but dipping was faster in *T. annulata*. Analysis of microhabitat choice showed that *T. arteriosa* males preferred vegetated areas to

establish their territories while *T. annulata* used a wide array of habitats including terrestrial ones. Our data suggest that, although the two congeneric species are phenotypically similar and demonstrate low interspecific recognition abilities, they can coexist syntopically because they differ slightly in their habitat use and reproductive behaviour." **16083.** Harisha, M.N. (2016): Evaluation of status and diversity of odonates of Kondajji lake, Kondajji village, Harihar Taluk, Davanagere district, Karnataka, India. *Journal of Entomology and Zoology Studies* 4(4): 384-388. (in English) ["A study on diversity of odonates was conducted at Kondajji Lake of Kondajji Village located in Harihar Taluk, Davanagere District of Karnataka. The study was conducted to explore status, diversity and threats of Odonates during February 2007 to January 2008. The study revealed a total of 34 species of Odonates in 24 genera belonging to 6 families have been reported. Among them Anisoptera dominated with 25 species, followed by the Zygoptera with 9 species. The family Libellulidae dominated with 20 species among the Anisoptera. Among the Zygoptera, Coenagrionidae was found to be the dominant family with 6 species. Based on the frequency of occurrence 35% of the species were common, 23% were very common, 21% were rare, 15% were occasional and 6% were very rare. According to IUCN categorization all the odonate species recorded from the study area comes under 'Least Concern' (LC) category. The study provides the baseline data on Odonates diversity of some major wetland water bodies of Davanagere District of Karnataka state for research on their biology and the conservation."] (Author)] Address: Harisha, M.N., Dept of Post Graduate Studies & Research in Applied Zoology & Wildlife Management, Kuvempu University, Jnana Sahyadri, Shankaraghatta, Shimoga, Karnataka, India

**16084.** Hellmund, M.; Hellmund, W. (2016): Reproduction structures of damselflies (Odonata, Zygoptera): are they trace fossils or not? *Palaeodiversity* 9(1): 89-94. (in English) ["Following a review of relevant mechanisms and structures, we propose to use binary nomenclature for characterizing and naming most fossil egg-sets, clutches and ovipositions of damselflies as trace fossils. We recommend to sharply distinguish between structures caused by insects and adjoining plant tissues. Only the former are trace fossils, the latter are not."] (Authors)] Address: Hellmund, M., Zentralmagazin Naturwissenschaftlicher Sammlungen, Martin-Luther-Universität Halle-Wittenberg, Domplatz 4, 06108 Halle (Saale), Germany. **16085.** Henze, M.J.; Oakley, T.H. (2016): The dynamic evolutionary history of Pancrustacean eyes and opsins. *Integrative & Comparative Biology* 55(5): 1-13, 25 pp app. (in English) ["Synopsis: Pancrustacea (Hexapoda plus Crustacea) display an enormous diversity of eye designs, including multiple types of compound eyes and single-chambered eyes, often with colour vision and/or polarization vision. Although the eyes of some pancrustaceans are well-studied, there is still much to learn about the evolutionary paths to this amazing visual diversity. Here, we examine the evolutionary history of eyes and opsins across the principle groups of Pancrustacea. First, we review the distribution of lateral and median eyes, which are found in all major pancrustacean clades (Oligostraca, Multicrustacea, and Allotricarida). At the same time, each of those three clades has taxa that lack lateral and/or median eyes. We then compile data on the expression of visual r-opsins (rhabdomeric opsins) in lateral and median eyes across Pancrustacea and find no evidence for

ancient opsin clades expressed in only one type of eye. Instead, opsin clades with eye-specific expression are products of recent gene duplications, indicating a dynamic past, during which opsins often changed expression from one type of eye to another. We also investigate the evolutionary history of peropsins and r-opsins, which are both known to be expressed in eyes of arthropods. By searching published transcriptomes, we discover for the first time crustacean peropsins and suggest that previously reported odonate opsins may also be peropsins. Finally, from analyzing a reconciled, phylogenetic tree of arthropod r-opsins, we infer that the ancestral pancrustacean had four visual opsin genes, which we call LW2, MW1, MW2, and SW. These are the progenitors of opsin clades that later were variously duplicated or lost during pancrustacean evolution. Together, our results reveal a particularly dynamic history, with losses of eyes, duplication and loss of opsin genes, and changes in opsin expression between types of eyes." **16086.** Herzog, R.; Osigus, H.-J.; Feindt, W.; Schierwater, B.; Hadrys, H. (2016): The complete mitochondrial genome of the emperor dragonfly *Anax imperator* LEACH, 1815 (Odonata: Aeshnidae) via NGS sequencing. Mitochondrial DNA Part B 1(1): 783-786. (in English) ["Here we report the complete mitochondrial genome of *A. imperator* as the first of its genus. Data were generated via next generation sequencing (NGS) and assembled using an iterative approach. The typical metazoan set of 37 genes (13 protein-coding genes, 22 tRNA genes, and 2 rRNA genes) was detected in the same gene order as in other odonate mitogenomes. However, only three intergenic spacer regions are present in *A. imperator* lacking the distinct s5 spacer, which was regarded as informative feature of the odonate suborder Anisoptera but absent in Zygoptera. With 16,087 bp, it is the longest anisopteran mitogenome to date, mainly due to the long A+T-rich control region of 1291 bp." **16087.** Heynen, M.; Fick, J.; Jonsson, M.; Klaminder, J.; Brodin, T. (2016): Effect of bioconcentration and trophic transfer on realized exposure to oxazepam in two predators, the dragonfly larvae (*Aeshna grandis*) and the Eurasian perch (*Perca fluviatilis*). Environmental Toxicology and Chemistry 35(4): 930-937. (in English) ["Psychoactive substances are used worldwide and constitute one of the most common groups of pharmaceutical contaminants in surface waters. While these pharmaceuticals are designed to be efficiently eliminated from the human body, we know very little about their trophic-transfer potential in aquatic wildlife. Therefore, the goal of this study was to quantify and compare uptake of an anxiolytic (oxazepam) from water (bioconcentration) and via the consumption of contaminated diet (trophic transfer) in *P. fluviatilis* and *A. grandis*. We found bioconcentration (BC) and trophic transfer (TT) of oxazepam in both predator species. However, we observed higher BC for perch (bioconcentration factor [BCF]

3.7) than for dragonfly larvae (BCF 0.5). Perch also retained more oxazepam from consumed prey (41%) than dragonfly larvae (10%), whereas the relative contribution via prey consumption was 14% and 42% for perch and dragonflies, respectively. In addition, we found that BC was negatively correlated with perch weight, indicating that exposure levels in natural contaminated environments differ between individuals of different size or between different developmental stages. Hence, TT of pharmaceuticals may indeed occur, and estimates of environmental exposures that do not consider intake via food or size-dependent bioconcentration may therefore lead to wrongful estimations of realized exposure levels in natural contaminated ecosystems." (Authors)] Address: Heynen, Martina, Dept of Ecology & Environmental Science, Umeå University, Sweden. E-mail: martina.heyne@umu.se

**16088.** Higashikawa, W.; Yoshimura, M.; Yagi, T.; Maeto, K. (2016): Microhabitat use by larvae of the endangered dragonfly *Sympetrum pedemontanum elatum* (Selys) in Japan. Journal of Insect Conservation 20: 407-416. (in English) ["*S. pedemontanum*, which is distributed widely in the Eurasian continent and its neighbouring islands, is listed as a Least Concern species in the International Union for Conservation of Nature Red List (2015). In Japan, however, the population of its subspecies *S. pedemontanum elatum* has been rapidly decreasing since the 1970s. In order to conserve this subspecies, it is important to understand the seasonal microhabitat use by its larvae. However, this has been a difficult task because larvae of *S. pedemontanum elatum* often coexist with those of a common congener, *S. eroticum*, and cannot be morphologically distinguished from the latter. Thus, in this study, we first established a molecular technique based on the polymerase chain reaction to accurately identify each species. In the subsequent field survey in 2015 with its application in the Sakasegawa River, Hyogo Prefecture, we found that *S. pedemontanum elatum* larvae hatch in stagnant water and subsequently advance into weakly flowing water. Our results indicated a change in the microhabitats during the larval developmental process, reflecting the need for a continuous spectrum of stagnant, transitional, and flowing water. Such aquatic environments with a spectrum of water conditions are disappearing in Satoyama, a rural farming area in Japan. This has endangered species such as *S. pedemontanum elatum* and *Oryzias latipes* (Beloniformes: Adrianichthyidae) by depriving them of their favourable habitats. For their conservation, it is necessary to develop methods to recover the traditional aquatic environments in Satoyama." (Authors)] Address: Higashikawa, W., Laboratory of Insect Biodiversity & Ecosystem Science, Graduate School of Agricultural Science, Kobe Univ., Rokkodai-cho 1-1, Nada-ku, Kobe, Hyogo 657-8501, Japan. **16089.** Hill, M.J.; Ryves, D.B.; White, J.C.; Wood, P.J. (2016): Macroinvertebrate diversity in urban and rural ponds: Implications for freshwater biodiversity conservation. Biological Conservation 201: 50-59. (in English) ["Ponds are among the most biodiverse freshwater ecosystems, yet face significant threats from removal, habitat degradation and a lack of legislative protection globally. Information regarding the

habitat quality and biodiversity of ponds across a range of land uses is vital for the long term conservation and management of ecological resources. In this study we examine the biodiversity and conservation value of macroinvertebrates from 91 lowland ponds across 3 land use types (35 floodplain meadow, 15 arable and 41 urban ponds). A total of 224 macroinvertebrate taxa were recorded across all ponds, with urban ponds and floodplain ponds supporting a greater richness than arable ponds at the landscape scale. However, at the alpha scale, urban ponds supported lower faunal diversity (mean: 22 taxa) than floodplain (mean: 32 taxa) or arable ponds (mean: 30 taxa). Floodplain ponds were found to support taxonomically distinct communities compared to arable and urban ponds. A total of 13 macroinvertebrate taxa with a national conservation designation were recorded across the study area and 12 ponds (11 floodplain and 1 arable pond) supported assemblages of high or very high conservation value. Pond conservation currently relies on the designation of individual ponds based on very high biodiversity or the presence of taxa with specific conservation designations. However, this site specific approach fails to acknowledge the contribution of ponds to freshwater biodiversity at the landscape scale. Ponds are highly appropriate sites outside of protected areas (urban/arable), with which the general public are already familiar, for local and landscape scale conservation of freshwater habitats." (Authors)] Address: Hill, M.J., Inst. Science & the Environment, Univ. of Worcester, Henwick Grove, Worcester WR2 6AJ, UK. E-mail: matthew.hill@worc.ac.uk

**16090.** Hunger, H. (2016): *Sympetma paedisca* am westlichen Bodensee - weitere neue Beobachtungen zu Bestandsschwankungen und Fortpflanzungshabitaten (Odonata: Lestidae). *Mercuriale* 16: 33-43. (in German, with English summary) ["*S. paedisca* at the westerly Lake Constance - more new findings on population fluctuations and reproduction habitats - New data from surveys carried out in 2015 und 2016 within the shore zones of westerly Lake Constance are presented and compared with the water level fluctuations of Lake Constance between April and September, the period of oviposition, larval development and emergence. The data support the hypothesis presented by Hunger & Schiel (2014) that falling water levels during the summer lead to the death of many larvae in their shallow water habitats. The knowledge about larval habitats of *S. paedisca* remains insufficient, however, findings of exuviae within the nature reserve „Wollmatinger Ried“ can be reported." **16091.** Huplalo, K.; Tonczyk, G. (2016): Dragonflies (Odonata) of high mountain habitats. *Kosmos* 65(2): 267-275. (in Polish, with English summary) ["The aim of this article is to characterize the odonatofauna in the mountainous areas and to examine variations in the diversity of Odonata species in different regions of the world. Dragonflies are widespread on all continents except of Antarctica. However, the fossils found in Antarctica suggest that dragonflies were there present 150-200 million years ago. Their diversity reaches its peak in the tropics and in the Oriental regions. Due to the hard environmental

conditions present at high altitudes, dragonflies of high mountain habitats have developed a number of adaptations that enable their development and reproduction even at the height of 5000 m. Dragonflies are merolimnic, so the main factor limiting their occurrence is the lack of water. The highest altitude at which any dragonfly was found was in Himalayas, where at 6300 m a single individual of the common species *Pantala flavescens* was collected. In the distribution of the odonatofauna in high mountain habitats in different world regions there occur both some differences and similarities. On the every continent, with an increase in the altitude the number of species diminishes. However, the diversity of dragonflies occurring at certain heights varies depending on the continent and the mountain chain. So, for example, at the altitude of 3500 m different species are present in the Andes Himalayas, and Cordillera. These differences are mainly due to location of the mountain ranges in different climate zones and on different continents." **16092.** Hykel, M.; Harabis, F.; Dolny, A. (2016): Assessment of the quality of the terrestrial habitat of the threatened dragonfly, *Sympetrum depressiusculum* (Odonata: Libellulidae). *European Journal of Entomology* 113: 476-481. (in English) ["The majority of the conservation strategies for threatened dragonflies are designed to protect only their aquatic habitats. *S. depressiusculum* is a species threatened not only by the destruction of its aquatic habitats but also by its association with a specific terrestrial environment. In this study, we aimed to identify the key elements of the terrestrial environment of adult *S. depressiusculum*. We used generalized linear mixed models to determine habitat preferences of adults and the particular features of habitat patches, such as vegetation cover, vegetation structure and the availability of potential prey. Our results indicate that *S. depressiusculum* adults preferred mainly riparian vegetation but beyond ponds they utilized only certain terrestrial habitats (abandoned fields, meadows, forest clearings). Adults responded positively to habitat patches with a high cover of vegetation and suitable vegetation structure. Adult abundance was affected also by the distance of patches from the natal site. In an agricultural landscape, the availability of such habitat patches may be limited and could influence the abundance and distribution of this species. We suggest that conservation efforts for this species should not only focus on the larval environment but also include suitable surrounding terrestrial habitats. Effective management around natal sites should concentrate on maintaining a heterogeneous landscape, which is extensively managed (e.g. leaving several fields fallow, maintaining managed hay meadows)." **16093.** Inamura, T.; Hirohashi, K (2016): Abstract: M21.00009: Hovering and targeting flight simulations of a dragonfly-like flapping wing-body model by IB-LBM. *Bulletin of*

the American Physical Society 61(20) (69th Annual Meeting of the APS Division of Fluid Dynamics): (in English) [Verbatim: Hovering and targeting flights of the dragonfly-like flapping wing-body model are numerically investigated by using the immersed boundary-lattice Boltzmann method (IB-LBM). The governing parameters of the problem are the Reynolds number  $Re$  the Froude number  $Fr$ , and the non-dimensional mass  $m$ . We set the parameters at  $Re=200$ ,  $Fr=15$ , and  $m=51$ . First, we simulate free flights of the model for various values of the phase difference angle between the forewing and the hindwing motions and for various values of the stroke angle that the vertical motion of the model depends on the phase difference angle, and the horizontal motion of the model depends on the stroke angle  $\beta$ . Secondly, using the above results we try to simulate the hovering flight by dynamically changing the phase difference angle and the stroke angle  $\beta$ . The hovering flight can be successfully simulated by a simple proportional controller of the phase difference angle and the stroke angle. Finally, we simulate targeting flight by dynamically changing the stroke angle  $\beta$ .] Address: Dept. Aeronautics and Astronautics, Kyoto University

**16095.** Jacob, S.; Manju, E.K (2016): Potential of odonate (dragonflies and damselflies) diversity as a bioindicator of water quality. International Journal of Science and Research 5(7): 2033-2036. (in English) ["In order to determine whether a relationship existed between water quality and odonate fauna, data were collected from four selected sites of Pala Municipality, Kottayam District, Kerala. The Water Quality Index, Simpson's diversity index and Species abundance values were calculated. The area with highest water quality index shows highest species richness and the area with lowest water quality index shows lowest species richness. The abundance of *Brachythemis contaminata* sp. in the polluted area and

*Bradinopyga geminata* sp. in the non-polluted area shows their indicator efficiency. A potential exists for Odonata species diversity, numbers of individuals and occurrence of particular species to be used as a bioindicator of water quality. Advantages include, data that reflects a time period rather than a point in time and also low costs." (Authors)] Address: Jacob, Sonia, Dept Zool., Alphonso College, Pala, India

**16096.** Jawaheri, R.A.; Sahlen, G. (2016): Negative impact of lake liming programmes on the species richness of dragonflies (Odonata): a study from southern Sweden. Hydrobiologia 788: 99-113. (in English) ["Liming programmes aiming to restore fish populations are being implemented in many acidified aquatic systems in northern Europe. We studied Odonata communities in 47 forest lakes in SW Sweden, 13 that are currently being limed, and 8 that have previously been limed. 31 species were recorded, with the highest mean number in untreated lakes, followed by previously treated lakes and currently treated lakes. Species communities differed between untreated and limed lakes, but only few rare species found in the untreated lakes were absent in the treated lakes. Likewise, species known to thrive in acid environments were either rare or showed no preferences. Comparing the number of records of odonate species within a large regional area to the proportion of lakes inhabited in our study, we found that seven of the most commonly observed species occurred less frequently in limed lakes than in the untreated ones, including two of the three most common taxa. Reduced species numbers in limed lakes might be due to conditions on other trophic levels, including fish predation. We argue that Odonata should be considered when developing new biological indices of water quality, although the causes of the observed occurrence patterns need to be studied further." **16097.** Jisha Krishnan, E. K.; Sebastian, C. D. (2016): Analysis of taxonomic relationships and species divergence of Libellulidae (Odonata: Anisoptera) members using Cytochrome Oxidase I gene. International Journal of Advanced Biotechnology and Research 7(2): 545-550. (in English) ["Libellulidae are commonly called 'skimmers' or 'perchers' representing the largest dragonfly family in the world. They are cosmopolitan in distribution and consist of 142 genera and 871 species. This family displays remarkable diversity in behaviour and morphology and consequently focused on studies of comparative population ecology, sexual selection, phylogeography and the evolution of mating behaviour. In the present study we deciphered the phylogenetic relationships of nine Libellulidae members by Neighbour-joining (NJ) and Maximum likelihood methods using partial cytochrome oxidase I gene as the marker. The phylogenetic tree inferred the sister clade relationship of the representing libellulidae members and confirmed the evolutionary divergence in relation with branch length. The averages A+T content of all these species are 62.03 % while G+C content is 37.97 % showing strong A+T bias. The transition/ transversion ratio are found to be 0.858 for purines and 2.533 for pyrimidines indicating

higher mutations are exhibited by the transition of Thymine, Uracil and Cytosine. The present study thus concluded that the mitochondrial cytochrome oxidase subunit I (COI) gene sequence of Libellulidae members demonstrated substantial variation; therefore it can be used for molecular taxonomy and for the phylogenetic studies." **16104.** Kannagi, A.; Sivakumar, V.; Santhi, V. (2016): Diversity of dragonflies (Insecta: Odonata) in a deciduous forest of Thoothukudi district, Tamil Nadu, South India. *International Journal of Environmental Protection and Policy* 4(3): 58-63. ["The study of Odonata communities along deciduous forest requires the basic understanding of the abundance, distribution and number of species present. As habitat conditions change, they also exhibit changes in their diversity and distribution. The present study was carried out in Kuthiraimozhi theri deciduous forest located in Thoothukudi District, Tamil Nadu, South India during July 2009 to June 2010 to assess the diversity of odonates. The forest is open, sandy, low tree lands with predominance of thorny, usually hard wood species. Observations were carried out twice in a month during morning, and evening times. A total of 958 dragonflies belonging to 20 species (2 species unidentified) belonging to 16 genera and 4 families were recorded. The family Libellulidae (15 species) was found to be dominant in the study region, followed by families Aeshnidae, Chlorogomphidae and Gomphidae, which were represented by a single species. The data was analyzed for Species richness, Shannon's diversity index and Simpson's index. Maximum number (237) of dragonflies was collected during December 2009 and the

highest Species richness (2.35) and Shannon's diversity index (2.08) was recorded during June 2010. This study has shown that, Odonata diversities along the Kuthiraimozhi theri deciduous forest vary hence these populations can be monitored, related and used as indicators of the physical structure of the deciduous forest and its surrounding ecotones. This inventory has served as the baseline for Odonata communities in the deciduous forest hence can be a measure of monitoring in the near future. Finally, there must be an increase in education on the importance of using local insect species as first level indicators of environmental health which when improved upon can save the nation a lot of money otherwise used in the chemical evaluation and monitoring of environment." (Authors)] Address: Kannagi, A., Research Centre of Zoology, Jayaraj Annapackiam College for Women (Autonomous), Periyakulam, Tamil Nadu, India. E-mail: Anitaarul1911@gmail.com

**16105.** Kanthika, W.A.L.; Kuruppuarachchi, K.A.J.M; Dharmasena, M.C.M.; Cooray, M.G. (2016): Dragonfly (Odonata) species diversity in different land use patterns of lowland tropical wet zone, Colombo District of Sri Lanka. International Forestry and Environment Symposium 21: 30. (in English) [Verbatim: "Many species of Odonates inhabiting in agro-ecosystems, play a crucial role in controlling pest populations and can be considered as a pollution indicator. Damselflies are important bio-control agents especially in the control of mosquito larvae. Individual Odonata species have a wide range of environmental tolerances, and are good indicators of ecosystem health, particularly for wetlands. Odonata are also known to be highly responsive to ecosystem conditions in relation to broad-scale factors such as climate and urbanization. Huge knowledge gap displays in ecology of Odonata species and this preliminary study would provide a considerable knowledge on formulating conservation strategies and ecosystem services of dragonflies. The ecological survey examined the Odonata species diversity and habitat preference in different land use types at low country wet zone of Colombo district, Sri Lanka. Five (05) main land use patterns were selected as sub-urban land set up at Waga Area: a natural forest (Indikada Mukalana), a rubber plantation, a paddy field as an agricultural land use; Urban land setup: The Open university premises (OUSL) at Nawala, Colombo and "Diyatha Uyana" Battaramulla. The ecological survey was carried out with layout of belt transect (100m×2.5 ) adjacent (5-15 m distance) to selected water ways in each different sampling areas of different land use patterns which adapting purposive random sampling technique. Visual observations will be carried out adapting internationally accepted techniques for sampling of flying insects to identify and quantify of Dragonflies. Oonate species specific parameters were recorded in selected sampling sites. Total number of 26 Odonata species including 9 endemics was recorded in all land using patterns all land use patterns. Species diversity (richness and abundance) measured within study sites using Shannon wiener index indicated that the paddy field (2.185), rubber plantation (1.885), natural forest (0.9507), OUSL along polluted Wellawatte canal (0.6745) and Diyatha Uyana (0.619) respectively. The number of dragonfly species and abundance is

remarkably higher in urban sites while number of damselfly is higher in sub-urban paddy field and rubber plantation. *Neurothemis tulia* and *Rhyothemis variegata* species were recorded at all study sites except natural forest. *Brachythemis contaminata* is the most abundant species which is only recorded in urban sites. A considerable species diversity and variation of Odonata species among study sites were recognized. As a conclusive remark, further studies on find limiting factors for diversity, distribution and abundance of odonate species is recommended." **16106.** Karlsson, T.; Bjelke, U. (2016): Inventering av grön flodtrollslända *Ophiogomphus cecilia* 2015 – metodiktest, förstudie och första provtillfälle inom biogeografisk uppföljning. Länsstyrelsen Östergötland, rapport 2016:8. Länsstyrelsen Östergötland, 581 86 Linköping, Sweden. ISBN: 978-91-7488-408-1: 68 pp. (in Swedish, with English summary) ["The member countries in the European Union is obliged to report the conservation status for species listed in Habitat directive every 6th year. To gather information about population sizes and trends for the species in Sweden, the Swedish Environmental Protection Agency funds a monitoring named "Biogeographical monitoring". The County Administrative Board of Östergötland has been assigned to coordinate the biogeographical monitoring of Odonata and diving beetles (Dytiscidae) listed in the Habitat directive in Sweden. As a first step for establishing a monitoring programme for *O. cecilia*, a survey and method test was performed during the summer 2015. This report presents the result from the survey and suggests a strategy for monitoring the species. *O. cecilia* is restricted to the rivers (with tributaries) Råneälven, Kalixälven and Torneälven in the Sweden. These rivers are situated in the northeastern part of Sweden and are large rivers (often >100 meters width), unregulated and mainly surrounded by woodland, but near the coast to some extent also by cultivated land. The species is redlisted as "Near threatened" (NT) in Sweden due to small distribution area. The aim of this study was to test exuviae-search as a survey method and act as a pilot study to receive more information about timescale, costs and practical considerations. If the survey turned out well, it could also serve as a first sample in the monitoring programme. The survey was performed by Tommy Karlsson, the County Administrative Board of Östergötland and Ulf Bjelke, the Species Species Information Centre during the period 20-24 July 2015. A large number of previously known localities for the species were surveyed as well as new, potential localities. The latter category also includes rivers from which the species not was known. In total, 57 localities were surveyed och *O. cecilia* was found at 13 of these (Tab. 1 and Fig. 2). Exuviae were found at all localities, in total 50 exuviae. They were mainly found up to 30 cm height at straws of *Carex* sp. and within 50 cm from the shoreline. However, 15 exuviae were found 100-400 cm from the shoreline. This was probably due to a higher water level when the dragonflies emerged. Adults were found at three localities, in total four individuals, all newly emerged and close to the exuvia. In addition, an adult was found on the roadside during car driving

and wings from an individual, probably predated by a bird, was found at one locality. All visited localities are shortly described and showed in a map in annex 1 (Bilaga 1). Localities where *O. cecilia* were found is also presented with a picture of the habitat. We assess searching for exuviae as the most appropriate method for monitoring *O. cecilia* in Sweden. It is a quick method since the exuviae are easy to find and the risk of mixing up with other dragonflies species is very low. No other species of the family Gomphidae coexist with *O. cecilia* in Sweden, and the other species that you could find exuviae of at localities for *O. cecilia* (*Aeshna* sp. *Somatochlora metallica*, *Cordulegaster boltonii*) are easy to distinguish (Fig. 3-5). Furthermore, big advantages with surveying exuviae compared to adults is that it is not dependent of the weather and that records of exuviae gives information about the reproduction habitat for the species. Searching for exuviae is a common survey method for *O. cecilia* in several other European countries, and the number of observed exuviae during a certain length of a river (e.g. 50 or 100 meters) is often used to estimate status and trend for a population. However, the trend for the Swedish population is assumed to be stable and annual variation, when the surveyed is performed in relation to emergence and variation between surveyors would probably influence the result more than possible trends with the economic resources available for monitoring today. An appropriate strategy for monitoring *O. cecilia* in Sweden is instead to recurring detect occurrence of the species at a selected number of localities. In table 2 and figure 6, 20 localities for monitoring are suggested." (Authors)] Address: Karlsson, T., Länsstyrelsen Östergötland, 581 86 Linköping, Sweden

**16109.** Kasai, A.; Takehiko I.H.; Hitoshi, O.; Kazutaka, S.; Daisuke, H.; Koichi, G. (2016): Fipronil application on rice paddy fields reduces densities of common skimmer and scarlet skimmer. Scientific Reports 6:23055. DOI: 10.1038/srep23055: 10 pp. (in English) ["Several reports suggested that rice seedling nursery-box application of some systemic insecticides (neonicotinoids and fipronil) is the cause of the decline in

dragonfly species noted since the 1990s in Japan. We conducted paddy mesocosm experiments to investigate the effect of the systemic insecticides clothianidin, fipronil and chlorantraniliprole on rice paddy field biological communities. Concentrations of all insecticides in the paddy water were reduced to the limit of detection within 3 months after application. However, residuals of these insecticides in the paddy soil were detected throughout the experimental period. Plankton species were affected by clothianidin and chlorantraniliprole right after the applications, but they recovered after the concentrations decreased. On the other hand, the effects of fipronil treatment, especially on Odonata, were larger than those of any other treatment. The number of adult dragonflies completing eclosion was severely decreased in the fipronil treatment. These results suggest that the accumulation of these insecticides in paddy soil reduces biodiversity by eliminating dragonfly nymphs, which occupy a high trophic level in paddy fields." **16110.** Kastner, F.; Buchwald, R. (2016): Habitate von *Coenagrion mercuriale* am nördlichen Arealrand (Kreis Minden-Lübbecke, NRW, Deutschland) (Odonata: Coenagrionidae). *Libellula* 35(1/2): 23-42. (in German, with English summary) ["Habitats of *C. mercuriale* at the northern range (Minden-Lübbecke district, NRW, Germany) (Odonata: Coenagrionidae) – In North Rhine-Westphalia (Germany) the endangered damselfly *C. mercuriale* occurs in the catchment basins of the rivers Ems, Lippe, Hunte, and Weser and is recorded with several populations in the Minden-Lübbecke district. The reproduction habitats at the northern range are small unshaded ditches and brooks with low to moderate flow rate. The aquatic vegetation is lush with a mean cover of 82 % and dominated by *Berula erecta*, *Phalaris arundinacea*, and *Sparganium* spp. The waters exhibit high oxygen content and relatively high temperatures. They are moderately polluted (water quality class II) to considerably polluted (water quality class II–III) and can be classified as base-rich, calcareous waters. The water type, vegetation as well as temperature and oxygen content correspond with habitat descriptions in the literature. Differences consist in cover and height of vegetation, morphology as well as in physical and chemical characteristics of the waters. The populations in the Minden-Lübbecke district belong to the largest in North Rhine-Westphalia. In some of the small flowing waters the damselfly *C. ornatum* was found as well, these occurrences representing the only ones in North Rhine-Westphalia. The maintenance of these waters has been well adapted to the life cycle of the two species in Minden-Lübbecke but there are some more threat factors like further eutrophication and the occasional desiccation of the waterbodies." **16112.** Khelifa, R.; Mellal, M.K.; Zouaimia, A.; Amari, H.; Zebsa, R.; Bensouilah, S.; Laouar, A.; Houhamdi, M. (2016): On the restoration of the last relict population of a dragonfly *Urothemis edwardsii* Selys (Libellulidae: Odonata) in the Mediterranean. *Journal of Insect Conservation* 20(5): 797-805. (in English) ["The restoration of endangered relict populations is challenging in conservation biology because they require specific environmental conditions within an inhospitable regional climate. *U. edwardsii* is the most endangered dragonfly in the Mediterranean with only one known relict small population (Lac Bleu) left in Northeast Algeria. With the absence of successful (re-)colonization over the last two decades, the restoration of the species became a top priority. To improve the status of the species in Northeast Algeria, we carried out a reintroduction and translocation scheme during 2011–2015 and assessed the changes in distribution and population size. Our restoration plan led to the emergence of three populations of which one was restored (Lac Noir), one resulted from successful translocation (Lac Tonga Northeast), and one established after successful colonization (Lac Tonga Southwest). In three localities (Lac Noir, Lac Tonga Northeast, and Lac Tonga Southwest), signs of population growth were observed, whereas no significant trend in the source population (Lac Bleu) was detected. A new population (El Graeate) was also recorded in 2015, but its origin is uncertain. Capture-mark-recapture on adults conducted in 2015 in two sites (Lac Bleu and Lac Noir) showed low recapture rates and no sign of dispersal between the two sites. Dispersal capacity of the species and conservation implications of adult distribution are discussed. This study highlights the importance of using biological indicators in selecting host habitats for the restoration of critically threatened populations." **16113.** Khelifa, R.; Mahdjoub, H.; Aouaouche, M.S.; Houhamdi, M. (2016): Reproductive behaviour of a North African endemic damselfly, *Platycnemis subdilatata* (Odonata: Platycnemididae) and probable senescence effects. *International Journal of Odonatology* 19(3): 157-167. (in English) ["Although *P. subdilatata* is widespread in the Maghreb, many aspects

of its reproductive behaviour, biology and ecology are still unstudied. One particular feature of this species is that its coloration pattern continues to change during maturation and afterwards, which makes it a good model for assessing age effects on behavioural and biological components. This study aims first to investigate the reproductive behaviour and choice of oviposition site, and second to assess clutch size and egg deposition rate as a function of age in a natural population located in North-East Algeria during the reproductive season of 2012. Males seized females next to reproductive sites and in foraging sites. Non-receptive females refused to mate with males by raising their abdomen up while perched or by curving the abdomen up while flying; the angle of abdomen elevation when perched was correlated to male persistence (the number of times that a male tried to grasp the female prothorax while flying over her). Copulation lasted about 14 min, the subsequent oviposition 54 min. Field experiments on oviposition site selection showed that the females prefer to lay eggs in *Typha angustifolia* leaves. Clutch size and egg deposition rate pattern through age showed an increase in early mature life followed by a decrease later on." **16115.** Kim, J.-S.; Pi, J.-H.; Jung, T.-J.; Lee, K.-J. (2016): The characteristics of Odonata community according to age and size of pond. *Korean Journal of Environment and Ecology* 28(3): 293-301. (in Korean, with English summary) ["15 artificial ponds in Seoul have been examined to find out the characteristics of Odonata community according to age and size of pond. We found 6 families 36 species of Odonata community, and Libellulidae was the most frequent and 19 Species were observed among Libellulidae. Considering relative importance with frequency of appearance and density, *Ischnura asiatica* and *Orthetrum albistylum* was the most frequent. Also, 16 Species including *Lestes temporalis*, *Sympetrum parvulum*, and *Anax nigrofasciatus* were relatively rare. The result of dominant species tells that *I. asiatica* in 1 ~ 3 year old ponds, *Pantala flavescens*-*Orthetrum albistylum*-*Crocothemis servilla mariannae* in order of mention in 4 ~ 6 year old ponds, *Platycnemis phyllopada*-*Ischnura asiatica* in order of mention in 10 or more year old ponds are the dominant species. Species diversity index regarding age of pond has been researched, and species diversity index in 10 year old pond was higher than that of in 1 ~ 3 year old pond. Having done the analysis of variance for types of spawn, there are many species Endophytic egg-layers and pasting in mud or sand in 10 year old artificial ponds. The wider ponds get, the higher species diversity index gets. And, we suggest that desirable size for making artificial ponds to

increase the species diversity index of Odonata is 100~300m<sup>2</sup>. (Authors) ] Address: Pi, J.-H., Dept. of Landscape Architecture, Graduate School, Univ. of Seoul, Seoul 130-743, Korea. E-mail: farmer01@naver.com

**16116.** Kiyoshi, T.; Katatani, N.; Kompier, T.; Yeh, W.-C. (2016): A new species and additional records of the genus *Sarasaeschna* from Laos and Vietnam (Odonata, Anisoptera, Aeshnidae). *Bull. Natl. Mus. Nat. Sci., Ser. A*, 42(4): 181-188. (in English) ["*Sarasaeschna yoshitomii* sp. nov., collected from the northern regions of Laos (Mt. Phou Samsoum, 1640 m and 1940 m, Xiangkhoang) and Vietnam (Mt. Hoang Lien Son, 1900 m, Lao Cai) is mainly distinguished from *S. lienii* to which it is most similar by having a more robust abdomen with the 3rd segment weakly constricted and 7–9th segments broader, male cerci with no basal but two protuberances, one at middle and the other at the base of apical expansion, and flagella of penis smoothly curved in ventral view. A new species-group, *lieni*-group, is proposed to accommodate these species; it is characterized by the following features of the male penile organ: The 4th segment is elongate with crest-like ventro-basal sclerotized plates; the flagella are slightly twisted and protrude more or less obliquely in relation to the long axis of the 4th segment. New records of both *S. minuta* and *S. gao-fengensis* are reported from Vietnam for the first time." The existence of single female and exuvium of *Libellula fulva* O.F. MÜLLER, 1764 was reported there in

the June 2015. The site presented in the study is situated far more south than the known distribution of scarce chaser in the southern Poland." (Author)] Address: Kucharski, A., Uherce Mineralne 22H/9, Poland. e-mail: and\_kuch@op.pl

**16127.** Kumar Misra, P.; Elangovan, V. (2016): Light and scanning electron microscopic studies on food habit analysis of insectivorous bats. *Advances in Life Sciences* 5(9): 3649-3654. (in English) ["The food habit analysis of eight insectivorous bats such as *Rhinopoma hardwickii*, *R. microphylum*, *Scotophilus heathii*, *S. kuhlii*, *Pipistrellus coromandra*, *Tophozous nudiventris*, *Megaderma lyra* and *Hipposideros fulvus* were studied using light and scanning electron microscopes. The bat guano was collected from unused buildings, historical monuments and caves from 15 districts of Uttar Pradesh. The pellet analysis revealed that the insectivorous bats fed on nocturnal insects belong to orders Coleoptera, Hymenoptera, Odonata, Hemiptera, Neuroptera, Lepidoptera and Diptera over the study period. The insect remnants such as legs, wings, antennae and elytra were commonly observed in the faecal pellets. The results lead to the conclusion that different insectivorous bats selectively fed on nocturnal insects, possibly agricultural pests, thus the conservation of insectivorous bats would facilitate to control agricultural pests and maintain a balanced ecosystem." **16128.** Lanctôt, C.; Wilson, S.P.; Fabbro, L.; Leusch, F.D.L.; Melvin, S.D. (2016): Comparative sensitivity of aquatic invertebrate and vertebrate species to wastewater from an operational coal mine in central Queensland, Australia. *Ecotoxicology and Environmental Safety* 129(7): 1-9. ["Highlights: •Knowledge regarding the toxicity of coal mine wastewater to aquatic biota is limited. •We compared sensitivities of a range of Australian freshwater species. •Acute toxicity was observed in cladocerans and planarians, but not vertebrates. •Condition and hepatosomatic index were reduced in exposed vertebrates. •Tadpoles were generally more sensitive than fish. Abstract: Coal excavation and refinement processes generate substantial volumes of contaminated effluent that may be detrimental to aquatic ecosystems. As such, understanding the impacts of coal mine water releases on aquatic animals and ecosystems is essential for effectively managing and protecting neighbouring environments. Such information will ultimately be applied towards developing ongoing monitoring strategies that are protective of native wildlife. Despite intensive mining operations in Australia, few studies have documented toxicity associated with coal mine wastewater (CMW) on native species. To address existing knowledge gaps, we investigated acute toxicity (48–96 h) using eight native invertebrate species and sub-chronic effects (2 week) using three vertebrate species following exposure to wastewater from two dams (CMW1 and CMW2) located at an open-cut coal mine licensed to discharge into the Fitzroy catchment (Queensland, Australia). Wastewater from these sites is characterized by elevated conductivity, pH, sulfates as well as relatively high total and dissolved metal (loid)s (including As, Al, B, Cu, Mn,

Ni, Se and Zn). Acute exposures revealed cladocerans (*Daphnia carinata*) and planarians (*Dugesia* sp.) to be the most sensitive species, exhibiting significant mortality after 48 and 96 h exposure to CMW2, respectively. Neither wastewater was found to elicit acute toxicity in vertebrates, but a range of sub-lethal morphological effects were observed following the sub-chronic exposures. The overall response pattern was characterized by decreased condition factor and hepatosomatic index in the fish *Hypseleotris compressa* and *Pseudomugil signifier*, and in *Limnodynastes peronii* tadpoles. Tadpoles were generally more sensitive compared to the two fish species. Differences in responses were observed amongst CMW1 and CMW2, which likely relates to differences in physico-chemical properties between sites. Our results have identified several candidate vertebrate and invertebrate species that show promise for ongoing monitoring of water quality and toxicity risk in Central Queensland, Australia." **16130.** Lee, D.E.; Kaulfuss, U.; Conran, J.G.; Bannister, J.M.; Lindqvist, J.K. (2016): Biodiversity and palaeoecology of Foulden Maar: an early Miocene Konservat-Lagerstätte deposit in southern New Zealand. *Alcheringa* 40(4): 525-541. (in English) ["This paper highlights the biodiversity and palaeoecology of the 23 million year old Foulden Maar, the first Konservat-Lagerstätte deposit described from New Zealand and a key site for reconstructing early Miocene Southern Hemisphere terrestrial ecosystems. The 1000-m-diameter, ca 200-m-deep Foulden Maar volcanic crater lake was a closed system with anoxic bottom waters, capturing and preserving in exquisite detail organisms from the lake and adjacent rainforest. The fossils include numerous leaves, flowers with in situ pollen, fruits, seeds, fish and arthropods. Surrounding Foulden Maar was an evergreen, Lauraceae-dominated notophyll vine forest with a diverse understorey, lianes, epiphytes and mistletoes. Diverse pollination and seed dispersal modes are evident. Fish include larval to adult stages of articulated specimens of *Galaxias*, some with preserved soft tissue and a species of eel resembling *Anguilla*. The arthropod fauna comprises ca 20 families in the orders Araneae, Plecoptera, Odonata, Isoptera, Hemiptera, Diptera, Coleoptera, Trichoptera and Hymenoptera, representing faunas typical of soil, leaf litter, forest floor or freshwater habitats. Many fossil taxa have

close relatives in the extant New Zealand biota; others are now locally extinct. Coprolites containing quartz sands sourced from outside the lake indicate the presence of volant birds, presumably waterfowl. The Foulden Maar Lagerstätte is crucial for reconstructing Miocene lake and forest ecosystems in New Zealand, particularly the terrestrial arthropod component." **16133.** Levis, N.A.; Schooler, M.L.; Johnson, J.R.; Collyer, M.L. (2016): Non-adaptive phenotypic plasticity: the effects of terrestrial and aquatic herbicides on larval salamander morphology and swim speed. *Biological Journal of the Linnean Society* 118(3): 569-581. (in English) ["Phenotypic plasticity, although ubiquitous, may not always be advantageous. Non-adaptive plasticity is likely to occur in response to novel environmental stress. Anthropogenic contaminants, such as herbicides, are novel stressors that are not present in the evolutionary history of most species. We investigated the pattern and consequences of phenotypic plasticity induced by four glyphosate-based herbicides (two terrestrial and two aquatic) in larvae of the spotted salamander, *Ambystoma maculatum*, by determining (1) whether the herbicides induced different morphologies; (2) if different morphologies translated to differences in burst swim performance; and (3) how induced individuals performed relative to non-induced controls. Different herbicide formulations led to the production of significantly different head and tail morphologies, and tail morphology correlated with fastest escape speed. However, escape speed did not vary among treatments. In addition, three out of four herbicide treatments experienced accelerated growth rates, in terms of the lateral size of tails, although the tail shapes were either similar to preliminary controls or intermediate between preliminary and final controls. These observations suggest that herbicide-induced

morphology is a case of non-adaptive phenotypic plasticity, and that there is potentially a trade-off between growth and development for larvae exposed to different formulations. Understanding the functional significance of induced phenotypes is important for determining their importance in shaping an organism's ecological interactions and evolutionary trajectories. Furthermore, under different conditions, the morphological changes that we observed in response to exposure to herbicides might affect salamander fitness and influence population dynamics." **16134.** Li, S.; Zheng, D.-R.; Zhang, Q.; Liao, H.-Y.; Wang, H.; Wang, B.; Wang, J.; Lu, H.-B.; Chang, S.-C.; Zhang, H.-C. (2016): Discovery of the Jehol Biota from the Celaomiao region and discussion of the Lower Cretaceous of the Bayingebi Basin, northwestern China. *Palaeoworld* 25(1): 76-83. (in English) ["Some typical components of the Jehol Biota, including conchostracans *Eosestheria* sp., the mayfly *Ephemeropsis trisetalis* Eichwald, 1864, the aquatic beetle *Coptoclava longipoda* Ping, 1928, and a fragmentary dragonfly, are reported for the first time from the Bayingebi Formation in the Celaomiao region, western Inner Mongolia, China. This discovery indicates that the middle Upper Member of Bayingebi Formation can be correlated with the upper Yixian and the lower Jiufotang formations in western Liaoning Province. Combining it with the radio-isotopic dating result, we further believed that the Upper Member of Bayingebi Formation could be roughly correlated with the Yixian, Jiufotang, and Shahaï formations, and the overlying Suhongtu Formation with the Fuxin Formation in western Liaoning Province. In the major Bayingebi Basin, palaeontological and radio-isotopic dating evidence shows that the Bayingebi Formation has a long depositional history of over 30 Ma: its Upper Member bearing the Jehol Biota and the early Fuxin Biota is probably coeval to the Yixian, Jiufotang and Shahaï formations and has a Barremian–early Albian age; its Lower Member may be Berriasian–Hauterivian in age and could be correlated with the upper Tuchengzi, Zhangjiakou, and Dabeigou formations in northern Hebei Province. This suggests that the Bayingebi Formation should be promoted to the stratigraphic rank of group and subdivided into several secondary units (formations). Unlike the previous result, the Yingen Formation is considered across the Lower Cretaceous–Upper Cretaceous boundary and being late Albian–early Turonian in age." (2016): Playing hide-and-seek with the tiny dragonfly: DNA barcoding discriminates multiple lineages of *Nannophya pygmaea* in Asia. *Journal of Insect Conservation* 20(2): 339-343. (in English) ["We examined the utility of DNA barcode data for assessing genetic diversity of the tiny dragonfly *Nannophya pygmaea* Rambur in Asia. Data analyses inferred from the barcode region of cytochrome oxidase subunit I (COI) were performed with Malaysian *N. pygmaea*, along with the existing COI haplotypes distributed in Asia. We applied four

species delimitation analyses [automatic barcode gap discovery (ABGD), generalised mixed yule coalescent (GMYC), poisson tree processes maximum likelihood (PTP\_ML) and poisson tree processes simple heuristic solutions (PTP\_sh)] to investigate potential lineages in this geographically wide-spread species. Based on our dataset, we provisionally recognize four distinct lineages or operational taxonomic units of *N. pygmaea*, which were represented by the taxa from Japan/Korea, China/Laos/Taiwan, Malaysia and Vietnam, respectively. Phylogenetic analyses showed two well-supported assemblages of *N. pygmaea*: one restricted to the taxa from Malaysia and Vietnam; and the other covering all populations further north (i.e., China, Japan, Korea, Laos and Taiwan). An extraordinarily high degree of genetic distance (up to >12 %) was detected between these two assemblages—suggesting they represent two separate species." **16142.** Manenti, R.; Zanetti, N.; Pennati, R.; Scari, G. (2016): Factors driving semi-aquatic predator occurrence in traditional cattle drinking pools: conservation issues. *Journal of Limnology* 76(1): 34-40. (in English) ["In several cases, human

impact on water bodies and on their freshwater communities is detrimental, but in some cases the human activity may favour and enhance the biodiversity of small water bodies, as traditional cattle drinking pools. Despite their small size, small water bodies may constitute hot spot of biodiversity often representing the only lentic aquatic biotope in landscapes where superficial water lacks or flows in lotic environments like creeks and streams. Predators are good indicators of biodiversity in ponds and give information of food chain web complexity. In particular, semi-aquatic predators like amphibians and dragonflies may account for a substantial percentage of energy flow between aquatic and terrestrial ecosystems. In this study, we evaluated the conservation value of traditional cattle drinking pools building by assessing the factors determining the occurrence and distribution of the semi-aquatic predators. From April to August 2015, we investigated 30 distinct pools recording several abiotic and biotic environmental variables. We detected 4 semi-aquatic predators: *Salamandra salamandra* larvae, *Triturus carnifex*, *Aeshna* sp. larvae and *Libellula* sp. larvae. Abiotic features played a major role in shaping the predator community that resulted linked to stable, with no dryness period, and large drinking pools. Invertebrate prey biomass was not particularly important, while vegetation cover and occurrence of unpalatable tadpoles were the most important biotic features of the pools. Our study provides novel evidence on the importance of cattle drinking pools management to preserve biodiversity especially in areas where traditional pastoral activity is disappearing." **16144.** Mangaoang, C.C.; Mohagan, A.B. (2016): Odonata diversity at University of southern Mindanao, Kabacan, Cotabato. *Asian Journal of Biodiversity* 7(1): 112-123. ["Odonata are good biocontrol agents of agricultural pests and vector mosquitoes and even an indicator of environmental changes and health status of ecosystem. Despite, limited studies have been conducted especially lowland ecosystems. The study

was conducted using time constraint with 4 exposure hours and opportunistic sampling protocols. Result of the study revealed 13 species of Odonata belonging to three families, 2 of which are Zygoptera and only one family belonging to Anisoptera with 11 species. Libellulidae dominates the recorded species. 8 species are found in USMARC and 6 species in housing. One Philippine endemic was documented - *Rhinocypha colorata*. Diversity is low in the two sampling sites and high disturbance is found in housing (63%). Similarity index showed that 92% are discordant species. Low species diversity and low endemism of Odonata is an indicator that the area is already disturbed as measured by the high number of common/oriental species and existence of environmental and anthropogenic activities. Thus, a conservation strategy for this important species will be implemented." **16146.** Manolis, T. (2016): Odonate exuviae used for roosts and nests by *Sassacus vitis* and other jumping spiders (Araneae: Salticidae). *Peckhamia* 142: 1-16. (in English) ["I systematically collected dragonfly (Anisoptera) exuviae along the margins of backwater lagoons in the American River floodplain, Sacramento County, California, USA, in five years (2008-2010, 2012-13) to document and monitor secondary use of these structures by arthropods, particularly spiders. Of nearly 400 exuviae examined, 28.1% were occupied, or showed signs of occupancy (e.g., unoccupied retreats). Of these occupied exuviae, 93% contained spiders or evidence of spider occupancy, and at least 50% of these were occupied by *Sassacus vitis* (many unoccupied retreats were probably of that species as well). *S. vitis* showed a significant preference for using the exuviae of sedentary, burrowing dragonfly larvae versus those of active, clasping or sprawling larvae. I found *S. vitis* in exuviae as single males and females, in pairs, and using exuviae for molt retreats and nests. 44 *S. vitis* nests

in exuviae provided data on aspects of the species' breeding biology. In addition, a number of these nests were attacked by hymenopteran egg parasitoids in the genera *Idris* (Platygastridae) and *Gelis* (Ichneumonidae). I also found three other salticid species (*Sitticus palustris*, *Synageles occidentalis*, and *Peckhamia* sp.) in exuviae, all guarding egg sacs. Utilization of dragonfly exuviae by *Sassacus vitis* and other salticids is no doubt more frequent and widespread than previously noticed and deserves further scrutiny." **16147.** Marino, N.A.C.; Srivastava, D.S.; MacDonald, A.A.M.; Leal, J.S.; Campos, A.B.A.; Farjalla, V.F. (2016): Rainfall and hydrological stability alters the impact of top-predators on food web structure and function. *Global Change Biology* 23(2): 673-685. (in English) ["Climate change will alter the distribution of rainfall, with potential consequences for the hydrological dynamics of aquatic habitats. Hydrological stability can be an important determinant of diversity in temporary aquatic habitats, affecting species persistence and the importance of predation on community dynamics. As such, prey are not only affected by drought-induced mortality but also the risk of predation (a non-consumptive effect, NCE) and actual consumption by predators (a consumptive effect, CE). Climate-induced changes in rainfall may directly, or via altered hydrological stability, affect predator-prey interactions and their cascading effects on the food web, but this has rarely been explored, especially in natural food webs. To address this question, we performed a field experiment using tank bromeliads and their aquatic food web, composed of predatory damselfly larvae, macroinvertebrate prey and bacteria. We manipulated the presence and consumption ability of damselfly larvae under three rainfall scenarios (ambient, few large rainfall events and several small rainfall events), recorded the hydrological dynamics within bromeliads, and examined the effects on macroinvertebrate colonization, nutrient cycling and bacterial biomass and turnover. Despite our large perturbations of rainfall, rainfall scenario had no effect on the hydrological dynamics of bromeliads. As a result, macroinvertebrate colonization and nutrient cycling depended on the hydrological stability of bromeliads, with no direct effect of rainfall or predation. In contrast, rainfall scenario determined the direction of the indirect effects of predators on bacteria, driven by both predator CEs and NCEs. These results suggest that rainfall and the hydrological stability of bromeliads had indirect effects on the food web through changes in the CEs and NCEs of predators. We suggest that future studies should consider the importance of the variability in hydrological dynamics among habitats as well as the biological mechanisms underlying the ecological responses to climate change." (Authors)] Address: Marino, N.A.C., Lab.de Limnologia, Depto de Ecologia, Inst. Biol., Centro de Ciências da Saude, Universidade Federal do Rio de Janeiro, PO Box 68020, Rio de Janeiro, RJ, Brazil. **16148.** Marino Jr., J.A.; Holland, M.P.; Werner, E.E. (2016): Competition and host size mediate larval anuran interactions with trematode parasites. *Freshwater Biology* 61(5):

621-632. (in English) ["1. How parasites influence individual host traits and survival often depends on the ecological context of the host-parasite interaction, such as the presence of competitors or predators and trait variation among hosts. 2. We examined the effects of three key components of ecological context – host density, size structure and predator cue – on interactions between larval frogs and trematode parasites (Digenea: Echinostomatidae) in mesocosms. 3. We found that effects of parasites on host growth could be either negative or positive, depending on host size and overall growth rate, but not on predator presence. A surprising positive effect of parasites on host growth under some conditions could represent an adaptive host life history response, whereby enhanced growth allows escape from a smaller, less tolerant size class that experiences more negative fitness effects of infection. 4. Notably, only host size class was a strong predictor of infection intensity, but not host density or predator cue. 5. Overall, these results suggest that parasitism, competition and host size interact to influence host fitness. Ecological context thus mediates the interactions between parasites and their hosts, with implications for parasite effects in nature." **16149.** Marinov, M. (2016): A contribution to the dragonfly fauna of Guadalcanal, Solomon Islands (Insecta: Odonata) with description of two new species. *Faunistic Studies in Southeast Asian and Pacific Island Odonata* 17: 1-34. (in English) ["New data on Odonata of the Guadalcanal Island, Solomon Islands are provided following a recently completed Rapid Biodiversity Assessment of the Tetena Haiaja ridge. Two new species, *Lieftinckia ulunorum* and *Procordulia valevahalo* are described. The first is a new member of the Solomon Islands endemic genus while the second is a new genus for the country and the second validated species from the *Corduliidae* family known from this Pacific archipelago. As *L. ulunorum* is found to be very closely related to formerly known *L. lairdi* Lieftinck, 1963, which was also collected during the field trip, both are described in detail based on mature adults and teneral specimens. Comparison with *L. salomonis* Kimmins, 1957 (investigated only from figures published in the original species description) and *Salomocnemis gerdae* Lieftinck, 1987 (also sampled during this study) were provided as well. Additional morphological data is given on the following species: *Teinobasis bradleyi* Kimmins, 1957, female is illustrated here for the first time; *Anax* sp. cf. *gibbosulus*, second record of the genus for the country and *Gynacantha amphora* Marinov & Theischinger, 2012, originally described by a single male, here the description of the female is provided. All other species collected during the field trip will be published separately in the final expedition report." **16152.** Martin, K. (2016): Traveling across the toe: riverbank features and their impact on emergence distance of *Gomphus vastus* and *Stylurus spiniceps*. *Bulletin of American Odonatology* 12(1): 1-6. (in English) ["The distance that an emergent dragonfly nymph travels from the water's edge influences its chance of successful eclosion. In many riverine systems, heavy riverbank erosion has led to a variety of bank stabilization methods being applied. In the Turners Falls Reservoir (Massachusetts), bank stabilization methods have included the placement of rocks along the toe of the slope. Dragonflies that travel across these rocks are often exposed to boat wakes, water level changes, and predation. This study investigated how riverbank features (such as rock size, width of riprap zone, slope, and sediment) affected the distance traveled by two species of riverine dragonfly (*Gomphus vastus* and *Stylurus spiniceps*)."] (Author)] Address: E-mail: kirstenmartin@usj.edu

**16153.** Mastropasqua, F.; Liuzzi, C. (2016): New records of *Coenagrion ornatum* in Italy (Odonata: Coenagrionidae). *Fragmenta entomologica* 48(1): 29-31. (in English) ["*C. ornatum* is a damselfly ranging from northwestern Europe to southwestern Asia. It is highly local, and northwestern populations are experiencing a steep decline. In Europe, *C. ornatum* is a species of conservation interest and is listed as Near Threatened due to habitat loss; it is nearly extinct in Italy. We report the finding of 4 male *C. ornatum* on 3 June 2005 in Apulia, southeastern Italy. This is the only recent record for Italy, and highlights the need for further research on

this species in the country." (Authors)] Address: Mastro-pasqua, F., CSdR- Association "Centro Studi de Romita", c/o Filippo d'Erasmus, Via G. Postiglione 9, I-70126 Bari, Italy. E-mail: fabiomastro77@gmail.com

**16154.** Matushkina, N.A.; Buy, D.; Lambret, P. (2016): Egg clutch patterning in *Lestes virens* (Odonata, Lestidae) with evolutionary emphasis on endophytic oviposition in lestid dragonflies. *Insect Science* 23: 893-902. (in English) ["Egg deposition within plants is one of the most widely distributed and ancient behaviours in Odonata. The resulting clutch consists of eggs placed in peculiar pattern that can be characteristic for certain groups of Odonata. Despite their importance for paleontological and evolutionary research, data on egg-clutch positioning are missing or insufficient for most species. Here, patterning of egg clutches in *Lestes virens* was measured and described in detail for the first time. The female usually produces a linear row of single eggs directed at an angle rightward or leftward to the longitudinal axis of plant substrate. Less often eggs are arranged in egg-sets consisting of up to four eggs. Apparently, the female insect follows the rigid behaviour stereotypes during oviposition and is unable to easily switch to the alternate stereotypical behaviour of single egg deposition or production of multi-egg sets. Based on a literature review and original data, egg clutch patterning of European Lestidae is overlaid on pre-existing phylogenies. The resulting evolutionary scenario of egg-clutch patterning can be considered in the framework of egg-laying behaviour in Lestidae." **16155.** McDevitt-Galles, T. (2016): The ecology of aquatic macroinvertebrates: Understanding interactions among drought, introduced fishes, and parasites. M.Sc. thesis, University of Colorado at Boulder: 87 pp. (in English) ["Aquatic macroinvertebrates play key roles in structuring aquatic communities and provide a key link with the surrounding terrestrial environment through their metamorphosis from aquatic larvae to terrestrial adults. It is therefore important to understand how their distribution across a landscape shifts through time and in response to environmental change, such as prolonged drought. Concurrently, because relatively little is known about the parasites that use pond macroinvertebrates as hosts, I also explored the relative importance of factors affecting infection prevalence and parasite load within common invertebrate host taxa. For each year over four years, I sampled 36 ponds within the Bay Area of California, USA, to characterize the diversity and composition of aquatic macroinvertebrates and quantify the parasites that utilize these organisms as hosts. I specifically aimed to answer the following questions: (1) what are the relative influences of non-native fishes and hydroperiod in structuring communities? (2) How does the magnitude of such filters vary through time? And (3) how do host- and habitat-level factors combine to determine patterns of infection with larval dragonflies and damselflies? My results indicated that while fish play a dominant role in structuring the macroinvertebrate composition and

richness, the strength of this effect was attenuated during a prolonged drought such that, by the last year of the study and the height of California superdrought, fish had no detectable effect on the macroinvertebrate diversity or species composition. The parasite survey revealed six parasite taxa using macroinvertebrates as hosts with the majority infecting members of the Odonata. The hierarchical generalized mixed model results suggested that the majority of variation in both infection prevalence and load was associated with site-level variables, such as water chemistry, and with an interaction between the presence of fish and host suborder. These findings suggest that infection probability for odonates is more closely linked to site-level factors than host-level factors though there are potential interactions between the two levels that must be considered." **16158.** Michels, J.; Appel, E.; Gorb, S.N. (2016): Functional diversity of resilin in Arthropoda. *Beilstein J. Nanotechnol.* 7: 1241-1259. (in English) ["Resilin is an elastomeric protein typically occurring in exoskeletons of arthropods. It is composed of randomly orientated coiled polypeptide chains that are covalently cross-linked together at regular intervals by the two unusual amino acids dityrosine and trityrosine forming a stable network with a high degree of flexibility and mobility. As a result of its molecular prerequisites, resilin features exceptional rubber-like properties including a relatively low stiffness, a rather pronounced long-range deformability and a

nearly perfect elastic recovery. Within the exoskeleton structures, resilin commonly forms composites together with other proteins and/or chitin fibres. In the last decades, numerous exoskeleton structures with large proportions of resilin and various resilin functions have been described. Today, resilin is known to be responsible for the generation of deformability and flexibility in membrane and joint systems, the storage of elastic energy in jumping and catapulting systems, the enhancement of adaptability to uneven surfaces in attachment in reproductive, folding and feeding systems and the sealing of wounds in a traumatic reproductive system. In addition, resilin is present in many compound eye lenses and is suggested to be a very suitable material for optical elements because of its transparency and amorphousness. The evolution of this remarkable functional diversity can be assumed to have only been possible because resilin exhibits a unique combination of different outstanding properties." **16159.** Miguélez, D.; García-Tejero, S.; Hernández, A.; Valadares, L.F. (2016): Diet selection of the Aquatic warbler *Acrocephalus paludicola* during its post-nuptial migration stopover in NW Spain. *Ardea* 104(3): 273-282. (in English) ["Food availability and diet are two key issues in understanding the ecological requirements of a migratory species in stopover sites and in taking effective conservation measures. In the case of the globally threatened Aquatic Warbler, there have previously been no studies examining diet selection in the Iberian Peninsula, a key region for their post-nuptial movements. In this context, the availability of arthropods in different habitats (reeds, rushes and grassland), the composition and biomass of prey in faecal samples, and diet selection were all investigated in a wetland in northwest Spain. The results showed a higher total abundance of arthropods in grassland and rushes: habitats which were more similar to each other, in terms of vegetation physiognomy and composition of invertebrates, compared with reeds. In terms of prey abundance, diet was dominated by Araneae, Heteroptera and Homoptera. However, the groups that contributed most to the ingested biomass were Diptera (Tipulidae), Odonata and Orthoptera, followed by Araneae. Prey selection indices showed a preference for these groups, which all contain insects with a large body length. These diet characteristics showed many similarities with studies in other stopover and breeding areas, but differ in that Araneae were the main arthropod prey at this stopover site." (2016): Vergleichende Morphologie der Imagines von *Coenagrion lunulatum*, *C. pulchellum* und *C. puella* in einem syntopen Vorkommen (Odonata: Coenagrionidae). *Libellula* 35(3/4): 153-165. (in German, with English summary) ["Comparative adult morphology of *Coenagrion lunulatum*, *C. pulchellum*, and *C.*

*puella* in a syntopic situation (Odonata: Coenagrionidae) – Interspecific competition among odonate species for food, mating partner etc. is a common phenomenon. Because morphology mediates species' behaviour and microhabitat use, competition is expected to increase with species being more similar in their phenotypes. Here we present data for adult body morphology as well as abundance data of parasitic water mites in syntopically occurring *C. lunulatum*, *C. puella*, and *C. pulchellum* at a pond near Wilmersdorf (Brandenburg, Germany). Whereas all three species differed significantly in overall body size (head, thorax, abdomen, and legs), *C. lunulatum* also differed in their wing morphology from *C. puella* and *C. pulchellum*. No such differences were found in the latter two species. All three species also differed in total abundance of water mites, however those differences were completely attributed to body size differences among the three Coenagrion-species. Based on our results, we discuss potential differences in flight behaviour, hunting mode, and microhabitat use among the three studied species." (in English) ["The structure of the digestive, tracheal, muscular and nervous systems in the abdomen of aeshnid larvae is reviewed, with particular regard to the role of the abdomen in producing pressure changes that elicit respiration, jet-propulsive swimming and labial mask extension. The musculature of the labial mask is also described." (Author)] Address: Mill, P.J., School of Biology, University of Leeds, Leeds, LS2 9JT, UK

**16162.** Miyai, K.; Saito, M.; Jinguji, H. (2016): Practice and effectiveness of the program of risk assessment mitigation for Red Dragonflies with farmers' participation. *Transactions of the Japanese society of irrigation, drainage and rural engineering* 84(3): 201-207. (in English Japanese ) ["Recently the population of red dragonflies has declined nationwide in Japan. It is pointed out that the change of paddy field-management is one of the main causes for it. In order to mitigate the influence of such changes, it is necessary to introduce a proper management method suitably adaptable to farmland. To examine the effects of difference in cultivation management, we introduced the program of risk assessment mitigation and conducted of census of red dragonfly and cultivation management in paddy fields in Tajiri, Osaki City, Miyagi Prefecture from 2009 until 2013. We investigated the correlation between the emergence status of the red dragonflies and cultivation methods for paddy fields together with local farmers. The husks of red dragonflies were more sparsely found in the paddy fields where dinotefuran were applied. For conservation of red dragonflies, we started to employ the different pesticides with lower effects on red dragonflies and applied the pesticides only in the peripheral zone of each patch and successfully reduced the insecticidal effects on red dragonflies compared to broadcast application over

the entire fields. Each technique was observed that suppress the decrease of red dragonflies." (Authors)] Address: Miyai, K., Graduate School of Food, Agricultural and Environmental Sciences, Miyagi University

**16163.** Monnerat, M.; Al Dhafer, H.M. (2016): Odonata records from southwestern Saudi Arabia. *Notulae odonatologicae* 8(7): 231-239. (in English) ["Results are presented of a one-week field trip in November 2012 to southwest Saudi Arabia. 19 dragonfly species were collected, observed and photographed at 17 localities in the regions of Makkah, Bahah, 'Asir, and Jizan. A new record of the little known *Trithemis dejouxi* is documented. *Lestes pallidus*, which had not been recorded for decades, is confirmed and new for Jizan. *Anax imperator* and *A. parthenope*, rarely mentioned in literature, were recorded at several localities." **16164.** Monteiro, C.d.S.; Esposito, M.C.; Juen, L. (2016): Are the adult odonate species found in a protected area different from those present in the surrounding zone? A case study from eastern Amazonia. *Journal of Insect Conservation* 20(4): 643-652. (in English) ["We studied 30 streams in eastern Amazonia, 17 of which were located within a protected area (PA) and the other 13 in the surrounding zone, with the objective of evaluating the diversity of adult Odonata and if there was a difference between the physical habitat variables of the two environments. We hypothesized that a greater diversity of odonate species would be found in the PA due to a greater complexity of habitats. This hypothesis was rejected, however, due to the greater odonate diversity found in the surrounding zone in comparison with the PA. Differences were also found in the species composition of the two environments. Our results indicate that there are differences between the environmental variables in the areas, and the few alterations observed in the surrounding zone may have contributed to the formation of new conditions and habitats appropriate for species that may have been rare. The PA, despite having reduced species richness and abundance in comparison with the surrounding zone, was nevertheless characterized by a more heterogeneous species composition. A quarter of the species were common to both environments, while 34 % were exclusive to the surrounding zone. In this case, it appears that the combination of the protected area and the surrounding zone, which has a low level of disturbance, conserves a wider range of specialist species than either area on its own. The great challenge in the future is finding a way to identify the disturbance levels that would be acceptable, and to prevent over-exploitation of resources in such areas." **16165.** Montemayor, S.I.; Melo, M.C.; Scheibler, E.E. (2016): Forecasting the fate of high mountain ponds in the Andean region under future climate change. *Austral Ecology* 41(8): 983-992. (in English) ["The aims of this study are

(i) to identify areas in the Andean region where the climate will remain stable enough for the survival of the study species; (ii) to analyze how climate change will affect these areas under different climate scenarios; (iii) to generate spatially explicit predictive maps of the expansion or retraction of these areas; and (iv) based on this information, to identify areas with priority for conservation. The analysis was performed using presence-only data for 14 Heteroptera and Odonata species. Current and future models were developed to identify areas where the climate would be suitable for small ponds, using Maxent v3.3.3k, with future models based on three different Global Climate Models for the 2050 period (scenarios A2a and B2a). Model performance was evaluated using the jack-knife approach. Climatic niche breadth and climatic niche similarities were calculated through Levin's concentration metrics and the I statistic index (implemented in ENMTools), respectively. Maxent logistic outputs were converted into binary presence/absence maps, based on the 'minimum training presence logistic threshold', and used to build species richness maps for each condition considered (present and future). Current and future models with areas climatically suitable for small ponds were developed. All the study species proved to be narrow specialists and share similar climatic spaces. Our projections suggest that four of the species would not find suitable climate conditions for survival in the future. The priority area for conservation, where most species would find suitable climate conditions, is located between 33–47°S and 73–70°W. We identified future loss of the priority area towards the east and a small gain towards the north and south. The most probable situation for the year 2050 is a negative precipitation–evapotranspiration balance, and small ponds will probably be very short-lived or dry completely during summer, suggesting a drastic change in species assemblages and species richness of the region, which could become a hot-spot of extinction." **16166.** Moore, M.P.; Martin, R.A. (2016): Intrasexual selection favors an immune-correlated color ornament in a dragonfly. *Journal of evolutionary biology* 29(11): 2256-2265. (in English) ["Sexual signaling is predicted to shape the and benefits of ornamentation and the information that ornamentation provides to receivers is necessary to evaluating of a common color ornament in insects, melanin wing ornamentation, using the dragonfly *Pachydiplax longipennis*. We hypothesized that greater ornamentation would improve receive from territorial rivals, but that more ornamented males may have shorter lifespans. Using mark-recapture field observations, we found that more ornamented males had greater territory holding success, and that viability selection did not act on wing melanization. We then compared the aggression of territorial rivals to decoy males before and after experimentally augmenting wing melanization, finding that males significantly reduced aggression following the manipulation. We next hypothesized that wing melanization would signal fighting ability to territorial rivals by reflecting condition

via investment in the costly melanin-synthesis pathway. We observed a positive relationship between ornamentation and the likelihood of winning territorial disputes, suggesting that wing melanization provides information about fighting ability to rivals. We also found a positive relationship between melanin-based immune defense and ornamentation, supporting a link between the signal and condition. We conclude that wing melanization is a condition-related signal of fighting ability, and suggest that this may be a common mechanism promoting the evolution of melanin ornamentation." **16168.** Mwedzi, T.; Bere, T.; Mangadze, T. (2016): Macroinvertebrate assemblages in agricultural, mining, and urban tropical streams: implications for conservation and management. *Environmental Science and Pollution Research* 23(11): 11181-11192. (in English) ["The study evaluated the response of macroinvertebrate assemblages to changes in water quality in different land-use settings in Manyame catchment, Zimbabwe. Four land-use categories were identified: forested commercial farming, communal farming, Great Dyke mining (GDM) and urban areas. Macroinvertebrate community structure and physicochemical variables data were collected in two seasons from 41 sites following standard methods. Although not environmentally threatening, urban and GDM areas were characterised by higher conductivity, total dissolved solids, salinity, magnesium and hardness. Chlorides, total phosphates, total nitrogen, calcium, potassium and sodium were significantly highest in urban sites whilst dissolved oxygen (DO)

was significantly higher in the forested commercial farming and GDM sites. Macroinvertebrate communities followed the observed changes in water quality. Macroinvertebrates in urban sites indicated severe pollution (e.g. Chironomidae) whilst those in forested commercial farming sites and GDM sites indicated relatively clean water (e.g. Notonemouridae). Forested watersheds together with good farm management practices are important in mitigating impacts of urbanisation and agriculture. Strategies that reduce oxygen-depleting substances must be devised to protect the health of Zimbabwean streams. The study affirms the wider applicability of the South African Scoring System in different land uses." **16172.** Newton, I. (2016): Obituary: Norman Winfrid Moore (1923–2015). *Ibis* 158: 459–461. (in English) [With the death of Norman Moore aged 92, on 21 October 2015, Britain lost one of its most influential conservationists. To ornithologists, Norman was perhaps best known for his work on pesticide impacts on birds. He led the team at Monk's Wood Experimental Station that studied the biological impacts of DDT and other organochlorines in the 1960s. This work eventually contributed to a banning of these chemicals from agricultural use in Britain and elsewhere. However, he was an allround naturalist with a particular interest in birds, dragonflies and butterflies. He became a world authority on dragonflies and their conservation, and was one of the first to appreciate the problems for wildlife of agricultural intensification and habitat fragmentation, and the value of hedgerows in modern farmland. Norman firmly believed in the importance of integrating nature conservation with other landuses, whether agriculture or forestry. He realized that small nature reserves alone could not save biodiversity in a country as highly developed and populated as Britain. He was a founder and first Chairman of the Farming and Wildlife Advisory Group (FWAG). This was a charitable trust which aimed to find practical ways of conserving wildlife on working farms, thus bridging a widening gulf between farmers and conservationists. As a person, Norman was well-informed, charming and modest. With his naturally gentle and thoughtful manner, he became widely regarded as one of conservation's elder statesmen, much loved and respected by all who knew him. Norman was born on 24 February 1923, the son of a doctor, Sir Alan Moore. In 1934 the family moved from Lewes to near Battle in rural Sussex. From boyhood, Norman was a keen naturalist. Birds were his first love, but by his teens butterflies and dragonflies had caught his attention. His first scientific paper, 'Rare Lepidoptera and Odonata in East Sussex', was published in 1939, when he was aged 16. He was educated at Eton College and then Trinity College, Cambridge, where he read Natural Sciences, specializing in zoology. While in Cambridge, he became President of the University Bird Club. Like so many of his generation, his studies were interrupted by war service. He was called up in 1942 and served as a gunnery officer in the Royal Artillery, with active service in Belgium and the Netherlands. When manning observation posts, he kept two notebooks: one with reports on German military activity and the other on wildlife seen at the time. Late in 1944 he suffered a serious leg wound and was captured by German forces. He was one of only four British prisoners in a camp housing 23 000 Russians. Conditions were appalling. On a pint of mangel-wurzel soup per day and one small loaf of bread per week, prisoners were starving, and deaths in the camp numbered more than a hundred per day. On being liberated by the US 7th Armoured

Division in April 1945, more than 9000 men from the camp were hospitalized and de-loused with the new wonder chemical, DDT. After his return to Britain, Norman trained] Address: Ian Newton. E-mail: ine@ceh.ac.uk

**16173.** Ngiam, R.W.J.; Cheong, L.F. (2016): The dragonflies of Singapore: An updated checklist and revision of the national conservation statuses. *Nature in Singapore* 9: 149–163. (in English) ["Over the past few years, the popularisation of local dragonflies (Odonata) among academics and amateurs has resulted in several new records, rediscoveries, and a better understanding of the distribution and conservation significance. Consequently, the species checklist and conservation status categories based on published materials are outdated and do not accurately reflect the current knowledge. Hence, we have conducted a comprehensive assessment of all species to produce the most updated Singapore checklist and revised national conservation status. The total number of Odonata species ever recorded from Singapore now stands at 131 which are composed of nine Nationally Extinct and 122 extant species. Of the extant species, 14 are of highest conservation importance because they are considered Critically Endangered and Very Rare. This paper supersedes previous checklists and conservation statuses. It will be a useful reference for anyone with an interest in Singapore dragonflies." (Authors)] Address: Ngiam, R.W.J., Nat. Biodiversity Centre, Nat. **16177.** Nituda, C.J.P.; Nuoeza, O.M. (2016): Diet Composition of two species of swiftlets from caves of Northern Mindanao, Philippines. *Bulletin of Environment, Pharmacology and Life Sciences* 5(5): 48-52. (in English) ["Caves serve as sanctuaries for birds especially swiftlets, the most common cave-dwelling birds. This study was conducted to determine and compare the diet composition of the two species of swiftlets, *Collocalia esculenta* and *Aerodramus vanikorensis*. Examination of the gut contents showed that the two bird species are generally insectivorous and the prey items consisted of insects under Orders Coleoptera, Hymenoptera, Diptera, and damselflies. There was no significant difference in the frequency of occurrence of the prey items between species since both species prefer the same prey items. However, percentage occurrence of the different prey items within the same species was significantly different ( $p < 0.05$ ). Coleopterans were the abundant prey items. The wide diversity of the diet of cave swiftlets suggests that these birds are not particularly selective in their diet and are more probably dependent on the available prey. Results indicate that swiftlets are good insect control agents. Collection of swiftlet nests inside caves appears to be a major threat to cave swiftlets." (Authors)] Address: Nuoeza, Olga, Dept of Biological Sciences, College Science & Mathematics, Mindanao State Univ. – Iligan, Institute of Technology, Iligan City, Philippines. **16178.** Novelo-Gutiérrez, R.; Ramírez, A.; Delgado, D. (2016): The larvae of *Epigomphus jannyae* Belle, 1993 and *E. tumefactus* Calvert, 1903 (Insecta: Odonata: Gomphidae). *PeerJ* 4:e2338 <https://doi.org/10.7717/peerj.2338>: 13 pp. (in English) ["The taxonomic knowledge about immature stages of the insect order Odonata is rather limited in tropical America. Here, the larvae of *E. jannyae* and *E. tumefactus* Calvert, 1903 are described, figured, and compared with other described congeners. *E. jannyae* larva is characterized by 3rd antennomere 1.6 times longer than its widest part; ligula very poorly

developed, with ten short, truncate teeth on middle; apical lobe of labial palp rounded and smooth. Lateral margins on abdominal segments (S5–9) serrated, lateral spines on S6–9 small and divergent; male epiproct with a pair of dorsal tubercles at basal 0.66; tips of cerci and paraprocts strongly divergent. The larva of *E. tumefactus* is characterized by 3rd antennomere 2.3 times longer than its widest part, ligula with 6–7 truncate teeth, apical lobe of labial palp acute and finely serrate. Lateral margins of S6–9 serrate, lateral spines on S7–9; male epiproct with a pair of dorsal tubercles at basal 0.50. Differences with other species were found in 3rd antennomere, lateral spines of S7–9, and the caudal appendages. *Epigomphus* larvae inhabit small, shallow creeks (1st order streams) where they live in fine benthic sediments. When mature, the larva leaves the water in shady places, climbing small rocks at the water's edge and metamorphosing horizontally on flat rocks. These new descriptions bring the total number of *Epigomphus* species with known larval stages to eight; only 28% of the species in this genus are known as larva." **16179.** Opaev, A.S.; Panov, E.N. (2016): Variations of space use in males of the banded demoiselle (*Calopteryx splendens*, Zygoptera, Odonata): Alternative tactics or an age-dependent trend? *Entomological Review* 96(5): 525-536. (in English) ["Two spatial tactics are usually distinguished in males of *Calopteryx* damselflies: territorial and nonterritorial. These tactics are believed to underlie two alternative condition-dependent reproductive tactics in these insects, and territorial males are believed to copulate more often. With age, males become weaker, turn nonterritorial, and only occasionally manage to copulate. However, the details of space use by damselflies are poorly known, which hinders the interpretation of the existing empirical data. We describe the space use by individually marked males of the banded demoiselle *C. splendens* studied during three field seasons in Vladimir Province, Russia. Each male on each day of observations was characterized as either territorial or non-territorial, and the sites of encounter were mapped. The probability of being territorial declined with the male's age. The spatial tactics (territorial vs. non-territorial) on a given day strongly influenced the tactics used on the following day. We identified the territorial and non-territorial phases in the life of a male damselfly, which occurred consecutively and had a roughly similar duration. During the territorial phase, the male occupied a certain territory and tried to hold it as long as possible. The male abandoned its territory in two cases: (1) when it was driven onto a different territory as the result of competition with other males, or (2) when it was exhausted and became non-territorial. Thus, the space use by the male changed predictably during its life. Therefore, direct comparison of morphological or other characteristics in territorial vs. non-territorial males, frequently made in the literature, makes little sense. Further progress in studying the so-called "alternative reproductive tactics" in damselflies may be more successfully achieved by comparing individual life trajectories

of different males (e.g. duration of territorial and non-territorial periods, the number of consecutively occupied territories, etc.). We performed correlation analysis and found that the above parameters did not depend on the wing and abdomen length of the males." (Authors) Original Russian Text © A.S. Opaev and E.N. **16186.** Parr, A.J. (2016): Migrant and dispersive dragonflies in Britain during 2015. *Journal of the British Dragonfly Society* 32(2): 49-59. ["Like many of its immediate predecessors, the year 2015 was an eventful one for migrant dragonflies in Britain. During June/July there were large-scale immigrations of *Sympetrum fonscolombii*, with records as far north as east Lothian in Scotland. Later in the summer, four *Aeshna* affinis were unexpectedly recorded away from the recently-

established breeding population around the greater Thames Estuary, presumably as a result of fresh immigration. These sightings mostly involved southern counties (Cornwall, Sussex and Suffolk) but included a female in Lancashire. In addition to these highlights, other notable events included the first sightings of *Sympetrum flaveolum* for several years and further autumn appearances of *Anax ephippiger*. An intriguing series of dragonfly sightings over the Christmas period (unfortunately not all well-documented) probably also refer to migrants. In addition to this news relating to primary immigration, significant developments also affected several of our recent colonist species. Both *Erythromma viridulum* and, more especially, *Chalcolestes viridis* thus showed continuing range expansion. While *Lestes barbarus* and *Coenagrion scitulum* seem not to be spreading at present, their recently-established populations do appear stable. Continued monitoring of all of our recent colonist species would seem desirable." (Authors)] Address: Parr, A.J., 10 Orchard Way, Barrow, Bury St Edmunds, Suffolk, IP29 5BX, UK

(in English) ["Details are given of the records involving mixed coupling between male *Lestes sponsa* with six different species of Zygoptera in the UK from 2010 to 2015. A total of 11 couplings are recorded, one with another species of *Lestes*, the other 10 with species from other families - four with single females, three with males and three with pairs. As to why this behaviour occurs is still unclear. Possible reasons for it are discussed." (Authors)] Address: Pickess, B.P., 8 Shaw Drive, Sandford, Wareham, Dorset. BH20 7BT, UK

**16195.** Pitcher, K.A.; Soluk, D.A. (2016): Inter-patch connectivity and intra-patch structure differentially alter prey consumption by multiple predators. *Ecosphere* 7(11) Article e01598: 14 pp. (in English) ["Structural habitat complexity (SHC) and functional habitat connectivity (FHC) have important effects on predator-prey interactions and exert a strong influence on community structure/dynamics in terrestrial and aquatic ecosystems. Although these factors vary simultaneously in most systems, their interactive effects are poorly understood. Using artificial pond mesocosms and multiple prey types, we manipulated plant density (SHC: low, high) and inter-patch distance (FHC: short, long) in a full factorial design to test for potential interactive effects of these factors on competition and predation by a dragonfly larva (*Anax junius*) and fish predator (*Lepomis cyanellus*). When inter-patch distances (FHC) were short, *A. junius* consumed more amphipods ( $36\% \pm 4.6\%$ ) compared with long treatments ( $19\% \pm 4.8\%$ ). We detected no significant effects of plant density (SHC) on prey consumption by *A. junius*. There were significant interactive effects of FHC and SHC on *L. cyanellus* consumption of amphipods and damselflies. The most counterintuitive of these effects was that sunfish consumed more larval damselflies at high plant density ( $64\% \pm 6.0\%$ ) than at low plant density ( $38\% \pm 8.6\%$ ) but only in short connection treatments. This interactive effect of SHC and FHC on damselfly predation by *L. cyanellus* was likely because damselflies exhibited riskier behaviour at higher SHC. Prey consumption with both predators present was additive, but no significant effect of either SHC or FHC on interspecific predation was detected, suggesting compensatory foraging responses. Structural habitat complexity and FHC interactively influence predator foraging behaviour in complex, non-intuitive ways that are highly dependent on the predator/prey combination in question. Structural habitat complexity and FHC are currently being influenced by anthropogenic factors in multiple ways (e.g., habitat loss, global climate change), and being able to predict the responses of biotic communities to these changes should be an important consideration in restoration and conservation efforts."

**16196.** Poliak, T.N. (2016): Population status of the endemic San Francisco damselfly (*Ischnura gemina*). M.Sc. thesis, Biology: Conservation Biology, San Francisco State University: IX + 64 pp. (in English) ["*I. gemina* is endemic to the San Francisco Bay area, and is identified by the International Union for Conservation of Nature as a vulnerable species. Research from the late 1970s through the 1990s indicates a decline in the species' populations. This study completes a comprehensive survey for *I. gemina*, and the closely related species *I. denticollis*, to determine the status of both species in areas previously surveyed. The study also seeks to determine the extent that various habitat variables, such as water chemistry and vegetation structure, predict the presence of *I. gemina*. Data from this study show a dramatic decline in populations of *I. gemina* since the 1980s and 1990s. In addition, results from this study indicate that *I. gemina* persists in sites with cooler temperatures and lower salinity than do other ischnuran or coenagrionid species. Finally, this study considers past research related to species conservation in light of climate change, and assesses the long-term viability of *I. gemina* under climate change. Of key interest is the tolerance for *I. gemina* under increasing temperatures and sea level rise. The goal for this research is to provide information on the current status of *I. gemina* and recommendations for its long-term conservation." (Author)] Address: not stated

**16197.** Popova, O.N.; Haritonov, A.Yu.; Anishchenko, O.V.; Gladyshev, M.I. (2016): Export of biomass and metals from aquatic to terrestrial ecosystems via the emergence of dragonflies (Insecta: Odonata). *Contemporary Problems of Ecology* 9(4): 458-473. (in English) ["Long-term monitoring of the abundance and spatial distribution of 18 widespread species of Odonata has made it possible to assess their contribution to the export of aquatic productivity that entered the Barabinsk forest-steppe ecosystem. The annual emergence of Odonata varies from 0.8 to 4.9 g/m<sup>2</sup> of the land area and from 2.3 to 13.3 g/m<sup>2</sup> of the water area, which is 4–5 times larger than that in Diptera. The total flux of organic matter from water to terrestrial ecosystems remains relatively stable (sixfold inter-annual variability) irrespective of large interannual variations in the abundance of separate species (e.g., 42-fold interannual variability in *Libellula quadrimaculata*). The metal content was determined in nine Odonata species. Export of metals by dragonflies decreases in the series  $K > Na > Mg > Ca > Fe > Zn > Cu > Mn > Pb > Ni > Cr > Cd$ . Therefore, odonates appear to be quantitatively and qualitatively important providers of aquatic resources to the forest-steppe landscape of Western Siberia." **16204.** Rajabi, H.; Shafiei, A.; Darvizeh, A.; Gorb, S.N. (2016): Resilin microjoints: a smart design strategy to avoid failure in dragonfly wings. *Scientific Reports* 6:39039 DOI:

10.1038/srep39039: 5 pp. (in English) ["Dragonflies are fast and manoeuvrable fliers and this ability is reflected in their unique wing morphology. Due to the specific lightweight structure, with the crossing veins joined by rubber-like resilin patches, wings possess strong deformability but can resist high forces and large deformations during aerial collisions. The computational results demonstrate the strong influence of resilin-containing vein joints on the stress distribution within the wing. The presence of flexible resilin in the contact region of the veins prevents excessive bending of the cross veins and significantly reduces the stress concentration in the joint." **16205.** Rasmussen, N.L.; Rudolf, V.H.W. (2016): Individual and combined effects of two types of phenological shifts on predator-prey interactions. *Ecology* 97(12): 3414-3421. (in English) ["Timing of phenological events varies among years with natural variation in environmental conditions and is also shifting in response to climate change. These phenological shifts likely have many effects on species interactions. Most research on the ecological consequences of phenological shifts has focused on variation in simple metrics such as phenological firsts. However, for a population, a phenological event exhibits a temporal distribution with many attributes that can vary (e.g., mean, variance, skewness), each of which likely has distinct effects on interactions. In this study, we manipulated two attributes of the phenological distribution of a prey species to determine their individual and combined effects on predator-prey interactions. Specifically, we studied how shifts in the mean and variation around the mean (i.e., synchrony) of hatching by tadpoles (*Hyla cinerea*) affected interactions with predatory dragonfly naiads (*Tamea carolina*). At the end of larval development, we quantified survival and growth of predator and prey. We found that both types of shifts altered demographic rates of the prey; that the effects of synchrony shifts, though rarely studied, were at least as strong as those due to mean shifts; and that the combined effects of shifts in synchrony and mean were additive rather than synergistic. By dissecting the roles of two types of shifts, this study represents a significant step toward a comprehensive understanding of the complex effects of phenological shifts on species interactions. Embracing this complexity is critical for predicting how climate change will alter community dynamics." (Authors)] Address: Rasmussen, N.L., Dept Entomology & Nematology, Univ. California, Davis, California 95616 USA. E-mail: solifugae@gmail.com

**16209.** Remmers, W.; Gameiro, J.; Schaberl, I.; Clausnitzer, V. (2016): Elephant (*Loxodonta africana*) footprints as habitat for aquatic macroinvertebrate communities in Kibale National Park, south-west Uganda. *African journal of ecology* 55(3): 342-351. (in English) ["This is the first study where elephant footprints as habitat for aquatic macroinvertebrate communities were assessed. Preliminary observations during the dry season in Kibale Forest, Uganda, indicated that water-filled footprints constituted the majority of stagnant ponds. Consequently, this study aimed at giving an overview of the diversity and ecology of those habitats and the capacity of elephants as ecosystem engineers. The fauna and abiotic factors (age, size, substrate, organic matter, pH,

canopy cover, temperature, conductivity) of 30 water-filled natural elephant footprints were sampled, resulting in the record of 61 morphospecies among 27 families/orders. Species composition was dominated by Hydrophilidae and Dytiscidae and influenced by environmental variables, such as age and organic matter. To study the colonization process, 18 artificial footprints were created within different distances from the water source. After 5 days, 410 specimens were collected, with higher species richness in artificial footprints closer to a natural water source. We conclude that colonization of water-filled footprints is fast, they constitute important habitats with high diversity and variability, and they act as stepping stones for dispersal and add to the ability of elephants as ecosystem engineers. We emphasize the importance of elephants as a key species in ecosystem dynamics and conservation practice." (Authors) Tetrathemis sp., Coenagrionidae, Hadrothemis coacta] Address: Remmers, W., University of Koblenz-Landau, Universitätsstr. 1, 56070 Koblenz, Germany. E-mail: wremmers@uni-koblenz.de

**16210.** Renner, S.; Sahlén, G.; Périco, E. (2016): List of Odonates from the Floresta Nacional de São Francisco de Paula (FLONA - SFP), with two new distribution records for Rio Grande do Sul, Brazil. *Biota Neotrop.* 16(3) e20150132: 7 pp. (in English, with Portuguese summary) ["A survey of Odonata was carried out in the National Forest FLONA - SFP, Northeastern region of the Rio Grande do Sul state, Brazil. This conservation unit is mainly covered by Mixed Ombrophilous Forest (MOF), a subtype of Atlantic Forest biome, being also areas covered in planted Pinus, planted Araucaria and open fields. Our sampling efforts were conducted in thirty aquatic environments inside this reserve during the period between January 2014 and November 2014. The sampling sites were selected randomly, comprehending lakes, bogs, small streams and river sections, all inserted in the four vegetation types occurring in the reserve. 64 species of Odonata were collected and grouped into 23 genera and seven families. The dominant families were Coenagrionidae (32%), Libellulidae (32%), Aeshnidae (12%), and Calopterygidae and Lestidae (9%). As expected, the findings revealed the presence of a highly diverse Odonate assemblage, mainly represented by generalist species in the most human disturbed sectors (Pinus and Open fields) and some specialist species in the pristine forest. Two species were registered for the first time in the state of Rio Grande do Sul, Brazil: *Libellula herculea* Karsch, 1889 (Libellulidae) and *Heteragrion luizfelipei* Machado, 2006 (Heteragrionidae)."] (Authors)] Address: Renner, S., Centro Univer. Univates, Rua Avelino Tallini, 171, Lab. Evolução e Ecol., sala 104, Prédio 8, 95900-000, Lajeado, RS, Brazil

**16211.** Reznickova, P.; Petrovajová, V.; Nerudová, J.; Hadašová, L.; Kopp, R. (2016): The colonization of newly built fishponds by the macroinvertebrate assemblages. *Acta Universitatis Agric. Silv. Mendelianae Brun.* 64(1): 141-149. (in English) ["The succession of standing waters by aquatic macroinvertebrates is a present and insufficiently surveyed topic. This study is addressed to the issue of colonisation of newly created small standing waters. Two fishponds situated in the north of Moravia (Czech Republic) were studied. The aim of this study

was to determine the character and colonisation rate of these ponds by macroinvertebrates, to evaluate the abundance, taxonomic composition and changes in composition of freshwater assemblages as a result of the fish stock influence. Basic abiotic parameters were also measured within the sampling occasions (e.g. water temperature, dissolved oxygen, conductivity, pH, total nitrogen and phosphorus concentrations). Samples of aquatic macroinvertebrates were taken monthly during the years 2012 and 2013, by kick sampling method using the hand net. The character of sampled fishponds was very similar, environmental parameters (e.g. area, substrate, depth etc.) were comparable. The colonisation of both fishponds was very fast. The pioneer colonists were mainly insect larvae (e.g. chironomids). Very low numbers of macroinvertebrates as a result of fish stock influence were recorded on both sites during the observation with the highest abundances in summer season." (Authors)] Address: Reznicková, Ravla, Dept of Zoology, Fisheries, Hydrobiology and Apiculture, Faculty of AgriSciences, Mendel University in Brno, Zemedelská 1, 613 00 Brno, Czech Republic

**16212.** Rivas, M.; Martinez-Meyer, E.; Munoz, J.; Cordoba-Aquilar, A. (2016): Body temperature regulation is associated with climatic and geographical variables but not wing pigmentation in two rubyspot damselflies (Odonata: Calopterygidae). *Physiological Entomology* 41(2): 132-142. (in English) ["It has been proposed that wing pigmented spots function in temperature control in male calopterygids. Using two rubyspot species *Hetaerina americana* and *H. vulnerata*, the present study investigated whether (i) wing spot size and colour-modified aspect can predict temperature gain after a cooling event; (ii) wing spot size is related to the temperature needed to fly and how long it takes to initiate flight; and (iii) wing spot size is related to seasonality and altitude. The results obtained do not support any of these relationships. The results also indicate that *H. vulnerata* can achieve flight at 8 Å °C less than *H. americana*. The present study further investigates whether the species differ in their latitudinal and geographical distribution, and respond differently to bioclimatic variables. The results obtained provide support for this particular hypothesis, showing that *H. vulnerata* inhabits higher altitudes, and is able to tolerate colder environments compared with *H. americana*. Wing spots in the two *Hetaerina* species do not help in thermoregulation, although both species show different temperature control abilities. This difference in thermoregulatory ability may enable the species to colonize different environments and reduce interspecific competition." **16218.** Ruf, C.; Gufler, C.; Küry, D. (2016): Populationsentwicklung und Habitatpräferenzen der Westlichen Keiljungfer (*Gomphus pulchellus* Selys, 1840) in der Region Basel (Schweiz) (Odonata: Gomphidae). *Mitteilungen der Naturforschenden Gesellschaften beider Basel* 16: 109-122. (in German, with English summary) ["From 2012 to 2014 an isolated population of *G. pulchellus*, an endangered species of national priority was studied in the Spittelmat Ponds in Riehen (canton Basel-Stadt, Switzerland) and in two other potential breeding sites. The density at emergence was between 34.2 and 50.8 exuviae per 100 meter of shore line while the proportion of male exuviae varied from 42.7 to 54.5 %. The EM50 showed values from 4 to 12 days. The emergence period started when a mean temperature sum of  $1'113.8 \pm 69.3$  °C (January 31st until date of first emergence) was reached. Highest densities of exuviae were found on the south eastern shore of the ponds with approximately 80 % of them attached values on plants part like *Rubus* sp. and *Carex* sp. In the nearby gravel pit Käppelin (Weil am Rhein, Germany) only two exuviae were found and in the Entenweiher exuviae were lacking completely. In 2014 only three larvae of *G. pulchellus* were found in mainly sandy sediments covered by detritus. They seemed to have a very patchy distribution. In experiments larvae chose significantly a sandy sediment of a grain size between 0.05 and 0.5 mm. On sediments covered with detritus the larvae buried themselves after 36 minutes compared to 54 minutes without detritus. The Spittelmat ponds seem to be the main habitat of a metapopulation of which actual size and spread are unknown. To conserve and support the population of the *G. pulchellus* it is proposed to restore the ponds in vicinity of the Spittelmat ponds according to its habitat preferences." (Authors)] Address: Ruf, C., Junkerbifangstr. 14, 4800 Zofingen, Switzerland. E-mail: christian\_ruf@gmx.ch

**16219.** Rychla, A. (2016): Occurrence of the Spotted Darter *Sympetrum depressiusculum* (SELYS, 1841) (Odonata: Libellulidae) in western Poland. *Odonatrix* 126: 8 pp. (in Polish,

with English summary) ["*S. depressiusculum* is currently in decline at the European scale and further decrease of species localities has been already predicted for the next years. The situation of the species seems to be stable in Poland, so far. However, there are many regions without any information on the species occurrence. This paper presents 16 new records of *S. depressiusculum* and summarizes its current distribution in western Poland. Further, the habitat types of the species are described and habitat preferences are discussed. The new localities make up 9 % of all known records in Poland. The species was numerous (> 20 individuals) or fairly numerous (6–20 individuals) at 12 new sites. The reproductive behaviour as well as the breeding success were observed at 9 localities, respectively. *S. depressiusculum* was mostly found in fish ponds (37 % of all sites) and in dystrophic peat bogs (37 %). Almost 90 % of all sites were surrounded by forests. The results show that the species is widely distributed in western Poland and clearly prefers two types of habitats: fish ponds and peat bogs. Further investigations of *S. depressiusculum* should, therefore, focus on these habitat types in this region. The common occurrence of *S. depressiusculum* in the second habitat type is somehow unexpected as the species is not the typical faunistic element of peat bogs. The presented records constitute therefore a good basis to monitor the permanency and stability of the population in western Poland, especially in bog-like biotopes." **16220.** Rychla, A. (2016): Neue Libellenfunde aus der Niederschlesischen Heide (Bory Dolnoslaskie) in Polen. IDF-Report 100: 1-11. (in German, with English and Polish summaries) ["In this study, the results of the investigation of Odonata, conducted in the years 2015 and 2016 in three boggy protected areas („Zacisze“, „Przygielkowe Moczary“ und „Zurawie Bagno“) of the Lower Silesian Wilderness are presented. A total of 41 species was found. There were eight species new for the investigated area, six of which were of Mediterranean origin. The observation of *Orthetrum albistylum* shows that this species has already reached the western border of Poland and a further expansion to Germany is to be expected. The investigations did not reveal any new findings of *Aeshna subarctica* in the area, so the status of this species is still unclear. Of the rare species the new record of *Leucorrhinia caudalis* in the NSG "Zacisze" was demonstrated. It is the first observation of this species in the Lower Silesian Wilderness and as far as the only one in the southern part of Lubuskie Voivodeship, but the status of the species remains unknown. The study confirms that the biodiversity in the areas is very high. The thermophilous species increase the local diversity in the peat bogs on one hand, but they are also regionally new faunal elements, which may cause strong changes in the bog's dragonfly community on the other hand. Therefore, further systematic research in the peat bogs in this area is necessary." (Author)] Address: Rychla, A., Ul. Osiedlowa 12, Ploty, 66016 Czerwieńsk, Poland. E-mail: an.rychla@gmail.com

**16221.** Saetung, T.; Boonsoong, B. (2016): Description of the final instar larva of *Pseudagrion pruinosum* (Burmeister,

1839) (Odonata: Coenagrionidae) from Thailand. *Zootaxa* 4175(3): 292-300. (in English) ["Herein the final instar larva of *P. pruinosum* is described and illustrated for the first time, based on reared specimens from Thailand. When compared with the other known *Pseudagrion* larvae, *P. pruinosum* is distinguished by three setae on the labial palp, five teeth on the truncate, denticulate lobe on the distal marginal end of the labial palp, one premental seta and a row of three minute setae on each side of the midline, as well as shape and tracheation of caudal gills." **16222.** Saha, S.; Nirwal, S. (2016): Abstract: R20.00002: Viability of long range dragonfly migration across the Indian Ocean: An energetics perspective. *Bulletin of the American Physical Society* 61(20) (69th Annual Meeting of the APS Division of Fluid Dynamics): [Verbatim: Recently *Pantala flavescens* have been reported to migrate in millions from India to Eastern Africa on a multigenerational migratory circuit of length 14000-18000 kms [R Charles Anderson. (*Journal of Tropical Ecology*), 25(04): 347-358, 2009]. We attempt to understand the ability of dragonflies to perform long range migration by examining the energetics using computer simulations. In absence of a theory for long range insect migrations, we resort to the extensive literature on long range bird migration from the energetics perspective. The flight energetics depends upon instantaneous power and velocity. The mechanical flight power is computed from the power curve which is then converted to mass depletion using Brequet's equation. However, the mechanical flight power itself depends upon the instantaneous velocity which can vary depending upon the current mass. In order to predict the range in our simulations, we assume that the insect progressively tries to achieve the maximum range velocity. The results indicate that the migration range is approximately 1260 kms in 70 hours based on the true airspeed. However, our analysis is restricted by the lack of data and certain caveats in drag prediction and basal metabolism rate.]

**16223.** Saikia, R.; Mishra, H.; Devi, A.; Saikia, D.K. (2016): Biodiversity of odonates in rice eco-system, Titabar, Assam. *Journal of Entomology and Zoology Studies* 4(4): 1376-1381. ["The present study was conducted at Farmers field near Regional Agricultural Research Station, Titabar, main rice bowl of the district Jorhat, Assam. Visual count and catch per unit effort was adopted to record the odonate diversity in the rice field. 68 individuals of odonate belonging to 14 species, equal number of species were recorded from each sub-order, Zygoptera and Anisoptera. The study revealed more number of damselfly population (40) than the dragonfly (28). Vegetative growth of rice crop support more number of Odonates (17 damselfly and 10 dragonfly) followed by reproductive (15 damselfly and 10 dragonfly) and ripening stage (8 damselfly and 8 dragonfly). The most dominant damselfly and dragonfly species were *Ceragrion coromandelianum* and *Diplacodes trivialis* with 11 and 10 individuals respectively. Diversity of damselfly (1.73) was greater than dragonfly (1.42) same as in case of richness and evenness index in vegetative stage. But

dragonfly diversity (1.75) was more than damselfly (1.55) as in richness and evenness index particularly when the crop was at reproductive stage. The ripening stage of rice crop support more or less similar diversity of damselfly (1.32) and dragonfly (1.30) with richness and evenness index (1.44, 1.92 & 0.95, 0.81) respectively." **16224.** Salami, E.; Ganesan, P.B.; Ward, T.A.; Viyapuri, R.; Romli, F.I. (2016): Design and mechanical analysis of a 3D-printed biodegradable biomimetic micro air vehicle wing. IOP Conference Series: Materials Science and Engineering 152(1): 7 pp. (in English) ["The biomimetic micro air vehicles (BMAV) are unmanned, micro-scaled aircraft that are bio-inspired from flying organisms to achieve the lift and thrust by flapping their wings. There are still many technological challenges involved with designing the BMAV. One of these is designing the ultra-lightweight materials and structures for the wings that have enough mechanical strength to withstand continuous flapping at high frequencies. Insects achieve this by having chitin-based, wing frame structures that encompass a thin, film membrane. The main objectives of this study are to design a biodegradable BMAV wing (inspired from the dragonfly) and analyze its mechanical properties. The dragonfly-like wing frame structure was bio-mimicked and fabricated using a 3D printer. A chitosan nanocomposite film membrane was applied to the BMAV wing frames through casting method. Its mechanical performance was analyzed using universal testing machine (UTM). This analysis indicates that the tensile strength and Young's modulus of the wing with a membrane is nearly double that of the wing without a membrane, which allow higher wing beat frequencies and deflections that in turn enable a greater lifting performance." **16225.** Samways, M.; Simaika, J. (2016): Manual of freshwater assessment for South Africa: Dragonfly Biotic Index. *Suricata* 2: 224 pp. (in English) ["Overall, freshwater ecosystems are the most threatened ecosystem type in the world. The scarce South African freshwaters are threatened by alien organisms, high volumes of water abstraction, and pollution. Yet some South African freshwaters are being restored to their former condition. It is important to monitor these systems and note whether they are declining or improving. One way to do this is to use the Dragonfly Biotic Index, which is based on dragonfly biogeography, their sensitivity to change, and the degree to which they are threatened. This index is sensitive and robust and is suitable for assessing and monitoring freshwaters across the country. This manual explains how to use and apply the Dragonfly Biotic Index, while also providing guidelines for species identification. Published by the National Botanical Institute (NBI)." **16227.** Satpathi, C.R.; Mondal, A. (2016): Holistic survey on damselfly (Anisoptera [sic]: Odonata) diversity in rice ecosystem of eastern India. *International Research Journal of Natural Sciences* 4(4): 19-34. (in English) ["This study highlights the richness of damselfly (Anisoptera: Odonata) [sic] fauna associated with rice ecosystems in Eastern India. Sampling of the Damselfly community was conducted during 2010-14 to determine species composition, abundance and distribution in 3 different habitats of rice fields which were selected at 60 m (Chakdaha), 600 m (Cooch Behar) and 1250 m (Kalimpong) respectively. Each location was surveyed at a biweekly interval after transplanting of rice plants and about 10 species of damselfly were recorded as insect predators in rice crops of Eastern India. General morphology, biology, ecology, behavior of the damselfly are being highlighted in the present investigation. After comparing different body parts, double branching keys are prepared for their easy identification. The studies of their diversity showed that maximum and minimum value of both Simpson and Shannon-Weiner index were at the flowering and the vegetative stage of crop respectively. The value of Margalef index and Menhinck index also indicated that the highest value in reproductive stage of rice crop. The studies on Evenness index designated that the value of E1, E2 and E3 were influenced by species richness and not evenness. Consequently the influence of fertilizer on the incidence of damselfly in rice ecosystem showed that there was a remarkable increase of population where high doses of nitrogen (120 kg/ha) were applied followed by the use of mix fertilizer (120:60:60 N:P:K). Although the plot receiving high doses of phosphate @ 60 kg/ha exhibited increase in the level of damselfly population but the distribution was least in the field where potassium fertilizer was used in both kharif (rainy) and rabi (winter) season during 2010 to 2014. The sampling of damselfly population on weed, ratoon rice, rice fallow land exhibited that the bund weed provided resting site for damselfly. The colonization and succession of Damselfly species in the rice field habitat showed a uniform pattern in relation to the growth stage of rice crop. At the end of study, the relevance of Damselfly biosystematics in the context on bio diversities has been given in its legitimate status as bio control agent of rice insect

pests in Eastern India." (Authors) [Address: Satpathi, C.R., Dept of Agricultural Entomology Bidhan Chandra Krishi Viswa-vidyalaya (State agricultural University), P.O- Mohanpur, Dist. – Nadia, West Bengal -741252, India

Early hatching date and rapid larval development in *Aeshna affinis* (Odonata: Aeshnidae). *Odonatologica* 45(3/4): 155-177. (in English) ["The objective of our study was to identify mechanisms enabling typical inhabitants of vernal ponds in temperate climate zones to complete their larval development under the time-constrained conditions of temporary larval habitats. We compared both hatching phenology and larval development of *A. affinis* with those of its permanent water congener *A. mixta* under semi-natural conditions and with literature data on other European Aeshnidae. We identified the following traits enabling rapid univoltine development in vernal ponds: i) Seasonally early hatching: *A. affinis* hatched significantly – on average

22 days – earlier than *A. mixta*. ii) Relatively small size difference between the second and the final larval stadium: Second-stadium larvae of *A. affinis* were significantly larger than those of all other European Aeshnidae, but the exuviae are among the smallest of this family in Europe. Therefore, larval growth coefficient and the number of larval stadia are smaller than in any other European Aeshnidae. iii) A low degree-day sum during larval development, being significantly lower than that of *A. mixta*. Although median larval development time of the vernal pond species *A. affinis* was longer than that of *A. mixta*, the first emerged significantly – on average 18 days – earlier than the latter." **16239.** Severina, I. Yu.; Isavnina, L.; Knyazev, A.N. (2016): Topographic anatomy of ascending and descending neurons of the supraesophageal, meso- and metathoracic ganglia in paleo- and neopterous insects. *Journal of Evolutionary Biochemistry and Physiology* 52(5): 397-406. (in English)

["Topographic anatomy of ascending (AN) and descending (DN) neurons of the supraesophageal and thoracic ganglia in the nervous system of winged insects (Pterygota), representatives of the infraclasses Palaeoptera (Odonata, *Aeshna grandis*) and Neoptera (Blattoptera, *Periplaneta americana*), was studied. These insects differ in ecological niches, lifestyles, sets of behavioral complexes, levels of locomotor system development, evolutionary age and systematic position. Cell bodies and processes of ANs and DNs were stained with nickel chloride (NiCl<sub>2</sub>), and their topography was studied on total preparations of the supraesophageal and thoracic ganglia. Unlike cockroaches, the dragonfly protocerebrum was found to contain DNs sending their processes to ocelli. Dragonfly DN processes exhibit a specific branching pattern in thoracic ganglia, with collaterals coming off both ipsi- and contralaterally. In cockroaches, collaterals of DN processes come off ipsilaterally. The AN cell bodies in dragonfly meso- and metathoracic ganglia lie both ipsi- and contralaterally relative to the ascending process, whereas in cockroaches most of the AN cell bodies in the same ganglia are located contralaterally. Substantial differences in the distribution of DNs and ANs in insects with different manners of locomotion appear to reflect different degrees of control the supraesophageal ganglion exerts over the activity of segmental centers. This does not seem to be related to the evolutionary age of insects or their systematic position. Probably, different degrees of control over locomotion depend on the way of food acquisition: catching prey in the air in "paleopterous" dragonflies versus maneuverable walking or running over a solid substrate in "neopterous" cockroaches." **16240.** Shapiro, B.G. (2016): Physiology and structure of motion sensitive neurons in the dragonfly visual system. The FASEB Journal 30(1) Supplement 760.2 : (in English) [Verbatim: Aeshnid dragonflies are among the largest North American insects and also among the fastest and most accurate predators. During prey pursuit, they quickly respond to deviations in their flying-prey trajectory and alter their flight paths to intercept their quarry. Remarkably, a deviation in the prey's path results in a dragonfly turn in only 30 ms, much faster than the visual latencies in most animals. Visual neurons, called target-selective descending neurons (TSDNs) are hypothesized to mediate the dragonfly's fast response to flying prey. Once stimulated, these neurons send signals down the nerve cord to the wing-motor circuitry controlling flight, allowing for a flight path correction. In laboratory experiments with restrained dragonflies, TSDN activity is relatively weaker and slower than expected from the behaviour. We are testing the idea that this neural "lethargy" is due to the lack of neuromodulators such as octopamine in the restrained dragonfly's brain. We are investigating this hypothesis by comparing TSDN visual responses before and after injection of the octopamine mimic, chlordimeform. Our results show dramatic increases in TSDN spike activity after chlordimeform injection, suggesting that TSDN activity is augmented in the behaving animal by the neuromodulator, octopamine. Further, utilizing intracellular recording techniques, we aim to identify

the individual neurons which mediate responses to specific types of stimuli, such as approaching objects. Once a cell is identified, we will inject a dye through the recording microelectrode, which will travel within the cell in question up into the brain. This will allow us to obtain a structural representation of the neuron, which can then be linked back to its specific function in the visual processing cascade.] Address: Shapiro, B.G., Biology, Union College, Schenectady, NY, USA

**16241.** Sharkey, C.R.; Partridge, J.C.; Roberts, N.W. (2016): Polarization sensitivity as a visual contrast enhancer in the Emperor dragonfly larva, *Anax imperator* (Leach, 1815). J. Exp. Biol. 218(Pt 21): 3399-3405. ["Summary Statement: Behavioural evidence that polarization sensitivity in the larva of *A. imperator*, reduces the contrast-degrading effect of scattered light under naturalistic horizontally polarized underwater lighting conditions. Polarization sensitivity (PS) is a common feature of invertebrate visual systems. In insects, PS is well known for its use in several different visually guided behaviours, particularly navigation and habitat search. Adult dragonflies use the polarization of light to find water but a role for PS in aquatic dragonfly larvae, a stage that inhabits a very different photic environment to the adults, has not been investigated. The optomotor response of the larvae of *A. imperator*, was used to determine whether these larvae use PS to enhance visual contrast underwater. Two different light scattering conditions were used to surround the larval animals: a naturalistic horizontally polarized light field and nonnaturalistic weakly polarized light field. In both cases these scattering light fields obscured moving intensity stimuli that provoke an optokinetic response in the larvae. Animals were shown to track the movement of a square-wave grating more closely when it was viewed through the horizontally polarized light field, equivalent to a similar increase in tracking ability observed in response to an 8% increase in the intensity contrast of the stimuli. Our results suggest that larval PS enhances the intensity contrast of a visual scene under partially polarized lighting conditions that occur naturally in freshwater environments." **16242.** Sharma, D.; Brahma, S.; Saha, N.; Kundu, M.; Saha, G.K.; Aditya, G. (2016): Association of larval Odonata and hydrophytes in wetlands of West Bengal, India: implications for conservation and monitoring. Journal of Entomology and Zoology Studies 4(3): 35-39. (in English) ["The abundance and distribution of the larval odonates depend on the hydrophytes, which was tested in the present study. A total of 19 genera of Odonata were observed in different relative abundance against the hydrophytes. Among the genera, *Ceriatrigon* and *Pantala* respectively, remained dominant over others with significant variations in relative abundance in the samples. Hydrophytes like *Wolffia* and *Marsilea* were key factors in explaining the relative abundance of larval odonates as explained through the canonical correspondence analysis. The species specific abundance seemed highly dependent on the hydrophytes in the concerned water bodies. In order to enhance the

sustenance of the Odonata in wetland habitats, availability of different species of hydrophytes seems to be an essential criterion. Considering the multifunctional role of the larval odonates in the freshwater aquatic communities, conservation effort should include the systematic inclusion of the preferred hydrophytes in the wetlands." **16245.** Simaika, J.P.; Samways, M.J.; Frenzel, P.P. (2016): Artificial ponds increase local dragonfly diversity in a global biodiversity hotspot. *Biodiversity and Conservation* 25(10): 1921-1935. (in English) ["Human demands have led to an increased number of artificial ponds for irrigation of crops year-round. Certain insect species have established in these ponds, including dragonflies (Insecta: Odonata). There has been discussion around the value of artificial ponds for encouraging dragonfly diversity, with little work in biodiversity hotspots

rich in rare and endemic species. We focus here on the Cape Floristic Region (CFR) global biodiversity hotspot, which has many endemic dragonfly species but has few natural ponds. Yet it has many artificial ponds mostly used for irrigation on local farms. This leads to an interesting question: to what extent do these artificial ponds provide habitats for dragonflies in this biologically rich, agriculturally fragmented landscape? To answer this, we recorded dragonfly species richness and abundances from 17 artificial ponds and 13 natural stream deposition pools as reference, in an area of the CFR where there are no local, natural, perennial ponds. 13 environmental and physical variables were recorded at the ponds and pools. We found that although ponds attracted no rare or threatened dragonfly species, they increased the area of occupancy and population sizes of many generalist species. These came from nearby natural deposition pools or from unknown sources elsewhere in the region, so providing refuges which otherwise would not be there. Interestingly, some CFR endemic species were also recorded at our artificial ponds. Overall dragonfly assemblages and those of Anisoptera Zygoptera differed between artificial ponds and deposition pools, suggesting that artificial ponds are to some extent a novel ecosystem. Habitat type, elevation and temperature were significant drivers in structuring overall species assemblages. For the Anisoptera, riparian vegetation and level of landscape connectivity was important, while temperature was not. In contrast, Zygoptera species were most affected by river catchment, habitat type and temperature. In sum, these artificial ponds are stepping stone habitats across an increasingly fragmented landscape. Managing these ponds with perennial water, constant water levels, and maximum complexity and heterogeneity of habitats in terms of vegetation will conserve a wide range of generalists and some specialists." **16246.** Smith, W.A.; Tennessen, K. (2016): Description of the nymph of *Ophiogomphus smithi* (Odonata: Gomphidae), with a key to the species of *Ophiogomphus* in the Western Great Lakes Region. *The Great Lake Entomologist* 49(1-2): 78-96. (in English) ["*O. smithi* is a gomphid dragonfly with restricted distribution which includes northeast Iowa, southeast Minnesota, and central to northwestern Wisconsin. The nymph is described and illustrated based on 173 specimens (66 exuviae of reared specimens plus 107 nymphs) from throughout the species' range. The nymph of *O. smithi* is very similar to nymphs of *O. carolus* Needham, *O. colubrinus* Selys, and *O. rupinsulensis* (Walsh). Nearly all (99%) of *O. smithi* sampled can be distinguished from *O. colubrinus* by prementum terminal width less than or equal to 2.97 mm (98% of *O. colubrinus* greater than 2.97 mm), and from *O. carolus* and *O. rupinsulensis* by the ratio of metatibia length to abdominal segment 10 width being greater than 1.66 (96% of *O. smithi*) vs. less than 1.66 (98.5% of *O. carolus* and *O. rupinsulensis*). Several characters and character combinations previously unused for *Ophiogomphus* nymphs were found to be of taxonomic value, including color pattern on dorsal hooks and dorsum of abdomen, shape of abdominal mid-dorsal punctae,

length and shape of fronto-clypeal ridge setae, and ratio of metatibia length to width of abdomen on segments 9 and 10. An illustrated quantitative key to the 7 species of *Ophiogomphus* occurring in the western Great Lakes region is provided, along with a separate, more qualitative key enabling species identification in the field. *Ophiogomphus smithi* is regularly syntopic only with *O. rupinsulensis*, rarely with *O. carolus* and *O. colubrinus* and not with *O. anomalus*, *O. howei*, or *O. susbehcha*; nymphs inhabit small to medium-sized, sandy, cool to warm stream segments with patches of pea-sized gravel." Environ. Res. Public Health* 13, 529; doi:10.3390/ijerph-13060529: 12 pp. (in English) ["Children are becoming less likely to have direct contact with nature. This ongoing loss of human interactions with nature, the extinction of experience, is viewed as one of the most fundamental obstacles to addressing global environmental challenges. However, the consequences for biodiversity conservation have been examined very little. Here, we conducted a questionnaire survey of elementary schoolchildren and investigated effects of the frequency of direct (participating in nature-based activities) and vicarious experiences of nature (reading books or watching TV programs about nature and talking about nature with parents or friends) on their affective attitudes (individuals' emotional feelings) toward and willingness to conserve biodiversity. A total of 397 children participated in the surveys in Tokyo. Children's affective attitudes and willingness to conserve biodiversity were positively associated with the frequency of both direct and vicarious experiences of nature. Path analysis showed that effects of direct and vicarious experiences on children's willingness to conserve biodiversity were mediated by

their affective attitudes. This study demonstrates that children who frequently experience nature are likely to develop greater emotional affinity to and support for protecting biodiversity. We suggest that children should be encouraged to experience nature and be provided with various types of these experiences." **16249.** Solis, M.; Mugni, H.; Hunt, L.; Marrochi, N.; Fanelli, S.; Bonetto, C. (2016): Land use effect on invertebrate assemblages in Pampasic streams (Buenos Aires, Argentina). *Environmental Monitoring and Assessment* 188: 539. (in English) ["Agriculture and livestock may contribute to water quality degradation in adjacent waterbodies and produce changes in the resident invertebrate composition. The objective of the present study was to assess land use effects on the stream invertebrate assemblages in rural areas of the Argentine Pampa. The four sampling events were performed at six sites in four streams of the Pampa plain; two streams were sampled inside a biosphere reserve, and another one was surrounded by extensive livestock fields. The fourth stream was sampled at three sites; the upstream site was adjacent to agricultural plots, the following site was adjacent to an intensive livestock plot and the downstream site was adjacent to extensive breeding cattle plots. Higher pesticide concentrations were found at the site adjacent to agricultural plots and higher nutrient concentrations at the sites adjacent to agricultural and intensive breeding cattle plots. The invertebrate fauna were also different at these sites. Multivariate analysis showed a relationship between nutrient concentrations and taxonomic composition. Amphipoda (*Hyalella curvispina*) was the dominant group in the reserve and extensive breeding cattle sites, but was not present in the agricultural site. Also, Chironomidae were absent from the agricultural site while present at other sites. Gasteropoda (*Biomphalaria peregriana*), Zygoptera, and Hirudinea were dominant at the most impacted agricultural and intensive breeding cattle sites." (Authors)] Address: hernanmugni@gmail.com

**16250.** Sousa, E.; Quintino, V.; Palhas, J.; Rodrigues, A.M.; Teixeira, J. (2016): Can environmental education actions change public attitudes? An example using the pond habitat and associated biodiversity. *PLoS ONE* 11(5): e0154440. doi:10.1371/journal.pone.0154440: 13 pp. (in English) ["Ponds provide vital ecological services. They are biodiversity hotspots and important breeding sites for rare and endangered species, including amphibians and dragonflies. Nevertheless, their number is decreasing due to habitat degradation caused by human activities. The "Ponds with Life" environmental education project was developed to raise public awareness and engagement in the study of ponds by promoting the direct contact between the public and nature, researchers and pedagogical hands-on exploration activities. A pre-post- project survey was set-up to assess the effects of the project on the environmental consciousness, knowledge and attitude changes towards ponds and the associated biodiversity of school students aged 15 to 18. The survey questions were based on Likert scales and their pre-post project comparisons used

an innovative multivariate hypothesis testing approach. The results showed that the project improved the students' knowledge and attitudes towards ponds and associated biodiversity, especially the amphibians. Ponds can be found or constructed in urban areas and despite small sized, they proved to be interesting model habitats and living laboratories to foster environmental education, by encompassing a high number of species and a fast ecological succession." **16252.** Stigge, H.A.; Bolek, M.G. (2016): Evaluating the biological and ecological factors influencing transmission of larval digenetic trematodes: A test of second intermediate host specificity of two North American *Halipegus* species. *Journal of Parasitology* 102(6): 613-621. (in English) ["Host specificity of parasites is a basic principle in parasitology; however, it is not easily measured. Previously, host specificity was calculated as the number of species that a parasite infected, but this is not an accurate description of host usage because some species are capable of being infected but do not contribute to the completion of the life cycle. Instead, measures of host specificity should take into consideration interactions between a parasite and a potential host species as well as interactions between current and subsequent hosts in the life cycle. The objectives of this study were to track the development of 2 trematode species, *Halipegus eccentricus* and *H. occidialis*, in 3 phylogenetically and ecologically distinct microcrustacean second intermediate hosts, and then, evaluate the extent to which each of these hosts contributed to transmission of each *Halipegus* species to the next odonate host in the life cycle. All 3 microcrustacean species exposed became infected with both species of *Halipegus*. The patterns of growth of *H. eccentricus* and *H. occidialis* were similar, but there were consistent differences

in the rates of growth among the microcrustacean species in both *Halipegus* species. Regardless of host species infected, all individuals of both species were considered to be developmentally infective to the next host in the life cycle by 19 days post exposure (DPE) when they lost their excretory bladder. Worms of varying sizes were capable of surviving without this structure suggesting that there is not a strong relationship between the rate of growth of the metacercariae and the development of their osmoregulatory system. Although *Halipegus* species were capable of living without an excretory bladder at 19 DPE, there were differences in their size and rates in which the 3 microcrustaceans contributed to transmission of the parasites to subsequent odonate hosts. Collectively, under controlled laboratory conditions, there was an approximately 2-fold difference in the average percent of worms that established in odonates from the ostracod, *Cypridopsis* sp., than from the harpacticoid copepod, *Phyllognathopus* sp., and the difference was nearly 3-fold between *Cypridopsis* sp. and the cyclopoid copepod, *Thermocyclops* sp. Therefore, despite all 3 microcrustacean species becoming infected, not all species were equally suited for transmission and completion of the life cycle. Differences among the 3 microcrustacean species in cercaria ingestion, metacercarial growth and development, and odonate predation rates on infected microcrustacean species were important factors in determining transmission of the 2 *Halipegus* species to odonate hosts." **16253.** Suarez-Tovar, C.M.; Sarmiento, C.E. (2016): Beyond the wing planform: Morphological differentiation between migratory and non-migratory dragonfly species. *Journal of Evolutionary Biology* 29(4): 690-703. (in English) ["Migration is a significant trait of the animal kingdom that can impose a strong selective pressure on several structures to overcome the amount of energy that the organism invests in this particular behaviour. Wing linear dimensions and planform have been a traditional focus in the study of flying migratory species; however, other traits could also influence aerodynamic performance. We studied the differences in several flight-related traits of migratory and non-migratory Libellulid species in a phylogenetic context to assess their response to migratory behaviour. Wings were compared by linear measurements, shape, surface corrugations, and microtrichia number. Thorax size and pilosity were also compared. Migratory species have larger and smoother wings, a larger anal lobe that is reached through an expansion of the discoidal region, and longer and denser thoracic pilosity. These differences might favour gliding as an energy-saving displacement strategy. Most of the changes were identified in the hind wings. No differences were observed for the thorax linear dimensions, wetted aspect ratio, some wing corrugations, or the wing microtrichiae number. Similar changes in the hind wing are present in clades where migration evolved. Our results emphasize that adaptations to migration through flight may extend to characteristics beyond the wing planform and that some wing characteristics in libellulids converge in response to migratory habits whereas other closely related

structures remain virtually unchanged. Additionally, we concluded that despite a close functional association and similar selective pressures on a structure, significant differences in the magnitude of the response may be present in its components." **16254.** Sueyoshi, M.; Ishiyama, N.; Nakamura, F. (2016):  $\beta$ -diversity decline of aquatic insects at the microhabitat scale associated with agricultural land use. *Landscape and Ecological Engineering* 12: 187-196. (in Japan) ["Several studies report the decline of  $\beta$  diversity caused by agricultural impacts in river ecosystems. However, the susceptible scale of  $\beta$  diversity to agricultural impacts and the indirect effects on  $\beta$  diversity within hierarchically nested ecosystems are unclear. We first tested the hypothesis that  $\beta$  diversity between microhabitats is significantly influenced by agricultural land use. We also examined the indirect effects of agricultural land use on  $\alpha$  and  $\beta$  diversities at the microhabitat scale. Twelve microhabitat samples (25 cm<sup>2</sup>) were collected at 27 reaches within Kitamihorobetsu River, Japan. All reaches were classified into three agricultural intensities based on pasture area (low, middle, and high), and their hierarchical diversities (microhabitat, reach, and catchment) were calculated using additive partitioning. Indirect effects were demonstrated by structural equation modelling using indirect and direct environmental gradients. The  $\alpha$  and  $\beta$  diversities at the microhabitat scale decreased significantly with agricultural intensity. Increasing pasture cover within catchments showed a negative correlation with habitat heterogeneity and water quality (habitat homogenization and water degradation) and a positive correlation with sand cover on streambeds (sedimentation of fine particles). The  $\alpha$  diversity decreased with sedimentation of fine particles, and the  $\beta$  diversity decreased with habitat homogenization and water degradation. Our findings suggest that species diversity of aquatic insects at the microhabitat scale would be susceptible to agricultural land use. Furthermore, we emphasize that the diversity index used to evaluate restoration projects should be carefully selected because influential abiotic factors were different between  $\alpha$  and  $\beta$  diversities." **16259.** Takahashi, H.; Concordel, A.; Paik, J.; Shimoyama, I. (2016): The effect of the phase angle between the forewing and hindwing on the aerodynamic performance of a dragonfly-type ornithopter. *Aerospace* 2016, 3(1), 4; doi: 10.3390/aerospace3010004 : 15 pp. (in English) ["Dragonflies achieve

agile maneuverability by flapping four wings independently. Different phase angles between the flapping forewing and hindwing have been observed during various flight modes. The aerodynamic performance depends on phase angle control, as exemplified by an artificial flying ornithopter. Here, we present a dragonfly-like ornithopter whose phase angle was designed to vary according to the phase lag between the slider-cranks of the forewing and hindwing. Two microelectromechanical systems (MEMS) differential pressure sensors were attached to the center of both forewing and hindwing to evaluate the aerodynamic performance during flapping motions when the phase angle was changed. By varying the phase angle in both the tethered condition and free-flight, the performance of the forewing remained approximately constant, whereas that of the hindwing exhibited obvious variations; the maximum average value was two-fold higher than the minimum. The experimental results suggest that simple phase angle changes enable a flying ornithopter to control flight force balance without complex changes in the wing kinematics." **16260.** Takahashi, Y.; Suyama, Y.; Matsuki, Y.; Funayama, R.; Nakayama, K.; Kawata, M. (2016): Lack of genetic variation prevents adaptation at the geographic range margin in a damselfly. *Molecular Ecology* 25(18): 4450-4460. (in English) ["What limits a species' distribution in the absence of physical barriers? Genetic load due to asymmetric gene flow and the absence of genetic variation due to lack of gene flow are hypothesized to constrain adaptation to novel environments in marginal populations, preventing range expansion. Here we examined the genetic structure and geographic variation in morphological traits in *I. asiatica* and *I. senegalensis* along a latitudinal gradient in Japan, which is the distribution center of *I. asiatica* and the northern limit of *I. senegalensis*. Genome-wide genetic analyses found a loss of genetic diversity at the edge of distribution in *I. senegalensis* but consistently high diversity in *I. asiatica*. Gene flow was asymmetric in a south-north direction in both species. Though body size and wing loading showed decreasing latitudinal clines (smaller in north) in *I. asiatica* in Japan, increasing latitudinal clines (larger in north) in these phenotypic markers were observed in *I. senegalensis*, particularly near the northern boundary, which coincided well with the location where genetic diversity began a sharp decline. In ectothermic animals, increasing latitudinal cline in these traits was suggested to be established when they failed to adapt to thermal gradient. Therefore, our findings support the possibility that a lack of genetic variation rather than gene flow swamping is responsible for the constraint of adaptation at the margin of geographic distribution." **16261.** Takaki, Y.; Kinoshita, M.; Hayashi, K. (2016): Influence of a past nature experience to life form cognition of the students who want to become preschool teachers. *Research Bulletin of Kyushu Junior College of Kinki University* 46: 15-30. (in Japanese, with English summary) ["About five life species,

influence of a past nature experience to the grade of life form cognition based on a unified evaluation standard were investigated in the students who want to become preschool teachers. Although the differences of degree existed, the life form cognition grade of chicken, dragonfly and crab were higher in the students who experienced capture or breeding of them in the past. On the other hand, the life form cognition grade of carp and tulip were low regardless of having a past nature experience or not. Moreover, the students who could not recognize life form definitely were seen by factors such as a contribution degree to breeding, lack of observation, various form of species, difficulty to make a picture and influence of various media. The experience to watch the real thing directly is useful, but it is necessary to observe it consciously in that experience. Because the life form cognition grade of students seems to lower year by year, it is required to improve the power of observation and interest to nature by a practical lecture." **16262.** Talukder, R.; Shivakumar, K.N. (2016): Measurement of vibrational stiffness and air damping of damselfly wings. *Journal of Biomaterials and Nanobiotechnology* 7: 127-141. (in English) ["A simple cantilever beam vibration test method made of biomorph and insect wing, were used to measure the vibrational stiffness and the air damping of insect wings. Vibration tests were performed in vacuum pressures to atmosphere and the wing stiffness and air damping factor were measured. The test method was found to be a viable method for measuring wing stiffness, natural frequencies and mode shapes. The vibrational deformation of the insect wings was found to be combination of bending and torsion because of unsymmetrical geometry of wing. The measured stiffness (K) of damselfly wings varied from 0.18 to 0.31 N/m and the air damping ratio ranged from 0.72 to 0.79. The undamped natural frequency (fn) at 13 kPa varied from 249 to 299 Hz and at atmosphere it varied from 168 to 198 Hz." (Authors)] Address: Talukder, R., Center for Composite Materials Research (CCMR), Dept of Mechanical Engineering, North Carolina A&T State Univ. (NC A&T SU), Greensboro, North Carolina, USA

**16263.** Tanaka, K. (2016): Functional biodiversity indicators and their evaluation methods in Japanese farmlands. *The Challenges of Agro-Environmental Research in Monsoon Asia*. Edited by Kazuyuki Yagi and C. George Kuo, National Institute for Agro-Environmental Sciences (NIAES), Tsukuba, Japan, Food and Fertilizer Technology Center (FFTC) for the Asian and Pacific Region, Taipei, Taiwan. NIAES Series 6: 160-169. (in English) ["To mitigate the detrimental environmental effects of modern agriculture, such as those from chemical fertilizers and pesticides, environmentally friendly farming systems have been developed and propagated. Such farming systems are expected to conserve both the wildlife inhabiting agroecosystems and overall biodiversity. However, actually little is known about the effect of environmentally friendly farming systems on biodiversity in agroecosystems. To address this issue, the research project "Selection of functional biodiversity indicators and development of assessment methods" was conducted in Japan across the 2008-2011 fiscal years. After the conclusion of this project in March

2012, a manual was published that describes indicator animals and explains the survey and evaluation methods used. This paper outlines the research project and describes some examples of the manual's contents." **16264.** Tarasov, G.S.; Khamitov, O.I.; Frolova, L.A. (2016): Characterization of littoral macro-zoobenthos communities of the Kuybyshev Reservoir in the area of Kazan. Proceedings of Kazan University (Natural Sciences Series) 158(1): 135-147. (in Russian, with English summary) ["Seasonal fluctuations in the species composition and quantitative indices of benthic communities in the littoral zone of the Kuybyshev Reservoir were investigated near the village of Staroe Arakchino in the summer–autumn season of 2014. On the whole, 40 taxa of macrozoobenthos were identified during the period of investigation. These taxa belong to the following groups of invertebrates: the phylum of Mollusca (the classes of Bivalvia and Gastropoda), the class of Insecta (the orders of Diptera, Ephemeroptera, Odonata), and the phylum of Annelida (the classes of Oligochaeta and Hirudinea). The highest species diversity was observed for insects and mollusks species. There was a reduction in the species diversity compared to the data of a similar research performed in 2010–2013. Zoobenthos samples were characterized by the absence of some orders of insects (Trichoptera, Coleoptera larvae and adults) and Maxillopoda. The abundance and biomass indices of macrozoobenthos in 2014 were lower than the same indices in 2010–2013. Two classes of mollusks (Gastropoda and Bivalvia) formed the dominant group in abundance and biomass. The significant influence on the quantitative indices was produced by *Viviparus viviparus* (L., 1758), as well as by such invasive species as *Dreissena polymorpha* (Pallas, 1771) and *Lithoglyphus naticoides* (Pfeiffer, 1828)." **16271.** Tomazelli, O.Jr.; Franco, G.M.S.; Munarini, A.; Casaca, J.M.; Niero, R.; Monache, F.D. & Magro, J.D. (2016): *Melia azedarach* L. fruit extract as a potential candidate in controlling the *Neuraeschna* Hagen, 1867 (Odonata: Aeshnidae), predominant predators for fish fingerlings. *Braz. J. Aquat. Sci. Technol.* 20(1): 54-60. (in English) ["Odonata larvae in fishponds prey on fish fingerlings and decrease the profits from production. With the goal of eliminating these larvae from fishponds, large quantities of pesticides are applied. These products are toxic to fish and have unpredictable effects on the food chain. The objective of this study is to evaluate the effect of the plant extract of fruits of *Melia azedarach* (CEE) and of methyl parathion (MP) adsorbed in silica in the control of *Neuraeschna* larvae. The LC50-18h for CEE was 0.57 mg L<sup>-1</sup>, and for MP the LC50-12h was 0.17 mg L<sup>-1</sup>. Two compounds with the highest concentration were isolated and identified from CEE, linoleic acid and melianone. The latter is a triterpene precursor of limonoids, compounds with insecticide properties. The substitution of synthetic pesticides for natural products is a path towards the sustainability of fish farming." (Authors)] Address: Dal Magro, J., Programa de Pós-graduação em Ciências Ambientais (PPGCA) da Univ. Comunitária da Região de Chapecó, Chapecó, SC, Brazil. E-mail: jaci@unochapeco.edu.br

**16272.** Torres-Cambas, Y.; Cabana-Otero, M.; Lorenzo-Carballa, M.O.; Cordero-Rivera, A (2016): Conservation status and protection of three Antillean endemic damselflies. *Journal of Insect Conservation* 20(2): 277-284. (in English) ["*Hypolestes* (Odonata, Zygoptera) is a damselfly genus endemic to the Greater Antilles. The genus comprises three species: *H. clara* from Jamaica, *H. trinitatis* from Cuba, and *H. hatuey* from Hispaniola, which are currently evaluated by the IUCN as Endangered (EN), Vulnerable (VU) and Data Deficient, respectively. Here, we re-assess the conservation status of these species based on their extent of occurrence, as estimated from ecological niche models. In addition, we analyse the coverage offered to each of the three species by the protected areas from Jamaica, Cuba, Dominican Republic and Haiti. Our results support the maintenance *H. trinitatis* in the category of VU, and suggest the re-classification of *H. hatuey* as Near Threatened. The estimated extent of occurrence for *H. clara* is 6422 km<sup>2</sup>, a value close to the threshold of 5000 km<sup>2</sup> between VU

and EN. Therefore, we recommend keeping *H. clara* as EN, until new evidence based on population size and trend could support a change from this category to VU. We found that 14 % of the extent of occurrence for *H. clara* and *H. hatuey*, and 33 % for *H. trinitatis*, are within protected areas. However, the ongoing extensive deforestation in Hispaniola, coupled with the lack of protection in Haiti, could cause a decrease of the extent of occurrence of *H. hatuey* in the future." (Authors)] Address: Torres-Cambas, Y., Depto Biol., Fac. Cien. Naturales y Exactas, Univ. de Oriente. Patricio Lumumba s/n, Santiago de Cuba, Cuba. E-mail: yusdiel.torres@gmail.com

**16273.** Tsurusaki, N.; Yin, Z.; Iwamoto, M. (2016): Adult emergence pattern of the golden frangetail *Sinictinogomphus clavatus* (Odonata: Anisoptera: Gomphidae) in the last year of its occurrence in Lake Koyama, Tottori City, Honshu, Japan. *Sanin Natural History Research* 13: 37-44. (in Japanese, with English summary) ["*S. clavatus* was one of the commonest dragonflies in Lake Koyama in Tottori City (Tottori Prefecture, Honshu, Japan) before the intentional induction of higher salinity (3.5–8.75 ppt) in March in 2012 by the local government. We surveyed pattern of adult emergence of the species by collecting exuviae of larvae every day during the adult emergence from June to early August in 2012 which became the last year of the occurrence of the species in the lake. The results obtained were as follows: 1) There was a tendency that females tend to emerge earlier than males (protogeny). 2) Females were larger than males and individuals molted earlier were larger than those emerged later in both males and females. No adult emergence from the lake has been observed since 2013 due to high salinity." **16277.** Ujszegi, J.; Gál, Z.; Mikó, Z.; Hettyey, A. (2016): No effect of a glyphosate-based herbicide on larval *Aeshna cyanea* and adult newts (*Lissotriton vulgaris*) in a laboratory-based experiment. *Acta Zoologica Academiae Scientiarum Hungaricae* 62(4): 355-367. (in English) ["Pesticides can exert negative effects on aquatic organisms at very low concentrations. While several prey taxa are frequently used as models in ecotoxicology studies, there is little information about the pesticide-sensitivity of predators. We examined the effects of a frequently applied glyphosate-based herbicide on two common aquatic predators: larval *A. cyanea* dragonflies and adult male *Lissotriton vulgaris* newts, which are top predators in ephemeral water bodies lacking fishes. We exposed predators to the herbicide for 18 days under laboratory conditions and measured potential effects on survival, activity, body mass and predatory activity. To maximize detectability of effects, we applied the herbicide at a concentration of 6.5 mg a. e. glyphosate/L, corresponding to the highest concentration expected in nature. Our results showed that the tested herbicide formulation did not have severe effects on any of the measured fitness-related traits. Results of the present study support the hypothesis that the tested species

are insensitive to the herbicide and are able to fulfil their important ecological role of top-down regulation even in highly contaminated habitats. However, potential long-term or indirect effects of the herbicide on the fitness of aquatic predators remain unknown." **16278.** Upton, L.; Price, B.; Percy, D.; Brooks, S. (2016): Applying novel digital visualization tools and traditional morphometrics to the analysis of wing size and asymmetry and to male wing spot size in *Calopteryx splendens* (Harris) (Banded Demoiselle). *Journal of the British Dragonfly Society* 32(1): 8-25. (in English) ["*C. splendens* has sexually dimorphic wing pigmentation: males have a wing spot which is lacking in females. We investigated the relationship between wing size, wing asymmetry and, in males, the size of the pigmented area, against latitude, longitude, mean winter and summer temperatures and the time of year the specimen was collected. A total of 270 specimens were analysed, using Pearson's product moment correlation, from museum collections in England and Scotland. Wing size was significantly positively correlated with latitude and mean winter temperature, in both males and females, and wing spot size was positively correlated with collection day in males. Increasing wing size with latitude follows Bergmann's Rule and increasing wing size with increasing mean winter temperature may reflect increased larval growth during warm winters. Increase in wing spot size through the summer probably does not reflect a temperature response, since increasing summer temperature might be expected to lead to smaller wing spots if these had a thermoregulatory function. It is more likely that enhanced pigmentation of the wing spots may lead to increased reproductive success, which becomes a premium as the summer advances." (Authors)] Address: Upton, Laura, University College London, Gower Street, London, WC1E 6BT, UK

**16279.** Verma, P.; Andrew, R. (2016): Structure of the female reproductive system of the dragonfly *Orthetrum sabina sabina* (Drury 1770) (Anisoptera: Libellulidae). *Journal of Entomology and Zoology Studies* 4(5): 457-462. (in English) ["The female reproductive system in *O. s. sabina* consists of a pair of ovaries and a post ovarian genital complex (POGC). The ovaries are long, thin panoistic type germinal tissues occupying the first to the sixth abdominal segment. The mature ovariole consist of the terminal filament, germarium, vitellarium and pedicel. The POGC is composed of the sperm storage organ and vagina. The sperm storage organ is formed of a small bursa copulatrix and a pair of spermathecae with long tubular duct. The vagina is a short laterally folded tube covered by thick muscle bands. On the mid-dorsal region, the POGC bears a highly complex sclerotized cuticular collar formed of three pairs of cuticular plates. The POGC is ectodermal in origin and is composed of outer muscle, middle epithelial and inner cuticular layer. These layers exhibit site specific modifications with respect to the functional significance of the components." (Authors)] Address: Verma, P., P. G. **16285.** Wandera, D.A.; Mukhwana, M.N. (2016): Effect of flower farm effluents on diversity and composition of macroinvertebrates in Marura wetland. *Agriculture, Forestry and Fisheries* 5(6): 207-214. (in English) ["Wetlands are important sites for biological conservation due to their rich biodiversity which possess high productivity. They also offer shelter to many organisms and offers services such as water purification and flood control. However, biodiversity in wetlands has been reduced due to human activities that cause pollution like, flower farm effluents which are discharged directly to wetlands or river systems. Four water quality parameters; DO, BOD, pH, TDS, TSS and macro-invertebrates composition were investigated at four different stations (S1, S2, S3, S4) adjacent to Equator Flower Farm along the Marura wetland. PAST program was used to calculate diversity indices and richness in the macroinvertebrates communities. Station S2 had the highest temperature (22.6°C), whereas S4 had the lowest temperature (19.6°C). The pH value did not vary along the stations (8.3-6.3). The DO level fluctuated along the river, station S1 had highest level of 3.6 mg/l and lowest station S3 had 0.8mg/l. TSS and TDS did not show significant variations, while BOD levels varied with different stations. The highest value of TN was recorded at Station 3 (0.33±0.045mg/l-1). There was no significant difference ( $p=0.055$ ) in three stations (S1, S2, S4) except S3. In total 10 orders, 30 genera and 30 families of macroinvertebrates were identified. The orders; Odonata, Coleoptera, Hemiptera and Diptera were the main macroinvertebrates found in all station, while the members of orders; Ephemeroptera, Trichoptera, Oligochaeta Mollusca, Gnathobellidae and Isopoda were few in all sampling stations. Station S2 and S4 had the highest species diversity compared to station S1 and S3 which had the lowest diversity. DO, BOD and temperature were found to have a significant effect on abundance and composition of benthic organisms with S3 having less abundance due to its

proximity to the flower farm." (Authors)] Address: Wandera, D.A., Dept of Fisheries and Aquatic Science, University of Eldoret, Eldoret, Kenya. E-mail: dawandera@gmail.com

**16286.** Wasscher, M.T.; Verspui, K.; Cammaerts, R. (2016): An *Aeshna affinis* watercolour by Pierre Léonard Vander Linden (1797-1831) found in the Selys collection. *Notulae odonologica* 8(7): 240-245. (in English) ["A yet unknown watercolour by Pierre Léonard Vander Linden showing a male of *Aeshna affinis* was found in the collection of Edmond de Selys Longchamps in the Royal Belgian Institute for Natural Sciences (RBINS) in Brussels. The circumstances of discovery and a biographical sketch of the artist are provided and the biographical chronology of the drawing is established." **16287.** Westermann, E. (2016): Vorkommen und Schutz der Kleinen Moosjungfer (*Leucorrhinia dubia*) im Oberen Hotzenwald (Hochschwarzwald). *Naturschutz südl. Oberrhein* 8: 187-191. (in German, with English summary) ["From 2011 to 2015 populations of dragonflies in the moors of the upper Hotzenwald were recorded. *L. dubia* was recorded in the 1980ies in former peat-digging areas in five moors in this area, which, however, have been largely silted since then. A re-population has occurred since 2012 in artificial moor ponds, which evolved during restitution measurements when wide ditches were blocked. In the first moor the numbers of freshly emerged imagoes increased annually up to at least 700 individuals in 2015. In the second moor the numbers have remained low so far. During several months of draught and heat from July 2015 onwards the water level of the pond with the highest population by far decreased to small remainders, whereas the other water bodies had sufficient water during the whole development period. For the protection of the locally important population the water level needs to be stabilized by further improvement of the water blockings." (Author)] Address: Westermann, Elisabeth, Buchenweg 2, 79365 Rheinhausen., Germany

**16288.** Westermann, K. (2016): Zur Phänologie der Emergenz der Kleinen Moosjungfer (*Leucorrhinia dubia*) im Hochschwarzwald. *Naturschutz südl. Oberrhein* 8: 192-195. (in German, with English summary) ["In two bogs in the Southern Black Forest, in 2014 and 2015 *L. dubia* emerged from mid-May, reaching the highest abundance of emergence during the first ten days of June. Half of each annual population had hatched only after two to three weeks, and in two accurately investigated cases, after 16 and 18 days. In spatially adjacent bog ponds, imagoes emerged in both years on average at statistically significantly different times, which was probably dependent on the daily exposure of the water to sunshine. During the first ten days of July 2015, a pronounced second peak of emergence was observed in one bog. The obtained data about the phenology of emergence differ to existing literature data for the Black Forest. The differences can be explained sufficiently with different altitudes and different degrees of exposure to sunshine of each investigated water body." (Author).] Address: Westermann, K., Buchenweg 2, D-79365 Rheinhausen., Germany

**16289.** Westermann, K. (2016): Die Libellen des Naturschutzgebiets „Hinterzarter Moor“ – Moorlibellen als Indikatoren des Moorzustands. *Naturschutz südl. Oberrhein* 8: 139-165. (in German, with English summary) ["80 hectares of the "Hinterzarter Moor" are declared as a nature reserve. It consists of a natural transition and peat-bog called „Westmoor“, a partially drained peat-bog called „Ostmoor“, and spruce forests and meadows. In the „Westmoor“ some large bog pools as well as many small water bodies can be found. Between the end of May and beginning of September 2015 exuviae were collected over twelve days at the margins of the water bodies. Due to a pronounced emergence peak of *Aeshna subarctica* four controls were made at the first half of July. All bog dragonflies which can be regularly found in the Black Forest have reproductive populations in the "Westmoor". A very large population of *Aeshna subarctica* and fairly big populations of *Aeshna juncea*, *Somatochlora arctica*, *Leucorrhinia dubia* and *Coenagrion hastulatum* were found. A small but probably stable population of *S. alpestris* at its lower altitudinal distribution limit in the Black Forest was found. remarkably, a small population of *Lestes dryas* was found in a marginal sedge reed, which had been recorded for the first time approximately 40 years ago. A few decades ago marked population decreases of *A. subarctica* and other species were reported from the „Westmoor“, which were related to severe eutrophication and a rapid infilling caused by a nutritional load from a rubbish dump and rivulets. Although the populations of the dragonflies changed dynamically at that time, the present investigation was the first since this occurrence. The result was surprisingly high populations of the representative species, which could only be explained by a partial regeneration of the "Westmoor". *A. subarctica* stood out, which has obviously recently developed a new nucleus of the metapopulation of the area Hinterzarten/ Feldberg. In the future investigations should be carried out at regular intervals of approximately five years and the regeneration should be supported by diverse measurements. In the „Ostmoor“, natural moor water bodies have not existed for quite some time. At present only a few species with a small number of individuals exist in almost completely silted former drainage ditches and peat-digging areas. restitution measurements by the NABU Baden-Württemberg will however lead to a significant increase of the water level in the moor and create new habitats for bog dragonflies." (Author)] Address: Westermann, K., Buchenweg 2, D-79365 Rheinhausen., Germany

**16290.** Wildermuth, H. (2016): Auswirkung der Hochmoorregeneration auf die Libellenfauna (Odonata) des Torfrieds Pfäffikon (ZH). *Entomo Helvetica* 9: 41-51. (in German, with English and French summaries) ["Impact of raised bog restoration on the dragonfly fauna of an exploited peat bog in the Swiss Midlands. - The remains of a highly exploited and overgrown peat bog near Pfäffikon (ZH) (Switzerland) were restored in a step-by-step process between 2003 and 2015 by the impoundment of drainage ditches and the partial clearing of woodland. The removal of trees allowed for more sunlight at a number of former peat-ditches thus rendering them more suitable for dragonfly reproduction. Subsequent monitoring from 2010 to 2015 revealed that 16 species of indigenous

Odonata colonized up to ten bodies of water a year. Most of these species were recorded before bog restoration but only in small numbers and restricted to the four peat-ditches that had been left partially cleared. These species dispersed over the cleared area and some populations strengthened significantly. *Leucorrhinia pectoralis*, critically endangered and currently confined to peat-ditches in Switzerland, was of special interest. This libellulid reacted to the implemented measures by establishing a strong and stable population. In order to improve the breeding conditions of odonates, floating mats of vegetation were recently removed from five partially or completely overgrown peat-ditches. For sustainable conservation and promotion of the local dragonfly fauna, reeds are mowed annually and water bodies are managed using a rotational strategy." (2016): Perch selection by three cooccurring species of *Celithemis* (Odonata: Libellulidae): Testing for a competitive hierarchy among similar species. *Psyche*, Volume 2016, Article ID 9028105, <http://dx.doi.org/10.1155/2016/9028105>: 8 pp. (in English) ["In many communities of perching dragonflies (Odonata: Libellulidae), a size-dependent competitive hierarchy creates a positive relationship between male body size and perch height. We tested for this pattern among three similar-sized species: *Celithemis elisa*, *C. fasciata*, and *C. ornata*. Males were caught and photographed from May to July 2015 at Ashmore Heritage Preserve, Greenville County, SC, USA, and perch heights and perch distance to open water were measured. Five indices of body size were measured with ImageJ software: abdomen length, forewing length, hindwing length, area of forewing, and area of hindwing. *C. fasciata* was significantly larger than the other two species for all five anatomical characters and used perches that were significantly taller and closer to open water than the other species, though these differences changed over the summer. Aggressive interactions between and within species were tallied and compared to expected distributions based on mean relative abundances derived from hourly abundance counts. Patterns of interspecific aggression were also consistent with a size-dependent hierarchy: the large *C. fasciata* was attacked less frequently, and the small *C. ornata* more frequently, than predicted by their relative abundances. We conclude that even small differences in body size may contribute to niche partitioning in perch selection." **16299.** Yong, H.-S.; Song, S.-L.; Suana, I.W.; Eamsobhana, P.; Lim, P.-M. (2016): Complete mitochondrial genome of *Orthetrum* dragonflies and molecular phylogeny of Odonata. *Biochemical Systematics and Ecology* 69: 124-131. (in English) ["Complete mitogenome of *Orthetrum* dragonflies are determined by next generation sequencing. •Molecular phylogeny based on 13 PCGs is concordant with 15 mitochondrial genes (13 PCGs and 2 rRNA genes). •The Libellulidae (Anisoptera) is monophyletic with two lineages: (*Orthetrum*) + (*Brachythemis* + *Hydrobasileus*). •The Zygoptera is monophyletic with three lineages. •The enigmatic *Epiophlebia superstes* (*Epiophlebiidae*) forms a sister group with Zygoptera. Abstract: Dragonflies of the genus *Orthetrum* are members of the anisopteran family Libellulidae. To date,

there are no reports on the phylogeny of *Orthetrum* dragonflies based on the complete mitochondrial genome (mitogenome). There is only a single entry of a nearly complete mitogenome for *O. melania*. We report here the complete mitogenome of *O. chrysis*, *O. glaucum*, *O. sabina* and *O. testaceum* and their phylogenetic relationships with other taxa of Libellulidae as well as *Epiophlebiidae*, Anisoptera and Zygoptera. The whole mitogenomes of these four species possessed 37 genes (13 protein-coding genes – PCGs, 2 rRNA and 22 tRNA genes) and a non-coding region. Molecular phylogeny based on 13 PCGs was concordant with 15 mitochondrial genes (13 PCGs and 2 rRNA genes). The Libellulidae (Anisoptera) was monophyletic with two lineages: (*Orthetrum*) + (*Brachythemis* + *Hydrobasileus*). It formed a sister group with *Corduliidae*. The Zygoptera was monophyletic with three lineages: (*Calopterygidae*) + (*Euphaeidae* + *Pseudolestidae*) + (*Coenagrionidae* + *Platynemididae*). The enigmatic *Epiophlebia superstes* (*Epiophlebiidae*) forms a sister group with Zygoptera. The complete mitogenome is useful for determining the higher-level phylogenetic relationships of Odonata." **16302.** Zardo, E.L.; Behr, E.R. (2016): Trophic ecology of Loricariichthys melanocheilus Reis & Pereira, 2000 (Siluriformes: Loricariidae) in Ibicuí river, southern Brazil. *Maringá* 38(1): 67-76. (in English, with Portuguese summary) ["Aiming to characterize aspects of the trophic ecology of Loricariichthys melanocheilus in the Ibicuí River, bimonthly samples were taken in lotic and lentic ecosystems. Fish were caught and fixed in 10% formalin and dissected for stomach content analysis. Items were identified to the lowest taxonomic level possible. Stomach fullness (SF), repletion index (RI) and intestinal quotient (IQ) were estimated. Diet was assessed by the frequency of occurrence and the volumetric method, combined to obtain an Alimentary index. Feeding activity was analyzed with mean values of SF, RI and vacuity index (VI), which represents the percentage of empty stomachs. These parameters were compared seasonally, spatially, and according to the circadian rhythm. The main items in the trophic spectrum of *L. melanocheilus* were detritus, sediment, plant organic matter, nematodes, micro crustaceans (Copepoda, Cladocera) and insects (Diptera, Trichoptera, Ephemeroptera and Odonata). No environmental or seasonal variations were found for the consumed items. Feeding activity showed seasonal and environmental variations according to RI but did not significantly change according to SF. The IQ was 1.51, and showed seasonal variations, indicating changes in the diet." (Authors)] Address: Zardo, E.L., Faculdade de Agronomia, Universidade Federal do Rio Grande do Sul, Av. **16303.** Zhao, Y.; Wang, D.; Tong, J.; Sun, J. (2016): Nanomechanical behaviour of the membranous wings of dragonfly *Pantala flavescens* Fabricius. *Journal of Bionic Engineering* 13(3): 388-396. (in English) ["The dragonfly has excellent flying capacity and its wings are typical 2-dimensional composite materials in micro-scale or nano-scale. The nanomechanical behavior of dragonfly membranous wings was investigated with a nanoindenter. It was shown that the maxima of the reduced modulus and nanohardness of the in-vivo and fresh dragonfly wings are about at position of 0.7L, where L is the wing length. It was found that the reduced modulus and nanohardness of radius of the wings of dragonfly are large. The reduced modulus and nanohardness of Costa, Radius and Postal veins of the in-vivo dragonfly wings are larger than those of the fresh ones. The deformation, stress and strain under the uniform load were analyzed with finite element simulation software ANSYS. The deformation is little and the distribution trend of the strain is probably in agreement with that of the stress. It is shown that the main veins have better stabilities and load-bearing capacities. The understanding of dragonfly wings'

nanomechanical properties would provide some references for improving some properties of 2-dimensional composite materials through the biomimetic designs. The realization of nanomechanical properties of dragonfly wings will provide inspirations for designing some new structures and materials of mechanical parts." (Authors)] Address: Zhao, Y., College of Mechanical and Power Engineering, Henan Polytechnic Univ., Jiaozuo 454000, China. E-mail: yanruzhao@163.com

**16304.** Zheng, D.; Wang, B.; Chang, S.-C. (2016): *Palaeodisparoneura cretacica* sp. nov., a new damselfly (Odonata: Zygoptera: Platycnemididae) from mid-Cretaceous Burmese amber. *Comptes Rendus Palevol* 16(3): 235-240. (in English, with French summary) ["Abundant odonatans have been discovered from mid-Cretaceous Burmese amber, and Burma has played an important role in early damselfly diversification during the mid-Cretaceous. In this paper, a new damselfly, *Palaeodisparoneura cretacica* sp. nov., is described from Burmese amber. It is the second species of the extinct genus *Palaeodisparoneura* Poinar, Bechly et Buckley, 2010. *P. cretacica* sp. nov. differs from *P. burmanica* Poinar, Bechly et Buckley, 2010 in having more postnodal and postsubnodal crossveins, the base of IR1 being more cells distal of the base of RP2, a hyaline pterostigma and a longer RP3/4. Our find increases the diversity of damselflies during the mid-Cretaceous." (Authors)] Address: Zheng, D., State Key Lab. **16305.** Zheng, D.; Zhang, Q.; Nel, A.; Jarzembowski, E.A.; Zhou, Z.; Chang, S.-C.; Wang, B. (2016): New damselflies (Odonata: Zygoptera: Hemiphlebiidae, Dysagrionidae) from mid-Cretaceous Burmese amber. *Alcheringa* 41(1): 12-21. (in English) ["Two damselflies, *Burmahemiphlebia zhangi* gen. et sp. nov. and *Palaeodysagrion cretacicus* gen. et sp. nov., are described from the mid-Cretaceous Burmese amber. *Burmahemiphlebia zhangi* is the first record of Hemiphlebiidae from this amber, although the family was cosmopolitan during the Mesozoic. It can be readily distinguished from all other members of Hemiphlebiidae in having very short MP and CuA veins, and in its rectangular discoidal cell. The new fossils support the view that hemiphlebiid damselflies were one of the dominant groups of Zygoptera during the Mesozoic. *Palaeodysagrion cretacicus* is the first dysagrionid damselfly from Burmese amber and the second Mesozoic representative of this predominantly Paleogene group. It differs from other members of Dysagrionidae in having a unique elongate discoidal cell. These new finds increase the diversity of damselflies in mid-Cretaceous Burmese amber." (Authors)] Address: Nel, A., Lab. Ent. Mus. Natn. Hist. Nat., 45 rue Buffon, F-75005 Paris, France. E-mail: anel@cimrs1.mnhn.fr

**16306.** Zheng, D.; Wang, H.; Jarzembowski, E.A.; Wang, B.; Chang, S.C.; Zhang, H. (2016): New data on Early Cretaceous odonatans (Stenophlebiidae, Aeschniidae) from northern China. *Cretaceous Research* 67: 59-65. (in English) ["*Liaostenophlebia yixianensis* gen. et sp. nov., a new stenophlebiid damselfly, is described from the Lower Cretaceous Yixian

Formation of western Liaoning, northern China. It is the third Chinese damselfly belonging to the family Stenophlebiidae to be described. *Liaostenophlebia* gen. nov. differs from the other genera of Stenophlebiidae in having Ax2 shifted just above MAb, a transverse and narrow Hal, a more curved anterior side of the hypertriangle, and a broader cubital-anal area. *Sinostenophlebia zhanjiakouensis* Hong, 1984 was previously attributed to Stenophlebiidae and hardly compares with other genera within this family. A check of the plates of the type species (*Sinostenophlebia zhanjiakouensis* Hong, 1984) suggests that *Sinostenophlebia* Hong, 1984 should be a member of the family Aeschnidiidae and it is very likely that this genus is a junior synonym of *Leptaeschnidium* Pritykina, 1977. The new data increases the diversity of both Stenophlebiidae and Aeschnidiidae in the Lower Cretaceous of China." (Authors)] Address: Zheng, D., State Key Laboratory of Palaeobiology & Stratigraphy, Nanjing Institute of Geology & Palaeontology, Chinese Academy of Sciences, 39 East Beijing Road, Nanjing 210008, China. **16307.** Zheng, D.; Wang, B.; Jarzembowski, E.A.; Chang, S.-C.; Nel, A. (2016): The first fossil Perilestidae (Odonata: Zygoptera) from mid-Cretaceous Burmese amber. *Cretaceous Research* 65: 199-205. (in English) ["Palaeoperilestes electronicus gen. et sp. nov. is the first perilestid damselfly described from mid-Cretaceous Burmese amber. This new damselfly can be attributed to the family Perilestidae by the mid-fork being distal of the subnodus and the base of IR2 quite near to the base of RP2, both features found in the extant genera *Perilestes* and *Perissolestes*. *Palaeoperilestes electronicus* gen. et sp. nov. has a strongly zigzagged IR1, however, differing from *Perilestes* and *Perissolestes* which have a straight IR1. The discovery not only adds to the diversity of damselflies in Burmese amber, but also puts the origin of Perilestidae back to at least the mid-Cretaceous." (Authors)] Address: Zheng, D., Dept of Earth Sciences, University of Hong Kong, Hong Kong Special Administrative Region, China. E-mail: dranzheng@gmail.com

**16308.** Zhao, Q.; Pan, Y.; Griffin, J.N.; Sun, J.; Sun, S. (2016): Contrasting trophic-cascade effects driven by variation in morphology of the perches used by a larval damselfly. *Freshwater Biology* 61(5): 693-701. (in English) ["(1.) The presence of habitat structures (e.g. caves, ledges, branches) has well-documented ecological effects. However, it remains largely unknown how variation in the morphology of particular habitat structures affects ecological interactions. (2.) Using an algae-cladoceran grazer-larval damselfly food chain as a model in a series of microcosm experiments, we manipulated food-chain length and the length (long versus short) and diameter (thick versus thin) of vertically orientated damselfly perches (habitat structure) and examined the density of the grazers and algae. Because the larval damselflies are usually more flexible on thinner perches and have broader foraging domains on longer perches, we predicted that when on long and thin perches they would suppress grazer density more efficiently and hence confer a more positive trophic-cascade effect on algal growth. (3.) As predicted, larval damselflies occupying long and thin perches most strongly reduced grazer

density and increased algal density, illustrating a positive trophic cascade. In all other damselfly treatments, and despite reduced grazer density, algal density declined, showing a negative trophic cascade due to an elevation in grazer foraging efficiency under predation risk. This probably resulted from the increased activity of the grazers and their spatial shift to the lower water column where algal density was higher. (4.) In conclusion, perch morphology affected the direction and strength of the trophic cascade by altering both density-mediated and behaviour-mediated indirect interactions. Considering that anthropogenic disturbance is dramatically changing the morphological diversity of habitat structures, we call for more research into the ecological consequences of such physical diversity at community and ecosystem." **16311.** Zou, Y.; van Telgen, M.D.; Chen, J.; Xiao, H.; de Kraker, J.; Bianchi, F.J.; van der Werf, W. (2016): Modification and Application of a Leaf Blowvac for Field Sampling of Arthropods. *Journal of Visualized Experiments* 114, e54655, doi:10.3791/54655 (2016): 5 pp. (in English) ["Rice fields host a large diversity of arthropods, but investigating their pop-

ulation dynamics and interactions is challenging. Here we describe the modification and application of a leaf blower-vac for suction sampling of arthropod populations in rice. When used in combination with an enclosure, application of this sampling device provides absolute estimates of the populations of arthropods as numbers per standardized sampling area. The sampling efficiency depends critically on the sampling duration. In a mature rice crop, a two-minute sampling in an enclosure of 0.13 m<sup>2</sup> yields more than 90% of the arthropod population. The device also allows sampling of arthropods dwelling on the water surface or the soil in rice paddies, but it is not suitable for sampling fast flying insects, such as predatory Odonata or larger hymenopterous parasitoids. The modified blower-vac is simple to construct, and cheaper and easier to handle than traditional suction sampling devices, such as D-vac. The low cost makes the modified blower-vac also accessible to researchers in developing countries." **16312.** Abdul, N.H.; Rawi Che, S. Md.; Ahmad, A.H.; Al-Shami, S.A. (2017): Effect of environmental disturbances on Odonata assemblages along a tropical polluted river. *Ekológia (Bratislava)* 36(4): 388-402. (in English) ["Odonata larvae have been intensively used as bioindicators for freshwater pollution as their community structure closely follow changes in the environment and habitat settings. In this study, 28 taxa of Odonata larvae were collected from three stations (upper, middle and lower) of a polluted river in Malaysia. The upper river basin receives effluents from an oil palm plantation. However, the middle station is presumably contaminated with anthropogenic wastes. The lower station is found to receive polluted discharges from aquaculture outlet. Several environmental parameters of water and sediment were continuously measured during the study. The water parameters showed no significant differences amongst the three stations. The species richness of Odonata was 22, 24 and 20 in the upper, middle and lower stations, respectively. The abundance of Odonata was significantly different among the studied sites. The tolerant damselfly, *Pseudagrion* sp. (41.22%), and facultative dragonflies, *Onychothemis* sp. (17.12%), were the most dominant taxa along the river stations. *Onychothemis* sp. and *Paragomphus capricornis* were equally important at the upper station [Important Species Index (ISI) 25.3 and 24.2%, respectively]. *Pseudagrion* sp. only scored an ISI value of 9.7%. *Pseudagrion* sp., *P. capricornis* and *Onychothemis* sp. were dominant in the middle station (ISI: 41.2%, 25.9% and 10.9% respectively), and *Pseudagrion* sp., *Onychothemis* sp. and *Prodasineura* sp. dominated the areas with dense growth of submerged aquatic weeds *Hydrilla* sp. in the lower station (ISI: 47.9, 24.5 and 13.8%, respectively). On the basis of the variations in larval abundance and ISI values, microhabitats differences partly in response to different types of pollutions entering the water structured the Odonata communities in this river basin." **16314.** Adham, F.K.; Gabre, R.M.; Ibrahim, I.A. (2017): Effect of some chemical parameters on the abundance degrees of some aquatic insects and invertebrates in El-Zomor and El-Mariotyia canals, Giza (Egypt). *Journal of Basic and Environmental Sciences* 4: 290-297. (in English) ["The effect of some chemical changes in water quality were studied during two years (October 2001 - August 2003) and recorded at six sampling sites situated at El-Zomor and El-Mariotyia canals (branches from the River Nile). The aim of the present work is to study the effect of some chemical parameters on the abundance degrees of some aquatic insects and invertebrates in these two canals. Determination and estimation of the chemical parameters and abundance degrees are carried out in the field and laboratory of Dept of Entomology, Faculty of Science, Cairo University. Data of chemical factors and abundance degrees of collected aquatic invertebrates were analyzed by using one-way analysis of variance (ANOVA). The data obtained showed that, there is a strong correlation coefficients ( $P < 0.05$  &  $r = 0.634$ ) and ( $P < 0.10$  &  $r = 0.506$ ) between electrical conductivity values and insects (Diptera and Odonata) that distributed in these two canals. The semi-logarithmic graphs showed that the water quality of samples is changed to some extent where the chloride ions is higher than bicarbonate and; sulphate, magnesium are higher than calcium and sodium during some reported months especially at El-Zomor canal." **16319.** Ahn, S.J.; Chiluwal, K.; Choi, S.H.; Park, C.G. (2017): Diversity of insect fauna in Junam wetland of Korea. *Korean J. Appl. Entomol.* 56(2): 135-145. (in English, with Korean

summary) ["A sampling survey was conducted at three reservoirs of Junam wetland (6.02 km<sup>2</sup>) in Korea to identify the wetland insect fauna along with their dominance, diversity, richness and evenness. Methods of monitoring were visual inspection and sweeping in 2010, Malaise trapping in 2011, light trapping and pitfall trapping in 2012. In total, 9,269 individuals (36.3% coleopterans, 21.3% lepidopterans and 13.9% odonates) were collected, belonging to 574 species, 141 families and 14 orders. For the number of species, lepidopterans shared the highest (31.2%), followed by coleopterans (28.0%) and hemipterans (12.9%). Dominant species were *Enochrus simulans* (Coleoptera) (7.9% of total individuals) followed by *Hydaticus grammicus* (Coleoptera) (4.3%), *Galerucella nipponensis* (Coleoptera) (4.1%), *Elophila interruptalis* (Lepidoptera) (3.1%) and *Apis mellifera* (Hymenoptera) (2.2%). Total counts of coleopterans, lepidopterans and odonates in the three reservoirs were quite high, but the counts were not significantly different among the reservoirs. Insect diversity index (H') and richness index (RI) of the Junam wetland were 5.04 and 59.10, respectively." **16321.** Alvia, I.; Veliz, D.; Esquivel, C.; Vila, I. (2017): Lack of genetic structure in *Pantala flavescens* among Central and South American localities (Odonata: Libellulidae). *Odonatologica* 46(1/2): 67-82. (in English) ["*P. flavescens* is the most widespread odonate on Earth, absent only in Antarctica and parts of Europe. A recent study performed with sequences of mtDNA suggested the presence of one panmictic population of the species at a global scale. However, combining mitochondrial and nuclear markers could offer more information about the genetic variability of populations. Here, we sequenced a fragment of the COI gene and genotyped eight microsatellite loci in order to analyze the population genetic structure and diversity in individuals collected in Central America (two sites in Costa Rica, separated by 147 km) and two localities in South America (one site in Chile and one in Peru, separated by 52 km). The global FST estimated from COI and microsatellite data showed no evidence of genetic structure. Furthermore, an Analysis of Molecular Variance (AMOVA) performed with both COI and microsatellites also showed no evidence of genetic structure despite the >5 000 km of distance between both geographic regions. These results suggest an extraordinary movement of *P. flavescens* along the American continent, thus corroborating the previous study conducted on this species." (Authors)] Address: Alvia, Ingrid,

**16332.** Batty, P. (2017): Odonata monitoring for the Scottish Beaver Trial 2009-2014 with notes on the post-trial period. *J. Br. Dragonfly Society* 33(2): 79-103. (in English) ["The British Dragonfly Society surveyed *Brachytron pratense* and *Calopteryx virgo* for Scottish Natural Heritage (SNH) as part of the monitoring for the Scottish Beaver Trial 2009-2014. The beavers drastically reduced the aquatic Vegetation in some lochs and constructed dams, increasing the size of one loch four-fold. At the end of the survey *B. pratense* was still breeding at the affected lochs. The study period was too short to evaluate the full effects on this species. Although there was a decline in the numbers of larvae and exuviae at one of the lochs where there was high beaver activity there were no obvious trends at the other three. Since the trial, beavers have moved into new lochs and built dams on one burn. In 2016 *B. pratense* was seen at all lochs and larvae found at the main lochs sampled. The Scottish Government's decision is to allow beavers to remain in Scotland and spread naturally. Results from the survey of *C. virgo* have not been included as the beavers did not use the burns during the survey period. However, these data will be important for future monitoring." **16333.** Benchalel, W.; Merah, S.; Bouslama, Z.; Ramdani, M.; Elmsellem, H.; Flower, R. (2017): Odonata as indicators of environmental impacts in rivers, case of wadi El-Kébir-East (northeastern Algeria). *Moroccan Journal of Chemistry* 5(4): 610-621. (in English) ["This paper presents results of two monitoring programs carried out in two decades during April 1993-May 1994, and April 2015 May 2016 in the East Wadi of El-Kébir, a protected area (PNEK) of eastern Numidia (northeastern Algeria). Monitoring was located in areas with different degrees of anthropogenic impacts. Selected environmental variables were recorded during the monitoring periods. The Odonata fauna and biological indices were used

to characterize development of the study area, after two decades and to assess the quality of the environment. The alteration of this river has resulted in a marked simplification of the original (1993-1994) odonatological fauna. Over the past two decades, odonatological species richness has decreased from 14 to 7 species inventoried during the 1993 and 2015 seasons. The phenology of adult was extended until early December 2015, possibly as a result of global warming. Odonata are identified as useful as indicators of environmental change in the monitored river systems. The majority of species such as the Gomphidae are not tolerant of increased contamination and changes in structure of the river. Only some species such as *Lestes vidis*, *Platycnemis subdilatata*, *Ischnura graellsii* and *Ceriatrigonia tenellum*, appear to be adapted to changed conditions and became dominant in heavily disturbed sites. The species disappeared from these sites are clearly associated with good water quality and less disturbance, which highlights the importance of the conservation of the habitats of freshwater and regular monitoring." **16336.** Blanke, A.; Schmitz, H.; Patera, A.; Dutel, H.; Fagan, M.J. (2017): Form–function relationships in dragonfly mandibles under an evolutionary perspective. *Journal of the Royal Society Interface* 14(128): 11 pp. (in English) ["Functional requirements may constrain phenotypic diversification or foster it. For insect mouthparts, the quantification of the relationship between shape and function in an evolutionary framework remained largely unexplored. Here, the question of a functional influence on phenotypic diversification for dragonfly mandibles is assessed with a large-scale biomechanical analysis

covering nearly all anisopteran families, using finite element analysis in combination with geometric morphometrics. A constraining effect of phylogeny could be found for shape, the mandibular mechanical advantage (MA), and certain mechanical joint parameters, while stresses and strains, the majority of joint parameters and size are influenced by shared ancestry. Furthermore, joint mechanics are correlated with neither strain nor mandibular MA and size effects have virtually play no role for shape or mechanical variation. The presence of mandibular strengthening ridges shows no phylogenetic signal except for one ridge peculiar to Libelluloidea, and ridge presence is also not correlated with each other. The results suggest that functional traits are more variable at this taxonomic level and that they are not influenced by shared ancestry. At the same time, the results contradict the widespread idea that mandibular morphology mainly reflects functional demands at least at this taxonomic level. The varying functional factors rather lead to the same mandibular performance as expressed by the MA, which suggests a many-to-one mapping of the investigated parameters onto the same narrow mandibular performance space." **16337.** Blanke, A.; Watson, P.J.; Holbrey, R.; Fagan, M.J. (2017): Computational biomechanics changes our view on insect head evolution. *Proceedings of the Royal Society B* 284(1848): 9 pp. (in English) ["Despite large-scale molecular attempts, the relationships of the basal winged insect lineages dragonflies, mayflies and neopterans, are still unresolved. Other data sources, such as morphology, suffer from unclear functional dependencies of the structures considered, which might mislead phylogenetic inference. Here, we assess this problem by combining for the first time biomechanics with phylogenetics using two advanced engineering techniques, multibody dynamics analysis and finite-element analysis, to objectively identify functional linkages in insect head structures which have been used traditionally to argue basal winged insect relationships. With a biomechanical model of unprecedented detail, we are able to investigate the mechanics of morphological characters under biologically realistic load, i.e. biting. We show that a range of head characters, mainly ridges, endoskeletal elements and joints, are indeed mechanically linked to each other. An analysis of character state correlation in a morphological data matrix focused on head characters shows highly significant correlation of these mechanically linked structures. Phylogenetic tree reconstruction under different data exclusion schemes based on the correlation analysis unambiguously supports a sistergroup relationship of dragonflies and mayflies. The combination of biomechanics and phylogenetics as it is proposed here could be a promising approach to assess functional dependencies in many organisms to increase our understanding of phenotypic evolution." **16338.** Bode-Oke, A.; Zeyghami, S.; Dong, H. (2017): Abstract: L8.00007: How insects initiate flight: Computational analysis of a damselfly in takeoff flight. *Bulletin of the American Physical Society, 70th Annual Meeting of the APS Division*

of Fluid Dynamics. Sunday–Tuesday, November 19–21, 2017; Denver, Colorado: (in English) [Verbatim: Flight initiation is essential for survival in biological fliers and can be classified into jumping and non-jumping takeoffs. During jumping takeoffs, the legs generate most of the initial impulse. Whereas the wings generate most of the forces in non-jumping takeoffs, which are usually voluntary, slow, and stable. It is of interest to understand how non-jumping takeoffs occur and what strategies insects use to generate the required forces. Using a high fidelity computational fluid dynamics simulation, we identify the flow features and compute the wing aerodynamic forces to elucidate how flight forces are generated by a damselfly performing a non-jumping takeoff. Our results show that a damselfly generates about three times its bodyweight during the first half-stroke for liftoff while flapping through a steeply inclined stroke plane and slicing the air at high angles of attack. Consequently, a Leading Edge Vortex (LEV) is formed during both the downstroke and upstroke on all the four wings. The formation of the LEV, however, is inhibited in the subsequent upstrokes following takeoff. Accordingly, we observe a drastic reduction in the magnitude of the aerodynamic force, signifying the importance of LEV in augmenting force production.] Address: Bode-Oke, A.T., Mechanical & Aerospace Engineering, University of Virginia, Charlottesville, VA 22903, USA

**16343.** Borkenstein, A.; Schröter, A.; Jödicke, R. (2017): Matutinal mating in *Aeshna grandis* and *A. viridis* – a behavioural pair of twins prefers early-morning sex (Odonata: Aeshnidae). *Odonatologica* 46(3/4): 207-226. (in English) ["We investigated the hitherto unknown matutinal mating behaviour of *Aeshna grandis* and found that matings basically occurred at dawn. With the first morning light males began performing a searching flight for females that roosted deep in terrestrial vegetation characterized by reed, rush and grass. Matutinal mating in the distinctive twistedwheel position is documented. Twisted wheels are unique as they are not formed in flight but while perching on vegetation and they show no readiness to escape. The twisted position, with the male hanging upside down and his appendages being obliquely slipped across the female's head, is the result of the formation of mating wheels with the female perched. Later in the morning we observed feeding flight at suitable sites and resting in low vegetation of a wet meadow. During this resting phase some males inspected the vegetation on the wing, described here as 'mid-morning searching flight'. In this situation and also when foraging individuals aggregated, we found untwisted, upright hanging couples, which we interpret as wheels formed in flight – an indication of alternative mating tactics. *A. viridis*, also known to exhibit matutinal matings, occurred syntopically and behaved similarly. We interpret the energy-sapping searching flight at dawn as sexual selection: females select genetic quality by choosing only the fittest mates." **16345.** Brodin, T.; Piovano, S.; Fick, J.; Klaminder, J.; Heynen, M.; Jonsson, M. (2017): Ecological effects of pharmaceuticals in aquatic systems—impacts through behavioural alterations. *Phil. Trans. R. Soc. B* 369. 20130580. 10 pp. (in English) ["The study of animal behaviour is important for both ecology and ecotoxicology, yet research in these two fields is currently developing independently. Here, we synthesize the available knowledge on drug-induced behavioural alterations in fish, discuss potential ecological consequences and report results from an experiment in which we quantify both uptake and behavioural impact of a psychiatric drug on a predatory fish (*Perca fluviatilis*) and its invertebrate prey (*Coenagrion hastulatum*). We show that perch became more active while damselfly behaviour was unaffected, illustrating that behavioural effects of pharmaceuticals can differ between species. Furthermore, we demonstrate that prey consumption can be an important exposure route as on average 46% of the pharmaceutical in ingested prey accumulated in the predator. This suggests that investigations of exposure through bioconcentration, where trophic interactions and subsequent bioaccumulation of exposed individuals are ignored, underestimate exposure. Wildlife may therefore be exposed to higher levels of behaviourally altering pharmaceuticals than predictions based on commonly used exposure assays and pharmaceutical concentrations found in environmental monitoring programmes." **16348.** Buczynski, P.; Buczyńska, E.; Tarkowski, A.; Banach-Binska, B. (2017): An interesting record of *Somatochlora arctica* (ZETTERSTEDT, 1840) (Odonata: Corduliidae) in the Polesie (middle-eastern Poland). *Odonatrix* 111 (2017): 8pp. (in Polish, with English summary) ["*S. arctica* was recorded in 2017 in the nature reserve "Magazyn" in the Sobiborskie Forests (51°27'06"N, 23°37'35"E, UTM: FC80). On a small (1.2 ha), transitional peat bog one imago (18.05.) was observed and one larval exuvium (26.09) was collected. The exuvium was obtained from bare patch overgrown with *Sphagnum* sp. caused by uprooted *Betula pubescens*, the only place that did not dry in the summer. A peat bog in the reserve "Magazyn" is the first site of *S. arctica* found in Polish part of the Polesie. The closest sites of the occurrence of this species has been reported in: south-eastern Poland – about 100 km from the described location, in north-eastern Poland – about 140 km, in the central part of the Polesie on Ukraine and Belarus – almost 400 km. For the time being it is difficult to say whether this population is completely isolated and may be ephemeral or it is a discrete subpopulation within a metapopulation that also inhabits some other peat bogs in this region. Peatlands of the Polish part of the Western Polesie have been intensively investigated since the early 1990s, therefore this species is very rare; otherwise it must have been found earlier. However, its ability to colonize small isolated sites, often clearly astatic may cause that it can be easier to overlook than other typhobionts. Taking this into consideration the further studies on optimal habitats of *S. arctica* are needed in the Western Polesie in Poland as well as the adjacent areas in Ukraine and Belarus." (Authors)] Address: Buczynski, P., Dept Zool., Maria Curie-Skłodowska University, Akademicka 19, PL-20-033 Lublin, Poland. E-mail: pawbucz@gmail.com

**16349.** Büsse, S.; Heckmann, S.; Hörschemeyer, T.; Bybee, S. (2017): The phylogenetic relevance of thoracic musculature: a case study including a description of the thorax

anatomy of Zygoptera (Insecta: Odonata) larvae. Systematic Entomology 43(1): 31-42. (in English) ["New morphological techniques allow for the evaluation of novel character systems that are potentially important for phylogenetic analysis. Only a few studies so far have used character systems from the insect thorax for phylogenetics; the reasons for this might include a lack of common terminology or established homology for pterygote insect thorax musculature. Still, recent studies have proposed common terminology and hypotheses of homology, now allowing for an evaluation of thoracic morphological character systems among the groups of winged insects. Using X-ray microtomography ( $\mu$ CT) we present a detailed study of the thorax musculature of Odonata as an important phylogenetic character system, with a matrix of 298 characters with 697 character states, including novel data from the thoracic anatomy of eight damselfly larvae. We also included additional Odonata, Ephemeroptera and Neoptera taxa from the literature and demonstrate the phylogenetic relevance of this character system by reproducing phylogenetic topologies of established relationships. We also compared high-resolution data from Odonata larvae from our study and from recent literature with data from older literature in the adult Odonata. All major clades were successfully recovered, (e.g. Odonata, Epiprocta, Anisoptera and Zygoptera) with high node support, but obtained higher phylogenetic resolution with the larval data. The best phylogenetic resolution was achieved by combining the adult and larval characters. The taxon sampling and character matrix is the largest to date and underlines the potential relevance of the thorax musculature as an important phylogenetic character system." (Authors) Eight Zygoptera larvae (intermediate to late instars) were examined from Coenagrionidae: *Ischnura elegans* (Vander Linden), *Ceriagrion tenellum* (De Villiers), *Coenagrion puella* (L.), *Enallagma cyathigerum* (Charpentier), Calopterygidae (*Calopteryx haemorrhoidalis* Vander Linden, *Calopteryx splendens* (Harris) and Platycnemididae (*Platycnemis pennipes* (Pallas), *Platycnemis latipes* Rambur (see Table S1 for more detail). All applicable regulations for the protection of wildlife species have been followed in each case. The responsible authorities, when necessary have approved the collection of Odonata. The immature stage in Odonata, Ephemeroptera and Plecoptera is referred to as 'naiad', following the terminology suggestions in Bybee et al. (2015). However, for Odonata, the more commonly used term is larva, and thus we have decided to be consistent within the community and use the more general term (cf. Sahlén et al., 2016; Büsse & Bybee, 2017] Address: Büsse, S., Functional Morphology and Biomechanics, Zoological Institute, Christian-Albrechts-University, Am Botanischen Garten 9, D-24118 Kiel, Germany. **16350.** Büsse, S.; Hörschemeyer, T.; Gorb, S.N. (2017): The head morphology of *Pyrhosoma nymphula* larvae (Odonata: Zygoptera) focusing on functional aspects of the mouthparts. *Frontiers in Zoology* 14:25: 13 pp. (in English) ["Background: The understanding of concerted movements and its underlying biomechanics is often complex and elusive.

Functional principles and hypothetical functions of these complex movements can provide a solid basis for biomechanical experiments and modelling. Here a description of the cephalic anatomy of *P. nymphula* focusing on functional aspects of the mouthparts using micro computed tomography ( $\mu$ CT) is presented. Results: We compared six different instars of the damselfly *P. nymphula* as well as one instar of *Aeshna cyanea* and *Epiophlebia superstes* each. In total 42 head muscles were described with only minor differences of the attachment points between the examined species and the absence of antennal muscle *M. scapopedicellaris medialis* (0an7) in *Epiophlebia* as a probable apomorphy of this group. Furthermore, the ontogenetic differences between the six larval instars are minor; the only considerable finding is the change of *M. submentopraementalis* (0la8), which is dichotomous in the early instars (I1, I2 and I3) with a second point of origin at the postero-lateral base of the submentum. This dichotomy is not present in any of the older instars studied (I6, middle-late and pen-ultimate). Conclusion: However, the main focus of the study herein, is to use these detailed morphological descriptions as basis for hypothetical functional models of the odonatan mouthparts. We present blueprint like description of the mouthparts and their musculature, highlighting the caused direction of motion for every single muscle. This data will help to elucidate the complex concerted movements of the mouthparts and will contribute to the understanding of its biomechanics not in Odonata only." **16351.** Buskirk, J. van (2017): Spatially heterogeneous selection in nature favors phenotypic plasticity in anuran larvae. *Evolution* 71(6): 1670-1685. (in English) ["Theory holds that adaptive phenotypic plasticity evolves under spatial or temporal variation in natural selection. I tested this prediction in a classic system of predator-induced plasticity: frog tadpoles (*Rana temporaria*) reacting to predaceous aquatic insects. An outdoor mesocosm experiment manipulating exposure to *Aeshna* dragonfly larvae revealed plasticity in most characters: growth, development, behavior, and external morphology. I measured selection by placing 1927 tadpoles into enclosures within natural ponds; photographs permitted identification of the survivors 6–9 days later. Fitness was defined as a linear combination of growth, development, and survival that correlates with survival to age 2 in another anuran species. In enclosures with many predators, selection favored character values similar to those induced by exposure to *Aeshna* in mesocosms. The shift in selection along the predation gradient was strongest for characters that exhibited high predator-induced plasticity. A field survey of 50 ponds revealed that predator density changes over a spatial scale relevant for movement of individual adults and larvae: 17% of variation in predation risk was among ponds separated by tens to thousands of meters and 81% was among sites =10m apart within ponds. These results on heterogeneity in the selection regime confirm a key tenant of the standard model for the evolution of plasticity." (Author)] Address: Buskirk, J. van, Inst. Zool., Univ. Zürich, 8057 Zürich, Switzerland. E-mail: jvb@zool.unizh.ch

(2017): *Boyeria irene* (Fonscolombe, 1838) y *Cordulegaster boltonii* (Donovan, 1807) (Odonata): Dos estrategias en cuanto a sustratos de emergencia de larvas en un mismo hábitat. *Graellsia* 73(2): e059: 6 pp. (in Spanish, with English summary) ["*B. irene* and *C. boltonii*: two strategies of substrates for emergence in the same habitat: Data on the emergence of coexisting *C. boltonii* and *B. irene* in a mountain stream in the center of Spain (altitude 1200 m a.s.l.) are presented in the study, based on the weekly collection of exuviae. *B. irene* began to emerge 28 days later than *C. boltonii*. Larvae of both species overlapped extensively in their selection of substrates for emergence, although a significantly higher use of trees was found in *C. boltonii*. In comparison to other geographical areas, both species have modified their strategy, delaying the onset of the emergence period. The importance of environmental conditions (especially temperature) is discussed." (Authors)] Address: Casanueva, Patricia, Depto de Ciencias Experimentales, Univ. **16355.** Casanueva, P.; Sanz Requena, J.-F.; Angeles Hernández, M. (2017): Altitudinal variation of wing length and wing area in *Libellula quadrimaculata* (Odonata: Libellulidae). *Odonatologica* 46(3/4): 227-240. (in English) ["The area and length of the right fore and hind wings and the abdomen length were

analysed in specimens from two Iberian populations of *L. quadrimaculata* Linnaeus, 1758, one on a plateau (782 m a.s.l.) and another in the mountains (1 909 m a.s.l.), with a view to ascertaining whether their morphometric characteristics vary with altitude. Allometric relationships in terms of length and area of the fore and hind wings of both populations were found. The wings are longer and have a greater area in plateau specimens whereas the length of the abdomen did not vary between populations. Between the populations there was an overlap in the wing length measurements. The significance of these parameters in aiding the dragonflies' flight capacity and hence the effects on their lifestyle under different environmental conditions is discussed." **16356.** Casanueva, P.; Hernández, M.A.; Campos, F. (2017): ¿Varía el tamaño de las exuvias de *Cordulegaster boltonii* (Donovan, 1807) (Odonata: Cordulegasteridae) durante el periodo de emergencia en ríos de montaña? *Boletín de la Sociedad Entomológica Aragonesa* 61: 271-272. (in Spanish, with English summary) ["Does the size of the exuviae of *C. boltonii* fluctuate during the emergence period in mountain rivers? It is known that in some species of odonates body size decreases as the emergence is delayed. In this paper we analyse whether this is true in *C. boltonii*. Values of head width, tibia length, and length and width of prementum from 165 exuviae from the Eresma river (central Spain, at 1200 m. a.s.l.) showed that females were bigger than males, but no interaction between date of emergence and gender was found. These data suggest that in this river there is no significant change in body size along the emergence period." **16357.** Ceder, P.; Jönsson, C. (2017): Tillväxttakt hos sydsvenska populationer av trollsländor (Odonata) i ett varmare klimat - en pilotstudie. B.Sc. thesis, School of Business, Engineering and Science, Halmstad University: 16 pp. (in Swedish, with English summary) ["In order to gain better understanding of climate change effects on ecosystems, it is necessary to study the response of different species to predicted climate change. Dragonflies are, due to their ecology, a suitable organism group for conducting such studies. In this pilot study we examined the response in growth- and mortality rate to increased ambient temperatures in an experimental set-up of three temperature levels (20°C, 22°C and 24°C) in larvae of three species from the Aeshnidae family (*Aeshna grandis*, *A. cyanea* and *Anax imperator*). *A. imperator* were, due to insufficient number of collected specimens, excluded in the 22°C temperature regime. The studied species are reproducing in Sweden, but *A. grandis* and *A. cyanea* are native, whereas *A. imperator* is considered newly established since it was first discovered in Sweden in the early 2000's. Our results show that *A. grandis* and *A. cyanea* reacted positively to an increased ambient temperature, in terms of

growth rates. However, the response to increased temperatures differed between the two species as *A. grandis* showed both higher growth- and mortality rate, compared to *A. cyanea*. Thus, we assume that both species are likely to benefit from the ongoing climate change, but that interactions between them may change. Further studies are required to elucidate how the two species will be affected in presence of newly established species, such as *A. imperator*. Although, based on our results, the competitiveness of both native species might increase with rising temperatures - which should be considered in future conservation planning." (in German, with English summary) ["Near-natural retention areas in the Lower Austrian lowland as habitat of a rivertype-specific dragonfly fauna (Odonata). In the lowlands of Eastern Austria the morphology of three running waters situated in four near-natural retention areas was evaluated by dragonfly surveys. In line with the requirements of the EU Water Framework Directive, the Dragonfly Association Index was applied to assess the differences between the current odonate fauna and the rivertype-specific reference conditions. The ecological status of the four river sections was classified as "high" and "good" respectively, due to the increased sinuosity of the rivers, the in-stream habitat heterogeneity and the pronounced lateral connectivity by creating backwaters. These measures provided a mosaic of different habitats for both, rheophilic and limnophilic dragonfly species. A total of 38 species were recorded in the four retention areas, which correspond to 49 % of the Austrian dragonfly inventory of 78 species; 33 species were classified as autochthonous in at least one of the investigation areas. The necessity of management measures for the dragonfly fauna, such as preventing tree canopy cover or mowing of reed, is pointed out." **16367.** Ciach, M.; Maslanka, B.; Krzus, A.; Wojas, T. (2017): Watch your step: insect mortality on hiking trails. Insect Conservation and Diversity 10(2): 129-140. (in English) ["1. Hiking may have a negative effect on vertebrates, but the impact on insects is unknown. Large-scale hiking may lead to habitat degradation, the introduction of alien species and the killing of insects occurring in places visited by people. 2. The aim of this study was to determine the influence of hiking on the mortality of insects. Randomly selected hiking trails in the western Carpathians (southern Poland) were surveyed and dead insects lying on the trails were collected. To compare the composition of ground-dwelling insects killed on trails, insects from free-living populations were sampled with ground pitfall traps. 3. The species abundance of insects killed on trails and those caught in traps differed significantly. Apart from common species, rare and legally protected insects were also found on the trails. Trail mortality peaked in July along with increasing hiking activity. 4. Body size did not affect mortality, at either the species or individual levels. Species mobility influenced mortality, with less mobile species being more vulnerable to trampling. Trampled insects remained on the ground for a maximum of 72 h, although 50% disappeared within 24 h. 5. Our results indicate that trail-killing is, to some degree, a random process and that hiking can influence insects by the elimination of individuals. Given the total length of hiking trails in Poland (76 400 km), and the significant human impact on natural areas resulting therefrom, hiking may be having a negative influence on insect populations." Odonatology 12(2): 7-19. (in English) ["Riverine odonates are indicators of riparian health. Since these species are relatively well-surveyed, we can build species distribution models (SDMs) to predict how future climate conditions may impact their habitat availability. Locality data from state surveys were used to generate SDMs for 15 species of riverine odonates in a 784,982 km<sup>2</sup> portion of the northeastern US. Ensemble climate model projections to the year 2080 indicate that climate change will decrease the number of suitable river reaches by 45–99% depending on species, with 935 km of river identified as climate refugia for 20% or more of these species. Among the 15 focal species, the most vulnerable to climate change were *Lanthus parvulus*, *Stylurus scudderi*, and *S. spiniceps*, whereas the least affected were *Hylogomphus abbreviatus* and *Neurocordulia yamaskanensis*. Less suitable habitat was available in the future, meaning that even species that are not currently considered imperiled may become so in future climates unless actual preservation of refugia is enacted." **16374.** Cuevas-Yañez, K.; Espinosa-Rivera, J.C.; Martínez-Falcón, A.P.; Córdoba-Aguilar, A. (2017): Are all Mexican odonate species documented? An assessment of species richness. *Systematics and Biodiversity* 15(3): 253-258. (in English) ["With the aim of protecting Mexican diversity, one current governmental task is to complete national biological inventories. In the case of odonate insects, several researchers have hypothesized that species richness is complete (205 dragonflies and 151 damselflies), but there has not been any formal exercise to test this. Thus, we have investigated whether odonate species richness (for Mexican endemics, Anisoptera, Zygoptera) and total species) is complete using sample-based and coverage-based rarefaction curves. Along with this, we also showed how good distribution data are in the country. The rarefaction curves have indicated 100% completeness for all groups suggesting that the inventory is complete. However, species' distribution data is highly patchy regarding areas either well (e.g. central Mexico) or badly (e.g. coast of Guerrero and Oaxaca) collected. We encourage researchers to continue odonate sampling in order to support at least three conservation actions: (i) conservation assessment of endangered species; (ii) knowledge of range shifts given rising global temperatures; and (iii) increase public interest and awareness in protected, touristic areas." **16376.** Danko, M.J.; Danko, A.; Golab, M.J.; Stoks, R.; Sniegula, S. (2017): Latitudinal and age-specific patterns of larval mortality in the damselfly *Lestes sponsa*: Senescence before maturity? *Experimental Gerontology* 95: 107-115. (in English) ["Highlights: • Populations at high latitudes face higher time constraints and develop faster. • We studied effects of time constraints on accelerated ageing in damselfly larvae. • The high-latitude population exhibited higher mortality rates and ageing rates. • Late hatched individuals showed higher mortality rates. • All populations showed accelerated mortality rates with age in the larval stage. Abstract: Latitudinal differences in life history traits driven by differences in seasonal time constraints have been widely documented. Yet, latitudinal patterns in (age-specific) mortality rates have been poorly studied. Here, we studied latitudinal differences in pre-adult age-specific mortality patterns in the strictly univoltine damselfly *Lestes sponsa*. We compared individuals from three latitudes reared from the egg stage in the laboratory at temperatures and photoperiods simulating those at the latitude of origin (main experiment) and under common-garden conditions at a fixed temperature and photoperiod (supplementary experiment). Results from the main experiment showed that the high-latitude population exhibited higher mortality rates than the central and southern populations, likely reflecting a cost of their faster development. Age-specific mortality patterns, also indicated higher ageing rates in the high-latitude compared to the low-latitude population, which likely had a genetic basis. The strong within-population variation in hatching dates in the low-latitude population caused variation in mortality rates; individuals that hatched later showed higher mortality rates presumably due to their shorter development times compared to larvae that hatched earlier. In both experiments, larvae from all three latitudes showed accelerated mortality rates with age, which is consistent with a pattern of senescence before adulthood." **16377.** Dao, T.-P.; Huang, S.-C. (2017): Compliant thin-walled joint based on Zygoptera nonlinear geometry. *Journal of Mechanical Science and Technology* 31(3): 1293-1303. (in English) ["This paper introduces a Compliant thin-walled joint (CTWJ) that expands the group of existing compliant joints. The CTWJ design is based on the nonlinear geometry of the Zygoptera animal. With a thin-walled structure, the CTWJ allows a considerably large range of motion in the x-and-y

axes. In addition, the thin-walled structure is then filled by polydimethylsiloxane material to reinforce the stiffness of the CTWJ. First, design of experiment methodology is used for the sensitive analysis of the width and the thickness to the strain of joint. The range of motion, the strain, the buckling behavior, and the first natural frequency of CTWJ are investigated via finite element analysis and experiments. The behavior of the CTWJ is subsequently compared with the conventional compliant joints to realize the efficient performance of the CTWJ. The results revealed that the CTWJ has a range of motion and strain energy larger than those of traditional compliant joints. Finally, an example of vibration isolator is modeled by using the CTWJ as planar spring. It is believed that the CTWJ has a great potential for the development of compliant mechanisms in terms of large range of motions in multiple axes." **16378.** Davis, D.R.; DeSantis, D.L.; Gabor, C.R. (2017): Antipredator behavior of the Barton Springs salamander (*Eurycea sosorum*) in response to aquatic invertebrates: potential consequences of habitat restoration. *Hydrobiologia* 795: 129-137. (in English) ["*E. sosorum*, is a fully aquatic salamander found in Barton Springs in Texas, USA, and has benefited from habitat restoration efforts. While important to improve overall habitat quality for this imperiled species, current management and restoration practices may also inadvertently increase the abundance of non-target organisms such as predatory invertebrates. Fish represent major predators of this species, but little is known about the role of invertebrates as potential predators. It is important to understand the role of these aquatic invertebrates as predators of *E. sosorum*, especially if habitat restoration also increases predator abundance. Using adult, predator-naïve salamanders, we examined the antipredator response of *E. sosorum* to chemical cues from the following treatments: crayfish, dragonfly larvae, snails, and water. Salamanders decreased activity (antipredator behaviour) only in response to the crayfish treatment. The responses to dragonfly larvae, snails, and water did not differ, suggesting that dragonfly larvae are not perceived as predators by these salamanders. Our study provides preliminary evidence suggesting that habitat restoration has unexpectedly increased crayfish abundance, which in turn may negatively affect *E. sosorum*, and that future management strategies should consider crayfish removal if salamander abundances decline with increasing crayfish abundance." **16379.** De Knijf, G. (2017): Recent observations and status of the Yellow Clubtail (*Gomphus simillimus*) in Belgium and northern France. *Brachytron* 19(2): 71-76. (in Dutch, with English summary) ["A male of the Yellow Clubtail (*Gomphus simillimus*) was observed at the river Chiers where it forms the border between Belgium (Torgny) and France (Velosnes). This is the sixth observation of this species for Belgium and the first for the French region Lorraine. In the last decade, *Gomphus simillimus* has been observed several times from the rivers Aisne, Marne, Seine and Aube in the region

Champagne-Ardenne. Among them several freshly emerged individuals in several years. This indicates the presence of populations at several localities in northeastern France. The habitat requirements of *G. simillimus* seem to be present at the river Chiers between Torgny and Velosnes, so local reproduction may not be excluded, near the locality of the observation or further downstream where the species has also been seen." (2017): Distribución ibérica de *Gomphus graslinii*, *Oxygastra curtisii* y *Macromia splendens* (Insecta: Odonata), especies protegidas por la Directiva Hábitats. Boletín Rola 9, primer semestre 2017: 15-54. (in Spanish, with English summary) ["This paper reviews and compiles the information on the distribution of the three species of Anisoptera protected and included in the Habitats Directive that are present in the Iberian Peninsula namely *M. splendens*, *O. curtisii* and *G. graslinii*. In recent decades, these three species have greatly expanded their range and number of localities, primarily due to increased interest from both professionals and amateurs in dragonflies and damselflies found in the Iberian Peninsula. In summary, current evidence shows that the north-west quadrant represents the area of greatest frequency followed by the south-west and north east quadrants. A large number of localities are included within the sites protected by the Natura 2000 Network, and it is in Spain where the three species are most represented. As a result of the data contained in this paper, we propose that the threat status of *G. graslinii* should be revised from "Near Threatened" to "Vulnerable". With regard to the other two species we propose their status remains unchanged. Finally we emphasise the need to sample historical localities from which these species have not been recorded in recent years to ascertain if populations still exist and their viability." **16381.** De Roo, P. (2017): Enige bemerkingen over een kwetsbare populatie van de Bosbeekjuffer (*Calopteryx virgo*) in het Peerdsbos (Antwerpse Kempen, België). *Brachytron* 19(1): 16-21. (in Dutch, with English summary) ["During the period 1990-2000 there were no known populations of *C. virgo* anymore in the western part of the Antwerp Campine area (Belgium), where they occurred in the first half of the 20th century. In 2006 however, the author observed some individuals in this region, at the Laarse Brook in the Peerdsbos forest at Brasschaat/Schoten (lon 51,275 lat 4,486). Since 2006 the species has been counted yearly along a 5 km long transect of the Laarse Brook, which has been divided into 9 sections of several hundreds of meters. The article describes the habitat in the different sections and presents an overview

of the monitoring results. After an increase in the first years there was a significant drop in numbers in 2011, but later the population increased again to 141 individuals. In 2015 there was again a prominent drop to only 66. In this year some sections of the brook had been subject to fluctuations in water level or alterations of the habitat structure, and in one of them the habitat of *C. virgo* was completely altered after construction works and reinforcement of the banks with heavy stones. Other sections suffered from extremely low water levels. This case shows that local habitat loss could have serious effects on rather small and vulnerable populations of *C. virgo*. The next years will show to what extent the population of the Laarse Brook will recover." (Author)] Address: E-mail: pierre.de.roo@telenet.be

**16382.** de Vries, R.; Buesink, R.; van Leeuwen, J.; Baller, G. (2017): Odonata observations in the Danube Delta, Romania, from July 2016. *Brachytron* 19(1): 35-43. (in Dutch, with English summary) ["The Danube Delta is one of the most important wetlands of Europe, but its Odonata fauna is still relatively poorly known. This article presents Odonata observations from a visit to the Romanian Danube Delta in July 2016. Records are from around the village of Sfantu Gheorghe as well as from around the villages of Caraorman, Murighiol and Mahmudia. 25 species were recorded in total. In the Sfantu Gheorghe region we found eleven species that had not been reported previously from this part of the delta. These include the first records of *Anax ephippiger* from the Romanian Danube delta, as well as records of *Lestes macrostigma*, *Chalcolestes parvidens* and *Selysiothemis nigra*." - 16385.** Debecker, S.; Dinh, K.V.; Stoks, R. (2017): Strong delayed interactive effects of metal exposure and warming: latitude-dependent synergisms persist across metamorphosis. *Environ. Sci. Technol.* 51(4): 2409-2417. (in English) ["As contaminants are often more toxic at higher temperatures, predicting their impact under global warming remains a key challenge for ecological risk assessment. Ignoring delayed effects, synergistic interactions between contaminants and warming, and differences in sensitivity across species' ranges could lead to an important underestimation of the risks. We addressed all three mechanisms by studying effects of larval exposure to zinc and warming before, during and after metamorphosis in *Ischnura elegans* damselflies from high- and low-latitude populations. By integrating these mechanisms into a single study we could identify two novel patterns. Firstly, during exposure zinc did not affect survival, whereas it induced mild to moderate post-exposure mortality in the larval stage and at metamorphosis, and very strongly reduced adult life-span. This severe delayed effect across metamorphosis was especially remarkable in high-latitude animals, as they appeared almost insensitive to zinc during the larval stage. Secondly, the well-known synergism between metals and warming was manifested not only during the larval stage but also after metamorphosis, yet notably only in low-latitude damselflies. These results highlight that a more complete life-cycle approach that incorporates the possibility of delayed interactions between contaminants and warming in a geographical context is crucial for a more realistic risk assessment in a warming world." **16396.** Dube, T.; DeNecker, L.; van Vuren, J.H.J.; Wepener, V.; Smit, N.J.; Brendonck, L. (2017): Spatial and temporal variation of invertebrate community structure in flood-controlled tropical floodplain wetlands. Journal of Freshwater Ecology 32(1): 1-15. (in English) ["The Phongolo floodplain in South Africa is a unique system because of its biodiversity and socio-economic value. The spatial and temporal changes of invertebrate communities of the downstream floodplain influenced by controlled flooding from an upstream dam are poorly understood. The study investigated the spatial and temporal changes in community assemblage of macroinvertebrates and zooplankton in the permanent wetlands (pans) of the Phongolo floodplain in relation to controlled flooding. This was achieved by sampling during the dry period (September) and after controlled release of water (December). Although controlled flooding did not coincide with significant changes in the taxon diversity of macroinvertebrates and zooplankton, macroinvertebrate regional taxa richness ( $\gamma$ -diversity) was relatively higher in the period coinciding with controlled flood (December) compared to the dry period. For zooplankton, regional taxa diversity was similar in both periods. The average local taxa richness ( $\alpha$ -diversity) was higher after the controlled flooding period for both macroinvertebrates and zooplankton. Spatial species turnover ( $\beta$ -diversity) was lower after the controlled flooding period suggesting the homogenization of aquatic communities

through flooding. The community pattern of macroinvertebrates, but not of zooplankton, significantly changed after the controlled flooding period. The most important local environmental variables determining the distribution of both macroinvertebrates and zooplankton were macrophyte cover and dissolved oxygen. As the invertebrate diversity in this unique floodplain is at least partly dependent on release of water from the dam, future management schemes aimed to meet irrigation demands for agriculture should always consider flooding of the precious floodplain wetlands to maintain ecosystem integrity." **16397.** DuBois, R.B.; Pratt, D.M. (2017): Species and life stages of Odonata nymphs sampled with large drift nets in two Wisconsin rivers. *The Great Lakes Entomologist* 50(1): 11-16. (in English) ["Because relatively few nymphs of Odonata are caught in most drift studies, they have been inconsistently reported and little is known about the species and life stages that are predisposed to drift. We used large drift nets with relatively coarse mesh sizes (1500 µm) to sample late-instar odonate nymphs in two large rivers in Wisconsin. These nets were presumed to have advantages over smaller, conventional aquatic insect drift nets, including the capability to sample greater water volumes more quickly, sampling for longer periods of time before nets become clogged with debris, and a reduced likelihood of large, active insects escaping from the nets. Nymphs of 14 species of Odonata in five families were caught, but drift densities were low (0.042 m<sup>-3</sup> overall; .0.007 m<sup>-3</sup> for most species) and final instar nymphs (F-0) were collected less frequently than younger nymphs (F-1 through F.4). Gomphidae comprised 83% of the nymphs collected, and three species of Ophiogomphus comprised 78% of the total in the St. Croix River. *O. howei* was the most commonly sampled species (drift density of 0.026 m<sup>-3</sup>), with at least five instars collected." **16400.** Duong, T.M.; Gomez, A.B.; Sherratt, T.N. (2017): Response of adult dragonflies to artificial prey of different size and colour. *PLoS ONE* 12(6): e0179483. [https://doi.org/10.1371/12\(6\): e0179483](https://doi.org/10.1371/10.1371/12(6): e0179483). 14 pp. (in English) ["Aposematism is an evolved, cross-species association between a preys' unprofitability and the presence of conspicuous signals. Avian predators have been widely employed to understand the evolution of these warning signals. However, insect predators are abundant, diverse, and highly visual foragers that have been shown to be capable of learned aversion. Therefore, it is likely that their behaviour also shapes the nature of anti-predator traits. In this study, we evaluated the rates of attack of a community (13 species) of mature adult dragonflies on artificial prey of varying size (2.5–31 mm lengthwise) and colour pattern (black, black/yellow striped). The relative attack rates of dragonflies on prey increased as prey size decreased, but there was no evidence that the attack rates by dragonflies were affected by prey colour pattern and no evidence for an interaction between colour pattern and size. To investigate prey selection by specific predator species under field conditions, we compared the time to attack distributions of black-painted prey presented to two common dragonflies: *Leucorhina intacta* and the larger, *Libellula pulchella*. We found that the two dragonfly species, as well as the two sexes, had different foraging responses. *L. pulchella* was more likely to attack larger prey, and females of both species more likely to attack prey than males. Collectively, our results indicate that dragonflies are highly size selective. However, while the nature of this selectivity varies among dragonfly species, there is little evidence that classic black/yellow warning signals deter attack by these aerial invertebrate predators." **16402.** Dwari, S.; Mondal, A.K. (2017): Diversity of Odonates in agricultural fields of Howrah district, West Bengal, India. *Journal of Entomology and Zoology Studies* 5(3): 1588-1595. (in English) ["The present study documented the odonates of agricultural fields of Howrah, West Bengal, India. Agricultural fields are unique ecosystems that provide some odonates to complete their life cycle. So the main aim of this study to prepare a list of those odonates which use these fields. A total number of 17 species of order Odonata were observed, among them 12 species belongs to sub order Anisoptera and 5 species belongs to suborder Zygoptera. Sub-order Anisoptera was represented by the family Libellulidae and suborder Zygoptera by the family Coenagrionidae. Species composition was highest in the family Libellulidae (70%) followed by the family Coenagrionidae (30%). Among all agricultural fields Rice fields (13) contain highest number of odonates followed by Sugarcane (5), Sesame (5) and others. Rice field is show highest diversity of odonates showing 76.471% of total odonates. Odonata documentation is highly necessary in order to assess the agroecosystem health. The fact that health of agroecosystem is proportionately at par with the presence of the odonates can be easily perceived from this study." **16414.** Feurle, A. W.; Holzinger, W. E. (2017): Die Libellenfauna des Dörmleesee in Lingenau (Naturpark Nagelfluhkette), mit dem Erstnachweis der Gabel-Azurjungfer (*Coenagrion scitulum*, Odonata, Insecta) für Vorarlberg. *inatura – Forschung online* 46: 6 pp. (in German, with English summary) ["A survey of the Odonata fauna of the pond Dörmlesee in Lingenau (Vorarlberg; coordinates (WGS84): 9,9106 E; 47,4536 N) carried out in 2017 revealed a total of 14 species. On 21-VI-2017, we spotted a single male of *C. scitulum*. This is the first confirmed record of this species in Vorarlberg. In Austria, *C. scitulum* is autochthonous in its eastern parts (Styria, Burgenland, Lower Austria and Vienna) and has been recorded in Salzburg recently. In addition, an unconfirmed record for Vorarlberg was published in 2002. It is a species with holo-mediterranean distribution and a distinct range expansion (due to climate change) towards Central Europe in recent decades, where it usually inhabits low altitudes. Our record of *C. scitulum* at 663 m a.s.l. therefore is unusual and can be explained by the fact that the Dörmlesee is favoured

by a warm climate." (Authors)] Address: Feurle, A.W., Schwarzen 365/4, A-6861 Alberschwende, Austria. E-Mail: alexander.feurle@gmail.com

**16415.** Filion, A.; Lagrue, C.; Presswell, B.; Poulin, R. (2017): Behavioural modification of personality traits: testing the effect of a trematode on nymphs of the red damselfly *Xanthocnemis zealandica*. *Parasitology Research* 116: 1773-1779. (in English) ["Research on animal personality is increasingly demonstrating that individuals in a population are characterised by distinct sets of behavioural traits that show consistency over time and across different situations. Parasites are known to alter the behaviour of their hosts, although their role in shaping host personality remains little studied. Here, we test the effect of trematode infection on two traits of their host's personality, activity and boldness, in nymphs of *X. zealandica*. Genetic analyses indicate that the undescribed trematode species falls within the superfamily Microphalloidea. Results of laboratory behavioural tests indicate that the two behavioural traits are related to each other: bolder individuals also show higher levels of spontaneous activity than shy ones. However, parasite infection had no effect on either of these behaviours or on their repeatability over three separate testing sessions. Although our findings suggest that this trematode does not influence personality traits of the damselfly host, it remains possible that other standard personality traits not tested here (exploratory tendency, aggressiveness) are affected by infection." (Authors)] Address: Poulin, R., Département des Sciences de l'environnement, Université du Québec à Trois-Rivières, C.P. 500, Trois-Rivières, Québec G9A 5H7, Canada. **16416.** Fitt, R.; Lancaster, L.T. (2017): Range shifting species reduce phylogenetic diversity in high latitude communities via competition. *Journal of Animal Ecology* 86(3): 543-555. (in English) ["1. Under anthropogenic climate change, many species are expanding their ranges to higher latitudes and altitudes, resulting in novel species interactions. The consequences of these range shifts for native species, patterns of local biodiversity, and community structure in high latitude ecosystems are largely unknown but critical to understand in light of widespread poleward expansions by many warm-adapted generalists. 2. Using niche modelling, phylogenetic methods, and field and laboratory studies, we investigated how colonisation of Scotland by a range expanding damselfly, *Ischnura elegans*, influences patterns of competition and niche shifts in native damselfly species, and changes in phylogenetic community structure. 3. Colonization by *I. elegans* was associated with reduced population density and niche shifts in the resident species least related to *I. elegans* (*Lestes sponsa*), reflecting enhanced competition. Furthermore, communities colonized by *I. elegans* exhibited phylogenetic underdispersion, reflecting patterns of relatedness and competition. 4. Our results provide a novel example of a potentially general mechanism whereby climate change-mediated range shifts can reduce phylogenetic diversity within high latitude communities, if colonising species are typically competitively superior to members of native communities that are least-closely-related to the coloniser." **16417.** Fleck, G. (2017): Notes on the genus *Navicordulia* Machado & Costa, 1995 (Odonata: Anisoptera: Corduliidae s. str.): description of a new species, phylogenetic affinities and aspects of biogeography. *Zootaxa* 4272(2): 251-262. (in English) ["Based on a single male specimen, a remarkable new species of the genus *Navicordulia* is described from the Massif du Mitaraka in French Guiana (Tumuc-Humac Mountains). Another new species of this genus is also reported from the same locality but is not described. This is the first record of the genus from French Guiana, hitherto being unknown within a radius of more than 1000 km. Apparent rarity or absence of records is probably due to its secretive habits. *Navicordulia tumucurakensis* sp. nov. presents unique characters not present in other species of the genus including: almost no excavation of the anal angle, proximal sternal pilose ridge of abdominal segment 7 transformed into two large lateral oreillets disconnected from the median carina, additional distal sternal pilose ridge transformed into a medial knob, epiproct not extending beyond the distal half of the cerci, very long cerci surpassing those of described species, cerci lacking ventromedial carina and tubercle and exhibiting a distal ventral brush of hair-like setae. It is a forest species inhabiting hilly landscapes at low altitude, unlike other closely related intertropical species which are encountered in more elevated areas above 850 m. It is most closely related to *N. longistyla*, a typical cerrado species from the central Brazilian plateau or possibly to *N. nitens* from the central south Venezuelan Guaiquinima Tepui. Based on unique derived male abdominal structures and also on the female ovipositor and related structures, the South American genus *Navicordulia* and the Southeast Asian/Melanesian genus *Metaphya* are considered current adelphotaxa. This disrupted geographic distribution could be explained by a common ancestor having had a Gondwanian dispersal until the Late Cretaceous or Paleocene." (Author)] Address: Fleck, G. **16419.** Fontana-Bria, L.; Selfa, J.; Tur, C.; Frago, E.; (2017): Early exposure to predation risk carries over metamorphosis in two distantly related freshwater insects. *Ecological Entomology* 42(3): 255-262. (in English) ["1. Predation and competition play a central role in ecological communities, and it is increasingly recognised that animals use early warning cues to reduce the impact of these antagonistic interactions. 2. Strategies to avoid risk can occur during embryo development

through plasticity in egg hatching time. This strategy, and its associated costs and carryover effects on adults are little understood in insects. In this study, these are explored in two distantly related freshwater insects: the damselfly *Ischnura elegans* and the mosquito *Aedes albopictus*. 3. As predicted, damselfly eggs hatched earlier in response to larval predators cues, a treatment that also affected adult size. Risk cues did not affect mosquito egg hatching time, but they did affect larval development time in a sex-dependent manner. 4. The results suggest that responses aimed at avoiding risks can be triggered during the egg stage, and although they can vary dramatically among species, they are likely to be widespread in insects. Early warming responses can be particularly important to understand the ecology of aquatic insects, some of them global vectors of human diseases." **16421.** Frances, D.; Moon, J.; McCauley, S.J. (2017): Effects of environmental warming during early life-history on libellulid odonates. *Canadian Journal of Zoology* 95(6): 373-382. (in English) ["Climate warming affects ectotherms globally yet we know little regarding the variability in species' responses to warming, particularly in early life stages. Additionally, intraspecific variation in response to warming is understudied but may determine species' resilience to warming. To assess how temperature affects egg development rate in co-occurring dragonfly species, we manipulated temperature (range: 22° -31° C) and measured time to hatching. Warming decreased egg development time across all species, indicating that while climate warming will advance hatching phenology,

maintained synchrony in hatching order will likely not affect species interactions. Our second experiment examined early life history responses to warming in the dragonfly *Leucorrhinia intacta*. We measured time to hatching, hatchling size, growth rate and survival at four temperatures (23°-30° C), including a treatment with increased thermal variation. Warming resulted in smaller hatchlings with increased growth and mortality rates, while higher thermal variation did not have effects different from those of warming alone. We observed significant intraspecific variation in the responses to warming in both egg development time and hatchling size and this variation was correlated with date of oviposition. High levels of intraspecific variation may be important in buffering populations from the effects of climate warming." **16426.** Galicia-Mendoza, I.; Sanmartín-Villar, I.; Espinosa-Soto, C.; Cordero-Rivera, A. (2017): Male biased sex ratio reduces the fecundity of one of three female morphs in a polymorphic damselfly. *Behav. Ecol.* 28(4): 1183-1194. (in English) ["Females of *Ischnura graellsii* display 3 color morphs, a male-like androchrome morph and 2 other morphs, infuscans and aurantiaca, which are not male-like. Previous research has suggested that male harassment has a negative effect on female fitness in many different insect species. Studying how male harassment affects fitness of the different female color morphs is key to a better understanding of how these morphs are maintained in natural populations. This study evaluated the response of female morphs of *I. graellsii* to contrasting sex ratios under controlled laboratory conditions. In our experiments, male abundance, through increased harassment, affected differentially the fecundity of females of the 3 color morphs. A male biased (3:1) sex ratio drastically decreased the average fecundity of infuscans females but had no effect on androchrome and aurantiaca females. Taking into account our results and previous studies that indicate that males prefer infuscans females, we propose a mechanism for the maintenance of this polymorphism. In this scenario, within-generation fluctuations in male abundance produce 2 regimes: One in which male abundance disfavors infuscans females by decreasing their fecundity and other in which a low male abundance results in androchromes that do not mate because of their low appeal to males. By studying a simple population genetics model, we found that the mechanism that we propose may contribute to maintain a stable female-limited polymorphism under a wide range of parameter combinations." (in English) ["Biologists are still discovering diverse and powerful ways sexual conflicts shape biodiversity. The present study examines how the proportion of females in a population that exhibit male mimicry, a mating resistance trait, influences conspecific males' behaviour, condition and survival. Like most female-polymorphic damselflies, *Ischnura ramburii* harbours both "andromorph" females, which closely resemble males, and sexually dimorphic "gynomorph" counterparts. There is evidence that male mimicry helps andromorphs evade detection and harassment, but males can also learn to target locally prevalent morph(s) via prior mate encounters. I hypothesized that the presence of male mimics could therefore predispose males to mate recognition errors, and thereby increase rates of costly male-male interactions. Consistent with this hypothesis, male-male interaction rates were highest in mesocosms containing more andromorph (vs. gynomorph) females. Males in andromorph-biased mesocosms also had lower final body mass and higher mortality than males assigned to gynomorph-majority treatments. Male survival and body mass were each negatively affected by mesocosm density, and mortality data revealed a marginally significant interaction between andromorph frequency and population density. These findings suggest that, under sufficiently crowded conditions, female mating resistance traits such as male mimicry could have pronounced indirect effects on male behaviour, condition, and survival." **16430.** Gezie, A.; Anteneh, W.; Dejen, E.; Mereta, S.T. (2017): Effects of human-induced environmental changes on benthic macroinvertebrate assemblages of wetlands in Lake Tana Watershed, Northwest Ethiopia. *Environmental Monitoring and Assessment* 189(4): 152. (in English) ["Wetlands of Lake Tana Watershed provide various ecological and socioeconomic functions. However, they are losing their vigor

at alarming rate due to unwise management. Hence, there is an urgent need to monitor and assess these resources so as to identify the major drivers of its degradation and to provide information for management decisions. In this context, we aimed to assess the effects of human activities on macroinvertebrate assemblages of wetlands in Lake Tana Watershed. Biotic and abiotic data were collected from 46 sampling sites located in eight wetlands. A total of 2568 macroinvertebrates belonging to 46 families were recorded. Macroinvertebrate metrics such as Biological Monitoring Working Party score, Shannon diversity index, Ephemeroptera and Odonata family richness, and total family richness portrayed a clear pattern of decreasing with increasing in human disturbances, whereas Family biotic index score, which is an indicator of organic pollution, increased with increasing in human disturbances. The regression analysis also revealed that livestock grazing, leather tanning, and eucalyptus plantation were important predictors of macroinvertebrate metrics ( $p < 0.05$ ). In conclusion, human activities in and around the wetlands such as farming, leather tanning, solid waste dumping, and effluent discharges were contributed to the degradation of water quality and decreasing in the macroinvertebrate richness and diversity. These alterations could also reduce the availability of wetland products (sedges, craft materials, etc.) and the related ecosystem services. This in turn has an adverse effect on food security and poverty alleviation with considerable impact on communities who heavily depend on wetland products for their livelihood. Therefore, it is essential to formulate wetland policy for achieving wise use goals and necessary legal and institutional backup for sustainable wetland management in Ethiopia." **16431.** Guillermo-Ferreira, R.; Appel, E.; Urban, P.; Bispo, P.C.; Gorb, S.N. (2017): The unusual tracheal system within the wing membrane of a dragonfly. *Biology Letters* 13(5). pii: 20160960. doi: 10.1098/rsbl.2016.0960: 5 pp. (in English) ["Some consider that the first winged insects had living tissue inside the wing membrane, resembling larval gills or developing wing pads. However, throughout the developmental process of the wing membrane of modern insects, cells and tracheoles in the lumen between dorsal and ventral cuticle disappear and both cuticles become fused. This process results in the rather thin rigid stable structure of the membrane. The herewith described remarkable case of Zenithoptera lanei shows that in some highly specialized wings, the membrane can still be supplemented by tracheae. Such a characteristic of the wing membrane presumably represents a strong specialization for the synthesis of melanin-filled nanolayers of the cuticle, nanospheres inside the wing membrane and complex arrangement of wax crystals on the membrane surface, all responsible for unique structural coloration." **16439.** Hardersen, S.; Corezzola, S.; Gheza, G.; Dell'Otto, A.; La Porta, A. (2017): Sampling and comparing odonate assemblages by means of exuviae: statistical and methodological aspects. *Journal of Insect Conservation* 21(2): 207-218. (in English) ["Freshwater species are in serious decline all over the world. Thus, monitoring of freshwater ecosystems and species is crucial to guide policy actions and dragonflies are generally considered to be good indicators for these systems. The aquatic life stage of the Odonata is inherently more susceptible to changes in water quality than the imago and therefore exuviae give better insights into site-specific effects. However, utilizing exuviae for monitoring purposes introduces a number of problems. For example, they often do not persist long in the environment. Some of these problems have been addressed. However, there are no published data that distinguish the influence of sampling frequency and total sampling effort on the faunal completeness. Also the number of exuviae necessary to define local assemblages has not been investigated. These questions were addressed by analyzing the data on exuviae collected in seven sites and we found that for any given total amount of time invested, it was always preferable to conduct more short surveys, rather than fewer surveys lasting longer. The study also showed that a sample size of 300 exuviae allowed us to reliably estimate the similarity of two assemblages from different sites. However, when collecting 40 exuviae or

less, the reliability was low. Based on our findings we recommend sampling exuviae for a minimum of 5 days, evenly spread out over the entire season during which Odonata emerge, to sample each time for approximately 60 min and aim to collect not less than 300 exuviae in total."] Address: Hardersen, S., Centro Nazionale per lo Studio e la Conservazione della Biodiv. **16442.** Harter, T.S.; Brauner, C.J.; Matthews, P.G.D. (2017): A novel technique for the precise measurement of CO<sub>2</sub> production rate in small aquatic organisms as validated on Aeshnid dragonfly nymphs. *Journal of Experimental Biology* 220: 964-968. (in English) ["The present study describes and validates a novel yet simple system for simultaneous in vivo measurements of aquatic CO<sub>2</sub> production (MCO<sub>2</sub>) and oxygen consumption (MO<sub>2</sub>) rates, thus allowing the calculation of respiratory exchange ratios (RER). Diffusion of CO<sub>2</sub> from the aquatic phase into a gas phase, across a hollow fibre membrane, enabled aquatic MCO<sub>2</sub> measurements with a high-precision infrared gas CO<sub>2</sub> analyser. MO<sub>2</sub> was measured with a PO<sub>2</sub> optode using a stop-flow approach. Injections of known amounts of CO<sub>2</sub> into the apparatus yielded accurate and highly reproducible measurements of CO<sub>2</sub> content (R<sup>2</sup>=0.997, p<0.001). The viability of in vivo measurements was demonstrated on aquatic dragonfly nymphs (Aeshnidae; wet mass 2.17 mg - 1.46 g, n=15) and the apparatus produced precise MCO<sub>2</sub> (R<sup>2</sup>=0.967, p<0.001) and MO<sub>2</sub> (R<sup>2</sup>=0.957, p<0.001); average RER was 0.73±0.06. The described system is scalable, offering great potential for the study of a wide range of aquatic species, including fish." **16443.** Heino, J.; Bini, L.M.; Andersson, J.; Bergsten, J.; Bjelke, U.; Johansson, F. (2017): Unravelling the correlates of species richness and ecological uniqueness in a metacommunity of urban pond insects. *Ecological Indicators* 73: 422-431. (in English) ["City ponds have the potential to harbour a rich biodiversity of aquatic insects despite being located in an urban landscape. However, our current knowledge on the correlates of pond biodiversity is limited and even less is known about the factors that influence the ecological uniqueness of urban ponds. The multiple environmental gradients, at different spatial scales, that may affect biodiversity and ecological uniqueness of urban ponds can thus be seen both as an opportunity and as a challenge for a study. In this study, we aimed to fill this gap by focusing on aquatic insect assemblages in 51 ponds in the Swedish city of Stockholm, using a metacommunity perspective. We found that species richness was primarily determined by the density of aquatic insects, water depth and proportion of buildings around the pond. The uniqueness of ponds was estimated as local contributions to beta diversity (LCBD), and it was primarily related to the proportion of arable land and industry around the ponds. With regard to the metacommunity we found two interesting patterns. First, there was a negative relationship between richness and LCBD. Second, biodiversity was spatially independent, suggesting that spatially-patterned dispersal did not structure species richness or LCBD. These last two patterns are important when considering conservation efforts of biodiversity in city ponds. We hence suggest that the conservation of insect biodiversity in urban pond should consider the surroundings of the ponds, and that high-richness ponds are not necessarily those that require most attention because they are not ecologically

the most unique." (Authors)] Address: Heino, J., Finnish Environ. Inst., Natural Environ. Centre, Biodivers., Paavo Havaksen Tie 3, 90570 Oulu, Finland. E-mail: jani.heino@environment.fi

**16444.** Hinojosa, J.C.; Martín, R.; Maynou, X.; Vila, R. (2017): Molecular taxonomy of the *Sympetrum vulgatum* (Odonata: Libellulidae) complex in the West Palaearctic. *Eur. J. Entomol.* 114: 373-378. (in English) ["The *S. vulgatum* complex is composed of the subspecies *S. vulgatum vulgatum*, *S. vulgatum decoloratum* (Selys, 1884) and *S. vulgatum ibericum* Ocharan, 1985 in the West Palaearctic. These taxa have parapatric distributions and noticeable morphological differences in colour and body size, and their taxonomic status is debated. Here we revise the systematics of this group using molecular taxonomy, including molecular analyses of mitochondrial (cytochrome c oxidase subunit I, COI) and nuclear (internal transcribed spacer, ITS1) DNA taking into account known morphological differences. Each subspecies has a unique and differentiated COI haplotype, although divergences among them are low (0.4% maximum uncorrected p-distance). The subspecies are not differentiated by the nuclear marker ITS1. The genetic results for these taxa contrast with the deep divergence of the sister species *S. striolatum* (Charpentier, 1840). Given current evidence, we propose to maintain the subspecific status of the *S. vulgatum* complex and hypothesize their biogeographical history. It is likely that the three subspecies became isolated during one of the latest glacial periods, each in a different refugium: *S. vulgatum ibericum* possibly occupied the Iberian Peninsula, *S. vulgatum vulgatum* the Balkan Peninsula or territories further east and *S. vulgatum decoloratum* Anatolia.] Address: Hinojosa, J.C., Inst. **16445.** Hirohashi, K.; Inamuro, T. (2017): Hovering and targeting flight simulations of a dragonfly-like flapping wing-body model by the immersed boundary-lattice Boltzmann method. *Fluid Dynamics Research* 49(4) 045502: (in English) ["Hovering and targeting flights of the dragonfly-like flapping wing-body model are numerically investigated by using the immersed boundary-lattice Boltzmann method. The governing parameters of the problem are the Reynolds number  $Re$ , the Froude number  $Fr$ , and the non-dimensional mass  $m$ . We set the parameters at  $Re = 200$ ,  $Fr = 15$  and  $m = 51$ . First, we simulate free flights of the model for various values of the phase difference angle  $\phi_{gr}$  between the forewing and the hindwing motions and for various values of the stroke angle  $\beta$  between the stroke plane and the horizontal plane. We find that the vertical motion of the model depends on the phase difference angle  $\phi_{gr}$ , and the horizontal motion of the model depends on the stroke angle  $\beta$ . Secondly, using the above results we try to simulate the hovering flight by dynamically changing the phase difference angle  $\phi_{gr}$  and the stroke angle  $\beta$ . The hovering flight can be successfully simulated by a simple proportional controller of the phase difference angle and the stroke angle. Finally, we simulate a targeting flight by dynamically changing the stroke angle  $\beta$ ." (Authors)] Address: Inamuro,

(in English) ["Dragonflies are excellent flyers among insects and their flight ability is closely related to the architecture and material properties of their wings. The veins are main structure components of a dragonfly wing, which are found to be connected by resilin with high elasticity at some joints. A three-dimensional (3D) finite element model of dragonfly wing considering the soft vein joints is developed, with some simplifications. Passive deformation under aerodynamic loads and active flapping motion of the wing are both studied. The functions of soft vein joints in dragonfly flight are concluded. In passive deformation, the chordwise flexibility is improved by soft vein joints and the air. In active flapping, the wing rigidity in spanwise direction is maintained to achieve the required amplitude. As a result, both the passive deformation and the active control of inspire the design of biomimetic Flapping Micro Air Vehicles (FMAVs)."] (Authors)] Address: Hou, D., Dept Mechanical Engineering, Shanghai Maritime Univ., Shanghai 201306, China

**16447.** Huang, D.; Azar, D.; Cai, C.; Maksoud, S.; Nel, A.; Bechly, G. (2017): Mesomegaloprepidae, a remarkable new damselfly family (Odonata: Zygoptera) from mid-Cretaceous Burmese amber. *Cretaceous Research* 73: 1-13. (in English) ["Mesomegaloprepis magnificus gen. et sp. nov. is described from more than 14 specimens in eight pieces of mid-Cretaceous (earliest Cenomanian, ca. 99 Ma) amber from Myanmar. Possible phylogenetic affinities with the Neotropical Latibasaliidae, Thaumtoneuridae, and Pseudostigmatinae are discussed, and a relationship with Pseudostigmatinae considered as possible, but because of conflicting evidence separate family status as Mesomegaloprepidae fam. nov. is tentatively preferred. The remarkable degree of homoplastic conflict in the wing venational similarities indicates that these represent relatively weak evidence for phylogenetic relationships. The palaeoecology, including sexual dimorphism in wing colouration, of the new taxon is discussed, and the large number of inclusions explained with possible breeding behaviour in association with water-filled tree holes (phytotelmata) of the amber tree, similar to extant Pseudostigmatinae. The position of all alleged fossil Thaumtoneuridae are discussed and revised: Eothaumtoneura ptychoptera Pongracz, 1935 from the Eocene Geiseltal locality is restored in Thaumtoneuridae. Cretaceous Euarchistigma and Paleogene Eodysagrion are tentatively retained as subfamilies Euarchistigmatinae and Eodysagrioninae in Thaumtoneuridae. Paleogene Dysagrioninae and Petrolestinae are removed from Thaumtoneuridae and attributed to a restored family Dysagrionidae, and Paleocene Latibasaliidae is transferred from Amphipterygoidea to Epallagoidea." **16452.** Ioannidis, P.; Simao, F.A.; Waterhouse, R.M.; Manni, M.; Seppely, M.; Robertson, H.M.; Misof, B.; Niehuis, O.; Zdobnov, E.M. (2017): Genomic features of the damselfly *Calopteryx splendens* representing a sister clade to most insect orders. *Genome Biol Evol.* 9(2): 415-430. (in English) ["Insects comprise the most diverse and successful animal group with over one million described species that are found in almost every terrestrial and limnic habitat, with many being used as important models in genetics, ecology, and evolutionary research. Genome sequencing projects have greatly expanded the sampling of species from many insect orders, but genomic resources for species of certain insect lineages have remained relatively limited to date. To address this paucity, we sequenced the genome of *C. splendens*, a Zygoptera belonging to Palaeoptera, the clade containing the first winged insects. The 1.6 Gbp *C. splendens* draft genome assembly is one of the largest insect genomes sequenced to date and encodes a predicted set of 22,523 protein-coding genes. Comparative genomic analyses with other sequenced insects identified a relatively small repertoire of *C. splendens* detoxification genes, which could explain its previously noted sensitivity to habitat pollution. Intriguingly, this repertoire includes a cytochrome P450 gene not previously described in any insect genome. The *C. splendens* immune gene repertoire appears relatively complete and features several genes encoding novel multi-domain peptidoglycan recognition proteins. Analysis of chemosensory genes revealed the presence of both gustatory and ionotropic receptors, as well as the insect odorant receptor coreceptor gene (*OrCo*) and at least four partner odorant receptors (*ORs*). This represents the oldest known instance of a complete *OrCo/OR* system in insects, and provides the molecular underpinning for odonate olfaction. The *C. splendens* genome improves the sampling of insect lineages that diverged before the radiation of Holometabola and offers new opportunities for molecular-level evolutionary, ecological, and behavioral studies." **16453.** Ivicheva, K.N.; Philippov, D.A. (2017): Aquatic macroinvertebrates of raised bogs in the central part of the Vologda Region, Russia. *Transactions of the Karelian Research Centre of the Russian Academy of Sciences 9, Ecological Studies Series: 30-45.* (in Russian, with English summary) ["The aquatic macroinvertebrates fauna of raised bogs is considered as a complex of faunas of different types of within-bog waterbodies. This study was conducted in 2012-2014 at two large wetlands, Shichenskoe and Alekseevskoe (Vologda Region, Russia). Samples were collected from May to September from pools, spaces between hummocks of water tracks, a mire stream and two within-bog lakes. In total, 120 taxa were found (71 taxa identified to species, 25. to genus), belonging to 5 phyla, 8 classes. Insects were prevalent (91 species, among them 55. Diptera, 14. Odonata, 11. Coleoptera, 5. Trichoptera), other groups were scarce (including 12 species of Oligochaeta, 6 Hirudinea, 5 Mollusca). The greatest number of species was registered from Shichenskoe wetland. 109 species, 80 of which were found within the Shichenskiy Landscape Reserve. The

fauna was specific in each of the studied types of waterbodies. In the stream, amphibiotic insects were prevalent. In the water track, the main role belonged to oligochaetes and chironomids. In the lakes, mollusks and hirudineas were dominant. The most specific were the communities of pools, where odonates and chironomids were prevalent. The similarity between the faunas of the studied wetland waterbodies was minimal ( $K_{sc} = 0.07.0.36$ ). Analysis of the trophic structure showed that detritophagous insects were the most abundant, while predators prevailed in terms of biomass. The latter were well represented in most of the studied waterbodies, and this was a distinctive feature of within-wetland waterbodies as compared to non-mire ones. The most favourable conditions for aquatic invertebrates were found in within-bog lakes." (Authors)] Address: Ivicheva, Ksenya, L. S. Berg State Research Institute on Lake and River Fisheries, Vologda Branch, 5 Levichev St., 160012 Vologda, Russia. E-mail: ksenya.ivicheva@gmail.com

**16454.** Jacob, S.; Thomas, A.P.; Manju, E.K. (2017): Bio control efficiency of Odonata nymphs on *Aedes aegypti* larvae. *Journal of Environmental Science, Toxicology and Food Technology* 11(9): 1-4. (in English) ["The predatory potential of *Bradinopyga geminata*, *Crocothemis servilia* and *Ceriatrigon cerinorubellum* larvae on *Aedes aegypti* larvae were recorded for 8 hours with three replicates under laboratory condition to suggest biocontrol methods to get away from the spread of dengue fever. The maximum consumption rate of *B. geminata* was on 1st instar larvae of *Aedes aegypti*. *C. servilia* and *C. cerinorubellum* shows maximum consumption rate on 2nd instar larvae of *A. aegypti*. With respect to the One-way ANOVA test conducted, *B. geminata* shows highest predatory impact on all the instars of *A. aegypti*. The present study reveals that the release of odonata nymphs especially *B. geminata* in areas of dengue epidemics will effectively control the *A. aegypti* larval production and thereby dengue epidemics." **16455.** Jaggesar, A.; Shahali, H.; Mathew, A.; Yarlagadda, P.K.D.V. (2017): Bio-mimicking nano and micro-structured surface fabrication for antibacterial properties in medical implants. *Journal of Nanobiotechnology* 2017 15:64. 20 pp. (in English) ["Orthopaedic and dental implants have become a staple of the medical industry and with an ageing population and growing culture for active lifestyles, this trend is forecast to continue. In accordance with the increased demand for implants, failure rates, particularly those caused by bacterial infection, need to be reduced. The past two decades have led to developments in antibiotics and antibacterial coatings to reduce revision surgery and death rates caused by infection. The limited effectiveness of these approaches has spurred research into nano-textured surfaces, designed to mimic the bactericidal properties of some animal, plant and insect species, and their topographical features. This review discusses the surface structures of cicada, dragonfly and butterfly wings, shark skin, gecko feet, taro and lotus leaves, emphasising the relationship between nano-structures and high surface con-

tact angles on self-cleaning and bactericidal properties. Comparison of these surfaces shows large variations in structure dimension and configuration, indicating that there is no one particular surface structure that exhibits bactericidal behaviour against all types of microorganisms. Recent bio-mimicking fabrication methods are explored, finding hydrothermal synthesis to be the most commonly used technique, due to its environmentally friendly nature and relative simplicity compared to other methods. In addition, current proposed bactericidal mechanisms between bacteria cells and nano-textured surfaces are presented and discussed. These models could be improved by including additional parameters such as biological cell membrane properties, adhesion forces, bacteria dynamics and nano-structure mechanical properties. This paper lastly reviews the mechanical stability and cytotoxicity of micro and nano-structures and materials. While the future of nano-biomaterials is promising, long-term effects of micro and nano-structures in the body must be established before nano-textures can be used on orthopaedic implant surfaces as way of inhibiting bacterial adhesion." **16456.** Jentzsch, M.; Glinka, T.; Link, J.; Lehmann, B. (2017): Einsatz eines Autokeschers im Ziegelrodaer Forst – Ergebnisse und Bemerkungen zur Methode (Arachnida: Araneae, Pseudoscorpiones; Insecta: Ephemeroptera, Odonata, Hemiptera, Coleoptera, Hymenoptera, Lepidoptera, Mecoptera, Diptera). *Hercynia N.F.* 50: 31-93. (in German, with English summary) ["In the late summer of 2012 and in the early summer of 2013 the invertebrate fauna of the Ziegelrodaer Forst in the south of Saxony-Anhalt was collected by car-net. The recording of data took place three times daily on eleven days and on six different tracks especially in forest- and partially in open grassland-habitats. A total of more than 198 samples were collected. The intention was to make a contribution towards testing the car-net concerning its ability to catch invertebrates. Approximately 65.5 % of more than 200.000 captured specimens belong to the order of Diptera, followed by the order of Coleoptera with a percentage of about 17.6 %, whereas the third highest amount of about 11.6 % was determined by the order of Hymenoptera. The fourth and fifth places are taken by the order of Hemiptera at a percentage of round about 1.6 % and the class of Arachnida with approximately 0.5 %. The share of the remaining groups of species is around 0.6 %. Altogether 2.5 % of the collected material was classified as undeterminable. Additional to a huge amount of species included in the Red List of endangered animals of Germany and of Saxony-Anhalt, a total of six new records could be registered for Germany and another 18 records for Saxony-Anhalt. Four species were rediscovered in Saxony-Anhalt. Some species of different taxa are still undescribed and thus new to science. The evaluation of the collected sample material has shown that the car-net method is a valuable addition to common collection methods, it provides large amounts of individuals and species and promises the great

est success in capturing beetles and flies." Only four specimens of Odonata were captured: *Aeshna cyanea* (n=2), *Chalcolestes viridis* and *Orthetrum cancellatum*. **16459.** Kang, S.-H.; Lee, J.-E.; Hong, E.-J.; Kim, Y.-J.; Jeong, J.-C. (2017): A faunistic study of insects and arenaceous insects variation by oil spill accidents of Taeanhaean National Park. *Korean J. Environ. Ecol.* 31(6): 500-507. (in Korean, with English summary) ["The study of insect fauna in Taeanhaean National Park in Korea began with the first survey of natural resources in 1996, and then the surveys were conducted seasonally from 2005 to 2014. The surveyed sites were mostly coastal areas, sand dunes, and back grasslands. Insects were collected by sweeping with insect net, suction, pitfall trap, light trap, and Malaise trap. As a result, a total of 1,540 species of 215 families belonging to 17 orders were identified. Lepidoptera was the most populous group at 34.2% and followed by Coleoptera at 28.3%, Hemiptera at 12.7%, Diptera at 8.5%, Hymenoptera at 7.1%, Orthoptera at 4.7%, Odonata at 2.0%, and others. The analysis of change of arenaceous insect fauna before and after the accident by the Hebei Spirit that spilled oil in Taean in December 2007 showed that 45 arenaceous insect species, mostly belonging to Coleoptera, were observed through the whole survey period. The impact of oil spill on the number of arenaceous insect species appearing in the area was minor." (Authors)] Address: Jeong, J.-C., National Park Research Institute, Wonju-si, 26441, Korea. **16462.** Kassner, Z.; Ribak, G. (2017): Strategy and mechanism for intercepting unpredictable moving targets in the Blue-Tailed Damselfly (*Ischnura elegans*). *International Scholarly and Scientific Research & Innovation* 4(10): 1368. (in English) [Verbatim: "Members of the Odonata order stand out for their maneuverability and superb flight control, which allow them to catch flying prey in the air. These outstanding aerial abilities were fine-tuned during millions of years of an evolutionary arms race between Odonata and their prey, providing an attractive research model for studying the relationship between sensory input – and aerodynamic output in a flying insect. The ability to catch a maneuvering target in air is interesting not just for insect behavioral ecology and neuroethology but also for designing small and efficient robotic air vehicles. While the aerial prey interception of Anisoptera have been studied before, little is known about how Zygoptera intercept prey. Here, high-speed cameras (filming at 1000 frames per second) were used to explore how damselflies catch unpredictable targets that move through air. *I. elegans* were introduced to a flight arena and filmed while landing on moving targets that were oscillated harmonically. The insects succeeded in capturing targets that were moved with an amplitude of 6 cm and frequencies of 0-2.5 Hz (fastest mean target speed of 0.3 m s<sup>-1</sup>) and targets that were moved in 1 Hz (an average speed of 0.3 m s<sup>-1</sup>) but with an amplitude of 15 cm. To land on stationary or slow targets, damselflies either flew directly to the target, or flew sideways, up to a point in which the target

was fixed in the center of the field of view, followed by direct flight path towards the target. As the target moved in increased frequency, damselflies demonstrated an ability to track the targets while flying sideways and minimizing the changes of their body direction on the yaw axis. This was likely an attempt to keep the targets at the center of the visual field while minimizing rotational optic flow of the surrounding visual panorama. Stabilizing rotational optic flow helps in estimation of the velocity and distance of the target. These results illustrate how dynamic visual information is used by damselflies to guide them towards a maneuvering target, enabling the superb aerial hunting abilities of these insects. They also exemplifies the plasticity of the damselfly flight apparatus which enables flight in any direction, irrespective of the direction of the body." (Authors)] Address: not stated

**16463.** Kaunisto, K.; Kaunisto, P.; Ilvonen, J.; Suhonen, J. (2017): Parasitism, immune response and egg production of the damselfly *Coenagrion hastulatum*. *Canadian Journal Zoology* 95(5): 367-372. (in English) ["Theoretical models predict that parasites reduce reproductive success of their hosts, but very few empirical studies have given support to this. Using *C. hastulatum*, we tested how immune response, wing length, and the number of both endo- and ectoparasites affect egg production of host damselflies. The study was conducted with four different populations in Southwest Finland. We found a negative association between endoparasitic gregarines and the number of host eggs. Furthermore, immune response increased with the number of water mites, but decreased with the number of eggs. Contrary to previous studies with other damselfly species, the number of ectoparasitic water mites did not affect the number of eggs. Moreover, wing length, used as an indicator of individual size, was not associated with egg numbers. The negative effect of gregarine parasites on egg numbers is likely to affect the composition of host populations, i.e. damselflies that show higher resistance to these endoparasites will have more of their offspring represented in subsequent generations. In future, more experimental research on the varying effects of different parasite species on the number of eggs is needed." **16465.** Kerakova, M.; Uzunov, Y.; Varadinova, E. (2017): Comparison of trophic structure of the benthic macroinvertebrates in three Bulgarian riverine water bodies. *Turkish Journal of Zoology* 41: 267-277. (in English) ["The trophic structure of benthic macroinvertebrates in three different types of running water bodies subjected to varying degrees of anthropogenic pressure was analyzed. A seasonal survey was conducted at three Bulgarian rivers in 2011. An adapted version of the multihabitat sampling method was applied along with measuring physical and chemical variables. The ecological status was defined by means of biotic and trophic indexes. Distribution of the functional feeding groups shows that the most sensitive groups, shredders and scrapers, dominate the trophic structure of the mountain river types. In contrast, groups of deposit feeders and filterers prevail at the foothill and plain rivers. Multidimensional scaling plot and redundancy analysis demonstrated that anthropogenic impact and altitude are the main factors determining the distribution of the benthic macroinvertebrates by different functional groups. Seasonality has no leading role in the trophic structure formation of the benthic communities. Our results showed a difference between the trophic composition of the macrozoobenthos found in the mountain sections and those found in the foothill/plain stretches of the rivers. A comparison between the last two areas demonstrated that there was no clear distinction between the trophic composition of the functional feeding groups." (Authors)] Address: Kerakova, Maria, Institute of Biodiversity and Ecosystem Research, Bulgarian Academy of Science, Sofia, Bulgaria

**16466.** Khelifa, R. (2017): Partial bivoltinism and emergence patterns in the North African endemic damselfly *Calopteryx exul*: conservation implications. *African Journal of Ecology* 55(2): 145-151. (in English, with French summary) ["*C. exul* ... suffers considerable habitat degradation and local extinctions throughout its geographic range. Although recent studies have investigated its distribution, ecology and larval systematics, the life history of the species is still unknown. In this study, a field survey was conducted to determine larval development, temporal pattern of emergence and general spatial distribution of the species in the Seybouse watershed, north-east Algeria. Larval growth was investigated in two populations: one at about 200 m (low-elevation population) and the second at 600 m of elevation (high-elevation population). The species showed partial bivoltine life cycle in both low- and high-elevation population. The temporal pattern of emergence of the first flight season of the year at low-elevation population was asynchronous with an emergence season lasting 46 days and half of the population emerging in 15 days. The second flight season was shorter with a most likely smaller population size. Sex ratio at emergence was slightly male biased. After ecdysis, teneral stages stayed next to the water within a mean distance of  $4.76 \pm 4.35$  m ( $\pm$  SD) with no significant difference between sexes. Conservation measures that should be taken into account in the elaboration of future management plans for the species are discussed." (Author)] Address: Khelifa, R., Institute of Evolutionary Biology and Environmental Studies, Univ. of Zürich, 6 Winterthurerstr. 190, 8057 Zürich, Switzerland. E-mail: rassimkhelifa@gmail.com

**16467.** Khelifa, R.; Mellal, M.K. (2017): Host-plant-based restoration as a potential tool to improve conservation status of odonate specialists. *Insect Conservation and Diversity* 10(2): 151-160. (in English) ["1. Several species worldwide show rapid range retraction due to habitat degradation, and some of them have restricted distribution and specific resource needs. Such cases deserve particular attention and need urgent conservation actions to avoid extinction, and one way is to facilitate colonisation of new habitats by resource supplementation. 2. Here, we investigate the changes in range distribution, during the last decade (2007–2016), of *C. exul*, and assess the importance of its favourite host-plant (*Potamogeton nodosus*) in colonisation and population dynamics in the last existing population of Algeria. 3. We first used dynamic occupancy models to assess range distribution dynamics and we found that both occupancy and colonisation probabilities of the species were positively dependent on the occurrence of *P. nodosus*. There was also evidence that extinction probability increased with habitat disturbance but decreased with the occurrence of *P. nodosus*. Our experimental restoration showed that the augmentation of patches of *P. nodosus* increased the total number of individuals, the number of reproductive events and philopatry. 4. Our study highlights the importance of insect–plant relationship in the establishment of effective restoration plans because of their implication in colonisation and extinction processes and population dynamics. 5. Since most insect species from different orders and ecosystems are ecologically dependent on plants, our restoration approach may benefit a large range of threatened species and improve their conservation status." (2017): The influence of small hydroelectric power plants on the richness and composition of Odonata species in the Brazilian Savanna. *International Journal of Odonatology* 21(1): 33-44. (in English) ["Regardless of the economic and social development that damming processes related to hydroelectric power plants bring to a region, they represent a wide range of disturbances to the physical, chemical, and biological characteristics of rivers. We evaluated the effects of dams on Odonata communities from the southeastern region of Goiás, Brazil. 13 streams connected to three dams were studied: seven were used as reference samples (located upstream from the damming site, therefore not directly affected by damming) and six were used as affected area samples (located downstream from the dam). A total of 1128 odonates from six families, 22 genera, and 39 species were captured and identified. The results showed that Odonata richness was affected by the presence of dams, with different effects on Anisoptera and Zygoptera sub-orders. We discuss that these effects are related mostly to the physical and chemical variables in waterbodies directly affected by small hydroelectric power plants (SHPs). It is possible that negative effects on the Odonata community in SHP areas are related to changes in waterflow, pH and turbidity." **16472.** Kok, J.M.; Fatiaki, A.; Rosser, K.; Chahl, J.S.; Ogunwa, T. (2017): Dragonfly inspired MAVs - adaptive and evolutionary approaches. 17th Australian International Aerospace Congress: AIAC 2017. Melbourne, Vic.: Engineers Australia, Royal

Aeronautical Society, 2017: 129-138. (in English) ["Flapping wing flight is complex and has not been solved well enough in any technological system to meet any realistic mission requirements. This raises the question as to the value of flapping wing flight for unmanned aerial vehicles (UAV), and begs reasonable questions about the value of research into the topic. Flapping wings will continue to strive to be as efficient as rotary wing craft, with over-actuation. The justification for flapping wing flight is that a flapping wing craft can approach rotary wing hover efficiency while also being capable of efficient cruise of a fixed wing craft. In this paper, we discuss the existing Micro Air Vehicle (MAV) configurations and the pros and cons of each. We review the hybrid fixed wing, rotary wing configurations and present an argument against its use in addressing the MAV design gap. Key characteristics of the dragonfly were analysed and necessary degrees of freedom for the wing kinematics were identified. We reviewed high speed cinematography of existing systems to determine the range of motion of the dragonfly. We observe large variations between different species suggesting that the ideal wing kinematics are specific to the system. We present a case for adaptive learning and identify existing methods that have been applied to real world experimental systems. We also present a method for efficiently coevolving controller and morphological parameters that uses virtual design supplemented with experimental results from hardware." **16478.** Koneri, R.; Nangoy, M.J.; Saroyo; Tallei, T.E. (2017): Diversity and community composition of dragonfly (Insecta: Odonata) in Tangkoko, Nature Reserve, North Sulawesi, Indonesia. *Bioscience Research* 14(1): 1-8. (in English) ["Analysis of dragonfly diversity is one of the important factors in supporting species conservation. This study was aimed to assess community composition and diversity of dragonfly in the area of Tangkoko Nature Reserve, North Sulawesi. Sampling was carried out along the river in three habitat types. Dragonfly collection was done by a sweeping technique along four transect lines that were applied randomly along 1000 m in every type of habitat. Data analysis included species abundance, richness, diversity and evenness among habitats. The result showed that In these three habitats there were six families, 13 genera, 15 species and 1557 individuals. Family Libellulidae was the most common type of species. The family with the most abundance was Coenagrionidae, while the family with least abundance was Platystictidae. Species with the highest number of individuals was *Pseudagrion* sp and the lowest number was *Pantala flavescens*. The highest abundance and richness of species were found on agricultural land and

the lowest was in primary forest. The highest species diversity and evenness were found in primary forest and the lowest was in secondary forests. The highest diversity of dragonflies in all types of habitats was found in primary forest."] Address: Koneri, R., Dept Biology, Fac. Mathematics and Natural Sciences, Sam Ratulangi Univ., Kampus Bahu Street, Manado, 95115 Indonesia. E-mail: [ronicaniago@unsrat.ac.id](mailto:ronicaniago@unsrat.ac.id)

**16479.** Koroiva, R.; Kvist, S. (2017): Estimating the barcoding gap in a global dataset of *cox1* sequences for Odonata: close, but no cigar. *Mitochondrial DNA Part A* 29(5): 765-771. (in English) ["We evaluated the extent of intraspecific and interspecific genetic distances for two highly diverse infraorders of Odonata: Anisoptera and Zygoptera. All cytochrome c oxidase subunit I sequences (*cox1*), the region chosen for zoological DNA barcoding, present in GenBank for each infraorder were downloaded and curated. For Anisoptera, the final dataset consisted of 2,961 individual *cox1* sequences for 536 species and the equivalent numbers for Zygoptera were 2,477 sequences for 497 species. More than 7 million individual genetic comparisons were made and the results indicated that there is a tendency towards a barcoding gap, but that the size of the gap may not be sufficient to robustly infer identities for some taxa. DNA barcoding may be of less use for some odonate taxa, perhaps pertaining to misidentifications in global databases. However, at local scales or with more confined taxonomical sampling, this tool may yet be beneficial in identifying these charismatic organisms." (Authors)] Address: Koroiva, R., Ecology and Conservation Graduate Program, Univ. Federal de Mato Grosso do Sul, Campo Grande, Mato Grosso do Sul, Brazil. **16483.** Kosterin, O.E. (2017): A short survey of Odonata in Stung Treng Province in northern Cambodia in mid-summer 2016. *IDF-Report* 105: 1-40. (in English) ["Results are presented of an odonatological survey of 23 localities in Thala Barivat District of Stung Treng Province, northern Cambodia, on July 26 – August 1, 2016. Most localities were situated in areas of open low deciduous dipterocarp forests on gravel soils, some at hillside areas of tall evergreen dipterocarp forest. The great Mekong River right bank was studied within 7 km downstream of its Nimeth (Nimet, Khon Thai, Labak Koun, Khone Pha Pheng) Waterfall. In total, 55 species were found, of which 52 identified to species and three to genus. Two species, *Gynacantha saltatrix* Martin, 1909 and *Macrogomphus matsukii* Asahina, 1986, were recorded in Cambodia for the first time. Five obligatory lotic species were found at the Mekong River, namely *Dysphaea gloriosa*, *Prodasineura coerulescens*, *Burmagomphus asahinai*, *Nychogomphus duaricus* and *Onychothemis testacea*, including tenerals of *P. coerulescens* and *B. asahinai*. Most probably these species breed in the Mekong reach which is enriched with oxygen downstream of the great waterfall cascade." **16488.** Kulijer, D.; Miljevic, I. (2017): Dragonfly (Odonata) fauna of the Zelengora Mountain and Sutjeska National Park. *Glasnik Šumarskog fakulteta Univerziteta u Banjoj Luci* 26: 23-39. (in Croatian, with English summary) ["High mountain habitats of Bosnia and Herzegovina are often isolated and difficult to access. That is why to this day, the dragonfly fauna of the mountain region in BiH remained almost entirely unexplored. The aim of this study was to present the first overview of the dragonfly fauna of Zelengora Mt. and the National Park Sutjeska, the area which includes some of the most important habitats of these insects in the country. This paper is a result of the authors' research combined with the analysis of existing data. The dragonfly fauna of Zelengora Mt. and NP Sutjeska consists of a total of 35 species, representing 55% of the fauna of this insect order in BiH. Together with data obtained with the studies in 2015 and 2016, this paper also includes unpublished data collected by the authors between 2009 and 2014, literature data and the data from the collections of the National Museum of Bosnia and Herzegovina. A total of 457 records from 53 sites were collected and over 76% of these represent new data. According to the number of sites inhabited by a single species, the most numerous are: *Cordulegaster bidentata* (recorded at 26 sites), *Cordulia aenea* (23 sites), *Aeshna grandis* (15 sites), *Libellula quadrimaculata* (15 sites) and *Enallagma cyathigerum* (14 sites). The following localities were inhabited by the highest number of species: Orlovačko Lake (22 species), Gornje Bare Lake (20 species) and Donje Bare Lake (19 species), where also the highest number of threatened and endangered species was recorded. The most important recorded species were:

*Coenagrion scitulum*, *C. hastulatum*, *A. grandis*, *A. juncea*, *Somatochlora*, *Cordulegaster heros*, *C. bidentata* and *Sympetrum flaveolum*. For relict species *C. hastulatum* and *S. metallica*, mountain lakes of Zelengora Mt. are the only known habitat in Bosnia and Herzegovina so far. Additionally, these lakes were determined as the most important habitats in the country for *A. grandis* and *A. juncea*. Among the registered species, 30 species are included in the Red list of protected species in Republic of Srpska. Additionally, we have recorded all three dragonfly species listed on the Red list of the Federation of Bosnia and Herzegovina. Moreover, *C. heros* is listed in Annexes II and IV of the Habitats Directive of the European Union and as vulnerable (VU) species on the Mediterranean Red list." (Authors)] Address: Kulijer, D., Zemaljski muzej Bosne i Hercegovine, Zmaja od Bosne 3, 71000 Sarajevo, Bosnia i Hercegovina. E-mail: dejan.kulijer@gmail.com

**16491.** Kuznetsova, V.G.; Maryanska-Nadachowska, A.; Shapoval, N.A.; Anokhin, B.A.; Shapoval, A.P. (2017): Cytogenetic characterization of eight Odonata species originating from the Curonian Spit (the Baltic Sea, Russia) using c-banding and FISH with 18S rDNA and telomeric (TTAGG)<sub>n</sub> probes. *Cytogenet Genome Res* 153: 147-157. (in English) ["We studied the karyotypes of 8 dragonfly species originating from the Curonian Spit (the Baltic Sea, Russia) using C-banding and FISH with 18S rDNA and "insect" telomeric (TTAGG)<sub>n</sub> probes. Our results show that *Leucorrhinia rubicunda*, *Libellula depressa*, *L. quadrimaculata*, *Orthetrum cancellatum*, *Sympetrum danae*, and *S. vulgatum* from the family Libellulidae, as well as *Cordulia aenea* and *Epithecina bimaculata* from the family Corduliidae share  $2n = 25 (24 + X)$  in males, with a minute pair of m-chromosomes being present in every karyotype except for that of *C. aenea*. Major rDNA clusters are located on one of the large pairs of autosomes in all the species. No hybridization signals were obtained by FISH with the (TTAGG)<sub>n</sub> probe in the examined

species with the only exception of *S. vulgatum*. In this species, clear signals were detected at the ends of almost all chromosomes. This finding raises the possibility that in Odonata the canonical "insect" (TTAGG)<sub>n</sub> telomeric repeat is in fact present but in very low copy number and is consequently difficult to detect by in situ hybridization. We conclude that more work needs to be done to answer questions about the organization of telomeres in this very ancient and thus phylogenetically important insect order." (Authors) Dragonflies were collected from April 1 to October 26, 2016, on the Curonian Spit, 12 km S of Rybachy village, at the field station Fringilla (55°05' N, 20°44' E) belonging to the Biological Station of the Zoological Institute, Russian Academy of Sciences, and in some other localities of the Curonian Spit.] Address: Kuznetsova, Valentina, Dept of Karyosystematics, Zool. Inst., Russian Acad. Sci., Universitetskaya nab. 1, 199034 St. Petersburg, Russia. E-mail: valentina\_kuznetsova@yahoo.com

**16492.** Leandri, F. (2017): Contributo alla conoscenza dell'odonatofauna del Parco Nazionale Dolomiti Bellunesi (Dolomiti, Veneto). Frammenti Conocere e tutelare la natura Bellunese 7: 5-16. (in Italian, with English summary) ["This work surveyed dragonfly population in the Dolomiti Bellunesi National Park. Since dragonflies are hemimetabolic insects whose larval stages are linked to aquatic environments, the investigation took place in both lotic and lentic habitat within the Park or in nearby locations. The Dolomiti Bellunesi National Park is located in the Belluno province (North-Eastern Italy) and belongs to the Alpine Biogeographical Region. The park encompasses medium and high mountain habitat in the Southern portion of the Dolomites mountain range. A total of 25 species have been recorded (9 zygoterans, 16 anisopterans), 13 of which within the boundaries of the park. The most common species were *Cordulegaster bidentata*, which finds its natural habitat in streams in hilly and mountain areas, and *Aeshna cyanea*, a common species of wide ecological niche. Two wetland areas outside the Park host species rated as "near threatened" by the IUCN Red List of Italian dragonflies. Such sites are the Vedana lake, which hosts 17 species (including *Cordulia aenea*) and the Prà Toront peat bog, which hosts the alpine and peat bogs species *Somatochlora arctica*." **16493.** Leaphart, J.C., Zelmer, D.A. (2017): Wrecking the curve: Altered functional response of *Tetragoneuria* (Odonata: Corduliidae) naiads infected with metacercariae of *Haematoloechus floedae*. *Journal of Parasitology* 103(2): 147-151. (in English) ["The ubiquity of host-parasite interactions and their potential for substantial representation, in terms of overall biomass, within ecosystems suggests that parasites have the capacity to influence energy flow within an ecosystem. Although the influence of certain parasites on prey behavior has been well documented, parasites could also exert an influence on ecosystem dynamics by influencing predator feeding behavior. The functional response of *Tetragoneuria* naiads was characterized by presenting naiads with varying abundances of *Daphnia magna*, after which a subset of the naiads were exposed to cercariae of *Haematoloechus floedae*, and

the feeding trials repeated for both the control and exposed odonates. A type II functional response was chosen as an appropriate model for comparison. An indicator variable approach to nonlinear regression of the functional response data indicated that infected odonate naiads spent significantly more time foraging than they did before infection, whereas there was no significant change in the functional response of the control naiads. Infected odonates also had a slower rate of growth. These results imply a metabolic cost to infection of *Tetragoneuria* naiads by *H. floedae* that might be associated with the encapsulating response to the metacercariae that was observed in infected naiads." (Authors)] Address: Zelmer, D.A., Dept of Biology and Geology, University of South Carolina Aiken, Aiken, South Carolina 29801. USA. E-mail: derekz@usca.edu

**16494.** Leksono, A.S.; Feriwibisono, B.; Arifianto, T.; Pratama, A.F. (2017): The abundance and diversity of Odonata along an altitudinal gradient in East Java, Indonesia. *Entomological Research* 47(4): 248-255. (in English) ["Odonate diversity in East Java was surveyed, and samplings were made during 2 years in ten sites along an altitudinal gradient. The characteristics of odonate assemblages in East Java were analyzed regarding of the number of individuals, the number of species, and Shannon's diversity index. The differences in abundance, species richness, and diversity between study sites were analyzed by an independent t-test. There were 3270 individuals of Odonata belong to 30 species, 7 families and 2 suborders identified from all study sites. The abundance, species richness and diversity of Odonata varied between study sites. The greatest abundance of Odonata was found in Malang Coban Talun (MCT) ( $148.8 \pm 9.5$ ), while the lowest was in South Beach Forest (SBF) ( $14.4 \pm 3.6$ ). The highest species richness and diversity was found in Malang Paddy Field (MPF) (richness =  $14.4 \pm 0.8$  and  $H' = 2.4 \pm 0.1$ ), while the lowest was found in South Coastal Area (SCA) (richness =  $2.8 \pm 0.1$  and  $H' = 0.4 \pm 0.1$ ). A significant positive correlation was detected between the elevation and overall odonate abundance ( $P < 0.05$ ), while there was not significant correlation between that and odonate species richness and diversity." **16497.** López Colón, J.I.; Ceballos Escalera, J.M.; López Nieva, P.; Olivares Pantoja, A. (2017): Presencia de *Coenagrion mercuriale* (Charpentier, 1840) en la Zona Especial de Conservación (ZEC) Vegas, cuevas y páramos del sureste de Madrid (Odonata: Zygoptera: Coenagrionidae) (Comunidad Autónoma de Madrid, España). *Archivos Entomológicos* 17: 411-422. (in Spanish, with English summary) ["*C. mercuriale* is a dragonfly included in the Annex II of the Habitat Directive (92/43/EEC) with "Almost threatened" species status by IUCN which populations are declining alarmingly in recent decades. Its effective protection in Spain requires the development of research projects to determine the exact location of its populations and the life cycle and ecology in the different areas where it lives. In this case, the study of a Special Area of Conservation (SAC) in the Autonomous Community of Madrid has been carried out." (Authors)] Address: E-mail: lopezicolon@gmail.com

**16498.** López-González, B.; Quiroz-González, I.H.; Fabela, M.; Medina, G.T.; González, B.E.; Martínez, H.Q. (2017): Calidad del agua de tres sistemas acuáticos con insectos como modelo de estudio en la región fronteriza México – Estados Unidos de América con el enfoque al control de las descargas de aguas residuales. *Bol. Soc. Mex. Ento. (n.s.) Número especial* 3: 27-32. (in Spanish, with English summary) ["Water quality of three aquatic systems with insects as a study model in the border region Mexico-United States of America with the approach to the control of residual water discharges: Sampling was carried out in the Álamo River, Río Bravo and Río San Juan located in the US - Mexico border area to determine water quality based on aquatic macroinvertebrates, such as insects. To determine water quality, the data were analyzed using the Shannon-Wiener index and the Margalef index. In addition, to determine the ecological status of rivers based on diversity, richness and abundance of aquatic insects was used the index of species richness and the EPT index that considers groups of insects susceptible to drastic changes Ephemeroptera, Plecoptera and Trichoptera. The results of the analysis showed that the San Juan River presented the lowest values in the indexes used, categorized as severely impacted, with low diversity and poor water quality, unlike the Río Álamo that presented higher values in the indexes with a quality of moderate water. The main findings in the monitoring stations are aquatic insects of the orders: Ephemeroptera, Odonata, Hemiptera, Trichoptera, Diptera, Lepidoptera and Megaloptera, being presented greater abundance of Ephemeroptera." **16499.** Lorenzo-Carballa, M.O.; Hassall, C.; Encalada, A.C.; Sanmartín-Villar, I.; Torres-Cambas, Y.; Cordero-Rivera, A. (2017): Parthenogenesis did not consistently evolve in insular populations of *Ischnura hastata* (Odonata, Coenagrionidae). *Ecological Entomology* 42: 67-76. (in English) ["1. The evolutionary advantages that have driven the evolution of sex are still very much debated, and a number of benefits of parthenogenesis over sexual reproduction have been proposed. In particular, parthenogenetic individuals are thought to exhibit higher probabilities of establishment following arrival in new, isolated habitats such as islands. 2. One notable example of parthenogenesis occurring in islands is *I. hastata*, an American species that has colonised the Azores archipelago, where the populations consist only of females. This is the only known example of parthenogenesis within the insect order Odonata. 3. Here, two island populations of *I. hastata* were studied, one in the Galapagos and one in Cuba, to test whether island colonisation is consistently associated with parthenogenesis in this species. Field capture–mark–recapture studies and laboratory rearing of field-collected eggs were undertaken in both areas. 4. Sex ratios in the field were found to be heavily female-biased among mature individuals; however, fertility rates of field-collected eggs were high, and the sex ratios in the laboratory did not differ from 1:1. Data from laboratory rearing showed that shorter larval development times and shorter adult life spans in males result in protandry, which might explain the skewed sex ratios in the field. 5. These findings are consistent with sex differences in key demographic parameters which could predispose *I. hastata* to parthenogenesis. However, the Azores population of *I. hastata* remains the only documented case of asexual reproduction in this insect group." (2017): Pleistocene demographic expansion and high gene flow in the Globe Skimmer dragonfly *Pantala flavescens* Fabricius (Odonata: Libellulidae) in Peninsular Malaysia. *Zoologischer Anzeiger - A Journal of Comparative Zoology* 266: 23-27. (in English) ["The demographic history, population structure, and intraspecific diversity of *P. flavescens* in Peninsular Malaysia were characterized based on variation of the mitochondria-encoded cytochrome c oxidase subunit I (COI) sequences. A median-joining network of 94 taxa inferred 71 unique haplotypes across four distinct geographic regions (i.e., northern, southern, central, and eastern). The distribution of these haplotypes, however, revealed no apparent geographical pattern, indicating minimal population genetic structure and high gene flow among all populations. A Mantel test showed an absence of isolation by distance (IBD), no significant association between genetic dis-

tance and geographic distance was observed. Mismatch distribution and neutrality tests provided evidence of demographic expansion during the Pleistocene dating back to 190,000–260,000 years ago. Additionally, species delimitation analyses revealed two operational taxonomic units (OTUs) within so-called *P. flavescens*, one restricted to the isolate from Korea; and the other representing isolates from Malaysia, Japan, and India. The present DNA analyses reflect the impact of the Quaternary glaciation in shaping the current genetic diversity and genetic structure of *P. flavescens* in Peninsular Malaysia." **16502.** Maes, D.; Adriaens, D.; van der Meulen, M.; Poelmans, L.; Vandeghechuchte, M.; Everaert, J.; Verhaeghe, F.; Anselin, A.; Casaer, J.; Decler, K.; De Knijf, G.; Devos, K.; Engelen, G.; Gouwy, J.; Packet, J.; Stienen, E.; Stuyck, J.; Thomaes, A.; T'jollyn, F.; Speybroeck, J.; Van Den Berge, K.; Van Elegem, B.; Van Landuyt, W.; Vermeersch, G.; Wils, C.; Pollet, M. (2017): Potentially suitable habitat maps for threatened species. Possible applications for nature conservation policy and management in Flanders. *Natuur.focus* 16(2): 56-66. (in Dutch, with English summary) ["Nature policy and management often uses threatened and regionally important species as tools or goals. Knowledge about their ecology and distribution is, therefore, crucial to scientifically underpin conservation measures. Apart from known observations, sites where the focal species is not (yet) observed or sites where potentially suitable ecological conditions are available but that are out of its dispersal range are as important to conserve and manage since they might get colonised in the future or might serve as possible reintroduction sites. To determine potentially suitable sites in an evidence-based approach, we here use so-called mechanistic models that describe the ecological needs of species in a quantitative manner. Subsequently we use a GeoDynamix tool to translate these criteria into a very high resolution map (20 x 20 m) with clusters of grid cells indicating potentially suitable habitats for a given species. These maps are then validated using existing observations and, if necessary, corrected in an iterative way to maximally match the known distribution to the obtained suitability map. We give an example of this method using *Dolomedes fimbriatus*, a species of regional conservation importance. Several possible applications of delineating potentially suitable habitat maps are given: (1) directing people to the most probable sites

when looking for a species for which the distribution is not well known, (2) locating sites where nature management is most appropriate, (3) locating possible reintroduction sites with the highest amount of suitable habitat, (4) locating sites that have a high suitability for a high number of species can underpin the delineation of nature reserves or Natura2000 areas, (5) the tool is able to select the best option for increasing the area of potentially suitable habitats by including the maps of the different potential scenarios and calculating their impact and (6) locating priority sites for defragmentation of the landscape, especially for larger mammals." **16505.** Mandal, R.; Aditya, S. (2017): An observation on the Odonata diversity in and around Sarojini Naidu College campus, Kolkata, West Bengal, India. *International Journal of Entomology Research* 2(4): 31-34. (in English) ["Odonates play vital role in environmental monitoring and can be used as biological indicators of ecological health. The present investigation was undertaken as a pilot study to study the diversity and abundance of Odonata in Sarojini Naidu College campus, Kolkata, West Bengal, India. A combination of direct search and opportunistic sighting methods were applied to record 23 different Odonata species (18 dragonflies and 5 damselflies) from the study area during May, 2015 to April, 2016. In spite of the college campus being located in an industrial urban area, the present study revealed a striking diversity of odonates. A suitable geographic location, favourable climatic conditions, appropriate vegetation provided a comfortable shelter for Odonata species to flourish in this area. This study is aimed towards contributing to the plan of

biodiversity restoration in our campus and development of management strategies for conservation of this important group of insects." (Authors)] Address: Mandal, Ritu, Dept of Zoology, Sarojini Naidu College for Women, 30, Jessore Road, Dum Dum, Kolkata, West Bengal, India

**16506.** Manger, R. (2017): Behaviour of a female *Sympecma paedisca* during hibernation in the Netherlands. *Brachytron* 19(2): 104-113. (in Dutch, with English summary) ["A female *S. paedisca* has been studied for over three months in the winter, on a heathland in southwest Drenthe. Perching and roosting heights and movements were studied during this period. The weather conditions during this winter were normal for Dutch standards with 34 frost days and seven ice days. From the beginning of December 2016 a female *S. paedisca* stayed for 92 days within a range of about half a square meter. When it was cloudy or raining and the temperature was below five degrees for days, the damselfly remained at one place and moved only a few centimeters on these days. A few times, as the days became longer and the sun gained more power, the female moved a few centimeters. During one visit in the dark, she had not crawled down for extra shelter, but even stayed a little higher. It has been found that this winter damsel only traveled over distances > 10 cm when there was enough solar heat." (Author)] Address: Manger, R., Stoepveldsingel 55, 9403 SM Assen. The Netherlands. **16507.** Mansoor, R. (2017): Do herbicide effects on Odonata larvae, depend on their location of origin?: An ecotoxicological study using Glyphosate. Independent thesis Advanced level (degree of Master), Halmstad University, School of Business, Engineering and Science: 22 pp. (in English) ["Concentrations of herbicides in our aquatic ecosystems increase more and more. Among these, the herbicide glyphosate is the most common one. This ecotoxicological study was performed in order to examine the toxic effect of the herbicide glyphosate on aquatic invertebrates. Odonata were selected as study organisms in order to serve as bio-indicators of environmental contamination. Two populations, each of two species (*Erythromma najas* and *Libellula quadrimaculata*) were collected from four different locations, to study inter-specific differences, as well as, differences among populations within a species, in response to herbicide exposure. The experiment was conducted for 15 days in a 2 x 4 factorial design with 4 replicates (n = 32). The most common brand of weed-killer 'Roundup' containing 7.2 gL<sup>-1</sup> of glyphosate) was used as source of glyphosate. Glyphosate was applied at a concentration of 7.6 mgL<sup>-1</sup> in the experiment equalling the high end of environmentally relevant concentrations of glyphosate present in contaminated shallow waters. Response variables measured were larval survival, growth and activity. The results showed that glyphosate exposure reduced the survival of the larvae, but the magnitude of the glyphosate effects depended on species identity of the larvae and varied also with population within species. This study clearly shows that herbicide effects on invertebrate fitness depends on species identity and may even vary within species from different populations, possibly due to evolved resistance of random

genetic variations between populations or due to random genetic variation between populations." (Author)] Address: Mansoor, Ramla, Halmstad University, School of Business, Engineering and Science

**16508.** Marinov, M.; Campbell-Snelling, J.; Marinova, S. (2017): On a probable new oviposition style in female *Antipodochlora braueri* (Odonata: Corduliidae). *Agrion* 21(2): 72-75. (in English) ["Short investigations of known localities of *A. braueri* revealed a behaviour that is considered hitherto to be unrecorded for the species. Female *A. braueri* has usually been reported laying eggs in instream pools of water bodies. During the current study one adult was observed performing movements towards the water surface typical of ovipositing females and therefore considered as probable egg-laying behaviour. The utilised habitat was a small remnant pool completely isolated from other sections of the stream. Since the two sexes of *A. braueri* are morphologically very close, sex determination is preferably achieved in the hand. As the reported adult here was not caught and its sex confirmed the oviposition habitat choice remains to be validated by further observations." **16509.** Markovic, D.; Carrizo, S.F.; Kärcher, O.; Walz, A.; David, J.W. (2017): Vulnerability of European freshwater catchments to climate change. *Global Change Biology* 23: 3567-3580. (in English) ["Climate change is expected to exacerbate the current threats to freshwater ecosystems, yet multifaceted studies on the potential impacts of climate change on freshwater biodiversity at scales that inform management planning are lacking. The aim of this study was to fill this void through the development of a novel framework for assessing climate change vulnerability tailored to freshwater ecosystems. The three dimensions of climate change vulnerability are as follows: (i) exposure to climate change, (ii) sensitivity to altered environmental conditions and (iii) resilience potential. Our vulnerability framework includes 1685 freshwater species of plants, fishes, molluscs, odonates, amphibians, crayfish and turtles alongside key features within and between catchments, such as topography and connectivity. Several methodologies were used to combine these dimensions across a variety of future climate change models and scenarios. The resulting indices were overlaid to assess the vulnerability of European freshwater ecosystems at the catchment scale (18 783 catchments). The Balkan Lakes Ohrid and Prespa and Mediterranean islands emerge as most vulnerable to climate change. For the 2030s, we showed a consensus among the applied methods whereby up to 573 lake and river catchments are highly vulnerable to climate change. The anthropogenic disruption of hydrological habitat connectivity by dams is the major factor reducing climate change resilience. A gap analysis demonstrated that the current European protected area network covers <25% of the most vulnerable catchments. Practical steps need to be taken to ensure the persistence of freshwater biodiversity under climate change. Priority should be placed on enhancing stakeholder cooperation at the major

basin scale towards preventing further degradation of freshwater ecosystems and maintaining connectivity among catchments. The catchments identified as most vulnerable to climate change provide preliminary targets for development of climate change conservation management and mitigation strategies." **16517.** Mendes, T.P.; Oliveira-Junior, J.M.B.; Cabette, H.S.R.; Batista, J.D.; Juen, L. (2017): Congruence and the biomonitoring of aquatic ecosystems: Are odonate larvae or adults the most effective for the evaluation of impacts? *Neotropical Entomology* 46(6): 631-641. (in English) ["Odonata have been widely used as indicators for the biomonitoring of terrestrial and aquatic habitats due to their sensitivity to environmental impacts. We aimed to determine whether the larval or adult phases of these insects were the best predictors of variation in habitat parameters and the loss of environmental integrity. Specimens were collected during three seasons (dry, rainy, and ebb) from 12 points in the Suiá-missu River basin, at the headwaters of the Xingu River in Mato Grosso, Brazil. The Protest analysis indicated a high degree of congruence between the assemblages of larvae and adults in streams with varying degrees of habitat integrity ( $R = 0.832$ ,  $p < 0.001$ ,  $m^2 = 0.307$ ). When the congruence with environmental factors was analyzed, a significant association was found only for the larval phase ( $R = 0.318$ ,  $p = 0.03$ ,  $m^2 = 0.888$ ). When the suborders were analyzed separately, congruence was confirmed for anisopteran adults ( $R = 0.338$ ,  $p = 0.031$ ,  $m^2 = 0.885$ ) and larvae ( $R = 0.417$ ,  $p = 0.003$ ,  $m^2 = 0.826$ ) and for the zygopteran adults ( $R = 0.345$ ,  $p = 0.027$ ,  $m^2 = 0.881$ ) and larvae ( $R = 0.405$ ,  $p = 0.011$ ,  $m^2 = 0.836$ ). These results indicate that both larvae and adults respond systematically to environmental impacts. We suggest that either life phase can be used for biomonitoring, given their effectiveness for the interpretation of disturbance in terrestrial and aquatic habitats. These findings further reinforce the effectiveness of this insect order for the detection of modifications to the environment, showing that they are good indicators of environmental conditions." MSc. thesis, Tebessi University: 65 pp. (in French, with Arabian and English summary) ["From a systematic research perspective and of conservation of biodiversity. We have undertaken to improve our knowledge of wild life of the Algerian freshwater macroinvertebrates. Indeed, 8 species belonging to 4 families of Odonates have been identified in two stations in river (Oued Mellegue) of a region called El-Aouinet in the extreme east of Algeria with a considerable domination of Zygoptera with two species *Ischnura graellsii* 52,45% and *I. pumilio* 26,77%. Our research that focuses on inventory and the bioecology is a contribution of the update of the Odonata fauna used as bioindicators of aquatic environments in a semiarid bioclimatic. The same, their presence is therefore

a sure index of the faunistic. Whoever translates by weakness diversity with  $H' > 1.65$  bits and average equilibrium with  $E > 0, 50$ ." (Author)] Address: not stated

**16519.** Mikó, Z.; Ujszegi, J.; Gál, Z.; Hettyey, A. (2017): Effects of a glyphosate-based herbicide and predation threat on the behaviour of agile frog tadpoles. *Ecotoxicology and Environmental Safety* 140: 96-102. (in English) ["Highlights: •Glyphosate-based herbicides can cause behavioural changes in non-target organisms. •We found decreased activity and increased hiding at higher herbicide concentration. •At lower concentration tadpoles tend to move closer to the surface. •We did not find interactive effects of predation threat and herbicide exposure. •Examine behavioural changes effected by contaminants may relevant in ecotoxicology. Abstract: The widespread application of pesticides emphasises the importance of understanding the impacts of these chemicals on natural communities. The most commonly applied broad-spectrum herbicides in the world are glyphosate-based herbicides, which have been suggested to induce significant behavioural changes in non-target organisms even at low environmental concentrations. To scrutinize the behavioural effects of herbicide-exposure we exposed agile frog (*Rana dalmatina*) tadpoles in an outdoor mesocosm experiment to three concentrations of a glyphosate-based herbicide (0, 2 and 6.5 mg acid equivalent (a.e.) / L). To assess whether anti-predator behaviour is affected by the pesticide, we combined all levels of herbicide-exposure with three predator treatments (no predator, caged *Aeshna cyanea* dragonfly larvae or *Lissotriton vulgaris* newt adults) in a full factorial design. We observed hiding, activity, proximity to the predator cage and vertical position of tadpoles. We found that at the higher herbicide concentration tadpoles decreased their activity and more tadpoles were hiding, and at least at the lower concentration their vertical position was closer to the water surface than in tadpoles of the control treatment. Tadpoles also decreased their activity in the presence of dragonfly larvae, but did not hide more in response to either predator, nor did tadpoles avoid predators spatially. Further, exposure to the herbicide did not significantly influence behavioural responses to predation threat. Our study documents a definite influence of glyphosate-based herbicides on the behaviour of agile frog tadpoles and indicates that some of these changes are similar to those induced by dangerous predators. This may suggest that the underlying physiological mechanisms or the adaptive value of behavioural changes may similar." **16520.** Mikolajczuk, P. (2017): Mobility of imagines of *Nehalennia speciosa* (CHARPENTIER, 1840) (Odonata: Coenagrionidae): observations of dispersal behavior. *Odonatrix* 132: 4 pp. (in Polish, with English summary) ["Imagines of *N. speciosa* are considered as low mobile due to: 1) their small size and delicate body build; 2) strong attachment to narrow-leaved vegetation in a breeding habitat, within which

they fly at short distances; 3) infrequent observations outside of a breeding habitat; 4) results of mark-release-recapture studies. However, colonization of new habitats and less often adults' presence in unsuitable habitats are regularly reported. Flights, which may be related to colonization haven't been described so far. In the year 2014, several types of long-distance flights were observed at two acidic fens in Poland (Fig. 1). The flights occurred only at evening – after 18:30 CEST, as soon as surface of fens began shaded, with temperature more than 16 °C. The observations show that imagines of *N. speciosa* may actively relocate outside of vegetation at a breeding site and rise actively towards the air space above. Flight type D and E seem to lead to final leave of a site inhabited so far. In further part of flights D and E types, imagines may use air streams. Supposedly, flights related to search for new habitats, may have rather long-distance character, during which imagines observe terrain from a height and fall on suitable places. Occurrence of the dispersal behavior at evening may be related to avoidance of predation, especially by other odonates, which activity significantly decrease at evening." (Author)] Address: Mikolajczuk, P., ul. Partyzantów 59c/26, 21-560 Miedzyrzec, Poland. E-mail: gugapm@wp.pl

**16521.** Miller, E.; Miller, J. (2017): Zur Überwinterung von *Sympetma fusca* im bayerischen Alpenvorland (Odonata: Libellulidae). *Mercuriale* 17: 67-71. (in German, with English summary) ["Hibernation of *S. fusca* in the prealpine area of Bavaria - From 2005 to 2017, we observed the hibernation behaviour of *S. fusca*. The individuals left the developmental water during autumn by stages. During winter they perched at stems of different herbs, grasses and woody plants in a forest clearing. This behavior appears to assure the highest chance of surviving the humid winter climate of the prealpine area. We discuss an alternative hibernation mode hidden under leaf litter, which we consider impossible in our study area." (Authors)] Address: Miller, Elfi, Leharstr. 6c, 86179 Augsburg, Germany

**16522.** Minot, M.; Gaschignard, D. (2017): *Micrathyria wasscheri* sp. nov. from the coastal savannahs of French Guiana (Odonata: Libellulidae). *Odonatologica* 46(3/4): 287-300. (in English) ["On July 2014, a teneral specimen of an unknown *Micrathyria* species was found during the survey of an open marsh in Trou-Poissons in the coastal savannah of French Guiana. Further specimens were subsequently collected at the same place and at two other localities in Kourou and Macouria. The male and female of this new species are described here. *M. wasscheri* sp. nov. seems to depend on open marshes vegetated with *Eleocharis intersincta* (Cyperaceae), which constitute a very specific ecosystem of limited extent. This discovery highlights biodiversity issues in the coastal marshlands ("pri-pri"), which are currently threatened by demographic trends." **16528.** Mochon, A. (2017): Une odonatofaune inusitée à la tourbière du parc national de Frontenac. *Le Naturaliste canadien* 141(2): 26-41. (in French, with English summary) ["Odonata were surveyed in the string fen of the Frontenac National Park, situated in the mixed temperate zone of the Appalachian region of southern Québec (Canada). This fen biotope, considered exceptional due to its ecological uniqueness and southern location, was surveyed 22 times from 2014 to 2016, covering the full flight period of the study taxa. Hundreds of adult specimens and exuvia were collected, which together with behavioral observations of adults, served to rate species abundance and to establish which were resident. The fen hosts a unique community of at least 52 odonate species (22 common, 11 occasional and 19 accidental). In total, 33 were proven or considered likely to have resident populations. The ranges of 21 species show a clear northern affinity, with some likely being relic populations in the biogeographic context of the fen, such as *Somatochlora brevicincta*, which until recently, had never been observed south of the St. Lawrence River. Discoveries included 4 threatened or endangered species: *Gomphaeschna furcillata*, *Williamsonia fletcheri*, *S. brevicincta* and *Nannothemis bella*; and 3 species that have recently expanded into Québec: *Enallagma anna*, *E. civile* and *Libellula semifasciata*." (Author)] Address: Mochon, A.; E-mail: mochon.alain@sepaq.com

**16529.** Modiba, R.V.; Joseph, G.S.; Seymour, C.L.; Fouché, P.; Foord, S.H. (2017): Restoration of riparian systems through clearing of invasive plant species improves functional diversity of Odonate assemblages. *Biological Conservation* 214: 46-54. (in English) ["Riparian systems are threatened globally, but contribute disproportionately to biodiversity and ecosystem function. Restoration to reverse their loss is costly, and requires careful monitoring and evaluation. Odonates are amongst the most reliable arthropod bio-indicators

for monitoring riparian ecosystems. Despite functional diversity (FD) reflecting ecosystem pattern and processes better than taxonomic diversity, Odonate FD has yet to be used in evaluating riparian conservation and restoration outcomes. We surveyed 45 sites across six river-systems in northeastern South Africa, to compare Odonate FD and standardised effect size of Odonate FD (sesFD) in riparian systems that had been invaded by alien plants, cleared of alien invasives, and sites that had never been invaded (15 sites each). Although species richness did not differ between treatments, Odonate sesFD was lower in invaded sites than those that had been cleared of alien riparian vegetation and those that had never been invaded. Clearance of 40% of alien riparian vegetation was associated with sesFD greater than that of invaded sites by almost two standard deviations. Representation of traits varied between treatments but was similar between cleared and natural sites, suggesting that invasion by alien plants directly impacts food webs, and that clearance can restore ecosystem processes and ecological services. This study confirms that Odonate FD can respond to restoration efforts. Secondary impacts of restoration to complete suites of functional groups can be anticipated to enhance ecological services and impact food webs at a range of scales." (Authors)] Address: Modiba, R.V., School of Education, Sol Plaatje Univ., Private bag X5008, Kimberley, South Africa

**16530.** Moeller, K.T.; Moeller, A.K.; Moyano, F.; Lundgren, E.J. (2017): Observation of an American black bear eating odonates in Yosemite National Park. *Western North American Naturalist* 77(1): 99-101. (in English) ["American black bears (*Ursus americanus*) are opportunistic omnivores with diets that vary seasonally and geographically depending on food availability. Previous scat analyses across several populations suggest that the majority of animal material in the diet of black bears is from insects (mainly ants and wasps). In 2015, a black bear in Yosemite National Park was observed eating dragonflies, a previously unidentified insect food item. Emerging aquatic insects may be an important but overlooked aspect of black bear diet. Documenting the food sources of organisms is critical to understanding their natural history and ecology. In the case of highly digestible food items, visual observation is an important and underrepresented tactic for documenting diet." **16533.** Moskowicz, D.; May, M. (2017): Adult tiger spiketail (*Cordulegaster erronea* Hagen) habitat use and home range observed via radio-telemetry with conservation recommendations. *Journal of Insect Conservation* 21(5/6): 885-895. (in English) ["*C. erronea* is geographically restricted to the eastern half of North America, patchily distributed within the range and a habitat specialist of small spring and seepage fed headwater streams running through mature forest. These habitats are highly sensitive to disturbance and the Tiger Spiketail is of conservation concern throughout most of its range. Yet little is known about the habitat use of either sex away from the breeding stream hampering conservation strategies. In this study we use miniaturized radio transmitters to investigate the habitat use and home range of individual males and a female Tiger Spiketail in New Jersey. This is the first and only radio-telemetry for this species. We also provide recommendations for habitat protection and conservation. Our studies demonstrate that this species is critically dependent upon mature forest and the high quality, perennial headwater streams that run through them. These habitats are particularly sensitive to disturbance. Except when patrolling and ovipositing, both sexes are in the canopy above the breeding stream and in the adjacent mature forest, indicating the inseparable linkage between the aquatic and forested terrestrial habitat for this species. Our observations also suggest that *C. erronea* occurs in a metapopulation of nearby streams in our study area. Conservation of this species may therefore require forest protection far beyond the breeding stream. In New Jersey, and in other places throughout the range, there are many potential pressures on these habitats and current regulatory protections are not likely suitable. These same habitats may also be important for other Odonate species of conservation concern suggesting that protection of *C. erronea* may benefit a suite of species. We hope the information obtained from this study can assist resource managers in developing conservation and habitat protection measures."] (Authors)] Address: Moskowicz, D., EcolSciences, Inc., 75 Fleetwood Drive, Suite 250, Rockaway, NJ 07866, USA. **16535.** Nagahata, Y.; Futahashi, R.; Tshistjakov, Y.A. (2017): New record of *Sympetrum darwinianum* from Russia. *Tombo* 59: 84. (in English, with Japanese summary) ["So far *S. darwinianum* was known from Japan, continental China, and Korean Peninsula (Tsuda, 2000). Here we report an occurrence of this species from Russia from where it has been unknown. Material examined. 1 male (Figs.1 & 2), Lotus lake, near Khasan, Khasansky, Primorsky, Russia, (N 42.454240, E 130.641317), 14-IX-2010, Yoshiyuki Nagahata leg. This male perched on a branch of a broad-leaved tree (Fig. 2) while no other individuals of this species were involved within a hundreds of individuals of *S. uniforme*, *S. frequens*, and *S. kunckeli* observed around the tree at that occasion. Although one of the authors (Y.N.) had opportunities to survey *Sympetrum* species at this locality on September 9, 2008 and also at Vityas, Zarubino, Andreyevka in Gamov Peninsula (approx. 40 km to the north from Khasan) in eight occasions from 2003 to 2014, no other individuals of *S. darwinianum* has been found. This suggests that Khasan is located around the distribution edge of *S. darwinianum* though it remains unknown whether this species is resident at this locality or not. We would like to thank Dr. Oleg E. Kosterin and Mr. Akihiko Sasamoto for helpful information on the odonate fauna of Russia.] Address: Nagahata, Y., ZaoHango91, Yamagata, Yamagata, 990-2305, Japan E-mail: rosalia@muse.ocn.ne.jp

**16536.** Naik, K.L.; Sayeswara, H. (2017): Diversity, occurrence, and abundance of odonates of Tunga river bank, adjoining fields, and cultivated lands in Shivamogga district of Karnataka, India. *Innovare Journal of Science* 5(2): 1-7. (in English) ["Objective: The major objective of this study was to find out the diversity, occurrence, and abundance of odonates of Shivamogga at three localities, viz., Tunga river bank, adjoining fields, and cultivated lands. Methods: Odonates were sampled for 5 months from July to November 2016. Field observations were made once in a week. They were observed, captured, identified, and released immediately at the spot of capture. Odonates were identified using field guides and handbook of common odonates of central India. Results: A total of 29 species of odonates belonging to 7 families and 24 genera were recorded from the study localities. 14 species of dragonflies and 15 species of damselflies were observed and identified. Conclusion: The present investigation shows that the study localities host a number of odonates. Due to different anthropogenic activities, the odonates diversity is in declining mode."] (Authors)] Address: Naik, K.L., Dept Zool., Sahyadri Science College, Kuvempu Univ., Shivamogga - 577 203, Karnataka, India. E-mail: sscoutzoology@gmail.com

**16537.** Nair, V.P. (2017): Dragonflies: Additions to the Odonata (Insecta) fauna of Varadoor, Kannur, Kerala, South India. *Zoo's Print* 32(11): 24-30. (in English) ["Varadoor is a small village about 24 km east from Kannur city, near Sir Syed College Taliparamba, belonging to Kurumathur gramapanchayath of Kannur district (latitude 120.2'N & longitude 750.24'E), Kerala. The village has an area of 50 acres and has agricultural fields, rubber plantations, scrub jungles, home gardens, ponds etc. 44 species of odonates have been reported from Varadoor, Kannur, South India (Nair, 2014). Further surveys indicated the presence of 24 more species at Varadoor, Kerala. This raises the total species of odonates at Varadoor to sixty eight. In order to avoid collection and killing, most of the species which could be visually identified were photo documented and cross checked with field guides. Difficult species were collected with insect net, photographed and released after studying the characters. Certain odonates which resisted capture were photographed and identified upto generic level. The surveys were made during 2012-2016 in all three seasons viz. summer (March to May), monsoons (June to October) and winter (November to February). Collected odonates were identified with the help of standard field guides, Fraser (1933, 1934, 1936), Kiran & Raju (2013), Emiliyamma et. al., (2005, 2007) and Subramanian (2009). Nomenclature and classification followed is after Schorr et. al., (2013). Common name followed is after Kiran & Raju (2013). Odonates were categorized into four groups depending upon their occurrence during the study period. Accordingly species observed 75-100% of survey days were categorized as very common (VC), 50-75% as common (CO), 25-50% as occasional (OC) and below 25% as rare (RA). Species observed only once or twice in any one season is considered as very rare (VR). Of the 24 species observed additionally at Varadoor, three are endemic to Western Ghats. A systematic list of all the odonates reported so far has been given below with figures showing species richness of the suborders. [...] With the addition of 24 species, the odonate diversity of Varadoor reaches 68 species. Three new families viz. Euphaeidae, Chlorociphidae and Protoneuridae have been added under sub order Zygoptera and one family Macromiidae under Anisoptera. *Pseudagrion decorum* (Rambur, 1842), *Ischnura senegalensis* (Rambur, 1842), *Agriocnemis keralensis* Peters, 1981, *Prodasineura verticalis* (Selys, 1860), *Elatoneura tetrica* (Laidlaw, 1917), *Onychothemis testacea* Laidlaw, 1902 and *Epophthalmia vittata* Burmeister, 1839 has not been reported from Kannur as per Emiliyamma et. al., (2007). So they are new records from Kannur. *Paracercion calamorum* (Ris, 1916) is a very rare odonate of Kerala. It has been recorded for the first time from North Kerala in this study. *Pseudagrion indicum* Fraser, 1924, *Euphaea fraseri* (Laidlaw, 1920) and *Microgomphus souteri* Fraser, 1924 are endemic to Western Ghats. Apart from diversity studies, abundance studies and long term monitoring in this area may reveal interesting results. Majority of the odonates were found associated with the stream passing through the area. Urbanisation and water pollution are major threats to the wetlands of this area. Public attentiveness and involvement of local self government is required to conserve the habitat of these odonates." (Author)] Address: not stated

**16538.** Narzari, S.; Samah, J. (2017): Nutritional aspects of an aquatic edible insect *Sympetrum* sp. (Odonata: Libellulidae) of Assam, northeast India. *International Journal of Food Science and Nutrition* 2(4): 38-42. (in English) ["Insects are popularly consumed in different parts of the globe. The aquatic edible nymphs of *Sympetrum* sp. of Assam, Northeast India is little known to science but is a delicacy among certain tribal communities in the region. This study reports the nutritional compositions of the edible nymph of *Sympetrum* sp. The proximate composition analysis revealed that it contains 76.75 g/100g of protein. Mineral analysis by Atomic Absorption Spectrophotometer showed that this food can supplement rich amount of phosphorus, iron and copper to human nutrition. Amino acids analysed by High Performance liquid Chromatography presented all essential amino acids excluding leucine. Fatty acid analysis by Gas Chromatography Mass Spectrometry revealed that it contains 50.62% of Saturated Fatty Acids, 49.36% of Unsaturated Fatty Acids. This study first reports the rich nutritional aspects of the nymphs of *Sympetrum* sp. The results of this work would possibly be a nutritional reference for local consumers." (Authors)] Address: Narzari, Silistina, Dept of Biotechnology, Bodo-land University, Kokrajhar, -783 370, Assam, India

**16539.** Neiss, U.G.; De Marmels, J (2017): *Gynacantha dryadula* sp. nov. from the Guiana Shield (Odonata, Anisoptera: Aeshnidae). *Zootaxa* 4254(5): 563-574. (in English) ["The new species is described and illustrated on the basis of two reared, subterminal males from Brazil, their larval exuviae, a mature male from French Guiana, a mature female from Venezuela, and a mature female from Surinam. One of the Brazilian males is the holotype (BRAZIL, Amazonas State, Manaus, Reserva Florestal Ducke, BR 174-km 26, trail to Acará creek, 02°55'47"S, 59°58'22"W, 0.7 m elevation, deposited in INPA). The new species (total length 50–54 mm) differs from other small species of same genus by colour pattern of thorax, middle and hind tibiae dark with external (dorsal) yellow streak, male cercus with truncated tip lacking apical spine, and male epiproct reaching or slightly surpassing midlength of cercus. The larva, besides of its small size (28–31 mm), has an epiproct with well-developed and slightly diverging apical spines and an unusually long parapropod." **16540.** Nel, A.; Frese, M.; McLean, G.; Beattie, R. (2017): A forewing of the Jurassic dragonfly *Austroprotolindenia jurassica* from the Talbragar Fish Bed, New South Wales, Australia. *Alcheringa* 41(4): 532-535. (in English) ["The discovery of a well-preserved dragonfly forewing in the Upper Jurassic Talbragar Fish Bed near Gulgong and attributed to *Austroprotolindenia jurassica* Beattie & Nel allows this taxon to be placed in Protolindeniidae. It extends the palaeogeographical distribution of this family, previously known only from the Jurassic of Europe, to Australia." (Authors)] Address: Frese, M., Univ. Canberra, Institute for Applied Ecology & Faculty of Education, Science, Technology & Mathematics, Bruce, ACT 2601, Australia. E-mail: michael.frese@canberra.edu.au

**16541.** Nel, A.; Gross, M.; Engel, M.S. (2017): First fossil occurrence of the jewel damselflies (Odonata: Chlorocyphidae): a new species from the Late Miocene of Styria, Austria. *Annales de la Société entomologique de France (N.S.)* 53(4): 280–285. (in English, with French summary) ["The first fossil representative of the jewel damselflies (Calopterygoidea: Chlorocyphidae), a family of large, prominent, and often brilliantly colored Old World tropical Zygoptera, is described and figured. *Chlorocypha cordasevae* n. sp. was recovered from the Late Miocene (Early Pannonian, Serravalian to Tortonian, c.11 Ma) locality of Paldau, in the Styrian Basin, Austria. The fossil seems to be related to the African genus *Chlorocypha* Fraser, and within a larger group of African genera also including *Stenocypha* Dijkstra, *Africocypha* Pinhey, and *Platycypha* Fraser, and collectively set apart from southern Asiatic genera. The discovery of a central European species of *Chlorocypha* as recently as the Late Miocene reveals a much wider range to the family than its generally disjunctive modern distribution, demonstrating a Neogene contraction to their range, likely in connection with climatic cooling, drying, and developing seasonality. Modern chlorocyphids live under warm, humid climates, and the presence of *C. cordasevae* in the Pannonian fauna of Paldau further corroborates such a subtropical paleoclimate for the locality at that time." **16543.** Nieto, C.; Ovando, X.M.C.; Loyola, R.; Izquierdo, A.; Romero, F.; Molineri, C.; Rodríguez, J.; Martín, P.R.; Fernández, H.; Manzo, V.; Miranda, M.J. (2017): The role of macroinvertebrates for conservation of freshwater systems. *Ecology and Evolution* 7: 5502–5513. (in English) ["Freshwater ecosystems are the most threatened ecosystems worldwide. Argentinian protected areas have been established mainly to protect vertebrates and plants in terrestrial ecosystems. In order to create a comprehensive biodiverse conservation plan, it is crucial to integrate both aquatic and terrestrial systems and to include macroinvertebrates. Here, we address this topic by proposing priority areas of conservation including invertebrates, aquatic ecosystems, and their connectivity and land uses. Location: Northwest of Argentina. We modeled the ecological niches of different taxa of macroinvertebrates such as Coleoptera, Ephemeroptera, Hemiptera, Megaloptera, Lepidoptera, Odonata, Plecoptera, Trichoptera, Acari, and Mollusca. Based on these models, we analyzed the con-

tribution of currently established protected areas in the conservation of the aquatic biodiversity and we propose a spatial prioritization taking into account possible conflict regarding different land uses. Our analysis units were the real watersheds, to which were added longitudinal connectivity up and down the rivers. A total of 132 species were modeled in the priority area analyses. The analysis 1 showed that only an insignificant percentage of the macroinvertebrates distribution is within the protected areas in the North West of Argentina. The analyses 2 and 3 recovered similar values of protection for the macroinvertebrate species. The upper part of Bermejo, Sali-Dulce, San Francisco, and the Upper part of Juramento basins were identified as priority areas of conservation. The aquatic ecosystems need special protection and 10% or even as much as 17% of land conservation is insufficient for species of macroinvertebrates. In turn the protected areas need to combine the aquatic and terrestrial systems and need to include macroinvertebrates as a key group to sustain the biodiversity. In many cases, the land uses are in conflict with the conservation of biodiversity: however, it is possible to apply the connectivity of the watersheds and create multiple-use modules." **16544.** Nijjavalli, H.M.; Hosepti, B.B. (2017): Preliminary observations on Odonata fauna of Daroji Sloth Bear Sanctuary, Ballari District, North Karnataka (India). *Biodiversity Journal* 8(4): 875–880. (in English) ["The preliminary study was conducted from February 2011 to January 2012 at Daroji Sloth Bear Sanctuary, Hosept. The study revealed the occurrence of a total of 22 species of Odonates in 19 genera belonging to 5 families from the study area. Among them the order Anisoptera which includes dragonflies was predominated with 17 (76%) species, followed by the order Zygoptera which includes damselflies with 5 (24%) species. The family Libellulidae was found to be the most dominant by 13 species with high percentage composition i.e., 76%, followed by the family Coenagrionidae by 3 species with 40% of total odonates species recorded from the study area. The status based on the frequency of occurrence of shows that 8 (36%) were common, 5 (23%) were very common, 3 (14%) were occasional, 4 (18%) were rare and 2 (9%) were very rare. The study highlights the importance and also provides the baseline information on status and composition of Odonates at Daroji Sloth Bear Sanctuary, Ballari District of North Karnataka for research on their biology and the conservation." **16545.** Nishijima, S.; Nishikawa, C.; Miyashita, T. (2017): Habitat modification by invasive crayfish can facilitate its growth through enhanced food accessibility. *BMC Ecology* 17(37): 9 pp. (in English) ["Background: Invasive ecosystem engineers can facilitate their invasions by modifying the physical environment to improve their own performance, but this positive

feedback process has rarely been tested empirically except in sessile organisms. The invasive crayfish *Procambarus clarkii* is an ecosystem engineer that destroys aquatic macrophytes, which provide a physical refuge for animal prey, and this destruction is likely to enhance vulnerability to predators. Using two series of mesocosm experiments, we tested the hypothesis that the invasive crayfish increases its feeding efficiency on animal prey by reducing submerged macrophytes, thus increasing its individual growth rate in a positive density-dependent manner. Results: In the first experiment, increasing crayfish density reduced both macrophytes and animal prey (dragonfly and chironomid larvae) and, importantly, increased the growth rate of individual crayfish, in accordance with our expectation. In the second experiment, we used artificial macrophytes to clarify whether the physical architecture of macrophytes itself protects animal prey and limits crayfish growth rate. Increasing the artificial macrophyte quantity not only increased the survival of animal prey, but also retarded the crayfish growth rate. Conclusions: We conclude that macrophytes strengthen bottom-up control of crayfish, but this effect can be relaxed by increasing the density of crayfish via reduction in macrophytes. This positive feedback process may explain the crayfish outbreaks and regime shifts occasionally observed in invaded freshwater ecosystems." (Authors)] Address: Nishijima, S., Lab. Biodiversity Sci., School of Agricult. & Life Sciences, The Univ. of Tokyo, 1-1-1 Yayoi, Bunkyo, Tokyo 113-8657, Japan. E-mail: nishijimash@gmail.com

**16546.** Okude, G.; Futahashi, R.; Tanahashi, M.; Fukatsu, T. (2017): Laboratory rearing system for *Ichnura senegalensis* (Insecta: Odonata) enables detailed description of larval development and morphogenesis in dragonfly. *Zoological Science* 34(5): 386-397. (in English) ["In an attempt to establish an experimental dragonfly model, we developed a laboratory rearing system for *I. senegalensis*. Adoption of multi-well plastic plates as rearing containers enabled mass-rearing of isolated larvae without cannibalism and convenient microscopic monitoring of individual larvae. Feeding *Artemia* brine shrimps to younger larvae and *Tubifex* worms for older larvae resulted in low mortality, synchronized ecdysis, and normal development of the larvae. We continuously monitored the development of 118 larvae every day, of which 49 individuals (41.5%) reached adulthood. The adult insects were fed with *Drosophila* flies in wet plastic cages, attained reproductive maturity in a week, copulated, laid fertilized eggs, and produced progeny. The final larval instar varied from 9th to 12th, with the 11th instar (56.5%) and the 12th instar (24.2%) constituting the majority. From the 1st instar to the penultimate instar, the duration of each instar was relatively short, mainly ranging from three to 11 days. Afterwards, the duration of each instar was prolonged, reaching 7–25 days for the penultimate instar and 14–28 days for the final instar. Some larvae of final, penultimate and younger instars were subjected to continuous and close morphological examinations, which enabled developmental staging of larvae based on size, shape, and angle of compound eyes and other morphological traits. This laboratory rearing system may facilitate the understanding of physiological, biochemical, and molecular mechanisms underlying metamorphosis, hormonal control, morphogenesis, body color polymorphism, and

other biological features of dragonflies." (Authors)] Address: Okude, G., Dept. Biol. Sci., Graduate School Sci., Univ. Tokyo, Tokyo 113-0033, Japan Bioproduction Research Inst., Nat. Institute of Advanced Industrial Science & Technology (AIST), Tsukuba 305-8566, Japan. E-mail: g-okude@aist.go.jp

**16547.** Okuyama, H.; Takahashi, J. (2017): The complete mitochondrial genome of *Mnais costalis* Selys (Odonata: Calopterygidae) assembled from next generation sequencing data. *Tombo* 59: 77-83. ["We describe the complete mitochondrial genome of *M. costalis* from Shiga Prefecture, which is sympatric region where closely related species show loss of their wing-color polymorphism. The mitochondrial genome of *M. costalis* was determined to be a circular molecule of 15,484 bp. It was predicted to contain 13 protein-coding, 22 tRNA and two rRNA genes, and a non-coding control region. The organization of the genome is similar to that in the other Odonata species, including *M. costalis* (KU871065). The frequencies for occurrence of A, T, C and G nucleotides were 40.02, 26.25, 19.53 and 14.17%, respectively, with an average AT content of 66.27%. Four start codons (ATG, ATC, ATT, and TTG) and four stop codons (TAA, TAG and an incomplete TA and T) were observed in the 13 protein-coding genes. 22 tRNAs were predicted to form the cloverleaf secondary structures." (Authors)] Address: Okuyama, H., Fac. Life Sci., Kyoto Sangyo Univ., Kamigamo-Motoyama, Kita-ku, Kyoto, Kyoto, 608-8555 Japan. E-mail: k5533@cc.kyoto-su.ac.jp

**16548.** Op de Beeck, L.; Verheyen, J.; Stoks, R. (2017): Integrating both interaction pathways between warming and pesticide exposure on upper thermal tolerance in high- and low-latitude populations of an aquatic insect. *Environmental Pollution* 224: 714-721. (in English) ["Highlights: •Exposure to multiple chlorpyrifos (CP) pulses reduced thermal tolerance (CT<sub>max</sub>). •CP effect on CT<sub>max</sub> was lower under warming due to lower CP accumulation. •Reduction in CT<sub>max</sub> can partly be explained by reduction of the aerobic scope. •Thermal adaptation did not shape the impact of warming and CP on CT<sub>max</sub>. •Climate-induced toxicant impact shaped toxicant-induced climate sensitivity. Global warming and chemical pollution are key anthropogenic stressors with the potential to interact. While warming can change the impact of pollutants and pollutants can change the sensitivity to warming, both interaction pathways have never been integrated in a single experiment. Therefore, we tested the effects of warming and multiple pesticide pulses (allowing accumulation) of chlorpyrifos on upper thermal tolerance (CT<sub>max</sub>) and associated physiological traits related to aerobic/anaerobic energy production in *Ichnura elegans*. To also assess the role of latitude-specific thermal adaptation in shaping the impact of warming and pesticide exposure on thermal tolerance, we exposed larvae from replicated high- and low-latitude populations to the pesticide in a common garden rearing experiment at 20 and 24 °C, the mean summer water temperatures at high and low latitudes. As expected, exposure to chlorpyrifos resulted in a lower CT<sub>max</sub>. Yet, this pesticide effect on CT<sub>max</sub> was lower at 24 °C compared to 20 °C because of a lower accumulation of chlorpyrifos in the medium at 24 °C. The effects on CT<sub>max</sub> could partly be explained by reduction of the aerobic scope. Given that these

effects did not differ between latitudes, gradual thermal evolution is not expected to counteract the negative effect of the pesticide on thermal tolerance. By for the first time integrating both interaction pathways we were not only able to provide support for both of them, but more importantly demonstrate that they can directly affect each other. Indeed, the warming-induced reduction in pesticide impact generated a lower pesticide-induced climate change sensitivity (in terms of decreased upper thermal tolerance). Our results indicate that, assuming no increase in pesticide input, global warming might reduce the negative effect of multiple pulse exposures to pesticides on sensitivity to elevated temperatures." **16552.** Osozawa, S.; Sato, F.; Wakabayashi, J. (2017): Quaternary vicariance of lotic *Coelicia* in the Ryukyu-Taiwan Islands contrasted with lentic *Copera*. *Journal of Heredity* 108(3): 280-287. (in English) ["Lotic Odonata are expected to be more

affected by vicariance than lentic sister species. We demonstrated that severe vicariant speciation acted on lotic *Coelicia* in contrast to lentic *Copera* damselflies, which are both included in the family Platycnemididae. We constructed maximum likelihood and Bayesian inference trees of these Platycnemididae species from the continental islands of Ryukyu (Amami, Okinawa, and Yaeyama islands), Taiwan, and Japan relative to Chinese species using raxmlGUI and BEAST, based on the mitochondrial COI gene (682 bp), COII gene (494 bp), 16SrRNA (478 bp), and the nuclear 28SrRNA gene (807 bp). In BEAUti, we calibrated the splitting age of the MRCA of all the *Coelicia* species as 1.55-0.15 million years ago (Ma), a date that corresponds to a geologic constraint: the Okinawa trough and associated straits, including the Yilan basin in Taiwan, began to rift at 1.55 Ma, isolating the Ryukyu-Taiwan islands from the Chinese continent. The vicariance split *Coelicia* into the Ryukyu-side clade of *Coelicia ryukyuensis* (Coe. r. *ryukyuensis* in Okinawa and Coe. r. *amamii* in Amami) and *Coelicia flavicauda* (Coe. f. *masakii* in Yaeyama and Coe. f. *flavicauda* in southern Taiwan), and the Chinese-side clade of *Coelicia cyanomelas* (northern Taiwan and China), separated by the Okinawa trough. These *Coelicia* species were further deeply differentiated to form local populations on the major islands and some of the minor islands. The *Copera* clade constituted a sister of the lotic *Coelicia* clade, but genetic differentiation was not recognizable in lentic *Copera* between China, Taiwan, and Japan. Base substitution rates applying a strict clock model were estimated for COI: 0.0783, COII: 0.0803, 18SrRNA: 0.0186, 28SrRNA: 0.00577, and combined: 0.0408 substitutions/site/myr, and these rates are relatively high." Eine erste Zusammenstellung von Arten im Hinblick auf ihr Schädigungspotenzial für Libellen (Odonata). *Mainzer naturwissenschaftliches Archiv* 54: 193-217. (in German, with English summary) ["For the first time all invasive species – vertebrates and invertebrates – which have a known or potential impact on dragonflies in Rheinland-Palatinate have been compiled. They have direct and indirect effects and even both. To date adult dragonflies are not impacted, but the larval and aquatic stages are, even more and often to a large extent. The most negative impact derives from invasive crayfish (Decapoda), which even leads to destroyed habitats and reduced ecosystem services. Beside the invasive crayfish also some fish, molluscs and insects have a distinct impact. To avoid or at least reduce further damages the execution of existing environmental laws by the authorities must be intensified and the release of new invasive species must be avoided by all means. The expansion of already introduced invasive species must be stopped or should at least been reduced, as prevention is much better from the ecological as well as from the economic point of view. The populations of invasive species as well as their impact have to be monitored permanently. In the general public there is still a lack of knowledge concerning this topic, consequently also pro-

grammes for environmental education should be implemented." (Author)] Address: Ott, J., L.U.P.O. GmbH, Friedhofstr. 28, 67705 Trippstadt, Germany. E-mail: ott@lupogmbh.de

**16555.** Ott, J. (2017): Erfassung der Libellenfauna (Odonata) am Glan im Jahr 2015 – mit störungsökologischen Betrachtungen. Mitteilungen der Pollichia 98: 91-104. (in German, with English summary) ["The river Glan, 87.5 km long and situated in the German federal states Saarland and Rhineland-Palatinate, is used for canoe tourism. In particular in its lower section between the villages Lauterecken and Odemheim, where it flows into the river Nahe, this type of recreation led to conflicts with fishing, water management, nature conservation, and the residents. After a moderation in 2015, several studies had been carried out to provide evidence for this impact of canoeing, e.g. on birds, fish and also dragonflies. In this article, the study on the dragonfly fauna of the Glan with reference on their disturbance ecology is presented. 18 species were found in total during summer 2015. The rheophilic *Onychogomphus forcipatus* and *Ophiogomphus cecilia* (which is listed on Annex II and IV of the EC Habitats Directive and according to the national law "strictly protected") are of particular interest here. For these two species (larvae and adults) no significant negative impact could be found, as well as for the other species present at this river and consequently no contravention of the national law could be expected. However, on the basis of all studies some management measurements and some rules of action were proposed to minimize any possible impact, moreover suggestions for more detailed studies on the disturbance ecology of dragonflies were given." In 2016, the species was found in Kalamazoo County, Michigan. It is the least abundant *Cordulegaster* species in Michigan, and the habitat requirements in Michigan are compared with known *C. erronea* habitats in

Ohio and New Jersey." (Authors)] Address: O'Brien, M.A., Museum of Zoology, University of Michigan, 3600 Varsity Drive, Ann Arbor, MI 48108, USA.

**16557.** Padinjattayil, S.; Agrawal, A. (2017): Abstract: L8.00009: Flow around a corrugated wing over the range of dragonfly flight. Bulletin of the American Physical Society, 70th Annual Meeting of the APS Division of Fluid Dynamics. Sunday–Tuesday, Nov. 19–21, 2017; Denver, Colorado: (in English) [Verbatim: The dragonfly flight is very much affected by the corrugations on their wings. A PIV based study is conducted on a rigid corrugated wing for a range of Reynolds number 300-12000 and three different angles of attack ( $5^{\circ}$ - $15^{\circ}$ ) to understand the mechanism of dragonfly flight better. The study revealed that the shape of the corrugation plays a key role in generating vortices. The vortices trapped in the valleys of corrugation dictates the shape of a virtual airfoil around the corrugated wing. A fluid roller bearing effect is created over the virtual airfoil when the trapped vortices merge with each other. A travelling wave produced by the moving virtual boundary around the fluid roller bearings avoids the formation of boundary layer on the virtual surface, thereby leading to high aerodynamic performance. It is found that the lift coefficient increases as the number of vortices increases on the suction surface. Also, it is shown that the partially merged co-rotating vortices give higher lift as compared to fully merged vortices. Further, the virtual airfoil formed around the corrugated wing is compared with a superhydrophobic airfoil which exhibits slip on its surface; several similarities in their flow characteristics are observed. The corrugated airfoil performs superior to the superhydrophobic airfoil in the aerodynamic efficiency due to the virtual slip caused by the travelling wave.] Address: not stated

**16558.** Pandey, P.; Mohapatra, A.K. (2017): Diversity of two families Libellulidae and Coenagrionidae (Odonata) in Regional Institute of Education Campus, Bhubaneswar, Odisha, India. Journal of Threatened Taxa 9(2): 9851-9857. (in English) ["Libellulidae and Coenagrionidae are the most dominant families among Odonata. The present study deals with the diversity, occurrence and present status of libellulids and coenagrionids within the Regional Institute of Education Campus in Bhubaneswar, Odisha, India (RIEC). The major objectives of this study are to prepare a preliminary checklist of libellulids and coenagrionids species in the RIEC and to find out the status and distribution of genera and species in their respective families. This study is also aimed at systematic planning for developing different strategies for conservation of odonates in the campus. During this study a total of 24 species have been recorded out of which 20 species belong to the family Libellulidae representing 15 genera and four species belong to the family Coenagrionidae representing four genera. The findings of this study are based on the survey which was carried out for a period of four months in 2015." (Authors)] Address: Pandey, Priyamvada, Dept Life Sci. Education, Reg. Inst. **16559.** Parr, A.J. (2017): Migrant and dispersive dragonflies in Britain during 2016. J. Br. Dragonfly Society 33(2): 104-111.

(in English) ["The year 2016 was a relatively quiet one for migrant dragonflies in Britain, at least in terms of the volume of migration. *Anax parthenope* thus had no more than an 'average' season with reports from fourteen sites, while *Sympetrum fonscolombii* had one of its quietest years for some time. Some small scale arrivals of *S. fonscolombii* were never-the-less still observed. Despite the generally low numbers of migrants, a few highlights did, however, stand out. In particular, *Anax ephippiger* was noted at five sites during the autumn, with individuals being photographed on the Scilly Isles (2 sites), the Orkneys (2 sites) and in coastal Norfolk. Our recent colonist species in general seemed to fair well. In particular, *Chalcolestes viridis* continued its range expansion with sightings from no less than four new counties during the season, namely Bedfordshire, Buckinghamshire, Lincolnshire and Northamptonshire. A new breeding site for *Lestes barbarus* was discovered on the Isle of Wight during June, while in Essex not only did *Aeshna affinis* appear in numbers at its strongholds along the greater Thames Estuary, but what seems likely to be a new breeding site was discovered near St Osyth, well away from sites in the south of the county. Other events of note during the year involved important 'extralimital' sightings of a number of our more established resident species that are currently undergoing range expansion. In particular, *Libellula fulva* produced several unexpected sightings, including reports from Leicestershire and Lincolnshire. *Aeshna isoceles* also continued to be seen in new areas." **16565.** Peterson, M.G.; Lunde, K.B.; Chiu, M.-C.; Resh, V.H. (2017): Seasonal progression of aquatic organisms in a temporary wetland in northern California. *Western North American Naturalist* 77(2): 176-188. (in English) ["Seasonal wetlands are important habitats for biodiversity of both invertebrate and vertebrate fauna. Many aquatic species have life history traits adapted to colonizing and developing in temporary aquatic habitats, and these traits influence the annual succession of the macroinvertebrate community. The chronology of taxon appearance and the variation in relative abundances during the hydroperiod are important for understanding population dynamics, trophic interactions, and responses to drought. This study investigated the successional

changes in macroinvertebrate abundances in a seasonal wetland in northern California. Water quality parameters were measured regularly, including dissolved oxygen, temperature, pH, surface area, and specific conductance during the wet season (January–July) in 2007–2009. Macroinvertebrates were collected with net sweeps (mesh > 500 mm), and the presence of life stages of amphibians were visually observed from March to June each year. As the hydroperiod progressed, wetland surface area decreased, while water temperature and specific conductance increased. Macroinvertebrate abundance increased with the progression of the hydroperiod, and the richness of macroinvertebrate predator taxa tripled from 2 families in March to 6 families in June. The earliest part of the hydroperiod in the wetland was dominated by *Cyzicus* clam shrimp and *Linderiella occidentalis* fairy shrimp. *Limnephilus* caddisfly larvae were few in number but were found exclusively in the early season. Sequential changes of dominant invertebrate taxa and relative abundances of macroinvertebrates were evident, particularly among several macroinvertebrate predators. Among these predators, the early-season community was dominated by larval dytiscid beetles, while later-season communities demonstrated increased predator richness (e.g., *Notonecta* backswimmers) and were dominated by *Lestes* damselflies. Larvae of the vertebrate predator *Taricha torosa*, which may act as a top predator, were present during the later stages of the hydroperiod. The phenology of individual aquatic taxa and their specific life history strategies may impact the sensitivity of macroinvertebrate populations to increased annual variation in hydroperiod that may result from climate changes in this region." **16570.** Phan, Q.T.; To, V.Q.; Ho, V.H.; Pham, A.T.; Ta, P.M. (2017): Study on the damselfly genus *Prodasineura* Cowley, 1934 (Odonata: Zygoptera: Platycnemididae) of Vietnam. Proceedings of the 7th national scientific conference on ecology and biological resources: 989-997. (in English) ["Damselfly of the genus *Prodasineura* Cowley, 1934 had been placed in the family Protoneuridae before Dijkstra et al. (2014) rearranged it into the family Platycnemididae by using a molecular phylogenetic approach. They are very slender built damselfly, the male coloured usually with deep black, striped with blue, red or yellow, respectively. Thoracic pattern are usually used for identifying species in the genus. Superiors of anal appendages are hammer-like with pointed at apex; inferiors is broad at base and tapering abruptly to a round tip. The females are similar in shape of body and thoracic colour pattern. The posterior lobe of female prothorax characteristically well developed and can be good character for separating close species. They are usually found at the slowly flowing near the opened streams of secondary forests or backwaters of swift rivers in lowlands. In this study, three species of the genus *Prodasineura* are recorded for the first time for Vietnam, including *P. doisuthensis* Hoess, 2007, *P. hoffmanni* Kosterin, 2015 and *P. verticalis* Selys, 1860. This result brings the number of *Prodasineura* species known in Vietnam into 7. Moreover, we also provided an updating distribution of all recorded *Prodasineura* species based on several related publications and personal database of the authors." (Authors)] Address: Phan, Q.T., Entomology & Parasitology Lab., Center for Molecular Biology, Institute of Research and Development, Duy Tan University, 3 Quang Trung, Da Nang, Vietnam. **16575.** Polaskova, V.; Schenkova, J.; Bartosova, M.; Radkova, V.; Horsák, M. (2017): Post-mining calcareous seepages as surrogate habitats for aquatic macroinvertebrate biota of vanishing calcareous spring fens. *Ecological Engineering* 109, Part A: 119-132. (in English) ["Many studies have investigated the vegetation and terrestrial fauna of post-mining spoil heaps, but little is known about aquatic macroinvertebrates in these areas, particularly at spring-fed habitats. We studied nine seepages (i.e. spring-fed habitats) located at two neighbouring spoil heaps in the Sokolov brown-coal basin (Czech Republic),

characterised by basic water pH, calcium carbonate precipitation, high heavy metal and sulphate concentrations. Along with these nine artificial calcareous seepages, we also sampled macroinvertebrates at 15 natural and well-preserved calcareous spring fens to compare species richness and assemblage similarity between these two systems. We also categorised recorded species as spring specialists or generalists (i.e. matrix-derived species) to compare their importance for the similarity in diversity of these two habitat types. Our study revealed that post-mining calcareous seepages harboured unusually taxa-rich macroinvertebrate assemblages (158 taxa), despite their harsh conditions related to extreme water chemistry. Diptera, with 85 taxa, were the most diverse group, reaching taxon richness comparable with dipteran assemblages in natural calcareous spring fens. According to Sørensen pairwise dissimilarity, dipteran assemblages of postmining and natural sites were more similar in the composition of spring specialists than that of generalists, showing a strict relationship between specialist assemblages and specific environmental conditions of postmining and natural sites. In addition, dipterans inhabiting post-mining seepages were demonstrated not to be limited by their extreme water chemistry, but they seemed to be associated with specific substratum properties, creating a mosaic of various microhabitats. We can therefore conclude that calcareous post-mining seepages have great potential to offer valuable analogues of natural habitats and may create biodiversity refuges for a high number of aquatic invertebrates, including spring habitat specialists and nationally threatened species. Thus, post-mining seepages seem to have similar or even higher conservation potential to more complex and larger post-mining freshwater habitats, such as post-mining streams and mine subsidence pools." **16576.** Polette, P.; Abbott, C.; Gouys, J.; Jenard, P.; Julian, P.; Darnaud, S.; Boudot, J.-P. (2017): Premières mentions de *Trithemis kirbyi* (Odonata: Libellulidae) en France. *Martinia* 33(1/2): 15-25. (in French, with English summary) ["During two months starting on 21 June 2017, *T. kirbyi* has been recorded from five localities in continental France, in perfect agreement with the heatwave which reached the whole of the country and nearby regions from 18 to 25 June. These observations are discussed in the light of the expansion and dispersion of the species in Europe, which began in 2003 in remote insular localities and knew further developments since 2007 on the continent. Thanks to its opportunistic behaviour and physiology allowing it to carry out a successful reproductive cycle in most of natural and artificial waterbodies, and its propensity to nomadism allowing it to take advantage of warm atmospheric flows going from Africa to Europe, the species did not take more than ten years to expand from the South to the North of the Iberian Peninsula and to reach France. Rather than a simple step by step expansion, the 2017 French records appear to constitute a long-distance vagrancy which may have reached a mean of 45-90 km per day during six days, favoured by unusual warm weather conditions on the west of Europe. These records deal mostly

with isolated males standing during several consecutive days at a constant place, which suggests that the involved individuals remained the same throughout in a given locality, pointing to an onset of settlement. The possible establishment of the species on the long run in southern France will have to be surveyed during the following years.] Address: Polette, P., Impasse des Amoureux, F-11250 Couffoulens, France. **16577.** Poulin, B.; Lefebvre, G.; Muranyi-Kovacs, C., Hilaire, S. (2017): Mosquito traps: An innovative, environmentally friendly technique to control mosquitoes. *Int. J. Environ. Res. Public Health* 2017, 14, 313: 8 pp. (in English) ["We tested the use of mosquito traps as an alternative to spraying insecticide in Camargue (France) following the significant impacts observed on the non-target fauna through Bti persistence and trophic perturbations. In a village of 600 inhabitants, 16 Techno Bam traps emitting CO<sub>2</sub> and using octenol lures were set from April to November 2016. Trap performance was estimated at 70% overall based on mosquitoes landing on human bait in areas with and without traps. The reduction of *Ochlerotatus caspius* and *Oc. detritus*, the two species targeted by Bti spraying, was, respectively, 74% and 98%. Traps were less efficient against *Anopheles hyrcanus* (46%), which was more attracted by lactic acid than octenol lures based on previous tests. Nearly 300,000 mosquitoes from nine species were captured, with large variations among traps, emphasizing that trap performance is also influenced by surrounding factors. Environmental impact, based on the proportion of non-target insects captured, was mostly limited to small chironomids attracted by street lights. The breeding success of a house martin colony was not significantly affected by trap use, in contrast to Bti spraying. Our experiment confirms that the deployment of mosquito traps can offer a cost-effective alternative to Bti spraying for protecting local populations from mosquito nuisance in sensitive natural areas." (Authors)] Address: Poulin, Brigitte, Tour du Valat Research Institute for the conservation of Mediterranean wetlands, Le Sambuc, 13200 Arles, France. E-mail: poulin@tourduvalat.org

**16578.** Prokop, J.; Pecharova, M.; Nel, A.; Hömschemeyer, T.; Krzeminska, E.; Krzeminski, W.; Engel, M.S. (2017): Paleozoic nymphal wing pads support dual model of insect wing origins. *Current Biology* 27: 1-7. (in English) ["Highlights: \*Palaeodictyopteran wing pad joints corroborate dual origin of insect wings. \*Three pairs of wing pads were medially articulated and markedly fused with notum. \*Wing pads were functionally unable to perform active flight due to limited divergence. \*Arrangement of wing pad axillary sclerites corresponds to Hamilton's ancestral model. The appearance of wings in insects, early in their evolution [1], has been one of the more critical innovations contributing to their extraordinary diversity. Despite the conspicuousness and importance of wings, the origin of these structures has been difficult to resolve and represented one of the "abominable mysteries" in evolutionary biology [2]. More than a century of debate has boiled the matter down to two competing alternatives—one of wings representing an extension of the thoracic notum, the other

stating that they are appendicular derivations from the lateral body wall. Recently, a dual model has been supported by genomic and developmental data [3–6], representing an amalgamation of elements from both the notal and pleural hypotheses. Here, we reveal crucial information from the wing pad joints of Carboniferous palaeodictyopteran insect nymphs using classical and high-tech techniques. These nymphs had three pairs of wing pads that were medially articulated to the thorax but also broadly contiguous with the notum anteriorly and posteriorly (details unobservable in modern insects), supporting their overall origin from the thoracic notum as well as the expected medial, pleural series of axillary sclerites. Our study provides support for the formation of the insect wing from the thoracic notum as well as the already known pleural elements of the arthropodan leg. These results support the unique, dual model for insect wing origins and the convergent reduction of notal fusion in more derived clades, presumably due to wing rotation during development, and they help to bring resolution to this long-standing debate.] Address: Prokop, J., Dept Zoology, Fac. Science, Charles Univ., Vinicná 7, 128 44 Praha 2, Czech Republic. E-mail: jprokop@natur.cuni.cz

**16579.** Prunier, F. (2017): Observaciones de odonatos en la sierra de Baza, verano 2017. Boletín Rola 10: 19-38. (in Spanish, with English summary) ["The paper presents the results of the first faunistic study of dragonflies undertaken in the Sierra de Baza Natural Park, one of the most arid area in Andalusia. The water bodies present in the park are described, the most relevant ones for Odonata being four permanent streams and various water tanks associated with natural springs. The sampling was carried out during summer 2017 and allows for the detection of 18 species, highlighting populations of *Aeshna cyanea* in lentic waters and *Coenagrion mercuriale* in lotic ones. Finally, samples of benthonic macro-invertebrates allowed to established the water quality of the streams and the associated dragonflies." (2017): Territory behavior, copulation and oviposition in *Brachythemis contaminata* Odonata: Libellulidae. *International Journal of Applied Research 3 Special Issue Part E*: 125-128. (in English) ["The present investigation explains the reproductive behavior i.e. territory, copulation and oviposition for *B. contaminata* which was carried out for a year between June 2013 to April 2014. The male plays significant role in mating as competing for fertilization by attracting females, but in odonates female also actively involving as taking mating decision, male selection and activities during tandem formation. Territory of mating male is well marked of about 2 to 3 meter in diameter and is at the same place of oviposition. Male prefer territory attachment as strategies of mutual avoidance which reduces energy spent in inter-male fight. Male-females are generally in group with high male ratio till evening and male become more careful and aggressive in evening for his territory. When receptive female visits to mate in male's territory she chooses the fittest male for mating. Male shows aggressiveness, wing vibration, abdominal display, chasing to competitor are the main events use for mating strategies. Copulation takes place in air for only few seconds and mating success for territorial male is high." (Authors)] Address: Rathod, P.P., Dept. of Zoology, Shri Shivaji College of Arts, Commerce and Science, Akola (M.S.), India
- 16585.** Reshetnikova, S.N.; Babkina, I.B.; Simakova, A.V.; Susliaev, V.V.; Blohin, A.N.; Interesova, E.A. (2017): Macrozoobenthos diversity of the Middle Ob river tributaries. *International Journal of Environmental Studies 74(5)*: 803-810. (in English) ["The data show quantitative and qualitative composition of macrozoobenthos of the 12 left-bank confluences of the Middle Ob. The research has documented the presence of various groups, such as Oligochaeta, Diptera, Odonata, Hirudinea, Tabanidae, Trichoptera and Mollusca. The chironomids, molluscs and leeches play a significant role in the generation of biomass in the surveyed streams, and the abundance mostly depends on chironomids, oligochaetes and leeches. In general, zoobenthos abundance ranges from 8.8 (the Shudelka river) to 1839.9 (the Kochebilovka river) ind./m<sup>2</sup>, biomass is from 0.08 (Tatosh river) to 8.37 (Lozunga river) g/m<sup>2</sup>. The amount and benthos biomass of the Middle Ob's second-order tributaries is higher than in the first-order tributaries." - 16588.** Rychla, A. (2017): Die Libellenfauna des Tongrubengebiets bei Gozdnica (SW Polen) mit besonderer Berücksichtigung von *Leucorrhinia caudalis* (Charpentier, 1840). *International Dragonfly Fund Report 109*: 1-16. (in German, with English and Polish summary) ["Waters of anthropogenic origin potentially represent a high value for the dragonfly fauna. For this reason, post mining waters were examined for dragonflies in a clay pit area near Gozdnica (Lubuskie Voivodeship, SW Poland) in 2017. The main goals of this study were the verification of the potential occurrence of *L. caudalis* in this area as well as the contribution of these water bodies to the regional dragonfly diversity. As a result of the investigation were two new records of *L. caudalis* with reproduction evidence at one water body and the observations of imagines at two sites. Additionally, two further species protected according to national and European law: *L. pectoralis* and *L. albifrons* were found in the area. Furthermore, the entire area is particularly suitable for pioneer colonizers such as *Ischnura pumilio* and *Libellula depressa*, as well as for thermophilous species such as *Orthetrum coerulescens* and *Crocothemis erythraea*. A total of 30 species of dragonflies were detected. For 16 species the proof of reproduction was provided. The examined water bodies are an important habitat for widespread generalists and for rare specialists. Therefore, they significantly contribute to the regional biodiversity." - 16589.** Saha, S.K. (2017): Odonate (Insecta: Odonata) diversity of West Bengal State University Campus; a checklist and pictorial catalogue. *International Journal of Zoology Studies 2(5)*: 132-138. (in English) [Odonata "are amongst the most attractive creatures on earth, first to have conquered the aerial domain. Yet we know little of their diversity in India and detailed ecology and habitat preferences of many species are poorly documented. Although much work have been carried out regarding the abundance and distribution of insect orders, no sufficient effort has been made to study the diversity and distribution of Odonates. Thus, in the present study an attempt has been taken to study the diversity and abundance of Odonates in West Bengal State University (WBSU) campus, West Bengal, India. A total of 32 species of Odonates

were recorded from the study area from July to September, 2017. The family Libellulidae with 18 species was the most dominant among the Anisoptera followed by Gomphidae (1sp.) and family Aeshnidae (1 sp.). Among the Zygoptera, the 11 species recorded belong to the family Coenagrionidae and 1 species of family platycnemididae. As the area houses 32 species of Odonates including 20 species of Anisoptera and 12 species of Zygoptera, it can be presumed to have a good diversity which may be attributed to the grasslands, shrubs and small water bodies inside the campus." **16590.** Saito, V.; Senzaki, Y.; Yonezawa, C.; Chiba, K.; Jinguji, H. (2017): Assessment of mid-summer drainage regime on the potential for *Sympetrum frequens* conservation by using low threshold temperature and total effective temperature for development of larvae to 10th instar. *IDRE Journal* 304(85-1): 37-46. (in Japanese, with English summary) ["The aim of the present study was to clarify the effect of a mid-summer paddy field drainage regime on the conservation of *S. frequens*. We investigated the theoretical lower threshold temperature and total effective temperature required for *S. frequens* egg and larval development under laboratory conditions. The lower theoretical threshold temperature and total effective temperature for egg hatching under early, typical and late inundation conditions were 5.7°C and 55.2 degree-days, 5.6°C and 36.8 degree-days, and 6.8°C and 21.7 degree-days, respectively. The theoretical lower threshold temperature and total effective temperature for larval development to the 10th-instar stage were estimated at 5.6°C and 909.1 degree-days. We then estimated the water temperature in paddy rice fields in Miyagi Prefecture based on meteorological data represented on a 1-km grid. Mean days to hatching and days required for larval development to the 10th-instar stage were estimated based on the paddy field water temperature, theoretical lower threshold temperature, and total effective temperature. These results were then represented in a GIS to show the mean time to hatching in days and the time required for development of 10th-instar larvae. Finally, we compared the estimated time required for the development of 10th-instar larvae and the timing of mid-summer paddy field drainage. We considered that the drainage of paddy fields in mid-summer would be conducted before the development of 10th-instar larvae. Based on these findings, we consider that the adoption of a mid-summer drainage regime by rice farmers after *S. frequens* larvae development to 10th-instar stage would promote the conservation of this species. The risks associated with mid-summer drainage are also discussed." (Authors)] Address: Saito, V., Miyagi Univ., Graduate School of Food, Agricultural and Environmental Sciences, Japan

**16591.** Salmah, M.R.C.; Siregar, A.Z.; Hassan, A., Nasution, Z. (2017): Dynamics of aquatic organisms in a rice field ecosystem: effects of seasons and cultivation phases on abundance and predator-prey interactions. *Tropical Ecology* 58(1): 177-191. (in English) ["The influence of different rice growing seasons and rice cultivation phases on aquatic organisms was investigated in the Manik Rambung rice field (MRRF)

ecosystem in North Sumatera. Composite collections of core samples and aquatic net samples from four rice growing seasons and five cultivation phases (fallow, plough, transplanting-young, tiller, maturepreharvest) were analysed. There were marked seasonal variations in abundances of these organisms, but the abundance pattern in various rice cultivation phases was comparable among rice growing seasons. The rice field was dominated by tubificids, baetids, chironomids and ceratopogonids. High populations of these organisms were observed during the plough, transplanting-young, and tiller phases, but lower in the other rice cultivation phases. The proliferation of larval *Agriocnemis femina*, one of the rice pest predators in the adult stage, was dependent on its interactions with 14 aquatic taxa in different phases; nine taxa in the plough phase and three to five taxa in other phases. Hemipterans, coleopterans, other odonates, chironomids, baetids and tubificids were important for successful emergence of *A. femina* to a predatory adult. Rice cultivation managements that focus on enhancing the population of *A. femina* would contribute to more effective biological control of rice pests in MRRF." **16593.** Sanmartin-Villar, I.; Zhang, H.; Cordero-Rivera, A. (2017): Ontogenetic colour changes and male polymorphism in *Mnais andersoni* (Odonata: Calopterygidae). *International Journal of Odonatology* 20(2): 53-61. (in English) ["Colour-based traits are widespread in flying species due to the importance of visual perception in their communication. Ontogenetic colour changes and reversible physiological colours occur in some species and are used as communication signals to conspecifics. The genus *Mnais* (Zygoptera: Calopterygidae) shows both genetic colour polymorphism and age-related colour changes, making challenging even the identification of species. Here we study three Chinese populations of *M. andersoni* during one month by mark-resighting methods. We describe the ontogenetic body and wing colour changes

of male morphs (orange-winged and hyaline-winged) and females. With maturity, thoracic colour changes from metallic green to copper. The initially transparent wings of the hyaline winged males and females became light amber with age, while the orange-winged males show this colour since emergence to maturity. Whitish pruinosity covered all thorax in orange-winged males, while it remained limited to the ventral part of the thorax in hyaline-winged males and females. Hyaline-winged males presented less abdominal pruinosity than the rest of individuals. Our observations suggest that male morphs of *M. andersoni* are analogous to other species of the genus." (Authors)] Address: Sanmartín-Villar, I., ECOEVO Lab, Universidade de Vigo, Escola de Enxeñaría Forestal, Campus A Xunqueira, 36005 Pontevedra, Galiza, Spain.

**16594.** Sanmartín-Villar, I.; Rivas-Torres, A.; Gabela-Flores, M.V.; Encalada, A.C.; Cordero-Rivera, A. (2017): Female polymorphism and colour variability in *Argia oculata* (Coenagrionidae: Zygoptera). *Neotropical Biodiversity* 3(1): 203-211. (in English) ["Body colouration frequently possesses a communicative function, particularly in species with colour polymorphism and developed visual systems as odonates, and also affects the conspicuousness of animals in relation to the background. Therefore, these factors can influence colour evolution and its development. The ecology and ethology of *A. oculata* were studied in three populations with different degrees of habitat alteration. Three different sources of colour variability were found: female polymorphism, female ontogenetic change and daily change in both sexes. All males observed presented the same blue thoracic colouration pattern, without ontogenetic changes. Some of them (6–48%, variable between populations) showed a darkening of the thorax colouration in the afternoon. The frequency of androchrome females (male-like thoracic colouration) showed a negative relationship with human habitat disturbance. These females changed their body colour from bluish to brownish at old ages. Gynochrome females started their adult life with sky-blue thorax, which turned to olive green and finally to brown with sexual maturation. One gynochrome female returned to the immature colouration in late hours of the day. Colour changes were apparently not associated to sunlight intensity or temperature. Behavioural observations suggest that colour variability in females might contribute to reduce or avoid male harassment. We contextualise our findings in the *Argia* literature and propose physiological and evolutionary mechanisms for their explanation." (in German, with English summary) ["Expansion of *A. isoceles* into the southern part of the Upper Rhine valley: We report an apparent range expansion of *A. isoceles* in the German part of a 150 km long section of the Upper Rhine valley ranging from Rastatt in the north to Basel in the south. Only five records of this species are documented from the whole 20th century. Since 2006, however, the species has been reported from 34 waters. *A. isoceles* reproduced in at least eight of these waters. We compare our data with the development in the German land of Baden-Württemberg and in Germany and discuss the findings shortly in the context of current climate warming.] Address: Schiel, F.-J., Inst. Naturschutz und Landschaftsanalyse, Turenweg 9, D-77880 Sasbach, Germany. E-mail: Franz-Josef.Schiel@INULA.de

**16599.** Schiel, F.-J.; Salcher, M.; Förschler, M. (2017): Libellen im Nationalpark Schwarzwald (Odonata). *Mercuriale* 17: 27-36. (in German, with English summary) ["Odonata in the Black Forest National Park - The Black Forest National Park is situated in the northern Black Forest between the cities of Baden-Baden and Freudenstadt. It was founded in 2014. Altitudes in the Park range from 470 to 1,151 m a.s.l. with an average altitude above 800 m a.s.l. The Park area is characterized by extensive forests growing on poor soils that have developed mainly on red sandstone formations. With a mean annual temperature of 5°C and a mean precipitation of 2,200 mm, the climate in this part of the Black Forest is rough and wet. 25 species of Odonata have been recorded in the National Park area so far, with 20 of them being resident. Six species are confined to small and fish-free peat bog water bodies: *Coenagrion hastulatum*, *Aeshna juncea*, *A. subarctica*, *Somatochlora alpestris*, *Leucorrhinia dubia* and *Sympetrum danae*. *Somatochlora alpestris* is restricted to small semipermanent water bodies in the wet heathlands called "Grinden". These evolved on the mountain ridges since the Middle Ages through grazing with cattle, sheep and goats. In Southwestern Germany, *S. alpestris* occurs exclusively in the Black Forest at altitudes from about 1,000 m a.s.l. One of its distribution centres is in the young National Park. The most common kind of water body in the Park are streams and rivulets that are inhabited by both *Cordulegaster bidentata* and *C. boltonii*. Population densities of both species are low due to the rough climate, the very dynamic runoff and the nutrient-poor, acidic bedrock in the area." (Authors)] Address: Förschler, M., Nationalparkverwaltung Schwarzwald, Kniebisstr. 67, 77740 Bad Peterstal-Griesbach, marc.foerschler@nlp.bwl.de

**16600.** Schlemmer Brasil, L.; Vieira, T.B.; Oliveira-Junior, J.M.; Dias-Silva, K.; Juen, L. (2017): Elements of metacommunity structure in Amazonian Zygoptera among streams under different spatial scales and environmental conditions. *Ecology and Evolution* 7(9): 3190-3200. (in English) ["An important aspect of conservation is to understand the founding elements and characteristics of metacommunities in natural environments, and the consequences of anthropogenic disturbance on these patterns. In natural Amazonian environments, the interfluvies of the major rivers play an important role in the formation of areas of endemism through the historical isolation of species and the speciation process. We evaluated elements of metacommunity structure for Zygoptera sampled in 93 Amazonian streams distributed in two distinct biogeographic regions (areas of endemism). Of sampled streams, 43 were considered to have experienced negligible anthropogenic impacts, and 50 were considered impacted by anthropogenic activities. Our hypothesis was that preserved ("negligible impact") streams would present a Clementsian pattern, forming clusters of distinct species, reflecting the biogeographic pattern of the two regions, and that anthropogenic streams would present random patterns of metacommunity, due to the loss of more sensitive species and dominance of more tolerant species, which have higher dispersal ability and environmental tolerance. In negligible impact streams, the Clementsian pattern reflected a strong biogeographic pattern, which we discuss considering the areas of endemism of Amazonian rivers. As for communities in human-

impacted streams, a biotic homogenization was evident, in which rare species were suppressed and the most common species had become hyper-dominant. Understanding the mechanisms that trigger changes in metacommunities is an important issue for conservation, because they can help create mitigation measures for the impacts of anthropogenic activities on biological communities, and so should be expanded to studies using other taxonomic groups in both tropical and temperate systems, and, wherever possible, at multiple spatial scales." **16601.** Schneider, T.; Ikemeyer, D.; Ferreira, S.; Müller, O. (2017): *Gomphus kinzelbachi* Schneider, 1984, in Iran: identification, habitat and behaviour (Odonata: Gomphidae). *Zootaxa* 4216(6): 572-584. (in English) ["*G. kinzelbachi* was described on the basis of a single teneral male captured by B. L. Sage on the Alwand River in eastern Iraq. In late April to early May 2016 two of the authors (TS and DI) discovered three individual-rich populations of this species on the large lowland river Karkeh in southwestern Iran (Khuzestān). This is the first report of a breeding population of this species. Based on collected material we confirmed the structural differences of the male secondary genitalia between *G. kinzelbachi* and *G. davidi* on a larger number of animals. The female of the species is described. *G. kinzelbachi* resembles most closely *G. davidi*, compared to all other West-Palaearctic *Gomphus* species. Therefore, a direct comparison of the two species is given, and additionally some differential diagnostic hints for two other *Gomphus* species reported from Iran is provided. Our observations suggest that *G. kinzelbachi* reproduces on large clean lowland rivers in SE Iraq and SW Iran. In SW Iran only a free flowing stretch of the Karkeh, one of three parallel rivers (Karkeh, Karoon, Dez), seems to be suitable for this species. The other two rivers are affected by dams, dam construction, and increasing salinization. Additional dam constructions are also planned on the Karkeh River, thus, *G. kinzelbachi* may be on the brink of extinction." **16603.** Schneider, T.; Schneider, E.; Ikemeyer, D.; Seidenbusch, R.; Müller, O. (2017): Description of last instar larva of *Gomphus kinzelbachi* Schneider, 1984 and new aspects on distribution and habitats in Iran (Odonata: Gomphinae). *Zootaxa* 4365(4): 455-466. (in English) ["*G. kinzelbachi* was described on the basis of a single teneral male captured by B. L. Sage on the Alwand River in eastern Iraq. A detailed re-description of the male and description of the female were published recently. However, the larva of the species has remained unknown so far. In late April 2017 two of the authors (ES & TS) discovered freshly emerged *G. kinzelbachi*, some of them still on their exuviae, on the upper part of the Zoreh River in southwest Iran (Khuzestān). Larvae ready to emerge were observed leaving the water and climbing reed stalks. The development from last instar larvae to freshly emerged *G. kinzelbachi* was observed, some until maiden flight. Five exuviae and two freshly emerged males were collected for further identification and description. Male and female exuviae of *G. kinzelbachi* are described and compared with exuviae of *G. schneiderii* Selys, 1850, from Mazandarān province in Iran. Furthermore, a key is provided to determine the exuviae of four Iranian species belonging to the subfamily Gomphinae: *Gomphus kinzelbachi*, *G. schneiderii*, *Stylurus ubadschii* (Schmidt, 1953), and *Anormogomphus kiritshenkoi* Bartenev, 1913. In addition, the eastern Mediterranean *Gomphus davidi* Selys, 1887, is included in the comparison, because it seems to be the sister species of *G. kinzelbachi*. During the trips to Iran in 2017 eight new populations of *G. kinzelbachi* on different stretches of the river systems of Marun, Zoreh, Dalaki, Alwand, and Abi Zinkan were detected, enlarging the known range and habitat requirements significantly. The flight period of *G. kinzelbachi* in Iran is also discussed." (Authors)] Address: Schneider, T., Arnold-Knoblauch-Ring 76, 14109 Berlin-Wannsee, Germany. E-mail: thomas.rs@gmx.de

**16604.** Seehausen, M. (2017): Survey of Odonata from Timor Island, with description of the female of *Anax georgius* (Odonata: Aeshnidae). *Faunistic Studies in SE Asian and Pacific Island Odonata* 20: 1-34. (in English) ["The survey is based

on specimens held at Museums in Australia, Belgium and Germany. Altogether 487 specimens of 31 species from Timor were examined. These include: a recent collection from Timor-Leste of 148 specimens (25 species) at the Australian Museum Sydney, an historic collection from West Timor consisting of 338 specimens (20 species) of the ex-collection Eugène Le Moult, stored at the Institut Royal des Sciences Naturelles de Belgique in Brussels, and a single specimen from West Timor of the Coll. Ris stored at the Senckenberg Naturmuseum Frankfurt, Germany. The following nine species are reported from Timor for the first time: *Agriocnemis pygmaea*, *Austroallagma sagittiferum*, *Ischnura heterosticta*, *Xiphiagrion cyanomelas*, *Crocothemis servilia*, *Neurothemis ramburii*, *Orthetrum pruinosum* cf. *schneideri*, *Potamarcha congener* and *Zyxomma obtusum*. The female of *Anax georgius* is described and illustrated. An illustrated key to the *Anax* species of the Lesser Sunda Islands is given and specimens from the Lesser Sunda Islands formerly identified as *Anax gibbosulus* are considered to be *A. panybeus*. Some characters of the *O. pruinosum* taxa group of species, *Tramea stenoloba* and female *Z. obtusum* are discussed. Figures of the male appendages and genital ligulae of *A. sagittiferum*, *Aciagrion fragile* and *X. cyanomelas* are provided, as well as figures of the male secondary genitalia, appendages and the penis of *Trithemis lilacina* and the male appendages of *Epophthalmia vittigera*. A preliminary checklist for Timor including 36 species is given." (Authors)] Address: Seehausen, M., Museum Wiesbaden, Naturhistorische Sammlungen, Friedrich Ebert Allee 2, 65185 Wiesbaden, Germany. **16608.** Seidel, M.; Voigt, M.; Langheinrich, U.; Hoge-Becker, A.; Gersberg, R.M.; Arévalo, J.R.; Lüderitz, V. (2017): Re-connection of oxbow lakes as an effective measure of river restoration. *Clean. SoilAirWater* 45(3). 1600211: (in English) ["Six years after re-connection of an oxbow lake from periodically to permanently connected to the main channel, the restoration success was assessed. This permanently connected oxbow lake was compared with the main channel of the Elbe River and with a periodically connected oxbow lake by means of comparisons of the aquatic macroinvertebrates, fish and aquatic macrophyte communities. The permanently connected oxbow was suited as important replacement habitat for riverine invertebrates, especially for clubtails (Odonata) and unionid mussels (*Bivalvia*). The periodically connected oxbow lake was colonized by typical species for shallow lakes. As expected, riverine species did not occur. Meanwhile, the invertebrate community in the main channel was poor and dominated by invasive species (*Dikerogammarus villosus*, *Dreissena polymorpha*). The results concerning fish showed a clear dominance of the rheophilic species spined loach (*Cobitis taenia*) in the permanently connected oxbow lake and of the indifferent species roach (*Rutilus rutilus*) and European perch (*Perca fluviatilis*) in the periodically connected oxbow lake.

However, species number was highest in the main channel. For macrophytes, quantity, number of taxa and growth forms and diversity were lower in the permanently compared to the periodically connected oxbow lake. In conclusion, the re-connection of oxbow lakes to main channels can be an important measure for native species conservation, especially macroinvertebrates, and hence for the implementation of the Water Framework Directive." (in English) ["Delayed stall is the most dominant lift enhancing factor in insect flapping motion. Micro air vehicle operates at Reynolds number 104-105; slightly higher than the insects' Reynolds number (Re). In the present research, the focus is to investigate "stall-absent" phenomenon at Re representative of the micro air vehicles, the effect of spanwise flow on the leading edge vortex and also to study the effect of geometry variations on the aerodynamic performance of the wing in unsteady motion. Corrugated dragonfly airfoil with rectangular wing planform is used, however, with wing kinematics restricted to azimuth rotation only. Three-dimensional finite volume method is used, through commercial software Fluent, to numerically solve time-dependent incompressible Navier-Stokes equations. Computed results at Re 34000 and 100,000 reveal the same phenomenon of delayed stall, as observed in the case of insects. Furthermore, the performance of flat plate, profiled and corrugated wing in a sweeping motion at a high angle of attack is also compared." (2017): Annotated checklist of the dragonflies (Insecta: Odonata) of the Kaliningrad region, north-western Russia. *Ukrainian Journal of Ecology* 7(4): 157-168. (in English) ["The first comprehensive surveys on Odonata were made more than 100 years ago, at the beginning of 20th century by La Baume (1908) and especially by Le Roi (1911) and included 50 species. In the following years, no significant publications which particularly address faunistic and taxonomic studies related to the Kaliningrad region were published. Here we present the first modern, most complete checklist of the dragonflies of the Kaliningrad region with notes on the species composition, abundance, and periods of local flight and seasonal migrations. The current checklist is based on data collected by the authors on the Courish Spit (Kaliningrad region, Russia) in 2007-2016. In total, 278 955 specimens belonging to 57 species were recorded. Additional 7 species are included in the list based on the literature data. Thus, the number of species known for the territory of the Kaliningrad region has risen to 64." (in English) ["The reproductive behaviour of *P. flavescens* was studied in different localities of Aravalli Range and Desert Ecosystem of Rajasthan during 2008-15. Courtship is well marked and male demonstrate a circular territory with a radius of about 4-6 meters and defended it from the intruding intra or some inter specific male by chasing it away or by warning signals like wing vibration or abdomen raising. As female entered into the territory, the male starts following her and forms a tandem link, catching hold of her prothorax by his anal appendages. The before wheel tandem lasted for 10-40 seconds and during this period intramale sperm translocation is not observed. The male forced female to form courtship wheel. The courtship wheel lasts for about 70 seconds to 3 minutes and is performed in air above water body. The courtship wheel breaks and in tandem position the female oviposit exophytically on the surface of water and it lasts for 60 seconds to 2 minutes. During oviposition the male in tandem and after release of grip hovers around the female, to defend her from intruding intra or inter specific males. The total duration of reproductive behaviour lasts for 3-6 minutes." **16612.** Shi, L.; Cshen, R.-R.; Han, Y.; Gao, X.-F.; Chen, C.; Chen, Y.; Zhu, X.-X.; Tian, M.-q.; Sun, W.-J.; Jin, C.-Y.; De, C.-Q. (2017): A preliminary survey of species diversity of the freshwater insects in Inner Mongolia. *Acta Entomologica Sinica* 60(12): 1467-1480. (in Chinese, with English summary) ["[Aim] This study aims to provide the basic scientific data of aquatic insect species in Inner Mongolia and a solid base for their potential application in freshwater quality monitoring and protection by the government and scientists in the future. [Methods] Benthic aquatic insects were sampled by using a qualitative collection method and the water quality was assessed by the family biotic index (FBI), EPT species richness and Shannon-Wiener biodiversity index. [Results] Of 187 freshwater insect species in 72 genera, 59 families, 7 orders collected in the 52 localities, 1 species was new to science; 2 families, 3 genera and 25 species were newly recorded in Inner Mongolia; 1 genus and 2 species were recorded for the first time in China; and 56 additional species are under identification. The diversity of Trichoptera and Ephemeroptera were the highest while that of Plecoptera was the lowest in recorded 7 orders; the proportions of families and individuals of the two orders accounted for 42.37% and 84.29%, respectively, so Trichoptera and Ephemeroptera are dominant groups among the seven orders. The localities of rich species diversity were distributed mainly in the eastern Inner Mongolia, including Hulunber, Hinggan League, Tongliao and Chifeng. The water quality ranks assessed by the family biotic index, EPT species richness and Shannon-Wiener biodiversity index showed that the evaluation results of FBI and EPT species richness were similar, but differed greatly from that of Shannon-Wiener biodiversity index. [Conclusion] There are more abundant species of Trichoptera and

Ephemeroptera with lower tolerance value in Inner Mongolia, so the caddisflies and mayflies are more suitable and better candidates as indicators of water quality in this region." Entomol.* 114: 391-399. (in English) ["Infrastructure is one of the main causes of landscape fragmentation, which results in isolation and loss of populations. Although the negative effect of roads on insects is well documented, only a minority of studies has focused on roads in the context of barriers to dispersal. Flying species in particular have been neglected. We investigated the effect of a four-lane motorway as a barrier to the movement of an isolated population of the threatened dragonfly *S. depressiusculum* in an agricultural landscape in Central Europe. Generalized additive models were used to assess the motorway's effect on (i) the distribution of adult dragonflies in patches of terrestrial habitat surrounding their natal site, and (ii) individual flight behaviour (i.e. willingness or unwillingness to cross the motorway). Movement patterns of marked adults throughout the landscape were also investigated. During one season, significantly fewer adults were found at patches located on the far side of the motorway, indicating it has a barrier effect. Observations on flight behaviour revealed no apparent effect of the motorway. The possible barrier effect for the species studied was therefore presumed to be a consequence of road mortality. Our results indicate that the motorway may influence the dispersal of this threatened species of dragonfly, which is a habitat specialist with particular requirements for its terrestrial environment. Negative effects

on other species with similar behaviour and strategy can be presumed. When establishing new habitats, carrying out re-introductions or translocations, it is necessary to consider that roadways may reduce population size and affect population dynamics by limiting dispersal." **16616.** Simon, E.; Kis, O.; Jakab, T.; Kolozsvári, I.; Málnás, K.; Harangi, S.; E. Baranyai, E.; Miskolczi, M.; Tóthmérész, B.; Dévai, G. (2017): Assessment of contamination based on trace element concentrations in *Gomphus flavipes* (Odonata: Insect) larvae of the Upper Tisza Region. *Ecotoxicology and Environmental Safety* 136: 55-61. (in English) ["Highlights: • Dragonfly larvae are frequently used to assess the contamination level of aquatic systems. • The aim of our study was to assess the contamination in the Upper Tisza Region. • Trace element concentrations of *Gomphus flavipes* larvae were studied. • Significant differences were found in trace element concentrations of dragonfly larvae among studied localities. • Our results indicated a continuous pollution of studied rivers. Abstract: Odonata larvae are frequently used to assess the contamination of aquatic systems, because they tolerate a wide range of chemical and biological conditions in freshwater systems. In early 2000, the sediments of the Hungarian section of the River Tisza and the River Szamos were strongly enriched with heavy metals by an accidental mining spill. Earlier studies demonstrated higher contamination levels in the Szamos than in the Tisza, based on sediment analysis. The aim of our study was to assess the contamination in the Upper Tisza Region, along the upper reach of the Tisza, and the lower reach of the Szamos, based on the trace element concentrations of the *Gomphus flavipes* larvae. We collected 269 dragonfly specimens for the analyses. The Al, Ba, Cr, Cu, Fe, Mn, Pb, Sr and Zn element contents were analysed in the dragonfly larvae by microwave plasma atomic emission spectrometry (MP-AES). Significantly higher Ba and Cu concentrations were found in the dragonfly larvae of the Tisza than the Szamos. In spite of this, the Cr, Mn, Pb, Sr and Zn concentration was significantly lower in the dragonfly larvae of the Tisza than the Szamos. For all trace elements significant differences were found along the Tisza. Significant differences were also found in all trace element concentrations of dragonfly larvae among studied localities in the Szamos, except in the cases of Al and Ba. Our results demonstrated that the Szamos was more contaminated with Cr, Mn, Pb, Sr and Zn than the Tisza, but that the Tisza was more contaminated with Ba and Cu than the Szamos, based on the trace element concentrations in *Gomphus flavipes* larvae, which was likely to have been caused by the tributaries of the Tisza. In summary, our results indicated a continuous pollution of the Tisza and the Szamos and their tributaries." (Authors)] Address: Simon, Edina, Dept of Ecology, Univ. **16618.** Start, D.; Kirk, D.; Shea, D.; Gilbert, B. (2017): Cannibalism by damselflies increases with rising temperature. *Biology Letters* 13(5): 4 pp. (in English) ["Trophic interactions are likely to change under climate warming. These interactions can be altered directly by changing consumption rates, or indirectly by altering growth rates and size asymmetries among individuals that in turn affect feeding. Understanding these processes is particularly important for intraspecific interactions, as direct and indirect changes may exacerbate antagonistic interactions. We examined the effect of temperature on activity rate, growth and intraspecific size asymmetries, and how these temperature dependencies affected cannibalism in *Lestes congener*, a damselfly with marked intraspecific variation in size. Temperature increased activity rates and exacerbated differences in body size by increasing growth rates. Increased activity and changes in body size interacted to increase cannibalism at higher temperatures. We argue that our results are likely to be general to species with life-history stages that vary in their temperature dependencies, and that the effects of climate change on communities may depend on the temperature dependencies of intraspecific interactions." in dragonflies. *Archive of applied mechanics* 87(3): 521-554. (in English) ["In the recent decades, biomimetic robots have attracted scientific communities' attention increasingly, as people try to learn from nature in which exist astonishing and uniquely evolved mechanisms shown by very species. Dragonfly, as such one example, demonstrates unique and superior flight performance than most of the other insect species and birds. Researchers are obsessed with the aerodynamic characteristics of an in-flight dragonfly as two pairs of independently controlled wings provide them with an unmatched flying performance and robustness. In this paper, an extensive review of recent studies related to the flight aerodynamics of dragonflies has been conducted. The main research findings about effect of the motion parameters and body attitude on the resulting aerodynamic forces and power requirements in different flight modes of a dragonfly are summarized. Particular attention is given to functional characteristics of dragonfly wings and the importance of mutual interaction between forewing and hindwing for its flyability. This article aims to bring together current understandings of dragonfly aerodynamics and thus has certain reference value to design and control of dragonfly-inspired biomimetic devices." (in Thai, with English summary) ["The aim of this study is to assess the relationship between diversity and distribution of aquatic insect with water quality in Mae Chaem headwater stream, Kanlayaniwattana district, Chiang Mai. Aquatic macroinvertebrates were sampled at Mae Chaem wadeable-headstream at four sites including MJ1, MJ2, MJ3 and MJ4 from December 2014 to August 2015 using D-frame net and obtained some physico-chemical parameter of water quality. A total of 8,889 individuals belonging to 84 families and nine orders were examined. The most aquatic insect abundance were Diptera (54%), Ephemeroptera (26%), Coleoptera (8%), Trichoptera (6%), Odonata (4%), Hemiptera (3%) and others (<1%) respectively. The highest diversity index was recorded at MJ1, 2.564 and lowest diversity index was recorded at MJ2, 0.921. The highest evenness index was found at MJ1, 0.638 and lowest evenness index was found 0.521. In terms of the relative abundance, the most abundant taxa recorded was Chironomidae. The use of biological

indices as BMWPThai score and ASPT and physical and chemical parameters of standard fresh-water surface to evaluate water quality showed that the water quality was moderate to good quality in each sampling sites." (Authors)] Address: E-mail rungnapatag@gmail.com

**16623.** Takahashi, Y. (2017): Genome-wide population genetic analysis identifies evolutionary forces establishing continuous population divergence. *Ecological Research* 32(4): 461-468. (in English) ["Elucidating the mechanism shaping the spatial variations of traits has long been a central concern of evolutionary biologists. Geographic clines of allele/morph frequencies along environmental gradients are suggested to be established and maintained by the balancing of two opposing evolutionary forces, namely selection that generates spatial differentiation in morph frequencies, and selection and/or stochastic factors that lead to the coexistence of multiple morphs within a population. Thus, testing for both selection and stochastic factors is necessary for a comprehensive understanding of the mechanism underlying clinal variation in morph/allele frequency in natural populations. Here, I identified the evolutionary forces responsible for clinal variation of color morph frequency in *Ischnura senegalensis* by comparing the population divergence of putatively neutral loci generated by high-throughput next-generation sequencing (FSTn) with that of the putative color locus (FSTc). No strong correlation was observed between FSTn and FSTc, suggesting that stochastic factors contribute less to color-locus population divergence. FSTc was less than FSTn between populations exposed to similar environmental conditions, but greater than FSTn between populations exposed to different environmental conditions, suggesting that both balancing selection and divergent selection act on the color locus. Therefore, two antagonistic selection factors rather than stochastic and historical factors contribute to establishing the clinal variation of morph frequency in *I. senegalensis*." **16629.** Tennessen, K.T.; Trapero-Quintana, A., Cruz Ferreira, F. (2017): Description of the nymph of *Tramea binotata* (Rambur, 1842) (Odonata: Libellulidae). Zootaxa 4337(3): 445–450. (in English) ["The nymph of *T. binotata* is described and illustrated based on reared specimens from Brazil and Ecuador, and also matching nymphs from Venezuela. A new character was discovered, i.e., density of minute spiniform setae scattered on the dorsum of abdominal segments 7 & 8, that separates the Neotropical species into two groups: high density of the tiny setae separates *T. binotata*, *T. insularis* Hagen, 1861 and *T. calverti* Muttkowski, 1910 from the other known species which have zero to only a few of these setae. *T. binotata* is distinct from most other Neotropical species known in the nymph stage by having only 7 or 8 palpal setae, rarely 6 or 9, on one side (versus 10–12); *T. calverti* and

*T. insularis* have similar low numbers of palpal setae (8–10) but each has more premental setae per side (11–14 in *calverti* and *insularis* vs. 8–10, rarely 11, in *binotata*). The nymphs of *Tramea minuta* De Marmels & Rácenis, 1982 and *T. rustica* De Marmels & Rácenis, 1982 are still unknown." (Authors)] Address: Tennesen, K.T., Florida State Collection of Arthropods, Gainesville, USA. E-mail: ktennessen@centurytel.net

**16630.** ter Hofstede, H.; Voigt-Heucke, S.; Lang, A.; Römer, H.; Page, R.; Faure, P.; Dechmann, D. (2017): Revisiting adaptations of neotropical katydids (Orthoptera: Tettigoniidae) to gleaning bat predation. *Neotropical Biodiversity* 3(1): 41-49. (in English) ["All animals have defenses against predators, but assessing the effectiveness of such traits is challenging. Neotropical katydids (Orthoptera: Tettigoniidae) are an abundant, ubiquitous, and diverse group of large insects eaten by a variety of predators, including substrate-gleaning bats. Gleaning bats capture food from surfaces and usually use prey-generated sounds to detect and locate prey. A number of Neotropical katydid signaling traits, such as the emission of ultrasonic frequencies, substrate vibration communication, infrequent calling, and ultrasound-evoked song cessation are thought to have evolved as defenses against substrate-gleaning bats. We collected insect remains from hairy big-eared bat (*Micronycteris hirsuta*) roosts in Panama. We identified insect remains to order, species, or genus and quantified the proportion of prey with defenses against predatory bats based on defenses described in the literature. Most remains were from katydids and half of those were from species with documented defenses against substrate-gleaning bats. Many culled remains were from insects that do not emit mate-calling songs (e.g. beetles, dragonflies, cockroaches, and female katydids), indicating that eavesdropping on prey signals is not the only prey-finding strategy used by this bat. Our results show that substrate-gleaning bats can occasionally overcome katydid defenses." (Authors)] Address: ter Hofstede, Hannah, Dept of Biol. Sciences, Dartmouth College, Hanover, NH, USA. **16633.** Thomas, K. (2017): Four-spotted Chaser *Libellula quadrimaculata* Roosting in Large Numbers at Ham Wall Nature Reserve, Somerset. *Atropos* 60: 47-49. (in English) [Verbatim: On 1-VI- 2017 a small group of RSPB staff, including Reserves Ecologists Graham White and Bex Cartwright, were visiting RSPB's Ham Wall nature reserve for an early morning bird survey. Ham Wall sits in the Avalon Marshes, Somerset. Not long after reaching the site, between 04.30 and 05.15hrs, a group of roosting *L. quadrimaculata* were observed in an area of reeds. These were counted, and there were over 600 individuals present. However, it was soon realised that there were more present, and further counting estimated 2,000-3,000 individuals in the area. It is assumed that the dragonflies had roosted there overnight and would then disperse during the daytime. They were observed over subsequent days, but within two weeks the roost was no longer present in this area, although some wings could be found amongst the reeds. Ham Wall is a wetland created on an area previously worked by the peat industry. We are encouraged that the habitat created is suitable for a range of wildlife, including this spectacular display of dragonflies. We will re-visit the area at a similar time in 2018 to determine if this event is repeated (please note, the area that the roost was observed in is a sensitive area for wildlife and is off the path network). This was an interesting observation of a dragonfly roosting in such large numbers; we have not been able to find any similar documented sightings and would be interested to hear if similar observations have been recorded elsewhere.] Address: Thomas, Kelly, Reserves Ecologist, RSPB, The Lodge, Bedfordshire, SG19 2 DL, U.K. E-mail: kelly.thomas@rspb.org.uk

**16634.** Thompson, A.C.; Bazelet, C.S.; Naskrecki, P.; Samways, M.J. (2017): Adapting the Dragonfly Biotic Index to a katydid (Tettigoniidae) rapid assessment technique: case study of a biodiversity hotspot, the Cape Floristic Region, South Af-

rica. *Journal of Orthoptera Research* 26(1): 63-71. (in English) ["Global biodiversity faces many challenges, with the conservation of invertebrates among these. South Africa is megadiverse and has three global biodiversity hotspots. The country also employs two invertebrate-based rapid assessment techniques to evaluate habitat quality of freshwater ecosystems. While grasshoppers (Acrididae) are known indicators of terrestrial habitats, katydids could be as well. Here, we adapt a South African freshwater invertebrate-based rapid assessment method, the Dragonfly Biotic Index (DBI), for the terrestrial katydid assemblage, and propose a new assessment approach using katydids: the Katydid Biotic Index (KBI). KBI assigns each katydid species a score based on a combination of: 1) IUCN Red List status, 2) geographic distribution, and 3) life history traits (which consist of mobility and trophic level). This means that the rarer, more localized, specialized and threatened katydid species receive the highest score, and the common, geographically widespread and Least Concern species the lowest. As a case study, we calculated KBI across one of South Africa's global biodiversity hotspots, the Cape Floristic Region (CFR). We then correlated KBI/Site scores of individual ecosystems with their ecosystem threat scores. The CFR's katydid assemblage did not differ significantly from that of the overall South African katydid assemblage in terms of its species traits, threat statuses, or distribution among tettigoniid subfamilies. Likewise, KBI/Site scores did not differ significantly among ecosystem threat statuses. This may be explained by the coarse spatial scale of this study or by the lack of specialization of the CFR katydid assemblage. Nevertheless, the KBI holds promise as it is a relatively simple and non-invasive technique for taking invertebrate species composition into account in an assessment of habitat quality. In regions where katydid assemblages are well-known, acoustic surveys and KBI may provide an efficient means for assessing habitats." **16636.** Torres-Cambas, Y.; Ferreira, S.; Cordero-Rivera, A.; Lorenzo-Carballa, M.O. (2017): Identification of evolutionarily significant units in the Cuban endemic damselfly *Hypolestes trinitatis* (Odonata: Hypolestidae). *Conservation Genetics* 18(5): 1229-1234. (in English) ["Species classification may not reflect the underlying/cryptic genetic diversity which should otherwise be conserved as it represents the potential of populations to evolve and adapt. The identification of evolutionarily significant units (ESUs) allows cryptic genetic diversity to be taken into account when designating conservation priorities. Here, we used mitochondrial and nuclear DNA sequences integrated with ecological niche models (ENM) to identify ESUs in *H. trinitatis*, a threatened Cuban endemic damselfly species. We found that this species comprises two distinct genetic groups in Central and Eastern Cuba respectively, which are also geographically isolated, as shown by ENM. Therefore, we propose these groups to be considered as different ESUs. According with their extent of occurrence, number of locations and inferred decline of habitat extent and quality, Central and Eastern ESUs qualify as Endangered [EN B1b(iii)] and Vulnerable [VU B1b(iii)], respectively." (Authors)] Address: Torres-Cambas, Y., Depto de Biol., Fac.Ciencias Naturales y Exactas, Univ. de Oriente, Santiago de Cuba, Cuba

**16637.** Torres-Pachón, M.; Novelo-Gutiérrez, R.; Espinosa de los Monteros, A. (2017): Phylogenetic analysis of the genus *Argia* Rambur, 1842 (Odonata: Coenagrionidae), based on morphological characters of larvae and mitochondrial DNA sequences. *Organisms Diversity & Evolution* 17(2): 409-420. (in English) ["The study of the evolutionary interrelationships among the species encompassed in the Neotropical genus *Argia* has been neglected. The goal of this study is to infer the phylogenetic relationships among 36 species of *Argia* Rambur, 1842, using complementary data sets (i.e., larval morphology and mitochondrial DNA). The morphological data set comprises 76% of the larvae currently described for this genus and includes 97 morphological characters. From those, 47 characters have not been previously used in taxonomic studies involving dragonflies' larvae. This is the first cladistic study based on larvae morphology for species within the sub-order Zygoptera. Data partitions were analyzed individually, as well as total evidence, using parsimony and Bayesian inference as criteria for optimal-tree selection. The results support the monophyly of the North American species of *Argia*. This genus can be identified by the combination of eight synapomorphies, four of which are exclusively found in *Argia*. According to the optimal trees, the individual data sets (i.e., morphology and DNA sequences) have a high level of ho-

moplasia, resulting in soft polytomies and low support for several nodes. The specific relationships of the terminal units differ between the phylogenies; nonetheless, there is historical congruence among them. Within *Argia*, five clades were consistently recovered. Most of those clades have been identified, at least in part, in previous phylogenetic and taxonomic studies. Indubitably, the morphological characters from larvae have historical signal useful for cladistic and taxonomic inference. Therefore, it should be a priority to pay more attention to this source of characters." (Authors)] Address: Espinosa de los Monteros, A., Depto Biol. Evol. Inst. Ecol., A. C. (in German, with English summary) ["Observation of a teneral female *A. cyanea* attacked by a female Common Newt. On June 6th, 2011, a freshly hatched female *A. cyanea* was attacked by a female Common Newt (*Lissotriton vulgaris*) for several hours in a garden pond. In this paper this presumably rarely occurring interaction between an anisopteran imago and a newt is discussed by means of comprehensive literature on predator-prey-relationships between dragonflies and amphibians. The ultimately unsuccessful attack was documented by a photo." (Authors)] Address: Chovanec, A., Krottenbachgasse 68, 2345 Brunn am Gebirge, Austria. E-mail: andreas.chovanec@bmlfuw.gv.at

**16639.** Tüzün, N.; Stoks, R. (2017): Carry-over effects across metamorphosis of a pesticide on female lifetime fitness strongly depend on egg hatching phenology: A longitudinal study under seminatural conditions. *Environ. Sci. Technol.* 51(23): 13949-13956. (in English) ["Current ecological risk assessment of pesticides fails to protect aquatic biodiversity. For the first time, we tested two potential reasons for this failure with regard to carry-over effects across metamorphosis: their dependence on hatching period, and the lack of studies quantifying adult fitness under seminatural conditions. Using *Coenagrion puella* sampled from six populations, we designed an outdoor longitudinal one-year study starting from the egg stage. We exposed the aquatic larvae to the pesticide esfenvalerate (0.11 µg/L) during the initial microcosm part. Next, we monitored the lifetime fitness of the terrestrial adults in an insectary. Exposure to the pesticide negatively impacted not only larval traits, but also drastically reduced lifetime mating success of adult females. The impact of this postmetamorphic effect of the pesticide on the population level was three times more important than the effects in the larval stage. Importantly, this carry-over effect was only present in females that hatched early in the season, and was not mediated by metamorphic traits (age and mass at emergence). We provide proof-of-principle under seminatural conditions for two potential pitfalls that need to be considered when improving risk assessment: carry-over effects on adult fitness can (i) be much more important than effects during the larval stage and may not be captured by metamorphic traits, and (ii) be strongly modulated by egg hatching dates."

**16640.** Turnmore, M. (2017): An early morning dragonfly sighting. *Atropos* 58: 55. (in English) [Verbatim: "In the early hours of 30 August 2016 I was carrying out a pre-dawn bat survey in St Ives, on the north coast of Cornwall, as part of my work as an ecologist. This involved standing looking northwards (towards the sea) at one aspect of a large flat-roofed building, approximately 100m from the seafront. The survey began at approximately 04.50hrs. Weather conditions were dry and calm with a temperature of 15°C and complete cloud cover; sunrise was at 06.36hrs. It was a fairly uneventful survey with a single Common Pipistrelle *Pipistrellus pipistrellus* returning to roost behind hanging tiles on the exterior of the building at around 06.10hrs, after which all bat activity ceased. At around 06.20hrs my attention was drawn towards a movement low over the roof of the building and I was surprised to see a dragonfly appear, flying down to circle a few metres in front of me at around head height, gaining height over the roof, before doing one more similar circuit and disappearing. This appeared to be a patrolling flight rather than a foraging flight. The insect was not seen again, much to my frustration. It appeared to be a small hawk-type dragonfly but unfortunately as it was not yet fully light it was not possible to discern any colours or markings on the insect and confirm the identity. This part of St. Ives is fairly urban with lots of buildings and small gardens but no obvious areas of water—not classic Odonata habitat by any means. The nocturnal occurrence of Odonata at moth-traps is well-known in the UK, being particularly associated with species that are known migrants, and it is generally accepted that most such records refer to migrant insects (Parr, 2006). Whilst Odonata species occurring in the UK are diurnal species that are particularly active in sunny conditions, it is clear that some are capable of nocturnal activity when on migration. Activity at sunrise and sunset is known in some European species, which also includes *Anax imperator* in Spain (Corbet, 1999); the same author notes that many aeshnids may exhibit occasional episodes of activity over water at sunrise and sunset, especially during warm weather. All things considered I suspect this particular sighting relates to *Aeshna mixta*." (Author)] Address: Tunmore, M., The Boat House, Church Cove, Lizard, Cornwall, TK12 7PH, UK

**16645.** VeenaChoubey, R.B (2017): Benthos and venomous snakes in Narmada valley Jabalpur for environment and human welfare. *Global Journal of Multidisciplinary Studies* 6(7): (in English) ["Narmada River, a mighty west flowing river is the fifth largest river in India. At present pollution load of river increases rapidly. Benthic macroinvertebrates are used as pollution indicators that live on or inside the river bed of a water body. Recently this region is rapidly undergoing industrialization, township etc., and such these areas are prone to habitat loss due to which different types of poisonous and non-poisonous snakes are being noticed in the residential areas. Snake bite is an acute life threatening hazard often faced by farm labors and farmers leads to death. This study aims to reduce such problems. The whole Narmada valley of Jabalpur region was selected as study site for the collection of sample. The present study was carried out from January 2014 to December 2016. Sampling of snakes was done as per the requirement of local people. Four study sites had been selected for the investigation of benthos were Bargi dam, Gwarighat, Tilwaraghat and Bhedaghat. Organisms were identified by using standard identification keys provided by Fraser (1933, 1934 and 1936); Mitra (2006); Subramanian (2005, 2009); Andrew et al., (2009); Varshney (1983); Tonapi (1980); Adoni et al., (1985); SubbaRao (1993), Smith (1943); Whitaker & Captain (2004) and indian-snakes.org. In present study total 81 species of various fauna have been recorded viz., Odonata 37 species (7 Families), Lepidoptera 25 Species (5 Families), Mollusca 13 Species (2 Class), Reptiles 06 species (2 families). Benthos helps to assess quality of water and play an important role in food chain for the natural balance. In the same way this study will help people to know venomous snakes when encountered namely, Common Krait, Spectacled Cobra, Russell's viper and Saw-scaled Viper; responsible for more than 80% fatalities in Indian Subcontinent. The whole study on benthos as well as reptile encircle around environment and human welfare." (Authors)] Address: not stated

WallisDeVries, M.F. (2017): Differentiating the effects of climate and land use change on European biodiversity: A scenario analysis. *Ambio* 46(3): 277-290. (in English) ["Current observed as well as projected changes in biodiversity are the result of multiple interacting factors, with land use and climate change often marked as most important drivers. We aimed to disentangle the separate impacts of these two for sets of vascular plant, bird, butterfly and dragonfly species listed as characteristic for European dry grasslands and wetlands, two habitats of high and threatened biodiversity. We combined articulations of the four frequently used SRES climate scenarios and associated land use change projections for 2030, and assessed their impact on population trends in species (i.e. whether they would probably be declining, stable or increasing). We used the BIOSCORE database tool, which allows assessment of the effects of a range of environmental pressures including climate change as well as land use change. We updated the species lists included in this tool for our two habitat types. We projected species change for two spatial scales: the EU27 covering most of Europe, and the more restricted biogeographic region of 'Continental Europe'. Other environmental pressures modelled for the four scenarios than land use and climate change generally did not explain a significant part of the variance in species richness change. Changes in characteristic bird and dragonfly species were least pronounced. Land use change was the most important driver for vascular plants in both habitats and spatial scales, leading to a decline in 50–100% of the species included, whereas climate change was more important for wetland dragonflies and birds (40–50 %). Patterns of species decline were similar in continental Europe and the EU27 for wetlands but differed for dry grasslands, where a substantially lower proportion of butterflies and birds declined in continental Europe, and 50 % of bird species increased, probably linked to a projected increase in semi-natural vegetation. In line with the literature using climate envelope models, we found little divergence among the four scenarios. Our findings suggest targeted policies depending on habitat and species group. These are, for dry grasslands, to reduce land use change or its effects and to enhance connectivity, and for wetlands to mitigate climate change effects." **16649.** Vilela, D.S.; Del-Claro, K.; Guillermo-Ferreira, R. (2017): The influence of body size and agility in displacement capacity of male damselflies (Odonata, Protoneurinae). *Journal of Insect Behavior* 30(6): 759-767. (in English) ["Alternative mating tactics (AMT) occur in several animal taxa as a way to respond to physiological or environmental factors that affect reproductive success. In other words, males can exhibit different mate acquisition tactics associated with phenotypic variations. Here we present the case of *Epipleoneura williamsoni*, a non-territorial Neotropical damselfly in which larger males actively search for females along the margins of streams and smaller males remain perched on the vegetation and adopt a sit-and-wait strategy. Males were captured, marked and behavioral observations were conducted to take notes on the spatial displacement of individuals. We then measured male body size and agility to test whether these traits could be used to predict flight ability and thus AMT's. Agility was measured by the 2(S) coefficient, which is a surrogate of flight ability and maneuverability. The results show that body size was positively correlated with male flight ability and agility. However, male agility did not predict the adopted AMT. These results suggest that the strategies adopted by *E. williamsoni* males may be a reflection of body condition. This study adds evidence on how selection may act on different phenotypes within a population and how body size variations may result in different displacement capacities and flight agility." **16650.** Vilela, D.S.; Ricioli, L.S.; Del-Claro, K.; Guillermo-Ferreira, R. (2017): Female color polymorphism of *Ischnura capreolus* Hagen, 1861 (Odonata: Coenagrionidae) with notes on behavior and ontogenetic color changes. *International Journal of Odonatology* 20(3/4): 191-200. (in English) ["Polymorphism in coenagrionids is widely known, mainly for *Ischnura*. Here, we present the case of *I. capreolus*, a Neotropical species of which, until now, little information concerning color polymorphism and ontogenetic color changes was known. We used a marking and recapture method to evidence ontogenetic coloration changes in females. We show that, in addition to the gynochrome morph, *I. capreolus* females also exhibit at least one additional morph: an androchrome color pattern. Gynochrome females (97.1% of marked females) are green-yellow when young and change to a brownish pattern with age, within a week. Androchrome females (2.9% of marked females) exhibit blue coloration, similarly to males. Our study provides

the first evidence of ontogenetic color change in *I. capreolus*. Furthermore, field observations show that *I. capreolus* is similar to other *Ischnura* species regarding sexual harassment behavior." **16651.** Villalobos-Jiménez, G.; Hassall, C. (2017): Effects of the urban heat island on the phenology of Odonata in London, UK. *International Journal of Biometeorology* 61: 1337-1346. (in English) ["Urbanisation is one of the major drivers of ecosystem change, and includes increased temperatures in cities leading to an urban heat island (UHI). This study quantified the phenological response of odonates across London, UK, from 1990 to 2012 using a database of 1,031,277 historical sightings. The ordinal flight dates of each species were used to calculate the leading edge, middle, and trailing edge of the flight period (P5, P50, and P95, respectively). The results suggest that the phenology of odonates is affected by the UHI only at a community level: no significant changes in the P5 or P50 of the flight period were found, although the P95 shows a mean advance of 4.13 days compared to rural areas, thus suggesting a contraction of the flight period in urban areas. However, only one individual species (*Sympetrum striolatum*) exhibited an advance in the P95 of the flight period in urban areas compared to rural areas. On the other hand, climate change (minimum temperature) had a much stronger impact on the phenology of odonates at the community level with a significant advance of 6.9 days °C<sup>-1</sup> in the P5 of the flight period, 3.1 days °C<sup>-1</sup> in the P50, and 3.3 days °C<sup>-1</sup> in the P95 flight date. Similarly, a significant advance in P5 was found in 7 of the 15 species tested in response to minimum temperature and 2 species showed a significant advance in P50 in response to minimum temperature, but no species showed a shift in the P95 flight date due to minimum temperature. As shown in previous studies, life history influences the phenological response of odonates, with spring species and those species lacking an egg diapause being the most responsive to increased temperatures, although summer species and species with obligate egg diapause also respond to the UHI by advancing the P95 by 3.8 days and 4.5 days respectively compared to rural areas, thus contracting the flight period. The present study shows that the UHI has negligible impacts on emergence patterns of odonates compared to climate change, which may result from the capacity of aquatic habitats to buffer the microclimatic conditions of the surrounding terrestrial habitats. We conclude by highlighting the importance of climate change on freshwater habitats over the impacts of the UHI." (Authors)] Address: Villalobos-Jiménez, Giovanna, School of Biol., Univ. **16655.** Wang, A.R.; Kim, M.J.; Kim, S.S.; An, J.; Kim, I. (2017): Development and validation of microsatellite markers from the Tiny dragonfly, *Nannophya pygmaea* (Odonata: Libellulidae) populations that are endangered in Korea. *Proceed-*

ings of the Korean Society of Applied Entomology, 2017 Annual Meeting of the Korean Soc. Appl. Ento. & Intern. Symp., Emergence of Applied Insects: 153. (in English) [Verbatim: "N. pygmaea is one the smallest dragonflies in the world and listed as a second-degree endangered wild animal in Korea. We developed microsatellite markers and applied selected markers to South Korean populations to understand population genetic characteristics, along with two mitochondrial DNA (mtDNA) gene sequences (COI and ND5). Two mtDNA-based population genetic analysis indicates substantially reduced genetic diversity in an island population (Muuido) compared to others. On the other hand, population-based FST and RST consistently support that N. pygmaea populations are overall well interconnected with a relatively high gene flow. These results may collectively indicate that N. pygmaea populations in South Korea may have rather larger population size than we previously acknowledged based on a single-locus mtDNA sequence and field observation." **16656.** Wang, M.; Wang, M.; Shen, L.; Sun, X.; Shi, G.; Ma, W.; Yan, X. (2017): High-performance flexible surface-enhanced Raman scattering substrates fabricated by depositing Ag nanoislands on the dragonfly wing. *Applied Surface Science* 436: 391-397. (in English) ["Highlights: •Dragonfly wing with irregular surface for template gets a high SERS performance. •The optimized structure of Ag on irregular DW was obtained by magnetron sputtering. •The prepared substrates are flexible, low-cost, large-scale and environment-friendly. •The limit of detection reaches 10<sup>-10</sup> M to 4-aminothiophenol. •Rapid and quantitative detection of crystal violet can be achieved by our substrates. Abstract: Natural dragonfly wing (DW), as a template, was deposited on noble metal sliver (Ag) nanoislands by magnetron sputtering to fabricate a flexible, low-cost, large-scale and environment-friendly surface-enhanced Raman scattering (SERS) substrate (Ag/DW substrate). Generally, materials with regular surface nanostructures are chosen for the templates, the selection of our new material with irregular surface nanostructures for substrates provides a new idea for the preparation of high-performance SERS-active substrates and many biomimetic materials. The optimum sputtering time of metal Ag was also investigated at which the prepared SERS-active substrates revealed remarkable SERS activities to 4-aminothiophenol (4-ATP) and crystal violet (CV). Even more surprisingly, the Ag/DW substrate with such an irregular template had reached the enhancement factor (EF) of ~1.05×10<sup>5</sup> and the detection limit of 10<sup>-10</sup> M to 4-ATP. The 3D finite-different time-domain (3D-FDTD) simulation illustrated that the "hot spots" between neighbouring Ag nanoislands at the top of pillars played a most important role in generating electromagnetic (EM) enhancement and strengthening Raman signals." **16660.** Wild, N. (2017): Spatio-temporal patterns of dragonfly occurrence on meadows in the Donau-Auen National Park, Lower Austria. *Conference Volume, 6th Symposium for Research in Protected Areas, 2 to 3 November 2017, Salzburg: 727-732.* (in English) ["Dispersal is a characteristic trait in Odonata. While dispersal behavior of dragonflies and damselflies between waterbodies has generally received a great deal of attention, dispersal processes subjected to terrestrial habitats and hence, Odonate's use in the context of foraging activities, have previously only attracted limited interest. This study aimed to investigate the dispersal of dragon-

flies and damselflies to floodplain meadows used for foraging or as refuge. The primary focus was on assessing species-specific dispersal characteristics influencing the spatial distribution of species, species richness and community structure on meadows. Therefore, Odonata were sampled between May and September 2016 at 16 meadow and eight waterbody sites in the Donau–Auen National Park (DANP), Eastern Austria near Orth an der Donau. In total, 1.427 dragonflies were recorded, including 667 observed on meadows. Anisopterans were more likely to disperse long distances from waterbodies than zygopterans, and females showed proportionally higher abundances on meadows than at waterbodies. Species composition, species richness and occurrence of dragonflies were highly influenced by the distance meadows were situated away from waterbodies. Moreover, the results from this study demonstrated that occurrence of Odonata, species richness and the structure of species assemblages are associated with structural characteristics of forest margins adjacent to meadows. For most Odonata species, a positive relationship between heterogeneity in forest margin vegetation structure and occurrence could be found. This study provides important insight into odonate's utilization of meadows embedded in floodplain systems and provides some basis for potential conservation management considerations with the aim to protect terrestrial habitats of rare dragonflies." **16665.** Xue, J.; Yu, X.; Zhang, H.; Chen, X.; Bu, W. (2017): Population genetics and ecological niche modeling shed light on conservation of the island endemic damselfly *Pseudolestes mirabilis* (Odonata, Pseudolestidae). *Hydrobiologia* 790: 273-286. (in English) ["Island endemic species have a much higher risk of extinction than those of mainland. *P. mirabilis*, the single representative of the family Pseudolestidae which is endemic to Hainan Island, is facing a danger of extinction along with the acceleration of urbanization. To investigate population genetics and further evaluate the conservational importance, the mitochondrial gene COI of 126 individuals from 11 populations of the phoenix damselfly were sequenced and analyzed. This is the first comprehensive population ecological study for this species. The results recovered low genetic diversity and weak phylogeographic structure. Mul-

multiple lines of evidence including neutrality test, mismatch distribution analysis, phylogenetic topologies, and Bayesian skyline plot supported a population expansion just after the Last Glacial Maximum. Statistics of genetic diversity, gene flow, and potential habitats reconstruction suggested that the refugia constricted to the south central areas of the island. Meanwhile, the small population size and low genetic variation in some peripheral populations also implied a niche reduction. Increasing human activity and severe environment destruction may be the main reasons causing a recent decline of the population and increasing the risk of extinction. Therefore, urgent conservation efforts must be implemented to ensure the long-term survival of *P. mirabilis*. The present research has provided a way to prioritize and assess management strategies of this charismatic species." (Authors)] Address: Yu, X., Institute of Entomology, College of Life Sciences, Nankai University, Tianjin, China

**16666.** Yalles Satha, A.; Sanraoui, B. (2017): Environmental factors influencing Odonata communities of three Mediterranean rivers: Kebir-Est, Seybouse, and Rhumel Wadis, northeastern Algeria. *Revue d'Ecologie (Terre et Vie)* 72(3): 314-329. (in English, with French summary) ["Odonata are an important component of lotic communities and their abundance and diversity may inform on the health of running waters. The survey of the odonatofauna of three major Algerian wadis: Kebir-East, Seybouse, and Rhumel, led to the identification of 40 species. Our results revealed the presence of *Calopteryx exul*, a Maghrebian endemic, at Wadi Seybouse and seemed to confirm the extinction of the type population at Wadi Rhumel where the species was first recorded in the XIXth Century. The results also indicated the range expansion of several species: *Coenagrion caeruleum*, *Orthetrum nitidum*, *Trithemis kirbyi* and *Urothemis edwardsii* whose relict population is critically endangered. Additionally sampling of abiotic factors (altitude, water temperature, conductivity, etc.) was carried out and data analysed in view of exploring a possible co-structure between the faunistic and environmental data sets. Data analysis indicated that correlation between abiotic factors (hydroperiod, water conductivity and water temperature) and species richness differed between streams and thus Odonata may prove useful in evaluating the ecological integrity of Mediterranean lotic systems." **16667.** Yoon, S.S.; Kim, M.-H.; Choi, S.K.; Eo, J.; Kwon, S.-I.; Song, Y.J. (2017): The development of a sampling instrument for aquatic organisms in rice paddy fields: Submerged funnel traps with attractants. *Korean Journal of Environmental Biology* 35(4): 640-647. (in Korean, with English summary) ["The need for an efficient sampling technique to collect aquatic organisms has risen with the increase of interest in rice paddy fields, which have been recognized as important ecosystems supporting biodiversity. In the present study, a submerged funnel trap used with the assistance of attracting agents (fish meal and chemical light) was designed as an easy, objective and quantitative tool for collecting aquatic organisms in the rice paddy fields. The preference for collecting aquatic organisms as a means for attracting agents was analyzed

using a generalized linear mixed model. Also, based on the data of previous research, we compared the community composition of the aquatic macroinvertebrates, which were collected using the quadrat method, and newly designed submerged funnel traps, by analyzing non-metric multidimensional scaling. The results showed that the catching efficiency of 18 of the total 65 taxa was affected by the attracting agents. 12 taxa including *Pomacea canaliculata*, *Hippeutis cantori*, *Austropeplea ollula*, *Erpobdella lineata*, *Ostracoda* spp. *Branchinella kugenumaensis*, *Hydracarina grammicus*, *Rhantus pulverosus*, *Chironomidae* spp., *Rana nigromaculata*, *Cobitidae* spp. etc., favored fish meal and 6 taxa including *Ischnura asiatica*, *Coenagrionidae* spp. *Stemolophus rufipes* etc., were attracted by chemical light. The submerged funnel trap used as a measurement tool for biodiversity was less applicable than the quadrat method; however, it was more effective for the selective collection of specific taxa. We expect that this newly designed trap can be a simple and quantitative method for collecting aquatic organisms, and could be used for long term and extensive surveys in rice paddy fields in the future." (Authors)] Address: Yoon, S.S., National Institute of Agricultural Sciences, RDA, Wanju 55365, Republic of Korea

**16668.** Younas, S.; Rehman, H.U.; Gul, S.; Gul, R.; Khattak, B. (2017): Animal diversity of district Karak, KP, Pakistan. *Journal of Entomology and Zoology Studies* 5(4): 1126-1134. (in English) ["The present study was conducted to explore the vertebrate and invertebrate fauna of district Karak, Khyber Pakhtunkhwa province of Pakistan during the period from May 2016 to May 2017. Karak includes all the vertebrates, including fishes, amphibians, reptiles, birds and mammals. During the present survey, 184 different species of the both vertebrates and invertebrates fauna of the district Karak were observed. ... and 56 species of invertebrates. So from the present study, it may be concluded that the families Cyprinidae, Ranidae, Agamidae, Phasianidae, Equidae, Bovidae, Libellulidae, Formicidae were very dominant in the district Karak." ["There were several suitable habitats for dragonflies, comprising ponds and wetlands in the pacific coastal area of Aomori prefecture before the Great East Japan Earthquake and tsunami. Some of them were damaged by the big tsunami, but other water environments, including ponds and wetlands, were reproduced by the tsunami. Many insects including dragonflies invaded those areas, therefore we need to continuously observe them, because such environments are easily changed or could vanish in near future."] Address: not stated

**16670.** Zawal, A.; Thery, L.; Stoks, R.; Michonski, G. (2017): New records of host-parasite relationships between *Coenagrion scitulum* (Rambur, 1842) (Odonata) and water mite larvae (Hydrachnidia) in core and edge host populations. *Acta Parasitologica* 62(1): 38-45. (in English) ["The relationships between water mite larvae parasitizing *C. scitulum* in core

and edge populations were described. A total of 636 larvae of 7 water mite species were found on 143 *C. scitulum* adults (82 females and 61 males). *C. scitulum* was recorded for the first time as a host species for *Arrenurus cuspidator*, *A. bruzelii*, *A. bicuspidator*, *A. tricuspidator*, *A. claviger* and *Hydryphantes octoporus*. The degree of infestation by particular parasite species was typical for these species. In contrast, the parasites' preferences for host body parts were not typical, as they preferred abdominal segments 2-4, which in earlier studies had been avoided by water mite larvae. No differences were found in degree of infestation of *C. scitulum* individuals between core and edge populations, with the exception of *Hydryphantes octoporus*, which parasitized damselflies only in core populations." **16673.** Zhang, L.; Wen, C.-L.; Wang, M.-Y.; Yang, X.-Z.; Yuan, M.-L. (2017): The complete mitochondrial genome of *Enallagma cyathigerum* (Odonata: Coenagrionidae) and phylogenetic analysis. *Mitochondrial DNA Part B, Resources* 2(2): 640-641. (in English) ["To better understand the diversity and evolution of Odonata, we sequenced and annotated the complete mitochondrial genome (mitogenome) of *Enallagma cyathigerum*. This mitogenome was 16,661 bp in size

and encoded the typical 37 genes, i.e. 13 protein-coding genes (PCGs), 22 transfer RNA genes (tRNAs) and two ribosomal RNA genes. The nucleotide composition of the *E. cyathigerum* mitogenome was significantly biased toward A and T, with an A + T content of 74.2%. Eleven PCGs started with a typical ATN codon, whereas the remaining two PCGs (*nad1* and *nad3*) used TTG as the initial codon. All the 22 tRNAs had a typical secondary cloverleaf structure. The Bayesian phylogenetic analysis based on the concatenated nucleotide sequences of 13 PCGs strongly supported the sister relationship of *E. cyathigerum* and two *Ischnura* species from the same family Coenagrionidae. The phylogenetic tree strongly supported the monophyly of each of the two suborders (Zygoptera and Anisoptera) and recovered a phylogeny of Zygoptera + (Anisoptera + Anisozygoptera)."] Address: Zhang, L., State Key Laboratory of Grassland Agro-Ecosystems, College of Pastoral Agricultural Science & Technology, Lanzhou Univ., Lanzhou, Gansu, People's Republic of China

**16674.** Zheng, D.; Chang, S.-C.; Jarzembowski, E.A.; Wang, B. (2017): The first aeshnoid dragonfly (Odonata: Anisoptera: Telephlebiidae) from mid-Cretaceous Burmese amber. *Cretaceous Research* 72: 105-109. (in English) ["A new true dragonfly, *Cretaeshna lini* gen. et sp. nov., is described based on a forewing from mid-Cretaceous Burmese amber. *Cretaeshna* is probably a member of Telephlebiidae: Telephlebiinae, but differs from the latter in having a weakly-defined IR1 and a short pterostigma. *Cretaeshna lini* is the first aeshnid dragonfly to be found as an amber inclusion and the third Cretaceous true dragonfly recorded in amber. Our find augments the diversity of Mesozoic true dragonflies, and enhances our understanding of the palaeogeographic distribution of aeshnid dragonflies." **16678.** Zheng, D.; Nel, A.; Jarzembowski, E.A.; Chang, S.-C.; Zhang, H.; Xia, F.; Liu, H.; Wang, B. (2017): Extreme adaptations for probable visual courtship behaviour in a Cretaceous dancing damselfly. *Sci. Rep.* 7, 44932; 8 pp. (in English) ["Courtship behaviours, frequent among modern insects, have left extremely rare fossil traces. None are known previously for fossil odonates. Fossil traces of such behaviours are better known among the vertebrates, e.g. the hypertelic antlers of the Pleistocene giant deer *Megaloceros giganteus*. Here we describe spectacular extremely expanded, pod-like tibiae in males of a platycnemidid damselfly from mid-Cretaceous Burmese amber. Such structures in modern damselflies, help to fend off other suitors as well as attract mating females, increasing the chances of successful mating. Modern Platycnemidinae and Chlorocyphidae convergently acquired similar but less developed structures. The new

findings provide suggestive evidence of damselfly courtship behaviour as far back as the mid-Cretaceous. These data show an unexpected morphological disparity in dancing damselfly leg structure, and shed new light on mechanisms of sexual selection involving intra- and intersex reproductive competition during the Cretaceous." (Authors)] Address: Nel, A., Lab. Ent. Mus. Natn. Hist. Nat., 45 rue Buffon, F-75005 Paris, France. E-mail: anel@cimrs1.mnhn.fr

**16679.** Zheng, D.R.; Nel, A.; Wang, B.; Jarzembowski, E.A.; Chang, S.-C.; Zhang, H.C (2017): The first Triassic 'Protodonatan' (Zygophlebiidae) from China: stratigraphical implications. *Geological Magazine* 154(1): 169–174. (in English) ["The clade Triadophlebioptera within the Odonoptera greatly diversified and became widely distributed worldwide during the Triassic. Although abundant insect fossils have been reported from the Triassic of China, no Triassic dragonflies have been recorded. In this paper, *Zygophlebia tongchuanensis* sp. nov., the first species of Zygophlebiidae discovered outside the Madygen Formation of Kyrgyzstan, is described from the Middle–Upper Triassic Tongchuan Formation of Shaanxi Province, northwestern China. The discovery extends the distribution of the family Zygophlebiidae in Asia, indicating a high diversity of Triadophlebioptera during Middle–Late Triassic times. Combined with the palaeontological and geochronological evidence, the age of the Tongchuan Formation is considered to be Anisian – Early Carnian, and the insect-bearing layers are considered to be Ladinian." ## 2018

**16680.** A Mahyoub, J. (2018): Mosquito larvicidal activity of seaweed extracts against *Anopheles d'thali* with reference to its side effects on aquatic non-target organisms. *International Journal of Mosquito Research* 5(6): 34–38. (in English) ["The biological effects of three Seaweed extracts *Seagrass Thalassia hemprichii*, *Sea lettuce Ulva lactuca*, and *Gray Mangrove Avicennia marina* against 4th instar mosquito larvae of *A. d'thali* were evaluated. Values of IC50 (concentration which to inhibit the emergence of 50% of mosquito adults survived from larval treatments) indicated that *A. marina* (107.3 ppm) proved to be the most effective extract against *A. d'thali*, followed by *T. hemprichii* (197.3 ppm) while the seaweed extract *U. lactuca* (335.3 ppm) was the least effective one. Variations in susceptibility levels of *An. d'thali* mosquito larvae may probably due to differences in toxicity levels among the active components of seaweed extracts. On the other hand, treatments with IC90 values of the test extracts *A. marina* (284.7 ppm), *T. hemprichii* (293.8 ppm) and *U. lactuca* (588.3 ppm) did not have any adverse effects towards some aquatic non-target organisms (Odonata naiads, aquatic hemipterous, aquatic coleopterans) prevailing in mosquito breeding sites." - 16683.** Acquah-Lampsey, D.; Brandl, R. (2018): Effect of a dragonfly (*Bradinopyga strachani* Kirby, 1900) on the density of mosquito larvae in a field experiment using mesocosms. *Web Ecol.* 18: 81-89. (in English) ["Laboratory experiments with food-deprived larvae of odonates suggested that these predators may have the potential to control mosquito populations. However, it remains unclear whether larvae of odonates co-occur with mosquito larvae in the field and whether larvae of odonates reduce the density of mosquito larvae in the field. We exposed 35 water-filled concrete containers in the field in shady and sunny conditions. Some of these containers were partially covered (for simplicity called closed containers, allowing only mosquitoes to lay eggs), whereas others remained open. The density of mosquito larvae was higher in shaded containers and in closed containers. The multivoltine odonate *B. strachani* colonized open containers and the occurrence of these predators resulted in a clear reduction of the mosquito population. Our results indicate that increasing the colonization of water bodies by *B. strachani* is a promising strategy for controlling populations of mosquitoes." (2018): Female colour form has no effect on copulation duration of the polymorphic *Ischnura fluviatilis* (Odonata: Coenagrionidae). *Odonatologica* 47(3/4): 229-243. (in English) ["We studied a population of *I. fluviatilis* in Mato Grosso do Sul (Brazil), to establish the range of female colour polymorphism and associated mating behaviour. We found three female colour

forms: orange and brown, which were the immature and mature coloration of the commoner gynochrome morph, and a blue androchrome morph. We observed mating couples and analysed the relationship between copulation duration and phenotypic characteristics of males and females. There were significant differences between colours for female body size, fecundity, egg size and copulation duration, and in most cases the most deviant colour form was the immature orange. These females were significantly larger, and had the highest fecundity. Androchrome females produced smaller eggs. Copulations lasted on average 65 min, with the shortest copulation durations observed for brown females. Male size and the order of observation (indicative of seasonal effects) explained a significant proportion of variation in copulation duration, but female colour form, fecundity and size were not significant. We found evidence for assortative mating by size. Our results indicate that female colour does not explain variation in copulation duration, and therefore the possibility of cryptic male choice seems unlikely." **16689.** Ansari, M.I.; Anwer, S.F. (2018): Numerical analysis of an insect wing in gliding flight: Effect of corrugation on suction side. *Fluid Dynamics and Materials Processing* 14(4): 259-

279. (in English) ["We have conducted a numerical study to investigate the relationship between the aerodynamic performance of an insect wing section and the effect of corrugation in gliding flight. In particular, an Airfoil-CR, corresponding to Kesel's Profile 2 (Kesel, *Journal of Experimental Biology*, vol. 203, 2000), has been used. This profile represents exactly the cross section of the so-called "*Aeshna cyanea*". A smoothed variant of this profile (referred to in the present study as Airfoil-SM) has also been considered. Introducing five different variants of the Airfoil-CR corresponding to different levels of corrugation, namely M1, M2, M3, M4 and M5, an unsteady fluid flow analysis has been carried out in the framework of a Fraction-Step Method (based on a velocity-pressure coupling scheme). Another airfoil M6 has also been considered by taking all the corrugations on the suction side simultaneously while the pressure side remains smooth. Simulations were performed for variety of Reynolds numbers ranging from 150 to 10000, while angle of attack was varied from 0° to 20°. According to the results, the performances (in terms of shear and pressure drags) change as a function of the corrugation and Reynolds number. While the performances of the Airfoil-CR are relatively good at low Reynolds numbers, its behavior changes completely at higher Reynolds number where the best performances are achieved by using the Airfoil-SM. Moreover, steady or oscillatory flow can emerge depending on the considered situations. Address: Ansari, M.I., Zakir Husain College of Engineering & Technology, Aligarh Muslim University, Aligarh, 202002, India. E-mail: mailimran99@gmail.com

**16691.** Arjangpay, A.; Darvizeh, A.; Tooski, M.Y. (2018): Effects of structural characteristics of a bionic dragonfly wing on its low velocity impact resistance. *Journal of Bionic Engineering* 15(5): 859-871. (in English) ["The influence of the structural features of dragonfly wings, including the sandwich-type configuration of longitudinal veins and the longitudinal corrugations, on the impact response of a bio-inspired structure is investigated. According to experimental observations of the wing morphology, a novel foam-based composite structure is introduced consisting of E-glass/epoxy face-sheets bonded to a polyurethane foam core. A finite element model is employed to simulate the structural responses of the biomimetic structure under low velocity impact. The initiation and evolution of the impact-induced damage in composite skins are simulated by applying a user-defined progressive damage model together with the interfacial cohesive law for intra- and inter-laminar damages, respectively. To simu-

late the nonlinear behavior of the foam core, a crushable plasticity model is implemented. The numerically obtained results are found to correlate with the experimentally measured ones, acquired by drop-weight testing on a bio-inspired structure. It is numerically predicted that reinforcing the structure with the veins gives the more impact load-bearing capacity and the longitudinal corrugation can increase the stiffness and damage resistance of the structure. Effects of the change in impact location, the configuration of the veins and the corrugated angle on damage resistance of the structures are fully discussed." **16696.** Barbosa, M.S.; Rodrigues Borges, L.; Vilela, D.S.; Venâncio, H.; Santos, J.C. (2018): Comunidade de odonatas de um trecho do Reservatório Sucupira, Rio Uberabinha, Uberlândia, Minas Gerais. Trabalho de Conclusão de Curso (Graduação em Ciências Biológicas) – Universidade Federal de Uberlândia, Uberlândia: 36 pp. (in Portuguese, with English summary) ["Dragonflies (Insecta: Odonata) are widely distributed among freshwater ecosystems of tropical and temperate environments and are sensitive to anthropogenic changes. The objective of this study was to inventory the odonate fauna of a section of the Scupira Reservoir on the Rio Uberabinha, Uberlândia, Minas Gerais, Brazil, and to analyze if seasonal patterns influence its diversity. In addition, the studied proposed to describe the Brazilian distribution of the species sampled. Sampling took place during the dry (August-September 2017) and rainy (February-March 2018) seasons, and recorded 860 individuals of 42 species belonging to 26 and six families. Seven new records for the Triângulo Mineiro Region were recorded, representing the families Gomphidae, Libellulidae and Coenagrionidae. 17 species were exclusive to the rainy season and seven to the dry season, while 18 species were found in both. The rainy season had greater abundance, with four times as many individuals as the dry season. This study contributes by increasing the number of records for odonate species in the Cerrado of Minas Gerais, and reinforces the trend for a greater predominance of this group during the rainy seasons in this biome." **16697.** Barbotte, Q.; Ruffoni, A. (2018): Réflexion sur l'utilisation de l'autochtonie des odonates à différentes échelles. Revue scientifique Bourgogne-Franche-Comté Nature 27: 277-290. (French, with English summary) ["At this time, regional Odonata datasets are substantial (usually thousands of data; around 100 000 for Burgundy-Franche-Comté), especially with monitoring for atlas or programs on endangered species. It becomes difficult to analyze such data, particularly concerning the establishment of populations on aquatic environment, because dragonflies tend to move away from their reproduction sites. The aim of the methodology is to identify high stakes stations and to create sophisticated regional maps. This work, based at first on bibliography, provides an autochthony level for species, like reproduction clues for birds, at different scales (station, plot level). In its application, the qualification of an autochthony level is more flexible at plot level than station level where it's strict. To be realized semi-automatically, data needs to be refined (biotopes, numbers, mating,

exuvia, etc.), presence of potential biotopes for dragonflies listed, and computer requests need to be done. The methodology works fairly well for the burgundy dataset and more easily on non streaming environments than on streaming environments, but it may need some requirements modifications." **16698.** Barnard, A.A.; Masly, J.P. (2018): Divergence in female damselfly sensory structures is consistent with a species recognition function but shows no evidence of reproductive character displacement. *Ecology and Evolution* 8(23): 12101-12114. (in English) ["Males and females transmit and receive signals prior to mating that convey information such as sex, species identity, or individual condition. In some animals, tactile signals relayed during physical contact between males and females before and during mating appear to be important for mate choice or reproductive isolation. This is common among odonates, when a male grasps a female's thorax with his terminal appendages prior to copulation, and the female subsequently controls whether copulation occurs by bending her abdomen to complete intromission. It has been hypothesized that mechanosensory sensilla on the female thoracic plates mediate mating decisions, but it has been difficult to test this idea. Here, we use North American damselflies in the genus *Enallagma* (Odonata: Coenagrionidae) to test the hypothesis that variation in female sensilla traits is important for species recognition. *Enallagma anna* and *E. carunculatum* hybridize in nature, but experience strong reproductive isolation as a consequence of divergence in male terminal appendage morphology. We quantified several mechanosensory sensilla phenotypes on the female thorax among multiple populations of both species and compared divergence in these traits in sympatry versus allopatry. Although these species differed in features of sensilla distribution within the thoracic plates, we found no strong evidence of reproductive character displacement among the sensilla traits we measured in regions of sympatry. Our results suggest that species-specific placement of female mechanoreceptors may be sufficient for species recognition, although other female sensory phenotypes might have diverged in sympatry to reduce interspecific hybridization." **16700.** Baux, V.; Krieg-Jacquier, R. (2018): *Leucorrhinia pectoralis* dans l'Ain: rigueur dans les inventaires, conséquences sur la gestion des habitats et la pérennité des populations. 2018. *Revue scientifique Bourgogne-Franche-Comté Nature* 27: 179-190. (in French, with English summary) ["Registered in Annex II and IV of the Habitats Directive, *L. pectoralis* is a protected species in France included in the Plan national d'actions en faveur des Odonates (PNAO) and regarded as « Near Threatened ». In Auvergne-Rhône-Alpes, it is included in the regional implementation of the PNAO and has the same status. To date, knowledge on the distribution of the species in the department of Ain is fragmentary and based mainly on observation of imagos. With the exception of one research, the data concerning reproduction and therefore the presence of perennial populations do not make it possible to decide on the conservation status of the species considered « Near Threatened » in 2013. For two years, after the announcement of a one year drying up of a major site for this species, we study the distribution and behavior of this species in the department. The poor results obtained against the prospecting endeavour suggest that the species is at serious risk of extinction. Today there are possible threats on the species (destruction, drying up of sites, habitat changes) and it is possible that its current status in Ain and hence in Rhône-Alpes is too optimistic. The risk is weighed down since the managers of the departmental natural areas seem to have underestimated the precarious situation of this species that they are supposed to protect." (Authors)] Address: Krieg-Jacquier, R., Groupe de recherche et de protection des Libellules *Sympetrum*. E-mail: regis.krieg.jacquier@gmail.com

**16701.** Bechly, G. (2018): First record and a new species of the fossil dragonfly genus *Proinogomphus* (Odonata: Liassogomphidae) from the Early Jurassic of Bascharage in the Grand Duchy of Luxembourg. *Zootaxa* 4450(1): 108-114. (in English) ["A new species of fossil dragonfly, *Proinogomphus kreuzerorum* sp. nov. (Liassogomphidae), is described from the Early Jurassic black shale of Bascharage in the Grand Duchy of Luxembourg, based on a very well-preserved isolated female hind wing. This genus was previously only known from the Liassic of Braunschweig region in Germany, and is here recorded for the first time for this fossil locality. The classification of the family Liassogomphidae Tillyard, 1935 and the genus *Proinogomphus* Cowley, 1942 is briefly discussed and the diagnosis of the latter is emended." **16702.** Bechly, G. (2018): *Chrismooreia michaelbehei* gen. et sp. nov. (Insecta: Odonata: Asiopteridae), a new fossil damsel-dragonfly from the Early Jurassic of England. *BIO-Complexity* 2018(1): 1–10. doi:10.5048/BIO-C.2018.1. (in English) ["A new fossil damsel-dragonfly *Chrismooreia michaelbehei* gen. et sp. nov. (Insecta: Odonata: Asiopteridae) is described from the Early Jurassic of Charmouth in England. This fossil is the best preserved and first complete specimen of the Mesozoic family Asiopteridae, which was previously only known from isolated wings, and actually represents one of the most complete Liassic odonates known. Body characters are described for the first time and include compound eyes that meet dorsally, robust thorax, legs with short spines, and very long leaf-like cerci. The forewing venation features a short fusion of AA+Cu with MP near the tip of the discoidal cell, which is an absolutely unique character state within the order Odonata, here described for the first time. The wing venation shows a mixture of sphenophlebiid and asiopterid characters, with the latter characters dominating. The classification of Sphenophlebiidae is discussed and its synonymy with Asiopteridae is tentatively rejected, but not ruled out. As further addition to the Liassic odonate fauna from the Charmouth fossil locality, a specimen of *Protomyzomelane* cf. *brunonis* is featured but not formally described as first record of the suborder Archizygoptera and the family Protomyzomelantidae." **16704.** Blanke, A. (2018): Analysis of modularity and integration suggests evolution of dragonfly wing venation mainly in response to functional demands. *J. R. Soc. Interface* 15: 20180277. <http://dx.doi.org/10.1098/rsif.2018.0277>. 10 pp. (In English) ["Insect wings show a high variability in wing venation. Selection for function, developmental pathways and phylogeny likely influenced wing vein diversification, however, quantitative data to estimate these influences and their interplay are missing. Here, it is tested how dragonfly wing vein configuration is influenced

by functional demands, development, phylogeny and allometry using the concepts of modularity and integration. In an evolutionary context, modules are sets of characters that evolve in relative independence to other characters, while integration refers to a high degree of association between subparts of a structure. Results show allometric and phylogenetic signal in the wing shape variation, however, patterns of integration and modularity are not influenced by these two factors. Overall, dragonfly wings are highly integrated structures with almost no modular signal. Configuration changes in one wing vein or wing area thus influence wing shape as a whole. Moreover, the fore- and hindwings correlate with each other in their evolutionary shape variation supporting biomechanical data of wing interdependence. Despite the overall high degree of evolutionary integration, functional hypotheses of modularity could be confirmed for two wing areas, the arculus–triangle complex at the base of the wing which is responsible for passive wing folding especially during flapping flight and the location of the pterostigma, a coloured wing cell which is more heavy than other wing cells and passively regulates wing pitch as well as critical flight speeds during gliding. Although evolving as distinct modules, these specific vein regions also show high integration and evolve at the same rates like the whole wing which suggests an influence of these structures on the shape evolution of the rest of the wing. Their biomechanical role as passive regulators of wing corrugation and wing pitch suggests that these structures decisively influenced the evolution of advanced modern flight styles and explains their retention once they had evolved early within the lineage Odonoptera." agricultural headwater streams. *Water* 2018, 10(1), 77; doi:10.3390/w10010077: 15 pp. (in English) ["Outdoor education (OE) stream classes provide students with an opportunity to gain hands-on experience with sampling methods for evaluating stream water quality. Trampling by students as a result of stream classes may disrupt the substrate and negatively impact aquatic macroinvertebrates. The impact of student-induced trampling in headwaters as a result of stream classes on aquatic macroinvertebrates has not been evaluated. Our aim was to document the short-term macroinvertebrate responses to an experimental disturbance that simulated the impacts of trampling by students in riffles within small headwater streams. We measured hydrologic variables, visually estimated substrate composition and sampled aquatic macroinvertebrates within control and experimental riffles in three agricultural headwater streams in central Ohio one day prior to experimental disturbance, immediately after disturbance and one day after disturbance. Hydrologic variables and substrate type did not differ daily or between riffle types. Macroinvertebrate abundance, percentage of Ephemeroptera Plecoptera Trichoptera and percentage of Leuctridae increased after experimental disturbance, while diversity, evenness, percentage of clingers and non-metric multidimensional scaling (NMS) axis 1 site scores declined after disturbance. Macroinvertebrate diversity, percent clingers and NMS axis 1 site scores were lower in experimental riffles than control riffles. None of the macroinvertebrate response variables exhibited a significant interaction effect of day × riffle type that is indicative of an effect of the experimental disturbance. Our results suggest the one-time use of an undisturbed riffle within an agricultural headwater stream for an OE stream class is not likely to impact aquatic macroinvertebrates."] Address: Bossley, J.P., Environmental Science Graduate Program, The Ohio State University, 3138A Smith Lab, 174 West 18th, Columbus, OH 43210, USA

**16708.** Bota-Sierra, C.A.; Sánchez-Herrera, M.; Palacino-Rodríguez, F. (2018): Odonata from protected areas in Colombia with new records and description of *Cora verapax* sp. nov. (Zygoptera: Polythoridae). *Zootaxa* 4462(1): 115-131. (in English) ["Colombia is one of the megadiverse countries in the world, but paradoxically it is one of the less explored. The recent red list assessments show the country has the highest number of endangered species in the Neotropical region. Nevertheless, the sampling effort is low especially in protected areas, which probably can harbor some of the rare species included in the red list. As a result of recent surveys in six protected areas of Colombia, we report twelve new records and describe *Cora verapax* sp. nov., a rare species, collected after more than 300 days of field surveys at the National Natural Park Tatamá. In addition, we compiled and mapped published Odonata records from 2001 until now for Colombian protected areas (136 spp.). Among the new records, some species were formerly known as endemics from Panama and Ecuador, and five species are reported for the first time inside protected areas, showing the importance of surveys in these special territories and bringing new data for conservation actions, as red

list assessment or future management plans." (Authors)] Address: Sánchez-Herrera, Melissa, Facultad de Ciencias Naturales y Matemáticas. Universidad del Rosario, Bogotá, Colombia. E-mail: melsanc@gmail.com

**16709.** Bouiedda, N.; Amari, H.; Guebailia, A.; Zebza, R.; Boucenna, N.; Hadjadj, S.; Mayache, B.; Houhamdi, M.; Khelifa, R. (2018): Reproductive behaviour of *Erythromma lindenii* in North-east Algeria (Odonata: Coenagrionidae). *Odonatologica* 47(3/4): 267-276. (in English) ["The reproductive behaviour of the Atlanto-Mediterranean *E. lindenii* has been studied before in Europe, but not in North Africa where the climate is warmer. We investigated the reproductive behaviour in a natural population in Northeast Algeria. We found that the species is non-territorial with quasi-exclusive underwater oviposition. The duration of underwater oviposition was positively correlated to the maximum water depth. We suggest that females predominantly lay eggs underwater to avoid water evaporation, which is common in North Africa. We discuss the differences in the reproductive behaviour between European populations and one in North Africa." **16710.** Brand, P.; Robertson, H.M.; Lin, W.; Pothula, R.; Klingeman, W.E.; Jurat-Fuentes, J.J.; Johnson, B.R. (2018): The origin of the odorant receptor gene family in insects. *eLife* doi: 10.7554/elife.38340: 13 pp. (in English) ["The origin of the insect odorant receptor (OR) gene family has been hypothesized to have coincided with the evolution of terrestriality in insects. Missbach et al. (2014) suggested that ORs instead evolved with an ancestral OR co-receptor (Orco) after the origin of terrestriality and the OR/Orco system is an adaptation to winged flight in insects. We investigated genomes of the Collembola, Diplura, Archaeognatha, Zygentoma, Odonata, and Ephemeroptera, and find ORs present in all insect genomes but absent from lineages predating the evolution of insects. Orco is absent only in the ancestrally wingless insect lineage Archaeognatha. Our new genome sequence of the zygentoman firebrat *Thermobia domestica* reveals a full OR/Orco system. We conclude that ORs evolved before winged flight, perhaps as an adaptation to terrestriality, representing a key evolutionary novelty in the ancestor of all insects, and hence a molecular synapomorphy for the Class Insecta." **16713.** Buczynski, P.; Obloza, P. (2018): First record of the introducing of exotic dragonfly *Ischnura senegalensis* (RAMBUR, 1842) (Odonata: Coenagrionidae) into Poland. *Odonatrix* 14\_1: 8 pp. (in Polish, with English summary) ["Four females and two males of *I. senegalensis* emerged in March 2018 in Siedlce (Central-Eastern Poland) in a home aquarium with tropical plants, strongly illuminated, with a constant water temperature of 26 °C, with water enriched with CO<sub>2</sub> and fertilized. They probably entered the aquarium as eggs on plants imported from Asia via the Netherlands, which were planted during the so-called restart of this aquarium. The developmental time to the imaginal stage lasted from 38 to 45 days, which is consistent with the data from the breeding at room temperature in Taiwan. This is hardly the third known case of the introduction of an exotic dragonfly into Poland. Earlier, *Mecistogaster* sp. and *Crocothemis servilia* were recorded. There is probably a very large "dark figure" of such cases, due to the fact that odonatologists usually work in the field and the reared dragonflies rarely get out of the closed rooms. So far, none of the introduced species has been acclimatized in Europe, but it cannot be excluded that this will happen if a species from a similar climatic zone arrives here, or if the current increase in air temperatures will continue. Therefore, it is worth observing this phenomenon by visiting distribution centres of aquarium plants

and cooperating with aquarists." (Authors)] Address: Buczynski, P., Dept of Zool., Maria Curie-Skłodowska Univ., Akademicka 19, 20-033 Lublin, Poland. E-mail: pawbucz@gmail.com

**16714.** Büsse, S.; Heckmann, S.; Hornschemeyer, T.; Bybee, S.M. (2018): The phylogenetic relevance of thoracic musculature: a case study including a description of the thorax anatomy of Zygoptera (Insecta: Odonata) larvae. *Systematic Entomology* 43(1): 31-42. (in English) ["New morphological techniques allow for the evaluation of novel character systems that are potentially important for phylogenetic analysis. Only a few studies so far have used character systems from the insect thorax for phylogenetics; the reasons for this might include a lack of common terminology or established homology for pterygote insect thorax musculature. Still, recent studies have proposed common terminology and hypotheses of homology, now allowing for an evaluation of thoracic morphological character systems among the groups of winged insects. Using X-ray microtomography ( $\mu$ CT) we present a detailed study of the thorax musculature of Odonata as an important phylogenetic character system, with a matrix of 298 characters with 697 character states, including novel data from the thoracic anatomy of eight damselfly larvae. We also included additional Odonata, Ephemeroptera and Neoptera taxa from the literature and demonstrate the phylogenetic relevance of this character system by reproducing phylogenetic topologies of established relationships. We also compared high-resolution data from Odonata larvae from our study and from recent literature with data from older literature in the adult Odonata. All major clades were successfully recovered, (e.g. Odonata, Epirocta, Anisoptera and Zygoptera) with high node support, but obtained higher phylogenetic resolution with the larval data. The best phylogenetic resolution was achieved by combining the adult and larval characters. The taxon sampling and character matrix is the largest to date and underlines the potential relevance of the thorax musculature as an important phylogenetic character system." (Authors)] Address: Büsse, S., Functional Morphology and Biomechanics, Zoological Inst., Christian-Albrechts-Univ., Am Botanischen Garten 9, 24118 Kiel, Germany. E-mail: sbuesse@zoologie.uni-kiel.de

**16715.** Büsse, S.; Gorb, S.N. (2018): Material composition of the mouthpart cuticle in a damselfly larva (Insecta: Odonata) and its biomechanical significance. *Royal Society Open Science* 5: 172117. <http://dx.doi.org/10.1098/rsos.172117>: 15 pp. (in English) ["Odonata larvae are key predators in their habitats. They catch prey with a unique and highly efficient apparatus, the prehensile mask. The mandibles and maxillae, however, play the lead in handling and crushing the food. The material composition of the cuticle in the biomechanical system of the larval mouthparts has not been studied so far. We used confocal laser scanning microscopy (CLSM) to detect material gradients in the cuticle by differences in autofluorescence. Our results show variations of materials in different areas of the mouthparts: (i) resilin-dominated pads within the membranous transition between the labrum and the anteclypeus, which support mobility and might provide shock absorption, an adaptation against mechanical damage; (ii) high degrees of sclerotization in the incisivi of the mandibles, where

high forces occur when crushing the prey's body wall. The interaction of the cuticle geometry, the material composition and the related musculature determine the complex concerted movements of the mouthparts. The material composition influences the strength, mobility and durability of the cuticular components of the mouthparts. Applying CLSM for extracting information about material composition and material properties of arthropod cuticles will considerably help improve finite-element modelling studies." (Authors)] Address: Gorb, S.N., Functional Morphology and Biomechanics, Zoological Institute, Christian-Albrecht University of Kiel, 24098 Kiel, Germany. E-mail: sgorb@zoologie.uni-kiel.de

**16716.** Buss, N.; Hua, J. (2018): Parasite susceptibility in an amphibian host is modified by salinization and predators. *Environmental Pollution* 236: 754-763. (in English) ["Secondary salinization represents a global threat to freshwater ecosystems. Salts, such as NaCl, can be toxic to freshwater organisms and may also modify the outcome of species interactions (e.g. host-parasite interactions). In nature, hosts and their parasites are embedded in complex communities where they face anthropogenic and biotic (i.e. predators) stressors that influence host-parasite interactions. As human populations grow, considering how anthropogenic and natural stressors interact to shape host-parasite interactions will become increasingly important. We conducted two experiments investigating: (1) the effects of NaCl on tadpole susceptibility to trematodes and (2) whether density- and trait-mediated effects of a parasite-predator (i.e. damselfly) and a host-predator (i.e. dragonfly), respectively, modify the effects of NaCl on susceptibility to trematode infection. In the first experiment, we exposed tadpoles to three concentrations of NaCl and measured parasite infection in tadpoles. In the second experiment, we conducted a 2 (tadpoles exposed to 0 g L<sup>-1</sup> NaCl vs. 1 g L<sup>-1</sup> NaCl) x 4 (no predator, free-ranging parasite-predator (damselfly), non-lethal host-predator (dragonfly kairomone), and free-ranging parasite-predator + dragonfly kairomone) factorial experiment. In the absence of predators, exposure to NaCl increased parasite infection. Of the predator treatments, NaCl only caused an increase in parasite infection in the presence of the parasite-predator. However, direct consumption of trematodes caused a reduction in overall infection in the parasite-predator treatment. In the dragonfly kairomone treatment, a reduction in tadpole movement (i.e. trematode avoidance behavior) led to an increase in overall infection. In the parasite-predator + dragonfly kairomone treatment, antagonistic effects of the parasite-predator (reduction in trematode abundance) and dragonfly kairomone (reduction in parasite avoidance behavior) resulted in intermediate parasite infection. Collectively, these findings demonstrate that NaCl can increase amphibian susceptibility to parasites, and underscores the importance of considering predator-mediated interactions in understanding how contaminants influence host-parasite interactions." von Helm- und Vogel-Azurjungfer in Nordthüringen. *Landchaftspflege und Naturschutz in Thüringen* 55(1): 11-19. (in German, with English summary) ["In Thuringia the evidence of the rare *C. ornatum* was first successfully proven in 1998 in the Helme-Unstrut lowland near Artern. At that time this area was a highly frequented and extended incidence of *C. mercuriale*. In 1999 the Natura 2000 site „Mönchenried und Helmegräben bei Artern" was designated to protect this species. From 1999 until 2014 a long-term monitoring in this Natura 2000 site took place supported by the Thuringian State Office for Environment and Geology. Of the 14 Stretches of water that were inhabited by *C. mercuriale* by 2014 only eight had remained. These incidences showed strong fluctuations in population sizes. By 2016 three more of those habitats had gone. For *C. ornatum* by 2014 only one out of the original seven incidences had survived. Throughout the whole study area a severe decline in the overall frequency of both species was recorded and these initially trans-regionally important population densities had seriously declined (population densities from up to 560 individuals of *C. mercuriale* and up to 130 individuals of *C. ornatum* per 100 m). The larvae prefer slightly flooded mud ponds in which the hatching also takes place. The main waterway is barely populated. Reasons for the decline are the uncertain yearly flow of many of the ditches, profile changes to the Kleine Helme that were implemented for flood protection as well as the changes in the water Vegetation due to nutrient discharges (eutrophication) and insufficient Conservation of water bodies. Furthermore, the *Nutria Myocastor coypus* feeds on the wintergreen submerged Vegetation, which then prevents successful laying of eggs (oviposition). The implementation of an existing species-assistance concept and of the Natura 2000 management plan as well as further reaching measures dealing with large-scale drying-up and eutrophication are urgently needed as is the involvement of experts." - 16719.** Cabuga Jr, C.C.; Dedel, J.I.C.; Delabahan, I.C.B.; Ayaton, M.A.; Busia, M.A.; Billuga, N.P.; Angco, M.K.A.; Havana, H.C. (2018): Wing shape variations in *Calopteryx splendens* along a latitudinal gradient using geometric morphometric analysis. *J. Bio. Env. Sci.* 12(3): 73-92. (in English) ["Fluctuating asymmetry (FA) quantifies the degree of variations from a perfect symmetry and therefore expected to reflect the state of genomic and ecological stress undergone by the single species and or populations throughout its development. It identifies the extent of differences from the symmetry of left and right sides of the organisms, as both sides are expected to be identical from its genetic activity and within the environment they inhabit. In this study, geometric morphometric was utilized to measure wing shape variation in the populations of *Calopteryx splendens*. A total of 120 samples consisting of 30 males and 30 females were randomly collected each of the latitudinal gradient and subjected to Procrustes ANOVA and Principal Component Analysis (PCA) by means of Symmetry and Asymmetry in Geometric Data (SAGE) software. In the three factors analyzed: individuals, sides, and individual  $\times$  sides result shows that the collected samples from the high altitude displayed high significant difference ( $P < 0.0001$ ) in the female forewings and hindwings while male forewings and hindwings showed partly non-significant. Whereas, the collected samples from the lower altitude result shows high significant difference ( $P < 0.0001$ ) in the female and male forewings while female and male hindwings shown partly non-significant. It implies that latitudinal gradients could influence wing shape pattern and phenotypic variability was evident between species of the same lineage. Further, utilizing geometric morphometrics is essential in identifying wing shape variations and co-variations among species relatively of the same ancestry." (2018): The engineering of the giant dragonflies of the Permian: revised body mass, power, air supply, thermoregulation and the role of air density. *Journal of Experimental Biology* 221 (19): jeb185405. 7 pp. (in English) ["An engineering examination of allometric and analogical data on the flight of giant Permian insects (Protodonata, Meganeura or griffinflies) indicates that previous estimates of the body mass of these insects are too low and that the largest of these insects (wingspan of 70 cm or more) would have had a mass of 100–150 g, several times greater than previously thought. Here, the power needed to generate lift and fly at the speeds typical of modern large dragonflies is examined together with the metabolic rate and subsequent heat generated by the thoracic muscles. This evaluation agrees with previous work suggesting that the larger specimens would rapidly overheat in the high ambient temperatures assumed in the Permian. Various extant mechanisms of thermoregulation are modelled and quantified, including behaviour, radiation and the constraints on convective respiration and evaporation imposed by air flow through spiracles. However, the effects of these on cooling an overheated insect are found to be limited. Instead, an examination of the heat budget in the flight medium indicates that, at about 1.6 bar (160 kPa), thermoregulation supply enters into equilibrium and, even at high ambient temperatures, overheating can be avoided and enough oxygen sourced. This approach indicates how fossil biology can be used to examine past atmospheres." (Author)] Address: Cannell, A.E.R., ISIPU, Rua Major Francisco Hardy 200 Casa 23, Curitiba 81230-164, Brazil. - 16723.** Cao, L.-z.; Fu, Y.-w.; Hu, C.-x.; Wu, K.-m. (2018): Seasonal migration of *Pantala flavescens* across the Bohai strait in northern China. *Environmental Entomology* 47(2): 264-270. (in English) ["*P. flavescens* is one of the most common species of migratory dragonflies. *P. flavescens* adults were captured by a searchlight trap on Beihuang Island (BH Island; 38°24'N, 120°55'E) from 2003 to 2016, where there is no freshwater. This inspired our research to analyze the pattern of seasonal migration and population dynamics. Stable hydrogen isotope measurement and the Hybrid Single Particle Lagrangian Integrated Trajectory (HYSPPLIT) were used to simulate the migration pathway of *P. flavescens* between different breeding habitats. The results showed that there was no significant difference among population numbers of this overseas migration across years ( $F_{13, 2161} = 0.85$ ,  $P = 0.604$ ); however, the numbers were significantly different across months ( $F_5, 2161 = 3.91$ ,  $P = 0.003$ ). Our geospatial natal assignment model suggested that *P. flavescens* trapped on BH were originated in different geographical regions and might have three movement strategies: wandering around northern China

and north-bound (positive) and south-bound (negative) movements. Among them, the majority were engaged in wandering around northern China. Model simulations suggested that *P. flavescens* toured around BH. The results contribute to the knowledge of *P. flavescens* population ecology in a large-scale geographic region and will aid in the prediction and interpretation of insect migration patterns in response to climate change." **16724.** Carr, D.M.; Ellsworth, A.A.; Fisher, G.L.; Valeriano, W.W.; Vasco, J.P.; Guimarães, P.S.S. (2018): Characterization of natural photonic crystals in iridescent wings of damselfly *Chalcopteryx rutilans* by FIB/SEM, TEM, and TOF-SIMS. *Biointerphases* 13, 03B406 (2018); <https://doi.org/10.1116/1.5019725>: 8 pp. (in English) ["The iridescent wings of *C. rutilans* are investigated with focused ion beam/ scanning electron microscopy, transmission electron microscopy, and time-of-flight secondary ion mass spectrometry. The electron microscopy images reveal a natural photonic crystal as the source of the varying colors. The photonic crystal has a consistent number and thickness (~195 nm) of the repeat units on the ventral side of the wing, which is consistent with the red color visible from the bottom side of the wing in all regions. The dorsal side of the wing shows strong color variations ranging from red to blue depending on the region. In the electron microscopy images, the dorsal side of the wing exhibits varied number and thicknesses of the repeat units. The repeat unit spacings for the red, yellow/green, and blue regions are approximately 195, 180, and 145 nm, respectively. Three-dimensional analysis of the natural photonic crystals by time-of-flight secondary ion mass spectrometry reveals that changes in the relative levels of Na, K, and eumelanin are responsible for the varying dielectric constant needed to generate the photonic crystal. The photonic crystal also appears to be assembled with a chemical tricomponent layer structure due to the enhancement of the CH<sub>6</sub>N<sub>3</sub><sup>+</sup> species at every other interface between the high/low dielectric constant layers." **16726.** Casas, P.A.C.; Sing, K.-W.; Lee, P.-S.; Nuñez, O.M.; Villanueva, R.J.T.; Wilson, J.-J. (2018): DNA barcodes for dragonflies and damselflies (Odonata) of Mindanao, Philippines. *Mitochondrial DNA Part A, DNA Mapping, Sequencing, and Analysis* 29(2): 206-211. (in English) ["Reliable species identification provides a sounder basis for use of species in the order Odonata as biological indicators and for their conservation, an urgent concern as many species are threatened with imminent extinction. We generated 134 COI barcodes from 36 morphologically identified species of Odonata collected from Mindanao Island, representing 10 families and 19 genera. Intraspecific sequence divergences ranged from 0 to 6.7% with four species showing more than 2%, while interspecific sequence divergences ranged from 0.5 to 23.3% with seven species showing less than 2%. Consequently, no distinct gap was observed between intraspecific and interspecific DNA barcode divergences. The numerous islands of the Philippine archipelago may have facilitated rapid speciation in the Odonata and resulted in low interspecific sequence divergences among closely related groups of species. This study contributes DNA barcodes for 36 morphologically identified species of Odonata reported from Mindanao including 31 species with no previous DNA barcode records." **16727.** Cavallaro, M.C.; Liber, K.; Headley, J.V.; Peru, K.M.; Christy A. Morrissey, C.A. (2018): Community-level and phenological responses of emerging aquatic insects exposed to three neonicotinoid insecticides: An in situ wetland limnocorral approach. *Environmental Toxicology and Chemistry* 37(9): 2401-2412. (in English) ["Seasonal aquatic insect emergence represents a critical subsidy link between aquatic and terrestrial ecosystems. Early and late instar larvae developing in wetlands near neonicotinoid-treated cropland are at risk of chronic insecticide exposure. An in situ wetland limnocorral experiment compared emergent insect community responses to imidacloprid, clothianidin, and thiamethoxam. Over 15 weeks, 21 limnocorrals were dosed weekly for 9 weeks to target peak nominal doses of 0.0, 0.05 or 0.5 µg/L, followed by a 6-week recovery period. Thirty-nine aquatic insect taxa were recorded but 11 taxa groups made up 97% of the community composition. Principal response curves indicated that during the dosing period, community composition among the treatments resembled the controls. During the 6-week recovery period, significant deviance was observed in the high imidacloprid treatment with similar trends in the clothianidin treatment, suggesting that community effects from neonicotinoid exposure can be delayed. Non-biting midges (Diptera: Chironomidae) and Zygoptera also emerged 18 to 25 days earlier in the imidacloprid and clothianidin neonicotinoid treatments, relative to controls. These data suggest that phenology and subtle community effects can occur at measured neonicotinoid concentrations of 0.045 µg/L (imidacloprid) and 0.038 µg/L (clothianidin) under chronic repeated exposure conditions. Synchronization and community dynamics are critical to aquatic insects and consumers; thus, neonicotinoids may have broad

implications for wetland ecosystem function." (Authors)] Address: Morrissey, Christy, Department of Biology, University of Saskatchewan, Saskatoon, Saskatchewan, Canada. E-mail: christy.morrissey@usask.ca

**16731.** Chapman, Olivia; Noyd, Martin; Seres, Kareen (2018): Differences in gregarine parasite load between male and female *Calopteryx maculata*. *Biological Station, University of Michigan (UMBS)*: 12 pp. (in English) ["Damselflies and other insects of the order Odonata are frequently parasitized by gregarine protists. In the trophozoite stage of the gregarine life cycle,

the parasite feeds on the contents of the host's gut and negatively affect its reproductive success. Possibly as a result of its impacts on the host's reproductive system, levels of gregarine parasitism has been observed to differ between male and female damselflies. We aimed to measure relative levels of gregarine parasitism of male and female damselflies of the species *Calopteryx maculata*. In order to do this, we collected damselflies at multiple sites in Michigan's Maple River and dissected individuals to observe the presence of gregarine parasites. Our results indicate that females experience significantly higher levels of gregarine parasitism than their male counterparts. We propose that this difference is the result of increased levels of migratory behavior in female damselflies due to increased parental investment." (Authors)] Address: not stated

**16732.** Chavez-Kendall, K. (2018): Invertebrate predator effects on California vernal pool community assembly. M.S. thesis, Biological Sciences (Ecology, Evolution, and Conservation)--California State University, Sacramento: IX + 44 pp. (in English) ["Predators can help determine the density and diversity of prey populations. Predators can reduce densities of prey, increase diversity of prey species, lower densities of other predators, and cause changes in the overall biomass production of a community. Schmitz (2007) developed a framework to test multi-predator effects, which included two predictions based on the predators' habitat and hunting mode. The first prediction is that increasing predator pressure causes a risk enhancing effect; multiple predators can be more efficient at removing prey and lowering overall prey densities. The second prediction is that competition among multiple predators develop a risk-reducing effect on prey; predators can interfere with one another by competition or intraguild predation, thus lowering their prey capture abilities. Even though there are many predator-prey studies, few have been focused in seasonal wetlands. The purpose of this study was to evaluate multiple predator effects on invertebrate community structure. I predicted that predators in vernal pools would have a risk-enhancing effect, resulting in the reduction of prey densities and increasing overall diversity. To test this hypothesis, I used two different species of predators, backswimmers (Family Notonectidae) and damselfly nymphs. The experimental mesocosm study consisted of nine treatments arranged in a factorial design. Density treatments consisted of three and six predators of the same species; diversity treatments consisted of equal numbers of Notonectidae and Odonata, as well as double density of predator of either species. I found that treatments containing Notonectidae had a negative effect on prey density, while treatments containing equal numbers of predators had a positive effect on prey density, and predator treatment did not have an effect on prey diversity. Communities were more likely to be similar within each treatment and not between treatments. I conclude that a risk-enhancing effect can occur when there are high densities of Notonectidae, additionally, the results suggest that when two different predator species are present in equal densities they may interfere with one another generating a risk-reduction effect on the prey community." **16733.** Cheeseman, S.; Owen, S.; Truong, V.K.; Meyer, D.; Ng, S.H.; Vongsvivut, J.; Linklater, D.; Tobin, M.J.; Wemer, M.; Baulin, V.A.; Luque, P.; Marchant, R.; Juodkazis, S.; Crawford, R.J.; Ivanova, E.P. (2018): Pillars of life: Is There a relationship between lifestyle factors and the surface characteristics of dragonfly wings? *ACS Omega* 2018, 3: 6039-6046. (in English) ["Dragonfly wings are of great interest to researchers investigating biomimetic designs for antiwetting and antibacterial surfaces. The waxy epicuticular layer on the membrane of dragonfly wings possesses a unique surface nanoarchitecture that consists of irregular arrays of nanoscale pillars. This architecture confers superhydrophobic, selfcleaning, antiwetting, and antibiofouling behaviors. There is some evidence available that suggests that lifestyle factors may have influenced the evolution of the wing nanostructures and, therefore, the resulting properties of the wings; however, it appears that no systematic studies have been performed that have compared the wing surface features across a range of dragonfly species. Here, we provided a comparison of relevant wing surface characteristics, including chemical composition, wettability, and nanoarchitecture, of 7 species of dragonfly from three families including Libellulidae, Aeshnidae, and Gomphidae. The characteristic nanopillar arrays were found to be present, and the chemical composition and the resultant wing surface superhydrophobicity were found to be well-conserved across all of the species studied. However, subtle differences were observed between the height, width, and density of nanofeatures and water droplet bouncing behavior on the wing surfaces. The results of this research will contribute to an understanding of the physical and chemical surface features that are optimal for the design of antiwetting and antibacterial surfaces." **16734.** Cheng, Y.-C.; Chen, M.-Y.; Wang, J.-F.; Liang, A.-P.; Lin, C.-P. (2018): Some mitochondrial genes perform better for damselfly phylogenetics: species- and population-level analyses of four complete mitogenomes of *Euphaea* sibling species. *Systematic Entomology* 43(4): 702-715. (in English) ["Animal mitochondrial genes continue to provide an efficient and inexpensive assessment of genetic diversity. However, which mitochondrial genes should be selected to best estimate species phylogeny and population genealogy remains uncertain for most under-sampled taxa. We analysed four complete mitochondrial genomes of sibling species of *Euphaea* damselflies, *E. decorata*, *E. ornata*, *E. formosa* and *E. yayeyamana*, to examine the patterns of selection and to evaluate the phylogenetic utility of the mitochondrial genes compared with nuclear genes. The results indicated that mitochondrial protein-coding *nad2* (NADH dehydrogenase subunit 2) and noncoding A + T-rich (control region) genes have the highest mutation rates and more phylogenetic utility [higher parsimony-informative sites; higher  $\alpha$  (the shape parameter of gamma distribution); lower rates of heterogeneity among sites; and higher relative substitution rates] than all the other mitochondrial and nuclear genes analysed. In contrast, the animal DNA barcoding gene cytochrome c oxidase subunit 1 (*cox1*)

had average values for all estimated parameters of phylogenetic performance and was sometimes outperformed by other mitochondrial genes. The majority of the mitochondrial and nuclear genes in *Euphaea* damselflies have experienced frequent purifying selection, except for two cases of potential positive selection in NADH dehydrogenase subunit 3 (*nad3*) and elongation factor 1a (*EF1a*), and all mitochondrial genes had experienced stronger purifying selection than nuclear genes. Our findings indicated that mitochondrial *nad2* and the A + T-rich region should be selected to provide efficient and high-resolution phylogenetic markers for damselflies at the species and population level." **16736.** Choong, C.Y.; Alwen, B.M.; Tan, C.C. (2018): Odonata (Insecta) fauna of Taman Negara National Park, Malaysia. *Serangga* 23(2): 49-58. (in English) ["Taman Negara National Park is divided into three parts according to states – Taman Negara Pahang, Taman Negara Kelantan and Taman Negara Terengganu. In this study we present the records of Odonata collected at Kuala Kelapoh, Taman Negara Pahang and Gua Bewah, Taman Negara Terengganu. A total of 61 species were recorded from Kuala Kelapoh and 52 species from Gua Bewah. Of these 46 species are the new records for Taman Negara National Park. The high number of new records in this study indicates the Odonata fauna of Taman Negara National Park was not well studied. Notable records from the

study include *Coeliccia sameerae*, *Phyllothemis raymondi* and *Rhinocypha pelops*. The records from Kuala Kelapoh and Gua Bewah are combined with the existing records in literature to produce a checklist of the Odonata for Taman Negara National Park with 101 species from 15 families." **16737.** Choong, C.Y.; Alwen, B.M.; Tan, C.C. (2018): Odonata of Sungai Dusun Wildlife Reserve, Selangor, Peninsular Malaysia. *Journal of Wildlife and Parks* 33: 57-64. (in English) ["Records of Odonata collected at Sungai Dusun Wildlife Reserve on two field surveys (8-14 June and 15-20 September 2015) are presented. Adult insects were collected in the field surveys. In total, 33 species from 11 families were recorded from both the field surveys. The species list was dominated by family Libellulidae (14 species), followed by family Platynemididae (five species) and Aeshnidae (four species). The other families (Calopterygidae, Chlorocyphidae, Euphaeidae, Argiolestidae, Philosinidae, Coenagrionidae, Gomphidae and Synthemitidae) were represented only by 1-3 species. Species found abundantly in the sampling site were *Tyriobapta torrida* and *Vestalis amethystina*. Interesting species recorded were *Gynacantha dohrni*, *Burmagomphus arthuri*, *Tetracanthagyna plagiata* and *Oligoaeschna foliacea*. *G. dohrni* is a new record for Peninsular Malaysia. Published Odonata records from other sources were compiled to produce a species list for Sungai Dusun Wildlife Reserve. At present 38 species from 11 families are known to Sungai Dusun Wildlife Reserve.] Address: Choong, C.Y., Centre for Insect Systematics, Universiti Kebangsaan Malaysia, 43600 UKM Bangi, Selangor, Malaysia. **16738.** Chovanec, A. (2018): Beobachtungen zum Sitzverhalten des Südlichen Blaupfeils (*Orthetrum brunneum*) und anderer Libellulinae (Odonata: Libellulidae). *Zeitschrift der Arbeitsgemeinschaft Österreichischer Entomologen* 70: 9-18. (in German, with English summary) ["Observations on the perching behaviour of *Orthetrum brunneum* and other Libellulinae. – At a small wetland in Lower Austria *O. brunneum* preferably perched on riparian helophytes (93 % of all documented perchings). Horizontal or slightly inclined vegetation structures were preferred. Open littoral ground was used only in few cases. Four-leg perching, which is described in the literature for Libellulinae, was confirmed in this study by evaluating photos: In 92 % of the situations males of *O. brunneum* used four legs; the number of legs used was higher with increasing instability of the substrate (e. g., *Typha* leaves). In ten out of 16 copulae, the *O. brunneum* male perched with six legs while embraced by four legs of the female (6/4-position). In a quite stable horizontal position, one pair showed a 4/2-position. Males of *O. cancellatum*, *Libellula depressa* and *L. quadrimaculata* also used four legs in the majority of the perching situations; *L. quadrimaculata* showed five- or six-leg perching with larger substrate angles." **16739.** Chovanec, A. (2018): Comparing and evaluating the dragonfly fauna (Odonata) of regulated and rehabilitated stretches of the fourth order metarhithron Gurtenbach (Upper Austria). *International Journal of Odonatology* 21(1): 15-32. (in English) ["Mitigation measures carried out at the regulated metarhithron Gurtenbach in Upper Austria were evaluated by a survey of the dragonfly fauna. The assessment method developed in this study was based on the longitudinal distribution of dragonflies along riverine biocoenotic regions (the "Rhithron-Potamon-Concept" explains changes in species composition along a river's length). Numerically expressed habitat preferences led to the definition of a set of six reference species. According to the requirements of the EU Water Framework Directive the current situation of the odonate species was compared with this inventory of river type-specific reference species and assessed in a five-tiered classification system of the "ecologic status". At the regulated stretch the record of five species (including one reference species) was classified as class IV ("poor ecological status"). At the three rehabilitated stretches a total of 23 species were found. Two stretches were classified as showing "good ecological status" (class II), due to the occurrence of two autochthonous reference species (*Calopteryx virgo*, *Onychogomphus forcipatus*). The sensitive method applied not only allowed the evaluation of the differences between regulated and rehabilitated stretches but also the assessment of potamalisation effects within the rehabilitated section due to river bed widening and backwater influences." **16745.** Cristiano, L.; Lantieri, A.; Boano, G. (2018): Comparison of Pallid Swift *Apus pallidus* diet across 20 years reveals the recent appearance of an invasive insect pest. *Avocetta* 42: 9-14. (in English) ["The diet of the *A. pallidus* in a NW Italian breeding colony was examined in the summers of 2012 and 2013 to compare the current diet against those assessed more than 20 years earlier (1987-1990). By screening 5980 prey items found in food boluses brought by adults to nestlings we identified 37 families or superfamilies pertaining to 8 arthropod orders (Araneae, Coleoptera, Diptera, Hymenoptera, Lepido-

ptera, Mallophaga, Odonata, Hemiptera). The highest percentage of prey was represented by Hemiptera Homoptera (42.9%) and Diptera Brachycera (21.6%), but we also found a good number of Coleoptera (7.0%). We did not find any significant differences in diets after 20 years when comparing prey abundance at higher taxonomic levels, but in the more recent samples, beetles were mostly (above 70%) represented by the allochthonous corn pest *Diabrotica virgifera*, a species totally absent in Italy before the year 2000. We conclude that swift colonies can destroy a huge number of agricultural insect pests, and perhaps even more importantly, regularly checking the swift's diet at specific localities could be a useful tool for monitoring changes and the biodiversity of flying insects in anthropized ecosystems." (Authors)] Address: Boano, G., Museo Civico di Storia Naturale - Via San Francesco di Sales 188, Carmagnola (Turin), Italy. E-mail: g.boano@gmail.com

**16746.** Davies, R.; von Hardenberg, A.; Geary, M. (2018): Recapture rates and habitat associations of *Leucorrhinia dubia* (Vander Linden), (White-faced Darter), on Fenn's and Whixall Mosses, Shropshire. *J. Br. Dragonfly Society* 34(2): 89-101. (in English) ["Land-use changes and habitat loss are important drivers of biodiversity decline at both global and local scales. To protect species from the impacts of land-use change it is important to understand the population dynamics and habitat associations across these scales. Here we present an investigation into the survival and habitat preferences of *L. dubia*, at the local scale at Fenn's and Whixall Mosses, Shropshire, UK. We used Mark-Release-Recapture (MRR) methods to investigate survival and used sightings of individual dragonflies along with habitat data to investigate habitat preference. We found that survival between capture-visits was very low and that *L. dubia* showed a clear preference for the open moss habitat on this site. We also found that the detectability, either through sightings or recaptures, was potentially very low and suggest that this should be taken into account in future analyses. We suggest that, by encouraging recorders to submit complete lists and to repeat visits to sites, detectability could be easily estimated for dragonfly species. Incorporating this into analyses would improve estimates of population trends and habitat associations." **16747.** de Almeida, T.R.; Cordero-Rivera, A.; Guillermo-Ferreira, R. (2018): Female colour form has no effect on copulation duration of the polymorphic *Ischnura fluviatilis* (Odonata: Coenagrionidae). *Odonatologica* 47(3-4): 229-243. (in English) ["We studied a population of *Ischnura fluviatilis* Selys, 1876 in Mato Grosso do Sul (Brazil), to establish the range of female colour polymorphism and associated mating behaviour. We found three female colour forms: orange and brown, which were the immature and mature coloration of the commoner gynochrome morph, and a blue androchrome morph. We observed mating couples and analysed the relationship between copulation duration and phenotypic characteristics of males and females. There were significant differences between colours for female body size, fecundity, egg

size and copulation duration, and in most cases the most deviant colour form was the immature orange. These females were significantly larger, and had the highest fecundity. Androchrome females produced smaller eggs. Copulations lasted on average 65 min, with the shortest copulation durations observed for brown females. Male size and the order of observation (indicative of seasonal effects) explained a significant proportion of variation in copulation duration, but female colour form, fecundity and size were not significant. We found evidence for assortative mating by size. Our results indicate that female colour does not explain variation in copulation duration, and therefore the possibility of cryptic male choice seems unlikely." (2018): Libélulas (Odonata) predadas por moscas-assassinas (Diptera: Asilidae) no estado de Minas Gerais, sudeste do Brasil. *Revista Brasileira de Zoociências* 19(1): 77-81. (in Portuguese, with English summary) ["Dragonflies preyed by robber flies (Diptera: Asilidae) in the state of Minas Gerais, southeastern Brazil. Insects of the Odonata order are important in aquatic ecosystems, acting sometimes as predators and sometimes as prey to birds, fish and other insects, such as the robber flies of the Asilidae family. However, records of this interaction are scarce for Brazil. The purpose of this report is notify the occurrence of predation of the Odonata species *Hetaerina longipes* and *Argia clausenii* by *Archilestris capnoptera* (Wiedemann, 1828). The records were occasionally made at the Parque Estadual Serra do Papagaio and at the Parque Estadual do Ibitipoca, in the years 2015 and 2017. Predation may be a reflection of the frequency of odonate species at the time of the registrations, because the asilids are opportunistic and generalist predators. New studies are however needed to assess the impacts of predation on dragonfly populations." **16753.** Denis, A.; Payet, O.; Danflous, S.; Gouix, N.; Santoul, F.; Buisson, L.; Pélozuelo, L. (2018): Intraspecific variability of the phenology and morphology of three protected dragonflies between natural and artificial habitats. *Journal of Insect Conservation* 22: 419-431. (in English) ["Changes in phenology and in body size are two of the three main consequences of global warming on organisms. We investigated whether living in a warm artificial habitat would induce changes in the phenology and body size of dragonflies. We monitored in natura the emergence pattern of three protected and red-

listed dragonfly species in three geographically close systems which differ in thermal profiles: a medium-sized river, one of its tributaries and an artificial lake fed by the water of the tributary. We also investigated the morphological variability of one of the species between the three systems. We showed an asynchrony of emergence for the three species, as well as morphological variability between the lake and the two rivers. Individuals from the lake emerged earlier and were smaller than those from the two rivers. These results are in agreement with a temperature-induced response hypothesis as the lake is warmer than the two rivers. Asynchrony of emergence between neighbouring populations triggers questions related to metapopulation functioning and about the fitness and the fate of the early-emerging individuals. Understanding the response of these species to local thermal conditions will help to improve population monitoring and conservation." **16754.** Denis, A.S. (2018): Impacts de l'anthropisation sur la diversité odonotologique au sein des cours d'eau: vers une meilleure prise en compte des espèces de la directive habitats faune flore. Laboratoire écologie fonctionnelle et environnement, Sciences de l'Univers, de l'environnement et de l'espace, Université Toulouse III: 174 pp. (in French, partly in English) ["Title: Anthropisation impacts on dragonfly diversity within streams: towards better assessment of anthropogenic impacts upon riverine species of European Community interest. Abstract: In a context of global biodiversity crisis, reconciling the development of wealthgenerating industry and agriculture with nature conservation is a crucial issue. Economic stakeholders are legally obliged to apply the mitigation hierarchy doctrine and thus "avoid, mitigate, and compensate" for their project's impacts. However, for invertebrate protected species, and particularly dragonfly species, basic knowledge on their ecology and population dynamics is lacking. It is thus difficult to accurately anticipate the impacts and propose efficient avoidance and compensation measures. This is particularly true on rivers, which are ecosystems under high pressure owing to their utility for human beings (i.e. water and food resources, transport, energy production, leisure). The aim of this work is to improve knowledge of three protected riverine species of dragonflies: *Oxygastra curtisii*, *Gomphus graslinii* and *Macromia splendens*, and to provide better assessment methods to evaluate the impacts of the anthropisation of streams on their populations. We sought in particular (1) to improve environmental impact assessments and management of these species within Natura 2000 sites by proposing a standardised survey protocol, (2) to assess the consequences of habitat change, especially water temperature warming, on their phenology and morphology, and (3) to describe and evaluate the impacts of weirs and hydroelectric dams on their populations. This work took place in the Midi-Pyrénées region in southern France, where populations of these three species are still present. It was carried out in close partnership with the Conservatoire d'Espaces Naturels de Midi-Pyrénées, which coordinates the Regional

action plan for Odonata, and the Functional Ecology Laboratory EcoLab to ensure direct transfer of the scientific knowledge acquired to the ecosystems managers, economic stakeholders and public authorities responsible for biodiversity conservation." (Author)] Address: not stated

**16755.** Diarra, B.; Konan, K.J.; Yapo, L.M.; Kouassi, K.P. (2018): Aquatic macroinvertebrates associated with free-floating macroinvertebrates associated with free-floating macrophytes in a marginal lentic ecosystem (Ono Lagoon, Côte d'Ivoire). *Journal of Entomology and Zoology Studies* 6(3): 1432-1441. (in English) ["This study aims to investigate macroinvertebrate communities associated with floating macrophytes of Ono lagoon (Côte d'Ivoire). Samples were monthly collected from September 2015 to August 2016. Similarly, abiotic variables (temperature, transparency, depth, conductivity, TDS, pH, dissolved oxygen, NH<sub>4</sub><sup>+</sup>, NO<sub>3</sub><sup>-</sup>, NO<sub>2</sub><sup>-</sup> and PO<sub>4</sub><sup>3-</sup>) were measured. A total of 150 macroinvertebrates belonging to 46 families and 15 orders were identified. Specifically, 125 taxa were found on *Eichhornia crassipes*, 77 on *Salvinia molesta* and 62 on *Pistia stratiotes* of which 52 taxa were exclusively associated with *E. crassipes*, 15 with *S. molesta* and 7 with *P. stratiotes*. Libellulidae (14.39-22.42%) and Corduliidae (10.56-16.47%) exhibited the highest densities. Higher values of taxonomic richness, Shannon index and evenness were recorded for macrophytes stands with a significant difference between invasive plants (*E. crassipes* and *S. molesta*) and native plant (*P. stratiotes*). In flood season, *E. crassipes* was greatly colonised by Odonata and Arachnida and was highly correlated with dissolved oxygen, temperature, PO<sub>4</sub><sup>3-</sup> and depth. The rainy season was characterised by Coleoptera, Diptera, and Gasteropoda as well as highest levels of pH and NO<sub>3</sub><sup>-</sup>. This season was correlated with *S. molesta* and *P. stratiotes*. In dry season, Heteroptera, Decapoda, Lepidoptera and Ephemeroptera were abundant and correlated with transparency." **16756.** Dias-Silva, L.; Teixeira Duarte, G.; Alves, R.; Ramos Pereira, M.J.; Paglia, A. (2018): Feeding and social activity of insectivorous bats in a complex landscape: The importance of gallery forests and karst areas. *Mammalian Biology* 88: 52-63. ["Worldwide, increasing human activity, such as agriculture and mining, and decreased landscape complexity, are negatively affecting numerous mammal species. For example, bat communities are becoming threatened in many locations mostly due to the loss of their preferred roosting and foraging habitats. Brazilian landscapes and their associated bat communities are no exception, with the situation being further exacerbated by recently adopted permissive environmental laws that have resulted in reduced biodiversity protection and conservation. Therefore, there is an urgent need to understand how landscape and environmental variables relate to bat activities in Brazil in order to support efforts for their conservation. We used acoustic monitoring data to investigate differences in foraging and social activity of insectivorous bats among four habitat types in a heterogeneous landscape in the Cerrado-Atlantic forest ecotone in southeastern Brazil.

We also sampled insect availability and measured temperature at the same sites. Our results showed increased social activity and a greater number of species emitting social calls in karst, and increased feeding activity with a greater number of species emitting feeding buzzes in gallery forest. We also found a positive influence of both temperature and insect abundance on foraging and social activity. Our study provides new insights regarding habitat use by bats in a heterogeneous landscape, and demonstrates the importance of preserving different habitats in heterogeneous landscapes for the conservation of bat species and the ecological functions they perform." **16758.** Dolmen, D.; Pedersen, J. (2018): *Coenagrion hastulatum* and *C. lunulatum* – their responses to the liming of acidified lakes and the release of fish (Odonata: Coenagrionidae). *Odonatologica* 47(1/2): 101-120. (in English) ["The rare and acidification-tolerant *C. lunulatum* became extinct in Romundstadtjern, a small acidic lake in southern Norway, at some time between 1950 and 1980. The reason was suspected to be liming of the lake to raise the pH level before releasing fish (trout). To substantiate the hypothesis, in 1998–2001 we experimentally limed two other small acidic lakes, Øynaheia A (pH 4.6) and B (pH 4.8), which were also inhabited by *C. lunulatum*. Instead of being made extinct by the liming and the rise of the pH to 7.0, the *C. lunulatum* population at Øynaheia grew strongly during the experimental period. However, when fish (perch) were released later, before 2011, the invertebrate fauna became tremendously impoverished, and *C. lunulatum* was not observed there in 2012, 2014 or 2016. Therefore, liming of lakes does not seem to be a threat to *C. lunulatum*, but the release of fish may probably lead to its extinction. A coexisting population of *C. hastulatum* also grew during the

years of liming, but not as much as *C. lunulatum*. However, it survived the introduction of fish, although in low numbers." (Authors)] Address: Dolmen, D., Norwegian Univ. of Science and Technology (NTNU), The Museum, NO 7491 Trondheim, Norway. E-mail: dag.dolmen@ntnu.no

**16759.** dos Santos, J.; Kroth, N.; Breaux, J.; Albeny-Simões, D. (2018): Do container size and predator presence affect *Culex* (Diptera: Culicidae) oviposition preferences? *Revista Brasileira de Entomologia* 62(1): 40-45. (in English) ["Organisms with complex life cycles typically do not exhibit parental care. Hence, the ability of adult females to choose quality oviposition sites is critical for offspring success. Gravid females of many insect taxa have the capability to detect environmental conditions in water-holding containers (e.g., resource level, presence of competitors or predators) and to choose the sites that are most suitable for offspring growth and development. Mosquitoes may also detect physical container characteristics related to water permanence such as surface area, volume, or container size, and some species such as those in the genus *Culex* have been shown to prefer larger containers. However, predators may also preferentially colonize larger containers; thus, ovipositing females may face decisions based on cues of site quality that balance costs and benefits for offspring. We used a field experiment to determine the oviposition preferences of two *Culex* species in response to experimental container size and predator abundances within the containers. We found that both species avoided ovipositing in the largest containers, which have high abundances of *Chaoborus* sp. and dragonfly larvae (predators). However, the container size most commonly chosen for oviposition (15-L buckets) also had high mean abundance per liter of dragonfly larvae. These results suggest either prey naiveté or reduced vulnerability of these species to dragonflies compared to *Chaoborus* sp. Other potential mechanisms for the observed patterns of are discussed." **16760.** Dosi, E.M.; Grinang, J.; Nyanti, L.; Khoon, K.L.; Harun, M.H.; Kamarudin, N. (2018): A preliminary study of the macroinvertebrate fauna of freshwater habitats in Maludam National Park, Sarawak. *Mires and Peat* 22, Article 06: 1-7. (in English) ["Macroinvertebrates are diverse and widespread, and they play important ecological roles in aquatic ecosystems; yet little is known about the macroinvertebrate fauna of the peat swamp forests of Borneo. In light of this knowledge gap, we present a preliminary species list of macroinvertebrates in the peat swamp forest of Maludam National Park, Sarawak, Malaysia. Macroinvertebrates were sampled between April 2011 and November 2014 from three stations on the Maludam River, which flows through the National Park. In total, 3,257 individual macroinvertebrates were examined, representing 37 morpho-species from 20 families and eight orders. Of the total number of individuals captured, 51 % were aquatic beetles (Order Coleoptera), 26 % were aquatic bugs (Hemiptera), 10 % were dragonflies (Odonata), 5 % were flies (Diptera) and 4 % were mayflies (Ephemeroptera). Other orders contributed less than 5 % of the total. The dominant species

was the whirligig beetle *Dineutus unidentatus* (36 % of all individuals caught) which may, thus, be a stenotopic habitat specialist. Despite the harsh environmental conditions of Maludam, where aquatic habitats are acidic and low in dissolved oxygen, the area was found to be inhabited by a diverse macroinvertebrate fauna which is likely to contribute to maintaining the important ecosystem services that the peat swamp forest provides." **16761.** Dossi, F.; Leitner, P.; Pauls, S.; Graf, W. (2018): In the mood for wood-habitat specific colonization patterns of benthic invertebrate communities along the longitudinal gradient of an Austrian river. *Hydrobiologia* 805: 245-258. (in English) ["Instream large wood (LW) constitutes an indispensable element of natural river ecosystems. It affects local hydraulics, morphology, nutrient budget, overall habitat complexity, and dynamics. Despite numerous studies about LW as a habitat for benthic communities, information on the varying importance along the longitudinal gradient of a river is lacking. The focus of this study is therefore to investigate general differences between lithal and xylal colonizers and to further investigate trends along the river course. We analyzed lithal and xylal communities at ten sites along the medium-sized Lafnitz River in Southeast Austria. Our results significantly show (1) a general differentiation between lithal and xylal communities, (2) an increasing distinction of the lithal and xylal fauna along the longitudinal gradient of the river, and (3) a distinct correlation between the distance from source and the number of exclusive xylal and nowadays predominantly rare taxa. The presence of LW is therefore directly linked to higher aquatic biodiversity compared to rocky substrates and presents a unique element for river restoration, especially in lower river sections." **16772.** Endah Hari Utari (2018): Dragonfly community (Odonata) in Sokokembang Forest, Pekalongan, Jawa Tengah. Undergraduate Thesis. Biologi Majors, Faculty- of Science and Technology, State Islamic University Syarif Hidayatullah, Jakarta: XIII + 53 pp. (in English) ["Odonata hold pivotal roles, as a bio indicator of water quality and as predators in the food chain. The availability of optimal environmental conditions and food resources effect the community structure in the habitat. This research want to find out the dragonfly community structure, to define its distribution patterns, and to describe the influence of the biotic factors. The method used in this research is survey. It was by determining the residential area. In taking the sample, the researcher used line transects along 200 m and insect net. Dragonflies were found 8 types in both observation

sites with a total of 625 individuals belonging to the Libellulidae, Platystictidae, Euphaeidae, Coenagrionidae, and Calopterygidae families. The most common types of dragonfly are *Orthetrum sabina*, *Vestalis luctuosa*, *Euphaea variegata*, and *Drepanosticta spatulifera*. *D. spatulifera* is a Javanese endemic dragonfly with conservation status DD = Data Deficient based on IUCN RedList data. Highest species diversity index ( $H'$ ) was found in the latrine river with a value of 1.605. the index ( $E$ ) of the highest heter value was hair river with a value of 0.860. the index of type of similarity of 77%. the distribution pattern in both locations grouped, uniform and random, and the highest ( $D_i$ ) index of dominance index is 28%. CCA (Canonical Correspondence Analysis) shows the pH of the water and the intensity of light gives a real effect on the dragon community in the smoked forest area. The community of dragonfly was organized based on species diversity, evenness type, similarity type, distribution pattern and index of type dominance." (Author)] Address: not stated

**16773.** Erdakov, L.N. (2018): Cyclicity of perennial changes in the density of the dragonfly population *Libellula quadrimaculata* L., 1758 (Odonata, Libellulidae). Eurasian Journal of Entomology 17(3): 216-222. (in Russian, with English summary) ["Based on the data published in 1969-2009 [Popova, Kharitonov, 2010], a spectrum of the density population fluctuation of *L. quadrimaculata* has been calculated. The resulted spectrum shows seven harmonic components, of which the 6.7-year periodicity predominates by its strength. In the middle frequencies, there is an 11.8-year rhythm. The remaining harmonic components are typical of the high-frequency region of the spectrum. In the order of decreasing their strength, these are 4.3, 3.4-, 2.7- and 2.3-summer rhythms. The dragonfly population is well-coordinated with changes of both the weather and hydrological conditions that are important for it. The dynamics of its density is in agreement with perennial precipitation fluctuations, as well as with changes in the surface area size of Lake Chany. Even external influences, of which the course is not synchronous with density fluctuations, may have harmonic components that could be adjustable for corresponding rhythms of the dragonfly.] Address: Erdakov, L.N., Institute of Systematics and Ecology of Animals, Russian Acad. of Sciences, Siberian Branch, Frunze Str. 11, Novosibirsk, 630091 Russia. **16775.** Eslami, Z., Ebrahimi, M.; Sadeghin, S. (2018): Late spring records of Odonata from the west margin of the Namak Lake, Northwest of Central Plateau of Iran. IDF-Report 125: 1-18. (in English) ["A total of 20 Odonata species were recorded from 15 water bodies (3 natural water bodies and 12 man-made reservoirs) in a desert landscape west of the Namak Lake in the northwest of the Central Plateau of Iran, from 27 May to 20 June, 2017. The study area included Qom province and the northern part of Esfahan province (34.07 to 35.14 N, 51.33 to 50.89 E). For Qom province, 17 out of 18 species found are new provincial records. In addition *Selysiothemis nigra*, *Orthetrum chrysostigma* and *Orthetrum taeniolatum* are new findings for Esfahan province. The species around the man-made reservoirs are characterized by a broad ecological amplitude ("generalists") while species assemblages of natural water bodies consisted of more sensitive species. In the arid climate of central part of Iran, man-made reservoirs are major habitats for Odonata species. Although these reservoirs have increased the amount of habitat for generalist species, they do not foster sensitive and specialist species. Furthermore, considering the more intense droughts predicted for these areas in the future, and the current scenario of environmental degradation, some sensitive species may be in danger of local extinction." Animal Research International 15(3): 3065-3069. (in English) ["A study on insect fauna in a fallow plot at Ifite-Ogwari was carried out in rainy season between April and June 2018 using the sweep net. On each sampling occasion thirty sweeps were made across the vegetation of the 39920 m<sup>2</sup> plot to monitor the insects on the foliage. A total of 63 insect species and their larvae comprising 12 families and 16 species were recorded during the sampling period. There was a preponderance of *Camponotus acvapimensis* followed by *Pheidole* sp., *Orthetrum icteromelas*, *Attractomorpha acutipennis*, *Heteropternis thoracica* and *Sphenoptera* sp., with the singletons including *Phaneropterat nana*, *Cardiochiles* sp., *Leptoglossus memberanaceus* and *Anoplocnemis curvipes*. There was no significant difference ( $p > 0.05$ ) in the environmental factors between the three months. The relationships between sweep net catches were not significant ( $p > 0.05$ ). *Pheidole* and species of Odonata served as faunal indicators. Factors that influence the sweep net catches included types of the plant species in the habitat, anthropogenic activities, management practices, locomotor activities and reproductive cycles of insect species. Other factors affecting sweep net catches were also discussed." (Authors)] Address: Ewuim, S. C. Dept Zool. Nnamdi Azikiwe Univ., Awka, Anambra State, Nigeria. Email: cewuim@gmail.com

**16777.** Feindt, W.; Oppenheim, S.J.; DeSalle, R.; Goldstein, P.Z.; Hadrys, H. (2018): Transcriptome profiling with focus on potential key genes for wing development and evolution in *Megaloprepus caerulatus*, the damselfly species with the world's

largest wings. PloS one [12 Jan 2018, 13(1):e0189898]: 17 pp. ["The evolution, development and coloration of insect wings remains a puzzling subject in evolutionary research. In basal flying insects such as Odonata, genomic research regarding bauplan evolution is still rare. Here we focus on the world's largest odonate species—the "forest giant" *M. caerulatus*, to explore its potential for looking deeper into the development and evolution of wings. A recently discovered cryptic species complex in this genus previously considered monotypic is characterized by morphological differences in wing shape and color patterns. As a first step toward understanding wing pattern divergence and pathways involved in adaptation and speciation at the genomic level, we present a transcriptome profiling of *M. caerulatus* using RNA-Seq and compare these data with two other odonate species. The de novo transcriptome assembly consists of 61,560 high quality transcripts and is approximately 93% complete. For almost 75% of the identified transcripts a possible function could be assigned: 48,104 transcripts had a hit to an InterPro protein family or domain, and 28,653 were mapped to a Gene Ontology term. In particular, we focused on genes related to wing development and coloration. The comparison with two other species revealed larva-specific genes and a conserved 'core' set of over 8,000 genes forming orthologous clusters with *Ischnura elegans* and *Ladona fulva*. This transcriptome may provide a first point of reference for future research in odonates addressing questions surrounding the evolution of wing development, wing coloration and their role in speciation." (Authors)] Address: Hadrys, Heike, ITZ – Forschungsstätte 'Alter Bahnhof Schapen' Braunschweig, Univ. of Veterinary Medicine Hannover, Hannover/Braunschweig, Germany. **16780.** Fincke, O.M.; Xu, M.; Khazan. E.S.; Wilson, M.; Ware, J.L. (2018): Tests of hypotheses for morphological and genetic divergence in *Megaloprepus* damselflies across Neotropical forests. *Biological Journal of the Linnean Society* 125(4): 844-861. (in English) ["Differences in sexual signalling may initiate speciation by limiting gene flow among diverging populations. *M. caerulatus* exhibits two, visually obvious 'wing types' across

its range. Males from one subspecies have sexually dimorphic, white-banded wings whereas males from the other subspecies lack the sex-specific white wing band. Using mitochondrial (cytochrome c subunit I and 16S) and nuclear (H3) markers, and measures of body size, wing ratio and secondary genitalia, we identified distinct genetic and morphological clades from Mexico to Panama; absence of a wing band was ancestral. To determine if relative reflectance properties of male and female wing tips cue sexual and competitor identity, as they do for wing dimorphic males, we noted reactions of males lacking wing bands to conspecifics with manipulated wings. Isolation by distance explained only 18% of the molecular variation among clades. Relative to wing dimorphic demes, wing monomorphic populations showed lower adult density, lower resource defence and fewer male–male interactions, suggesting lower sexual selection on males. However, not all were less sexually dimorphic in body size. Males lacking wing bands reacted to conspecifics with manipulated wings in ways suggesting that signals for potential mates and competitors do not differ across wing types, a conclusion that awaits more data. Wing mono- and dimorphic demes in *Megaloprepus* occur allopatrically over relatively short distances and may be isolated via secondary genitalia or unknown physiological constraints." **16783.** Frantsevich, L.; Frantsevich, L. (2018): Leg deformation during imaginal ecdysis in the downy emerald, *Cordulia aenea* (Odonata, Corduliidae). *Zoology* 127: 106-113. (in English) ["Highlights: •A molting dragonfly pulls its legs through immobile flexed exuvial legs. •Shapes of imaginal legs were viewed in instantly fixed specimens. •Transient intrapodomere bendings repeat angles in exuvial joints. •Bending sites shift distad during the whole molt. •Legs in molting dragonflies must be pliable (as in most arthropods). A dragonfly larva migrates from the water to the shore, perches on a plant stem and grasps it with strongly flexed legs. Adult legs inside the larval exoskeleton fit to the larval legs joint-to-joint. The adult emerges with stretched legs. During the molt, an imaginal leg must follow all the angles in exuvial joints. In turn, larval apodemes are withdrawn from imaginal legs. We visualized transient shapes of the imaginal legs by the instant fixation of insects at different moments of the molt, photographed isolated exuvial legs with the imaginal legs inside and then removed the exuvial sheath. Instant shapes of the imaginal tibia show sharp intrapodomere bends copying the angle in the larval femoro-tibial joint. The site of bending shifts distad during the molt. This is possible if the imaginal leg is pliable. The same problem of leg squeezing is also common in hemimetabolous insects as well as in other arthropods, whereas holometabolous insects overcome problems of a tight confinement either by using leg pliability in other ways but not squeezing (cyclorhaphan flies, mosquitoes) or by pulling hardened legs out without change of their pupal zigzag configuration (moths, ants, honey bees). The pupal legs are not intended to grasp any external substrate." (Authors)] Address: Frantsevich, L., Schmalhausen Institute of Zoology, B. Chmielnicky str. 15, Kiev-30, 01601, Ukraine. (2018): Abundanz und Habitatwahl von Imagines von *Ophiogomphus cecilia* an renaturierten und ausgebauten Abschnitten der Lippe, Nordrhein-Westfalen (Odonata: Gomphidae). *Libellula* 37(3/4): 1-22. (in German, with English summary) ["Abundance and habitat selection of imagines of *Ophiogomphus cecilia* at restored and unrestored sections of the river Lippe, North Rhine Westphalia, Germany – *O. cecilia* is an indicator species of near-natural streams and rivers. It is listed under appendix II and IV of the FFH-Directive and protected under German law. Since the beginning of the 2000s, the species has been extending its range in many regions. At the river Lippe in the district of Soest, North Rhine-Westphalia it has been found in increasing numbers since 2012. In 2017, densities of adult dragonflies as well as habitat parameters were recorded systematically along restored and unrestored Stretches of the Lippe. The highest densities were recorded along restored Stretches, but this difference was not statistically significant. Adult dragonflies preferred Stretches with low Vegetation along the bank and clayey substrates in the river. They avoided stretches with overhanging vegetation, turbulent water surface and muddy sediments. Regarding these parameters, the restored sections were significantly, or tendentially more suitable for colonization." **16792.** Garrouste, R.; Lapeyrie, J.; Steyer, J.-S.; Giner, S.; Nel, A. (2018): Insects in the Red Middle Permian of Southern France: first Protanisoptera (Odonoptera) and new Caloneurodea (Panorthoptera), with biostratigraphical implications. Historical Biology 30(4): 546-553. (in English) ["The Permian odonopteran Protanisoptera are discovered for the first time in the playa palaeoenvironments of Gonfaron and Lodève (Southern France). The new genus and species *Bansheeperton gonfaronensis* is erected and described on the basis of a distal half of a wing from the Guadalupian of Gonfaron. It is compared with all the previously described protanisopterans. Another specimen consisting of a basal half of a wing from the Guadalupian of Lodève, attributed to cf. *Bansheeperton gonfaronensis*, is also described. Furthermore, three new panorthopteran Caloneurodea are described from the Early to Middle Permian (Cisuralian and Guadalupian) of Southern France, viz. *Gallogramma galadrieli* gen. et sp. nov. from the le Luc Basin (Gonfaron, Var), and *Paleuthygramma* cf. *acuta* Carpenter, 1943 from the Lodève Basin (Hérault). These new fossils increase the palaeodiversity of the Caloneurodea, an interesting clade which now gathers six species in the red Permian of the Southern France, making it one of the most diverse clade in these palaeoenvironments after the Odonoptera. The present discoveries better support a Guadalupian age for the Gonfaron Formation, even if a Late Cisuralian affinities remains possible." (Authors)] Address: Nel, A., Lab. Ent. Mus. Natn. Hist. Nat., 45 rue Buffon, F-75005 Paris, France. E-mail: anel@cimrns1.mnhn.fr

**16794.** Gazzola, A.; Russo, G.; Balestrieri, A. (2018): Embryonic and larval defensive responses of agile frog (*Rana dalmatina*) to alien crayfish. *Ethology* 124(5): 347-356. (in English) ["Red swamp crayfish *Procambarus clarkii*, a widespread invasive alien crayfish, represents a serious threat for several freshwater species, including amphibians, which are declining at a global scale. As a shared coevolutionary history is the main factor determining the emergence of antipredator responses, Anuran tadpoles may not be able to cope effectively with this introduced predator. We performed two experiments to assess *R. dalmatina* defensive responses to both *P. clarkii* and native dragonfly larvae (*Anax imperator*). First, we conditioned embryos (collected from two ponds 30 km away from each other) with predators' chemical cues to explore possible variation in hatching time caused by predation risk. In the second experiment, to evaluate how predators' diet affects tadpole behavior, we conditioned tadpoles for a 5-week period with cues from tadpole-fed and gammarid-fed predators and recorded behavioral and morphological responses. Embryos did not alter hatching time in the presence of any predator cue, while tadpoles from both populations strongly reduced activity and visibility when raised in the presence of tadpole-fed dragonfly larvae. Morphological changes were less straightforward and were induced only in one population, for which broader tails and a slight increase in body size of tadpoles exposed to tadpole-fed predators were observed. The lack of defensive responses in crayfish-exposed tadpoles suggests that the spreading of this invasive species in agricultural lowlands of northern Italy may represent a further threat to their conservation." **16796.** Govenor, H.; Krometis, L.A.H.; Willis, L.; Angermeier, P.L.; Hessiony, W.C. (2018): Macroinvertebrate sensitivity thresholds for sediment in Virginia streams. *Integrated Environmental Assessment and Management* 15(1): 77-92. (in English) ["Sediment is the most commonly identified pollutant associated with macroinvertebrate community impairments in freshwater streams nationwide. Management of this physical stressor is complicated by the multiple measures of sediment

available (e.g., suspended, dissolved, bedded) and the variability in natural "healthy" sediment loadings across ecoregions. Here we examine the relative importance of 9 sediment parameters on macroinvertebrate community health as measured by the Virginia Stream Condition Index (VSCI) across 5 ecoregions. In combination, sediment parameters explained 27.4% of variance in the VSCI in a multiregion data set and from 20.2% to 76.4% of variance for individual ecoregions. Bedded sediment parameters had a stronger influence on VSCI than did dissolved or suspended parameters in the multiregion assessment. However, assessments of individual ecoregions revealed conductivity had a key influence on VSCI in the Central Appalachian, Northern Piedmont and Piedmont ecoregions. In no case was a single sediment parameter sufficient to predict VSCI scores or individual biological metrics. Given the identification of embeddedness and conductivity as key parameters for predicting biological condition, we developed family-level sensitivity thresholds for these parameters, based on extirpation. Resulting thresholds for embeddedness were 68% for combined ecoregions, 65% for the Mountain bioregion (composed of Central Appalachian, Ridge and Valley, and Blue Ridge ecoregions), and 88% for the Piedmont bioregion (composed of Northern Piedmont and Piedmont ecoregions). Thresholds for conductivity were 366 mS/cm for combined ecoregions, 391 mS/cm for the Mountain bioregion, and 136 mS/cm for the Piedmont bioregion. These thresholds may help water quality professionals identify impaired and at-risk waters designated to support aquatic life and develop regional strategies to manage sediment-impaired streams. Inclusion of embeddedness as a restoration endpoint may be warranted; this could be facilitated by application of more quantitative, less time-intensive measurement approaches. We encourage refinement of thresholds as additional data and genus-based metrics become available. *Integr Environ Assess Manag* 2019; 15:77–92. Published 2018. This article has been contributed to by US Government employees and their work is in the public domain in the USA." **16800.** Hallworth, M.T.; Marra, P.P.; McFarland, K.P.; Zahendra, S.; Studds, C.E. (2018): Tracking dragons: stable isotopes reveal the annual cycle of a long-distance migratory insect. *Biol. Lett.* 14: 20180741. <http://dx.doi.org/10.1098/rsbl.2018.0741>: 5 pp. (in English) ["Insect migration is globally ubiquitous and can involve continental-scale movements and complex life histories. Apart from select species of migratory moths and butterflies, little is known about the structure of the annual cycle for migratory insects. Using stable-hydrogen isotope analysis of 852 wing samples from eight countries spanning 140 years, combined with 21 years of citizen science data, we determined the full annual cycle of a large migratory dragonfly *Anax junius*. We demonstrate that darners undertake complex long-distance annual migrations governed largely by temperature that involve at least three generations. In spring, the first generation makes a long-distance northbound movement (further than 650 km) from southern to northern range limits, lays eggs and dies. A second generation emerges and returns south (further than 680 km), where they lay eggs and die. Finally, a third resident generation emerges, reproducing locally and giving rise to the cohort that migrates north the following spring. Since migration timing and nymph development are highly dependent on temperature, continued climate change could lead to fundamental changes in the biology for this and similar migratory insects." **16801.** Hecca, D.; Arinafril, A.; Novia, N. (2018): Diversity of Odonata and aquatic environmental conditions in lake area (water ski and OPI) Jakabaring Palembang - South Sumatra. *Biovalentia* 4(2): 7 pp. (in English) ["Odonata are considered to be good indicators of environmental health and water quality with its presence and diversity in the Jakabaring lake area (Water Ski and OPI). The research location (Water Ski and OPI) utilized by the community as water catchment areas (flood control), recreation and habitat. The Activity in the lake area can affect the benefit of the lake, affecting the quality of the lake waters as a living habitat for animals and plants. However, to describe the diversity of odonata as indicator of the waters in the area of Water Ski and Lake OPI lakes, there is no such thing, therefore the researchers to look at Odonata diversity in the area of Water Ski Lake and Lake OPI Jakabaring Palembang-South Sumatra. The location of the study was determined using the purposive sampling method conducted in April 2018. The species found to identified at the FMIPA Animal Taxonomy Laboratory of Sriwijaya University. Sampling in the morning (07.00 – 10.00 AM) and afternoon (15.00 – 18.00 AM). The results of research in the lake area found 2 families, 11 genere, and 18 species, the total number of all 984 individual species. Odonata species data obtained in the analysis using Past3 software. The diversity index in the Water Ski lake is 1.992 and the diversity index in the OPI lake is 1.758. Diversity index value (2.014), dominance index (0.7922) and evenness index (0.4165). Odonata and environmental conditions of the lake (Water Ski and OPI) still have relationship, the condition of lake water quality is still below water quality criteria threshold. This is what makes the diversity on both lakes has a moderate value." (Authors)] Address: Hecca, Desven, Study Program of Management Environmental, Graduate Program at Sriwijaya University. (2018): Large net cage for captive breeding and behavioural studies of damselfly *Lestes sponsa* (Hansemann, 1823) (Odonata: Lestidae): submerged oviposition as a model behaviour. *Aquatic Insects* 39(1): 43-53. (in English) ["Odonata have a strong potential as model organisms for testing ecological and evolutionary hypotheses because of their short life history, relative ease and cost-effectiveness of care. Unfortunately, very few studies have examined how to create a semi-natural environment for odonates, limiting the biological validity of laboratory manipulation. To better study odonate life cycle and behaviour under controlled conditions, we designed a large net cage that imitated the natural terrestrial as well as aquatic habitat of *L. sponsa*. This species is thought to be capable of submerged oviposition, an unusual behaviour in odonates. We compared multiple variables across natural conditions and the net cage. We demonstrated that between-year variability under natural conditions was generally greater than variability between natural and artificial environments. Overall, semi-natural conditions did not substantially change the *L. sponsa* life cycle (including the unique behaviour of submerged oviposition), suggesting that results from the net cage are likely generalisable to the field." (2018): Catálogo y distribución geográfica de los Odonatos en la Región de Murcia (SE España). - Catalogue and geographical distribution of Odonata in the Region of Murcia (SE Spain). *Munibe, Cienc. nat.* 66: 137-143. (in Spanish, with English and Euskarian summaries) ["The catalogue and distribution of the Odonata order in the Murcia Region has been updated, comparing this to an earlier one made in the 1950s. The results indicate that 40 species were located in 17 localities in the mid-20th century, while the 2087 citations collected between 1991-2017 confirm the presence of 47 species in 191 localities. 11 new species have been identified for the Region of Murcia, which may have been favoured by the construction of ponds, reservoirs and other infrastructures to supply 225,000 hectares of irrigated land. Of these, the distribution areas of 9 species are expanding towards northern Europe and / or Asia, an effect that may relate to the current climate change process. On the contrary, in the current review 4 species cited in the study conducted in the mid-twentieth century have not been detected." (Authors)] Address: Ballesteros-Pelegrín, G.A., Univ. de Murcia. **16804.** Higashikawa, W.; Yoshimura, M.; Yagi, T.; Maeto, K. (2018): Grass and water preference during oviposition by *Sympetrum pedemontanum elatum* in Japan (Odonata: Libellulidae). *Odonatologica* 47(1/2): 161-178. (in English) ["*S. pedemontanum* is regionally endangered or extinct in several countries despite having a wide distribution across the Eurasian continent and its neighboring islands. Its subspecies *S. p. elatum* in Japan has been decreasing rapidly with the loss of larval habitat in rural areas since the 1970s. Previous studies have detailed habitat use by larvae and mature adults, but information on grass and water preferences during oviposition is still lacking. In this study, we tracked adults as they performed reproductive behaviors and documented the grass height and water conditions preferred for oviposition in a lowland, mid-slope river in Japan. Our results showed that females dipped their abdomens significantly more into stagnant than into flowing water for oviposition and that short surrounding grass and shallow water enhanced oviposition behavior. These findings emphasize the importance of riparian grass management and water flow regulation for the conservation of *S. p. elatum*." **16805.** Hjalmarsen, E. (2018): On the use of Odonata as ecological indicators. M.Sc. thesis, University of Oklahoma, Norman, Oklahoma: X + 49 pp. (in English) ["The insect order Odonata is unique to use as an ecological indicator for water quality because of its close relationship with aquatic ecosystems and relative ease of observation and species-level identification. My goal was to explore ways in which odonates can respond

to, and therefore indicate, sites with higher water quality. Determining where odonates breed as opposed to where they "merely" occur is key to an understanding of the importance of water quality. It has been asserted that one should conclude that an odonate species breeds if and only if physical (exuvia, teneral) or behavioral (tandem pairing, oviposition) evidence is obtained, yet gathering such evidence requires specialized observational and technical skills. In contrast, reliable observations and counts of adults can be had readily, creating a dilemma over which data to use. For my first chapter, I examined whether adult surveys and reproductive behaviors could predict breeding residency status, represented by presence of teneral (newly emerged odonates), using a large, multi-year dataset from across Oklahoma. Using an occupancy model combined with piecewise regression, I found thresholds and associated Bayesian credible intervals for a suite of odonate taxa. I found similar general thresholds across species but found specific indicator thresholds exist when examining groups on the family and genus level. Thresholds differed among taxonomic groups and decreased in models that included counts of females rather than just of counts of adults any (or unknown) sex. My results can guide future survey protocol: adult observations can remain the primary focus, which broadens the scope of potential observer skill levels (e.g., citizen scientists) while indirectly ensuring breeding to identify sites for water quality surveys. For my second chapter, I examined odonate biodiversity at urbanized water features to determine factors that promote species diversity and abundance, with a goal of using findings to make beneficial improvements to park management to increase water quality. I conducted surveys April–October 2016–2017 at 14 urban sites in central Oklahoma that varied in human use and habitat structure. I compared diversity and species composition among sites and tested which features best predicted higher abundance and species totals. Several variables were good predictors but use of a site for fishing purposes was an overarching indicator of both high species richness and high odonate abundance. Despite higher human use, presence of infrastructure, and increased management of these sites (which are typically negatively associated with biodiversity), odonates (and humans) benefit from maintaining them and ensuring proper water quality persists (i.e., if it is good for fish, it is good for insects)." **16810.** Hykel, M.; Harabiš, F.; Dolný, A. (2018): Diel changes  
in habitat use by dragonflies: Nocturnal roosting site selec-  
tion by the threatened dragonfly *Sympetrum depressiusculum*  
(Odonata: Libellulidae). *Entomological Science* 21(1): 154-163.

(in English) ["Although it is well recognized that insects' hab-  
itat use and requirements may change during the season, very  
little attention has been devoted to diel habitat changes in most  
insects. In this study, we compared habitat utilization patterns  
of *S. depressiusculum*) adult dragonflies between daytime ac-  
tivities and nocturnal roosting. During daytime, we captured  
and marked adult individuals with fluorescent paint in different  
habitats. At night, we searched, using UV light, for marked in-  
dividuals that remained on the habitats. We found that habitat  
selection for daytime activities and that for nocturnal roosting  
differed significantly. Adults clearly avoided ponds and their im-  
mediate surroundings for nocturnal roosting whereas this hab-  
itat type was frequently utilized for daytime activities. We sug-  
gest that nocturnal avoidance of the riparian area is associated  
with lower temperatures, which adversely affect thermoregula-  
tion, and that selection of specific habitats for nocturnal roosting  
is closely associated with vegetation structure providing stabil-  
ity during windy nights and serving as a suitable shelter. Such  
habitat properties are found especially on fallow land, a habitat  
type whose representation in agricultural areas has been grad-  
ually decreasing in recent decades." (Authors)] Address: Hykel,  
M., Department of Biology and Ecology, Faculty of Science,

**16811.** Ilvonen, J.J.; Kaunisto, K.M.; Suhonen, J. (2018): Odo-  
nates, gregarines and water mites: why are the same host spe-  
cies infected by both parasites? *Ecological Entomology* 43:  
591-600. (in English) ["1. Odonata are widely parasitised in-  
sects and numerous studies have tried to understand this host-  
parasite relationship. However, most of these studies  
have concentrated on a single host species, neglecting the  
larger pattern within the Odonata order. 2. The aim of this  
paper was to examine different Odonata species for common en-  
do- and ectoparasites and whether a general infection  
pattern can be found. Additionally, the goal was to investigate  
whether the phylogeny of the host species could explain these  
possible infection patterns. To this end, a dataset from the  
existing literature was compiled and the prevalence of endo-  
parasitic gregarines and ectoparasitic water mites was ana-  
lysed for 46 different odonate species. 3. Three distinct patterns  
were found: (i) most of the odonate host species had both greg-  
arines and water mites, rather than only either one or neither;  
(ii) there appears to be a positive association between grega-  
rine and water mite prevalences across host species; (iii) a  
weak phylogenetic signal was detected in gregarine preva-  
lence and a strong one in water mite prevalence. 4. It is hy-  
pothesised that, due to the infection and transmission mecha-  
nisms by which water mites and gregarines infect different odo-  
nate host species, parasitism is aggregated to common, high-  
density species. However, much research is needed in order  
to fully understand this relationship between odonates and their  
parasites, especially within the same host populations and host  
species assemblages." (Authors)] Address: Ilvonen, J.J., Dept  
Biol., 20014 Univ.y of Turku, Turku, Finland. E-mail: [jjilvo@utu.fi](mailto:jjilvo@utu.fi)

tion and fragmentation of mesoplastic fibres to microplastics by  
*Anax imperator* larvae (Odonata: Aeshnidae). *Odonatologica*

47(3/4): 57-66. (in English) ["Exposure to plastic litter in ecosystems is increasing globally. Marine and terrestrial ecosystems, as well as freshwater ecosystems, are affected. Despite this, the impact of increased exposure to plastics on the freshwater fauna is largely unexplored. The present work investigates the reactions of 42 *Anax imperator* larvae to plastics in their habitat. Mesoplastic fibres (ca 8 mm long) were presented with a *Chironomus* sp. larva that was placed behind the fibre. In the majority of the observations, ejection attempts using the labium and the front legs were observed. When ingestion occurred, macerated plastic fibres (0.5-3.5 mm) appeared in the faeces of several individuals. Consequently, Odonata larvae turned meso-plastics into microplastics. It is assumed that the mechanical comminution was achieved by the action of the gizzard, which contains strong chitinous teeth." **16813.** Islam, S.U.; Qasim, M.; Lin, W.; Islam, W.; Arif, M.; Ali, H.; Wu, Z. (2018): Genetic interaction and diversity of the families Libellulidae and Gomphidae through COI gene from China and Pakistan. *Acta Tropica* 182: 92-99. (in English) ["Highlights: •There are 67 sequences of Odonates, comprising two families, 15 genera and 21 species in the present study. •*Crocothemis servilia* had maximum population in the entire collection. •Cytochrome oxidase subunit I (COI) gene was used for whole molecular work. A total of 300 Odonata were collected from six different localities of China and Pakistan. 67 representative samples were selected to sequence their mitochondrial cytochrome oxidase subunit I (COI). An examination of the resultant sequences identified 21 different dragonfly species, belonging to 15 distinct genera, two families, Libellulidae and Gomphidae. Sequence alignment was executed using Clustal-W in BioEdit v6. The phylogenetic tree was constructed through Neighbor-joining method by using Jukes-Cantor model, and genetic divergence was calculated via Kimura 2-parameter using MEGA7, while Genetic diversity was calculated by DnaSP v5. The maximum genetic divergence was observed for *C. servilia*, at 20.49%, followed by Libellulidae sp. with 22.30% while minimum divergence (0.82%) was observed for *Meligomphus ardens*. Likewise, a significant genetic diversity was observed for all species. However, *C. servilia* species presented maximum value (176 mutations) followed by Libellulidae spp. (150 mutations), whereas minimum value (3 mutations) was observed by *Orthetrum testaceum*. Interestingly, the diversity of *C. servilia*, all of which are collected from a single location of China, is much higher than those from Pakistan, which were collected from 5 different places with a spatial distance exceeding 500 Kms. Our results are useful in gaining a full appreciation of the global diversity of dragonflies and the development of conservation measures of this insect." **16814.** Iswandaru, D. (2018): Diversity of dragonflies (Odonata) in swamp ecosystem university of Lampung. *Agricultura* 105-106: 101-109. (in English) ["Swamp is a unique wetland ecosystem with waterlogged conditions, overgrown with distinctive

vegetation types. Swamp ecosystem in University of Lampung are freshwater swamps that are well watered throughout the year and overgrown with aquatic vegetation, making it ideal for the habitat of various types of Odonata. The life cycle of the dragonfly is in two environments, pre-adult phase is aquatic and adult life around the waters, so the dragonflies can be used as an environmental bioindicator. The study aims to find the species of dragonflies with conservation status and trading status, analyzing the relative abundance and diversity of dragonflies founded in the swamp ecosystem at the University of Lampung. This research conducted with exploration method or (field to field) in three locations (R1, R2, R3), the random exploration was done two times at morning and afternoon. The results showed that 12 species of dragonflies from 3 families encountered during study. The highest abundance of dragonfly species *Orthetrum sabina* with 20.14% and the smallest was *Acisoma panorpoides* and *Zyxomma obtusum* with 2.16%. Conservation status of the 12 species are Least Concern (IUCN), unprotected (UU / PP) and non-appendix (CITES). The value of diversity index shows a moderate scale with 2.26, which means the condition of swamp ecosystem in University of Lampung still has good productivity as a habitat to support the life of dragonfly." (Author)] Address: Iswandaru, D., Dept of Forestry, Fac. of Agriculture, Univ. of Lampung. E-mail: univasahanpress@gmail.com

**16815.** Itagawa, S.; Ichinose, T. (2018): Factors affecting the migration range of *Calopteryx atrata* in urban small and medium-sized rivers. *Landscape Research* 11: 32-38. (Japanese, with English summary) ["We investigated the migration range of *C. atrata* using the mark and recapture method in Akuwa River and Ooka River which run through the urban area of Yokohama City, Kanagawa Prefecture, Japan. 286 individuals were marked and released at four spots, and 64 marked individuals were recaptured after several days. Initial findings showed that the maximum total migrant distance was 1319 meters, and the average was 323 meters. The individuals that migrated upper stream were more than those in the lower stream, and the migration range to upper was significantly longer than to the lower. Secondly, we analyzed the factors that promote or stunt the migration of *C. atrata* by GLMM with random effect. Results showed that survival days from release, the area of lower riverbed and coverage of shade were positively correlated with total migration distance. Meanwhile, the coverage of three types of the aquatic plant commonly had a negative correlation with the total migration distance. Also, the coverage area ratio of forest around rivers partly promotes the migration distance of *C. atrata*, if values of factors were added up in a more wide range from the release spot. The study's results showed that continuously establishing preferred riparian habitats with aquatic vegetation and a conservation of forests close to rivers enhance *C. atrata*'s large migration and expanded habitats." **16816.** Jackson, C.; McCalla, S.G.; Amberg, J.; Soluk, D.; Britten, H. (2018): The complete mitochondrial genome of Hine's emerald dragonfly (*Somatochlora hineana* Williamson) via NGS sequencing. *Mitochondrial DNA Part B* 3(2): 562-563.

(in English) ["Data were generated via next generation sequencing (NGS) and assembled using a mitochondrial baiting and iterative mapping approach. The full length circular genome is 15,705 bp with 26.6% GC content. It contains the typical metazoan set of 37 genes: 13 protein-coding genes, 22 transfer RNA (tRNA) and 2 ribosomal RNA (rRNA) genes, and an A + T-rich control region. To our knowledge, this is the first report of the complete *S. hineana* mitogenome." (Authors)] Address: Jackson, C., UMESC, 2630 Fanta Reed Road, La Crosse, WI 54603, USA. E-mail: cjackson@usgs.gov

**16817.** Jacquelin, L.; Desutter-Grandcolas, L.; Chintauan-Marquier, I.; Boistel, R.; Zheng, D.; Prokop, J.; Nel, A. (2018): New insights on basivenal sclerites using 3D tools and homology of wing veins in Odonoptera (Insecta). *Scientific Reports* 8, Article number: 238 (2018). 7 pp. (in English) ["Being implied in flight, mimetism, communication, and protection, the insect wings were crucial organs for the mega diversification of this clade. Despite several attempts, the problem of wing evolution remains unresolved because the basal parts of the veins essential for vein identification are hidden in the basivenal sclerites. The homologies between wing characters thus cannot be accurately verified, while they are of primary importance to solve long-standing problems, such as the monophyly of the Palaeoptera, viz. Odonoptera, Panephemeroptera, and Palaeozoic Palaeodictyoptera mainly known by their wings. Hitherto the tools to homologize venation were suffering several cases of exceptions, rendering them unreliable. Here we reconstruct the odonatopteran venation using fossils and a new 3D imaging tool, resulting congruent with the concept of Riek and Kukalová-Peck, with important novelties, viz. median anterior vein fused to radius and radius posterior nearly as convex as radius anterior (putative synapomorphies of Odonoptera); subcostal anterior (ScA) fused to costal vein and most basal primary antenodal crossvein being a modified posterior branch of ScA (putative synapomorphies of Palaeoptera). These findings may reveal critical for future analyses of the relationships between fossil and extant Palaeoptera, helping to solve the evolutionary history of the insects as a whole." **16818.** Jang, J.H.; Yang, G.-H. (2018): Design of wing root rotation mechanism for dragonfly-inspired micro air vehicle. *Applied Sciences* 2018, 8, 1868; doi:10.3390/app8101868 www.mdpi.com/journal/. 18 pp. (in English). ["This paper proposes a wing root control mechanism inspired by the drag-based system of a dragonfly. The previous mechanisms for generating wing rotations have high controllability of the angle of attack, but the structures are either too complex or too simple, and the control of the angle of attack is insufficient. In order to overcome these disadvantages, a wing root control mechanism was designed to improve the control of the angle of attack by controlling the mean angle of attack in a passive rotation mechanism implemented in a simple structure. Links between the proposed mechanism and a spatial four-bar link-based flapping mechanism were optimized for

the design, and a prototype was produced by a 3D printer. The kinematics and aerodynamics were measured using the prototype, a high-speed camera, and an F/T sensor. In the measured kinematics, the flapping amplitude was found to be similar to the design value, and the mean angle of attack increased by approximately 30 at a wing root angle of 0. In the aerodynamic analysis, the drag-based system implemented using the wing root control mechanism reduced the amplitude of the force in the horizontal direction to approximately 0.15 N and 0.1 N in the downstroke and upstroke, respectively, compared with the lift-based system. In addition, at an inclined stroke angle, the force in the horizontal direction increased greatly when the wing root angle was 0 at the inclined stroke angle, while the force in the vertical direction increased greatly at a wing root angle of 30. This means that the flight mode can be controlled by controlling the wing root angle. As a result, it is shown that the wing root control mechanism can be applied to the MAV (micro air vehicle) to stabilize hovering better than the MAV using a lift-based system and can control the flight mode without changing the posture." **16820.** Jiao, J.; Zhang, F.; Jiao, T.M Gu, Z.; Wang, S. (2018): Bioinspired superdurable pestle-loop mechanical interlocker with tunable peeling force, strong shear adhesion, and low noise. *Advanced Science* 5(4), 1700787: 7 pp. (in English) ["Velcro, the most typical hook-loop interlocker, often suffers from undesirable deformation, breaking, and noise because of the structure of the hook. Inspired by the arrester system of dragonfly, a new mechanical interlocker with a nylon pestle instead of the traditional hook is developed. The pestle-loop mechanical interlocker shows a tunable peeling force from  $0.4 \pm 0.14$  to  $6.5 \pm 0.72$  N and the shear adhesion force of pestle-loop mechanical interlocker is about twice as much as

that of velcro. The pestle tape can be separated and fastened with the loop tape up to 30 000 cycles while keeping the original adhesive force and the pestle structure. In comparison, only after 4000 cycles most hooks of the commercial velcro are deformed and even broken, completely losing their adhesive function and their hook structure. These experimental results are further supported by finite element simulations—the base of pestle mainly bears the separation-caused strain while the middle of hook does. Notably, the sound volume during the separation of pestle-loop mechanical interlocker is merely  $49 \pm 7.4$  dB, much lower than  $70 \pm 3.5$  dB produced by the velcro." **16821.** Jinguji, H.; Sawada, D.; Morimoto, M. (2018): Suppression of *Aedes* mosquito larvae using dragonfly larvae released into ovitraps (Diptera: Culicidae; Odonata: Libellulidae). *Odonatologica* 47(3/4): 67-84. (in English) ["There has been a marked increase in the number of dengue cases reported in Japan. In 2014, 162 people contracted dengue fever from the virus transmitted by *Aedes albo-pictus*. The increased prevalence of the disease in Japan implies that climate change and globalization have accelerated the risk of dengue fever spreading to Japan. This study aimed to develop a method for using dragonflies as biocontrol agents for mosquito control. We conducted a field study to determine whether dragonfly larvae could suppress populations of *A. albopictus* larvae. Eighth instar larvae of *Sympetrum frequens* were released into an ovitrap in which they preyed upon mosquitos. Compared to the control treatment, mosquito larvae decreased significantly in ovitraps containing *S. frequens* and *S. infuscatum* (i.e., experimental treatment). The mean number of mosquito larvae remaining in *S. frequens* and *S. infuscatum* ovitraps was  $1.5 \pm 4.6$  (mean  $\pm$  SD) and  $0.6 \pm 1.1$ , respectively. The results showed that *S. frequens* and *S. infuscatum* preyed on 410 to 710 and 339 to 592 mosquito larvae per ovitrap at each site. Based on estimates of the number of mosquito eggs laid in ovitraps during the field trial, *S. frequens* larvae consumed approximately 20.3 to 45.0 % of mosquito eggs in the ovitrap. Suppression effects of *S. frequens* and *S. infuscatum* lasted  $41 \pm 13$  and  $35 \pm 13$  days, respectively. The results obtained suggest that *S. frequens* in ovitraps is effective for regulating larval populations of mosquito vectors." **16825.** Jude, D.J.; Hensler, S.R.; Murray, M.M. (2018): Round goby and zebra mussel interactions with darters in a warm-water stream community in southern Michigan, USA. *Journal of Freshwater Ecology* 33(1): 395-412. (in English) ["The non-indigenous round goby (*Neogobius melanostomus*) entered the Flint River, Michigan, USA around 1996 while zebra mussels (*Dreissena polymorpha*) invaded in late 1998. We wanted to identify if there were round goby or darter (*Etheostoma/Percina* spp.) diet or density alterations by comparing 1998 data with our 2002 data after mussel colonization. Chironomids dominated the round goby's pre-zebra mussel diet in August 1998 (89% by number), followed by hydrophy-chids (10%). After zebra mussels arrived, diets diversified; chironomids declined to 52%, hydrophy-chids stayed the same, gastropods were more prominent (22%) and 4% were zebra mussels. Data from a site upriver (with no round gobies or zebra mussels) showed darters consumed mostly chironomids (49%), mayflies (11%) and hydrophy-chids (9%), suggesting

reliance on chironomid prey and other interactions compromised the ability of darters to coexist with round gobies downstream, since only one of three species present during 1998 was collected in 2002. Benthic assemblages on rocks changed dramatically ( $R$ -values =0.95) from 1998 to 2002. Blackside darter (*Percina maculata*) density in the presence of round gobies increased eightfold compared with 1998. We hypothesized zebra mussels fostered the growth of macrophytes, resulting in odonates composing 42% by volume of blackside darter diets in 2002 compared with 10% in 1998. Diet overlaps between small and large round gobies and blackside darters were high (Schoener Index =0.55–0.59,  $R$ -values =0.11–0.24), suggesting potential negative competitive interactions. Zebra mussel-mediated ecosystem changes may have decreased interspecific competition for food with blackside darters, allowing coexistence with round gobies. Native darters with varied diets feeding in mid-water, are most likely to coexist with round gobies, especially where dreissenids potentially mediate competitive interactions." **16828.** Kalkman, V.J.; Boudot, J.-P.; Bernard, R.; De Knijf, G.; Suhling, F.; Termaat, T. (2018): Diversity and conservation of European dragonflies and damselflies (Odonata). *Hydrobiologia* 811: 269-282. (in English) ["Based on a distribution database brought together for the recently published Atlas of the European dragonflies and damselflies, we describe the patterns of diversity and endemism of these insect groups. Highest species richness, as well as richness of predominantly lentic species, occurs in central and western-central Europe. Strictly lotic species have their centre of diversity in southwest France and parts of the Iberian Peninsula. The highest number of endemic species is found in southwest France, the Iberian Peninsula and the Balkan Peninsula. A comparison of the diversity patterns of Odonata species listed in the EU Habitats Directive with those listed in the European Red List highlights a strong mismatch between species threatened in Europe, which

are mainly found in the Mediterranean, and species legally protected by the European Union, which are concentrated in central and western Europe. This mismatch has a historical origin, as the species listed in the Habitats Directive were mostly selected in the 1970s and 1980s when water quality in western and central Europe was poor. Since the 1990s, water and habitat quality has improved in these parts of Europe while in the same period the pressure on aquatic habitats in the Mediterranean has increased greatly." **16830.** Kamps, A.; Scieszka, C.; Westmoreland, B. (2018): Effect of body size and Zebra Mussel attachment on exuviae emergence-site selection in five dragonfly species (*Hagenius brevistylus*, *Didymops transversa*, *Macromia illinoiensis*, *Dromogomphus spinosus*, *Epitheca* sp.). University of Michigan: 14 pp. (in English) ["Emergence-site selection in dragonflies is an important factor for their survival during metamorphosis because of possible predation and other factors that may end the dragonfly life cycle during this vulnerable process. This study examined the emergence-site selection of exuviae in five dragonfly species from a lake in Northern Michigan to identify whether or not body size or presence of zebra mussels has a significant impact on site selection. We found that as length increased in proportion to body area, dragonflies were able to travel farther away from the shore. Individual species showed differing trends, when it came to body size relating to distance travelled from the shore. Understanding trends in emergence-site selection is

important to understanding how dragonfly larvae have adapted to their individual environments in order to increase their chances of surviving to adulthood.] Address: Kamps, A., Univ. of Michigan Biol. Station, EEB 392 and Natural History & Evolution

**16831.** Karube, H.; Kosterin, O.E. (2018): *Mattigomphus* gen. nov., a new gomphid genus from Indochina region, separated from *Anisogomphus* (Odonata: Gomphidae). *Tombo* 60: 61-65. (in English) ["A new gomphid genus *Mattigomphus* gen. nov. is described. The new genus consists of two species (*M. tamdaoensis* (Karube, 2001) distributed in northern Vietnam and *M. pinratani* (Hämäläinen, 1991) distributed in northern Thailand) first described and so far placed in *Anisogomphus* Selys, 1858. The genus is characterized mainly by a peculiar male penis (prolonged median segment, reduced posterior lobe and very simple depressed glans) and cerci." **16833.** Kastner, F.; Buchwald, R.; Biedermann, R. (2018): Occurrence of *Aeshna viridis* in marsh ditches in relation to habitat conditions (Odonata: Aeshnidae). *International Journal of Odonatology* 21(3/4): 205-219. (in English) ["Habitat loss and fragmentation induce a decline and endangerment of freshwater organisms such as *A. viridis*, an endangered dragonfly species characterised by a specific insect-plant association to the macrophyte *Stratiotes aloides*. In order to implement conservation measures, a good level of knowledge about the occurrence, habitat requirements and quality, as well as patch size of the species is important. We analysed the influence of several habitat parameters on the presence/absence and abundance of *A. viridis* exuviae using habitat models (generalised linear mixed-effect models). The ditches populated by *A. viridis* were classified as moderately polluted and meso- to eutrophic with a high cover of emerged *S. aloides* stands. The main factor contributing to the presence of *A. viridis* was the coverage of emerged *S. aloides* combined with the ditch width. The 90% probability of the presence of *A. viridis* was achieved at a cover of 14% (8.4 m<sup>2</sup>) and/or 77% (46.2 m<sup>2</sup>) of emerged *S. aloides*. The number of *A. viridis* exuviae was

positively affected by the cover of emerged *S. aloides* and negatively affected by the sediment thickness, water maintenance and water temperature in March and August. The habitat parameters – water temperature and sediment thickness – are associated with *S. aloides* in the beginning of siltation of ditch succession. If ditch cleaning takes place during larvae development, eggs and larvae are removed by these procedures. In an optimal situation, the *S. aloides* populations occur in a mosaic of different states of siltation, which is managed by adapted water maintenance." **16834.** Kaunisto, K.M.; Morrill, A., Forbes, M.R. (2018): Negative covariance between water mite and gregarine parasitism for adult dragonflies, *Leucorrhinia intacta* (Hagen): an age-related pattern? *Parasitology Research* 117(12): 3909-3915. (in English) ["Studies on parasite-mediated selection often focus on single parasite taxa infecting single species of hosts. However, host populations experience infections by multiple parasite taxa simultaneously; coinfection is expected to influence how host- and/or parasite-related factors affect host exposure and susceptibility to various parasites, and the resulting patterns of infection. We sampled adult dragonflies from a population of *L. intacta* in eastern Ontario, Canada. Dragonflies were exposed to parasitism by both water mites (Arrenuridae) and gregarines (Eugregarinidae). We tested for covariation between these ecto- and endoparasites, while considering potential sex and age biases in host sampling and patterns of infection. Mite parasitism differed dramatically between host sexes: nearly all collected males were parasitized, whereas only half of females were infested. This was likely due to differences in age distributions between sexes in sampled dragonflies. Water mite and gregarine parasitism showed strong, negative covariation, and coinfection occurred far less often than expected by chance, although these patterns were restricted to samples of females which, unlike male samples, likely included many old and young dragonflies. We report the first observation of negative covariation between internal and external parasite taxa in an anisopteran host and suggest this relationship between water mites and gregarines may be more widespread among Odonata and perhaps other insects than previously surmised. We advance hypotheses based on host age-parasitism relationships as well as variable parasite-mediated selection to help explain the sex specificity of observed coinfection patterns in our samples." **16836.** Kay, R.T.; Gahala, A.M.; and Bailey, C. (2018): Assessment of water resources in areas that affect the habitat of the endangered Hine's emerald dragonfly in the Lower Des Plaines River Valley, Illinois. U.S. Geological Survey Scientific Investigations Report 2018–5074, <https://doi.org/10.3133/sir20185074>.: 104 pp. (in English) ["Review of previous investigations indicates that potential decreases in groundwater recharge and increased groundwater extraction in the vicinity of the Lower Des Plaines River Valley in Will County, Illinois, may reduce the amount of groundwater flow in the Silurian aquifer in this area. Groundwater discharge from the Silurian aquifer to wetlands in the Lower Des Plaines River Valley plays an important role in sustaining the habitat of the endangered *Somatochlora hineana*. Groundwater modeling performed by previous investigators indicates that increasing the amount of water pumped from the aquifer in support of expanded quarry operations near the Lockport Prairie Nature Preserve has the potential to reduce groundwater discharge to the most productive *S. hineana* habitats in Illinois, potentially degrading the habitat. Model simulations indicate that mitigation procedures designed to artificially enhance groundwater recharge in the vicinity of dragonfly habitats near the Lockport Prairie Nature Preserve are likely to offset the effects of increased pumping. Several areas with smaller, often intermittent populations of *S. hineana* have been identified in other parts of the Lower Des Plaines River Valley and elsewhere in Illinois. Human activities have the potential to produce changes in hydrology and water quality that can threaten all of these habitats." (Authors)] Address: not stated

**16837.** Keilsohn, W.; Narango, D.L.; Tallamy, D.W. (2018): Roadside habitat impacts insect traffic mortality. *Journal of Insect Conservation* 22(2): 183-189. (in English) ["Paved roadways, spanning 6.6 million kilometres across the continental United States, are often bordered by natural or restored habitats and could provide opportunities for pollinator conservation. Because insects are frequently killed by auto traffic, roadside habitats may be ecological traps that kill more pollinators than they produce. Here we compare insect traffic mortality when roadsides are bordered by woodlots, meadows, or lawns. We also compare study sites with and without restored medians to examine the impact of creating habitat that can only

be accessed by crossing traffic. We confined our study to high speed roads (70–90 km h<sup>-1</sup>) with heavy traffic volume. Both habitat type and the presence of a vegetated median affect vehicle strikes fatal to insects. Insect mortality in general, and its effect on bees and butterflies in particular, was consistently lower when roads were bordered by woodlots than when they were bordered by lawn or meadows. Which roadside habitats were associated with the highest insect mortality depended on the taxon in question and the presence or absence of a vegetated median. Butterfly and dragonfly mortality was highest on roads with meadow medians, while bee mortality was highest on roadsides with lawn medians. Across most site comparisons, vegetated medians significantly elevated fatal insect-vehicle strikes. Regardless of the habitat bordering roadsides, insect mortality was unacceptably high for areas being considered for conservation. We suggest four research directions that may lead to reduced insect mortality in roadside habitats." **16843.** Kietzka, G.J.; Pryke, J.S.; Samways, M.J. (2018): Comparative effects of urban and agricultural land transformation on Odonata assemblages in a biodiversity hotspot. *Basic and Applied Ecology* 33: 89-98. (in English) ["Rivers of the Cape Floristic Region (CFR) biodiversity hotspot are threatened by land transformation. This region is a centre of endemism for many taxa, including Odonata. These insects are highly sensitive to changes in physical habitat structure, which makes them good bioindicators, and this led to the development of the Dragonfly Biotic Index (DBI). We investigated the effects of local agricultural and urban land transformations on Odonata species richness, assemblage composition and DBI scores in three CFR rivers. A total of 48 sites were selected and categorized as natural, agricultural or urban land use. Adult male Odonata and four environmental variables were rec-

orded over two seasons. Land transformation significantly influenced Odonata assemblage composition but did not always significantly reduce species richness. Average vegetation height also affected Odonata assemblage composition and decreased species richness. Agricultural and urban sites had Odonata assemblages differing from those in the natural areas. Agricultural and urban local land use types reduced opportunities for some endemic species but provided for the persistence and establishment of widespread, generalist species, as indicated by great changes in DBI scores. Mitigating the adverse influences of land transformation through establishment of protected areas is essential for the conservation of rare taxa, particularly in an area with a high number of endemic species." **16844.** Kim, M.J.; Jeong, S.Y.; Wang, A.R.; An, J.; Kim, I. (2018): Complete mitochondrial genome sequence of *Macromia daimoji* Okumura, 1949 (Odonata: Macromiidae). *Mitochondrial DNA Part B* 3(1): 365-367. (in English) ["*M. daimoji* has been listed as an Endangered insect in South Korea. We sequenced the complete 15,198 bp mitochondrial genome (mitogenome) of this organism, which is the first mitogenome sequence reported from the family Macromiidae. The genome includes a typical set of genes [13 protein-coding genes (PCGs), 2 rRNA genes, and 22 tRNA genes] and one non-coding region with an arrangement identical to that observed in most insect genomes. Phylogenetic analyses using concatenated sequences of the 13 PCGs and 2 rRNA genes using the Bayesian inference (BI) method placed Macromiidae, represented by *M. daimoji*, as a sister group to Libellulidae with the highest nodal support [Bayesian posterior probabilities (BPP)?=71]. Unlike conventional phylogenetic analysis, the suborders Anisozygoptera and Zygoptera formed a strong sister group (BPP =1), justifying the use of different molecular markers for phylogenetic analysis." (Authors) ] Address: Kim, I., Department of Applied Biology, College of Agriculture and Life Sciences, Chonnam National University, Gwangju, Republic of Korea;

**16845.** Kiyama, K.; Suda, D.; Handa, H. (2018): New record of *Ophiocordyceps odonatae* in Saitama Prefecture. *Bull. Saitama Mus. Nat. Hist. [N. S.]* 12: 29-32. (in Japanese, with English title). **16846.** Kiyoshi, T.; Katatani, N.; Hong, T.P. (2018): *Sundaeschna* gen. nov. with descriptions of two new species from Vietnam and Myanmar (Odonata, Anisoptera, Aeshnidae). *Bull. Natl. Mus. Nat. Sci., Ser. A*, 44(1): 1-9. (in English) ["*Sundaeschna* gen. nov. is proposed to accommodate two new species in the family Aeshnidae. One species, *S. cattienensis* sp. nov., is described from Dong Nai Province, Vietnam. Another species, *S. tanintharyiensis* sp. nov., is described from Tanintharyi Township, Myeik District, Tanintharyi Region, Myanmar. This new genus resembles the genus *Sarasaeschna* in the tribe Gomphaeschnini, but is easily distinguished by the structure of the fourth penile segment and by the pigmental

spots on the posterior margins of all wings. Both these new species are recorded from lowlands, in contrast with *Sarasaeschna*, whose members generally occur in mountainous regions. These two new species are easily distinguished from each other by the shape of the male epiproct." (Authors)] Address: Kiyoshi, T., Dept of Zoology, National Museum of Nature and Science, 4-1-1 Amakubo, Tsukuba, Ibaraki, 305-0005, Japan. E-mail: kiyoshi@kahaku.go.jp

**16847.** Klein, C.E.; Pinto, N.S.; Spigoloni, Z.V.A.; Bergamini, F.M.; de Melo, F.R.; De Marco, P.; Juen, L. (2018): The influence of small hydroelectric power plants on the richness and composition of Odonata species in the Brazilian Savanna. *International Journal of Odonatology* 21(1): 33-44. (in English) ["Regardless of the economic and social development that damming processes related to hydroelectric power plants bring to a region, they represent a wide range of disturbances to the physical, chemical, and biological characteristics of rivers. We evaluated the effects of dams on Odonata communities from the southeastern region of Goiás, Brazil. 13 streams connected to three dams were studied: seven were used as reference samples (located upstream from the damming site, therefore not directly affected by damming) and six were used as affected area samples (located downstream from the dam). A total of 1128 odonates from six families, 22 genera, and 39 species were captured and identified. The results showed that Odonata richness was affected by the presence of dams, with different effects on Anisoptera and Zygoptera suborders. We discuss that these effects are related mostly to the physical and chemical variables in waterbodies directly affected by small hydroelectric power plants (SHPs). It is possible that negative effects on the Odonata community in SHP areas are related to changes in waterflow, pH and turbidity." **16848.** Klop-Toker, K.; Valdez, J.; Stockwell, M. (2018): Community level impacts of invasive mosquitofish may exacerbate the impact to a threatened amphibian. *Austral Ecology* 43(2): 213-224. (in English) ["Invasive fish threaten many native freshwater fauna. However, it can be difficult to determine how invasive fish impact animals with complex life cycles as interaction may be driven by either predation of aquatic larvae or avoidance of fish-occupied waterbodies by the terrestrial adult stage. Mosquitofish (*Gambusia* spp.) are highly successful and aggressive invaders that negatively impact numerous aquatic fauna. One species potentially threatened by *Gambusia holbrooki* is the green and golden bell frog (*Litoria aurea*). However, *G. holbrooki*'s role in this frog's decline was unclear due to declines driven by the chytrid fungal disease and the continued co-existence of these fish and frogs in multiple locations. To clarify the extent to which *Gambusia* is impacting *L. aurea*, we conducted 3 years of field surveys across a deltaic wetland system in south-east Australia. We measured the presence and abundance of aquatic taxa including *G. holbrooki*, and *L. aurea* frogs and tadpoles, along with habitat parameters at the landscape and microhabitat scale. Generalized linear models were used to explore patterns in the abundance and distributions of *L. aurea* and *G. holbrooki*.

We found strong negative associations between *G. holbrooki* and tadpoles of most species, including *L. aurea*, but no apparent avoidance of *G. holbrooki* by adult frogs. Native invertebrate predators (Odonata and Coleoptera) were also absent from *G. holbrooki*-occupied ponds. Due to the apparent naivety of adult frogs toward *G. holbrooki*, the separation of *G. holbrooki* and tadpoles, plus the abundance of alternative predators in *G. holbrooki*-free ponds, we conclude that the impact of *G. holbrooki* on *L. aurea* recruitment is likely substantial and warrants management action." (Authors)] Address: Klop-Toker, K., Conservation Biology Research Group, University of Newcastle, C/O Michael Mahony, School of Environmental and Life Science, University of Newcastle, Callaghan, NSW, 2308 Australia. **16849.** Knight, K. (2018): Dragonfly haemolymph looks more like ancestors'. *Journal of Experimental Biology* 2018 221: jeb187112 doi: 10.1242/jeb.187112 Published 3 August 2018: 1. (in English) ["Observing metamorphosing tadpoles pull themselves from the water is a rite of passage shared by budding naturalists the world over. Yet, frogs are not the only animals to pass their early life stages immersed in water. Dragonflies spend the majority of their lives submerged before emerging as aerobic adults, trading in their water-breathing gills for trachea that deliver oxygen to every tissue in the body. However, Philip Matthews from the University of British Columbia (UBC), Canada, explains that the dragonflies and frogs have converged on the same aquatic lifestyle choice from different origins. Dragonfly larvae re-evolved the ability to breathe water from terrestrial ancestors, in contrast to amphibian tadpoles, which spent the whole of their evolutionary history immersed. And Matthews was puzzled; air-breathing animals carry high CO<sub>2</sub> concentrations in their body fluids, while water-breathing species have lower internal concentrations of CO<sub>2</sub> thanks to the high solubility of the gas in water. Would the body fluids of water-breathing dragonfly nymphs resemble those of their aerial ancestors or the species that they re-joined in water? Describing trapping dragonfly nymphs and adults on the UBC campus, Matthews says, 'For the adult dragonflies, you need to be fast', recalling how he, Master's student Dan Lee and undergraduate Raman Ubhi captured the adults with insect nets while the nymphs were easier to collect with dip nets from ponds. Back in the lab, Lee skilfully collected samples of haemolymph (the insect equivalent of blood) from the adults and nymphs at various stages of development, to measure the total amount of CO<sub>2</sub> – which can occur in several different forms – in the insects' bodies. 'We had to develop our own equipment to measure the CO<sub>2</sub> that was released from our tiny 5 µl haemolymph sample', says Matthews, remembering how Lee worked closely with a glass blower to build the bespoke system. In addition, Lee worked with Martin Gutbrod and Fernando Ferreras from PreSens, Germany, who had built a prototype CO<sub>2</sub> probe, to measure the partial pressure of the gas (the pressure exerted by the CO<sub>2</sub> molecules in a liquid) in the haemolymph of early dragonfly nymphs. However, Matthews needed convincing that the partial pressure readings were accurate, so Lee also measured the CO<sub>2</sub> partial pressure of crayfish haemolymph. 'This gave us confidence in the values we recorded in dragonfly nymphs', says Matthews,

as he could compare the new crayfish measurements with values in the literature. Despite their aquatic lifestyle, which should have resulted in low CO<sub>2</sub> levels, the total CO<sub>2</sub> concentration in the haemolymph of the dragonfly nymphs was three times higher than that of crayfish and rainbow trout. 'When we saw this, we were very excited', says Matthews, adding, 'This suggests that they aren't expelling CO<sub>2</sub> as easily as one would expect while breathing water'. And when Lee compared how the dragonflies' total CO<sub>2</sub> levels changed as the insects prepared to depart the water, the total CO<sub>2</sub> levels increased to approach those experienced by the air-breathing adults: '[which] suggests that they might be preparing to become air breathers (or becoming poorer water breathers) during their final instar', says Matthews. So, water-breathing dragonfly nymphs have relatively high levels of CO<sub>2</sub> in their bodies compared with those of other water-breathing creatures, with the consequence that the transition that they undergo – to high total CO<sub>2</sub> levels – as they shift to an aerial lifestyle is less dramatic than it is for emerging tadpoles. And Matthews is eager to find out why aquatic dragonfly nymphs differ so much from other aquatic residents. 'There's so much more to do', he says." **16850.** Kohli, M.K.; Sahlén, G.; Kuhn, W.R.; Ware, J.L. (2018): Extremely low genetic diversity in a circumpolar dragonfly species, *Somatochlora sahlbergi* (Insecta: Odonata: Anisoptera). *Scientific Reports* 8:15114 | DOI:10.1038/s41598-018-32365-7: 10 pp. (in English) ["We present the first empirical treatment of the northernmost breeding dragonfly, *S. sahlbergi*. We sequenced populations from United States, Canada, Finland, Sweden and Norway for cytochrome oxidase I (COI) and D2 region of 28s. We found that, despite geographic barriers across its vast arctic range, *S. sahlbergi* is a single species. Not only does it appear to interbreed across its entire range, there also seems to be almost no variation among European and North American populations in their COI gene fragment (the barcode gene), which is usually extremely variable. We further found that characters thought to be diagnostic for the larvae of *S. sahlbergi* were absent in our European samples. We review and re-describe the habitat of this species based on new findings from recent field observations. Finally, we report for the first time the likely presence of this species in Japan. We hope our findings will encourage further study of this species and other under-studied insect taxa that inhabit the remote Arctic." **16853.** Kopij, G. (2018): Diet of sympatrically breeding Southern Carmine Bee-eater *Merops nubicoides* and White-fronted Bee-eater *Merops bullockoides*. *Ostrich* 89(2): 191-194. (in English, with French summary) ["*M. nubicoides* and *M. bullockoides* are insectivore, cavity-nesting bird species, both of which occur in the Zambezi Region, north-eastern Namibia. I examined there the diet composition of these species by an analysis of prey remnants. The Southern Carmine Bee-eater chick's diet consisted of exclusively insects, represented by seven orders. The most numerous were orthopterans and beetles (40.9% and 26.1%, respectively; n = 582 prey items). Hymenopterans (18.7%) and bugs (12.9%) supplemented the diet, whereas dragonflies (Odonata) and moths (Lepidoptera) were preyed only occasionally. In the diet of the White-fronted Bee-eater, nesting at the same site, beetles were the most important prey (81.2% of all 101 prey items identified), with scarabaeids comprising more than half of the beetle diet. In comparison with the White-fronted Bee-eater, a lower proportion of beetles, but much larger proportion of orthopterans were recorded in the diet of the Southern Carmine Bee-eater. In both bee-eater species, hymenopterans appear to be less important than was expected. The essential difference in the proportion of main prey groups recorded in Southern Carmine and White-fronted Bee-eaters breeding at the same site may represent a shift in food niche due to both temporal segregation in breeding, and differences in food preferences (feeding sites)." (Authors)] Address: Kopij, G., Dept of Integrated Environmental Sciences, Ogongo Campus, University of Namibia, Oshakati, Namibia. E-mail: gkopij@unam.na

**16854.** Korbaa, M.; Ferreras-Romero, M.; Ruiz-García, A.; Boumaiza, M. (2018): TSOI - a new index based on Odonata populations to assess the conservation relevance of water-courses in Tunisia. *Odonatologica* 47(1/2): 43-72. (in English) ["Global ecological conditions existing in the streams of north-

em Tunisia are very unequal. In consideration of their appropriate management and restoration requirements, breeding populations of 28 Odonata species were studied over an annual cycle in twentyeight watercourses (22 permanent, 6 intermittent). In total, 7 363 larvae and 337 exuviae were collected. We developed a new indicator, the Tunisian Stream Odonatological Index (TSOI), to assess conservation aspects of Odonata biodiversity in African Mediterranean streams by analysing dragonfly communities. The TSOI operates at the species level. Taxonomic richness, voltinism, endemism, relative taxonomic distinctiveness, and regional conservation status (IUCN) are elements taken into account to design this index. Accordingly, presence of both Maghreb endemic and semivoltine species (*Calopteryx exul*, *Platynemis subdilatata*, *Aeshna cyanea*, *Boyeria irene*, *Gomphus lucasii*, *Onychogomphus costae*, *O. forcipatus*, and *O. uncatus*) may provide useful information about the refuge quality of each habitat type for species with different biological features, and their interest level from a conservation point of view. The results of a first application of this approach are presented in the paper as well. As far as we know, a biodiversity conservation index based on benthic invertebrates in the African Mediterranean area has never before been proposed nor used." (Authors)] Address: Korbaa, M., Unit of Hydrobiology, Laboratory of Environment Biomonitoring, Faculty of Sciences of Bizerte, 7021, Jarzouna, Tunisia. E-mail: manelkorbaa@yahoo.fr

**16855.** Kosterin, O.E. (2018): Rediscovery of *Lestes nigriceps* Fraser, 1924 (Odonata: Lestidae) in eastern Cambodia. *Zootaxa* 4526(4): 561-575. (in English) ["*L. nigriceps* was described from a male (later the lectotype) and two non-con-specific females collected in 1922 at Pusa, Bihar State, India, and has never been reported since. In June 2018 a population of *L. nigriceps* was unexpectedly found in eastern Cambodia, Mondulhiri Province. The Cambodian males, their variation and, for the first time, the true female of *L. nigriceps* is described." (Author)] Address: Kosterin, O.E., Institute of Cytology & Genetics SB RAS, Acad. **16864.** Kumar, D.; Kamath, G.M.; Mohite, P.M.; Kamle, S. (2018): Realization and dynamic studies of CNTs-PDMS

membranes for biomimetic flapping wing applications. *Mechanics of Biological Systems & Micro- and Nanomechanics* 4: 35-37. (in English) ["Aerial and aquatic animals including bats, insects and fish use their wings/fins to generate propulsive forces. Natural fliers deform their wings, actively and/or passively, in bending and twisting modes to generate lift and thrust. Within a flapping cycle, wing skin interacts with surrounding fluid and transfers dynamic loads to the internal stiffening structure. Biomimicking of such complex natural flapping wings is possible if the development involves both materials and structural aspects. In the present study, thin PDMS films are chosen for developing the skin of the biomimetic flapping wings. The films are first characterized for dynamic mechanical properties (storage modulus, loss modulus and loss factor) using a dynamic mechanical analyzer. The tests are done in frequency and strain sweep modes to analyze the effect of strain-rates and strain-amplitudes on the dynamic mechanical properties and generate experimental data for constitutive modeling. The dragonfly and cicada wings are taken as the bioinspiration for developing the biomimetic wings. The fabrication of wing skeletons and their integration with the PDMS membranes are achieved through advanced manufacturing techniques including laser micromachining, photolithography and casting. Two types of composite materials are used for making the wing skeletons, i.e., carbon nanotubes (CNTs)/polypropylene (PP) nanocomposite sheet for cicada inspired wing and carbon fiber/epoxy composite strands for dragonfly inspired wing. Structural dynamic analysis of such light, flexible and small size biomimetic structures are interesting and useful for evaluation of biomimicking performance of used materials and manufacturing methods, but difficult to perform. A real-time high-speed non-contact dynamic testing method based on DIC-FPGA coupling (3D digital image correlation technique coupled with real-time data acquisition system, developed at our lab) is used for determining the natural frequencies and corresponding mode shapes of fabricated wings. Structural dynamic analysis of such light, flexible and hyperviscoelastic structures are interesting and useful but difficult to perform. A high-speed non-contact dynamic testing method based on DIC-FPGA coupling (3D-DIC technique coupled with real-time data acquisition system, developed at our lab) will be used for determining natural frequencies, mode shapes and loss factors of the membranes. Similar studies will also be carried out computationally using Abaqus and validated with the experimental results. The experimental measurements will be performed inside a vacuum chamber to observe the effect of air and compare with computational results. Quasi-static and dynamic mechanical testing of PDMS films will be performed to do hyperelastic and viscoelastic constitutive modelling for FE simulations. The computational study will also be used to design the biomimetic wing structures with internal stiffening structure. The membranes will be reinforced with carbon nanotubes (CNTs) based nanocomposites skeletons and tested for structural dynamic characteristics. This will be done to achieve coupled bending and twisting fundamental mode shape for a wing tested in cantilever form, which is useful to maximize efficiency and generate both lift and thrust. PDMS wings will be developed with different wing skeletons and tested for performing optimization exercise towards the

biomimicking goal. Integration of membrane and nanocomposite skeletons will be achieved through advanced manufacturing techniques including laser micromachining and photolithography. The piezoelectric properties of CNTs could potentially be exploited for sensing and control for morphing and flapping wing applications." **16865.** Kumar, P.; Sharma, S.; Barman, J. (2018): Habitat preference of odonates (dragonfly and damselfly) along with its diversity, abundance, and richness in Madan Kamdev Temple area (Dewangiri Hill of Kamrup (R) district, Assam, India. *International Journal of Plant, Animal and Environmental Sciences* 8(3): 8-18. (in English) ["The present study was piloted at Madan Kamdev Temple area of the Kamrup (R) district, Assam during December 2017 to May 2018. A total of 32 species of Odonata including 19 species of Anisoptera and 13 species of Zygoptera under 2 families were recorded. 12 species were documented from zone 1 (forest area), 31 species were documented from zone 2 (river bank) and 20 species were from zone 3 (crop fields). 11 species were common in all the zones. The most abundant Anisopteran species was *Pantala flavescens* and most abundant Zygopteran species was *Ceriatrigon coromandelianum*. Shannon Weiner Index (H') was estimated to be 2.644, in forest it was 2.126, near river 2.649 and in crop field it was 2.366. Margalef's Richness Index (DMg) was found to be 4.705, in forest it was 2.456; in near river 4.898 and in crop field it was 3.654. In the present study 4 species i.e. *Crocothemis servilia*, *Neurothemis fulvia*, *Orthetrum sabina* and *Ceriatrigon coromandelianum* used all types of habitat. Maximum number of species and individuals of Odonates were recorded during the mid-day time when temperature is high." **16866.** Kuncce, W. (2018): Sub-lethal effects of anthropogenic contaminants on aquatic invertebrates. *Digital Comprehensive Summaries of Uppsala Dissertations from the Faculty of Science and Technology* 1692. Uppsala: Acta Universitatis Upsaliensis. ISBN 978-91-513-0382-6.: 70 pp. (in English) ["Anthropogenic contaminants are considered to play a substantial role in the decline of freshwater invertebrate diversity. Sub-lethal effects of many of these contaminants on behaviour and life history traits of aquatic invertebrates may contribute to their decline. As contaminants are rarely present in the environment alone, the effects of mixture exposures are highly relevant in assessing the risk these substances pose to the biota. This thesis focuses on sub-lethal effects of exposure to aquatic pollutants, separately and in combination, on fresh-water invertebrates. To investigate the single and combined effects of pesticides, larvae of the midge, *Chironomus riparius* were exposed to a 1 hour pulse of two neonicotinoids and two pyrethroids. This short exposure to environmentally relevant concentrations of pesticides decreased the survival and delayed development in *C. riparius*. The combination of neonicotinoids and pyrethroids did not produce synergistic effects; however, there was some

indication of antagonism. Additionally, larvae of the damselfly, *Coenagrion puella*, were exposed for 14 hours to two environmentally relevant concentrations of pyrethroid pesticides, alone and in combination. Exposure to the pyrethroid, deltamethrin, reduced the larvae's predatory ability. Combined exposure to both deltamethrin and esfenvalerate inhibited the Glutathione S-transferase detoxification pathway and may have additive toxic effects on the larvae's predatory ability. Microplastics are increasingly gaining attention as an aquatic pollutant of major concern with respect to the toxicity of the microplastics themselves as well as their capacity to adsorb persistent organic pollutants like pesticides. To investigate the effects of microplastics and a pyrethroid, alone and in combination, *C. riparius* larvae were raised in sediment spiked with two sizes of polystyrenebased latex microbeads and an environmentally relevant concentration of esfenvalerate under normal and food-restricted conditions. Exposure to both sizes of microplastics and esfenvalerate lead to equally decreased emergence under food-restricted conditions. Additionally, exposure to esfenvalerate led to decreases in survival when food was scarce that did not occur when microplastics were co-present. Antihistamines are also an emerging aquatic contaminant of concern with very little known about their biological effects on aquatic wildlife. Antihistamines could potentially interfere with the histaminergic pathways and thus affect thermal tolerance and temperature preference in aquatic invertebrates. The freshwater snail, *Planorbis corneus*, was exposed for 24 hours to the antihistamine, diphenhydramine. This exposure increased thermal tolerance and righting time, but did not affect temperature preference. The results of the investigation suggest that anthropogenic contaminants alone and/or in combination have sub-lethal effects on life history, behavior and physiology of aquatic invertebrates. Such sublethal effects have the potential to affect populations and community structure in the aquatic and terrestrial environment." (in English) ["Evidence for the adaptive value of oviposition site selection in terms of increased offspring fitness is rare in predatory insects. We tested this in *Lestes macrostigma* that prefers the plant *Bolboschoenus maritimus*. We carried out two experiments with shoots containing eggs: we flooded (1) some shoots of the same type (i.e. combination of species and desiccation state) at different dates and (2) different shoot types at the same date. Earlier flooding increased hatching success. Because *B. maritimus* grows in deeper parts of temporary ponds, it is flooded before other plants after the drought season, suggesting that adult oviposition site selection is driven by lower egg desiccation risk. Independently of flooding date, hatching success was higher and larvae hatched earlier when eggs were laid in *B. maritimus*. Faster embryonic development enhances chances to complete larval development before pond desiccation and reduces costs associated with time stress. Offspring higher fitness was more constant between shoots of *B. maritimus* compared to the other types of shoot, suggesting that laying eggs in one shoot of this plant leads offspring to high fitness more surely. Our results indicate that adults choose oviposition plants maximizing offspring fitness (higher hatching success and faster embryonic development)."] (Authors)] Address: Lambret, P., Tour du Valat, Res. (2018): Dragonfly (Odonata: Corduliidae, Macromiidae, Gomphidae, Aeshnidae) and damselfly (Odonata: Calopterygidae) exuviae observed at record heights in *Pinus strobus* and *Picea abies* canopies. *The Great Lakes Entomologist* 51(1): 26-29. (in English) ["Most odonate species do not typically climb higher than 50 cm when choosing an emergence support. We observed multiple species of odonate nymphs using trees as emergence supports at heights greater than 50 cm and up to 4, 6.9, and 14.6 m for *Calopteryx maculata*, *Somatochlora*, and *Didymops transversa*, respectively. These heights represent the greatest heights ever documented for odonate nymph emergence supports. Our research suggests that some species (*S. minor*; *D. transversa*) appear to have a greater affinity for climbing to great heights during emergence than others (*Dromogomphus spinosus*; *Basiaeschna janata*; *Macromia illinoensis*. Odonate nymphs appeared to have a strong preference for emergence sites at the underside or base of branches. Researchers have hypothesized that competition for emergence sites drives climbing to such great heights. We propose three alternative hypotheses that could potentially explain these unique behaviors."] (Authors)] Address: Laughlin, M.M., Northland College, USA: E-mail: laughm986@myemail.northland.edu
- 16871.** Lee, D.J.; Gutbrod, M.; Ferreras, F.M.; Matthews, P.G. D. (2018): Changes in hemolymph total CO<sub>2</sub> content during the water-to-air respiratory transition of amphibiotic dragonflies. *Journal of Experimental Biology* 2018: jeb.181438 doi: 10.1242/jeb.181438: 9 pp. (in English) ["Anisoptera are amphibiotic; the nymph is aquatic and breathes water using a rectal gill before transitioning to the winged adult that breathes air through spiracles. While the evolutionary and developmental transition from water- to air-breathing is known to be associated with a dramatic rise in internal CO<sub>2</sub> levels, the changes in blood-gas composition experienced by amphibiotic insects, which represent an ancestral air-to-water transition, are unknown. This study measured total CO<sub>2</sub> (TCO<sub>2</sub>) in hemolymph collected from aquatic nymphs and air-breathing adults of *Anax junius*, *Aeshna multicolor* (Aeshnidae), *Libellula quadrimaculata*, and *L. forensis* (Libellulidae). Hemolymph PCO<sub>2</sub> was also measured in vivo in both Aeshnid nymphs and marbled crayfish (*Procambarus fallax* f. *virginalis*) using a novel fiber-optic CO<sub>2</sub> sensor. The hemolymph TCO<sub>2</sub> of the pre- and early-final instar nymphs was found to be significantly lower than that of the air-breathing adults. However, the TCO<sub>2</sub> of the late-final instar Aeshnid nymphs was not significantly different from the air-breathing adult, despite the late-final nymph still breathing water. TCO<sub>2</sub> and PCO<sub>2</sub> were also significantly higher in the hemolymph of early-final Aeshnid nymphs compared to the water-breathing crayfish. Thus, while dragonfly nymphs show an increase in internal CO<sub>2</sub> as they transition from water to air, from an evolutionary standpoint, the nymph's ability to breathe water is associated with a comparatively minor decrease in hemolymph TCO<sub>2</sub> relative to the air-breathing adult.] Address: Lee, D.J., Dept of Zoology, Univ. of British Columbia, Vancouver, BC, V6T 1Z4, Canada. (2018): Distribution patterns of odonate assemblages in relation to environmental variables in streams of South Korea. *Insects* 2018, 9(4), 152; <https://doi.org/10.3390/insects9040152>: 14 pp. (in English) ["Odonata species are sensitive to environmental changes, particularly those caused by humans, and provide valuable ecosystem services as intermediate predators in

food webs. We aimed: (i) to investigate the distribution patterns of Odonata in streams on a nationwide scale across South Korea; (ii) to evaluate the relationships between the distribution patterns of odonates and their environmental conditions; and (iii) to identify indicator species and the most significant environmental factors affecting their distributions. Samples were collected from 965 sampling sites in streams across South Korea. We also measured 34 environmental variables grouped into six categories: geography, meteorology, land use, substrate composition, hydrology, and physicochemistry. A total of 83 taxa belonging to 10 families of Odonata were recorded in the dataset. Among them, eight species displayed high abundances and incidences. Self-organizing map (SOM) classified sampling sites into seven clusters (A–G) which could be divided into two distinct groups (A–C and D–G) according to the similarities of their odonate assemblages. Clusters A–C were characterized by members of the suborder Anisoptera, whereas clusters D–G were characterized by the suborder Zygoptera. Non-metric multidimensional scaling (NMDS) identified forest (%), altitude, and cobble (%) in substrata as the most influential environmental factors determining odonate assemblage compositions. Our results emphasize the importance of habitat heterogeneity by demonstrating its effect on odonate assemblages." **16875.** Lesch, V.; Bouwman, H. (2018): Adult dragonflies are indicators of environmental metallic elements. *Chemosphere* 209: 654-665. (in English) ["Highlights: • 115 Adult dragonflies from 21 sites in South Africa analysed for metallic elements. • Species and sizes had no influence on concentrations, but habitat type did. • Mining was associated with higher concentrations of As and Pb at some sites. • Geographic distributions of concentrations indicated possible pollution sources. • Dragonflies would be good indicators of metallic elements. Abstract: Adult dragonflies (Insecta; Odonata) are aerial predatory arthropods that occur globally except in the polar regions. However, we know of no research on adult dragonflies as potential indicators of metallic elements in the environment or metallic element concentrations and relative contribution patterns between sites, species, size classes, habitat types, and relation to possible pollution sources. There is also no information available about adult dragonflies and their responses to toxic metals. However, metallic elements are toxic in elevated concentrations to all organisms. We predict that adult dragonflies would be suitable indicators of elemental concentrations. We analysed 105 adult male dragonflies from 21 sites in South Africa for 33 metallic elements including Hg, As, Pb, Cr, Cu, Cd, Ni, Se, Al, and Au. The results indicated that all species of dragonflies, regardless of body size, are suitable indicators. Furthermore, different aquatic habitat types did not affect the metallic element concentrations at the scale of this study. Dragonflies collected near wastewater treatment plants showed concentrations of certain elements such as Au higher than from elsewhere. Elements such as As and Pb were found at elevated concentrations (relative to the other sites) in dragonflies collected near mines. Dragonflies from sampling sites near potential pollution sources, but had seemingly isolated water sources, showed lower metallic element concentrations when compared with other sites. We conclude that adult dragonflies would be good indicators of environmental metallic elements." (2018): Experimental and numerical investigation on dragonfly wing and body motion during voluntary take-off. *Scientific Reports* 8, Article number: 1011 (2018): 16 pp. (in English) ["We present a detailed analysis of the voluntary take-off procedure of a dragonfly. The motions of the body and wings are recorded using two high-speed cameras at Beihang University. The experimental results show that the dragonfly becomes airborne after approximately one wingbeat and then leaves the ground. During this process, the maximum vertical acceleration could reach  $20\text{m/s}^2$ . Evidence also shows that acceleration is generated only by the aerodynamic force induced by the flapping of wings. The dragonfly voluntary take-off procedure is divided into four phases with distinctive features. The variation in phase difference between the forewing and hindwing and angle of attack in the downstroke are calculated to explain the different features of the four phases. In terms of the key parameters of flapping, the phase difference increases from approximately 0 to 110 degrees; the angle of attack in down-stroke reaches the maximum at first and then decreases in the following take-off procedure. Due to experimental limitations, 2-D simulations are conducted using the immersed boundary method. The results indicate that the phase difference and the angle of attack are highly correlated with the unsteady fluid field around the dragonfly's wings and body, which determines the generation of aerodynamic forces." **16880.** Luck, J.C. (2018): Discovery of new populations of *Libellula fulva* Muller (Scarce Chaser) in East Sussex. *J. Br. Dragonfly Society* 34(2): 61-78. (in English) ["Although *Libellula fulva*, Scarce Chaser, is known to have established populations on the two main West Sussex rivers the Arun and the Adur, it was thought to be absent in East Sussex. With sightings on both the Cuckmere and Ouse rivers in 2006, it was decided to conduct surveys on both rivers to establish the extent of the populations. This was carried out by the author for the first three years and, for the following three years, with the assistance of a team of helpers. *Libellula fulva* was shown to be present on the Cuckmere River from the White Horse (TQ514007) upstream to Michelham Priory (TQ565099), and on the River Ouse from Hamsey Weir (TQ415127) upstream to Sutton Hall Weir (TQ440187), as well as on some of the tributaries of the River Ouse. Whereas, uniquely, the abdomen of a male *L. fulva* displays clear evidence of mating, it does not, of course, reveal the location. To resolve this, various methods were deployed using larval survey, exuviae search and field observations. It was determined that the species has a preference for breeding in slow moving or still areas of water. This held true even where the male may be holding territory

on faster, moving stretches of river. Copulation was observed on several occasions, supporting this theory, but rarely observed ovipositing was only seen on one occasion." (Author)] Address: Luck, J.C., 4 Mill View, Ringmer, Lewes, East Sussex, BN8 5EP, UK

Soc. Linn. Bordeaux* 153, nouv. série n° 46(2-4): 341-358. (in French, with English summary) ["Presentation of biological indicators of the effects of climate change on biodiversity in the New Aquitaine region (South West, France): the climate sentinel species: Understanding the local effects of climate change on biodiversity is essential to guide environmental and management policies for natural areas. The lack of knowledge at the regional level has led to the development of a research program "Climate sentinels". The main hypothesis of the program is that effects on biodiversity are particularly detectable in species that have low movement abilities. These "climate sentinel" species would be the first to respond to local climatic variations by adaptation or local extinction. From the territory of New Aquitaine (France), 20 biological indicators of climate change in different ecosystems (dune, dry, wet, mountain and forest) were chosen: plants communities of ecosystems, insects (butterflies, dragonflies, bumblebees), amphibians (*Rana pyrenaica*, *Hyla molleri*, *H. arborea*), reptiles (*Iberolacerta bonnali*, *Timon lepidus*, *Zootoca vivipara*, *Emys orbicularis*, *Vipera berus*) and mammals (*Marmota marmota*, micromammals). This paper presents the method of development of these indicators and the research hypotheses associated with climate sentinel species." **16885.** Marthelot, J.; Dupuis, T.; Brun, P.-T. (2018): K57.00011: Dragonfly-inspired deployable structures: how to inflate and stay flat? *Bulletin of the American Physical Society, APS March Meeting 2019, Monday–Friday, March 4–8, 2019; Boston, Massachusetts, Session K57: The Extreme Mechanics of Balloons, 8:00 AM–11:00 AM, Wednesday, March 6, 2019: (in English) [Verbatim: Programming the final shape of a soft inflatable structure is a nontrivial challenge. Such a task is routinely accomplished in nature, for example when the wing of an emerging dragonfly deploys over just a couple of minutes. This expansion is guided by a network of veins where hemolymph is injected and subsequently solidifies to generate rigidity. Inspired by dragonflies, we build a model experiment to investigate inflatable deployable structures composed of a tubular network of the veins. We first mimic differential growth to fabricate wrinkled tubular structures. They comprise a soft annular core surmounted by a stiffer and thinner annulus prepared so as to yield a wrinkling instability. We then study the mechanical response of a single wrinkled tubular structure under pressure. We then characterize the in-plane expansion of the structure and study its correlation to the network geometry and the pressure applied to the system. A systematic variation of the geometric and elastic parameters allows us to search for optimal design and operational conditions for a maximal extension while minimizing the input pressure.] Address: not stated.*

**16888.** Martin, A.E.; Graham, S.L.; Henry, M.; Pervin, E.; Fahrig, L. (2018): Flying insect abundance declines with increasing road traffic. *Insect Conservation and Diversity* 11(6): 608-613. (in English) ["1. One potentially important but underappreciated threat to insects is road mortality. Road kill studies clearly show that insects are killed on roads, leading to the hypothesis that road mortality causes declines in local insect population sizes. 2. In this study we used custom-made sticky traps attached to a vehicle to target diurnal flying insects that interact with roads, sampling along 10 high-traffic and 10 low-traffic rural roads in south-eastern Ontario, Canada. We used a paired sampling design to control for potentially confounding differences in the road characteristics (e.g. road width) and surrounding land covers (e.g. housing density) between high-traffic and low-traffic roads. We then used these data to test the prediction that fewer flying insects collide with vehicles, per vehicle (i.e. insect abundance is lower), on high-traffic than low-traffic roads. 3. We found significantly fewer insects at the high-traffic roads than at the low-traffic roads as predicted. There was a 23.5% decline in the number of insects/km/vehicle on high-traffic relative to low-traffic roads. 4. Given the high rates of insect mortality observed in previous studies, it is likely that road mortality contributes to these observed negative effects of traffic intensity. Thus the growing global road network is a concern for conservationists and land managers, not only because insect population declines contribute to the ongoing global losses of biodiversity but also because insects play a vital role in food webs and provide important ecosystem services." **16889.** McCauley, S.J.; Hammond, J.I.; Mabry, K.E. (2018): Simulated climate change increases larval mortality, alters phenology, and affects flight morphology of a dragonfly. *Ecosphere* 9(3): 14 pp. (in English) ["For organisms with complex life cycles, climate change can have both direct effects and indirect effects that are mediated through plastic responses to

temperature and that carry over beyond the developmental environment. We examined multiple responses to environmental warming in a dragonfly, a species whose life history bridges aquatic and terrestrial environments. We tested larval survival under warming and whether warmer conditions can create carry-over effects between life history stages. Rearing dragonfly larvae in an experimental warming array to simulate increases in temperature, we contrasted the effects of the current thermal environment with temperatures +2.5° and +5°C above ambient, temperatures predicted for 50 and 100 yr in the future for the study region. Aquatic mesocosms were stocked with dragonfly larvae (*Erythemis collocata*), and we followed survival of larvae to adult emergence. We also measured the effects of warming on the timing of the life history transition to the adult stage, body size of adults, and the relative size of their wings, an aspect of morphology key to flight performance. There was a trend toward reduced larval survival with increasing temperature. Warming strongly affected the phenology of adult emergence, advancing emergence by up to a month compared with ambient conditions. Additionally, our warmest conditions increased variation in the timing of adult emergence compared with cooler conditions. The increased variation with warming arose from an extended emergence season with fewer individuals emerging at any one time. Altered emergence patterns such as we observed are likely to place individuals emerging outside the typical season at greater risk from early and late season storms and will reduce effective population sizes during the breeding season. Contrary to expectations for ectotherms, body size was unaffected by warming. However, morphology was affected: at +5°C, dragonflies emerging from mesocosms had relatively smaller wings. This provides some of the first evidence that the effects of climate change on animals during their growth can have carry-over effects in morphology that will affect performance of later life history stages. In dragonflies, relatively smaller wings are associated with reduced flight performance, creating a link between larval thermal conditions and adult dispersal capacity." - 16891.** Medina, M.N.D.; Cabras, A.A. (2018): Assessment of Odonata and Lepidoptera fauna of the University of Mindanao Matina, Davao City, Philippines. *Univ. of Min. Intl. Mult. Disc. Res. Jour.* 3(1): 6 pp. (in English) ["Under the umbrella of the "Biodiversity assessment of the University of Mindanao (UM), Matina Campus" a rapid assessment of Odonata and Lepidoptera fauna was conducted between October 2016 and November, 2017. Opportunistic sampling and photo-documentation was conducted in three sampling areas: grassland, mini forest, and open landscapes near the college buildings. Nine species of Odonata were documented where the miniforest has the highest species richness and open landscapes near the buildings have the poorest. One Philippine endemic Odonata species *Ceriagrion lieftincki* was found inhabiting the fluvial systems near the grassland. At present, this endemic species is considered least concern with stable population in the wild. ... The minimal number of Odonata and Lepidoptera within the campus can be attributed to its severely disturbed fluvial systems limiting the survival of endemic species paving the way to more tolerant oriental species. The low species richness of Lepidoptera can be attributed to the low diversity of angiosperms in the campus serving as their host and food plants. The present microhabitat within UM Matina campus is not suitable haven for endemics." (Authors)] Address: Medina, M.N.D., Research and Publication Center, Univ. of Mindanao, Davao City Philippines. - 16892.** Mendes, T.P.; Luiza-Andrade, A.; Cabette, H.S.R.; Juen, L. (2018): How does environmental variation affect the distribution of dragonfly larvae (Odonata) in the Amazon-Cerrado transition zone in Central Brazil? *Neotropical Entomology* 47(1): 37-45. (in English) ["This study investigated the effects of environmental variation on assemblages of dragonfly larvae (Odonata). We hypothesize that there is a significant correlation between species richness, species composition, and abundance of Odonata individuals, and habitat integrity and abiotic variables. To test this hypothesis, we sampled odonate larvae at 12 streams in the Suiá-Miçú River basin in Mato Grosso, Brazil, during three different periods of the year. Local physical and chemical variables (temperature, pH, turbidity, electrical conductivity (EC), dissolved oxygen (DO), total dissolved solids (TDS), and oxidation reduction potential (ORP)) were measured at each site using a multi-parameter probe, and integrity was assessed using the Habitat Integrity Index (HII). The variation in richness, abundance, and composition of Odonata species was related to the environmental variables analyzed, primarily by the abiotic factors pH, electrical conductivity, dissolved oxygen, total dissolved solids, and oxidation reduction potential. Our hypothesis was corroborated for the suborder Anisoptera, which showed a significant relationship with these variables, whereas Zygoptera was only related to pH. Our results show the importance of physical and chemical conditions in ecological studies using Odonata larvae as tools for the management and conservation of freshwater ecosystems." - 16893.** Menon, V. (2018): Dynamical modelling for a dragonfly Micro Aerial Vehicle. M.Sc. thesis, University of Toronto Institute for Aerospace Studies: XI, 117 pp. (in English) ["Researchers are developing ever smaller aircraft called Micro Aerial Vehicles (MAVs). The Space Robotics Group has joined the field by developing a dragonfly-inspired MAV. This thesis presents two contributions to this project. The first is the development of a dynamical model of the internal MAV components to be used for tuning design parameters and as a future plant model. This model is derived using the Lagrangian method and differs from others because it accounts for the internal dynamics of the system. The second contribution of this thesis is an estimation algorithm that can be used to determine prototype performance and verify the dynamical model from the first part. Based on the Gauss-Newton Batch Estimator, this algorithm uses a single camera and known points of interest on the wing to estimate the wing kinematic angles. Unlike other single-camera methods, this method is probabilistically based rather than being geometric." (Authors)] Address: not stated

**16900.** Mitchell, W. (2018): Seasonality of odonate-mediated methylmercury flux. Honors thesis, Dept of Biology, Texas Christian Univ., Fort Worth, Texas: 13 pp. (in English) ["Methylmercury (MeHg) is an aquatic contaminant that can be transferred to terrestrial predators by emergent aquatic insects such as odonates. We observed the effects of season on odonate-mediated MeHg flux (calculated as emergent odonate biomass × MeHg concentration) in 20 experimental ponds and the potential risk to nestling Red-winged Blackbirds (*Agelaius phoeniceus*) posed by consuming MeHg-contaminated odonates. Emergent odonates were collected weekly from ponds using emergence platforms from February to October 2017. The MeHg flux from damselflies, aeshnids, and libellulids began in March and peaked in May, June, and July, respectively, and then declined throughout the rest of the summer. Nesting of Red-winged Blackbirds overlapped with peak odonate emergence and odonate-mediated MeHg flux, suggesting that MeHg-contaminated odonates may pose a health risk to nestling Red-winged Blackbirds." **16906.** Moore, M.P.; Lis, C.; Martin, R.A. (2018): Immune deployment increases larval vulnerability to predators and inhibits adult life-history traits in a dragonfly. *Evolutionary Biology* 31(9): 1365-1376. (in English) ["While deploying immune defenses early in ontogeny can trade-off with the production and maintenance of other important traits across the entire life cycle, it remains largely unexplored how features of the environment shape the magnitude or presence of these lifetime costs. Greater predation risk during the juvenile stage may particularly influence such costs by 1) magnifying the survival costs that arise from any handicap of juvenile avoidance traits and/or 2) intensifying allocation trade-offs with important adult traits. Here, we tested for predator-dependent costs of immune deployment within and across life stages using the dragonfly, *Pachydiplax longipennis*. We first examined how larval immune deployment affected two traits associated with larval vulnerability to predators: escape distance and foraging under predation risk. Larvae that were induced to mount an immune response had shorter escape distances but lower foraging activity in the presence of predator cues. We also induced immune responses in larvae and reared them through emergence in mesocosms that differed in the presence of large predatory dragonfly larvae (*Aeshnidae* spp.). Immune-challenged larvae had later emergence overall and lower survival in pools with predators. Immune-challenged males were also smaller at emergence and developed less sexually selected melanin wing coloration, but these effects were independent of predator treatment. Overall, these results highlight how mounting an immune defense early in ontogeny can have substantial ecological and physiological costs that manifest both within and across life stages." (Authors)] Address: Moore, P.M., Dept of Biology, Case Western Reserve Univ., Cleveland, Ohio, USA. E-mail: mpm116@case.edu

**16907.** Moore, P.M.; Lis, C.; Martin, R.A. (2018): Larval body condition regulates predator-induced life-history variation in a dragonfly. *Ecology* 99(1): 224-230. (in English) ["Organisms with complex life cycles commonly exhibit adaptive plasticity in the timing of transitions between life stages. While the threat of predation is predicted to induce earlier transitions, empirical support has been equivocal. When predation risk affects both the propensity to transition to the next life stage and the ability to reach the energetic thresholds necessary to complete the transition, only those individuals in the best physiological condition may be able to accelerate development and emerge earlier. To test this hypothesis, we followed uniquely marked dragonfly larvae (*Pachydiplax longipennis*) through emergence in pools where we factorially manipulated the presence of a large heterospecific predator (*Anax junius*) and cannibalism risk via conspecific size variation. Consistent with our hypothesis, high-condition larvae were more likely to emerge in the presence of the heterospecific predator than in its absence, and low-condition larvae were more likely to emerge in its absence than in its presence. Moreover, high-condition larvae emerged earlier when cannibalism risk was high than when it was low. Predation risk therefore has condition-dependent effects on emergence. As predation risk frequently affects resource accumulation, similar mechanisms across

taxa could commonly underlie the incongruence between empirical results and theoretical expectations for predator-induced life-history variation." (Authors)] Address: Moore, P.M., Dept of Biology, Case Western Reserve University, Cleveland, Ohio, USA. E-mail: mpm116@case.edu
