**18251.** Delpon, G. (2012): Contribution à l'inventaire des Odonates du Tarn Maitre de stage caeruleus, l'agrion bleuissant, coeur copulateur. Rapport de Stage, Août 2012. OPIE-MP: 43 pp. (in French) ["The Tarn is home to a large number of Odonata species, due to the variety of climates and environments found there. Despite this richness, the department has long remained little surveyed and has hardly been taken into account in defining the French distribution of many species. Furthermore, despite the adoption in 2011 of a National Action Plan for Odonates, no such plan has been put in place by the Midi-Pyrénées region, even though several of the species present there are highly threatened. Based on these observations, a dynamic collection of naturalist data has emerged over the last few years in the department. The OPIE-MP is thus involved in a project to inventory the Odonata of the Tarn, alongside the "albistylum" group of the LPO Tarn. This report presents the results of the surveys carried out during June and July 2012 with the aim of making a significant contribution to this project. Particular interest was taken in five species targeted by the PNA Odonates, for which the Midi-Pyrénées region has a significant conservation responsibility, in order to update their distribution: *Macromia splendens*, *Oxygastra curtisii*, *Gomphus graslinii*, *Coenagrion mercuriale* and *C. caeruleus*." **18255.** Dobias, J. (2012): Factors affecting dragonfly species composition in newly created pools and assessment of invertebrate predation on pools zooplankton. Diplomová práce, Katedra ekologie, Přírodovědecká fakulta, Univerzita Karlova v Praze: 97 pp. (in Czech, with English summary) ["To identify and quantify the influence of physico-chemical, biotic and geographic factors on the population of Odonata is an essential tool for research of their ecology. The aim of this study was to 1) assess how these factors influence species richness, diversity and spatial distribution of dragonflies in 42 newly constructed or renewed pools located in the Kokořínsko Protected Landscape Area, which is characterized by two valleys of Libichovka and Pšovka creeks, low human impact, and a great diversity of small water bodies and 2) use laboratory experiments in order to estimate the relationship between large predatory invertebrates of these pools (*Aeshna cyanea*, *Coenagrion puella*, *Chaoborus crystallinus* and *Notonecta glauca*) and their common prey (*Daphnia curvirostris*) in an artificial environment with or without aquatic macrophytes. The pools were monitored and sampled between years 2005 and 2006. In total, 23 dragonflies species were found inhabiting these lentic habitats, comprising 11 species belonging to the suborder Zygoptera and 12 species belonging to the suborder Anisoptera, including a rare species *Sympetrum depressiusculum* (larvae). Most variability in the dragonfly species richness was explained by the size of the water surface area, followed by the location of the pools (inside or outside the floodplain) and after all, by the number of available pools in the neighbourhood. Much of the residual variability was explained by the species composition of zooplankton, which is a common food source for dragonfly larvae. Based upon the geographical location of pools, I have found out that the species richness of dragonflies is positively autocorrelated only over short distances (up to 1 km distance from other pools), this autocorrelation is very similar between the two suborders (Zygoptera and Anisoptera). The species composition of dragonflies in the pools was monitored for two years. No high differences occurred over the two years, however, the studied pools differed from each other. The variability in dragonfly species composition was largely explained by the size of the water surface area, followed by the age of the pools, the history of the habitat and lastly, by the connection to a spring or a ditch. Whilst most variance in the species composition variability of the Zygoptera suborder was explained by the size of the water surface area, in the Anisoptera suborder most

variation in diversity was explained by the position of the pool (in a floodplain or a ravine), followed by the number of available pools in the neighbourhood. Dependence of the diversity on the distance to neighbouring pools has not been significant, except for the long-distant pools on the peripheral areas of the region. Laboratory experiments were conducted to assess predation pressure of either individual predator species or their combinations, under presence/absence of submersed macrovegetation. In combined treatments, an interference between predators has been detected in one out of three experiments. The effect of aquatic macrophytes on prey consumption has been significant, however, its influence differed remarkably between assessed species: presence of vegetation had a negative effect to *Coenagrion puella* and a positive one on *Aeshna cyanea*." **18256.** Drinan, T.J. (2012): The impact of conifer plantation forestry on the ecology of peatland lakes. PhD Thesis, School of Biological, Earth and Environmental Sciences, College of Science, Engineering and Food Science, University College Cork: VIII + 286 pp. (in English) ["Blanket bog lakes are a characteristic feature of blanket bog habitats and harbour many rare and threatened invertebrate species. Despite their potential conservation value, however, very little is known about their physico-chemical or biological characteristics in western Europe, and their reference conditions are still unknown in Ireland. Furthermore, they are under considerable threat in Ireland from a number of sources, particularly afforestation of their catchments by exotic conifers. Plantation forestry can potentially lead to the increased input of substances including hydrogen ions (H<sup>+</sup>), plants nutrients, dissolved organic carbon (DOC), heavy metals and sediment. The aims of this study were to investigate the effect of conifer plantation forestry on the hydrochemistry and ecology of blanket bog lakes in western Ireland. Lake hydrochemistry, littoral Chydoridae (Cladocera) and littoral macroinvertebrate communities were compared among replicate lakes selected from three distinct catchment land use categories: i) unplanted blanket bog only present in the catchment, ii) mature (closed-canopy) conifer plantation forests only present in the catchment and iii) catchments containing mature conifer plantation forests with recently clearfelled areas. All three catchment land uses were replicated across two geologies: sandstone and granite. Lakes with afforested catchments across both geologies had elevated concentrations of phosphorus (P), nitrogen (N), total dissolved organic carbon (TDOC), aluminium (Al) and iron (Fe), with the highest concentrations of each parameter recorded from lakes with catchment clearfelling. Dissolved oxygen concentrations were also significantly reduced in the afforested lakes, particularly the clearfell lakes. This change in lake hydrochemistry was associated with profound changes in lake invertebrate communities. Within the chydorid communities, the dominance of *Alonopsis elongata* in the unplanted blanket bog lakes shifted to dominance by the smaller bodied *Chydorus sphaericus*, along with *Alonella nana*, *Alonella excisa* and *Alonella exigua*, in the plantation forestry-affected lakes, consistent with a shift in lake

trophy. Similarly, there was marked changes in the macroinvertebrate communities, especially for the Coleoptera and Heteroptera assemblages which revealed increased taxon richness and abundance in the nutrient-enriched lakes. In terms of conservation status, despite having the greatest species-quality scores (SQS) and species richness, three of the four International Union for the Conservation of Nature (IUCN) red-listed species of Coleoptera and Odonata recorded during the study were absent from lakes subject to catchment clearfelling. The relative strengths of bottom-up (forestry-mediated nutrient enrichment) and top-down (fish) forces in structuring littoral macroinvertebrate communities was investigated in a separate study. Nutrient enrichment was shown to be the dominant force acting on communities, with fish having a lesser influence. These results confirmed that plantation forestry poses the single greatest threat to the conservation status of blanket bog lakes in western Ireland. The findings of this study have major implications for the management of afforested peatlands. Further research is required on blanket bog lakes to prevent any further plantation forestry-mediated habitat deterioration of this rare and protected habitat." **18257.** Emmanuel, J.; Joshua, G.; Shams, S.B. (2012): Comparative study of ecological conditions of four wetlands of Punjab using macroinvertebrates as bioindicators. *The Journal of Animal & Plant Sciences* 22(4): 908-914. (in English) ["A baseline study was conducted from November 2006 to October 2007 to investigate the status of aquatic macroinvertebrates [including Odonata, not further detailed] as bioindicators and their ecological linkages to physico-chemical characteristics of four wetland areas of Punjab namely, Balloki Headworks, Qadirabad Headworks, Rasul Headworks and Kalar Kahar Lake, India. The sampling points were marked on a map using GPS... The hydrological parameters such as temperature, pH, LDO, salinity and TDS were recorded to get knowledge of the effect of season on the pond ecosystem. Macroinvertebrate sampling from the pelagic water was done using a dip net of mesh size approximately 0.6 mm, dragged in the water for 15 minutes. These were then preserved and identified up to the order level. The results revealed that Balloki area being under the effect of dry season and agricultural stress had more tolerant species. The presence of pollution sensitive Ephemeroptera was justified by low TDS and high LDO at Rasul Headworks. The hydrology and fauna of Kalar Kahar Lake was exclusively different from the other sites. In this case pH, TDS, salinity were highest whereas LDO was the lowest. The relative abundance of sensitive to tolerant species was in accordance with the hydrological data." Chancen in Prozessschutz-, Entwicklungs- und Managementzonen aus naturschutzfachlicher Sicht. *Naturschutz und Landschaftsplanung* 44(9): 273-281. (in German, with English summary) ["Ecological Potential of a National Park in the Northern Black Forest – Opportunities in zones for process protection, development and management from a nature conservation point of view The discussion about a possible national park on the Northern Black Forest is currently in full swing. The National Park initiative aims to make available an area of at least 10,000 ha in the medium to long term for the cycle of natural processes in the forest. In an initial phase of 30 years it will be possible to instigate certain forest developments in partial areas, e.g. the promotion of firs, beeches or pines in favour of the upcoming generation. The central question from a nature conservation perspective is which are the positive effects of such a large protection area for the preservation of rare species and the re-establishment of the local species diversity. Summing up, it is expected that the protection of the natural processes in an area of this size will promote many typical species and ecological interactions. These processes and developments should be accompanied by a specialist monitoring (including research) of nature conservation, regional experts of species protection and scientists." **18259.** Gallo, S. (2012): Trophic transfer of contaminants in tree swallows (*Tachycineta bicolor*) nesting near Lake Calumet, Illinois. M.Sc thesis, University of Illinois at Urbana-Champaign: 125 pp. (in English) [Tree swallow nestlings, eggs, and diet and sediment grab samples were used to quantify risks of exposure to 15 trace elements, 31 polychlorinated biphenyl (PCB) congeners, 15 polybrominated diphenyl ether (PBDE) congeners and 13 organochlorine pesticides in the Calumet area of northeastern Illinois, USA. Nesting success and clutch size were measured in tree swallows to determine whether local contaminants reduced tree swallow fitness. Overall nesting success was not reduced when compared among sites and to range averages; 71-90% of clutches started had at least one nestling fledge. Likewise there were no differences among sites in the proportion of eggs that hatched and nestlings that fledged. Generally, contaminant concentrations in the media were considered low or not elevated, although sediment concentrations of cadmium, chromium, and nickel at some sites were higher than the "probable effects concentration" or the "probable effects level" for sediment dwelling organisms, and lead, manganese, and zinc were above the "severe effects levels" at some sites. Calumet nestlings in 2005 were fed between 51 and 64% aquatic insects by mass. Terrestrial insects

in the nestling tree swallow diet contained significantly greater concentrations of lead than aquatic insects consumed by the nestling tree swallows. Mean mercury concentrations in nestlings ranged from 0.10 to 0.18 mg/kg dry weight (dw) and egg concentrations ranged from 0.11 to 0.23 mg/kg dw and approximately 5% of the total mercury mass in nestlings came from the eggs. Egg mercury concentrations, which are acquired directly from the mother, were positively correlated with the timing of nesting, and negatively correlated with brood size. Nestlings at Indian Ridge in 2004 and Powderhorn in 2005 accumulated the greatest mass of mercury. Mean sum PCB concentrations in tree swallow eggs ranged from 463 to 830 ng/g wet weight (ww) and from 105 to 208 ng/g ww in nestlings. Egg concentrations contributed approximately 48% of the total PCB mass in nestlings. Nestlings at Big Marsh in both years, and Indian Ridge in 2004 accumulated the greatest mass of PCBs. Nestlings from both Big Marsh and Indian Ridge in 2005 accumulated the most PBDEs, with approximately 21% of the total mass in nestlings coming from the eggs. Mean sum PBDE concentrations in eggs ranged from 47 to 78 ng/g ww and from 20 to 62 ng/g ww in nestlings, and these results appear to be among the first reported PBDE concentrations in tree swallows. Powderhorn had no record of sediment contamination that was found, however low levels of contaminants were in the sediment and biota there. Tree swallow nestlings accumulated a variety of contaminants from the Calumet sites through their diet, though eggs contributed significant amounts for some compounds like PCBs. Understanding contaminant presence and uptake in wetlands of the Calumet area is particularly useful due to the loss of wetland habitat in this region.] Address: not stated

**18260.** Gamboa, M.; Kimbirauskas, R.K.; Merritt, R.W.; Monaghan, M.T. (2012): A molecular approach to identifying the natural prey of the African creeping water bug *Naucoris*, a potential reservoir of *Mycobacterium ulcerans*. *Journal of Insect Science* 12:2: 10 pp. (in English) ["The extra-oral digestion of creeping water bugs (*Naucoridae*: Hemiptera) hinders the study of their diet using the standard method of identifying prey body parts in the gut. Genetic methods are available, but rely on PCR tests or similar diagnostics to confirm suspected prey. Where the potential prey is unknown and a broad search for all possible prey is desirable, methods that can potentially capture any prey item are required. *Naucoris* sp. is known to harbor *Mycobacterium ulcerans* (*Actinomycetales*: *Mycobacteriaceae*), the causative bacterium of Buruli ulcer. Outbreaks of Buruli ulcer have been associated with disturbed freshwater habitats, but the mode of transmission to humans remains unclear. Here we examine the diet of *Naucoris* sp., a dominant aquatic predator in water bodies in Ghana where the prevalence of Buruli ulcer is high. We cloned and sequenced 576 PCR products (mtDNA *rrnL*, *cox1*) isolated from the gut of 60 *Naucoris* sp. individuals to determine diet composition as broadly as possible. Using phylogenetic analysis of newly sequenced clones and 6 potential prey taxa collected from the site, sequences isolated from *Naucoris* sp. guts matched locally collected *Coleoptera* (*Hydrophilidae*). Blastn queries to

GenBank of other clone sequences produced matches to (*Anura*) (*n* = 1), *Rotifera* (*n* = 5), and *fungi* (*n* = 4) as additional components of the diet. Our results suggest that sp. in this Buruli ulcer-endemic area feeds on a wide range of prey and body sizes, and that the approach could be successfully applied to studies of aquatic food webs where morphological identification of prey is impossible and where little or no a priori knowledge is available. ... Genomic DNA was extracted from ... *Odonata* (*Zygoptera*) (*n* = 8) ..." **18262.** Geguzis, R. (2012): Benthic macroinvertebrate communities in natural and channelized sites of the merkys river basin streams. *Žemes Ukio Mokslai* 19(4): 273-287. (in Lithuanian, with English summary) ["The present study contains the results of an investigation of the abundance and taxonomic composition of benthic macrofauna, collected in natural and straightened sites of 3 streams of the basin of the Merkys River. The current The current velocity, velocity, velocity, water discharge, riverbed overgrowth with plants and direct sun pass were highest in the natural sites of the investigated streams and lowest in the straightened sites of the investigated streams. A total of 72 macroinvertebrate taxa belonging to 48 families were identified in the investigated sites of the streams. 18 macroinvertebrate taxa were found only in the natural sites in the forest of the investigated streams and 7 were found in the straightened sites of the investigated rivers. The data obtained showed that the total taxon number and EPT taxon number of macroinvertebrates in the same stream natural sites in the forest were higher than those in the straightened stream sites. Caddisflies *Brachycentrus maculatus* dominated in the natural sites of the streams Spengla and Amarnia, chironomids *Cricotopus algarum* dominated in the straightened sites of all investigated streams. It has shown that the total abundance of macroinvertebrates in the natural sites in the forest of the investigated streams in the forest of the investigated streams as significantly higher in comparison with the straightened sites in the field. The highest total abundance of macroinvertebrates was determined in the natural site in the forest of the stream Spengla ( $4180 \pm 45 \text{ ind.m}^{-2}$ ) and the lowest abundance was found in the straightened site in the field of the stream Gruda ( $640 \pm 17 \text{ ind.m}^{-2}$ ). The data of this investigation showed that the abundance of mayflies (*Ephemeroptera*), caddisflies (*Trichoptera*), EPT was significantly higher in the natural sites in the forest of the investigated streams, while the percentage of pollution-tolerant *Chironomidae* was higher in the straight straightened sites in the field of the streams Spengla and Amarnia." **18263.** Hassall, C.; Hollinshead, J.; Hull, A (2012): Temporal dynamics of aquatic communities and implications for pond conservation. *Biodiversity and conservation* 21: 829-852. (in English) ["Conservation through the protection of particular habitats is predicated on the assumption that the conservation value of those habitats is stable. We test this assumption for ponds by investigating temporal variation in macroinvertebrate and macrophyte communities over a 10-year period in northwest England. We surveyed 51 ponds in northern England in 1995/6 and again in 2006, identifying all macrophytes (167 species) and all macroinvertebrates (221 species, excluding Diptera) to species. The alpha-diversity, beta-diversity and conservation value of these ponds were compared between surveys. We find that invertebrate species richness increased from an average of 29.5 species to 39.8 species between surveys. Invertebrate gamma-diversity also increased between the two surveys from 181 species to 201 species. However, this increase in diversity was accompanied by a decrease in beta-diversity. Plant alpha-, beta- and gamma-diversity remained approximately constant between the two periods. However, increased proportions of grass species and a complete loss of charophytes suggests that the communities are undergoing succession. Conservation value was not correlated between sampling periods in either plants or invertebrates. This was confirmed by comparing ponds that had been disturbed with those that had no history of disturbance to demonstrate that levels of correlation between surveys were approximately equal in each group of ponds. This study has three important conservation implications: (i) a pond with high diversity or high conservation value may not remain that way and so it is unwise to base pond conservation measures upon protecting currently-speciose habitats; (ii) maximising pond gamma-diversity requires a combination of late and early succession ponds, especially for invertebrates; and (iii) invertebrate and plant communities in ponds may require different management strategies if succession occurs at varying rates in the two groups." **18266.** Kelly, P.T. (2012): Insect emergence from a large river system in the presence and absence of bighead (*Hypophthalmichthys nobilis*) and silver (*H. molitrix*) carp. M.Sc.

thesis, College of Science and Allied Health, Biology – Aquatic Science, University of Wisconsin-La Crosse: IX, 58 pp. (in English) ["Aquatic insect emergence is an important resource for terrestrial insectivores that rely on aquatic insects while raising young, or when terrestrial production is low. Emerging insects also transfer valuable high-energy lipids from phytoplankton to terrestrial consumers. The objectives of this project were to: (1) quantify insect emergence in two large-river systems that differed in primary productivity, and (2) determine the impacts of bighead and silver carp on the emergent insect community. Floating traps (surface area = 0.25 m<sup>2</sup>) were used to sample emerging adult insects, and were placed in study sites with and without Asian carp. Insects were sorted, identified to family, and individually weighed to determine emergent biomass rates. Sites with carp displayed the greatest insect flux; however, insect diversity was greatest at sites without carp, and lowest at the sites with carp. Emergent insect diversity was correlated with the presence of aquatic vegetation. Insect abundance was also linearly related to algal standing stock (measured as chlorophyll a). This suggests that primary productivity in large river systems have a positive impact on the magnitude of insect emergence, and that the diversity of insects increases with aquatic vegetation. Bighead and silver carp may positively impact insect emergence by removing zooplankton competitors, but may decrease insect diversity by a reduction in large-sized phytoplankton food resources." (Author) Taxa - including Odonata - are treated at family level: Coenagrionidae, Corduliidae, Macromiidae] Address: not stated

**18267.** Lambert, J.-L. (2012): Potentialités de présence de *Boyeria irene* (Fonscolombe, 1838) et *Ophigomphus cecilia* (Fourcroy, 1785) en Champagne-Ardenne. *Naturelle* 4: 8-16. (in French) ["Within the framework of the regional version of the National Action Plan for Odonates, we need to improve our knowledge of the priority species in Champagne-Ardenne, including *B. irene* and *O. cecilia*. The still fragmentary knowledge on the distribution and habitat of *B. irene* in the region must be improved. The confirmation or denial of the presence of *O. cecilia* in the Champagne-Ardenne also needs to be clarified (Ternois, 2011). These two taxa appear in particular on the benthic macrofauna listings established according to the samples taken at several IBGN stations (DREAL Champagne-Ardenne studies since 1988). However, experience shows that confusion can easily arise at the generic level when using the dichotomous key used by the determiners responsible for drawing up the taxonomic lists. The 5th annual day devoted to odonates at the Metz Interregional Delegation of the Office National de l'Eau et des Milieux Aquatiques is an opportunity to carry out targeted investigations on two stations where IBGN (Indice Biologique Global Normalisé) surveys are carried out in the river Aube where the genera *Boyeria* McLachlan, 1896 and *Ophigomphus* Selys, 1854 appear in the listings." **18268.** Liberski, J. (2012): Breath of levante – odonatological impressions from the Strait of Gibraltar. *Odonatrix* 8(2): 43-51. (in Polish, with English summary) ["The paper presents data from southern Andalusia (Spain), from the period between 16.08 to 2.09.2011. It was at 8 sites during ornithological studies. Those were: 1. Bolonia (36°6'3,92" N, 5°43'58,12" W, UTM TE59); 2. Cabrito (36°3'19,05" N, 5°33'12,97" W, TE69); 3. La Peña (Valle de Santuario) (36°3'52,77" N, 5°38'52,35" W, TE69); 4. La Janda (36°13'10,84" N, 5°46'59,01" W, TF41); 5. El Algarrobo (36°5'25,21" N, 5°29'2,28" W, TE79); 6. Palmones (36°10'9,59" N, 5°26'35,91" W, TF80); 7. Los Barrios (36°13'44,69" N, 5°29'6,96" W, TF71), 8. Algeciras (36°6'24,63" N, 5°26'28,45" W, TE89). At site no. 3 there was a small stream, at site no. 4 rice field with irrigating canals, at site no. 6 – the estuary of the River Rio Palmones and its pools, at site no. 7 – strongly polluted small water bodies within the area of rubbish dump. The rest of the bird-watching sites was situated far from the potential breeding sites of dragonflies. 11 dragonfly species were noted: *Calopteryx haemorrhoidalis*, *Ischnura pumilio*, *I. graellsii*, *Anax ephippiger*, *A. parthenope*, *Orthetrum chrysostigma*, *Brachythemis imparita*, *Crocothemis erythraea*, *Sympetrum fonscolombii*, *Trithemis annulata* and *T. kirbyi*. The most distributed was *S. fonscolombii*, observed at every sites, and *O. chrysostigma*. The most numerous were *S. fonscolombii* and *C. erythraea*. The richest in dragonflies were rice fields in La Janda. The observed species are common in southern Spain. An exception and, at the same time, the most interesting one among others was *T. kirbyi*. This is African species, in continental Europe known until recently from the study area, otherwise noted in Sardinia. Nowadays, it has been in territorial expansion; it has inhabited the neighbouring province Malaga and was noted in central-western Andalusia (Seville)." **18272.** Lis, L. (2012): *Leucorrhinia albifrons* (Burmeister, 1839) (Odonata: Libellulidae) in an anthropogenic habitat in the former sulfur mine "Jeziórko" (Sandomierz Basin). Odonatrix 8(2): 55-58. (in Polish, with English summary) ["In the year 2012 a small autochthonic population of *L. albifrons* was discovered in the area of the former underground mine of sulphur Jeziórko (south-eastern Poland, 50°33'34"N, 21°48'00"E, UTM EB50). It inhabited one of the artificial water bodies created in the frames of reclamation of this area, situated in the depression, gathering flowing or discharging waters from the surrounding areas. In May and June a few individuals of *L. albifrons* was observed, with juvenile specimens of both sexes in it. The habitat of *L. albifrons* was characterized by abundant swamp vegetation (*Phragmites australis* mainly) and moderately abundant floating and submerged vegetation (*Potamogeton natans*, *Ceratophyllum demersum*, *Utricularia vulgaris*). Water was transparent, moderately alkaline (pH: 7.71), quite strongly mineralized (electrolytic conductivity: 2325  $\mu\text{S}\cdot\text{cm}^{-1}$ , dissolved solids: 1163  $\text{mg}\cdot\text{dm}^{-1}$ , salinity: 1.2 PSU). Compact range of *L. albifrons* in Poland is limited to lakelands in the north of the country. Farther towards the south there is a zone of the insular occurrence, on single sites or their groups. This zone reaches south-eastern Poland through which the range boundary is running from Slovakia only one single sites is known, historical and doubtful one. The site in Jeziórko situated near the southern range boundary of *L. albifrons* which is marked nowadays by three sites in the Przemysl Foothills. Its discovery is a valuable supplement to the knowledge about the distribution of the species on the edge of its range. This shows that this species can occur at more sites and in more regions than previously thought. The new site confirms also the previous data that the occurrence of the species in the marginal zone of the range is in large part connected with secondary habitats which can locally contribute to the increase in species distribution in comparison to historical period." **18273.** Lorthiois, M., Cheyrezy, T.; Gaudet, S.; Lecomte, T.; Simon, A. (2012): *Leucorrhinia* à gros thorax en Haute Normandie - *Leucorrhinia pectoralis* (Charpentier, 1825) (Odonata, Libellulidae). L'Entomologiste Haut-Normand 2: 2-10. (in French) ["Conclusion The odonatological fauna of Haute Normandie, France has thus included a 50th species since spring 2012: the *L. pectoralis*. Observed at 5 stations in the region, 3 in Seine-Maritime and 2 in Eure, this species has reached us thanks to an exceptional invasion phenomenon. This has affected the whole of north-eastern France and the region constitutes its known western limit. Many potentially favourable environments were surveyed despite the difficult weather conditions during the presence of the species in the region. However, many peat ponds were not visited and the species may have swarmed on some of them. Even if evidence of reproduction was only formally observed on one of the five sites where the species was found, we cannot exclude the temporary establishment of other populations elsewhere in Haute-Normandie. Consequently, we will have to be particularly vigilant in the spring of 2014 and 2015, and even as early as 2013, to detect any new populations of this protected species." **18274.** Mahmoud, M.F. (2012): Insects associated with sesame (*Sesamun* [i.e. *Sesamum*] *indicum* L.) and the impact of insect pollinators on crop production. Pesticides and Phytomedicine 27(2): 117-129. (in English) ["A survey of insects associated with sesame, *Sesamum indicum* L. (Pedaliaceae) was conducted at the Agriculture Research Farm of The Faculty of Agriculture, University of Suez Canal during the growing seasons 2010 and 2011. All different insect species found on the experimental site were collected for identification. Sampling was done once a week and three times a day. Three methods were used to collect insects from the sesame plants (a sweep net, pitfall traps, digital camera and eye observation). A total of 31 insect species were collected and properly identified during the survey. Insects recorded on the plants were divided into four groups, true pollinators (Hymenoptera), other pollinators (Diptera, Coleoptera and Lepidoptera), pests (Orthoptera, Odonata [*Ischnura senegalensis*, *Crocothemis erythraea*], Hemiptera and Homoptera) and natural enemies (Coleoptera, Hymenoptera, Neuroptera and Dictyoptera). For studying the impact of insect pollination on sesame production, the experiment was divided in two: opened and non-opened pollination of sesame. 50 plants from nonopened pollination were covered with a perforated paper bag to allow the air to pass through and to prevent insects from approaching the plants. Quantitative and qualitative parameters were measured as follows: pod weight, number of seeds in each pod, weight of 1000 seeds, germination (%), seedlings vigour and oil content (%). Results clearly demonstrate that the opened pollination improved the crop production." (Authors)] Address: Mahmoud, M.F., Suez Canal University, Ismailia (Egypt). - 18275.** Milton Montaña, C.; Meza, A.M.; Dias, L.G. (2012): La colección entomológica cebuc y su potencial como colección de referencia de insectos acuáticos. *Bol. cient. mus. hist. nat.* 16(2): 173-184. (in Spanish, with English summary) [Entomology collections constitute a country or region's natural history archive, where specimen preservation and its associated information are the basis for taxonomic, ecological, phylogenetic, and biogeographic studies. The Entomology Collection of the Biology Program of the Universidad de Caldas (CEBUC) has had an entry and deposit of reference specimens since 1993. Despite the time passed since its creation, it did not count on an appropriately organized collection. With the objective of optimizing the collection and organizing the information associated with the conserved species, its curation process was carried out. In parallel, an analysis of the taxonomic determination of the exemplars was done, finding that a total of 34184 exemplars were identified to the family level, of which 29542 (86.42%) are identified to the genus level. A total of 28542 liquid-stored aquatic insects are recorded, distributed in 28 orders, 90 families, and 215 genera and/or morphotypes, collected from different rivers and streams of the Caldas department. By analyzing the source data of the aquatic insect exemplars of the CEBUC, it was possible to determine that the greatest richness and abundance of aquatic insects is associated to leaf litter substrate. The generalist collectors' trophic guild is the dominant group among the aquatic insects deposited in the collection. In regards to the dry-preserved collection, it currently contains 5642 individuals, grouped in 14 orders belonging to 111 families. In this manner, CEBUC becomes an important reference tool for future investigations, in addition to manifesting the diversity of Colombia's central coffee region." (Authors) The collection includes 101 specimens with five families] Address: Milton Montaña, C., Programa de Biol., Fac. de Ciencias exactas y naturales, univ. de Caldas. milf-m@hotmail.com

(2012): Physical, chemical and biological characteristics in habitats of high and low presence of anopheline larvae in western Kenya highlands. *PLoS ONE* 7(10): e47975: 7 pp. (in English) ["Background: Characteristics of aquatic habitats determine whether mosquitoes will oviposit, hatch, develop, pupate and successfully emerge into adults or not, thus influencing which mosquito species will occupy a habitat. This study determined whether physiochemical and biological characteristics differ between habitats with high and low presence of anopheline larvae. Methods: Physical, chemical and biological characteristics were evaluated in selected habitats twice per month within three highland valleys in western Kenya. Aquatic macro-organisms were sampled using a sweep-net. Colorimetric methods were used to determine levels of iron, phosphate, nitrate, ammonium and nitrite in water samples. Generalized Estimating Equations (GEE) was used to compare parameters between the two categories of anopheline presence. Results: Habitats with high anopheline presence had greater abundance of mosquito aquatic stages and tadpoles and two times more levels of nitrate in water, whereas habitats with low anopheline presence had wider biofilm cover and higher levels of iron in water. Conclusion: Habitats of high and low presence of anopheline larvae, which differed in a number of physical, chemical and biological characteristics, were identified in valleys within western Kenya highlands. Differences in habitat characteristics are critical in determining the number of anopheline larvae that will fully develop and emerge into adults." **18282.** Poulin, B. (2012): Indirect effects of bioinsecticides on the nontarget fauna: The Camargue experiment calls for future research. *Acta Oecologica* 44: 28-32. (in English) ["Following its high selectivity and low toxicity to nontarget organisms, *Bacillus thuringiensis* var. *israelensis* (Bti) has become the most commonly used microbial agent to control mosquitoes worldwide. Considered non-toxic to mammals, birds, fish, plants and most aquatic organisms, Bti direct effects on the nontarget fauna are largely limited to non-biting midges (Chironomidae). Studies addressing the indirect effects of Bti through food web perturbations are scanty and showed no significant results. Mosquito-control in southern France was implemented in 1965 using various insecticides over 400 km of coast. In spite of a high mosquito nuisance, the Camargue wetlands were excluded from this control programme to preserve biodiversity. The expanding use of Bti

has prompted the implementation of an experimental mosquito control in 2006 involving 2500 of the 25,000 ha of larval biotopes of the Camargue, accompanied by impact studies on the nontarget fauna. Using birds from natural and human-inhabited areas as model species, we assessed trophic perturbations caused by three years of Bti applications. The preliminary results of this 5-yr programme revealed significant effects of Bti spraying on abundance of reed-dwelling invertebrates serving as food to passerines [including Odonata], as well as on the diet and breeding success of house martins nesting in rural estates and small towns. Very few studies (if any) have provided such compelling evidence of an insecticide affecting vertebrate populations, putting into question the environmental-friendly character of Bti, at least in some areas. The significance of these results are discussed within a wider context and completed with an analysis of the current Bti bibliography to highlight and orient priorities for future research on this topic." (Author)] Address: Poulin, Brigitte, Tour du Valat Research Center, Le Sambuc, 13200 Arles, France. E-Mail: poulin@tourduvalat.org.

**18283.** Sannier, D. (2012): Inventaire des Odonates (Odonata) et synthèse des connaissances dans les réserves naturelles catalanes. Master 2ème Année Pro, Biodiversité – Écologie - Environnement, Université Joseph Fourier Grenoble 1: 152 pp. (in French, with English summary) ["Odonata are insects highly dependent on wetlands, making it a taxonomic group endangered. Thus, respectively 30 % and 15 % of world's and European species are considered as "threatened" and over a quarter of French species are on a Red List in preparation. The Catalan federation of nature reserves initiated a campaign of inventories to better know these insects and apprehend local conservation issues. It's in this context that this study is included: its main objective is to make an Odonata inventory of the Madres-Coronat south side. So, 26 taxa were inventoried, which 21 of them are formally indigenous. Among this species, six are news for the nature reserve of Nohèdes and three for the Catalan nature reserves. Spatial distribution and time division of every taxa as well as the four main odonatological corteges of Madres-Coronat are characterized. The conservation issues are significant, in particular for 6 highly interesting species: *Somatochlora arctica*, *Cordulegaster bidentata*, *Coenagrion hastulatum*, *Sympetrum flaveolum*, *S. danae*, *Aeshna juncea*. Many efforts are still needed to complete knowledge about Odonata in the Catalan nature reserves, except perhaps Madres-Coronat's ones. The implementation of population monitoring at the Estany del Clot should also allow to measure their evolution in the Nohèdes's nature reserve." (Author)] Address: Sannier, D., Univ. Rapport VS2012.022, De Vlinderstichting, Wageningen: 22 pp. (in Dutch, with English summary) ["The goal of the 'Green Deal Temporary Nature' is to stimulate temporary nature development and to study the problems faced. One of the main targets is research on development of this new nature areas. Amsterdam Harbour has initiated as the first Dutch company a pilot 'Temporary Nature' on their site. Simple provisions were made to improve biodiversity like constructing artificial relief and creating ponds on the pilot site. In addition of the monitoring of Natterjack Toad and Orchids, research on quality of the temporary nature areas is started using an inventory of butterflies, dragonflies and grasshoppers. In this research three areas (in total 21 ha) in Westpoort where potentially nature could develop were studied. The pilot area, which was the focus of this research, is the biggest and it was created by Amsterdam Harbour in 2007. For the purpose inventory of butterflies, dragonflies and grasshoppers was done for their good qualities as indicators of nature development. In total 30 species of butterflies, dragonflies [10 species recorded] and grasshoppers in the three temporary nature areas of Westpoort were found and their relation with the habitat were assessed. These species are associated to the nature

development and quality. Many indicative species of pioneer vegetation and (flowery) grasslands were found. These species were found here because of the early stage of development of the area. The discovery of at least two individuals of Bluewinged grasshoppers was promising surprise of the study. They most probably have colonised the area from the dunes nearby. This indicative species of open sandy areas and pioneer habitat proves the available ecological balance in the pilot area. The dragonfly diversity seemed to be increasing and quality of good fresh water improving. The quality of the flowery grasslands is high and provide good quality of habitat that not only for butterflies, but also for rare plant species like Orchids, Grass of Parnassus and Yellow-wort. The conclusion is was that this 'temporary nature' develops fast and in the right direction. There are already flowery meadows with high grassland butterfly diversity, which is positive since they are under high pressure. The investigated area of 'temporary nature' functions as important stepping stone in the region for this group and other species associated with open sand and pioneer habitat. These are usually dynamic systems from where species can disperse. Due to the natural succession, the species typical of pioneer habitat will disappear and the terrain transform potentially to a more developed habitat and host other species. The data from the National Databank Flora & Fauna shows that the species diversity is available in the direct vicinity. The pilot project of Amsterdam Harbour creating the artificial relief and ponds in the temporary nature area, achieved a very good positive development for the biodiversity in the area. At this moment the area is a very important habitat and stepping stone for species of pioneer habitat and grasslands, which are currently threatened in the Netherlands." **18288.** Ajuria Ibarra, H.; Reader, T. (2013): Reasons to be different: do conspicuous polymorphisms in invertebrates persist because rare forms are fitter? *Journal of Zoology* 290(2): 81-95. (in English) ["Many invertebrate species show conspicuous colour polymorphisms, the study of which has provided us with important insights in evolutionary biology. The potential importance of frequency-dependent selection

in the maintenance of polymorphisms was identified by theoretical studies more than 50 years ago, and since then, the topic has received considerable attention from those seeking to explain observed diversity in natural populations. Here, we consider the different ecological interactions that have been shown to lead to negative frequency-dependent selection in invertebrate populations in the wild, and assess the likely relative importance of this mechanism in comparison with alternatives that may promote genetic and phenotypic diversity. The literature shows that frequency dependence can result from a wide array of ecological interactions, in particular, those involving mate choice, sexual conflict and predation. However, even though negative frequency-dependent selection is the most common explanation for the occurrence of conspicuous polymorphisms in invertebrates, conclusive evidence of its importance in natural populations is largely absent. A particular problem is that in most studies, it is the only explanation considered. In the most comprehensively studied systems, it has been shown that multiple mechanisms (both selective and neutral) operate to maintain observed phenotypic variation, and that negative frequency-dependent selection is not the most important of these. Thus, as yet at least, we do not have strong grounds for believing that negative frequency-dependent selection is a major diversifying force in invertebrate morphology. However, without more comprehensive studies in a wider range of ecological contexts, we are equally unable to dismiss it as weak and/or irrelevant." **18289.** Alcorlo, P.; Baltana, A. (2013): The trophic ecology of the red swamp crayfish (*Procambarus clarkii*) in Mediterranean aquatic ecosystems: a stable isotope study. *Limnetica* 32(1): 121-138. (in English) ["The red swamp crayfish (*Procambarus clarkii*) is an invasive species in most of its current distribution range. As an omnivorous species that feeds on items of many trophic levels [including Odonata] and is eaten by many others, it occupies a key trophic position within the invaded food webs. This trophic position, in combination with its active physiology, makes *P. clarkii* a suitable organism for ecotoxicological studies and, more specifically, a bio-indicator of heavy metal pollution. These characteristics also make *P. clarkii* a likely vector of contaminants toward higher trophic levels. In this study, we (i) describe aquatic food webs in three contrasting Mediterranean wetlands in the lower Guadalquivir River Basin, southwestern Spain, each populated by invasive *P. clarkii* but having a different heavy metal concentration, (ii) assess the trophic role of crayfish and temporal trends in its diet using stable isotope analysis ( $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$ ), and (iii) assess the relationship of crayfish isotopic signatures to the content of heavy metals (Cu, Zn, Pb, Cd, As) bioaccumulated in crayfish body tissues. We detected significant between-site differences in carbon and nitrogen isotopic signatures but found significant between-date differences only for nitrogen signatures. Between site changes in carbon and nitrogen isotopes were due primarily to variations in the relative contribution of autochthonous vs.

allochthonous primary producers and shifts in crayfish abundance through time, respectively. Isotopic food web models were used to distinguish between systems driven by a detritus-based energy pathway and systems supported by detritus and primary producers. The trophic positions estimated for crayfish and other invertebrates at each site were low, suggesting the prevalence of omnivory and the occurrence of a trophic continuum rather than discrete levels. Isotopically, crayfish occupy a predator position in the observed food webs, which is consistent with the predominance of animal food sources in the species' diet. No significant changes were found between crayfish ontogenetic stages using isotopic ratios. The site with the highest concentration of heavy metals showed the highest  $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$  values, and a significant correlation was found between five heavy metal elements (As, Cd, Zn, Cu, Pb) measured in crayfish and their nitrogen isotope signatures ( $r = 0.72$ ,  $p < 0.0001$ ), thus reinforcing its contamination biomarker role." **18290.** Amann, P. (2013): Die Libellenfauna der Jagdberggemeinden. Naturmonographie Jagdberggemeinden. Dornbirn (inatura Erlebnis Naturschau Dornbirn): 207-228. (in German, with English summary) ["Within the framework of inatura's investigation into the flora and fauna of the Jagdberg communities, I was given the task of examining and documenting the dragonfly populations in the region. Collections were taken on dragonfly habitats over a period of two years (2010-2012). These recent collections were supplemented with unpublished data from Georg Amann from 2003-2004. This work should interest experts as well as laymen who are interested in nature. The dragonfly species which inhabit the investigated region were described, their typical behaviours were documented, and hints were given on how and where to observe them. The results: Of the 55 dragonfly species registered in Vorarlberg, 27 were detected in the Jagdberg communities. Six of the observed species are considered highly endangered according to Hostettler (2001). (*Calopteryx virgo*, *Cordulegaster bidentata*, *C. boltonii*, *Ischnura pumilio*, *Sympetma paedisca*, *Sympetrum pedemontanum*) Especially the *C. virgo* and both the *Cordulegaster* species could be observed over a number of years. These insects have found their final retreat and reproduction space in the small, flat moorlands in the Jagdberg communities in Vorarlberg. In conclusion, three examples of development possibilities are presented which the Jagdberg communities could implement to create living and protection space for dragonflies. A concrete catalogue of measures and positive examples of successful intervention by the communities completes the work." (Author)] Address: Amann, P., Wiesenbachweg 8, A-6824 Schlins, Austria. **18291.** Assmann, B.R.; Silva, J.E.A.; Marinho, J.R. (2013): Analise da dieta alimentar de tartarugas-de-agua-doce da familia Chelidae em lagos rasos costeiros em Rio Grande, RS. *Vivencias* 9(16): 36-52. (in Portuguese, with

English summary) ["Feeding analysis of freshwater turtles in coastal shallow lakes in Rio Grande, RS: Turtles are vertebrates most easily recognizable due to their morphological specializations associated with different habitats they occupy basically aquatic or semi-aquatic, exist species that are carnivorous, herbivores and omnivores. There is a significant lack of research lines on turtles in academic institutions outside the region southeast, mainly of Chelidae Family. The increase in the concentration of nutrients through the artificial enrichment of aquatic ecosystems can influence the availability of certain food items in the diet of turtles Chelidae Family. Obtaining data on the diet of these turtles allows to know the variations and food preferences when they are exposed to different conditions of human disturbance in their aquatic environment. The objective of this study was to determine the feeding diet composition of freshwater turtles of genres *Acanthochelys* and *Phrynops*, Chelidae Family. Catches and recaptures of specimens family Chelidae occurred during two weeks in August, October, November, December 2011 and January 2012, a period corresponding between 8 hours and 18 hours in three shallow lakes in Campus Carreiros of FURGS in Rio Grande, RS. Catches were performed manually with dip nets and traps water cylindrical of type covo average size. After immobilization of the animal, the analyzes of diet occurred through the technique by of gastric lavage in specimen captured, and subsequent analysis of the stomach contents of each individual. We collected a total of 19 individuals in the three lakes, 14 of espécie *Acanthochelys spixii* and five species of *Phrynops hilarii*. The diet was primarily composed of aquatic invertebrates and individuals of the order Diptera that were the most representative. The availability of food for *Acanthochelys spixii* and *Phrynops hilarii* and is directly related to the limnological conditions of the lakes where these species live." **18294.** Bulankova, E.; Beracko, P.; Derka, T. (2013): Occurrence of protected species (*Gomphus flavipes*, Odonata and *Palingenia longicauda*, Ephemeroptera) in the Danube River and its deltas (Romania, Slovakia). Scientific Annals of the Danube Delta Institute Tulcea, Romania 19: 21-24. (in English) ["Large population of *Gomphus flavipes* was found in the Malý Dunaj (Small Danube), in the area called Danube's "Inland Delta", in 2000–2001. Watching of dragonflies in the Danube Delta (Romania) demonstrated another large population in 2007–2008. In contrast with these observations are our results, from long-term monitoring of dragonflies in the Danube, in the area influenced by the Gabčíkovo power plant (operational since 1992). Changes in hydromorphology in this section started in 19th century and at present dam represents a significant impact on the functioning of the Danube ecosystem. During 20 years monitoring we found only one larva of *Gomphus flavipes* in the Danube at the site downstream of the dam. Another critically endangered species, mayfly *Palingenia longicauda* was found in the Danube Delta in 2009. We observed emergence of giant mayfly in the Danube's arm in Romania. *Palingenia longicauda* disappeared totally in the 1930s from many European rivers. At present it occurs in Tisza and Rába rivers (Hungary) and has been reintroduced in Lippe and Odra rivers (Germany). New findings of large populations of *Palingenia longicauda* in the Romanian Delta has been unknown till now. Findings of large population of *Gomphus flavipes* in deltas confirm that river deltas are of high importance for aquatic biodiversity conservation." **18295.** Caut, S.; Angulo, E.; Díaz-Paniagua, C., Gomez-Mestre, I. (2013): Plastic changes in tadpole trophic ecology revealed by stable isotope analysis. *Oecologia* 173(1): 95-105. (in English) ["Amphibian larvae constitute a large fraction of the biomass of wetlands and play important roles in

their energy flux and nutrient cycling. Interactions with predators and competitors affect their abundance but also their foraging behaviour, potentially leading to non-consumptive cascading effects on the whole trophic web. We experimentally tested for plastic changes in larval trophic ecology of two anuran species in response to competitors and the non-lethal presence of native and non-native predators, using stable isotope analysis. We hypothesized that tadpoles would alter their diet in the presence of competitors and native predators, and to a lesser extent or not at all in the presence of non-native predators. First, we conducted a controlled diet experiment to estimate tadpole turnover rates and discrimination factors using *Pelobates cultripis* and *Bufo calamita*. Turnover rates yielded a half-life of 15–20 days (attaining a quasi-isotopic equilibrium after 2 months), whereas discrimination factors for natural controlled diets resulted in different isotopic values essential for calibration. Second, we did an experiment with *P. cultripis* and *Rana perezi* (= *Pelophylax perezi*) where we manipulated the presence/absence of predators (*Anax imperator*, *Procambarus clarkii*) and heterospecific tadpoles using microcosms in the laboratory. We detected a significant shift in trophic status of both amphibian species in the presence of non-native crayfish: the  $\delta^{15}\text{N}$  values and macrophyte consumption of tadpoles increased, whereas their detritus consumption decreased. This suggests that tadpoles could have perceived crayfish as a predatory risk or that crayfish acted as competitors for algae and zooplankton. No dietary changes were observed in the presence of native dragonflies or when both tadpole species co-occurred. Stable isotopic analysis is an efficient way to assess variation in tadpoles' trophic status and hence understand their role in freshwater ecosystems. Here we provide baseline isotopic information for future trophic studies and show evidence for plastic changes in tadpoles' use of food resources under different ecological scenarios." **18299.** Colborne, S.F.; Peres-Neto, P.R.; Longstaffe, F.J.; Neff, B.D. (2013): Effects of foraging and sexual selection on ecomorphology of a fish with alternative reproductive tactics. *Behavioral Ecology* 24(6): 1339-1347. (in English) ["The foraging ecology of fish is often considered to be the primary determinant of body shape due to tight links between morphology, swimming performance, and foraging efficiency. Fish foraging on littoral benthic macroinvertebrates typically have a deeper body shape than those foraging on pelagic zooplankton in the water column. However, morphological traits often have multiple ecological functions, which could result in performance trade-offs between functions. Here, we provide the first examination of body shape and diet in a species with alternative reproductive tactics, in this case, bluegill sunfish (*Lepomis macrochirus* Rafinesque, 1819). Bluegill males mature into either "parental" or "cuckolder" reproductive tactics. Parentals build nests and provide sole parental care and defense of the young. Cuckolders instead act as "sneakers" darting into the nests of parental males while mating is occurring and then later in life become "satellites," mimicking female appearance and behavior. Using stable carbon and nitrogen isotopic analysis of diet, we found that parentals and females consumed primarily pelagic zooplankton yet were the deepest in body shape. Sneakers consumed more littoral resources but were the most streamlined. Satellite males also consumed predominately littoral resources but had a deeper body form that was more similar to females than to size-matched juveniles. Our results differ from past studies of foraging ecomorphology and suggest that other selection pressures, such as sexual selection in species with alternative reproductive tactics, may also be an important factor influencing shape. ... we collected the 5 most common littoral prey groups in Lake Opinicon (snails, amphipoda, isopoda, larval ephemeroptera, and larval Odonata)."] (Authors)] Address: Neff, B.D., Dept Biology, Univ.

(2013): Diet of the gracile mouse opossum *Gracilinanus agilis* (Didelphimorphia: Didelphidae) in a neotropical savanna: intraspecific variation and resource selection. *Acta Theriologica* 59(1): 183-191. (in English) ["Investigation of the effect of endogenous and exogenous factors on the diet of animals is necessary for a better understanding of their feeding habits. This approach can provide relevant information on the autoecology of a species and its ecological interactions. We investigated the composition and intraspecific variation in the diet of the marsupial *Gracilinanus agilis* in areas of dry woodland forests (i.e., cerrado) in the Cerrado of Central Brazil, taking into consideration the availability of prey (arthropods) in the environment. We found insects, spiders, birds, and fruits in the scats of *G. agilis*. Insects (orders Hymenoptera, Isoptera, Hemiptera, and Coleoptera) and fruits were the most frequently consumed resources. Males fed more heavily on insects than females did, whereas during the warm-wet season (October to April), the reproductive females fed on insects more than the nonreproductive females did. On the other hand, the consumption of fruits and vertebrates did not vary between seasons, sexes, or according to female reproductive condition. Moreover, reproductive females fed more frequently on ants and beetles than nonreproductive females did. We also detected both positive (for Isoptera and Hemiptera) and negative (for Hymenoptera) selection of insects during the cool-dry season, whereas in the warm-wet season, these resources were consumed according to their availability in the environment. Our study revealed that *G. agilis* is an insectivore-omnivore species, but fruits also are a relevant part of its diet. This marsupial seemed to select their prey qualitatively according to its energy demands and nutritional requirements." (Authors) Odonata: Percentage of the total number of samples (0,92%) and absolute frequency (N=4) of food items detected in 422 scat samples of *Gracilinanus agilis* in four areas of cerrado (closed woodland forest) located in central Brazil (Brasília, DF).] Address: Vieira, E.M., Laboratório de Ecologia de Vertebrados, Departamento de Ecologia, Instituto de Ciências Biológicas, CP 04457, Universidade de Brasília (UnB), Brasília, DF, 70919-970, Brazil. **18302.** Delpont, G. (2013): Étude de l'écologie et gestion conservatoire de *Leucorrhinia pectoralis* sur le territoire du Parc Naturel Régional des Volcans d'Auvergne. PNR des Volcans d'Auvergne: 111 pp. (in French) ["*L. pectoralis*, is a scarce and threatened dragonfly species. It is listed in Annexes II and IV of the UE Habitats Directive (92/43/EEC) and it is a protected species in France. In Auvergne (France), the Jolan peatbog is the only site where its reproduction has been proven. This peatbog is located in the Parc naturel régional des Volcans d'Auvergne and is integrated in a Natura 2000 site. The species is known to grow in former peatdiggings. Nowadays, this population is highly threatened because of its isolation and the small number of individuals. In order to apply conservation measures adapted to the local context, a characterization of larval habitats and a survey across the site were carried. The results of this study allowed to localize seven peatdiggings which are potentially favorable to *L. pectoralis*. They are isolated on a fen dominated by sedges (*Carex rostrata*). They are characterized by a depth approaching 3 meters, by the presence of water plants (*Utricularia minor*, *Sparganium minimum*, *Potamogeton natans*, ...) and by a high density of *Salix* sp groves around them. A reduced number of adults have been observed during a period of only 18 days. A single male territory has been inventoried on the only peatdiggings which has a free water area higher than 30%. Rapid evolution of other pits to advanced successional stages over the last years has been highlighted. This dynamic implies a decrease of the availability of suitable habitat for the species. Based on these findings, measures were built to restore breeding habitats of *L. pectoralis* in the Jolan peatbog in order to maintain the local population. Linked to these actions, a standardized survey protocol has been proposed. Beyond these emergency measures, management recommendations on a larger scale were given to ensure the sustainability of the population over the long term. In the future, it will be essential to gradually broaden the discussion to a larger scale in order to restore a network of favorable and interconnected sites." **18304.** Florencio, M.; Diaz-Paniagua, C.; Gomez-Rodriguez, C.; Serrano, L. (2013): Biodiversity patterns in a macroinvertebrate community of a temporary pond network. *Insect Conservation and Diversity* 7(1): 2-21. (in English) [Donana National Park (SW Spain) "(1.) Macroinvertebrate assemblages of temporary ponds are ideal model systems to explore biodiversity patterns and metacommunity ecology. In addition, the study of the environmental variables driving such biodiversity patterns is essential in establishing proper guidelines for the conservation of the singular fauna of temporary ponds, especially since such ponds are vulnerable systems. (2.) We analysed the macroinvertebrate assemblages and environmental characteristics of 80 ponds spread across the Donana National Park, SW Spain to (i) analyse macroinvertebrate b-diversity and metacommunity structure; and (ii) discern the main environmental and spatial drivers of these patterns. (3.) The pond network was highly heterogeneous as temporary ponds were highly variable. Macroinvertebrate b-diversity partitioning showed that species replacement made the greatest contribution to total b-diversity while the contribution of nestedness was small. The macroinvertebrate community structure and b-diversity were similarly driven by: electrical conductivity (and co-variables alkalinity, pH, and ion concentrations), plant richness (and the co-variable pond surface area), maximum depth, marsh, and coastal proximity as well as two spatial descriptors extracted from Moran's eigenvector maps. The spatial descriptors indicated that large interpond distances were involved, suggesting that species dispersal limitations only take place over long distances in the area. (4.) Those taxa that departed from the general nested pattern, termed idiosyncratic, significantly contributed to the maintenance of high pond network diversity through the species replacement and occurred within particular environmental conditions in the pond network. (5.) These results reveal that environmental heterogeneity and connectivity are key factors in the preservation of high macroinvertebrate diversity in nested pond networks with high numbers of idiosyncratic species. ...Odonatans preferred northern temporary ponds with the lowest conductivity values; for example *S. fonscolombii* was observed almost exclusively in these ponds." **18305.** Fontanarrosa, M.S.; Chaparro, G.N.; O'Farrell, I. (2013): Temporal and spatial patterns of macroinvertebrates associated with small and medium-sized free-floating plants. *Wetlands* 33(1): 47-63. (in English) ["Macrophytes play an important role in structuring communities in aquatic ecosystems due to their influence on ecological processes and attributes of biological aquatic assemblages. Freshwater macroinvertebrates comprise a functionally and taxonomically diverse group in shallow lakes, which serve as food for fish, amphibians, and water birds, and are involved in the breakdown of organic matter and nutrients. Here, we investigated macroinvertebrate assemblages associated with small and medium-sized free-floating plants (FFP) by describing their structure, analyzing functional aspects (considering functional feeding groups and habits), and determining how much of the variation in fauna composition is explained by environmental factors, mainly FFP. Differences in structure, functional feeding groups and habits of macroinvertebrate assemblages were associated with different compositions and percentages of cover of FFP. Gradients of richness and diversity of macroinvertebrates were positively related to the complexity of FFP mats, which was associated with the structure of roots and leaves." **18306.** Gering, E.J. (2013): Causes and consequences of color polymorphism in Rambur's forktail (*Ischnura ramburii*). PhD thesis, Faculty of the Graduate School of The University of Texas at Austin, University of Texas at Austin: XVI + 121 pp. (in English) ["Variation in male and female forms occurs in countless animal taxa, and has fascinated evolutionary biologists since Darwin and Wallace. The underpinnings of male variation have been elucidated in diverse groups; less is known about the selective forces that diversify female forms in nature. Female-polymorphic damselflies provide ideal systems in which to study how female variation evolves. Colour polymorphic damselflies typically contain one female morph that resembles the male ("andromorph") and one or more alternative morphs with distinctive coloration ("gynomorphs" or "heteromorphs"). My thesis draws upon the unique context of a biological invasion to elucidate factors that promote and maintain this variation in female colour. Empirical work in my dissertation is focused upon Rambur's Forktail (*Ischnura ramburii*), a species native to the Americas that invaded Hawaii in the 1970s. I first examine whether female colour morphs diverge in mating rates

or other reproductive traits within the native and invasive range, to see whether such traits might affect morph frequency dynamics in the invasion context (Chapter 2). Next, I test whether variation in selective regimes, both across female development and among populations, predicts variation in andromorph coloration (Chapter 3). Upon finding andromorphs to follow predictions of mimicry theory, I ask whether andromorph presence might result in increased male-male interaction rates, due to sex recognition errors (Chapter 4). Finally, I document recent, rapid evolution of andromorphy within Hawaii populations, and conduct mesocosm experiments to test the potential for density- and frequency-dependent selection to promote and maintain colour polymorphism. Results indicate 1) andromorphs may benefit from reduced mating, but male-like morphology may also incur reproductive constraints; 2) andromorph colour variation accords with mimicry theory: andromorphs resemble syntopic males, and resemblance is maximized after reproductive onset; 3) male-male interactions increase in the presence of andromorphs, to male detriment; 4) gynomorphs are subject to negative-frequency dependence in high-density populations, which may have driven the rapid evolution of andromorphy in Hawaii following introduction to the islands. These findings offer new insights into multiple mechanisms by which colour polymorphism can arise and be maintained within native and invasive contexts.] Address: Gering, E.J., Integrative Biology, University of Texas at Austin, 1 University Station C0930, Austin, TX 78712, USA

**18307.** Graf, W.; Chovanec, A.; Hohensinner, S.; Leitner, P.; Schmidt-Kloiber, A.; Waringer, J.; Ofenböck, G. (2013): Das Makrozoobenthos als Indikatorgruppe zur Bewertung großer Flüsse unter Einbeziehung aquenökologischer Aspekte. *Österreichische Wasser- und Abfallwirtschaft* 65(12): 386-399. (in German, with English summary) ["With the guideline 2000/60/EG, which called for the creation of a framework on water policy, the environmental policy of the European Community took on a new dimension. The goal of the guideline is (among others) the creation of a framework for the protection of inland surface waters, transitional waters, coastal waters and groundwater in order to avoid their deterioration; and to protect and improve the status of aquatic ecosystems, their associated land ecosystems directly dependent on them, and wetlands in terms of their water budget. Thanks to various forms of use, e.g. hydropower production, flood protection and ship traffic, especially major European rivers like the Danube, Rhine and Elbe have changed massively from their original typological characteristics. Reference conditions are hardly anywhere to be found, many native species are now extinct, and river biotopes are often dominated by invasive species. The size and depth of these rivers also pose challenges in terms of taking samples, and it has also become apparent that all methods currently used to assess rivers' ecological status focus solely on the main channels; the various habitats to be found in large rivers' riparian systems aren't taken into account. However, there is international consensus that these systems are key elements in rivers' processes and biodiversity, and as such are significant for the continuing functionality of major rivers. In

the context of an Austrian Ministry of Life-funded research project, the Institute of Hydrobiology and Aquatic Ecosystem Management's Working Group on Benthic Ecology and Ecological Status Assessment, together with the University of Vienna and the Environment Agency Austria, is currently working to develop a practice-oriented riparian zone index based on macrozoobenthos as an indicator of quality. To date, Europe has no Water Framework Directive-compliant assessment systems for riparian zones. Given the fact that established methods are limited to river's main channels, precluding a holistic view of and approach to river ecosystems, this project represents a pioneering work in the field of European water resource management.] Address: Chovanec, A., Umweltbundesamt, Spittelauer Lände 5, 1090, Wien, Austria. (2013): The evolutionary consequences of interspecific aggression. *Annals of the New York Academy of Sciences* 1289(1): 48-68. (in English) ["Competition has always been a cornerstone of evolutionary biology, and aggression is the predominant form of direct competition in animals, but the evolutionary effects of aggression between species are curiously understudied. Only in the past few years, existing theoretical frameworks have been extended to include interspecific aggression, and significant empirical advances have been made. After arguing that agonistic character displacement (ACD) theory provides the most suitable theoretical framework, we review new empirical evidence for ACD and the results of mathematical models of the process. We consider how ACD can be distinguished empirically from ecological and reproductive character displacement and the additional challenges posed by developmental plasticity. We also provide the first taxonomically broad review of theoretical and empirical work on the effects of interspecific aggression on species coexistence and range limits. We conclude by highlighting promising directions for future research on the evolutionary effects of interspecific aggression." **18309.** Guillermo-Ferreira, R.N. (2013): Morfologia funcional da coloração das asas em Odonata. Dissertation, Tese apresentada à Faculdade de Filosofia, Ciências e Letras de Ribeirão Preto da Universidade de São Paulo: IX + 150 pp. (in Portuguese, with English and Spanish summaries) ["In Nature, animals carry particularities such as courtship and territorial behaviors which show their conspicuous coloration and call the attention of scientists since the primordial ages of biological sciences. Several animal groups exhibit coloration patterns which are used as intraspecific signals for communication. These signals can be derived from pigments, structural colors, fluorescence and bioluminescence. Although such signals have been studied for more than a century, the functional morphology of colorful characters in animals have been underexplored. Therefore, this thesis had the goal of studying the morphology and optical properties of

sexual ornaments in insects of the order Odonata, regarding their function in reproductive and territorial behavior. Three Neotropical species of Odonata were used as models in this study: *Chalcopteryx scintillans* (Polythoridae), *Zenithoptera lanei* (Libellulidae) and *Mnesarete pudica* (Calopterygidae). The results obtained show the relationship between coloration and behavior in these species, suggesting that wing structures and pigmentation are signals used by these animals during sexual recognition, territorial contests and courtship behavior, with the potential role of individual quality indicators." **18310.** Ha, N.S.; Truong, Q.T.; Goo, N.S.; Park, H.C. (2013): Relationship between wingbeat frequency and resonant frequency of the wing in insects. *Bioinspiration & Biomimetics* 8(4):046008. 12 pp. (in English) ["In this study, we experimentally studied the relationship between wingbeat frequency and resonant frequency of 30 individuals of eight insect species from five orders: Odonata (*Sympetrum flaveolum*), Lepidoptera (*Pieris rapae*, *Plusia gamma* and *Ochloides*), Hymenoptera (*Xylocopa pubescens* and *Bombus rustricus*), Hemiptera (*Tibicen linnei*) and Coleoptera (*Allomyrina dichotoma*). The wingbeat frequency of free-flying insects was measured using a high-speed camera while the natural frequency was determined using a laser displacement sensor along with a Bruel and Kjaer fast Fourier transform analyzer based on the base excitation method. The results showed that the wingbeat frequency was related to body mass ( $m$ ) and forewing area ( $A_f$ ), following the proportionality  $f \sim m^{1/2}/A_f$ , while the natural frequency was significantly correlated with area density ( $f_0 \sim m_w/A_f$ ,  $m_w$  is the wing mass). In addition, from the comparison of wingbeat frequency to natural frequency, the ratio between wingbeat frequency and natural frequency was found to be, in general, between 0.13 and 0.67 for the insects flapping at a lower wingbeat frequency (less than 100 Hz) and higher than 1.22 for the insects flapping at a higher wingbeat frequency (higher than 100 Hz). These results suggest that wingbeat frequency does not have a strong relation with resonance frequency: in other words, insects have not been evolved sufficiently to flap at their wings' structural resonant frequency. This contradicts the general conclusion of other reports—that insects flap at their wings' resonant frequency to take advantage of passive deformation to save energy." LAP Lambert Academic Publishing: 100 pp. (in English) ["Dragonflies are predators, they themselves are subject to predation by frogs, spiders, fish, water bugs, birds, lizards, and even other large dragonflies. Dragonflies have great agricultural importance because they are voracious predators of those insects which are pest of many field crops. In the present studies about 600 specimens of the order Odonata were collected from the various localities, include sixteen species belonging to eleven genera, representing three families, two subfamilies of the suborder Anisoptera, and were described in detail with special reference to their male and female genitalia from Sindh, Pakistan. The research techniques and information are helpful for graduate and research students of Zoology, Entomology & Agricultural Sciences." (Publisher)

**18313.** Janssens, L.; Stoks, R. (2013): Predation risk causes oxidative damage in prey. *Ecology letters* 9(4): 20130350: 4 pp. (in English) ["While there is increasing interest in non-consumptive effects of predators on prey, physiological effects are understudied. While physiological stress responses play a crucial role in preparing escape responses, the increased metabolic rates and shunting of energy away from other body functions, including antioxidant defence, may generate costs in terms of increased oxidative stress. Here, we test whether predation risk increases oxidative damage in *Enallagma cyathigerum* damselfly larvae. Under predation risk, larvae showed higher lipid peroxidation, which was associated with lower levels of superoxide dismutase, a major antioxidant enzyme in insects, and higher superoxide anion concentrations, a potent reactive oxygen species. The mechanisms underlying oxidative damage are likely to be due to the shunting of energy away from antioxidant defence and to an increased metabolic rate, suggesting that the observed increased oxidative damage under predation risk may be widespread. Given the potentially severe fitness consequences of oxidative damage, this largely overlooked non-consumptive effect of predators may be contributing significantly to prey population dynamics." **18314.** Johansson, H (2013): Fish stocking and its effect on biodiversity in Hökensås area: A comparison of invertebrate fauna between lakes. BcS. Student thesis: 22 pp. (in Swedish, with English summary) ["Pisciculture has been

shown to affect biodiversity negatively, e.g. owing to increased nutrient loading and modified genetic set by breeding at other qualities than what is advantageous in the wild. The purpose of this study was to investigate which impact stocked fish has on the invertebrate fauna and thereby biodiversity. The study is performed at Hökensås area in Västra Götalands län, where there are about 20 lakes included in a sport fishing business. There are seven lakes included in the study; four which yearly became stocked with fish and three non-stocked. By bottom fauna samples invertebrate fauna has been collected, identified, counted and measured [including "Odonata"]. No significant differences have been detected between the lake groups considering diversity index, number of taxa or size of taxa. Nor has significant correlation between amount stocked fish/year- and (a) diversity index, (b) number of taxa been shown. A possible factor that may have affected the result is, from a statistical point of view, the low number of lakes, the varying qualities of the lakes and that the collecting of invertebrate fauna was performed too early in the year than optimal. Strong correlation between number of taxa and grade of acidification was detected." (Author)] Address: Johansson, Hanna, University of Skövde, School of Life Sciences

(2013): Bottom-up nutrient and top-down fish impacts on insect-mediated mercury flux from aquatic ecosystems. *Environmental Toxicology and Chemistry* 32(3): 612-618. (in English) ["Methyl mercury (MeHg) is one of the most hazardous contaminants in the environment; it adversely affects the health of both wildlife and humans. Recent studies have demonstrated that aquatic insects biotransport MeHg and other contaminants to terrestrial consumers, but the factors that regulate the flux of MeHg out of aquatic ecosystems via emergent insects have not been studied. We used experimental mesocosms to test the hypothesis that insect emergence [Libellulidae] and the associated flux of MeHg from aquatic to terrestrial ecosystems is affected by both bottom-up nutrient effects and top-down fish consumer effects. In the present study, nutrient addition led to an increase in MeHg flux primarily by enhancing the biomass of emerging insects whose tissues were contaminated with MeHg, whereas fish decreased MeHg flux primarily by reducing the biomass of emerging insects. Furthermore, we found that these factors are interdependent such that the effects of nutrients are more pronounced when fish are absent, and the effects of fish are more pronounced when nutrient concentrations are high. The present study is the first to demonstrate that the flux of MeHg from aquatic to terrestrial ecosystems is strongly enhanced by bottom-up nutrient effects and diminished by top-down consumer effects." **18318.** Kolariková, K.; von Tümpling, W.; Bartels, P. (2013): Bioaccumulation of HCH isomers in selected macroinvertebrates from the Elbe River: sources and environmental implications. *Environmental Monitoring and Assessment* 185(5): 4333-4346. (in English) ["Sediments of the Elbe River have been extremely polluted by contaminants originating from previous large-scale hexachlorocyclohexane (HCH) production and the application of  $\gamma$ -HCH (lindane) in its catchment in the second half of the twentieth century. In order to gain knowledge on bioaccumulation processes at lower trophic levels, field investigations of HCHs in macroinvertebrates were carried out along the longitudinal profile of the Elbe and tributary. Among the sites studied, concentrations in macroinvertebrates ranged within five orders of magnitude (0.01–100  $\mu\text{g}/\text{kg}$ ). In general, lower values of HCH isomers were observed at all Czech sites (mostly <1  $\mu\text{g}/\text{kg}$ ) compared with those in Germany. At the most contaminated site, Spittelwasser brook (a tributary of the Mulde), extremely high concentrations were measured (up to 234  $\mu\text{g}/\text{kg}$   $\alpha$ -HCH and 587  $\mu\text{g}/\text{kg}$   $\beta$ -HCH in *Hydropsychidae*). In contrast, the Obríství site, though also influenced by HCH production facilities, showed only negligibly elevated values (mostly <1  $\mu\text{g}/\text{kg}$ ). Results showed that fairly high levels of  $\alpha$ -HCH and  $\beta$ -HCH compared to  $\gamma$ -HCH can still be detected in aquatic environments of the Elbe catchment, and these concentrations are decreasing over time to a lesser extent than  $\gamma$ -HCH. Higher HCH concentrations in sediments in the springtime are considered to be the result of erosion and transport processes during and after spring floods, and lower concentrations at sites downstream are thought to be caused by the time lapse involved in the transportation of contaminated particles from upstream. In addition, comparison with fish (bream) data from the literature

revealed no increase in tissue concentrations between invertebrates and fish." (Authors)] Address: Kolariková, Kateřina, Institute for Environmental Studies, Charles University, Benátská 2, 128 01, Praha 2, Czech Republic. E-mail: katarina.kolarikova@natur.cuni.cz

**18319.** Kremer, P. (2013): Entwicklung, Interpretation und Vergleich von ökologischen Nischenmodellen ausgewählter Segellibellen (Odonata: Libellulidae) in Deutschland. Wissenschaftliche Prüfungsarbeit gemäß §12 der Landesverordnung über die Erste Staatsprüfung für das Lehramt an Gymnasien vom 07. Mai 1982, in der derzeit gültigen Fassung der Johannes Gutenberg-Universität in Mainz, Fach: Biologie: 90 pp. (in German) ["The ecological niche is defined as an n-dimensional hyperspace composed of the sum of all abiotic and biotic environmental factors in which a species can survive and reproduce. Each living being has its specific ecological niche, limited by the total amount of tolerance areas, which can be modelled by known information about a species. Dragonflies are considered bioindicators that indicate the condition of water bodies and make the influence of climate change clear through migration. On the one hand, they are of great ecological importance, and on the other hand, there is a very high level of knowledge about these relatively large insects. Therefore, they are very suitable objects for niche modelling. Libellulidae are the most species-rich family within the Anisoptera. In this work, I created ecological niche models for nine of the 22 species of damselfly found in Germany. I was interested in whether it is generally possible to create niche models for dragonflies. I also checked how well the models can predict the actual distribution and how differences in the quality of the models come about. I then investigated whether the models could be transferred to other geographical areas. The study area comprised the eight southern German states of Baden-Württemberg, Bavaria, Rhineland-Palatinate, Saarland, Hesse, Thuringia, Saxony and North Rhine-Westphalia. Abiotic environmental parameters and distribution data of the species at mixed table leaf level were used as prediction parameters. The study period covers the years 1991 to 2006. 127 initial parameters were used, which were tested for correlation in pairs. There remained 61 and 62 independent parameters, respectively, which were used in the calculation of the models. The model calculation was carried out with the Maximum Entropy Method (MaxEnt). In order to incorporate the strongly correlated climate parameters into the models, four basic models were first created for each species. The climate parameters used were adapted to the life cycle of the dragonflies and were tested individually in the basic models. The basic models were gradually reduced to a few parameters and a final model was created for each of the nine species. The results were validated both in the study area (internally) and in the five northern federal states of Saxony-Anhalt, Brandenburg, Lower Saxony, Schleswig-Holstein and Mecklenburg-Western Pomerania (externally). For validation, the average AUC value, kappa, sensitivity and specificity were determined. The results varied greatly in terms of quality (AUC values between 0.518 and 0.968). Two models had very low quality. For seven species, I was able to model the ecological

niche and it was possible to create raster maps with distribution predictions of good to very good quality for the study area. The model parameters could be explained with the help of the habitat requirements of the respective species. A correlation was found between the AUC values and the number of occupied survey table sheets of the respective species. The more frequently the species occurred in the study area, the lower the AUC values achieved. This could explain the differences in model quality. For the external validation area, only very low values for sensitivity and kappa were achieved. It was not possible to transfer the model to the validation area and produce raster maps with distribution predictions. For dragonflies in general, several relevant parameters could be identified. Temperature plays the decisive role. Especially for the endangered and threatened species, models of high quality could be created, which makes it possible to identify habitats worth protecting and to stop their destruction or to renature them." (Author, DeepL)] Address: not stated

**18322.** MacColl, A.D.C.; El Nagar, A.; de Roij, J. (2013): The evolutionary ecology of dwarfism in three-spined sticklebacks. *Journal of Animal Ecology* 82(3): 642-652. (in English) ["Body size is a defining phenotypic trait, but the ecological causes of its evolution are poorly understood. Most studies have considered only a single putative causal agent and have failed to recognise that different environmental agents are often correlated. Darwin suggested that although trait variation across populations is often associated with abiotic variation, evolution is more likely to be driven by biotic factors correlated with the abiotic variation. This hypothesis has received little explicit attention. We use structural equation modelling to quantify the relative importance of abiotic (pH, metal concentrations) and biotic (competition, predation) factors in the evolution of body size in three-spined sticklebacks *Gasterosteus aculeatus* on the island of North Uist, Scotland. We combine phenotypic data from multiple isolated populations, detailed characterisation of their environment and a common garden experiment that establishes the genetic basis of size differences. Three-spined sticklebacks on North Uist show almost unprecedented intraspecific evolution of body size that has taken place rapidly (<16 000 years). The smallest fish mature at only 7% of the mass of ancestral, anadromous fish. Dwarfism is associated with reduced abundance of a smaller competitor species, the nine-spined stickleback *Pungitius pungitius*, and with low pH indicative of poor resource conditions. Dwarfism also tends to occur where an important predator, the brown trout *Salmo trutta*, is also small. The abundance of *P. pungitius* and the size of *S. trutta* are themselves related to underlying abiotic environmental variation. Despite the close association between abiotic and biotic factors across populations, our results support Darwin's hypothesis that biotic factors, associated with variation in the abiotic environment, are more important in explaining evolution than is abiotic variation per se. This study demonstrates the importance of considering the relationships between environmental variables before conclusions can be drawn about the causes of (body size) evolution on islands." (Authors) *Aeshna juncea* and *Sympetrum* spp. larvae are present at low density where there is emergent vegetation, which is rare in the North Uist lochs.] Address: MacColl, A., School of Biology, Univ. London B Biol. Sci.* 368(1619): 9 pp. (in English) ["Large-scale cattle and crop production are the primary drivers of deforestation in the Amazon today. Such land-use changes can degrade stream ecosystems by reducing connectivity, changing light and nutrient inputs, and altering the quantity and quality of streamwater. This study integrates field data from 12 catchments with satellite-derived information for the 176 000 km<sup>2</sup> upper Xingu watershed (Mato Grosso, Brazil). We quantify recent land-use transitions and evaluate the influence of land management on

streamwater temperature, an important determinant of habitat quality in small streams. By 2010, over 40 per cent of catchments outside protected areas were dominated (greater than 60% of area) by agriculture, with an estimated 10 000 impoundments in the upper Xingu. Streams in pasture and soya bean watersheds were significantly warmer than those in forested watersheds, with average daily maxima over 4°C higher in pasture and 3°C higher in soya bean. The upstream density of impoundments and riparian forest cover accounted for 43 per cent of the variation in temperature. Scaling up, our model suggests that management practices associated with recent agricultural expansion may have already increased headwater stream temperatures across the Xingu. Although increased temperatures could negatively impact stream biota, conserving or restoring riparian buffers could reduce predicted warming by as much as fivefold." **18325.** McGoff, E.; Aroviita, J.; Pilotto, F.; Miler, O.; Solimini, A.G.; Porst, G.; Jurca, T.; Donohue, L.; Sandin, L. (2013): Assessing the relationship between the Lake Habitat Survey and littoral macroinvertebrate communities in European lakes. *Ecological Indicators* 25: 205-214. (in English) ["Implementation of the EU Water Framework Directive (WFD) has drawn much attention to hydromorphological alterations of surface waters. The Lake Habitat Survey (LHS) protocol provides a method for characterising and assessing the physical habitats of lakes and reservoirs. Two metrics were developed based on this method: the Lake Habitat Modification Score (LHMS) and the Lake Habitat Quality Assessment (LHQA), as measures of lake modification and habitat value, respectively. However, the use of these metrics to predict measures of ecological quality remains largely untested. Thus, we assessed the relationships between LHS metrics and the littoral macroinvertebrate community in 42 lakes across Europe. A significant relationship was found between littoral macrophyte descriptors and riparian natural land cover variables of the LHQA score and macroinvertebrate community composition in 2 out of 4 European regions. No relationship was found between macroinvertebrate community composition and the LHMS. Some significant correlations were found between selected macroinvertebrate metrics and the LHS scores, but this pattern was not consistent across regions, and no relationship was found with the overall LHMS or LHQA scores. This demonstrates that the LHS metrics do not consistently predict the quality

of littoral macroinvertebrate communities across Europe, and a region specific approach may be necessary. However, we could demonstrate a relationship between the site specific LHS variables and the macroinvertebrate community at the site level, and in some cases at the regional level. Therefore, although the LHS metrics do not appear to be a useful for relating habitat quality and pressure to littoral macroinvertebrate communities, selected LHS variables may exhibit stronger relationships with the biota." **18326.** Meng, X.G.; Sun, M. (2013): Aerodynamic effects of wing corrugation at gliding flight at low Reynolds numbers. *Phys. Fluids* 25, 071905 (2013); doi: 10.1063/1.4813-804: 15 pp. (in English) ["Corrugation gives an insect-wing the advantages of low mass, high stiffness, and low membrane stress. Researchers are interested to know if it is also advantageous aerodynamically. Previous works reported that corrugation enhanced the aerodynamic performance of wings at gliding flight. However, Reynolds numbers considered in these studies were higher than that of gliding insects. The present study showed that in the Reynolds number range of gliding insects, corrugation had negative aerodynamic effects. We studied aerodynamic effects of corrugation at gliding motion using the method of computational fluid dynamics, in the Reynolds number range of  $Re = 200-2400$ . Different corrugation patterns were considered. The effect of corrugation on aerodynamic performance was identified by comparing the aerodynamic forces between the corrugated and flat-plate wings, and the underlying flow mechanisms of the corrugation effects were revealed by analyzing the flow fields and surface pressure distributions. The findings are as follows: (1) the effect of corrugation is to decrease the lift, and change the drag only slightly at  $15^\circ-25^\circ$  angles of attack, lift is decreased by about 16%; at smaller angles of attack, the percentage of lift reduction is even larger because the lift is small). (2) Two mechanisms are responsible for the lift reduction. One is that the pleats at the lower surface of the corrugated wing produce relatively strong vortices, resulting in local low-pressure regions on the lower surface of the wing. The other is that corrugation near the leading edge pushes the leading-edge-separation layer slightly upwards and increases the size of the separation bubble above the upper surface, reducing the "suction pressure," or increasing the pressure, on the upper surface." **18327.** Mikołajczuk, P. (2013): New sites of Pygmy Damselfly *Nehalennia speciosa* (Charpentier, 1840) (Odonata: Coenagrionidae) in the southern part of Podlasie with notes on ecology and species mobility. *Odonatrix* 9(1): 1-12. (in Polish, with English summary) ["The Author discusses 7 new sites of *N. speciosa* in the southern Podlasie (central-eastern Poland). Two of them (no. 4 and 5) are situated within

agricultural landscape and have no forest buffering zone. It shows that the environment without forest surrounding but with suitable spatial structure of vegetation – a key factor for *N. speciosa* – can be inhabited by this species. Microhabitat preferences of Pygmy Damselfly found during studies were interesting. Except for sedge species given in the literature as most preferable plant species by *N. speciosa*, at sites discussed in this paper the leading plant components for this species were *Equisetum fluviatile* (sites 4 and 5) and *Eriophorum vaginatum* (site 2). These are, respectively, only the fourth and second confirmed records of this kind in Poland. At two sites within the study area imagines as well as larval development in larger patches of *Carex vesicaria* (site 6 in this paper) were also found. Moreover, at one of them, many larvae were collected in the aggregation of *Eriophorum angustifolium*. At both known sites with *E. vaginatum* imagines were present in its clumps while larvae – at their bases and probably in spaces between, with flooded *Sphagnum*. These are the examples of inconsiderable spatial separation of larval and imaginal habitats although they were close. The similar situation was found in south-eastern Poland, where *Molinia caerulea* grew on land in the direct neighbourhood to a flooded peat bog excavation. *Carex elata* as the leading plant component was found at one of the sites from eastern Mazowsze. The clumps of *C. elata* were not massive and did not display typical hummock-hollow structure. Loose clump formations of *Carex* sp. (*C. elata* probably) are also known at one site in south-eastern Poland. All of these observations confirm that ecological plasticity and habitat spectrum of *N. speciosa* are bigger than previously thought. Presented data shows the ability of *N. speciosa* for the colonization of new sites. Site 3 was not the place of development: the observed individuals are the example of dispersion. However, site 2 had originally the character of a bog forest with large trees. Suitable conditions appeared there until 2011 due to a record increase in groundwater level and the death of almost all the trees – the site was colonized in this year. Distance from the nearest active site is ca. 400 and 700 m. Therefore *N. speciosa* is fully mobile, at least for close distances (ca. 1 km) and certainly these are not exceptional cases. Many sites of *N. speciosa* in southern Podlasie dry up partly or entirely during dry summers. At some of them the periods without water could be longer than hydration periods. It is not clear whether the presence of the species in many of these sites is the result of surviving by the larvae unfavourable hydrological conditions, or rather the result of colonization. Clarification of this issue should provide further observations of dried sites in the year 2012." (Author)] Address: Mikołajczuk, P., ul. Partyzantów 59c/26, 21-560 Międzyrzec Podlaski, Poland. **18328.** Miler, O.; Porst, G.; McGoff, E.; Pilotto, F.; Donohue, L.; Jurca, T.; Solimini, A.; Sandin, L.; Irvine, K.; Aroviita, J.; Clarke, R.; Pusch, M.T. (2013): Morphological alterations of lake shores in Europe: A multimetric ecological assessment approach using benthic macroinvertebrates. *Ecological Indicators* 34: 398-410. (in English) ["Besides pollution, lakes are affected by human alterations of lake-shore morphology.

However, ecological effects of such alterations have rarely been studied systematically. Hence, we developed tools to assess the ecological effects of anthropogenic morphological alterations on European lake-shores based on pressure-specific response patterns of littoral macroinvertebrate community composition. Littoral invertebrates were sampled from 51 lakes in seven European countries. Sampling covered a range of natural to heavily morphologically degraded sites including natural shorelines, recreational beaches, ripraps and retaining walls. Biological data were supplemented by standardized morphological data that were collected via a Lake Habitat Survey (LHS) protocol and subsequently used to develop a morphological stressor index. Two biotic multimetric indices were developed based on habitat-specific samples (Littoral Invertebrate Multimetric based on Habitat samples, LIMHA) and composite samples (Littoral Invertebrate Multimetric based on Composite samples, LIMCO) through correlations with the morphological stressor index. Similarity analyses showed strong spatial differences in macroinvertebrate community composition between four main geographical regions, i.e. Western, Northern, Central and Southern Europe. The morphological stressor index as well as LIMCO and LIMHA have been developed for each geographical region specifically, thereby optimizing correlations of LIMCO and LIMHA with the respective morphological stressor index. The metric composition of LIMCO and LIMHA and their correlation coefficients with the morphological stressor index are comparable to existing national and regional methods that assess morphological lakeshore degradation via macroinvertebrate communities. Hence, LIMCO and LIMHA indices constitute a new stressor-specific assessment tool that enables comparable lake morphology assessment across Europe, as it has been developed involving a uniform methodology followed by regionalized optimization. These tools fulfil the standards of the EU Water Framework Directive and thus may complement existing assessment approaches used in lake monitoring focusing solely on lake eutrophication so far." **18330.** Monvoisin, C. (2013): Etude des cortèges d'Anisoptères des cours d'eau et de l'implication des microhabitats ligneux dans leur répartition. Rapport de stage Master 1 Patrimoine Naturel et Biodiversité, UFR SVE: 23 pp. (in French) ["The study was carried out on sections of four rivers in the Pays de la Loire region: the Sèvre nantaise (between the Grossière bridge and Terbin, in Boussay), the upstream part of the Erdre (between Nort sur Erdre and Joué sur

Erdre), the Huisne (between Saint Mars La Brière and Monfort le Gesnois and between Brêteau and Vouvray sur Huisne), and the upstream part of the Mayenne (between Gué de Loré and la Frétière). Conclusion: Anisopteran species and their environment are linked by complex relationships that are difficult to define. Multiple factors are involved throughout their life cycle. The effects of certain variables such as the nature of the sediments, the nature and presence of hydrophytes, helophytes, herbaceous plants as well as the physico-chemical quality of the water have yet to be studied on these rivers. Furthermore, the sampling carried out could not be standardised in terms of the total length of bank surveyed per river, so comparisons between sites seem less relevant. Research must be continued over several years and several rivers to try to define the factors involved in the presence of particular species of Anisoptera." **18331.** Morgenstern, R. (2013): Vergleich von Nischenmodellen bei Libelluliden (Odonata). Diplomarbeit Johannes-Gutenberg Universität Mainz Fachbereich Biologie. Institut für Zoologie, Abteilung Ökologie, Johann-Joachim-Becherweg 13, 55128 Mainz: 58 pp, appendix- (in German) ["The concept of the ecological niche, established by Hutchinson in 1958, is still relevant today. The underlying principle, namely that a species has a certain fitness along the gradients of certain environmental parameters, is used in current studies to predict, for example, the distribution or the change in distribution of a species under certain conditions. In this work, I investigated the similarities and differences of niche models within two genera of the damselfly family. I also tested whether species with more occurrences or rarer species could be modelled better. For this purpose, I first collected data on topography, land use, landforms and climate for all federal states in Germany, in addition to occurrence data for the 13 species of the two genera *Orthetrum* and *Sympetrum*. From these raw data, I created 127 prognostic variables, which were then tested for correlation with each other in order to use only parameters in the models that do not correlate with each other. This allowed me to calculate five seasonally different niche models for each species using MaxEnt software and validate the best ones internally and externally. For this purpose, I chose central and southern Germany as the internal model creation space and northern Germany as the external validation space. The specificity, sensitivity and kappa value were used for validation. It turned out that all models produced an AUC value (goodness of fit measure from 0 to 1) above 0.5, which made them better than a model based on random predictions. However, only for the less widespread species were very good niche models found with AUC values above 0.7. These good models used temperature parameters most often, indicating the thermophily of damselflies, because as temperatures increased, so did the probabilities of occurrence. In addition, it became apparent that soil pH values seem to play a greater role than previously assumed, as these also very often played an important role in the niche models. However, the models created for Central and

Southern Germany did not transfer so well to the external validation area of Northern Germany, which could probably be due to the very different characteristics of the two areas as well as the fact that a complete fitness curve, i.e. niche mapping, was not achieved for all parameters. As a conclusion, it can be said that the niche modelling of the damselflies was quite successful and that the results of this work were also found in the other genera of the family. For more comprehensive models that can be better transferred to unknown territory, a finer observation level, a larger study area, more specific parameters or a combination of these three is probably necessary. After all, Germany only represents a section of the total distribution of the species studied, and the chosen level of observation and the characteristics studied do not seem to lead to the desired results for all species." **18334.** Siepielski, A.M.; Wang, J.; Prince, G. (2013): Non-

consumptive predator driven mortality causes natural selection on prey. *Evolution* 68(3): 696-704. (in English) ["Predators frequently exert natural selection through differential consumption of their prey. However, predators may also cause prey mortality through non-consumptive effects, which could cause selection if different prey phenotypes are differentially susceptible to this non-consumptive mortality. Here we present an experimental test of this hypothesis, which reveals that non-consumptive mortality imposed by predatory dragonflies causes selection on their damselfly prey favouring increased activity levels. These results are consistent with other studies of predator driven selection, however, they reveal that consumption alone is not the only mechanism by which predators can exert selection on prey. Uncovering this mechanism also suggests that prey defensive traits may represent adaptations to not only avoid being consumed, but also for dealing with other sources of mortality caused by predators. Demonstrating selection through both consumptive and non-consumptive predator mortality provides us with insight into the diverse effects of predators as an evolutionary force." **18336.** Soucek, D.J.; Levenson, J.M.; Gallo, S.; Hill, W.R.; Bordson, G.O.; Talbot, J.L. (2013): Risks to birds in the Lake Calumet region from contaminated emergent aquatic insects. RR Series (Illinois Sustainable Technology Center); RR-122: 76 pp. (in English) ["The highly industrialized Grand Calumet River basin includes an extensive wetlands complex that has been severely degraded through heavy industrial activity, sewage and industrial discharges, landfills, and hazardous waste storage/disposal. Sediments and other environmental media in this area are contaminated with heavy metals and organic compounds. Our objective was to empirically quantify risks to insectivorous birds in the Lake Calumet wetlands region from contaminated sediments via ingestion of aquatic insects using tree swallows (*Tachycineta bicolor*) as a model organism. To accomplish this objective, we completed the following tasks: (1) assessed organic contaminant transfer (polychlorinated biphenyls [PCBs], organochlorine pesticides, polybrominated diphenylethers [PBDEs]) from an aquatic ecosystem (sediment

and benthic macroinvertebrates) to a terrestrial food chain (tree swallows feeding on emergent aquatic insects), (2) quantified elemental contaminants in these locales and biota, (3) evaluated ecological effects these contaminants may have on tree swallows, comparing mercury loads and nesting ecology data at different sites as a case study, and (4) assessed the value of stable isotope data in determining how food chain length and food source (aquatic versus terrestrial, location of origin) affects contaminant loads in tree swallows nesting at Lake Calumet wetlands. With the exception of timing of nest initiation and other variables that are dependent on nest initiation timing (e.g., clutch size, and nestling mass), we observed no differences among sites in tree swallow nesting ecology endpoints. A variety of inorganic and organic contaminants were accumulated by nestlings via their insect diets, but concentrations of nearly all the contaminants were at the lower end of ranges in the literature. The exception to this trend was dichlorodiphenyldichloroethylene (DDE) concentrations in eggs and nestlings at Big Marsh which were among the higher reported values. To our knowledge, this paper is the first report of PBDEs concentrations in tree swallow nestlings. Our stable isotope analysis suggested a terrestrial origin for many of the contaminants as has been suggested by others." (Authors)] Address: not stated

**18337.** Susmita, G.; Sushmita, D.; Pinki, P. (2013): Use of aquatic insects in Water quality assessment of ponds around two cement factories of Assam, India. *International Research Journal of Environment Sciences* 2(7): 15-19. (in English) ["Present study was carried out using aquatic insects as bio monitors in a few ponds located near Badarpur and Bokajan cement factories, Assam, North East India. Study revealed presence of aquatic insect order Hemiptera, two families (Gerridae and Notonectidae) and three species (Anisops sp., Gerris sp. and Buena sp.) from the ponds located around Cement factory, Badarpur. Anisops sp. was found eudominant in all the ponds except pond 1 where Gerris sp. was eudominant. Ponds (pond 5 and 6) located around Bokajan Cement Factory revealed presence of two aquatic insect orders (Hemiptera and Odonata), five families (Notonectidae, Gerridae, Nepidae, Coenagrionidae and Libellulidae) and eight species (Gerris sp., Anisops sp., Limnometra sp., Ranatra sp., Pseudogriion sp., Ischnura sp., Libellula sp., Sympetrum sp.). In Pond 5, Gerris sp. was found eudominant. In Pond 6, Anisops sp. was found eudominant. In each of the five ponds diversity index (Shannon H' Log Base 10) values were found less than 1 where as signal values were found less than 5.5. Study reported low diversity and occurrence of only tolerant group of aquatic insects in the aquatic systems around the cement factories confirming the fact that aquatic insects are good indicator of water quality." **18340.** Varshney, P.K.; Agrahari, R.K.; Singh, S.K.; Yadav, A.K.; Pandey, A.K. (2013): Biological diversity of live food spectrum at Maa Chandrika Devisite in upstream of river Gomti in Lucknow (India). *Journal of Ecophysiology & Occupational Health* 12(3/4) (2012): 113-127. (in English) ["An upstream location along the course of river Gomti in Lucknow, Maa Chandrika Devi, was identified for the present study. The water quality of the river at the site was moderate with mean DO 6.15 mg l<sup>-1</sup> whereas nitrate (22.70 mg l<sup>-1</sup>), phosphate (2.40 mg l<sup>-1</sup>) and COD (48.72 mg l<sup>-1</sup>) were high. The high concentration of nutrients as well as COD during pre-monsoon may be due to low precipitation and influx of effluents during summer. Phytoplanktons were represented by Chlorophyceae, Bacillariophyceae and Xanthophyceae. Phytoplankton mainly contributed by Gonatozygon (10.89%), Closteridium (30%), Cladophora (34.94%) and Cosmerium (14.49%). Protozoa, Ostracoda, Rotifera, Cladocera, Copepoda, Diptera and Oligochaeta were the zooplankton phyla. The dominant zooplankton genera were Brachionus (13.38%), Daphnia (5.55%), Moinodaphnia (6.94%), Cyclops (22.22%), Mesocyclops (11.11%) and Diaptomus (8.33%) apart from worms (8.33%). Benthic fauna was represented by Oligochaeta, Chironomus, Crustacea, Diptera, Odonata, Nematoda, Pelecypoda, Gastropoda and leech. Chironomus with contribution of 54.09% dominated the fauna. Other predominant groups were Oligochaeta (20.16%), Pelecypoda (16.57%) and Diptera (4.99%). In general, high population density of phytoplankton, zooplankton and benthos were encountered during premonsoon season. Low population of zooplankton compared to phytoplankton and increasing number of rotifers next to copepods and cladocerans as well as presence of protozoans indicated substantial load of organic matter. The organic pollution indicator benthic species like Branchiura, Tubifex, Chironomus, Cullicoid larvae (Diptera), Lamellidans, Corbicula, Lymnaea and leech also supported the polluted environment. Shannan-Wiener index of less than 1 for Diptera, Gastropoda and Pelecypoda indicated the stressed environment. Low abundance of plankton population in spite of high nutrient budget of the ecosystem was the function of great infestation of water quality which indicated extreme state of pollution." **18342.** Zurawlew, P. (2013): Dragonflies (Odonata) of the borderland between the Kalisz High Plain and Rychwalska Plain (Great Poland). *Odonatrix* 9(2): 33-54. (in Polish, with English summary) ["Paper summarizes six-year long (2007–2012) studies on dragonflies (Odonata) in the county of Pleszew (Western Poland) as well as the eight border sites located in the area of adjacent counties (Fig. 1). The whole area is in the macroregion of the Południowopolska Lowland, in the borderland of two mesoregions: the Kalisz High Plain and Rychwalska Plain. The research was aimed at understanding the species composition of dragonflies and discovering as many sites of rare species as possible. 58 sites lying on the Kalisz High Plain and 85 sites located in the Rychwalska Plain were controlled. Noteworthy is the presence of tens Sphagnum peat bogs in the studied part of the Rychwalska Plain. ... Most of the sites were controlled irregularly (mainly between June and August), often only once. The records of particular species were differentiated into three categories: 1) development confirmed (larvae, exuviae, teneral imagines, intensive reproductive behavior – copulations, tandems, laying eggs), 2) development likely (single reproductive behavior, territorial imagines, a large population in the environment suitable for development), 3) development possible (single imagines observed only). In the years 2007–2012 in the discussed area 55 species of dragonflies were recorded (data in this paper), as well as *Aeshna juncea* given earlier (Bernard, Tończyk 2011). Total number of 56 species comprise 77% of the species reported in Poland so far (Bernard et al. 2009). For many species important information clearly enriching the knowledge of their distribution in this part of Poland was collected. This particularly refers to the species associated with Sphagnum bogs (*Aeshna subarctica*, *Leucorrhinia albifrons*, *L. dubia* and *L. rubicunda*), thermophilous species (*Aeshna affinis*, *Orthemis albistylum*, *O. brunneum*, *O. coerulescens*, *Crocothemis*

*erythraea*, *Sympetrum fonscolombii* and *S. meridionale*) as well as rare and very rare in south-western Poland (*Lestes barbarus*, *Sympecma paedisca*, *Coenagrion lunulatum*, *Epi-theca bimaculata* and *Leucorrhinia caudalis*). Protection of the studied Sphagnum peat bogs, where many rare and protected species of vascular plants (Zurawlew & Zurawlew 2010) and the dragonflies (this study) are present, should be one of the priorities of the Forestry Grodziec managing this area. The four tables given in this paper show: studied habitats with the number of species (Tab. 1), a list of the sites of all species and the observed flight period (Tab. 2), the sites with the highest number of species (Tab. 3) and the listing of the occurrence of dragonflies for 15 UTM squares covering the studied area (Tab. 4)." ## 2014

**18343.** Hanciková, B. (2014): Local dispersal of golden-ringed dragonfly *Cordulegaster boltonii* - Lokální disperse páskovce *Cordulegaster boltonii*. MSc. thesis, Faculty of Science, Department of Ecology, Univerzita Karlova, Praha: 47 pp. (in Czech, with English summary) ["We carried out a pilot study of local dispersion and patterns of movement of *C. boltonii*. *Cordulegasteridae* is a family with many primitive traits present and rather restricted geographical distribution ranges (at least among European species). Their migration seems to be limited despite the body size that predetermines them to high mobility over large spatial scale. Linear habitat (upper parts of narrow forest streams) specialisation along with behavioural ecology (peculiar premating habit of scanning streams for females) is a unique life history, which bring lot of questions. We collected mark-release-recapture data during two adult flight seasons in year 2010 and 2011. We were simultaneously capturing patrolling males along three separate streams (Dracice, Koštenický and Struha) in total length of 9.9 km in, located in the Natural park Česká Kanada, in the Southern Czech Republic. We captured and marked 440 individuals and recorded 113 recapture events (26 % recapture rate) in year 2010 and 355 individuals were marked, 171 recapture events made (48 % recapture rate) in 2011. Our data suggested high level of stream fidelity (only 10 inter stream dispersal events, 2.8 % dispersal rate). What was as well reflected in a closeness of population estimated by Craig analyse. Patrolling males had home range about 250 m, home ranges had large overlaps that resulted in a high-density male cooccurrence not territoriality. Despite general expectation males rather stayed within favoured and crowded patch than moved into a bit more unfavourable low density patches, which were readily being abandoned. There was not observed a correlation between female (even though very rare) visits and patches favoured by males. We have not found any preference for patrol flight direction (upstream vs. downstream). During sampling we observed interesting behavioural interaction when we found that time schedule of patrolling males on streams is not random and a large proportion of males were patrolling subsequently within one minute interval." **18345.** Morikawa, M.; Akihito, A.; Kobayashi, T. (2014): The litter supply regulates the structure of the dragonfly larva community. Journal of the Japanese Society of Vegetation Technology 39(1): 15-20. (Japanese, with English summary) ["The species diversity and population of dragonfly larvae are spatially different. In this study, we did mesocosm experiments to examine the effect of litter supply on the dragonfly larvae community. Size and species composition of dragonfly larvae and presence / absence of chironomid, a food resource for dragonfly larvae, were also controlled in the experiment. The results indicated that the litter provide the hiding places for small larvae, and consequently extend the survival time of them. Therefore, the litter supply regulates the structure of the dragonfly larva community." (Authors)] Address: E-mail : masatonium@yahoo.co.jp

**18346.** Ojha, N. (2014): A new tool for predicting distribution patterns of African dragonflies in space and time: sensitivity analyses of model parameters and environmental variables. PhD. thesis, Faculty of Environment and Natural Resources, Albert-Ludwigs-Universität, Freiburg im Breisgau, Germany. xvi, 154 pp. (in English) [*Pseudagrion kersteni* "In the last few decades, Africa has been a dynamic continent regarding the changes in landscape, population and climate. To identify effects of the changes in environmental conditions on biodiversity, species distribution modelling (SDM) can be of use and SDM has been used in wide array of ecological applications such as determining hotspots, planning of reserves, designing survey for biodiversity inventory, or assessing the impacts of environmental change on biodiversity. Odonata which require both terrestrial and aquatic ecosystem for a lifecycle, is suitable species to consider as flagship species for many ecological studies. Here, a logistic regression based new SDM tool, the 'SpeeDi Tool' is presented focusing on modelling the distribution of African Odonata species using the Odonata Database of Africa. The use of geographic information system (GIS) in pre- and postprocessing is integral part of the SDM workflow and GIS and statistical modelling is integrated in the SpeeDi Tool. The user centred approach for the development of the SpeeDi Tool offers usability and achievement of the goal (i.e. predicting the distribution range) with ease. *Pseudagrion kersteni*, a widely spread dragonfly species in

sub-Saharan Africa, is taken as species of interest to demonstrate the use and ability of the SpeeDi Tool. An expert-drawn watershed based range map from IUCN serves the purpose for visually comparing the modelled spatial distribution and, thus, enables to evaluate the predicted range. The SpeeDi Tool has several modelling parameters, some of which have been new in SDM field, namely, elastic-net factor which has not been applied to SDM using background samples until now, soft buffer threshold (SBT) which is a new concept introduced here, and weights for samples. In addition to the use of background samples, it introduces the modelling by using presence samples with absence and / or background samples; the combination of presence, absence and background samples is a new option not found in existing SDM tools yet. In order to gain confidence in using the SpeeDi Tool, several sensitivity analyses are performed using *P. kersteni* samples for different modelling approaches for applying different modelling parameters and for using different environmental geodatasets. These sensitivity analyses are thought for determining the optimum values of different regression parameters to maximise the model's performance, and for finding the important environmental variables and their effects on the prediction of distribution ranges. The concept similar to that of a virtual species is used to evaluate general applicability of the SpeeDi Tool. The sensitivity analyses of modelling parameters showed a) the elastic-net regularisation is superior to L1 or L2 regularisation, b) the uncertainty in population prevalence in background samples can be reduced by applying SBT, c) weights can be effective in reducing effects of sampling bias, d) the number of background samples is sensitive for fitting the model, and e) product interaction of variables are necessary for better prediction of distribution range. The sensitivity of environmental datasets showed a) monthly climate datasets should be preferred over synthesised bioclimatic datasets, b) predicted distributions using land-cover datasets with different classification schemes are not much different but the contribution of land cover classes in different datasets indicated that false interpretation regarding ecological significance of these classes can be possible. Further, the results for the modelling of *A. minuscula* showed that there is not much difference in distribution range when modelled at spatial resolutions of 1 km and 8 km. The results also indicated that modelling extent should not extend too far beyond the species' native region." (Author)] Address: not stated

**18349.** Zajac, A. (2014): Effects of herbicides on the Hine's Emerald Dragonfly. M.Sc. thesis, University of South Dakota. 75 pp. (in English) ["We are currently experiencing a global decline in biodiversity that is resulting in endangered species becoming increasingly prevalent. This decline has many causes, but threats from habitat contamination and invasive species have become especially concerning for the federally endangered Hine's emerald dragonfly (*Somatochlora hineana*) whose already limited habitat is being invaded by reed canarygrass (*Phalaris arundinacea*). There is concern that this invasive grass could have negative effects on *S. hineana* populations. An herbicide, Fusilade DX (fluazifop-p-butyl) can be effective in reducing this invasive grass. However, herbicide application could result in habitat contamination and could have significant negative effects on aquatic fauna. To safely apply this herbicide, we need to know how *S. hineana* and plant and animal community members will react to the presence of Fusilade DX and if it will reduce reed canarygrass in the area. However, an endangered organism can be difficult to experiment with and mortality from experiments could be harmful to the continuation of the species. We therefore set out to find a surrogate for *S. hineana* to use in toxicological experiments. We did this by capturing *Aeshna umbrosa*, *Boyeria vinosa*, *Epitheca princeps*, and *Somatochlora williamsoni* dragonfly larvae and comparing their response to one and two year old *S. hineana* larvae in toxicological testing. Glyphosate was used for this testing as Fusilade DX had been shown to have very little effect in pre-experiment work and there was also interest in using a more powerful herbicide if Fusilade DX proved to be ineffective. We exposed dragonfly larvae to glyphosate at concentrations of 0mg/L, 100mg/L, 1,000mg/L, 10,000mg/L and 50,000mg/L for 96 hours. We

found significant differences between the two age classes of *S. hineana* with two year old larvae experiencing no mortality, but found *S. hineana* to be the least sensitive of all species tested. We also found *S. williamsoni* to react most similarly to *S. hineana* and would recommend its use in further surrogate studies. We also set out to determine the effects of Fusilade on plant and animal communities. We did this by applying Fusilade DX to *S. hineana* habitat and comparing control and treatment plots. We found Fusilade to decrease growth of reed canarygrass by 32.5%, but not overall coverage. It also had no significant effect on native plant coverage or any direct or indirect effect on *S. hineana* populations." (Author)] Address: not stated

**18350.** Zandigiacomo, P.; Chiandetti, I.; Fiorenza, T.; Nadalon, G.; Uboni, C. (2014): Odonata of Friuli Venezia Giulia: Second update of checklist and further remarks. *Gortania* 36: 33-44. (in English, with Italian summary) ["Within the Project "Atlas of the Odonatofauna of the Friuli Venezia Giulia region", additional remarks of the Odonata of the region (North-eastern Italy) was carried out in the years 2010-2014. The new data have allowed us to enrich the regional Checklist of Odonata with five species: *Chalcolestes parvidens* and *Lindenia tetraphylla* that have not been observed previously in the region and *Anax ephippiger*, *Gomphus vulgatissimus*, and *Sympetrum flaveolum* that have been detected in previous years. In addition, knowledge of the distribution of twelve species that are rare or of natural interest has been improved. At the present time the Checklist of Odonata of Friuli Venezia Giulia includes 62 species representing 66% of the Italian fauna. Two species, *L. tetraphylla* and *Cordulegaster heros* Theischinger, 1979, are listed in the Annexes of the Habitats Directive. The list includes some species that have migratory tendencies and probably do not breed regularly in the region, such as *L. tetraphylla* and *A. ephippiger*. It is possible that in the near future other species might be found, some of which have already been reported for the region. Despite the considerable richness of species, we highlight a critical status for some species that are typical of mountain or alpine habitats, such as *Coenagrion hastulatum*, *C. heros*, *Somatochlora alpestris*, *S. arctica*, *Sympetrum danae* and *Leucorrhinia*. In addition, *Nehalennia speciosa* is near extinction at the regional and national level due to the presence of just one breeding site located in a peat bog in the morainic hilly area." ## 2015

**18351.** Amoroso, N.; Chalcraft, D.R. (2015): Duration of colonization and interactions between early and late colonists determine the effects of patch colonization history on patch biodiversity. *Oikos* 124(10): 1317-1326. (in English) ["Patches can vary in their colonization history as the result of many factors, including differences in patch size and isolation, which alter the timing and duration in which one or

more species colonize a patch. Prior work has found that the particular time that a species colonizes a patch can affect the performance of co-occurring species, but it is less clear whether it affects the biodiversity of the patch. Our objective was to evaluate how two components of colonization history affect biodiversity – the total duration of the colonization window in which a predator is able to colonize the patch and the particular time in the patch's colonization history (i.e. early versus late in community development) that colonization by a predator occurs. We conducted an experiment to examine how the duration and timing in which predatory dragonflies colonize recently filled ephemeral ponds affects insect biodiversity. Dragonfly colonization history had an important effect on insect biodiversity. Ponds with a longer colonization history by dragonflies had fewer insect morphotypes than ponds with a shorter colonization history. The timing of dragonfly colonization (i.e. early versus late in community development) had no effect on the number of insect morphotypes present despite altering both the rate of dragonfly metamorph production and the abundance of larval dragonflies present at the end of the study. The effect of duration of long-term dragonfly colonization on biodiversity stemmed from early colonists weakening the influence of later colonists on insect biodiversity. Though colonization by dragonflies reduced adult insect abundance, differences in the time in which dragonflies colonized ponds had no effect on total insect abundance. Moreover, differences in patch biodiversity appears to be affected more by variation in the duration a patch was colonized by a predator than variation in the time in which a patch was colonized by a predator." **18352.** Angot, D. (2015): Présentation et répartition communale des Libellules de Chalonnes sur Loire, Atlas de la Biodiversité Chalonnoise. Ville de Chalonnes sur Loire: 64 pp. (in French) ["Conclusion: The inventories have made it possible to significantly improve our knowledge of the dragonflies of the Chalonnois. 45 species are now known in the area, which represents almost three quarters of the species in the department and a little less than half of the species in France. The data collected over the last 10 years, and particularly in 2015, has made it possible to collect more than 1100 data on the group. This work would not have been possible without the work of naturalists and local associations such as the CPIE Loire Anjou and the LPO Anjou. The synthesis of these data made it possible to publish distribution maps, to specify the status and the autochthony of each species in order to present the results in the communal monographs presenting the ecology and the local distribution. Following the synthesis and study of the group in the commune, it appears that the great wealth of environments allows a large number of species to carry out their life cycle. The Chalonnois region is home to special habitats that allow certain remarkable species to develop and maintain their populations. On the Louet and the Loire, Gomphus flavipes and Ophiogomphus cecilia seem to be well established. On the old quarries, Oxgastrea curtisii breeds (three quarries in

Chalonnes). On two small streams, Coenargion mercuriale is present and breeds. These four species are protected at French and European level, but other species also have a special status. There are, for example, 18 species that are determinants for the establishment of Natural Zones of Faunistic and Floristic Interest (ZNIEFF). All these data give Chalonnes a particular responsibility in terms of the preservation of aquatic ecosystems (ponds, watercourses, ponds), but also for terrestrial environments and in particular natural meadows which host a significant number of individuals during the maturation period. The complementarity and relative proximity of these environments enables the needs of a large number of species to be met. These species can then carry out their life cycle from the aquatic to the aerial phase in good conditions. It should be emphasised that the publication of this document does not mean that data collection has stopped. Specific data and certain studies on the commune will enable the improvement of knowledge to be continued (monitoring of pools, collection of exuviae, monitoring of the mouth of the Layon). The distribution maps, even if they largely specify the distribution of the species, are far from exhaustive and only reflect the state of knowledge at a given moment. The wealth of odonatological species in the Chalonnois is a perfect illustration of the diversity and quality of the Chalonnois landscapes, which express this beautiful and fragile biodiversity, a real heritage that should be preserved and made known." **18353.** Bai, Y.; Dai, D.-F.; Bao, K.-O.; Quin, A.-N.; Ling, R.-J.; Wang, H.-R. (2015): Using geometric morphometrics to quantify the sexual dimorphism of Pantala flavescens. Chinese Journal of Applied Entomology 52(2): 363-369. (in Chinese, with English summary) ["We obtained wing shape information by digitizing the fore and hindwings of P. flavescens. Sexual dimorphism in wing shape and vein structure was then analyzed by principal component analysis (PCA) and the thin-plate spline (TPS) graphical technique. The PCA results indicate significant sexual dimorphism in the fore and hindwing. TPS indicates that forewing differences are mainly in the nodus and triangle, whereas hindwing differences were mainly in the nodus and in the area of the cubital and anal veins. Centriod size (CS) indicates that females have a bigger fore and hindwing than males. Sexual dimorphism in wing shape in P. flavescens probably reflects selection for different wing shape and vein structure in each sex." **18354.** Ball-Damerow, J.E.; Oboyski, P.T.; Resh, V.H. (2015): California dragonfly and damselfly (Odonata) database: temporal and spatial distribution of species records collected over the past century. ZooKeys 482: 67-89. (in English) ["The recently completed Odonata database for California consists of specimen records from the major entomology collections of the state, large Odonata collections outside of the state, previous literature, historical and recent field surveys, and from enthusiast group observations. The

database includes 32,025 total records and 19,000 unique records for 106 species of dragonflies and damselflies, with records spanning 1879–2013. Records have been geographically referenced using the point-radius method to assign coordinates and an uncertainty radius to specimen locations. In addition to describing techniques used in data acquisition, georeferencing, and quality control, we present assessments of the temporal, spatial, and taxonomic distribution of records. We use this information to identify biases in the data, and to determine changes in species prevalence, latitudinal ranges, and elevation ranges when comparing records before 1976 and after 1979. The average latitude of where records occurred increased by 78 km over these time periods. While average elevation did not change significantly, the average minimum elevation across species declined by 108 m. Odonata distribution may be generally shifting northwards as temperature warms and to lower minimum elevations in response to increased summer water availability in low-elevation agricultural regions. The unexpected decline in elevation may also be partially the result of bias in recent collections towards centers of human population, which tend to occur at lower elevations. This study emphasizes the need to address temporal, spatial, and taxonomic biases in museum and observational records in order to produce reliable conclusions from such data." (Authors)] Address: Oboyski, P.T., Collections Manager & Curatorial Supervisor, Essig Museum of Entomology, 1170 Valley Life Science Building, University of California, Berkeley, 1101 VLSB, #4780, Berkeley, CA 94720, USA

**18355.** Brabender, M. (2015): The impact of shore types on benthic macroinvertebrate community structure and functioning in a large lowland river. Dissertation, Fakultät Umweltwissenschaften, Technische Universität Dresden: 129 pp. (in English, with German summary) ["Shore zones of large rivers are hot spots of biodiversity and contribute significantly to riverine ecosystem functioning. Today, shore degradation and other structural impairments like river straightening and channelization are strong impact factors on river ecosystem health. However, we still lack a thorough understanding of how structural shore zone degradation affects benthic community composition and their inherent ecosystem functions. In this thesis I tested the influence of training structure induced environmental factors on benthic macroinvertebrate community composition and the share of non-native species. Moreover, I assessed the community-associated ecosystem functions in terms of secondary production and resource utilization. In the main channel, communities were composed of only a few specialized taxa with low abundances, which contributed little to riverine secondary production. This is probably due to the harsh conditions produced by constantly high flow velocities and relocation of the fine sandy sediment. Main channel habitats were hardly affected by the adjacent training structure. Hence, species compositions and productivities were similar at all investigated main channel sites. By contrast, each of the shore communities was diverse, highly abundant and productive in comparison to the main channel. However, variations between shore structure communities and their ecosystem

functions were prominent. One particular training structure, i.e. the off-bankline revetment, bore the most diverse and by far most productive benthic community, which utilized vast total amounts of basal resources ( $1,323 \text{ g DM m}^{-2} \text{ y}^{-1}$ ). Varying sediment compositions, availability of macrophytes and diverse flow velocities, including lentic conditions, were revealed as key factors for increasing biodiversity, secondary production and resource utilization. Allochthonous boulder habitats were generally highly prone to non-native species invasion. Neozoa proved less productive than many native community members and consumed minor relative and total amounts of the prevailing resource pelagic algae. The present quantitative comparison of shore type specific effects on biodiversity, biomass and productivity provides managers with a tool to improve the ecological attributes of large river ecosystems with an unchangeable, impaired macrostructure. In its entirety, this thesis constitutes a sound basis to increase the mechanistic understanding of the way in which shore zone manipulation can affect riverine benthic communities and their associated ecosystem functions." (Author) The paper includes data on Gomphidae (*Stylurus flavipes*, *Gomphus vulgatissimus*)] Address: not stated

**18357.** Guliyeva, S.A.; Aliyev, R.A. (2015): Species composition and quantitative distribution of larvae of dragonflies (Odonata) in the new ecological conditions of the lake Aggol. *Journal of Zaporizhzhya National University* 2(2015): 93-98. (in Russian, with English summary) ["The paper presents new data on species composition, number and distribution of the larvae of Odonata in new environmental conditions of the different habitats of in the lake Aggol. Field works conducted in 2011-2012 in the lake Aggol resulted in the rearings of 28 species and forms of dragonfly larvae. Six of these *Coenagrion concinnum*, *C. armatum*, *Aeshna viridis*, *Sympetrum striolatum*, *S. sanguineum*, *S. meridionale* are new to the lake. Species *Coenagrion concinnum* and *C. armatum* were found in winter, spring and autumn of 2011 and winter and autumn of 2012; *Aeshna viridis* in winter and autumn of 2011; *Sympetrum striolatum* - winter, spring and autumn of 2011; *S. sanguineum* in winter and autumn of 2011-2012; *S. meridionale* in winter and spring of 2011-2012. The widest distributed species belong to the genera *Coenagrion*, *Aeshna* and *Sympetrum*. The maximum development of larvae of dragonflies was registered in winter ( $106 \text{ ind./m}^2$ ,  $1,10 \text{ g/m}^2$ ) and minimum in summer ( $12 \text{ ind./m}^2$ ,  $0,14 \text{ g/m}^2$ ). Ecology of the fauna is studied in detail. In the study period (2011-2012) the number of species of dragonfly larvae reaches a minimum in summer (6 species), and the maximum (27 species) in winter. Species

Coenagrion scitulum, C. lunulatum, C. puella, C. mercuriale [sic!], Anax imperator, Sympetrum flaveolum are observed in the lake in all seasons and are dominated by widespread. It should be noted that the decrease in the number of larvae of dragonflies in the summer, especially at depths of up to 0.5 m is due to their intensive consumption by fish and water birds and emergence of adult dragonflies which leave the lake. On the other hand, in summer period, the volume of oxygen in shallow water of the lake Aggol is greatly reduced, and as a result of evaporation of water, the amount of salts in water is increased. In such circumstances, the probability of occurrence of freshwater organisms in the benthos is naturally decreased. Average annual number of dragonfly larvae per square meter of the lake Aggol in 2011 was 88 ind./m<sup>2</sup>, and biomass - 0.31 g/m<sup>2</sup>. During this period, the maximum development of the larvae of dragonflies observed in winter (141 ind./m<sup>2</sup>, 0.50 g/m<sup>2</sup>), and the minimum - in the summer (25 ind./m<sup>2</sup>; 0.10 g/m<sup>2</sup>). In contrast to 2011, in 2012 the average annual number of dragonfly larvae per square meter lake was 66 ind./m<sup>2</sup>, and biomass -0.24 g/m<sup>2</sup>. It is shown that the maximum development of dragonfly larvae was observed in winter (126 ind./m<sup>2</sup>; 0.47 g/m<sup>2</sup>) and the minimum (11 ind./m<sup>2</sup>, 0.03 g/m<sup>2</sup>) - during the summer season. The study of the distribution of larvae of dragonflies on specific habitats of the lake revealed their maximum development on plant and silty habitats, and the minimum - on black silty sand. Changes in biomass of benthic organisms as well as larvae of dragonflies, which developed very poor is analyzed. The index of the average biomass of dragonfly larvae per square meter of lake in the 60s was 0.27 g/m<sup>2</sup> in 70s - 0, 20 g/m<sup>2</sup>, in 80s - 0.13 g/m<sup>2</sup>, and in 2011-2012 - 0.28 g/m<sup>2</sup>. Poor development of dragonfly larvae in the lake Aggol is characterized, on the one hand with their intensive consumption by fish and water birds and on the other hand - the steady worsening of the environmental conditions of the lake." **18359.** He, H.C.; Fan, Q.-x.; Chu, W.-h.; Wang, F.; Wu, Q.-w.; Zaho, Z.-b.; Zhang, C.-m.; Zhang, Y.-l. (2015): The predation intensity of *Pantala flavescens* nymph on *Paramisgurnus dabryanus* larvae and juveniles and its prey selection.

*Freshwater Fisheries* 45(6): 108-112. (in Chinese, with English summary) ["This study was conducted to determine the predation intensity of *Pantala flavescens* nymph on *Paramisgurnus dabryanus* (5, 15, 25, 35 days after hatching, DAH) and the prey selection of the *Pantala* nymph on loach larvae, chironomus larvae, and tubificidae. The results showed that both the instar of *Pantala* nymph and the size of loach were related to the predation intensity of the *Pantala* nymph on Chinese loach. The predation intensity of 9 ~ 12 instar *Pantala* larvae on *P. dabryanus* was significantly stronger than that of 5~8 instar larvae. *P. dabryanus* at 25 DAH couldn't be captured and eaten by *Pantala* larvae less than 5-8 instar, and *P. dabryanus* at 35 DAH couldn't be captured and eaten by *Pantala* larvae less than 9-12 instar. The feeding rates of 5 -8 instar *Pantala* larvae on 5 and 15 DAH loach showed no significant difference, and the feed rates of 9 - 12 instar *Pantala* larvae on 5, 15, and 25 DAH loach showed no significant difference. *P. flavescens* nymph could prey on *P. dabryanus*, chironomus larvae, and tubificidae, with the preference in the order of chironomus larvae > tubificidae > *P. dabryanus*." **18360.** Hothem, R.L.; May, J.T.; Gibson, J.K.; Brussee, B.E. (2015): Concentrations of Metals and Trace Elements in Aquatic Biota Associated with Abandoned Mine Lands in the Whiskeytown National Recreation Area and Nearby Clear Creek Watershed, Shasta County, Northwestern California, 2002–2003. Prepared in cooperation with the National Park Service. Open-File Report 2015–1077. U.S. Department of the Interior, U.S. Geological Survey: 64 pp. (in English) ["Park management of the Whiskeytown National Recreation Area, in northwestern California, identified a critical need to determine if mercury (Hg) or other elements originating from abandoned mines within the Upper Clear Creek watershed were present at concentrations that might adversely affect aquatic biota living within the park. During 2002–03, the U.S. Geological Survey, in cooperation with the National Park Service, collected aquatic invertebrates, amphibians, and fish, and analyzed them for Hg, cadmium, zinc, copper, and other metals and trace elements. The data from the biota, in conjunction with data from concurrent community bioassessments, habitat analyses, water quality, and concentrations of metals and trace elements in water and sediment, were used to identify contamination "hot spots." In 2002, we selected collection sites within the study area based on the presence of historical mines and results from sampling of bed sediment in 2001. In 2003, collection sites were selected based on sediment data as well as data on water and biota from this study in 2002. Eleven sites were sampled in both 2002 and 2003, 11 sites were sampled only in 2002, and 14 sites were sampled only in 2003. Comparisons of sites within the Upper Clear Creek watershed indicated that most of the more contaminated sites were outside of the park boundaries, especially at sites within the French Gulch, Cline Gulch, and Whiskey Creek watersheds. The site with the highest overall contamination within the park, based on both fish and invertebrate data, was WLCC, a site on Willow Creek impacted by acid mine

drainage and listed as impaired under Section 303(d) of the Clean Water Act. Compared with other recently evaluated mine-impacted watersheds in northern California, invertebrates, amphibians, and fish from sites within the Upper Clear Creek watershed tended to have significantly lower concentrations of Hg than at most other sites. For other metals and trace elements, Upper Clear Creek sites were only compared with the Deer Creek watershed, Nevada County, California. Copper from both Willow Creek sites (WLCC and WLTH) in the Clear Creek watershed was the only metal with concentrations in biota that were significantly higher than biota from Deer Creek. ... The target aquatic macroinvertebrates for elemental analysis in this study were predatory insects, depending on their abundance and availability at each sample site. Taxa collected were larval dragonflies (Gomphidae, Libellulidae, Aeshnidae, and Cordulegastridae), adult water striders (Hemiptera: Gerridae), larval stoneflies (Plecoptera: Perlidae), larval dobsonflies (Megaloptera: Corydalidae), and adult predaceous diving beetles (Coleoptera: Dytiscidae). Banana slugs (Gastropoda: Arionidae) also were collected at a limited number of sites. ... The highest mean concentration of HgT in dragonflies (Gomphidae) was from MDOX in 2003 (0.115 µg/g), with the second highest from CLN2 (0.110 µg/g). All the most elevated HgT concentrations were from sites outside the park boundaries." **18361.** Jäckel, K.; Koch, K. (2015): Anisoptera-Exuvien (Odonata): nur leere Hüllen? *Libellula* 34(3/4): 143-159. (in German, with English summary) ["Anisoptera exuviae: Only empty husks? – Many organisms leave moulting skins that can be utilised by secondary users. Exuviae of Anisoptera are relatively robust and remain relatively long on the substrate. Therefore, we asked ourselves the following questions: To what extent and for what purpose can secondary users be found in exuviae? Which taxa can be found as secondary users? Do secondary users prefer exuviae of certain dragonfly species? For our study, we systematically collected exuviae of Anisoptera in the nature reserve area Eich-Gimbsheimer Altrhein (Germany, Rheinland-Palatinate) in 2013 and 2014. In 2013 secondary users were found in 30 % and 2014 in 67 % of the exuviae. The differences in the occupation rate with secondary users likely roots in the modified method. The exuviae were screened in the field with flashlights and only taken inside the lab when we found a secondary user in 2013. We certainly missed some secondary users or their traces, like faeces or spider webs. In 2014, all exuviae found were collected. Overall, we found arthropods from 18 genera and 18 families. The secondary users distributed to the orders Arachnida, Diplopoda (Millipedes), Collembola (Springtails), and Insecta (Insects). The family of spiders (Araneae) was most common (2013: 71 %, 2014: 78 %). Within the spiders, the genus Clubiona of the family of Clubionidae (sack spiders) was most abundant. Clubiona sp. was found at all ages. With a few exceptions, only one secondary user per exuviae was found. The taxa compositions of secondary users at the family level were

significantly different in the two years. In 2013, large-volume exuviae were occupied primarily; in 2014, this pattern was not confirmed. In general, exuviae of Anisoptera can be used by different arthropods as a temporarily microhabitat." **18362.** Jisha Krishnan, E. K.; Sebastian, C. D. (2015): Assessment of the phylogenetic relationship among Coenagrionidae family (Odonata: Zygoptera) using Coi gene marker. Proceedings 25th SWADESHI SCIENCE CONGRESS, a national seminar, 16-18 December 2015, Sree Sankaracharya University of Sanskrit, Kalady, Ernakulam, Kerala: 337-339. (in English) ["Zygoptera represents the most ancient damselflies with their ancestors known to exist 250 million years ago. They are geographically distributed in all continents except Antarctica and ecologically important as bioindicators and biocontrol agents. Coenagrionidae is the most abundant damselfly family among the Zygopterans. In the present study, we assessed the phylogenetic relationships of 3 Coenagrionidae members (*Ischnura aurora*, *Ceragrion coromandelianum* and *Copera marginipes*) using mitochondrial cytochrome oxidase subunit I (COI) gene marker. The partially amplified PCR product of this gene yielded 606 bp, 573 bp and 616 bp long DNAs respectively. The nucleotide BLAST analysis confirmed the taxonomic identity of all these species. We had taken two species from Coenagrionidae and Calopterygidae families from NCBI GenBank for comparative study. Phylogenetic tree constructed by Neighbour joining method showed that Coenagrionidae members represent monophyletic ancestry due to its consistent divergence from a common ancestor. Among these members, *Ischnura aurora* are having a sister clade relationship with *Copera marginipes* which remained in the same clade and *Ceragrion coromandelianum* with *C. cerinorubellum* in another clade. The average A+T content of all these species are 62.03% while G+C content is 37.97% showing a strong A+T bias. The nucleotide substitution analysis states that *Copera marginipes* is having highest value than other members due to the transition of Cytosine and Thymine. Thus the present study concluded that cytochrome oxidase I is an effective tool for the species identification and phylogenetic relationships of closely related species." **18363.** Kastner F.; Buchwald, R.; Willen, M. (2015): Artenhilfsprogramme für die FFH Libellenarten *Aeshna viridis*, *Coenagrion mercuriale* und *Coenagrion ornatum* in NW-Deutschland. Abschlussbericht zum gleichnamigen DBU-Projekt, Oldenburg: 59 pp, Anh. (in German) ["The development of watercourses and the intensification of land use have led to a loss of many typical floodplain habitats and small water bodies. This loss of primary habitats can be compensated for a number of species by colonising anthropogenic ditch systems as secondary habitats. The odonates A.

viridis, *C. mercuriale* and *C. ornatum*, which were selected as target species in this project, are classified as "Critically Endangered" (RL 2), "Critically Endangered" (RL 1) or "Extinct" (RL 0) on the German Red List as well as for Lower Saxony and North Rhine-Westphalia and are listed in the Annexes of the Habitats Directive. The aim of the project was to determine the current distribution and population structure of the three dragonfly species in the study areas and to describe the colonised habitats in more detail. Based on this, initial measures for habitat optimisation and habitat connectivity were carried out as the basis for a species protection concept. *A. viridis*, which is bound to *Stratiotes aloides* plants, was detected in the Hunte-Weser lowlands in the sub-areas NSG Bornhorster Huntewiesen, Iprump/Oberhausen, Huntorf and Warleth as well as in the areas of Delmenhorst, NSG Werderland and NSG Hollerland. However, the recorded exuviae numbers per sub-area differ significantly from each other. The importance of large and dense emerged *S. aloides* stands for the occurrence of *A. viridis* can be confirmed and a lower threshold value of 20 % cover or 12 m<sup>2</sup> growth area of a *S. aloides* stand can be determined. In terms of water chemistry, the colonised ditches are classified as meso- to eutrophic and moderately to significantly anthropogenically polluted. The results of the reintroduction of *S. aloides* into suitable water bodies show that this is a suitable method for planning and implementing species protection measures precisely targeted at target species. For the long-term protection and conservation of *A. viridis* and *S. aloides* populations, ecological ditch maintenance following the example of Bremen plays an essential role. The conservation, optimisation and networking of habitats (with *S. aloides* populations) is the basis for the protection of *A. viridis*. The populations of *C. mercuriale* in the areas of Espelkamp and Ilwede with Barlage and Großer Dieckfluss in the district of Minden-Lübbecke are among the largest of the species in North Rhine-Westphalia. The population of *C. ornatum* near Espelkamp represents the main population of the species in North Rhine-Westphalia. The colonised water bodies in Minden-Lübbecke are characterised as follows: narrow incised water bodies with wide banks, mostly strongly sunlit, low to moderate flow velocity, shallow water depth, cover of emerged vegetation between 20 % and almost 100 %, well-developed submerged vegetation. Characteristic plant species are *Berula erecta*, *Phalaris arundinacea* and *Sparganium* spp. In terms of water chemistry, the waters can be classified as eutrophic and moderately to significantly anthropogenically polluted. The dispersal tendency of *C. mercuriale* is very low overall, but few individuals travel long distances. For the long-term conservation of both species, the continuation of adapted watercourse maintenance and a further reduction of emerging woody plants along the Kleine Aue near Espelkamp play a decisive role. Furthermore, the drying up of water bodies and their eutrophication pose a challenge for the future conservation of both species." (in English) ["Internal energy reserves of animals are limited, and the current investment in reproduction often decreases survival or future reproductive success. Some studies showed that copulatory activities impair the strength of immune function in insects, while the recent evidence is contradictory. In this study we tested whether copulatory activity affects the rate of encapsulation response in males of *Calopteryx splendens* damselfly in allopatric populations, and in sympatric populations where *C. splendens* stay together with their superior competitor *C. virgo*. We also counted the number of eugregarines, which are common parasites of damselflies. Copulation activity did not affect the immunity of *C. splendens* males in allopatric populations. In sympatric populations *C. splendens* males had more gut parasites, and we found a significant interaction between parasite number and copulatory activity on the rate of encapsulation. Our results suggest that the costs of reproduction are higher in infected males, which may affect reproductive investment and sexual selection." **18365.** Kreder, M.; Colleu, M.-A., Pont, L. (2015): Amélioration des connaissances de l'Agriion à lunules *Coenagrion lunulatum* sur le territoire du Parc naturel régional des Volcans d'Auvergne. *Syndicat Mixte du Parc naturel régional des Volcans d'Auvergne*: 49 pp + 16 p d'annexes.- (in French) ["*C. lunulatum* is a rare and discreet species found only in the French Massif Central. Its habitat is mainly comprised in the region of Auvergne, more specifically in the territory of the Volcans d'Auvergne Natural Regional Park, which is the entity responsible for the protection and preservation of this species. The study of 2014 aims at improving the knowledge of the habitat and distribution of this species. Surveys have identified 39 stations, whose 9 were not yet known. The analysis of the species' distribution shows a fragmented population, however without landscape discontinuity. Thus, according to the displacement abilities of the species, exchanges between different populations are hypothetically possible. The results of habitat characterization show the importance of the presence of emergent plants, but also highlights the importance of sunny banks, low intensity of pasture as well as the absence of fishes. A strategy of effective preservation of *C. lunulatum* will consist, on one hand, in the implementation of concrete and direct population management measures at the site scale and, on the other hand, by protecting a continuum of potentially favourable sites to different populations and thus allowing for the establishment of a sustainable population." **18367.** Lancaster, L.T.; Dudaniec, R.Y.; Hansson, B.; Svensson, E.I. (2015): Latitudinal shift in thermal niche breadth results from thermal release during a climate-mediated range expansion. *Journal of Biogeography* 42(10): 1953-1963. (in English) ["Aim: Climate change is currently altering the geographical distribution of species, but how this process contributes to biogeographical variation in ecological traits is unknown. Range-shifting species are predicted to encounter and respond to new selective regimes during their expansion phase, but also carry historical adaptations to their ancestral range. We sought to identify how historical and novel components of the environment interact to shape latitudinal trends in thermal tolerance, thermal tolerance breadth and phenotypic plasticity of a range-shifting species. Location: Southern and central Sweden. Methods: To evaluate phenotypic responses to changes in the thermal selective environment, we experimentally determined the upper and lower thermal tolerances of > 2000 wild-caught damselflies (*Ischnura elegans*) from populations distributed across core and expanding range-edge regions. We then identified changing correlations between thermal tolerance, climate and recent weather events across the range expansion. Niche modelling was employed to evaluate the relative contributions of varying climatic selective regimes to overall habitat suitability for the species in core versus range-edge regions. Results: Upper thermal tolerance exhibited local adaptation to climate in the core region, but showed evidence of having been released from thermal selection during the current range expansion. In contrast, chill coma recovery exhibited local adaptation across the core region and range expansion, corresponding to increased climatic variability at higher latitudes. Adaptive plasticity of lower thermal tolerances (acclimation ability) increased towards the northern, expanding range edge. Main conclusions: Our results suggest micro-evolutionary mechanisms for several large-scale and general biogeographical patterns, including spatially and latitudinally invariant heat tolerances (Brett's rule) and increased thermal acclimation rates and niche breadths at higher latitudes. Population-level processes unique to climate-mediated range expansions may commonly underpin

many broader, macro-physiological trends." (Authors)] Address: Lancaster, Lesley, Univ. of Aberdeen, School of Biological Sciences, Zoology Building, Tillydrone Avenue, Aberdeen AB24 2TZ, UK. E-mail: lesleylancaster@abdn.ac.uk

**18370.** Marino, N.A.C.; Srivastava, D.S.; Farjalla, V.F. (2015): Predator kairomones change food web structure and function, regardless of cues from consumed prey. *Oikos* 125(7) : 1017-1026. (in English) ["Predation risk in aquatic systems is often assessed by prey through chemical cues, either those released by prey or by the predator itself. Many studies on predation risk focus on simple pairwise interactions, with only a few studies examining community-level and ecosystem responses to predation risk in species-rich food webs. Further, of these few community-level studies, most assume that prey primarily assess predation risk through chemical cues from consumed prey, even heterospecific prey, rather than just those released by the predator. Here, we compared the effects of different predation cues (predator presence with or without consumed prey) on the structure and functioning of a speciose aquatic food web housed in tropical bromeliads. We found that the mere presence of the top predator (a damselfly) had a strong cascading effect on the food web, propagating down to nutrient cycling. This predation risk cue had no effect on the identity of colonizing species, but strongly reduced the abundance and biomass of the macroinvertebrate colonists. As a result, bacterial biomass and nitrogen cycling doubled, with a concomitant decrease in bacterial production, but CO<sub>2</sub> flux was unaffected. These community and ecosystem effects of predator presence cues were not amplified by the addition of chemical cues from consumed prey. Our results show that some of the consequences of predation risk observed in controlled experiments with simplified food webs

may be observed in a natural, species-rich food web." (Authors)] Address: Marino, N.A.C., Lab. de Limnologia, Depto de Ecologia, Inst. de Biologia, Centro de Ciências da Saúde, Univ. Federal do Rio de Janeiro, PO Box 68020, Rio de Janeiro, RJ, Brazil. E-mail: nac.marino@gmail.com

**18371.** Mikó, Z.; Ujszegi, J.; Gál, Z.; Imrei, Z.; Hettyey, A. (2015): Choice of experimental venue matters in ecotoxicology studies: Comparison of a laboratory-based and an outdoor mesocosm experiment. *Aquatic Toxicology* 167: 20-30. (in English) ["The heavy application of pesticides and its potential effects on natural communities has attracted increasing attention to inadvertent impacts of these chemicals. Toxicologists conventionally use laboratory-based tests to assess lethal concentrations of pesticides. However, these tests often do not take into account indirect, interactive and long-term effects, and tend to ignore different rates of disintegration in the laboratory and under natural conditions. Our aim was to investigate the importance of the experimental venue for ecotoxicology tests. We reared tadpoles of the agile frog (*Rana dalmatina*) in the laboratory and in outdoor mesocosms and exposed them to three initial concentrations of a glyphosate-based herbicide (0, 2 and 6.5 mg a.e./l glyphosate), and to the presence or absence of caged predators (dragonfly larvae [*Aeshna cyanea*]). The type of experimental venue had a large effect on the outcome: The herbicide was less lethal to tadpoles reared in outdoor mesocosms than in the laboratory. Further, while the herbicide had a negative effect on development time and on body mass in the laboratory, tadpoles exposed to the herbicide in mesocosms were larger at metamorphosis and developed faster in comparison to those reared in the absence of the herbicide. The effect of the herbicide on morphological traits of tadpoles also differed between the two venues. Finally, in the presence of the herbicide, tadpoles tended to be more active and to stay closer to the bottom of laboratory containers, while tadpole behaviour shifted in the opposite direction in outdoor mesocosms. Our results demonstrate major discrepancies between results of a classic laboratory-based ecotoxicity test and outcomes of an experiment performed in out-door mesocosms. Consequently, the use of standard laboratory tests may have to be reconsidered and their benefits carefully weighed against the difficulties of performing experiments under more natural conditions. Tests validating experimentally estimated impacts of herbicides under natural conditions and studies identifying key factors determining the applicability of experimental results are urgently needed." **18372.** Ngo, C.D.; Ngo, B.V.; Hoang, T.T.; Nguyen, T.T.T.; Dang, H.P. (2015): Feeding ecology of the common sun skink, *Eutropis multifasciata* (Reptilia: Squamata: Scincidae), in the plains of central Vietnam. *Journal of Natural History* 49(39-40): 2417-2436. (in English) ["We studied the feeding ecology of *Eutropis multifasciata* in the tropical plains

of central Vietnam to understand better the foraging mode, spatiotemporal and sexual variation in dietary composition, and rarefaction curves of prey-taxon richness for males and females. Stomach contents (n = 161) were collected from October 2013 to May 2014 using a nonlethal stomach-flushing technique. A total of 680 food items (624 animal items and 56 plant items, [and including Odonata]) was found in 161 stomachs of skinks, representing 19 unique animal categories. We found that the diet of *E. multifasciata* is composed mainly of small, sedentary and clumped prey and that this skink specialises on spiders, insect larvae, snails, grasshoppers and crickets (with a combined importance index of 60%). Dietary composition, prey size and total prey volume in *E. multifasciata* changed between dry and rainy seasons and among regions. The total volume of food items consumed by males was larger than that of females, and the diversity and evenness index of prey categories were larger in males than in females. However, using rarefaction curves revealed that females have the higher prey-taxon richness after points between 130 and 140 prey items for frequency, and between 160 and 170 prey items for number of items, and the differences were not statistically significant. The foraging behaviour of *E. multifasciata* best fits a 'widely foraging' model." (Authors)] Address: Ngo, C.D., Faculty of Biology, College of Education, Hue University, Hue, Vietnam. **18373.** Orlofske, S.A.; Jadin, R.C.; Johnson, P.T.J. (2015): It's a predator–eat–parasite world: how characteristics of predator, parasite and environment affect consumption. *Oecologia* 178(2): 537-547. (in English) ["Understanding the effects of predation on disease dynamics is increasingly important in light of the role ecological communities can play in host–parasite interactions. Surprisingly, however, few studies have characterized direct predation of parasites. Here we used an experimental approach to show that consumption of free-living parasite stages is highly context dependent, with significant influences of parasite size, predator size and foraging mode, as well as environmental condition. Among the four species of larval trematodes and two types of predators (fish and larval damselflies [*Enallagma* sp.]) studied here, parasites with larger infective stages (size >1,000 µm) were most vulnerable to predation by fish, while small-bodied fish and damselflies (size <10 mm) consumed the most infectious stages. Small parasite species (size approx. 500 µm) were less frequently consumed by both fish and larval damselflies. However, these results depended strongly on light availability; trials conducted in the dark led to significantly fewer parasites consumed overall, especially those with a size of <1,000 µm, emphasizing the importance of circadian shedding times of parasite free-living stages for predation risk. Intriguingly, active predation functioned to help limit fishes' infection by directly penetrating parasite species. Our results are consistent with established theory developed for predation on zooplankton that emphasizes the roles of body size, visibility and predation modes and further suggest that consumer–resource theory may provide a predictive framework for when predators should significantly influence parasite transmission. These results

contribute to our understanding of transmission in natural systems, the role of predator–parasite links in food webs and the evolution of parasite morphology and behavior." **18374.** Pamungkas, D.W.; Ruspindi, E.C.A.; Ani, N.L. (2015): Diversity and distribution of dragonflies (Odonata) in Bromo Forest Area (BKPH Lawu Utara : KPH Surakarta) Central Java. Proceedings of International Conference on Life Sciences and Biotechnology (ICOLIB). Exploration and Conservation of Biodiversity, Jember. ISBN : 978-602-9030-98-3: 123-127. (in English) ["Odonates diversity in Bromo forest area (KPH Surakarta) was observed, where we recorded 21 species. Libellulidae was the richest family with 12 species and Orthetrum was the most common genera. Zygoptera were represented by 7 species and 14 species represent Anisoptera. River stream along the forest area with multiple vegetation structure may provides good habitat to Odonata lives. Mostly odonates were aggregated due to habitat specific nature, the presence of family Gomphidae, *P. reinwardtii* in this study showed there is a good condition of water. A detailed list of odonates recorded from Bromo forest area is presented." Sutami 36A Surakarta 57126, Central Java, Indonesia. E-mail: diagal.wisnu@gmail.com

**18375.** Ramlee, S.N.S. (2015): Studies of breeding habitats and seasonal occurrence of mosquitoes in Putrajaya and Kuala Selangor, with laboratory experiments of guppies and dragonfly nymphs as potential biocontrol predators against mosquito larvae. PhD thesis, University of Malaya: xxviii, 305 pp. (in English) ["Mosquito control is essential for the control of vector borne diseases. Many synthetic insecticides are widely used for controlling adult and larval mosquito populations. However, there are multirole effects: e.g. the harmful effects of chemicals on non-target organisms, the development of resistance to these chemicals in mosquitoes and the recent resurgence of different mosquito-borne diseases. The objectives of this study are to determine the potential breeding habitats of the mosquitoes, mosquito indices, mosquito species, density of mosquito larvae, perceptions of respondents on bio control and to conduct captivity studies on predator–prey relationships. Entomological surveillance was carried out in six localities in the urban and suburban areas from January until December 2010 to identify potential breeding sites for mosquitoes and mosquito species populations. A total of 442 representative households in six localities were selected. Breeding habitats were sampled outdoors in the surroundings of the housing areas. There was a significant difference in the number of mosquito larvae collected, where the urban areas had a higher density in contrast to suburban areas. The study indicated that the most predominant species found in both areas was *Aedes albopictus* with gardening utensils as a preferred breeding habitat for urban area and artificial containers for

suburban area. Entomological indices were calculated to predict future outbreaks in the localities. Ovitrap surveillance was carried out in one year to study the relationship between ovitrap surveillance and environmental parameters, which revealed no significant difference in the population numbers for both areas and no correlation to the environmental factors. Questionnaires on the perceptions of chemical in mosquito control and the potential use of bio control were distributed to staffs in health office and also public in both study areas. In general the public had high uncertainties (scoring on 'not sure' for all the 4 questions given ranging from 47.9% to 27%). This is due to the public being unfamiliar to bio control as indicated in question 1 (56%) in contrast to staff very aware on bio control (75%). Fatigue was the most frequently reported symptom by staff and breathing difficulty reported by public. Natural bio control agent surveillance was conducted in both study areas. *Poecilia reticulata* and Odonata nymph species was the most natural predator collected at study areas. Three species of Odonata nymphs consumed more *Aedes* species than *Culex* species but there was no significant difference in the predator feeding efficiency. In terms of prey preferences of guppy, both male and female consumed more *Aedes* species than *Culex* species. The behaviour of mosquito larvae species and predator (guppy and Odonata nymph) species showed direct influence on the predatory activities. All predators exhibited diurnal activities; they were day-time stalkers and actively consumed more mosquito larvae during the day time. The efficiency of predatory activities depends on several factors such as water volume, number of predator, and number of prey density. These results concluded that both common biocontrol agent (guppies) and potential biocontrol agent (Odonata nymphs) are efficient predators in laboratory experiment and thus likely candidates to be utilized as an environmental friendly mosquito management strategy." **18376.** Salcher, M.; Schiel, F.-J. (2015): Neunachweise der Helm-Azurjungfer (*Coenagrion mercuriale*) bei Tübingen (Odonata: Coenagrionidae). *Mercuriale* 15: 5-12. (in German, with English summary) ["We report about new records of *C. mercuriale* west of the city of Tübingen in the federal state of Baden-Württemberg (southwestern Germany). The species was found there by the first author in the years 2013 to 2015 at eight sites in the valleys of the rivers Ammer and Neckar. The reproduction sites are small rivulets and ditches with dense aquatic and riparian vegetation, which are typical habitats for the species. The populations are separated both from those at the Prealpine Area and the Upper Rhine valley by distances from at least 70 km of mountainous and forested landscape. Therefore we suppose the populations to be overlooked. Furthermore there seems to be a high extinction risk because of the high isolation of the habitats." (2015): Evolutionary consequences of climate-induced range shifts in insects. *Biological Reviews* 91(4): 1050-1064. (in English) ["Range shifts can rapidly create new areas of geographic overlap between formerly allopatric taxa and evidence is accumulating that this can affect species persistence. We review the emerging literature on the short- and long-term consequences of these geographic range shifts. Specifically, we focus on the evolutionary consequences of novel species interactions in newly created sympatric areas by describing the potential (i) short-term processes acting on reproductive barriers between species and (ii) long-term consequences of range shifts on the stability of hybrid zones, introgression and ultimately speciation and extinction rates. Subsequently, we (iii) review the empirical literature on insects to evaluate which processes have been studied, and (iv) outline some areas that deserve increased attention in the future, namely the genomics of hybridisation and introgression, our ability to forecast range shifts and the impending threat from insect vectors and pests on biodiversity, human health and crop production. Our review shows that species interactions in de novo sympatric areas can be manifold, sometimes increasing and sometimes decreasing species diversity. A key issue that emerges is that climate-induced hybridisations in insects are much more widespread than anticipated and that rising temperatures and increased anthropogenic disturbances are accelerating the process of species mixing. The existing evidence only shows the tip of the iceberg and we are likely to see many more cases of species mixing following range shifts in the near future." **18379.** Sivtseva, L.V. (2015): On the seasonal activity of Odonata in Central Yakutia. *Science and Education* 2015(4): 137-142. (in Russian, with English summary) ["The phenology of 25 species of damselflies and dragonflies in the cryosemiarid conditions of Central Yakutia is studied. Total flight activity of the imago is continued during 5 months from May to September. Six seasonal groups are revealed: hibernating – the first 10 days of May – the last 10 days of August (*Sympetma paedisca*), late spring-summer – the last 10 days of May – the last 10 days of July (3 species), late spring-late

summer – the last 10 days of May – the last 10 days of August (1), summer – 10 days in the middle of June – the last 10 days of July (9), summer-late summer – 10 days in the middle of June – the first 10 days of September (9), and the summer-autumn – 10 days in the middle of July – the last 10 days of September (2 species). Emergence of damselflies and dragonflies from reservoirs occur within seventy days from the last 10 days of May to the last 10 days of July and their greatest diversity (25 species) is observed in the period from the 11th to the end of July. The period of seasonal flight activity of adults Odonata in the investigated area essentially does not differ from the period of flight in the North-East of the European part of Russia. The terms of flight of damselflies and dragonflies in the Central Yakutia, in comparison with phenological data of the north of the Far East appear longer for a month, and is shorter for a month than in the south of Siberia and the Far East." **18383.** Jung, S.-W.; Min, H.-K.; Hwang, H.-S.; Seo, Y.-J.; Bae, Y.-J.; Paek, W.-K. (2016): Diversity of aquatic insects of Taean area in South Korea, with notes on species-specific distribution. Korean Journal of Environment and Ecology 30(1): 58- 70. (in Korean, with English summary) ["An investigation was carried out to study the diversity of aquatic insects, functional feeding groups (FFGs), habitat oriented groups (HOGs), and species-specific distribution in the Taean area in Korea from June to August, 2015. As a result, a total of 72 species belonging to 30 families and six orders were identified in all the investigated regions. Odonata (22 spp.: 30.56%) was the largest group in species richness followed by Coleoptera (21 spp.: 29.16%), Hemiptera (17 spp.: 23.61%) and Diptera (8 spp.: 11.11%) while for Ephemeroptera and Trichoptera, only two species (2.78%) were found. In addition, Plecoptera and Megaloptera inhabiting clean and flowing waters were not found. In the FFGs, predators (48 spp.: 66.67%) were relatively larger as represented by Odonata, Coleoptera, and Hemiptera, whereas shredders and scrapers were lower in proportion. The dominant groups of HOGs were swimmers (24 spp.: 33.33%), climbers (18 spp.: 25.0%), and sprawlers (12 spp.: 16.67%), which were characterized as aquatic insects community of island. Four species: *Cybister lewisianus* Sharp, *Helophorus auriculatus* Sharp, *Agrypnia pagetana* Curtis, *Diplonychus esakii* Miyamoto & Lee that are designated as Endangered, Near Threatened, and Vulnerable (Korean Red List) have been found to inhabit the Taean area. Also, two species belonging to the exportable species group (*Ceriagrion auranticum* Fraser, *Paracercion melanotum* (Selys)) and one species belonging to the climate-sensitive biological indicator group (*Ischnura elegans* (Van der Linden)) were identified. In this study, four significant species including the Endangered are presented on the Korean distribution map based on the information in the national ecosystem survey accumulated for 7 years (2006-2012) by the Ministry of Environment." **18384.** Minot, M. (2016): Suivi des populations de *Leucorrhinia pectoralis* (Insecta: Odonata) et étude des habitats favorables à l'implantation de l'espèce dans le Canton de

Neuchâtel. Master's Thesis, Université de Rouen: 48 pp, app. (in French, with English summary) ["After the restoration of peatlands which were previously exploited in two valleys, the dragonfly *Leucorrhinia pectoralis* settled down in the Swiss Jura. This species listed at the second annexe of the Bern Convention is critically endangered in Switzerland. **18385.** As part of a 5 years populations study, this work enabled to estimate the size of the biggest populations based on the mark-recapture of 529 individuals. The numbers of mature males are estimated at 296 and 80 on both main peatlands. This is respectively as many and two times less than than in 2015. This decline for one of the populations is probably due to the unfavourable climatic conditions in 2016. Only three inter-peatland movements were observed. Two of them were done by immatures, among the 134 individuals that we marked. Contrary to the value found in the bibliography, the sex-ratio at the emergence seems to be much more favourable to the females with only 38 % of males. Beside the mark-recapture study, the vegetation was mapped and abiotic factors were recorded on 111 water ponds. A statistical study enabled then to highlight the environmental factors that attract *L. pectoralis* on the sites and are favourable to its reproduction. Habitats seems to be more attractive when the pH is high, with few sphagnum and the presence of *Potentilla palustre* and *Typha latifolia*. *L. pectoralis* prefers the water ponds with several different units of vegetation: a patchwork of structures. Conservation measures can be applied to maintain transition environments, which structure is similar to the old natural low-marshes. An example of management on 7 water ponds in the « Marais de Brot » based on dredging at regular time intervals was then presented." **18386.** Renner, S.; Sahlén, G.; Périco, E. (2016): Testing dragonflies as species richness indicators in a fragmented subtropical Atlantic forest environment. Neotropical Entomology 45(3): 231- 239. (in English) ["We surveyed 15 bodies of water among remnants of the Atlantic Forest biome in southern Brazil for adult dragonflies and damselflies to test whether an empirical selection method for diversity indicators could be applied in a subtropical ecosystem, where limited ecological knowledge on species level is available. We found a regional species pool of 34 species distributed in a nested subset pattern with a mean of 11.2 species per locality. There was a pronounced difference in species composition between spring, summer, and autumn, but no differences in species numbers between seasons. Two species, *Homeoura chelifera* and *Ischnura capreolus*, were the strongest candidates for regional diversity indicators, being found only at species-rich localities in our surveyed area and likewise in an undisturbed national forest reserve, serving as a reference site for the Atlantic Forest. Using our selection method, we found it possible to obtain a tentative list of diversity indicators without having detailed ecological information of each species, providing a reference site is available for comparison. The method thus allows for indicator species to be selected in blanco from taxonomic groups that are

little known. We hence argue that Odonata can already be incorporated in ongoing assessment programs in the Neotropics, which would also increase the ecological knowledge of the group and allow extrapolation to other taxa." (Authors)] Address: Renner, S., Lab de Evolução e Ecologia, Centro Universitário Univates, Rua Avelino Talini, 171, Bairro Universitário, 95900-000 Lajeado, RS, Brasil; samuelrenner@hotmail.com

**18388.** Wang, X.; Zhang, Z.; Ren, H.; Chen, Y.; Wu, B. (2017): Role of soft matter in the sandwich vein of dragonfly wing in its configuration and aerodynamic behaviors. *Journal of Bionic Engineering* 14(3): 557-566. (in English) ["The microstructure of the main longitudinal veins of the dragonfly wing and the aerodynamic behaviours of the wing were investigated in this paper. The microstructure of longitudinal vein presents two circumferential chitin layers and a protein-fiber soft layer. The dragonfly wing is corrugated due to the spatial arrangement of longitudinal veins. It was found that the corrugation angle could significantly influence the lift/drag ratio across a range of attack angles by the wind tunnel experiments. The results of the finite element analysis indicate that the protein soft layer of vein facilitates the change of the corrugation angle by allowing substantial relative twisting deformation between two neighbouring veins, which is not possible in veins without a soft sandwich layer." **18390.** Wellenreuther, M. (2017): Balancing selection maintains cryptic colour morphs. *Molecular Ecology* 26: 6185-6188. (in English) ["Animals display incredibly diverse colour patterns, a testament to evolution's endless innovation in shaping life. In many species, the interplay between males and females in the pursuit of mates has driven the evolution of a myriad of colour forms, from the flashy peacock tail feathers to the tiniest colour markings in damselflies. In others, colour provides crypsis by allowing to blend into the background and to escape the eyes of predators. While the obvious benefits of this dazzling diversity for reproduction and survival seem straightforward, its maintenance is not. Theory predicts that genetic drift and various forms of selection reduce variation over time, making the persistence of colour variants over generations a puzzle. In this issue of *Molecular Ecology*, Lindtke et al. (2017) study the cryptic colour morphs of *Timema cristinae* walking sticks to shed light on the genetic architecture and mechanisms that allow colour polymorphism maintenance over long timescales. By combining genome-wide data with phenotyping information from natural populations, they were able to map the green and melanistic colour to one genomic region with highly reduced effective recombination rate between two main chromosomal variants, consistent with an inversion polymorphism. These two main chromosomal variants showed geographically widespread heterozygote excess, and genomic signatures consistent with long-term balancing selection. A younger chromosomal variant was detected for the third morph, the green-striped colour morphs, in the same genomic regions as the melanistic and the green-unstriped morphs. Together, these results suggest that the genetic architecture of cryptic *T. cristinae* morphs is caused by nonrecombining genomic blocks that have been maintained over extended time periods by balancing selection making this study one of the few available empirical examples documenting that balancing selection of various forms may play an important role in maintaining adaptive genetic variation in nature." The paper includes references to *Ischnura elegans*. (Authors)] Address: Wellenreuther, Maren, Seafood Res. Unit, Plant & Food Research Limited, Nelson, New Zealand. **18391.** Westenbrink, F.; Ketelaar, R. (2017): Veranderingen in de libellenfauna van de Gorsselse Heide: 1949-

2016. *Brachytron* 19(1): 22-34. (in Dutch, with English summary) ["The Gorssele Heide is a heathland remnant with some bogs and ponds in an area called De Achterhoek in the eastern part of the Netherlands. Since 1949 was this nature area regularly visited by odonatologists who observed a total of 43 species of dragonflies. Acidification and desiccation resulted in a decrease and the disappearance of typical species like *Sympetma paedisca*, *Leucorrhinia rubicunda* and *Aeshna juncea*. Eutrophication in the second part of the former century caused an increase of *Pyrrhosoma nymphula*, *Sympetrum sanguineum* and *Brachytron pratense*. Since the beginning of this century species from the southern part of Europe were added to the species list. Due to climate changes *Crocothemis erythraea*, *Aeshna affinis*, *Erythromma lindenii* and *Sympetrum fonscolombii* colonized the Gorssele Heide. A special observation was the settlement and rapid increase of *Lestes virens* and the simultaneous disappearance of *L. sponsa*. The last three years the area was intensively managed to restore the quality of the degenerated heath and ponds. As a consequence a rapid increase of former scarce species like *Orthetrum cancellatum* and *Libellula depressa* occurred. As the landscape of the Gorssele Heide basically did not change, the observed variations in the dragonfly population seem to be a derivative of the extreme nationwide fluctuations seen the last decades in the Netherlands and Flanders." (Authors)] Address: Westenbrink, F. E-mail: f.westenbrink@kpnmail.nl

**18392.** Westermann, K. (2017): Die Libellen des Hirschbädermooses im Feldberggebiet. *Naturschutz am südlichen Oberrhein* 9: 123-140. (in German, with English summary) ["The Hirschbädermoos is a moor which is mainly supplied by precipitation, and which is located in the Feldberg area (southern Black Forest) at an altitude of roughly 1280 m. In 2016, the moor dragonflies emerged there from 5th of June onwards. until and including the 2nd of September all exuviae were collected 15 times. until the end of the 20th century, this moor was the last remaining habitat in the Black Forest in which *Aeshna caerulea* bred. Since then, there have been no recordings and it is probably now extinct in the Black Forest. Although 2015 was a very hot and dry year, in 2016 main habitats of the moor dragonflies *Aeshna subarctica*, *Leucorrhinia dubia*, *Somatochlora arctica* und *S. alpestris* were found here. Therefore, an increase and stabilisation of the former two species must have occurred. In 2011, the upper parts of three old drainage ditches, which had a damaging effect on the moor, were blocked. It is very likely that this was the main cause for the population increase in some species. However, this measurement is not sufficient, because in 70 % of the 77 big pools and other water bodies, no or only very small populations of successfully emerged moor dragonflies were recorded. The water bodies dried up even in the "normal" summer of 2016 and were very likely dried up for a long period in 2015. Suggestions for a continuing reconstitution of the moor were elaborated. Moor dragonflies are perfectly suited as indicators of the condition of the water bodies in which they develop and also indirectly of the moor." (Author)] Address: Westermann, K., Buchenweg 2, D-79365 Rheinhausen, Germany

**18393.** Westermann, K. (2017): Zur Drift der Larven der Kleinen Zangenlibelle (*Onychogomphus forcipatus*) im Fluss-System Elz-Dreisam-Leopoldskanal-Restrhein. *Naturschutz am südlichen Oberrhein* 9: 141-154. (in German, with English summary) ["The drift of larvae of *O. forcipatus* in the river system Elz-Dreisam-Leopoldskanal-Restrhein. According to investigations along a 34 km channel-like constructed section of the river system of the Elz, Dreisam, Leopoldskanal and Restrhein (districts of Emmendingen and Breisgau-Hochschwarzwald, Baden-Württemberg) the hatching abundance of *O. forcipatus* reached a high number of up to 27 exuviae / meter and year along the river bank at the lower reaches. at the middle reaches, there were significantly fewer. In contrast, the abundance of adult males along the middle reaches was much higher than along the lower reaches. This phenomenon can only be explained by downstream drift of a high portion of larvae over a large distance which is compensated by an upstream flight movement of the imagoes. The downstream drift of the larvae facilitates the buildup of a large population of *O. forcipatus* with several hundreds of thousands of freshly emerged imagoes. Drifted larvae find a large supply of refuges which are protected from flooding and with lower stream velocity along the Leopoldskanal and lower reaches of Elz and Dreisam. In the significantly warmer eutrophic lower reaches, which are presumably richer in feed, the development is faster, leading to an earlier emergence on average of the imagoes. adult imagoes gather along the middle reaches in the area of quickly flowing and turbulent sections, which seem to be the preferred sites for pairing and oviposition. the eggs and young larvae are deposited on water which is cooler and has higher oxygen levels than in the lower reaches. If this drift is enforced due to severe floods in the form of a „catastrophic drift“ or if the larvae drift more spontaneously as a strategy in view of an advantage of the biology of the population, remains unclear." (Author)] Address: Westermann, K., Buchenweg 2, D-79365 Rheinhausen, Germany

**18394.** White III, H.B.; O'Brien, M.F. (2017): Naming an undescribed dragonfly: Williamson's *Williamsonia* and the travails of R. Heber Howe Jr.. *Northeastern Naturalist* 24 (Monograph 14): 1-43. ["R. Heber Howe Jr. (1875–1932), a New England preparatory school teacher and natural historian, became interested in dragonflies after one of his students found the rare *Williamsonia lintneri* (Hagen) school property. Subsequently, Howe quickly became a prominent regional authority on Odonata through his own studies and through his frequent correspondence with E.B. Williamson and other established dragonfly authorities. In 1922, while Howe was drafting an article on the history of *W. lintneri*, Williamson discovered a second species of *Williamsonia*, which Howe may have also recognized. Correspondence archived from this period reveals a dispute between Howe and Williamson about naming and describing the new species that peripherally involved Philip P. Calvert and Clarence H. Kennedy, other well-established dragonfly specialists, and Canadian entomologists James H. McDunnough and Edmund M. Walker. Howe's position in the dispute that the new species had previously been named in the literature, though not

formally described, did not prevent Williamson from describing and naming *Williamsonia fletcheri*. Yet behind the scenes, expressed in letters, the saga reveals tensions that can develop, exposing personality traits, among specialists with competing interests." **18395.** Wiederman, S.D.; Fabian, J.M.; Dunbier, J.R.; O'Carroll, D.C. (2017): A predictive focus of gain modulation encodes target trajectories in insect vision. *eLife* 2017; 6:e26478: 19 pp. (in English) ["When a human catches a ball, they estimate future target location based on the current trajectory. How animals, small and large, encode such predictive processes at the single neuron level is unknown. Here we describe small target-selective neurons in predatory dragonflies that exhibit localized enhanced sensitivity for targets displaced to new locations just ahead of the prior path, with suppression elsewhere in the surround. This focused region of gain modulation is driven by predictive mechanisms, with the direction tuning shifting selectively to match the target's prior path. It involves a large local increase in contrast gain which spreads forward after a delay (e.g. an occlusion) and can even transfer between brain hemispheres, predicting trajectories moved towards the visual midline from the other eye. The tractable nature of dragonflies for physiological experiments makes this a useful model for studying the neuronal mechanisms underlying the brain's remarkable ability to anticipate moving stimuli." **18396.** Wildermuth, H. (2017): Die Libellenfauna (Odonata) zweier neu angelegter Wiesenweiher - Sukzession, Prädation, Manipulation. *Libellula* 36: 109-134. (in German, with English summary) ["Odonata of two newly created meadow ponds: succession, predation, and manipulation – In the southern Canton of Zürich (Switzerland) the Odonata fauna of two meadow ponds, created in autumn 2010, was recorded on 72 days from 2012 to 2017. In total, ca 1.000 data sets were collected for 37 recorded species, 14 of them with regular reproduction. The results are summarized in tables with regard to the following aspects: (1) yearly presence and evidenced reproduction of all species, (2) maximum yearly number of imagines per recording day, and (3) number of recording days per year with presence of the species. Spectrum of species, origin, and reproduction success of the various species are discussed in respect of the neighbouring potential of species, water regime, water fowl as possible predators, vegetation and its succession, and clearing of prevailing aquatic vegetation. For the promotion of the local odonate fauna at newly created small ponds in rural landscape adequate habitat maintenance is indispensable." **18397.** Williams, E.B.; Chumchal, M.M.; Drenner, R.W.; Kennedy, J.H. (2017): Seasonality of odonate-mediated

methyl mercury flux from permanent and semi-permanent ponds and potential risk to red-winged blackbirds (*Agelaius phoeniceus*). *Environmental Toxicology and Chemistry* 36 (10): 2833-2837. (in English) ["Methyl mercury (MeHg) is an aquatic contaminant that can be transferred to terrestrial predators by emergent aquatic insects such as odonates. We assessed the effects of month and pond permanence on odonate-mediated MeHg flux (calculated as emergent odonate biomass x MeHg concentration) in 10 experimental ponds and the potential risk to nestling red-winged blackbirds (*Agelaius phoeniceus*) posed by consuming MeHg-contaminated odonates. Emergent odonates were collected weekly from permanent ponds with bluegill (*Lepomis macrochirus*) (n = 5) and semi-permanent ponds without fish (n = 5) over an 8-month period (January - August, 2015). Methyl mercury flux from damselflies, aeshnid dragonflies and libellulid dragonflies began in March and peaked in April, May and June, respectively, and then declined throughout the rest of the summer. Odonate-mediated MeHg flux from semi-permanent ponds without fish was greater than odonate-mediated MeHg flux from permanent ponds with fish. Nesting of red-winged blackbirds overlapped with peak odonate emergence and odonate-mediated MeHg flux. Because the diet of nestling red-winged blackbirds can be dominated by damselflies and dragonflies, we tested the hypothesis that MeHg-contaminated odonates may pose a health risk to nestling red-winged blackbirds. Methyl mercury concentrations in odonates exceeded wildlife values (the minimum odonate MeHg concentrations causing physiologically significant doses in consumers) for nestlings, suggesting that MeHg-contaminated odonates can pose a health risk to nestling red-winged blackbirds." **18398.** Willink, B.; Svensson, E.I. (2017): Intra- and intersexual differences in parasite resistance and female fitness tolerance in a polymorphic insect. *Proc. R. Soc. B* 284 (1847): 8 pp. (in English) ["To understand host-parasite interactions, it is necessary to quantify variation and covariation in defence traits. We quantified parasite resistance and fitness tolerance of a polymorphic damselfly (*Ischnura elegans*), an insect with three discrete female colour morphs but with monomorphic males. We quantified sex and morph differences in parasite resistance (prevalence and intensity of water mite infections) and morph-specific fitness tolerance in the females in natural populations for over a decade. There was no evidence for higher parasite susceptibility in males as a cost of sexual selection, whereas differences in defence mechanisms between female morphs are consistent with correlational selection operating on combinations of parasite resistance and tolerance. We suggest that tolerance differences between female morphs interact with frequency-dependent sexual conflict, which maintains the polymorphism locally. Host-parasite interactions can therefore shape intra- and intersexual phenotypic divergence and interfere with sexual selection and sexual conflict." **18399.** Worthen, W.B. (2017): Perch selection in a guild of tropical dragonflies (Odonata: Libellulidae): relationships with body size and thermal ecology. *International Journal of Odonatology* 20(2): 63-78. (in English) ["In the temperate zone, male perch height of co-occurring dragonfly species (Odonata: Libellulidae) often correlates with species body size. I tested for this relationship in a guild of tropical dragonflies at a wetland at La Selva Biological Station, Heredia, Costa Rica. Males of 12 species were observed perching in January–February 2016. Mean male perch height was positively correlated with species body size. For six common species, I quantified differences in perch substrate selection, relationships between diurnal activity, temperature and radiation, and aggressive interactions. The largest species, *Libellula herculea* and *Orthemis discolor*, exhibited typical heliotherm behavior: they used sunny perches at mid-day, and activity correlated more with radiation than temperature. *Orthemis cultriformis*, a slightly smaller heliotherm, was active at mid-day but used shadier perches. *Micrathyrina atra* – previously classified as a “behavioral endotherm” – behaved accordingly, avoiding over-heating by flying early and perching in moderate light. The smallest common species, *Erythrodiplax fervida*, departed from the expected “thermoconformer” behavior by showing no relationship between activity and temperature, perching throughout the day in shaded grasses. The medium-sized *Cannaphila insularis* was unusual, perching 1 m higher than other species. Like larger heliotherms, activity occurred mid-day and correlated with solar radiation. Larger species exhibited greater degrees of interspecific aggression than smaller species. *Cannaphila insularis* is a docile species, but juveniles and females resemble the larger, more aggressive *O. cultriformis*. I hypothesize that *C. insularis* perches high to escape harassment and “reproductive interference” by *O. cultriformis*.” (Author)] Address: Worthen, W.B., Biology Dept, Furman Univ., Greenville, SC, USA, 29613. **18400.** Wright, I.A.; Belmer, N.; Davies, P.J. (2017): Coal mine water pollution and ecological impairment of one of Australia's most 'Protected' High Conservation-Value rivers. *Water Air and Soil Pollution* 228:90: 19 pp. (in English) ["The environmental regulation of a coal mine in the greater Sydney area has failed to recognise the importance of and protect a high conservation-value river located in a World Heritage listed area. This study measured the water quality and ecological health (using macroinvertebrates) of the Wollangambe River and its tributaries near the point of the waste water discharge of a coal mine and assessed the longitudinal impact for 22 km downstream. The investigation revealed two important aspects. The first is the significant impact of the waste water discharge when compared to the otherwise near-pristine condition of the high conservation value river system. The second is the spatial extent of the pollution from the mine that extends at least 22 km downstream from the outflow of coal mine wastes. The resulting water pollution is causing major impairment of the aquatic ecosystem, with reduced abundance, taxonomic richness and loss of pollution-sensitive macroinvertebrate groups. Water pollu-

tion from the mine includes thermal pollution, increased salinity and increased concentrations of zinc and nickel. The mine's waste discharge also strongly modified the river's ionic composition. The study also highlights the failure of the regulatory and governance systems that enable the mine to operate in a manner that causes major environmental impacts.” Aeshnidae (Authors)] Address: Wright, I.A., School of Science & Health, Western Sydney Univ., Locked Bag 1797, Penrith 2751, Australia. **18402.** Younes, A.; El-Sherief, H.; Gawish, F.; Mahmoud, M. (2017): Experimental evaluation of Odonata nymph in the biocontrol of schistosomiasis intermediate hosts. *Asian Pacific Journal of Tropical Biomedicine* 6(12): 995-1000. (in English) ["Highlights: •*Bulinus truncatus* and *Biomphalaria alexandrina* snails are obligatory hosts of *Schistosoma*. •Elimination or reducing these snails will reduce the chances of transmission of Schistosomiasis disease. •The predator *Hemianax ephippiger* was evaluated against these snails. •*H. ephippiger* can be used in biological control of the freshwater snails. Abstract: Objective: This study has been carried out to evaluate the predatory potential of the Odonata nymph on freshwater snails that serve as intermediate hosts for *Schistosoma* species (*Bulinus truncatus* and *Biomphalaria alexandrina*). Methods: Observations on the searching, attacking and devouring of the two snail types with series of laboratory-based predation experiments, whose aims were to determine daily predation rate, differential predation, prey preference considering small-, medium- and large-sized snails were conducted. Results: Laboratory evaluation revealed that, the Odonata nymph could kill and consume the two intermediate hosts. The number of snails consumed differed according to the snail type, size and density. The times taken for searching and handling times were dependent on

the snail size, type and satiation of the predator. The predation rate varied also with respect to snail type, size and density. This study also evaluated that Odonata nymphs consumed more *B. truncates* per unit time than *B. alexandrina*, and that there may be a preference for smaller than larger snails. Conclusion: According to our observation, the predator, *H. ephippiger* nymph may be a suitable bio-control agent in connection with *Schistosoma* intermediate hosts." (2017): Distribution of rare invertebrate animals listed in the Red Data Book of Ukraine in Ivano-Frankivsk Region. Ukrainian Entomological Journal 2(13): 77-94. (in Ukrainian, with Russian and English summaries) ["In the current study we present comprehensive list of 65 rare invertebrate animal species listed in third edition of the Red Data Book of Ukraine and their records in Ivano-Frankivsk Region of Ukraine. Some of the listed species are under protection of International legal acts such as Bern Convention – 15 species, European Red List – 14 species, Red List of IUCN – 21 species and EU Habitats Directive – 11 species. We provide detail data on their records, estimation of populations size and their range in Ivano-Frankivsk Region. We found that two species are, possibly, extinct in the Region. Populations of three species are critically endangered and dramatically decreasing in the size. Fifteen species are characterized by small and stable populations. We revealed that populations of fourteen species are large in size with high density of individuals. Two species rapidly increased their range northward and currently penetrated into Ivano-Frankivsk Region. However, there are no sufficient data on population size for the rest 29 species. We described distribution of the rare species within Ivano-Frankivsk Region. According to our data, 21 species are widely distributed in the Region occupying the Carpathian Mountains, the Precarpathian Lowland and the Podillya Eminence. Seventeen species were registered only in the Carpathian Mountains; all other species distributed mainly within the Precarpathian Lowland and/ or the Podillya Eminence. Present data can be used in preparation the IV edition Red data Book of Ukraine, and also be a base for creation Red book of Ivano-

Frankivsk Region." (Authors)] Address: Zamoroka, A.M.. E-mail: andrii.zamoroka@pu.if.ua,

**18405.** Zeuss, D.; Brunzel, S.; Brandl, R. (2017): Environmental drivers of voltinism and body size in insect assemblages across Europe. Global Ecology and Biogeography 26(2): 154-165. (in English) ["Aim: General geographical patterns of insect body size are still a matter of considerable debate, mainly because the annual number of generations (voltinism) and its relationship with body size have largely been ignored. We present the first analyses of voltinism and body size of insect assemblages at a continental scale using lepidopteran and odonate species. We hypothesize that voltinism is strongly driven by environmental conditions and constrains body size on macroecological scales. Location: Europe. Methods: We compiled the distribution, voltinism and body size of 943 lepidopteran and odonate species within a 50 km × 50 km grid system, thereby presenting a novel method for estimating the body volume of species from digital images. Regressions and structural equation modelling were applied to distinguish the effects of temperature, productivity and season length on mean voltinism and body size within grid cells. We accounted for spatial autocorrelation with autoregressive models and analysed the possible effect of species richness and intraspecific variability. Results: Voltinism consistently decreased with latitude for both lepidopterans ( $r^2 = 0.76$ ) and odonates ( $r^2 = 0.86$ ), with species having on average fewer generations per year in northern Europe and more generations per year in southern Europe. The effects of temperature, productivity and season length on body size contrasted in sign between lepidopterans and odonates, leading to opposing geographical patterns across Europe. Main conclusions: Voltinism in insect assemblages is strongly driven by environmental temperature, and trade-offs between voltinism and body size influence the occurrence of species at macroecological scales. Insects with the ability to extend their generation time over multiple years can overcome this constraint, allowing for a relatively large body size in cold areas. Our results furthermore support the idea that body sizes of terrestrial and aquatic insects form contrasting geographical patterns because they are differently affected by temperature and resource constraints." **18406.** Zeyghami, S.; Bode-Oke, A.T.; Dong, H. (2017): Quantification of wing and body kinematics in connection to torque generation during damselfly yaw turn. Science China Physics, Mechanics & Astronomy 60(014711): 13 pp. (in English) ["This study provides accurate measurements of the wing and body kinematics of three different species of damselflies in free yaw turn flights. The yaw turn is characterized by a short acceleration phase which is immediately followed by an elongated deceleration phase. Most of the heading change takes place during the latter stage of the flight. Our observations showed that yaw turns are executed via drastic rather than subtle changes in the kinematics of

all four wings. The motion of the inner and outer wings were found to be strongly linked through their orientation as well as their velocities with the inner wings moving faster than the outer wings. By controlling the pitch angle and wing velocity, a damselfly adjusts the angle of attack. The wing angle of attack exerted the strongest influence on the yaw torque, followed by the flapping and deviation velocities of the wings. Moreover, no evidence of active generation of counter torque was found in the flight data implying that deceleration and stopping of the maneuver is dominated by passive damping. The systematic analysis carried out on the free flight data advances our understanding of the mechanisms by which these insects achieve their observed maneuverability. In addition, the inspiration drawn from this study can be employed in the design of low frequency flapping wing micro air vehicles (MAV's)." **18407.** Zhang, R.; Xie, P.; Zhou, C.; Wang, C. (2017): Three-dimensional numerical study on the interaction of contralateral insect wings in asymmetric stroke. Proceedings of the Institution of Mechanical Engineers, Part G: Journal of Aerospace Engineering 232(9): 1671-1684. (in English) ["Asymmetric flight of insects and birds is often seen in nature which is a conventional way for them to obtain the flexibility of maneuver in turning, hovering, and gliding. A numerical study on the interaction between contralateral wings of a dragonfly in asymmetric forward flight is carried out using the finite volume method. Various asymmetric flights with different advance ratios are considered where the aerodynamic forces, torques of each wing, pressure distributions, vorticity, and velocity fields are analyzed. A number of symmetric flights corresponding to the asymmetric flights are also studied. The results indicate that the interaction between the contralateral wings of a dragonfly is very small even when the dragonfly is in an asymmetric flight no matter how the advance ratios vary in the range concerned. With a typical example of asymmetric forward flights the difference in the mean value of vertical force coefficient is generally less than 5% compared with that for its corresponding symmetric flight. It is found that a small lateral flow region (LFR) is formed near the body, and there is a small lateral flow across the symmetric plane of the body. But this flow is very weak and resulted interaction between contralateral wings is very small. The result has confirmed in a way that dragonflies take a quite different way from fruit flies to obtain the lift with the contralateral wings. That is, fruit flies employ clap-and-fling mechanism which needs contralateral wings to be close enough to extrude the flow and generate lift, which means the contralateral two wings are so close that strong interaction happens, while dragonflies flap their contralateral wings on two sides of the vertical central plane with a relatively far distance between the wings where the interaction of contralateral wings is negligibly weak." **18409.** Zhu, C.; Wang, P.; Li, Y.; Chen, Z.; Li, H.; Ssebuge, P.; Zhang, Q.; Jiang, G. (2017): Trophic transfer of hexabromocyclododecane in the terrestrial and aquatic food webs from an e-waste dismantling region in East China. Environmental Science: Processes & Impacts 19(2): 154-160. (in English) ["A Trophic transfer of hexabromocyclododecane (HBCD) was investigated in both the terrestrial and aquatic food webs from an e-waste dismantling region in East China. The mean  $\Sigma_3$ HBCDs concentrations in the terrestrial species varied from 0.91 (0.16-1.85) ng g<sup>-1</sup> lipid weight (lw) in *Pantala flavescens* to 40.3 (22.1-51.1) ng g<sup>-1</sup> lw in rat (*Rattus norvegicus*). Isomeric profile indicated that  $\alpha$ -HBCD presented a decreasing trend along the trophic level (TL) (from 97.2% to 16.3% of  $\Sigma_3$ HBCDs), while  $\gamma$ -HBCD showed a reversed trend (from 2.8% to 73.6% of  $\Sigma_3$ HBCDs). Trophic magnification factor (TMF) derived from the slope of regression line between TLs and ln-transferred  $\Sigma_3$ HBCDs was 0.10, suggesting a trophic dilution of HBCD in the terrestrial food web. By contrast, in the aquatic species,  $\Sigma_3$ HBCDs concentrations varied from 5.02 (3.5-6.55) ng g<sup>-1</sup> lw in apple snail (*Ampullaria gigas* spix) to 45.9 (14.9-67.8) ng g<sup>-1</sup> lw in grass carp (*Ctenopharyngodon idellus*).  $\alpha$ -HBCD was the dominant isomer, followed by  $\gamma$ -HBCD in the majority of species. Positive linear relationship was observed in the plots of ln  $\Sigma_3$ HBCDs versus TLs ( $R^2=0.81$ ,  $p=0.06$ ). TMF for  $\Sigma_3$ HBCDs was 6.36, indicating a trophic magnification of HBCD in the aquatic food web. Although these results demonstrated the distinct trophic transfer of  $\Sigma_3$ HBCDs in the different ecosystems, further research is needed to eliminate the uncertainty of the tendencies, due to the non-significant relationship and limited species." (Authors)] Address: Wang, P., State Key Lab. of Environmental Chemistry & Ecotoxicology, Research Center for Eco-Environmental Sciences, Chinese Academy of Sciences, Beijing 100085, China. **18410.** Šidagyte, E.; Razlutskiy, V.; Alekhovich, A.; Ry-

bakovas, A.; Moroz, M.; Šniaukštaite, V.; Vaitonis, G.; Arbačiauskas, K. (2017): Predatory diet and potential effects of *Orconectes limosus* on river macroinvertebrate assemblages of the southeastern Baltic Sea basin: implications for ecological assessment. *Aquatic Invasions* 12(4): 523-540. (in English) ["Invasive crayfish can affect macroinvertebrate assemblages and thus alter conventional macroinvertebrate-based ecological assessment. We aimed to reveal potential impacts of the North American crayfish *Orconectes limosus* on river assessment in the Neman River basin (southeastern Baltic Sea). A laboratory experiment using identical macroinvertebrate assemblages was conducted to compare feeding selectivity and effects between *O. limosus* and the European *Astacus leptodactylus*. Field experiments were conducted to evaluate potential impacts of *O. limosus* on disturbed and undisturbed crayfish-free macroinvertebrate assemblages: one dominated by Oligochaeta vs. one co-dominated by Ephemeroptera-Plecoptera-Trichoptera and Mollusca (EPT codominated). In the laboratory experiment, both crayfish species preferred feeding on Diptera (mostly chironomids), but *O. limosus* also selected Trichoptera and Ephemeroptera. Family richness did not change, but both species inflated the Shannon Diversity index by reducing Diptera domination. *Astacus leptodactylus* treatments had higher Shannon Diversity and percentage of EPT abundance compared to *O. limosus* treatments. Field experiments indicated (1) negative, (2) assemblage-specific, or (3) no effects of *O. limosus* on macroinvertebrate metrics. A negative effect, especially in the undisturbed assemblage, was observed on simple additive metrics based on taxa presence data, such as total or EPT family richness, or BMWP (Biological Monitoring Working Party) score. Assemblage-specific effects were indicated for some metrics based on relative abundances. In the Oligochaeta dominated assemblage, Shannon Diversity was inflated and the percentage of Oligochaeta abundance was reduced. In the EPT codominated assemblage Shannon Diversity was deflated while the relative abundance of Oligochaeta was not affected. No effects were observed when using the ASPT (Average BMWP Score Per Taxon) or percentage of EPT abundance. We conclude that *O. limosus* may have a more diverse predatory diet than *A. leptodactylus*, and thus can have a stronger effect on macroinvertebrate taxa sensitive to disturbances. Therefore, the invasion of *O. limosus* can alter macroinvertebrate assemblages and compromise conventional ecological assessment, even when it displaces resident *Astacus* species. ... No changes were observed in Odonata (Calopterygidae, Gomphidae) and Coleoptera abundances after terminating the experiment in any aquarium" (Authors)] Address: Šidagyte, E., Nature Research Centre, Akademijos St. 2, 08412 Vilnius, Lithuania. **18411.** Anderson, C.B.; Johnson, M.; Lopez, M.E. (2018): Establishing habitat-specific indicator species in Tierra del Fuego with freshwater macroinvertebrates. *New Zealand Journal of Marine and Freshwater Research* 52(1): 145-154. ["As a tool to understand Tierra del Fuego's basic ecology and detect changes due to human pressures, this

study develops habitat bioindicators. We compared the freshwater benthic macroinvertebrates at 61 study sites in six habitat types: grassland streams, urbanised streams, forested streams, beaver ponds, lakes and peat bog ponds. Forty-nine taxa were identified; insects were the most diverse group. Beaver pond, lake and grassland stream assemblages were similar, as were those from lakes, grassland streams and peat bog ponds. Fourteen taxa were habitat-specific. In forests, these included mayfly scrapers (*Andesiops*, *Meridialaris*) and blackfly filterers (*Gigantodax*). In lakes, two copepod filterers were indicators, and in urban streams, one shredder (*Aphroteniella*) and three collector-gatherers (springtail, earthworm, aquatic worm). Predators (*Corixa*, *Aeshna*) were characteristic of peat bog ponds. Beaver ponds had no indicator species. Establishing links between species and ecosystems constitutes the beginning of a broader effort to understand anthropogenic impacts to Fuegian watersheds." **18412.** Bried, J.T.; Murray, S.N.; Jog, S.K.; De Marco Jr, P. (2018): Emergence timing and fixation height in *Pachydiplax longipennis* (Odonata: Libellulidae) at varying substrate density and sunlight exposure. *International Journal of Odonatology* 21(3-4): 181-187. (in English) ["Emergence substrate and sunlight penetration inherently trade off in patchy vegetation. Given the importance of solar radiation at emergence, we expected greater sunlight availability in sparse vegetation to advance emergence timing and reduce the average height of emergence fixation. We used outdoor mesocosms stocked with varying cattail (*Typha*) densities and late-stage *Pachydiplax longipennis* larvae. As predicted, emergence based on exuviae observations began significantly earlier (5 d) at lower cattail density and greater sunlight exposure, with over 60% of the emergence completed midway into the experiment period, compared to about 50% in the medium and higher density cattail. This finding suggests lag effects under relatively limited light availability in a temperate-centered lentic-breeding heliotherm. Contrary to our prediction, we found significantly greater emergence heights at lower cattail density ( $x=18.0\text{cm}$ ) than at medium ( $x=13.0\text{cm}$ ) and higher ( $x=10.0\text{cm}$ ) densities. We recommend further study of emergence heights using larval choice experiments in natural settings. Variation in emergence timing and fixation height under the substrate-sunlight trade-off may be driven proximally by larval choices/development and ultimately by adult activity." **18413.** Bried, J.T.; Hinchliffe, R.P. (2018): Improving taxonomic resolution in large-scale freshwater biodiversity monitoring: an example using wetlands and Odonata. *Insect Conservation and Diversity* 12: 9-17. (in English) ["1. Immature aquatic insects are a major source of taxonomic difficulty in large-scale freshwater biodiversity monitoring. Adult stages could improve taxonomic resolution for assessing

distributions and trends of biodiversity. Odonata have accessible adult stages that should greatly enhance the amount of species-level information. 2. We used Odonata and a wetland monitoring programme in Alberta, Canada to illustrate how much taxonomic information can be lost in larval collections, and an extensive adult records database to estimate what could be gained from adult surveys. 3. Despite processing 22 638 odonate specimens from 975 wetlands throughout Alberta, larval monitoring failed to collect or identify almost 60% of the lentic-breeding Odonata species known from adult records. A total of 25 lentic-breeding dragonfly species and 12 lentic-breeding damselfly species were present in adult records and not the larval data, including species of conservation concern. Due to the abundance of early instars, a substantial 82% of the processed damselfly collection and 62% of the processed dragonfly collection was left at suborder. 4. We recommend supplementing aquatic sampling with adult rearing, collecting, and observing (at least Odonata) to improve the basic inventory and overall status assessment in large-scale freshwater biodiversity monitoring. This is especially true when aquatic sampling is restricted to a suboptimal time of year for species identifications." **18414.** Bried, J.T.; Siepielski, A.M. (2018): Opportunistic data reveal widespread species turnover in *Enallagma* damselflies at biogeographical scales. *Ecography* 41: 958-970. (in English) ["An information tradeoff exists between systematic presence/absence surveys and purely opportunistic (presence-only) records for investigating the geography of community structure. Opportunistic species occurrence data may be of relatively limited quality, but typically involves numerous observations and species. Given the quality-quantity tradeoff, what can opportunistic data reveal about spatial patterns in community structure? Here we explore opportunistic data in describing geographic patterns of species composition, using over 4,600 occurrence records of *Enallagma* damselflies in the United States. We tested phylogenetic scale (genus level, *Enallagma* major clades, *Enallagma* subclades) and spatial extent (U.S. vs. watershed regions), hypothesizing that nonrandom structure is more likely at larger spatial extents. We also used three sets of systematic presence/absence surveys as a benchmark for validating opportunistic presence-only records. Null model analysis of matrix coherence and species replacements showed many cases of nonrandom structure and widespread species turnover. This outcome was repeated across spatial and environmental gradients and community composition scenarios. Turnover dominated across the U.S. and two watersheds spanning biogeographic boundaries, but random assemblages were prevalent in a third watershed with limited longitudinal extent. Turnover also pervaded each level of phylogeny. Opportunistic presence-only datasets showed identical patterns as systematic presence/absence datasets. These results indicate that extensive opportunistic data can be used to detect species turnover, especially at geographic scales where range

margins are crossed." (Authors)] Address: Bried, J.T., Department of Biological Sciences, University of Arkansas, Fayetteville, AR, USA. E-mail: bried@uark.edu

**18415.** Carey, N.; Strachan, S.R.; Robson, B.J. (2018): Impacts of Indian waterfern (*Ceratopteris thalictroides* (L.) Brongn.) infestation and removal on macroinvertebrate biodiversity and conservation in spring-fed streams in the Australian arid zone. *Aquatic Conservation: Marine and Freshwater Ecosystems* 28(2): 466-475. (in English) ["1. Removal of invasive macrophytes is a priority for river managers. However, the ecological effects of macrophyte removal on macroinvertebrate diversity are rarely examined but may be of particular significance in conservation reserves and when threatened species are present. 2. This study investigated the macroinvertebrate fauna inhabiting invasive and native macrophytes in spring-fed channels in the Millstream-Chichester National Park, Australia. The effects of waterfern management (periodic hand-weeding) were examined by comparing assemblages at weeded and unweeded reaches on three occasions. 3. *Ceratopteris thalictroides* harboured a diverse, insect-dominated macroinvertebrate assemblage, including the endangered damselfly *Nososticta pilbara*. Total taxon richness was similar between waterfern and native macrophytes, but macroinvertebrate assemblages differed in the dry season. Damselflies (including *N. pilbara*) were associated with waterfern-dominated reaches, whereas dragonfly nymphs were more common among native macrophytes. 4. Weeding altered macroinvertebrate assemblage composition. Some weeded reaches developed assemblages indistinguishable from those in native-dominated reaches, but others did not. Weeded reaches often supported taxa that were rare or absent from waterfern-dominated reaches, including suspension feeders, found also in native-dominated reaches. 5. Odonata are particularly diverse at Millstream, with 18 species recorded. Odonate species richness was significantly lower at weeded reaches than unweeded reaches. *Nososticta pilbara* and other short-range endemic species were absent from weeded reaches. As most odonates are univoltine, these adverse effects on local population size may affect species persistence. 6. Invasive macrophyte species may support a high diversity of native invertebrates, including endangered and short-range endemic species. Furthermore, although hand-weeding appeared to enable a greater diversity of species to co-exist, the removal of a large biomass of macrophytes appeared to remove whole cohorts of insect populations from stream reaches, including endangered species. Removal of invasive macrophytes should not be implemented without understanding their effects on invertebrate assemblage composition and life-cycles." **18417.** Henry, E.R.; Rivera, J.A.; Linkem, C.N.; Scales, J.A.; Butler, M.A. (2018): Damselflies that prefer dark habitats illustrate the importance of light as an ecological resource. *Biological Journal of the Linnean Society* 123(1): 144–154. (in English) ["Habitat associations provide clues to the resources that influence the life of animals. Food distribution, structural microhabitat or degree of insolation can determine species' strategies for energy acquisition, locomotor strategy or thermoregulation. A growing body of research suggests that insolation may be important not for heat, but rather for visual performance in communication, crypsis or prey capture. Odonates are famous for their heliothermic habitat associations. *Megalagrion nigrohamatum nigrolineatum* is a forest-dwelling damselfly endemic to the island of O'ahu and part of an ecologically diverse adaptive radiation with spectacular body coloration. Although many *Megalagrion* exploit full sun, *nigrolineatum* can be curiously found in deep shade raising the possibility that it is shade-seeking. Here, we show that *nigrolineatum* selects perches based on light, and not perch type or temperature. Surprisingly, they did not select the brightest locations available (as might be expected if they are extending their visual function in a challenging habitat), but chose darker perches in a fairly dark habitat. This strategy opens up niche space that is abundantly available in forests, yet little-occupied by other odonates. We discuss implications of shade-seeking for communication, evolutionary diversification and preserving future evolutionary potential." **18418.** Jesús, F.; Hladki, R.; Gérez, N.; Besil, N.; Niell, S.; Fernández, G.; Heinzen, H.; Cesio, M.V. (2018): Miniaturized QuEChERS based methodology for multiresidue determination of pesticides in odonate nymphs as ecosystem biomonitors. *Talanta* 178(1): 410–418. (in English) ["Highlights: •A method to determine 73 pesticide residues in 0.2 g odonate nymphs was developed. •The methodology is simple, low cost, miniaturized and environmentally friendly. •LOQs of 1 µg kg<sup>-1</sup> for many compounds were achieved. •Two positive findings of metsulfuron-methyl were obtained in real samples. •The developed and validated methodology can be used for monitoring programs. Abstract: The impacts of the modern, agrochemicals based agriculture that threatens the overall systems sustainability, need to be monitored and evaluated. Seeking for agroecosystems monitors, the present article focus in the occurrence and abundance of aquatic macroinvertebrates, that have been frequently

used as bioindicators of water quality due to their relationship with land use. Some of these organisms are on the top of the food chain, where bioaccumulation and biomagnification processes can be observed, and they can turn into secondary pollution sources of systems and terrestrial organisms as well. Odonate nymphs, which belong to the functional group of predators, were selected for this study. A methodology to determine 73 pesticide residues in odonate nymphs by LC-MS/MS and GC-MS/MS was developed. A QuEChERS sample preparation strategy was adapted. As it is complex to obtain samples especially in disturbed ecosystems, the method was minimized to a sample size of 200 mg of fresh nymphs. The method was validated and good recoveries (71–120%) with RSDs below 20% for the majority of the studied pesticides at least at two of the assayed levels 1, 10 and 50 µg kg<sup>-1</sup> were obtained. For 32 analytes the limit of quantitation was 1 µg kg<sup>-1</sup> and 10 µg kg<sup>-1</sup> for the others. The lineal range was observed between 1–100 µg kg<sup>-1</sup> in matrix-matched and solvent calibration curves for most of the assessed pesticides. LC-MS/MS matrix effects were evaluated, 40% of the analytes presented low or no signal suppression. Only flufenoxuron presented high matrix effects. The obtained methodology is adequate for pesticide multiresidue analysis in aquatic macroinvertebrates (odonates) aiming to contribute to the ecological state evaluation of freshwater ecosystems." **18419.** Suhonen, J.; Ilvonen, S.; Dunn, D.W.; Dunn, J.; Härmä, O.; Ilvonen, J.J.; Kaunisto, K.M.; Krams, I. (2018): Parasitism affects variation in a male damselfly sexual ornament. *Ethology Ecology & Evolution* 30(3): 256–266. (in English) ["Sexually selected ornaments in animals are costly, with parasitism often affecting the degree to which they are expressed. Male *Calopteryx splendens* damselflies exhibit melanised 'wing spots'. Those possessing large spots are favoured by females but also have an increased likelihood of being attacked by *C. virgo*, a common sympatric competitor. Melanin is used to produce the wing spots, but it is also used in immune defence against parasites that commonly infect damselflies. A total of 261 *C. splendens* males were collected from 26 Finnish and Latvian populations, of which half were found to be sympatric with *C. virgo*. It was found that males which originated from populations in which eugregarine parasites were present had smaller wing spots than individuals from parasite-free populations. Contrary to previous studies, the wing spots of *C. splendens* males in populations sympatric with *C. virgo* were not found to be smaller than those in allopatric populations. Parasite presence in *C. splendens* was found to be strongly associated with populations sympatric with *C. virgo*. The results suggest that the presence of *C. virgo* may increase rates of parasitism in *C. splendens*, and show that parasitism is an important additional factor to interspecific aggression in determining variation in the sizes of the wing spots of *C. splendens* males. These findings highlight a lack of understanding on the determinants of the expression of secondary sexual characters

and the processes of how parasitism affects hosts." (Authors)] Address: Suhonen, J., Dept of Biology, University of Turku, FI-20014 Turku, Finland

**18420.** Debecker, S.; Stoks, R. (2019): Pace of life syndrome under warming and pollution: integrating life history, behavior and physiology across latitudes. *Ecological monographs* 89(1): 22 pp. (in English) ["To fully comprehend and predict the impact of drivers of global change such as climate warming and pollution, integrated multi-trait approaches are needed. As organismal traits are often correlated, responses to stressors are expected to induce coordinated changes in many traits. A promising framework to study this is the pace-of-life syndrome (POLS), which predicts the integration of life-history, behavioral and physiological traits along a fast-slow continuum. Using an integrative multi-trait approach we evaluated the presence of a POLS both within and across latitudes and how POLS patterns are affected by warming and metal pollution. We studied this in *Ischnura elegans* damselfly larvae of replicated low-and high latitude populations that strongly differ in voltinism (3-4 generations per year vs. 1 every two years) reared in a common-garden experiment at two temperatures. Across latitudes, life history, behavior and physiology covaried in accordance with the POLS, with the fast-paced low-latitude damselflies characterized by a fast growth rate, high activity and more explorative and risk taking behavior, fast metabolic rate and low investment in immune function (activity of phenoloxidase). This fast POLS strategy was associated with a higher sensitivity to metal exposure and a higher vulnerability to predation. Warming caused opposite responses between the latitudes consistent with differential thermal adaptation in growth rate, behavior and oxidative stress parameters. Despite this, damselflies of both latitudes showed a consistent pattern in phenotypic correlations among traits that, moreover was not affected by warming and metal exposure. Within latitudes there was no full support for the POLS. More active larvae were more explorative and risk taking, which aligned with the fast-slow life-history axis, but less strong than at the across-latitude level. Physiological traits were also integrated within latitudes, yet there was no unambiguous coupling with the fast-slow life-history continuum. The consistent syndrome structure, if underpinned by genetic correlations, may restrict the independent evolution of individual traits, yet may not necessarily constrain adaptive evolution of integrated trait sets. This is because the covariance pattern was to a large extent similar across latitudes and within latitudes, suggesting adaptive trait integration guiding adaptive evolution of trait sets along the fast-slow continuum." **18421.** Lavimi, R.; Hojaji, M.; Manshadi, M.D. (2019): Investigation of the aerodynamic performance and flow physics on cross sections of dragonfly wing on flapping and pitching motion in low Reynolds number. *Proceedings of the*

*Institution of Mechanical Engineers, Part G: Journal of Aerospace Engineering* 233(2):095441001773732: 589-603. (in English) ["In this research, the flow physics and aerodynamic performance of dragonfly cross sections, used in Micro Aerial Vehicles (MAVs), in low Reynolds are investigated. The main objective of the research is to study the performance of dragonfly wing cross-sections flapping motion in Reynolds 5000 and 10,000. Pitching motion is one of the most important mechanisms in force lifting generation, and the effects of Reynolds number and mean angle of attack on aerodynamic coefficients have been extensively investigated for the pitching motion. In the present study, the geometry of two cross sections of dragonfly was extracted. Incompressible, two-dimensional and unsteady Navier–Stokes equations have been used to simulate the flow. *k-ε* RNG model was used for turbulence modeling. To simulate the wing pitching motion, the dynamic mesh method was used. The results showed that in flapping motion, pitching-up rotation has caused a rapid increase in lift coefficient. Furthermore, it was found that the absence of stall does not increase the lift and drag coefficients, while formation of new strong vorticity layers have caused an increase in lift coefficient. On the other hand, corrugations on the cross sections of the dragonfly in the pitching motion cause the delay of separation and increasing the lift coefficient. In flapping motion and the pitching motion, the lift coefficients of three cross sections were increased due to stronger vorticity layers by reducing the Reynolds number. Due to the existence of corrugations, the first and the second cross sections have good aerodynamic performance, compared to the flat plate. The comparison carried out in the current research showed that the second cross section is a proper replacement for the flat plate in MAVs." **18423.** Zou, P.-Y.; Lai, Y.-H.; Yang, J.-T. (2019): Effects of phase lag on the hovering flight of damselfly and dragonfly. *Physical Review E* 100(6): 14 pp. (in English) ["In this work we investigated the mechanisms of hovering flight of damselflies (*Matrona cyanoptera*) and dragonflies (*Neurothemis ramburii*) with different phase lag between fore- and hindwings. The flight motion of damselflies and dragonflies in hovering were first recorded with two high-speed cameras, and the difference between the hovering motions of both species were analyzed. Because of differences in evolution, damselflies and dragonflies normally fly with forewing or hindwing in the lead, respectively. The fore- and hindwings of dragonflies are different shapes. In contrast, those of damselflies are very similar in size and shape. Therefore, they use different hovering strategies to adapt to differences in body morphology. Comparing the differences of wing phases in hovering, this work shows that the interactions between fore- and hindwings greatly affect their vortex structure and flight performance. The wake of a damselfly sheds smoothly; a vertical force is generated steadily during the stage of wing translation. Damselflies hover with a longer translation phase and a larger flapping amplitude. In contrast, the root vortex of a dragonfly impedes the shedding of wake vortices in the up-stroke, which results in the loss of a vertical force; the dragonfly therefore hovers with a large amplitude of wing rotation.] Address: Yang, J.-T., Dept Engineering Science & Ocean Engineering, National Taiwan Univ., 10617 Taipei, Taiwan. **18425.** Bos-Groenendijk, G.I. (2020): Opzet monitoring gevlekte witsnuitlibel in Gelderland. N2000-gebieden Veluwe en Korenburgerveen. Rapport VS2020.027, De Vlinderstichting, Wageningen: 20 pp. (in Dutch) ["In Gelderland, *Leucorhinia pectoralis* is a designated species in the Natura 2000 areas of Veluwe and Korenburgerveen. As input for the N2000 management plans, insight is required into the occurrence, distribution, numbers and development of the species. To this end, new routes have been established in the areas in 2020, after first exploring whether the species actually had populations here. In the Veluwe N2000 area, *L. pectoralis* is found in the Mosterdveen and in the Leemputten near Staverden. In both areas, there are now two routes for counting the species. The species is vulnerable here. In such a large area, two small populations, which are also far apart, are very few. The population in the Mosterdveen seems to be doing reasonably well, with reasonable numbers and moreover several suitable pools. Since 2012 (with one observation during an SNL mapping) the species seems to have increased considerably, but what the population trend is at the moment is not known. This will have to be ascertained from the results of the NEM monitoring that will be running from now on. In the Leemputten near Staverden, *L. pectoralis*, also since 2012, first increased, but recently collapsed due to drying up of the ponds in 2018. Time will tell whether the current population will survive here. In the Natura 2000 area of Korenburgerveen, five routes have been set out at two different locations. The species established itself in Korenburgerveen in 2003 and has since grown into a stable population. The current trend is unknown, as the species has not been counted within the NEM. When the new routes are counted annually, the number developments of *L. pectoralis* can be followed well. The populations on the Veluwe are small and vulnerable. A small disturbance in the form of dehydration or an incorrect management intervention can lead to the disappearance of the population. It is therefore important to take *L. pectoralis* into account in the management of the areas. At the moment, all sites are well managed and no interventions are necessary. However, it is important to think about the water management of the areas in the long term, so that the fens also keep enough water in dry periods." **18426.** Felker, A.S. (2020): New dragonflies of the family Permagoniidae (Odonata: Kennedyina) from Perm, European Russia. PALEOSTRAT-2020. Annual meeting (scientific

conference) of the paleontology section of the Moscow Society of Naturalists and the Moscow Branch of the Paleontological Society at the Russian Academy of Sciences. Moscow, January 27-29, 2020 Program & abstracts. Alekseev A.S. and Nazarov V.M. (ed.): Paleontological Institute im. A.A. Borisyaka RAN, 2020. 66 p.: 59. (in Russian) ["Verbatim: Permagnionidae Tillyard is classified as a fairly large extinct stalked dragonflies with markedly frequent transverse wing venation. The family itself is included in the infra-order Protozogyoptera, which in turn belongs to the suborder Kennedyina (Pritykina, 1989; Nel et al., 2012). Its first representative, Permagnion falklandicum Tillyard, was described from the Wuchapa (Lower Vyatka) deposits of the Bodie Grick Head locality (Falkland Islands) (Tillyard, 1928). Moreover, until the last revision of the protozogyopter (Nel et al., 2012), this family was considered monotypic. However, after re-studying the already described and identifying new material, the authors of the revision transferred to the Permagnionidae the taxa that previously belonged to the families Permolestidae Martynov and Solikamptilonidae Zalesky Nel et al., 2012). At the moment, the family includes 6 genera with 9 species, most of which are known from the Middle and Upper Permian deposits of Europe (Martynov, 1932, 1937; Nel et al., 1999, 2012; Fate et al., 2013). Most of the representatives of the family are known from the remnants of wings, therefore the main diagnostic features of permagnionids are: the presence of a "complete" nodule N) with thickened and noticeably inclined nodal (n) and subnodal (sn) veins; the presence of a pronounced prenodal vein (Asn), curvature of the main structures of the pedicle: arch (Arc), discoidal q) and subdiscoidal sq) cells, and the absence of a distinct anal vein (A), often accompanied by the formation of numerous additional cells at the posterior edge of the wing (Nel et al., New material is represented by 9 specimens of Permagnionids from the localities: Soyana (Kazan Stage; Arkhangelsk Prov.) 1 specimen, B. Kityak (Kazan I Russian; Kirov Prov.) 2 specimens, Kargala (Severodvinsk Stage; Orenburg Prov.) 1 specimens and Isady (Severodvinsk Stage; Vologda Prov.) 5 specimens Most of them belong to new species of already known genera Epilestes and Sushkinia from B. Kityak, Permolestes (2 new species, 5 specimens) from Isad, Scytolestes from Kargaly and Solikamptilon from Soyana The most interesting is a new species of the genus Solikamptilon from Soyana, which, in the presence of characters characteristic of Permagnionids, and undoubtedly belonging to this genus, has very specific features that make it with with small protozogyopters of the family Kennedyidae Tillyard, especially with the Middle Late Triassic species Kennedyia carpenter i Pritykina. This allows us to consider at a new level the question of the relationship between the Permagnionids and the Kennedyids. (google translate)] Address: Felker, A.S., Paleontological Institute. A.A. **18427.** Lu, S.; Qiu, R.; Hu, J.; Li, X.; Chen, Y.; Zhang, X.; Cao, C.; Shi, H.; Xie, B.; Wu, W.-M.; He, D. (2020): Prevalence of microplastics in animal-based traditional medicinal materials: Widespread pollution in terrestrial environments. *Science of The Total Environment* 709, 20 March 2020,

136214: 9 pp. (in English) ["Highlights: • 20 types of animal medicinal materials and 10 types of fresh animals were collected in China. • Microplastics (MPs) were found in all medicinal materials with average incidence rate of 94.67%. • The abundance of MPs was in the range of  $1.80 \pm 0.38$  to  $7.80 \pm 0.83$  items/individual. • Major MPs were microfibers (84.68%), or PET (40.45%), Rayon (30.64%) and PE (10.11%). • MPs show similar characteristics between medicinal materials and fresh animals. Abstract: Microplastics (MPs) pollution is an emerging environmental and health concern. MPs have been extensively observed in the aquatic environment, yet rarely investigated in the terrestrial ecosystem, especially in relation to health risks. To evaluate potential MPs pollution in land-dwelling animal medicine materials, we collected 20 types of small animal-based medicinal materials and 10 types of available fresh terrestrial animals from eight different regions in China. MPs were found in all medicinal materials with an average incidence rate of 94.67%. The abundance of MPs was in the range of  $1.80 \pm 0.38$  to  $7.80 \pm 0.83$  items/individual or  $1.59 \pm 0.33$  to  $43.56 \pm 9.22$  items/g (dry weight), with polymer distribution by polyethylene terephthalate (40.45%), rayon (30.64%), polyethylene (10.11%), nylon (7.35%), polypropylene (5.93%), and polyvinyl chloride (5.52%). The majority of MPs were microfibers (84.68%), with 15.32% of fragments. Moreover, MPs were directly observed in the intestine, detected in all ten types of fresh medicinal animals with the abundance of  $0.83 \pm 0.35$  to  $3.42 \pm 0.46$  items/individual. Furthermore, significant positive correlations ( $R: 0.32-0.99$ ,  $p < 0.05$ ) of MPs characteristics were found between medicinal materials and fresh animals, including shape, size, color, and polymer distribution of MPs. The results support that MPs in the medicinal materials were likely derived from living animals. This study demonstrates the prevalence of MPs in animal-based, traditional medicinal materials, and also suggests widespread MPs pollution in terrestrial environments and latent health risks." **18428.** Lupiyaningdyah, P. (2020): The past, present and future of dragonfly research in Indonesia. *BIO Web Conf.* 19(00024): 4 pp. (in English) ["Up to present, Indonesia has 900 described species of dragonflies with around 70% are endemic; among them, the most diverse is in Papua. This data is collected based on 356 publications from scientific journals, bulletins, magazines, books, theses, and proceedings from 1773 to 2019. There is still a lack of information about what is the most and least popular topics and where is the most explored regions in Indonesia for Odonata research. I categorized the topics into biodiversity, taxonomy and systematics, biogeography, conservation, ecology, education, ethnozoology, history, and molecular. The result shows that the most popular topic is biodiversity by 139 publications and the least are history and molecular by only one publication. Most popular group to be observed is dragonflies in general (both suborders) by 200 publications and the least observed is Anisoptera by only 71 publications. Java is the

most explored island for about 160 publications in 250 years." (Authors)] Address: Lupianingdyah, P., Zoology Division - Museum Zoologicum Bogoriense, Research Center for Biology, Indonesian Inst. **18429.** Néraudeau, D.; Vullo, R.; Bénédice, P.; Breton, G.; Dépré, E.; Gaspard, D.; Girard, V.; Le Couls, M.; Moreauf, J.-D.; Nel, A.; Perrichot, V.; Solórzano-Kraemer, M.M.; Wappler, T. (2020): The paralic Albian–Cenomanian Puy-Puy Lagerstätte (Aquitaine Basin, France): An overview and new data. *Cretaceous Research* 111, July 2020, 104124: (in English) ["Highlights: • Stratigraphy, palaeontology and palaeoecology of the Puy-Puy Lagerstätte, France. • Mid-Cretaceous Konservat-Lagerstätte formed in a quiet paralic environment. • Rich plant assemblage with diverse insect damages on angiosperm leaves. • Lagerstätte with insects preserved in both amber and lignitic clay. • Co-occurrence of marine, brackish, freshwater and terrestrial organisms. The Puy-Puy quarry at Tonnay-Charente (Charente-Maritime, SW France) is a sand quarry exposing a 9-m-thick series of latest Albian–earliest Cenomanian (mid-Cretaceous) age. The uppermost Albian deposits consist of lignitic clay containing fossiliferous amber. The lowermost Cenomanian sand deposits alternate with clay intercalations containing plant remains. One of these clay levels, named P1, shows an outstanding accumulation of conifer and angiosperm macrofossils including delicate reproductive structures such as flowers. Plant remains are associated with invertebrates such as insects (Odonata, Dictyoptera, Diptera), crustaceans (*Mecochirus* sp.), putative brachiopods (aff. *Lingula* sp.), and worms. A few vertebrate remains such as shark egg capsules (*Palaeoxyris* sp.) and a feather are present in the fossil assemblage, as well as an enigmatic specimen tentatively interpreted as a cephalochordate or a petromyzontiform. Various ichnofossils occur in abundance, such as crustacean coprolites and burrows (*Ophiomorpha* isp.), insect coprolites (*Microcarpolites hexagonalis*), and leaves with grazing structures, galls and mines. The sediments have been deposited in a coastal, calm and brackish area." **18432.** Fortunato, M.H.T.; Mendes, H.F.; Carmino Hayashi, C.; Rodrigues de Faria, L.; Lopes de Melo, C.; Carvalho Ananias, I.M. (2021): Survey of dragonfly immature (Insecta: Odonata) in excavated tanks of pisciculture in the mesoregion of Alfenas-MG. *Research, Society and Development* 10(11): 13 pp. (in Portuguese, with English and Spanish summaries) ["Dragonfly immatures are found in a vast number of freshwater aquatic environments, including excavated tanks of pisciculture. As they are predators during the aquatic phase, they end up causing great damage in the initial stages of production of freshwater aquaculture. However, studies on which dragonflies are most common in fish ponds are still scarce in Brazil, and this is the first step to think about an effective control. For this reason, we collected immature dragonfly (Odonata) with net "D" and macrophytes between October 2018 and March 2019. The physicochemical variables were measured with water quality kits, and they remained within the parameters for fish farming defined by CONAMA, with the exception of temperature. Of the 692 immatures collected, we found 12 genera distributed in the two suborders of Odonata, with *Miathyria* Kirby, 1889 and *Erythemis* Hagen, 1861 being the most abundant. After correspondence analysis and principal component analysis, we proved that rarer genera have a lower correlation with abundance, reinforcing the value attributed to the relative abundance of immatures." (Authors)] Address: Fortunato, M. H.T., Universidade José do Rosário Vellano, Brasil. E-mail: [mtank@live.com](mailto:mtank@live.com)

**18433.** Kamboj, N.; Kamboj, V. (2021): Sand-gravel mining as a threat to macro-benthic assemblage and habitat parameters: A case study of river Ganga, India. In: Siddiqui N.A., Bahukhandi K.D., Tauseef S.M., Koranga N. (eds) *Advances in Environment Engineering and Management*. Springer Proceedings in Earth and Environmental Sciences. Springer, Cham. <https://doi.org/10.1007/978-3-030-79065-335>: 463-476. (in English) ["The present study was conducted for assessing the impact of sand-gravel mining on the habitat parameters, diversity and abundance of macro-benthic species

in the mining impacted area of the Ganga river from April 2017 to March 2018. Samples were collected from four different zones i.e. zone A as reference zone while zones B, C and D are mining impacted area of Ganga river correspondingly. During the study, habitat parameters such as substratum type, pH, dissolved oxygen, biochemical oxygen demand, turbidity and TDS showed a significant difference at selected zones throughout the study. Besides, during the survey, a total of 29 macro-benthic species belonging to ten groups mainly Oligochaeta (2 species), Turbellaria (2 species), Hirudinea (3 Species), Odonata (2 species), Ephemeroptera (4 species), Trichoptera (3 species), Diptera (6 species), Gastropoda (3 species), Decapoda (1 species) and Coleoptera (3 species) were found respectively. The Diptera group was found a maximum of 30.77% throughout the study period at selected zones. Besides this, the other major groups were such as Coleoptera 12.73%, Gastropoda 10.80% and Ephemeroptera 9.65%. The result showed that the zone A contains the higher number 1205 ind./m<sup>2</sup> while zone B, zone C, and zone D contain 899 ind./m<sup>2</sup>, 714 ind./m<sup>2</sup> and 497 ind./m<sup>2</sup> respectively throughout the year. The canonical correspondence analysis (CCA) analysis showed a strong relationship with habitat parameters mainly substratum structure, pH, water temperature, dissolved oxygen with the macro-benthic species. Besides this, the reason for the decline in species number in respected zones (B, C & D) is the removal of the sand and gravel material. The removal of these materials causes habitat destruction in the form of increasing depth, slope, channelization of river and water quality." (Authors)] Address: Kamboj, V., Dept of Zoology & Environmental Sci., Haridwar, India

**18434.** Khan, M.A.; Padhy, C. (2021): Study on aerodynamic and structural analysis of bio-mimetic corrugated wing. *Research Trends and Challenges in Physical Science* 1: 90-100. (in English) ["The aerodynamic and static structural analysis of a newly developed bio-mimetic corrugated aerofoil inspired by dragonfly forewing is included in this work. The basal wing part of the dragonfly corrugated aerofoil structure used in this study was placed around the radius of the forewing. These corrugations define the stressed skin structure, which is made up of grider-like veins and a thin cuticle membrane that provides a sophisticated mechanical advantage for longitudinal bending resistance while allowing for wing camber and torsion. Dragonflies are recognised for their amazing flight abilities. They are designed to carry both aerodynamic and inertial loads. At a Reynolds number of 15000, a computational analysis of a newly designed dragonfly corrugated aerofoil is performed, with flow assumed to be laminar, steady, incompressible, and two dimensional. The project includes static structural analysis and aerodynamic flow analysis of a 2-D dragonfly corrugated aerofoil utilising Ansys Fluent and Ansys Mechanical APDL. It has been discovered that the design criteria employed, as well as simulations performed on a corrugated aerofoil, produce significantly better results than earlier studies. The structural analysis also demonstrates that it can withstand maximum pressure loads and provides high rigidity to the wing span. This discovery adds to our knowledge

of insect-inspired corrugated wing structure and facilitates the application for improved design of artificial wings for MAVs and UAVs." (Authors)] Address: Khan, M.A., GITAM Deemed to be University, Dept of Aerospace Engineering, Hyderabad, India

**18435.** Minot, M.; Besnard, A.; Husté, A. (2021): Habitat use and movements of a large dragonfly (Odonata: Anax imperator) in a pond network. *Freshwater Biology* 66(2): 241-255. (in English) ["1. Local movements of aquatic insects within the surroundings of waterbodies aim essentially to find food, mates, resting sites, or avoid predation. Distances moved are very variable among species and may also differ depending on sex or age at the intraspecific scale. Despite a large panel of studies on odonate activities near waterbodies, little is known about their movements and behaviour in the surrounding landscape matrix. This knowledge is, however, crucial to support management schemes of pond networks and allow improvement of connectivity between them. 2. In this study, 87 individuals of *Anax imperator* were identified with a unique code on the wings and monitored visually on five ponds during summers 2017 and 2018. Simultaneously, 54 individuals were equipped with radio transmitters and tracked for up to 15 days. 3. We built Cormack Jolly Seber models to test which factors are important for movement and survival of individuals, and calculated home ranges. Additionally, we performed a step selection analysis on the telemetry data to identify the terrestrial habitats selected by *A. imperator* at the interface between a rural area and a suburban area in north-western France. 4. A reduction of the survival rate was observed on the day immediately following capture regardless of the marking method. Individuals equipped with radio transmitters had a lower estimated daily survival (0.78; 95% confidence interval = 0.70–0.85) compared to wing-marked individuals (0.89; 95% confidence interval = 0.85–0.92). Wing loading and age were the main variables influencing dragonfly survival for both methods. 5. The probability of movement between ponds was similar for both sexes, but radiotracking data showed that females moved significantly further away in the landscape matrix than males, with one female detected up to 1,902 m away from the release pond. Females also had a larger home range (mean 95% kernel: 50 ha) than males (mean 95% kernel: 5 ha). Reproductive behaviour of males and flying behaviour of females were positively related to air temperature. Individuals of both sexes were present on ponds more often than in all other habitats whatever their activity. High trees were the preferred place to rest when air temperatures were low, especially for females. 6. Overall, this study highlights the importance of integrating neighbouring trees in management schemes of ponds. It also confirms that preservation of pond networks must include on several hectares of land around ponds to meet the aquatic and terrestrial needs of amphibious organisms such as odonates. Our radio-tracking data provide a basis for further studies on the persistence of odonate meta-populations in fragmented landscapes." **18437.** Nugrahaningrum, A.; Soesilohadi, R.C.H. (2021): Variations of movement, dispersal, and morphometrics among subpopulations of Javan endemic damselfly, *Drepanosticta spatulifera* (Odonata: Platystictidae) in Petungkriyono Forest. *Journal of Tropical Biodiversity and Biotechnology* 6(3): 14 pp. (in English) ["*D. spatulifera* is a Javan endemic damselfly. The population is spread unevenly in the Petungkriyono Forest and is threatened due to environmental pressure. The aims of this research are to know the variation of the movement, dispersal, and morphometric among subpopulations of *D. spatulifera*. Movement and dispersal variation data collection was done using Mark Release Recapture (MRR) for six weeks from early August until mid-September 2020. The collection of morphometric samples was done during the last week of the MRR survey and 46 individuals were measured with 12 continuous characters. During the MRR survey, 596 males of *D. spatulifera* were marked and 302 were recaptured. *D. spatulifera* had short movement and dispersal thus no individuals were found across the subpopulations. The distance moved of successive capture and net lifetime movement were dominantly less or equal to five meters. The duration of the MRR survey had a low correlation with the dispersal distance of *D. spatulifera*. In the morphometric variations, closer subpopulations tended to have a similar cluster of morphometric characters. Variation of distance moved between successive capture and wing size from Mangli Stream was significantly different from other sites. The subpopulation of Mangli, the farthest and higher altitude of the sites, had the highest distance move, more disperse, and the largest wing size. Our study showed that *D. spatulifera* was extremely sedentary damselfly. It will enhance inbreeding and vulnerability to extinction. Therefore, the interaction between the subpopulations of *D. spatulifera* in the Petungkriyono Forest needs to be done more." (Authors)] Address: Soesilohadi, R.C.,H., Fac. Biology, Universitas Gadjah Mada, Teknika Selatan Street, Senolowo, Sinduadi, Mlati, Sleman, Yogyakarta 55281, Indonesia. E-mail: hidayat@ugm.ac.id

**18438.** Pérez, J.H.; Rocha-Gil, Z.E.; Pérez-Rubiano, C.C.;

Bernal-Figueroa, A.A. (2021): Biological quality in an aquatic system influenced by mining and agricultural activities: River Salitre, Boyacá (Colombia). *Tropical and Subtropical Agroecosystems* 24: 14 pp. (in Spanish, with English summary) ["Background. The study and monitoring of water quality is commonly carried out through the characterization of physicochemical and bacteriological parameters. However, the presence of point pollutants that are discharged at times when an exact record of their incidence may not be achieved, has led to the exploration of different methodologies in order to determine the quality of a body of water, one of which is the bioindication through the study of aquatic organisms. Objective. Analyze the biological quality of the Salitre river basin, Boyacá in areas of influence of mining and agricultural activity in the rainy season (April-May 2019) and dry season (September-October 2019). Methodology. The study was conducted by determining the diversity of aquatic macroinvertebrates present in three stations distributed in the upper (P1), middle (P2) and lower (P3) part of the river. Results. 3573 individuals distributed in eight orders, 28 families and 39 genera were observed, standing out in wealth and abundance: Diptera (79.54%), Ephemeroptera (9.51%) and Odonata (6.07%). Implications. The main limitation of this work was the transfer of the water samples to the laboratory for the physicochemical analysis, for the maintenance of the cold chain during all the samplings. Conclusions. Changes were registered in physicochemical and biological conditions of the system, mainly for the diversity in the three sampling points, which represents a low capacity of this system to take better and better use of nutrients and energy in areas of anthropogenic intervention, affecting self-purification of the river and the biological activities of the ecosystem." (Authors)] Address: Pérez, J.H., Grupo de Investigación Gestión Ambiental, Fac. Cien. e Ingen., Univ. de Boyacá, Carrera 2ª Este No. 64 – 169, Tunja-Boyacá, Colombia. **18439.** Schletterer, M.; Kurz, B.; Schönegger, A.; Egger, G.; Feistmantl, K. (2021): Transplantation of an alpine *Carex-fen* – a mitigation measure related to the construction of a reservoir in the Austrian Alps. *BIO Web of Conferences* 31, 00036 (2021): 7pp. (in English) ["Translocations are applied in the context of infrastructure projects to preserve certain vegetation types. Within the EIA of a large hydropower project in the Austrian Alps, manifold mitigation measures were defined. Among those, the transplantation of about 1.4 ha *Carex-fen* at an altitude of about 2000 m was defined. One year before the start of the construction works in 2021, basic infrastructure (roads) was established and different ecological measures were undertaken, e.g. translocation of amphibians to newly constructed habitats as well as the transplantation of the *Carex-fen*. The turf was cut from the initial area with an adjusted excavator shovel, delivered to a wheel loader which brought each single turf immediately to the target area, where another excavator mounted the turf in a pre-arranged area. At the donor site more than 1/2 of the area was based on wet gley, while especially areas in the vicinity of the river were based on fluvial gravel. With the 30 to 70 cm thick turfs also animals, e.g. Odonata, were transferred.

Before the translocation a monitoring of the donor sites was carried out. The monitoring concept foresees a detailed monitoring of the newly established sites for 10 years. Herein we provide insights in the applied technology and summarize first results of the monitoring. Overall, our project is unique regarding the vegetation type, the technology, the size and the intensity of monitoring... With this measure also larvae of Odonata were transferred with the substratum in their new habitat. Within the assessments for the EIA, three dragonfly species were detected by visual observation and net catches (adults and larvae) in the valley: *Enallagma cyathigerum*, *Aeshna juncea* and *Somatochlora alpestris*). During the pre-monitoring in 2020, also the occurrence of *Leucorhinia dubia* was confirmed by visual observations. All detected species are similar in terms of their larval habitat. The translocation of larvae by transplanting turf is the most effective method, which has also the advantage that the entire biotope is relocated. Beside the herein described measures, an additional measure related to the establishment." (Authors)] Address: Schletterer, M., TIWAG-Tiroler Wasserkraft AG, Innsbruck, Austria. **18442.** Taylor, P.; Smallshire, D.; Parr, A.J.; Brooks, S.J.; Cham, S.A.; Colver, E.F.; Harvey, M.; Hepper, D.; Isaac, N. J.B.; Logie, M.W.; McFerran, D.; McKenna, F.; Nelson, B.; Roy, D.B. (2021): 2021. State of Dragonflies in Britain and Ireland 2021. British Dragonfly Society, Old Weston, Huntingdon: 83 pp. (in English) ["• The current British and Irish list of damselflies and dragonflies (Odonata) comprises 56 species, of which 46 are residents or regular migrants since 2000; a further ten species have occurred as rare vagrants. • Trend analyses carried out by the UK Centre for Ecology & Hydrology for this BDS report show that 19 of our resident and/or regular migrant species (41%) have significantly increased in occupancy since 1970. These included both common and/or widespread species and scarce and/or localised species, as well as five new colonists. • Just five (11%) of our resident and regular migrant species have shown significant declines overall. One of these is a widespread damselfly, two are predominantly upland and/or northern species, and two are specialists of seepages, pools and small streams. In addition, one scarcer migrant has shown some signs of a decline, though appearances have always been somewhat erratic. • The production of species trends does not reveal the underlying causes. There has been little scientific study to determine the precise causes and their relative impacts on dragonfly populations, although climate change and habitat quantity and quality are clearly important. Our assessment of the driving forces behind the observed trends in this report is therefore based principally on expert opinion using what is known of dragonfly biology and ecology. • Dragonfly species new to Britain and Ireland are arriving and colonising at a greater rate than ever before. No less than six species have colonised Britain since 1996, while a seventh has recolonised after an absence of almost 60 years. The new colonists are *Anax parthenope* (first record 1996), *Sympetrum fonscolombii* (breeding from 1996), Small Red-eyed Damselfly (first record 1999), *Lestes barbarus* (first record 2002), *Chalcolestes viridis* (colonisation from 2007) and *Aeshna affinis* (colonisation from 2010). *Coenagrion scitulum* became extinct in Britain during the coastal floods of early 1953, but successfully recolonised around 2010. • Species richness has increased over time, especially in the northern half of Britain, but also in the south as new species arrive and colonise; increased recording intensity in recent

years may explain some of these increases. • Trends for individual species in Britain and Ireland are often mirrored by those in Europe. For example *Anax imperator* is increasing in the Netherlands and Germany, as well as in Britain and Ireland, while *Lestes sponsa* has declined in all these areas. • Trends and responses to climate or habitat changes in dragonflies are often matched by other taxa. For example, there is evidence of northwards range shifts for several birds and butterflies, and it has recently been found that despite overall insect declines, more of our larger moth species are increasing in occupancy, than decreasing. Additionally, populations of freshwater invertebrates such as caddisflies and mayflies have recovered in recent decades, a result in line with that seen overall for dragonflies. • Climate change in the form of increased temperatures is behind many of the positive dragonfly species trends and new colonisations, but it should be remembered that climate change does not act in isolation. Increases in the availability of suitable habitats through restoration and creation projects have also played a significant role. Climate change may also have negative impacts for some species, especially in the future. It is important that we continue to record and assess all species, but especially those in northern, upland and specialised habitats, although much still needs to be discovered about the individual needs of dragonfly species, especially during the larval stage. • Species declines are harder to record and explain, but habitat losses and degradation through land drainage, afforestation, acidification and lack of appropriate management are strongly indicated as major factors. Changes in weather patterns, causing both flood and drought conditions, are also implicated, as are pesticides, fertilisers and other pollutants of a similar nature. It is also the case that increases in distribution may mask underlying declines in species abundance. • The 50-year occupancy trends in this report are based on 1.4 million records, collected by some 17,000 individual recorders during 1970-2019. ...." **18443.** Viitaniemi, H.M.; Leder, E.H.; Suhonen, J. (2021): Influence of interspecific interference competition on the genetic structure of *Calopteryx splendens* populations. *Ann. Zool. Fennici* 59: 35-45. (In English) ["Understanding the effects of interspecific competition on genetic diversity will deepen our knowledge on species evolution. In the case of *Calopteryx splendens* and *C. virgo*, sympatric damselfly species, interspecific interference competition by *C. virgo* has remarkable effects on territoriality of *C. splendens* resulting in reproductive character displacement. Since territoriality is correlated with phenotype and mating success, we investigated the effects of interspecific interference competition on genetic diversity of *C. splendens* populations. Using amplified fragment length polymorphisms (AFLP), we determined the population genetic structure of 12 *C. splendens* populations and used the genetic diversity information to relate heterozygosity of *C. splendens* to abundance of *C. virgo* in sympatric populations. We found that heterozygosity of *C. splendens* males decreased with increasing abundance of *C. virgo* males. This result most likely reflects changes in effective population size due to interspecific interference competition

and shows an effect on genetic structure in damselfly populations." (Authors)] Address: Viitaniemi, H.M., Dept Biol., 20014 University of Turku, Finland. E-mail: hmviit@utu.fi

**18444.** Wu, G.; Tang, S.; Han, J.; Li, C.; Liu, L.; Xu, X.; Xu, Z.; Chen, Z.; Wang, Y.; Qiu, G. 2021): Distributions of total mercury and methylmercury in dragonflies from a large abandoned mercury mining region in China. *Archives of Environmental Contamination and Toxicology* 81: 25-35. (In English) ["Odonata are often considered to be biosentinels of environmental contamination. Dragonflies (n = 439) belonging to 15 species of eight genera were collected from an abandoned mercury (Hg) mining region in China to investigate the bioaccumulation of total Hg (THg) and methylmercury (MeHg). The THg and MeHg concentrations in dragonflies varied widely within ranges of 0.06–19 mg/kg and 0.02–5.7 mg/kg, respectively. THg and MeHg were positively correlated with bodyweight (THg:  $r^2 = 0.10$ ,  $P = 0.000$ ; MeHg:  $r^2 = 0.09$ ,  $P = 0.000$ ). Significant variations were observed among species, with the highest MeHg value (in *Orthetrum triangulare*) being 5-fold higher than the lowest (in *Pantala flavescens*). These variations were consistent with those of nitrogen isotope ( $\delta^{15}N$ ) values. A health risk assessment found hazard quotients for specialist dragonfly-consuming birds of up to 7.2, which is 2.4 times greater than the permissible limit of 3, suggesting a potential health risk of exposure." **18445.** Yamada, S.; Urabe, J. (2021): Role of sediment in determining the vulnerability of three littoral cladoceran species to odonate larvae predation. *Inland Waters* 11(898): 1-8. (In English) ["Small cladocerans, found abundantly on surfaces of macrophytes and sediments in the littoral zone, are important prey not only for small fish but also for various invertebrates such as larvae of odonates in freshwater habitats. However, no study has documented how habitat substrates affect their behavior and vulnerability to predators and predation. We conducted laboratory experiments to examine the movement of 3 littoral cladoceran species, *Chydorus sphaericus*, *Alona* sp., and *Ilyocryptus spinifer*, to determine if their vulnerabilities to predation by odonate larvae changed depending on the presence or absence of bottom sediment. We observed that when sediment was present, *Ilyocryptus* crawled in and ceased movement. However, in the containers without sediment, they continuously swam or crawled. Similarly, *Chydorus* also reduced frequency of movement in a container with sediment, but *Alona* movement did not change regardless of the presence or absence of sediment. In the predation experiments with 2 or 3 prey species, *Ilyocryptus* was the most vulnerable to predation by odonate larvae in the containers without sediment but least vulnerable in those with sediment. The vulnerability of *Chydorus* to the odonate larvae was as low as that of *Ilyocryptus* in the containers with sediment. *Alona* was less preyed upon by odonates in containers with sediment but highly vulnerable to predation when containers

had sediment with Chydorus and Ilyocryptus. These results indicate that behavior and vulnerability to predation of littoral cladocerans are species-specific and change depending on the presence of sediment and the existence of other species." (Authors)] Address: Yamada, S., Aquatic Ecology Lab, Graduate School of Life Sciences, Tohoku University, Aoba 6-3, Aramaki Aoba-ku, Sendai 980-8578, Japan. E-mail: sayumi.yamada127@gmail.com

**18446.** Yu, X. (2021): A survey of Odonata diversity in Zoige wetland, Sichuan Province, China. International Dragonfly Fund - Report 158: 1-22. (in English) ["At Zoige alpine Wetland, a total of 10 species belonging to 4 families and 6 genera were recorded. Obvious melanism in *Coenagrion lunulatum* and feigning death behaviour in *Enallagma cyathigerum* were observed. A preliminary trial on avoiding behaviour of *E. cyathigerum* confirmed that feigning death is one of the major strategies to protect themselves. All these new findings are discussed briefly." **18447.** Zach, P. (2021): Libellen-Artengemeinschaften des Raabtales. M.Sc. thesis, Karl-Franzens-Universität Graz: 134 pp. (in German, with English summary) ["Dragonfly species community of the Raab Valley (Styria, Austria). The present study is dedicated to the Dragonfly species community of the Raab Valley, located in Eastern Styria, and the assessment of the ecological status of this river valley area, which was formerly characterised by floodplains. For this purpose, nine 500 m long transects were defined in the study area, representing the range of water body types in the Raab Valley. The - largely homogeneous - transects, represent the river Raab itself, a stream (Schwengentalbach), ditches located in the valley bottom, a spring stream, and a still water body. Based on the hydromorphological models and the postulated original state of the water bodies, a water body type-specific dragonfly community (reference fauna) was derived. In 2020, the dragonfly fauna of the Raab Valley was documented in course of five field surveys per transect from May to September. The autochthony status and the abundance of the species were documented. The current dragonfly fauna was compared with the reference fauna and the dragonfly ecological status was determined. In the study area, 24 dragonfly species were detected, 18 of which could be classified as autochthonous and seven of which are sensitive species. According to the Austrian Red List, two of the detected species are "endangered": *Somatochlora meridionalis*, that was spotted at the pond in Perlstein, and *Libellula fulva*, that was documented at one of the ditches. Despite these remarkable dragonfly records, the surveyed dragonfly species community is clearly impoverished compared to the model. In particular, there is a lack of still water habitats in the Raab Valley. There is a lack of reed beds, floating leaf vegetation and submerged vegetation, which leads to the lack of dragonfly species associated with these vegetation types. Thus, the Raab Valley was ranked with a "moderate to good ecological status", which represents the third- to second-best class in the 5-tiered classification scheme." (Author)]

**18451.** Buczynski, P.; Mikolajczuk, P.; Tonczyk, G. (2011): New records of Norfolk Damselfly *Coenagrion armatum* (Charpentier, 1840) (Odonata: Coenagrionidae) on the south-western edge of its distribution area (Central and Eastern Poland). *Odonatrix* 7(2): 41-47. (in Polish, with English summary) ["*C. armatum* is a Siberian species whose south-western boundary of its distribution area goes through Poland. Formerly, it passed through the western part of the country. In the last 30–40 years it moped back ca. 300 km due to climatic and anthropogenic environmental changes. Currently, it runs through eastern regions – its putative form is shown on Fig. 1. The authors give five new sites of the species (Fig. 1). Breeding populations are probably at sites 1–3 (good habitat conditions, usually the large numbers of imagines) and less likely at site 5 (a water body partially dries out). In Pulawy (site 4) a single imago was recorded in an unusual environment (a river slope), however, the complexes of water bodies in the valleys of the River Kurówka and Wisla are located nearby. The sites 4 and 5 are the first known from over 10 years in Poland which are located to the west of 22°N. They confirm the hypothesis of Bernard et al. (2009) about the existence of scattered relict populations outside this line. Probably there are more of them but a short

and early flight period of *C. armatum* is the cause of its overlooking in faunistic studies. Nevertheless, the sites 1–3 are important because they confirm the form of the current species distribution area which was determined approximately due to the lack of precise data. The authors suggest the evaluation program as well as passive and active protection of *C. armatum*. It would be particularly important due to the regress and strong threats of the species in the neighbouring countries of Poland from the west and south – Poland is an important refugium of this species in Central Europe." **18453.** Cywinska, A.; Davies, R.W. (2011): Predation on the erpobdellid leech *Nepheleopsis obscura* in the laboratory.

Can. J. Zool. 67: 2689-2693. (in English) ["Six size classes of *Nephelopsis obscura* ranging from cocoons through hatchlings (2-4 mg) to mature individuals (150 mg) were exposed to a range of potential predators and also tested for cannibalism. Neither cannibalism nor interspecific leech predation was found, but nine species of Coleoptera, Amphipoda, Hemiptera, and Zygoptera (*Enallagma boreale*) consumed one or more size classes of *N. obscura*. In general, predation rates were highest on individuals < 10 mg and declined with increasing size of *N. obscura*. Larger predators (intra- and inter-specifically) usually had higher consumption rates than smaller ones. Because of the high abundance of the nine species of predators in prairie pothole lakes during the summer, it is speculated that predation on *N. obscura* hatchlings and cocoons is directly related to the recorded reductions in these size classes in the macrophyte zones during the summer." **18454.** De Knijf, G. (2011): Massale aantallen van de Noordse witsnuitlibel. Libellenvereniging Vlaanderen . nieuwsbrief 5(2): 8. (in Dutch) [Massive numbers of Northern white-faced darter (*Leucorrhinia rubicunda*): In recent weeks, *L. rubicunda* was observed in different places in Belgium. Outside the traditional sites in the Kempen region, this was the case in the Ghent canal zone at St-Kruis-Winkel on May 8, 2011 (Ward Vercruysse), in the Hainaut sand region at Stamburges on May 18, 2011 (Luc & Dirk Verroken) and also in May in a limestone quarry near Tournai (Benoît Gauquie). From the same period, there is a sighting from the centre of Lille, Northern France (Cédric Vanappelghem). This is all the more remarkable as there are no populations of the species in France. The question of where these animals could have come from was always raised. In the Netherlands, very large numbers of *L. rubicunda* have been observed in recent weeks on several locations. Witness a few photos from the northern part of the Netherlands. Whether such numbers were also observed in the south of the Netherlands or in the Belgian Kempen is not known to me at the moment. It is to be expected that at least part of those numbers of animals do not stay at the breeding site, but start swarming out. These numbers combined with persistent dry, warm weather with predominantly winds from the east to north-east have apparently led to the sighting of the Northern whitefly in many places where it was never observed before. This phenomenon probably also occurred in 2001, when *L. rubicunda* was observed in the Kraaibos at Moen in South-West Flanders (De Knijf 2001). And who knows, maybe on some suitable locations females have ended up laying eggs and allowing the larvae to develop. We'll have to wait and see in the years to come whether the Northern white-beaked dragonfly will eventually be able to establish itself there or not. google translator: In recent weeks at various locations in Belgium Nordic white-faced darter (*Leucorrhinia rubicunda*) were observed. Beyond the traditional sites in the Kempen, this was particularly the case in the Ghent Canal to St-Kruis-Store on May 8, 2011 (Ward Vercruysse), sand in the Hainaut region Stamburges on May 18, 2011 (L. & Dirk Verroken)

and also in May in a limestone quarry near Tournai (Benoît Gauquie). From the same period was an observation from the center of Lille, northern France (Med. Cedric Vanappelghem). That is all the more remarkable because no populations of the species present in France. This was always the question of where that animals could come. In the Netherlands the last week in different locations very large numbers of white-faced darter Nordic observed. Witnessed by a few pictures from the north of the Netherlands. Whether any such numbers were observed in the south of the Netherlands or in Belgium Kempen me at this moment unknown. It is expected that at least some of the numbers of animals location on reproduction remain, but begin to swarms. These numbers combined with continued dry, warm weather with mostly wind from the east to Northeast has apparently led to the perception of *L. rubicunda* in many places where they previously was never observed. This phenomenon has probably occurred in 2001, when *L. rubicunda* was observed in the Kraaibos to Moen in southwest Flanders (De Knijf 2001). And who knows, there are a number of suitable locations also landed females who take eggs and larvae which can develop. But look out next year white-faced darter or the Norse are finally able to establish or not.] Address: Knijf, G. de, Instituut voor Natuurbehoud, Kliniekstraat 25, B-1070 Brussel, Belgium. (in German) [Baden-Württemberg, Germany. On 24.06.2011, a *G. flavipes* exuvium was found on the southern test stretch directly above the former Kander mouth (Rhine-km 175.2) and a just-hatched animal at the exuvium shortly below the former Kander mouth (Rhine-km 175.4). On 03.08.2011, another exuvium was found at Rhine-km 175.4. Both sites are located on the Messtischblatt-Quadrant (MTBQ) 8311 SW. This is the first record of *G. flavipes*) for the Restrhein between Basel and the cultural weir Breisach. In terms of substrate and bank morphology, the hatching sites did not show any clear differences to other areas of the test stretch. In 2010, a total of four exuviae of *O. cecilia* but none of *Gomphus flavipes* had been collected on the southern sample stretch. Address: Hunger, H. E-mail: holger.hunger@inula.de

**18463.** Johnston, T. (2011): Comparison of riparian willows and riprap as habitat for fish and invertebrates in the Waikato River. MSc thesis. University of Waikato: XI + 145 pp. (in English) ["Willows (*Salix* spp.) are an abundant alien tree and have been the mainstay of river bank protection throughout New Zealand. Riprap is another method of bank stabilisation consisting of rocks used to amour shorelines to protect against erosion. There is a trend for increasing use of riprap to replace willow along the banks of large rivers in New Zealand, but there is limited information on the ecological roles of these different bank types to support management. The objectives of this research were to determine the effects of different bank habitats on nearshore fish and invertebrate communities in the Waikato River as it passes through Hamilton city. The study involves three sites situated along the river. Each site has four bank types consisting of willow, riprap, a mixture of willow and riprap, and beach. Invertebrate sampling was carried out on three occasions to assess if there was a seasonal effect on community composition. Fish were sampled bimonthly determine differences in

community composition. Assessment of fish populations was carried out with using boat electrofishing, Gee minnow trapping and spotlighting, while invertebrate populations were sampled by kick netting. Few significant differences were detected in invertebrate diversity between willow, riprap and willow/riprap habitats. However, community composition based on relative abundance was different among contrasting habitats in most seasons and Pielou's evenness was greater for the more homogenous beach and riprap habitats. Riprap had consistently high alpha diversity but had lower species accumulation on two out of three dates suggesting there was a limited pool of taxa colonising the riprap compared to other habitats. Pairwise dissimilarity coefficients and PERMANOVA comparisons indicated that, although low in alpha diversity, beach habitats contributed significantly to macroinvertebrate beta diversity, and that willow and riprap habitats also supported different combinations of taxa due to different physical conditions. The combination of beach and willow habitats gave the highest gamma diversity. Willow habitats supported the highest number of both introduced and native fish, mainly reflecting abundances of common smelt, likely due to provision of cover, complex aquatic habitat, and riparian vegetation supplying detritus and invertebrate food resources. Riprap habitats supported the highest number of common bully. Common bully were also significantly larger in this habitat. Variations in water temperature, amount of shade, and river levels were possible factors contributing to temporal influences on biological patterns. The findings of this study indicate that, if all banks habitats in Hamilton City were composed of a single type, invertebrate biodiversity would be reduced. While the combination of beach and willow habitats may sustain high diversity for invertebrates and fish, the novel habitat provided by riprap may also favour some native fish and invertebrates over others. Therefore, a balance of different bank habitat types would perhaps be best to sustain present-day biodiversity levels in near shore macroinvertebrate and fish communities." (Author) The list of taxa includes *Aeshna*, *Hemicordulia australiae*, *Procordulia*, *Xanthocnemis zealandica*, and *Zygoptera* indet.] Address: not stated

**18464.** Kim, D.E. (2011): The study on the habitat change of *Nannophya pygmaea* Rambur in the abandoned paddy field Ulsan city and its management. *Korea Journal of Ecology* 25(6): 867-877. (in Korean, with English summary) [In order to provide basic data for the conservation and restoration of *N. pygmaea* habitat, habitat changes and insect fauna inhabiting the fallow land were examined for 4 years from June 2008 to July 2011 in Daun-dong, Jung-gu, Ulsan Metropolitan City. The flora was investigated. As a result, a total of 10 orders, 32 families, and 53 species were investigated, and the order Dragonflies, Hemiptera, and Coleoptera were dominant with a total of 18.9%. A total of 23 orders, 30 families, and 60 species of plants were investigated, and Cyperaceae (13.3%) and the Gramineae (11.7%) were dominant. As woody plants are introduced into the survey area, the transition is progressing rapidly, and the habitats of aquatic plants are encroached and turned into land. In addition, phytophagous insects and mountainous insects

are increasing in this area. As a result, the habitat of *N. pygmaea* was maintained at a constant depth of 2.5 to 9.5 cm and moved to a place where the water surface was open. Therefore, long-term monitoring and appropriate management are required to identify ecological characteristics for the continuous conservation and maintenance of *C. dragonfly* habitat in this area.] Address: Kim, D.E., Environmental Resources Research Department, National Institute of Environmental Research, Incheon (404-708), Korea. **18465.** Kosík, M.; Cadkova, Z.; Prikryl, I.; Seda, J.; Pechar, L.; Pecharová, E. (2011): Initial succession of zooplankton and zoobenthos assemblages in newly formed quarry lake medard (Sokolov, Czech Republic). "Mine Water – Managing the Challenges" IMWA 2011 (International Mine Water Association): 517-522. (in English) ["This paper gives the results of the initial observation period of the development of zooplankton and zoobenthos (including *Enallagma cyathigerum*, *Ischnura elegans*, *I. pumilio*, *Lestes sponsa*, *Chalcolestes viridis*, *Anax imperator*) during flooding of the residual brown coal mine pit Medard. Changes in the quantity and quality of water, flowing from different sources, and development of stratification in the lake water affect the composition of zooplankton and zoobenthos. Original sources of zooplankton inoculum, which are the reservoirs in the Lake Medard own catchment area, are monitored too. Another important source, that will significantly affect the formation of the newly formed lake, is the river Ohre (Eger), which will contribute with the greatest volume of water. At the same time, the hydrochemical water quality parameters and their influence on the formation of zooplankton and zoobentos communities are monitored." (Authors)] Address: Pecharova, Emile, Czech Univ. Life Science Prague, Fac. Environmental Sciences, Dept of Landscape Ecology, Czech Republic

**18466.** Loureiro, N. S. (2011): *Libélulas e Libelinhas (Odonata) no Algarve*. *Guias Digitais Biodiversidade e Natureza* nº 1: 134 pp. (in Portuguese, with English, Spanish and German summaries) ["This ebook is the first publication focused on the Algarve's Odonata Order. It shouldn't, however, be perceived as the definitive edition on the subject, published only after exhausting all knowledge about. In fact, there still will be much to add in future editions. At this moment, its divulgation is aiming to contribute to the satisfaction of a recognized demand and, simultaneously, to fill in a blank mentioned on the European Red List of Dragonflies (p. 17). Therefore, this Digital Guide not only synthesizes, in Portuguese, a large amount of data already available though scattered, but also adds new one. As main results of our efforts: i. The number of records was duplicated, providing new data to significantly improved cartographies on the regional distribution of the 51 species; ii. Six new species were added to the Algarve's most recent checklist. The large number of photographs in this ebook also contributes to the fact that it can be easily used by those who are not, neither wish to be, experts on the subject. This Digital Guide has been prepared to be used as an independent source of information. It can, however, be consulted in parallel with some European

field guides, such as the Field Guide to the Dragonflies of Britain and Europe, by K-D B Dijkstra & R Lewington, and/or The Dragonflies of Europe, by R R Askew. In the other hand, this ebook can be easily consulted by non Portuguese speakers, because the indispensable technical terms are translated to English, allowing the comprehension of fundamental contents. In this way, it is assumed that the international community interested in the Algarve's Odonata fauna will find this Digital Guide to be a reference work of great importance. At last, it is presented in this Abstract a new contribute, equally enriching for those who wish to discover the Algarve' Odonata fauna: the 10 hotspots to observe and photograph dragonflies and damselflies at Algarve. Fully enjoy this natural resource, respecting it carefully and avoiding its degradation and extinction.] Address: not stated

**18467.** McGeoch, M.A., Sithole, H., Samways, M.J., Simaika, J.P., Pryke, J.S., Picker, M.; Uys, C.; Armstrong, A.J.; Dippenaar-Schoeman, A.S.; Engelbrecht, I.A.; Braschler, B.; Hamer, M. (2011): Conservation and monitoring of invertebrates in terrestrial protected areas. *Koedoe* 53(2), Art. #1000; doi:10.4102/koedoe.v53i2.1000: 13 pp. (in English) ["Invertebrates constitute a substantial proportion of terrestrial and freshwater biodiversity and are critical to ecosystem function. However, their inclusion in biodiversity monitoring and conservation planning and management has lagged behind better-known, more widely appreciated taxa. Significant progress in invertebrate surveys, systematics and bioindication, both globally and locally, means that their use in biodiversity monitoring and conservation is becoming increasingly feasible. Here we outline challenges and solutions to the integration of invertebrates into biodiversity management objectives and monitoring in protected areas in South Africa. We show that such integration is relevant and possible, and assess the relative suitability of seven key taxa in this context. Finally, we outline a series of recommendations for mainstreaming invertebrates in conservation planning, surveys and monitoring in and around protected areas. Conservation implications: Invertebrates constitute a substantial and functionally significant component of terrestrial biodiversity and are valuable indicators of environmental condition. Although consideration of invertebrates has historically been neglected in conservation planning and management, substantial progress with surveys, systematics and bioindication means that it is now both feasible and advisable to incorporate them into protected area monitoring activities.... Odonata: Several freshwater monitoring schemes involving macroinvertebrates are well developed with a long history, for example the River Invertebrate Prediction Classification System used in the UK to monitor the pollution status of water courses (Wright et al. 2000) and the South African Scoring System (SASS) (Revenga et al. 2005). Good taxonomic and biological information, along with knowledge of species conservation status and responses to habitat quality are amongst the key suitability criteria in invertebrate monitoring (Table 3). The Odonata in South Africa perhaps best exemplify this with existing Red Data information and comprehensive field guides that make working with the group broadly accessible to biologists, the public and citizen

scientists (Samways 2006, 2008). South Africa's freshwater systems are under intense pressure (Nel et al. 2007) and the Odonata are sensitive indicators of the quality of these systems. This includes their response to pollution and invasive alien species impacts (Chovanec 2000), as well as their recovery after alien plant removal in rivers in PAs in South Africa (Samways & Sharratt 2010). In addition to the well-known and widely used SASS system (Dallas & Day 1993; Revenga et al. 2005), the Dragonfly Biotic Index (DBI) provides a measure of ecological integrity for freshwater systems. The DBI is a weighted index (see Table 4) based on the quantitative assessment of three subindices of species distribution, threat status and sensitivity to disturbance (Simaika & Samways 2008, 2009a). The total DBI of a water body (stream, river or pool) reflects the total odonate assemblage, thus allowing for water bodies to be compared and restoration success to be monitored (Simaika & Samways 2008). Every South African odonate species has been assigned a score (Samways 2008). The DBI has been tested and applied in biomonitoring (Simaika & Samways 2009a), 2011 to measure habitat recovery (Simaika & Samways 2008) and select sites for conservation (Simaika & Samways 2009b). Previous work has shown a strong correlation between adult dragonfly scores and macroinvertebrate scores (Simaika & Samways 2011; Smith, Samways & Taylor 2007). An advantage of the DBI over conventional macroinvertebrate indices is that it operates at the species level and is therefore highly sensitive to habitat condition. It, therefore, has good potential for environmental assessment and monitoring freshwater biodiversity and quality, alongside SASS (Simaika & Samways 2011). The low field effort required to obtain a DBI score for a site also makes this a low-cost and readily applied method. Odonata are therefore particularly useful for monitoring freshwater quality and landscape physiognomy around riverine and other aquatic habitats in South Africa's PAs (Samways 1993b)." **18468.** Neff, M.R. (2011): Abiotic conditions in contrasting environments: An examination of Precambrian Shield lotic communities. PhD thesis, Ecology and Evolutionary Biology, University of Toronto: XX, 175 pp. (in English) ["the inherent complexity of the natural world has long been a central theme in ecological research, as the patterns and processes that govern ecosystems can operate at multiple spatial and temporal scales. It is clear that to develop general ecological frameworks, we must consider many different factors at different scales, and incorporate ideas from other disciplines. This thesis touches on several of these ideas, first through an analysis of literature, and then with field research examining the role of broad-scale abiotic factors on lotic systems. To determine how integrated aquatic science is currently understood among different researchers, I provide an analysis on communication and exchange of ideas among various subfields in aquatic science. I show that there are clear divisions within the aquatic science literature, suggesting that there is progress to be made on the integration of methods and ideas. Next, I examine the impact of a

large-scale geological feature, the Canadian Precambrian Shield, on abiotic conditions in lotic systems, and how these conditions in turn influence the species assemblages of aquatic organisms. This is addressed with both historical survey data, as well as contemporary data, and as a whole, incorporates ideas concerning the relative influence of regional versus local factors, the importance of historical factors on species distributions, and the relationship between the abiotic environment and biological communities. These analyses show that there are distinct fish and macroinvertebrate communities in Shield lotic systems compared to those found in nearby off-Shield sites, indicating that the Shield is an important broad-scale factor influencing local biological communities. This finding, in conjunction with previous knowledge on the influence of historical factors, provides further insight on the structuring of lotic fish and macroinvertebrate communities in Ontario." **18471.** Raio, C.B.; Espinoza, A.A.; Bennemann, S.T. (2011): Diversidade e similaridade entre populações de insetos aquáticos em riachos de primeira e segunda ordem, sul do Brasil similarity and diversity between aquatic insect populations in streams of first and second order, south of Brazil. *Semina: Ciências Biológicas e da Saúde, Londrina* 32(1): 69-76. (in Portuguese, with English summary) ["Aquatic communities of macroinvertebrates are influenced by rapid velocity, habitat heterogeneity and other characteristics. This study examined a relationship between aquatic insects diversity with hydrologic order of two streams. We tested following hypothesis: diversity of insects associated with the same substrate in equal parts of streams, classified in different orders, are similar. Samples of litter were collected in middle stretches of stream Cascatinha (first order) and stream João Pinheiro (second order), Tibagi river basin, Telêmaco Borba, Paraná, Brazil. Diversity of each stream was obtained by Shannon index. Diversity values were low for both streams (0.8 for the first order stream and 0.89 for the second order stream) with no statistical difference ( $t = -1.12$ ;  $p = 0.27$ ). Similarity between the streams was 0.51. These results allowed us to verify that, to studied streams,

hydrological order has no effect on aquatic insects diversity ( $F = 0.14$ ,  $p = 0.71$ ), so the hypothesis was accepted. The most abundant taxon in both streams was Chironomidae (Diptera), representing 82.7% of total collected. However when Chironomidae was removed from analysis, the hypothesis was refused. An high abundance of Chironomidae individuals had influenced values of local diversity." **18472.** Rehm, P.; Borner, J.; Meusemann, K.; von Reumont, B.M.; Simon, S.; Hadrys, H.; Misof, B.; Burmester, T. (2011): Dating the arthropod tree based on large-scale transcriptome data. *Molecular Phylogenetics and Evolution* 61(3): 880-887. (in English) ["Molecular sequences do not only allow the reconstruction of phylogenetic relationships among species, but also provide information on the approximate divergence times. Whereas the fossil record dates the origin of most multicellular animal phyla during the Cambrian explosion less than 540 million years ago (mya), molecular clock calculations usually suggest much older dates. Here we used a large multiple sequence alignment derived from Expressed Sequence Tags and genomes comprising 129 genes (37,476 amino acid positions) and 117 taxa, including 101 arthropods. We obtained consistent divergence time estimates applying relaxed Bayesian clock models with different priors and multiple calibration points. While the influence of substitution rates, missing data, and model priors were negligible, the clock model had significant effect. A log-normal autocorrelated model was selected on basis of cross-validation. We calculated that arthropods emerged ~600 mya. Onychophorans (velvet worms) and euarthropods split ~590 mya, Pancrustacea and Myriochelata ~560 mya, Myriapoda and Chelicerata ~555 mya, and 'Crustacea' and Hexapoda ~510 mya. Endopterygote insects appeared ~390 mya. These dates are considerably younger than most previous molecular clock estimates and in better agreement with the fossil record. Nevertheless, a Precambrian origin of arthropods and other metazoan phyla is still supported. Our results also demonstrate the applicability of large datasets of random nuclear sequences for approximating the timing of multicellular animal evolution... **18476.** Staufer, M.; Schulze, C.H. (2011): Diversität und Struktur von Libellengemeinschaften an Augewässern in den March-Auen. *Wiss. Mitt. Niederösterreich. Landesmuseum* 22: 171-202. (in German, with English and Slovak summaries)

["Hydrological dynamics at the Morava underwent dramatic changes in the first half of the 20th century due to river regulations that prevented the formation of new backwaters and simultaneously supported silting up processes. Nevertheless, the Morava floodplains are still characterised by a wide range of water bodies providing important habitats for a rich dragonfly fauna. The Austrian part of the Morava floodplains is home to 48 species of dragonflies and damselflies. Within the whole trilateral area (including the Czech and Slovakian parts) of the Morava floodplains, a total of 54 species have been recorded. The Odonata fauna at backwaters from Hohenau to Marchegg was surveyed in 2008 and 2009. A total of 7,056 adult dragonflies belonging to 34 species were observed along 24 transects, each with a length of 50 meters. 29 species with 6,748 individuals were classified as autochthonous at any of the survey sites. Species richness of individual sites varied between three and 18 species and differed between water body types. Lowest species numbers were recorded for water bodies completely embedded in forest whilst sunny parts of larger, permanent water bodies showed the highest species richness. Our data indicate a tendency towards an increasing percentage of endangered species with increasing species richness at backwaters. Species assemblages proved to be significantly nested, although a clear deviation from maximum nestedness was evident. From all tested parameters, the water body type and the degree of desiccation had the strongest effect on species composition. A considerable proportion of all Odonata species and endangered species was represented by dragonflies and damselflies that favour standing waterbodies or ephemeral conditions, indicating that the entire species assemblage is strongly affected by the reduced hydrodynamic conditions within the floodplain system." **18477.** Thomas, M. (2011): Untersuchungen zum Vorkommen der Helm-Azurjungfer *Coenagrion mercuriale* in einem Kalkflachmoor bei Köln (NRW) als Grundlage für Pflege und Entwicklung. Thesis, Bachelor of Engineering (B. Eng.). Hochschule Osnabrück: 92 pp + Anhänge. (in German) [Nordrhein-Westfalen, Germany. "The calcareous low moor bog Katharinenkammer is presumably the last primary habitat of *C. mercuriale* in NRW. The studies in 2011 found *C. mercuriale* flying from May 3rd to August 1st, 2011. In the main flight season between May 20th and June 17th more than 35 individuals were observed at each survey. The highest number of imagines was recorded on June 2nd, 2011 at 60 individuals. Using vegetation and water mapping of the area and GPS based localities of capture of imagines and exuviae the species' land use in the annual phenological progress was analyzed. Additionally three daily phenological studies during the main flight season were implemented. Analysis of the land use has shown that the species in the Katharinenkammer mainly populated the southern areas of the tall sedge meadows. A preference for moister areas containing small streamlets with varying vegetation structures, a

vegetation height of 40 to 80 cm and a dominance of 40 to 80 % was noticed. Areas with dense and high mantle of vegetation and shade were avoided. In the other parts of the investigation area there was a considerably lower concentration of individuals. However they could be observed occasionally on sun exposed areas of the purple moor grass meadows which border the tall sedge meadows. In addition to *C. mercuriale* the study has provided evidence for 16 other dragonfly species in the Katharinenkammer, including autochthonous appearances of the rare species *Ceriagrion tenellum*, *Orthetrum coerulescens* and *Cordulegaster boltonii*." **18482.** Kipping, J. (2012): Southern African Regional Environmental Program (SAREP). First Biodiversity Field Survey. Upper Cubango (Okavango) catchment, Angola May 2012. Dragonflies & Damselflies (Insecta: Odonata). Expert

Report. December 2012: 108 pp. (in English) ["Conclusion and outlook: From the perspective of the Odonata expert the first SAREP biodiversity survey in May 2012 was very successful and gave a first insight in the Odonata fauna of the region, their habitats and potential threats. On Angolan territory altogether 30 sites were sampled for Odonata, 28 within the Okavango catchment, 2 outside in the Cuanza catchment. The first survey focused in the middle and upper sections of the tributaries. Altogether 88 dragonfly species could be recorded on the survey in May 2012. More than 600 specimens of Odonata were collected and DNA samples of all recorded species. The survey led to the discovery of 4 undescribed species. One *Chlorocypha* sp. nov. near aphrodite is close to the tropical *Chlorocypha* aphrodite but differs in some characters. A *Pseudagrion* sp. nov. is near the Zambian *Pseudagrion* fisheri but unique in morphological features and colour markings. *Mesocnemis* sp. nov. and *Zygonyx* sp. nov. nr. *flavicosta* were recorded before in neighbouring countries but are still undescribed. 20 of the species were recorded for the first time in Angola (incl. the undescribed four), 27 are new for the whole Okavango catchment and 54 species are new for the Angolan part of the Okavango catchment. This survey brings the total number of Odonata known from the Okavango catchment to 160 species. A complete preliminary checklist of this catchment is provided (see Table 3 on page 74). The number of Odonata species known from Angola increases from 164 to 184, an updated preliminary checklist of the Odonata of Angola is provided in Table 4 on page 82. The single sampling sites are characterized by their habitat and the species that they inhabit. Observed and potential threats to freshwater diversity and Odonata in special are discussed. For the forthcoming surveys there are the following recommendations. As shown in the map of the Okavango catchment in Fig. 7 there are large gaps that were not covered by any research yet. Especially the headwaters of the Cuchi might be highly diverse in Odonata species. It forms the watershed of Okavango, Cuanza, Zambezi and Congo which promises very diverse habitats and a species rich dragonfly fauna with highly specialized taxa and even undescribed species. Also worth to sample are the middle section of the Cuito and also the Kwando. As known from own surveys and those from partners the rainy season, especially the beginning rainy season in late November is the period with the most species to be found. Next surveys should orientate on this fact and be conducted in November or shortly after the rain in March." (Author)] Address: Kipping, J., BioCart Ökologische Gutachten, Taucha/Leipzig, Germany. ## 2018

**18483.** Abbott, K.K.; Abbott, J.C.; Lozier, J.D.; Beasley, R.R. (2018): Development of polymorphic microsatellite markers for a rare dragonfly, *Cordulegaster sarracenia* (Odonata: Cordulegasteridae), with notes on population structure and genetic diversity. *International Journal of Odonatology* 21(3-4): 165-171. (in English) ["We isolated and characterized a total of 13 microsatellite loci from *C. sarracenia*. Loci were screened in 24 individuals from Louisiana and Texas. Within

*C. sarracenia*, the number of alleles per locus ranged from 0 to 5, and observed and expected heterozygosities ranged from 0.000 to 0.556 and 0.000 to 0.613, respectively. Overall differentiation among study populations was very high ( $F_{ST} = 0.423$ ), suggesting significant geographic population structure with low diversity within populations. Twelve of the 13 primers amplified in *C. sayi*, *C. diastatops*, *C. maculata*, and *C. obliqua* and polymorphism levels are reported. These new genetic markers will provide tools for addressing a number of population genetic and demographic questions relating to conservation of this rare dragonfly species." **18484.** Agembe, S.; Yongo, E.; Masese, F.; Njiru, J.; Manjala, J.; Ojwang, W. (2018): Shifts in the food of Nile perch (*Lates niloticus*) in Lake Victoria. *Lakes & Reserv.* 2018;1-5. [wileyonlinelibrary.com/journal/lre](http://wileyonlinelibrary.com/journal/lre) © 2018 John Wiley & Sons Australia, Ltd | 1: 5 pp. (in English) ["The study investigated diet of Nile perch in Lake Victoria and compared results with past data from the same lake in order to analyse diet shifts over time. Fish samples (2020) were collected by seining and trawling from 2012 to 2016. In overall, *Caridina nilotica* (59%) was the dominant food item in the diet, while *Rastrineobola argentea* (5%) contributed the least. The diet of Nile perch of 1 cm was copepods, cladocerans and rotifers. The diet changed to only copepods and cladocerans at 2 cm. The proportion of the relatively large calanoids increased with Nile perch size in 1988/89, comprising between 35 and 80% of the diet of fishes of 3-4 cm. Nile perch of 6-25 cm TL fed more on *C. nilotica* in 2012/2016, compared to 1988/1989 and 2006/08. Haplochromines were fed on more in 2006/2008 than in 2012/2016 by Nile perch of 6-30 cm TL as fish size increased. The frequencies of occurrence of *R. argentea* in the diet were highest in 1988/1989, and lowest in 2006/2008, for fish size of up to 30 cm TL. The proportion of Odonata in the diet of size class 16-20 and 21-30 cm TL were highest in 2012/2016 and 1988/1989, respectively. Thus, shifts in Nile perch diet was observed from zooplankton to *C. nilotica*, then to haplochromines and finally to fish prey as size increased. Nile perch preferred haplochromines with *C. nilotica* as the substitute food. Cannibalism was observed to have decreased, only being evidenced in Nile perch above 35 cm TL, which could actually have a positive impact on the Nile perch fishery. The information on shifts in diet of Nile perch in Lake Victoria is of considerable ecological importance." **18485.** Amrullah, S.H. (2018): [Odonata diversity index (Insecta: Odonata) as measurement of environmental quality of river in the area of Taman Nasional Bantimurung Bulusaraung]. *Prosiding Seminar Hasil Penelitian (SNP2M) 2018*: 86-91. (in Indonesian, with English summary) ["Dragonflies (Insecta: Odonata) has important roles in the ecosystem. They act as a predator, control population, and indicator of environmental pollution. The research objectives are to inventory and calculate the species diversity of dragonflies in

Bantimurung Bulusaraung National Park (Babul NP) region and also measure the environment quality of rivers according to the Species Diversity Index (SDI). The study was conducted through exploration in the six resorts. Dragonflies specimens will be identified and confirmed to LIPI Cibinong, Bogor, West Java. SDI calculated by the Shannon-Wiener formula. The results showed that there are 27 species of Odonata (17 of Anisoptera and 10 of Zygoptera) in Babul NP region. SDI shows >2.41 means that environmental quality is in very good category. The conclusion of this research was that dragonflies in the Babul NP is very diverse with the discovery of 27 species in six working area resort." **18487.** Arrowsmith, J.; Nagaraju Shivaprakash, K.; Larrivé, M.; Turgeon, J.; Lessard, J.-P. (2018): Environmental filtering along a broad-scale acidity gradient shapes the structure of odonate communities. *Ecosphere* 9(12) . Article e02473: 16 pp. (in English) ["Historical, evolutionary, and ecological processes jointly shape the structure of communities, and the relative influence of such process may vary from one region to another. Nevertheless, much of community ecology focuses on one or several communities in a given region. To assess the relative importance and the context-dependency of processes shaping communities, studies in community ecology must be conducted across regions and along broad-scale environmental gradients. Regionally, historical colonization and extinction events, as well as diversification, can influence community structure by shaping the pool of potential community members (i.e., the regional species pool). Locally, a suite of deterministic and stochastic processes can influence community structure. We constructed a large time-calibrated phylogenetic tree for North American odonates and used analyses of phylogenetic community

structure with explicit species pool definitions to assess the predominant processes structuring assemblages along a north-south environmental gradient spanning two biomes and 8° of latitude in eastern Canada. Phylogenetic analyses of 39 lentic (i.e., lake) odonate communities revealed that co-occurring species were on average more closely related than expected by chance, but only in the temperate biome. In addition, site-to-site variation in phylogenetic structure across the temperate and boreal biomes was most strongly related to variation in water pH. The most alkaline lakes were in the temperate biome and were also the most phylogenetically clustered, suggesting that water pH acts as a main environmental filter of odonate communities. An alternative explanation was that the recent radiation of damselflies increased the diversity of this group relative to that of dragonflies in the temperate species pool, thereby leaving a signature of clustering in that biome. However, our comparative null model analyses with explicit species pool definitions at least partially ruled out this explanation. Somewhat contrary to previous hypotheses regarding the assembly of odonate communities, our results suggest that stochastic processes alone cannot account for community structure in odonates and that deterministic, niche-based processes have a strong influence." **18488.** Aziz, M.A.A.A.; Mohamed, M. (2018): Diversity and species composition of odonates (Insecta: Odonata) of Hutan Lipur Soga Perdana, Batu Pahat, Johor, Malaysia: A green lung. *Journal of Science and Technology* 10(2): 1-9. (in English) ["In Malaysia, Odonates have been used widely in the assessment of water quality. This study is part of an effort to prepare a baseline data for the state of Johor, where development is happening at a fast rate which in turn could affect the water quality. Hutan Lipur Bukit Soga Perdana is a green lung for Batu Pahat which is considered as the second largest industrial town in Malaysia. Opportunistic sampling using sweep nets along 1 km line transect was conducted for a total of six days. 22 species of Odonata belonging to 17 genera and seven families were recorded. Among the seven families, the most species-rich were Libellulidae (12 species) followed by Coenagrionidae and Platycnemididae (3 species) while Gomphidae, Platystictidae, Devadattidae and Euphaeidae represented by single species. *Drepanosticta fontinalis*, a damselfly endemic to Peninsular Malaysia was collected. The abundance of the endemic *D. fontinalis* was 10.3% from a total of 126 individuals. *Tyriobapta torrida* (15.9%) was found to be the most abundant species found followed by *Prodasineura notostigma* (12.7%) and *Neurothemis fluctuans* (11.9%). The data were further analysed by using Shannon-Wiener Species Diversity Index giving a value of 2.63 indicating a moderate diversity. Simpson's Evenness is 0.91 indicating a high evenness in the distribution of Odonates. Since the forest gains high public interest in Batu Pahat and Odonates are visible and useful insects, more studies could be done, and the data could be transferred to the public as a model for biodiversity and conservation." **18491.** Bode-Oke, A.T.; Zeyghami, S.; Dong, H. (2018): Flying in reverse: kinematics and aerodynamics of a dragonfly in backward free flight. *J. R. Soc. Interface* 15: 20180102. <http://dx.doi.org/10.1098/rsif.2018.0102>: 14 pp. (in English) ["In this study, we investigated the backward free flight of a dragonfly, accelerating in a flight path inclined to the horizontal. The wing and body kinematics were reconstructed from the output of three high-speed cameras using a template-based subdivision surface reconstruction method, and numerical simulations using an immersed boundary flow solver were conducted to compute the forces and visualize the flow features. During backward flight, the dragonfly maintained an upright body posture of approximately 90° relative to the horizon. The upright body posture was used to reorient the stroke plane and the flight force in the global frame; a mechanism known as 'force vectoring' which was previously observed in manoeuvres of other flying animals. In addition to force vectoring, we found that while flying backward, the dragonfly flaps its wings with larger angles of attack in the upstroke (US) when compared with forward

flight. Also, the backward velocity of the body in the upright position enhances the wings' net velocity in the US. The combined effect of the angle of attack and wing net velocity yields large aerodynamic force generation in the US, with the average magnitude of the force reaching values as high as two to three times the body weight. Corresponding to these large forces was the presence of a strong leading edge vortex (LEV) at the onset of US which remained attached up until wing reversal. Finally, wing–wing interaction was found to enhance the aerodynamic performance of the hindwings (HW) during backward flight. Vorticity from the forewings' trailing edge fed directly into the HW LEV to increase its circulation and enhance force production." **18492.** Bowman, R.M.; Schmidt, S.; Weeks, C.; Clark, H.; Brown, C.; Latta IV, L.C.; Edgehouse, M. (2018): Phenotypic plasticity in a population of odonates. *Scientific Reports* 8, Article number: 8442: 6 pp. (in English) ["The maintenance of phenotypic plasticity within a species ensures survival through environmental flux. Plastic strategies are increasingly important given the number and magnitude of modern anthropogenic threats to the environment. We tested for phenotypic plasticity in the odonate *Argia vivida* in response to resource limitation. By limiting food availability, effectively inducing hunger, we were able to quantify shifts in agonistic behavior during intraspecific interactions. Scoring behavior in one-on-one combat trials after 1 and 4 days without food revealed phenotypic plasticity. Three classes of genotypes were identified, genotypes exhibiting either increased aggression, decreased aggression, or no phenotypic plasticity, in response to resource limitation. The variable plastic strategies in this population of odonates likely aids in maintaining fitness in fluctuating environments." **18493.** Bucciarelli, G.M.; Suh, D.; Davis, A.; Roberts, D.; Sharpton, D.; Shaffer, H.B.; Fisher, R.N.; Kats, L.B. (2018): Assessing effects of non-native crayfish on mosquito survival. *Conservation Biology* 33(1): 122-131. (in English) ["The introductions of non-native predators often reduce biodiversity and affect natural predator-prey relationships. However, non-native predators may increase the abundance of potential disease vectors (e.g. mosquitoes) indirectly through competition or predation cascades. The Santa Monica Mountains, situated in a global biodiversity hotspot, is an area of conservation concern due to climate change, urbanization, and the introduction of non-native species. We examined the effect that non-native crayfish (*Procambarus clarkii*) have on an existing native predator, dragonfly nymphs (*Aeshna* sp.) and their mosquito larvae (*Anopheles* sp.) prey. We used laboratory experiments to compare the predation efficiency of both predators, separately and together, and field data on counts of dragonfly nymphs and mosquito larvae sampled from 13 local streams. We predicted a lower predation efficiency of crayfish compared to native dragonfly nymphs as well as a reduced efficiency of dragonfly nymphs in the presence

of crayfish. Dragonfly nymphs were an order of magnitude more efficient mosquito predators compared to crayfish and dragonfly nymphs suffered reduced efficiency in the presence of crayfish. Analyses of field count data showed that populations of dragonfly nymphs and mosquito larvae were strongly correlated with crayfish presence in streams, such that sites with crayfish tended to have fewer dragonfly nymphs and more mosquito larvae. Under natural conditions, it is likely that crayfish reduce the abundance of dragonfly nymphs and their predation efficiency, and thereby, directly and indirectly, lead to higher mosquito populations and a loss of ecosystem services related to disease vector control." (Authors)] Address: Bucciarelli, G.M., UCLA La Kretz Center for California Conservation Science, Institute of the Environment and Sustainability, Los Angeles, CA, 90095 U.S.A. Email garyb@ucla.edu

**18494.** Cabaret, P. (2018): Présentation de la Réserve naturelle régionale de la haute vallée de la Vézère. *Annales Scientifiques du Limousin* 27: 72-81. (in French, with English summary) ["The Conservatoire d'espaces naturels du Limousin (CEN Limousin) was designated as responsible for managing the regional nature reserve (RNR) "Haute vallée de la Vézère" following his gazettement in November 2015. The site is located in the headwaters of the Vézère river, at the heart of Millevalles Plateau, on the communes of Saint-Merd-les-Oussines and Tarnac in the department of Corrèze. It covers a surface of 196 hectares. It is one of the last extensive and unspoiled network of heaths, dry grasslands and peatland in Limousin. The CEN Limousin has been involved in this space with local stock farmers for twenty years. The perimeter includes the pond of Chabannes with a quaking mire of exceptional vegetal diversity, and the pond of Oussines which is a local historical heritage. According to what we know, the large density of remarkable species (plants, birds, odonates in particular) as well as the substantial surface of habitats of community interest in good condition and the quality of aquatic environments, are the major conservation issues. The diagnostic of the management plan for the nature reserve is being currently written. It will clear this challenges issues and should set out the targets to be achieved. They will be the topic of dialogue and validation within the advisory committee of the RNR chaired by the President of Region "Nouvelle Aquitaine". Besides recognition of ecological and landscape site quality at regional level, the gazettement as RNR is a new action framework for experimental measures and pedagogical recovery of heritage." (Author) "The Odonata assemblage is the richest in Limousin, with 45 species recorded, i.e. 66% of the regional assemblage (75% of the known species in Corrèze). Amongst these species, 7 are included in the red list of threatened Odonata in Limousin (SLO, 2006): *Leucorrhinia dubia* is "critically endangered"; *Aeschna juncea*, *Coenagrion hastulatum*, *Somatochlora arctica*, *S. flavomaculata* and *Sympetrum flaveolum* are "endangered"; *Sympetrum danae* is "vulnerable". This exceptional diversity is largely attributed to the habitats of the Chabannes peat bog and its hydraulic annexes, the Oussines peat delta, and the Marcy stream, which is in very good ecological condition." **18495.** Cabezas Castillo, M.B.; Grether, G.F. (2018): Why are female color polymorphisms rare in territorial damselflies? *Ethology* 124(9): 667-673. (in English) [Costa Rica "In nonterritorial damselflies, females often come in multiple color morphs, perhaps because females with rare colors experience reduced sexual harassment, and thus have a frequency-dependent fitness advantage, compared to females of the most common color morph, but such polymorphisms are rare in territorial species. We consider three hypotheses to explain the rarity of female color polymorphisms in territorial species: (a) misdirected male aggression, (b) poor male mate recognition, and (c) low mating harassment rates. The first hypothesis has some empirical support, and can account for the absence of andromorphs (i.e., females that resemble males), but does not explain the absence of multiple heteromorphs. We tested the second hypothesis by presenting females of two novel color morphs (green. or red-banded abdomens) to territorial male *Hetaerina capitalis*. Females of both novel color morphs elicited fewer sexual responses than control females, and the red morph occasionally elicited aggressive responses. These results indicate that novel female color morphs would experience reduced mating harassment in this species, contradicting the hypothesis that male mate recognition is too poorly developed to reduce harassment of novel female morphs. By process of elimination, the third hypothesis, that harassment rates are too low in territorial species to provide rare female morphs a fitness advantage, is favored, but remains untested. Our findings also suggest that the common practice of color-marking odonates for behavioral research is likely to interfere with mate choice, as has long been known to be the case in birds." **18496.** Cao, L.Z.; Yuan, Y.G. (2018): Development of SSR markers based on the head transcriptome of *Pantala flavescens* (Fabricius, 1798) (Odonata: Libellulidae). *International Journal of Odonatology* 21(3-4): 1-7. (in English) ["*P. flavescens* is one of the most common species of dragonflies and has been found throughout from tropic to temperate zones worldwide. In this study, RNA-seq of *P. flavescens* was carried out through Illumina high-throughput sequencing technology. Approximately 37,868 unigenes and 47,188 transcripts were obtained. The average length of the assembled unigenes was 908.59 bp. We identified 1442 cDNA simple sequence repeats (SSRs) among the 37,868 unigenes, with 864 (59.91%) di-nucleotide repeats, 537 (37.32%) tri-nucleotide repeats, 32 (2.22%) complex-nucleotide repeats, and 9 (0.62%) with tetra-nucleotide repeats. Sixty microsatellite molecular markers were randomly selected to test amplification. Of the 60 markers, 32 (53.33%) produced clear amplicons of the expected size, 10 (16.67%) amplified nonspecific products, and 18 (30%) failed to amplify the DNA products. In order to assess their applicability, genetic diversity of the 32 SSR loci was tested

in 32 individuals from Nanchang in China. Of these loci, 14 markers were highly polymorphic, with the observed ( $H_o$ ) and expected ( $H_e$ ) heterozygosities ranged 0.69 to 0.88 and from 0.96 to 0.98 respectively. PIC ranged from 0.52 to 0.83. These highly polymorphic loci will be valuable for the genetic analysis of distinct populations of *P. flavescens*." **18498.** Carvalho, A.L. (2018): The larval ontogeny of *Coryphaeschna perrensi* (McLachlan, 1887): Supporting monophyletic groups in Aeshnidae dragonflies (Insecta: Odonata: Anisoptera). *Journal of Morphology* 279(9): 1321-1335. (in English) ["The development of the larval external morphology of *C. perrensi* is reported based primarily on a comparison of successive exuviae of reared specimens, with the second stadium larvae first described separately. Accentuated changes observable throughout successive moltings occur in some structures, such as the head capsule, labium, and anal appendages, allowing for the definition of characters with naturally ordered, polarized, and linear states (transformation series) by ontogenetic evidence. The terminal (less general) and nonterminal (more general) states of the described transformation series correspond by primary homology to the conditions found in larvae of other dragonfly species. Consequently, as the result of a parsimony analysis and subsequently ontogenetic rooting, the disposition of the states of 17 characters in a sample of final-stadium larvae of 23 species, representatives of the six Aeshnidae tribes (21) and Austroptelliidae (2), results in a hierarchical network comprising six distinct taxonomic levels of inclusion of *C. perrensi*. The levels correspond to Aeshnidae, Aeshninae, Aeshnini (part) + Gynacanthini, *Coryphaeschna*?+?-*Remartinia*, *Coryphaeschna*, and *Coryphaeschna* except *C. adnexa*, which are groups previously recognized as monophyletic resulting from analyses considering adult morphology. Immature insect morphology coupled with ontogenetic observation presenting great potential to hypothesize phylogenetic relationships and investigate heterochronic events." (Authors)] Address: Carvalho, A.L., Departamento de Entomologia, Museu Nacional, Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil.

**18499.** Cavallaro, M.C. (2018): Assessing the effects of

chronic neonicotinoid insecticide exposure on aquatic insects using multiple experimental approaches. PhD thesis. School of Environment and Sustainability, University of Saskatchewan, Saskatoon: XIV + 148 pp. (in English) ["Neonicotinoid insecticides are among the most widely used plant protection products in industrialized agriculture, and are hypothesized to be contributing to losses in non-target insect biodiversity. The lack of toxicological data evaluating the effects of neonicotinoids restricts the ability of regulators to adequately protect sensitive insects particularly those with aquatic larval stages. Many Prairie wetlands are in regions of intensive agriculture and are directly at risk of neonicotinoid contamination and require special considerations to best protect these ecologically important areas. Under laboratory conditions, I compared the effects of imidacloprid, clothianidin, thiamethoxam on the model aquatic insect, *Chironomus dilutus*. Reduced emergence success, advanced emergence timing, and male-biased sex ratios were observed across all compounds tested. Imidacloprid and clothianidin reduced emergence success at similar concentrations whereas thiamethoxam required a concentration an order of magnitude greater to observe similar toxicity. Normalizing the clothianidin and thiamethoxam toxic responses to imidacloprid, I calculated acute (lethality) 14-day toxic equivalency factors (TEFs) for imidacloprid, clothianidin and thiamethoxam as 1.00, 1.05 and 0.14, respectively, and chronic (emergence inhibition) 40-day TEFs as 1.00, 1.62 and 0.11, respectively. To expand upon these single-species laboratory assessments, in situ limnocorral were used to determine the chronic effects of the three neonicotinoids to emerging aquatic insect communities in a Prairie wetland. Imidacloprid and clothianidin treatments had similar community responses and non-biting midge (Diptera: Chironomidae) and damselfly emerged significantly earlier than the controls (18 to 25 days earlier). An additional limnocorral study with clothianidin was inconclusive. While laboratory and limnocorral studies were useful to isolate neonicotinoid effects, multiple anthropogenic stressors were hypothesized to cumulatively influence insect emergence from natural Prairie wetlands surrounded by neonicotinoid-treated canola fields. Multivariate analysis showed neonicotinoid concentration, turbidity, vegetation disturbance and continuity of grasses were significant factors modifying the abundance and composition of emerging insects. Total insect abundance was negatively affected by neonicotinoids ( $\beta \pm S.E. = -0.61 \pm 0.14$ ,  $P < 0.001$ ) but positively affected by vegetation disturbance ( $\beta \pm S.E. = 0.34 \pm 0.11$ ,  $P < 0.001$ ). Collectively, these data suggest more rigorous water quality guidelines and agricultural management strategies are needed to protect aquatic insects and the higher trophic organisms that rely on this important food source. ... *Lestes disjunctus* was the most negatively affected taxon with a species score of -0.34; the remaining odonate taxa species scores were negligible (range from *Enallagma annexum* - 0.02 to *Aeshna interrupta* 0.001)." **18500.** Chari, L.D.; Moyo, S.; Richoux, N.B.; (2018): Trophic ecology of adult male Odonata. II. Dietary contributions

of aquatic food sources. *Ecological Entomology* 43: 15-27. (in English) ["1. Insects that emerge from rivers provide nutritional subsidies to local riparian predators. Adult damselflies and dragonflies often benefit from aquatic resources, but their high mobility and evasiveness have made it difficult to monitor their diets. 2. A dual fatty acid and stable isotope analysis approach was used to investigate the links between Odonata size and behaviour with proportions of their aquatically derived nutritional sources. Additionally, the study investigated the variation in dietary contributions of aquatic food sources to Odonata between two sections of a river, each with different aquatic productivity rates. 3. Variations in body size and foraging method of Odonata in the Kowie River (South Africa) contributed to differences in the contributions of aquatic food sources to their diets. Large Odonata that consumed prey in flight had smaller proportions of aquatic indicator fatty acids and stable isotope-generated proportions of aquatic food sources than did the smaller Odonata that consumed prey from perches. 4. There was a considerable amount of interspecific variation in indicators of aquatic feeding, but Odonata at an upstream site had smaller proportions of aquatic indicators than those at a downstream site which had higher insect emergence rates. 5. The findings of this study contribute information on the dynamics of feeding ecology among adult Odonata, and the substantial contributions of aquatic prey (>80% of total diet in some cases) indicated that cross-boundary trophic linkages via odonates are strong in the Kowie River." **18501.** Chavez, M.Y. (2018): Wisconsin cranberry marshes support diverse communities of odonate biocontrol agents. MSc. thesis, Entomology and Agroecology, University of Wisconsin-Madison: III, 100 pp. (in English) ["Odonata are abundant generalist predators observed all summer on Wisconsin cranberry marshes and represent a potentially important group of biocontrol agents for a major moth pest of cranberries, *Acrobasis vaccinii*. The success of dragonflies as bio-control agents may be supported by on-site marsh habitats and the composition of the surrounding landscape. This landscape is composed of four major characteristics: cultivated cranberry marshes, forested areas, water bodies, and other (any non-cranberry agriculture, developed land, and wild marshes). We hypothesize that landscape patterns will vary by site, distance from field sites, and in composition of landscape characteristics. Given interspecific variation among odonate taxa, we hypothesize that dragonfly diversity will vary by month, site, and habitat type. We also expect that dragonfly abundance and diversity will be significantly influenced by on-marsh habitat types (cultivated cranberry beds, forest edges, or waterfront areas). Eight cranberry marshes were established as replicate tests of how landscape features may be influencing odonate abundance and diversity. Each marsh was characterized with USDA NASS cropland data layers at radii of 1 and 2 km from the marsh midpoint. Transects were established in each habitat type (i.e., bed, forest, waterfront) within these

sites during the summers of 2016 and 2017. Odonate populations were sampled within each habitat type. The eight surveyed marshes did not vary significantly in their respective proportions of surrounding landscape characteristics, but at both 1 and 2 km radii from the marshes, there was more forest and water habitat than cultivated cranberry acreage. On-site, dragonfly abundance and diversity were highest near water habitats. Dragonfly abundance was highest in June. A total of 6,577 dragonflies were observed, representing 11 taxa. The most common taxa were the following five species: *Epithea spinigera*, *Leucorrhinia frigida*, *L. intacta*, *Ladona julia*, and *Libellula quadrimaculata*. There appears to be no relationship between the surrounding landscape (at 1 or 2 km) and on-site odonate communities. To assess whether the five most abundant odonate species were consuming *A. vaccinii*, gutcontent analyses were conducted using real-time PCR. Consumption of *A. vaccinii* was consistently observed across all sites, sample dates, and among the five most abundant odonates. Thus, the dragonfly communities of Wisconsin cranberries appear to represent biocontrol agents for a major cranberry pest. Growers may benefit from this knowledge by promoting their land stewardship and sustainability practices in an environmentally conscious market." (Author)] Address: not stated

**18502.** Chovanec, A. (2018): Bewertung von Restrukturierungsmaßnahmen an der Ache (Oberösterreich) anhand von Libellen (Odonata) – Anwendung des Konzeptes der biozönotischen Regionen. *Libellula* 37(3/4): 135-160. (in German, with English summary) ["Assessment of regeneration measures at the river Ache (Upper Austria) based on Odonata – application of the Rhithron-Potamon-Concept – The Rhithron-Potamon-Concept explains the changes in species composition along a river's length. These longitudinal zonation patterns are described by biocoenotic regions. In the present paper, this concept is applied to the Austrian dragonfly fauna. Species-specific preferences for the biocoenotic regions are expressed by the allocation of ten valency points per species. A scheme for the assessment of the ecological status of rhithron sections was developed focusing on the definition of rivertype-specific reference Odonata species. In 2017, this method was applied at both a metarhithron stretch and a stretch in the transition zone of metarhithron and hyporhithron of the Ache, a river in Upper Austria. The methodological approach revealed as sensitive – also on a small scale – to detect and evaluate the impacts of regulation and rehabilitation measures as well as potamalisation effects due to impoundment." **18503.** Cordero-Rivera, A.; Vieira, V.; Utzeri, C. (2018): Clonal damselflies (*Ischnura hastata*) are not significantly affected by mite parasitism. *Entomologia Experimentalis et Applicata* 166(7): 583-591. (in English) ["We studied parasitism rate by the terrestrial mite *Leptus killingtoni* Turk (Acari: Erythraeidae) on asexual parthenogenetic damselflies, *Ischnura hastata*, and sexual *Ischnura pumilio* on Pico island (Azores, Portugal). We sampled 52 water bodies on the island

and recorded whether *Ischnura* specimens were parasitized. Half of the water bodies had either dried up or were almost dry or did not have *Ischnura* populations. In the remaining 23 ponds, mite parasitism was extremely low, with only 3.6% of *I. hastata* females bearing one or more mites. *Ischnura pumilio* was rare on the island (61 specimens examined) and had also very few parasites (9.8% parasitism). We examined the biology of the mite and its effects on the host, by studying mite attachment behavior and seasonal abundance, in an intensive study of one pond (Lagoa do Landroal). At this pond, mite prevalence peaked at the start of the sampling period, with 32% of females of *I. hastata* parasitized and decreased continuously until the end of the study, when only 2% were parasitized. The analysis of mark-recapture histories of 1 748 females of *I. hastata* indicates that mites did not affect female survival or recapture rate. Our results suggest that *L. killingtoni* is unlikely to represent a significant selective factor for odonates on the island of Pico, if its density is as low as during the period of our study, although it could be relevant when it is locally abundant or during periods of outbreak." **18504.** Díaz Flórez, B.; García, M.P.; Altamiranda-Saavedra, M.; Martínez-Hernández, N. (2018): Estructura poblacional de *Mecistogaster ornata* Rambur 1842 (Odonata: Pseudostigmatidae) en dos fragmentos de bosque seco tropical en el departamento del Atlántico, Colombia. *Bol. cient. mus. hist. nat.* 22(2): 107-131. (in Spanish, with English summary) ["Objective: The variation of the population structure of *M. ornata* was evaluated in two fragments (La Montana and Sarmiento) of Tropical Dry Forest in the Department of Atlántico, Colombia. Scope: To determinate the spatial and temporal variations of *M. ornata* abundance and its relationship with environmental variables, as well as the availability of phytotelmata and the structure of the vegetation. Methodology: 26 samplings were taken (13 per fragment) every 8 days between 8:00 a.m. and 5:00 p.m. (9 hours/man/fragment). A 600 m long and 30 m large area was established per fragment, where 10 points were marked 50 m apart from each other and in this way, 10 stretches with equal length were obtained. Odonata were captured with entomologic nets using a mark and recapture method. On the other hand, environmental temperature, relative moisture, and light intensity were measured in each stretch, as well as the number of phytotelmata and some of their characteristics (height, density, volume) and the structure of the vegetation (density of trees, vegetal cover, basal area and average height). Main results: A total of 90 individuals were captured in La Montana and released (35 ♂, 55 ♀), 40 of which were recaptured (15 ♂, 25 ♀) once or more times. The highest number of captures (19) occurred in sampling 2 carried out in March (7 ♂, 12 ♀). In Sarmiento, 31 individuals were captured and released (14 ♂, 17 ♀). In this fragment, the major number of captures was registered in event 1 carried out in March. Taking into account the sex proportions, in La Montana it was 2:1 (80 ♂, 50 ♀) with significant differences (X<sup>2</sup>=

23.403, p=0.02449), whereas in Sarmiento it was 27 ♂ and 29 ♀ (proportion 1:1) and without differences. With the principal component analysis (PCA), it was determined that the variation in the number of individuals between the places and fragments of sampling, can be explained in 59.76% because of vegetation variables as well as phytotelmata variables. Conclusions: it was established that temperature and light intensity are abiotic factors playing an important role in the temporal dynamics of the abundance of this species in the area of study. Additionally, the non random disposition of plant species and vegetation cover, as well as the height of phytotelmata influence the spatial variation of *M. ornata* in the area." (2018): Signatures of local adaptation along environmental gradients in a range-expanding damselfly (*Ischnura elegans*). *Molecular Ecology* 27: 2576-2593. (in English) ["Insect distributions are shifting rapidly in response to climate change and are undergoing rapid evolutionary change. We investigate the molecular signatures underlying local adaptation in the range-expanding damselfly, *Ischnura elegans*. Using a landscape genomic approach combined with generalized dissimilarity modelling (GDM), we detect selection signatures on loci via allelic frequency change along environmental gradients. We analyse 13,612 Single Nucleotide Polymorphisms (SNPs), derived from Restriction site-Associated DNA sequencing (RADseq), in 426 individuals from 25 sites spanning the *I. elegans* distribution in Sweden, including its expanding northern range edge. Environmental association analysis (EAA) and the magnitude of allele frequency change along the range expansion gradient revealed significant signatures of selection in relation to high maximum summer temperature, high mean annual precipitation, and low wind speeds at the range edge. SNP annotations with significant signatures of selection revealed gene functions associated with ongoing range expansion, including heat shock proteins (HSP40 and HSP70), ion transport (V-ATPase) and visual processes (long wavelength-sensitive opsin), which have implications for thermal stress response, salinity tolerance and mate discrimination,

respectively. We also identified environmental thresholds where climate-mediated selection is likely to be strong, and indicate that *I. elegans* is rapidly adapting to the climatic environment during its ongoing range expansion. Our findings empirically validate an integrative approach for detecting spatially explicit signatures of local adaptation along environmental gradients." **18509.** Fischer, I.; Sittenthaler, M.; Traugott, M.; Thauger, B.; Zangl, L.; Koblmüller, S.; Kunz, G.; Chovanec, A.; Sattmann, H.; Randolf, S.; Haring, E. (2018): Extended Abstract: Monitoring and DNA barcoding of dragonflies (Insecta: Odonata) in Vienna, Austria. *Acta ZooBot Austria* 155/2: 39-42. (in bilingual in English and German) [Verbatim: Surveys of dragonfly communities have become an important instrument for characterizing aquatic systems and assessing their ecological state (Samways 1993» Bulankova 1997, Chovanec & Wvrincer 2001, Oertli 2008, McGeoch et al. 2011). »Although dragonflies colonize a wide range of aquatic habitats, many species have specific habitat requirements concerning the morphology, hydrological dynamics and plant communities of their breeding waters and the riparian zones (CORBET 1999, SCHINDLER et al. 2003, Kadoya et al. 2004). In addition to their role as bioindicators, dragonflies are of conservation concern; 56 % of the 78 »Austrian dragonfly species are classified as vulnerable, endangered or critically endangered (Raab 2006). On a Europe-wide scale,

11 of them are listed in the Fauna-Flora-Habitat (FFH) directive by the European Union (KALKMAN et al. 2010). Hence, knowledge on distribution and abundance of these species is of relevance for both water management and conservation issues. Molecular genetic methods have found their way into the field of biomonitoring: Environmental DNA (eDNA) for either single-species detection or for surveying whole species communities (metabarcoding) has proven to be a useful tool in biodiversity research to monitor aquatic organisms, e. g. fish and amphibians (THOMSEN et al. 2012, Valentini et al. 2016, Deiner et al. 2017). However, before setting up standardized protocols for the specific taxonomic group of interest, it is indispensable to evaluate the potential of such methods first (Goldberg et al. 2016). Moreover, the availability of extensive DNA reference databases based on correctly identified voucher specimens is crucial for the successful application of eDNA metabarcoding (TABERLET et al. 2018). In the light of this, a current study titled 'Dragonflies in Vienna; DNA barcoding and survey, with focus on FFH species' includes a combination of traditional fieldwork via observation of imagines and molecular methods. The overall objective of the project is a complete dragonfly species inventory in the rural areas of Vienna with a special focus on two FFH species: *Cordulegaster heros* and *Leucorrhinia pectoralis*. Within the project, species-specific DNA barcodes are generated of collected dragonflies. Further, collecting and barcoding of dragonflies is extended to whole »Austria, to setup a complete DNA reference database or »Austrian dragonfly species within the .Austrian Barcode of Life (.ABOL) initiative. All voucher specimens are stored at the Natural History Museum Vienna. Based on this reference database, a pilot study on eDNA using filtered water samples from four running and six standing water bodies will be carried out. Both, protocols of single-species detection for rare species as well as metabarcoding approaches will be set up. The combination of traditional field surveys and DNA-based methods will allow a direct comparison between species inventories obtained by observation of imagines and detected via eDNA. Within the first project year (2017), 47 species have been recorded in Vienna by observation so far, including both FFH species. »Additionally, the first record of *Leucorrhinia albifrons*, also listed as FFH species, was obtained for Vienna (Fischer et al. 2018). In total, 342 individuals of 51 »Austrian dragonfly species have been collected during the field season in 2017 by sampling in Vienna, Styria and Burgenland. For amplifying the whole DNA barcoding region of the mitochondrial cytochrome c oxidase subunit 1 (COI) gene as well as shorter sections of the gene a new set of Odonata primers has been designed. By now, 162 DNA barcodes have been generated for the .Austrian dragonfly DNA database and the subsequent pilot study on eDNA metabarcoding. The results of this study will contribute to the development and evaluation of eDNA approaches and will reveal their potential as an additional tool for monitoring aquatic macroinvertebrates in modern biodiversity research and habitat quality assessment.] Address: Fischer, Iris, Central Research Laboratories, Museum of Natural History Vienna, Burgring 7,1010 Vienna, Austria. **18510.** Girardin, V. (2018): Source origin of Polycyclic Aromatic Hydrocarbons (PAHs) in sediment, and fate of organic contaminants in dragonfly larvae (Aeshnidae) from highway sedimentation ponds and natural ponds. Master thesis in toxicology. University of Oslo. Department of Biosciences. Faculty of Mathematics and Natural Sciences: X + 87 pp. (in English) ["Road and tunnel wash runoff contain a mixture of organic and inorganic contaminants that threatens the quality of natural water bodies, and the health of the organisms dependent on these waters. A variety of treatment solutions can be established to reduce potential runoff impact. The most common mitigation adopted in Norway is the installation of nature-based sedimentation ponds. A variety of organisms migrate to these ponds over time, and are thus at risk of exposure to high levels of traffic-related contaminants. Dragonflies, with their aquatic life stage, can potentially transfer these substances back to the terrestrial environment. This aim of this study was to assess the source origin and fate of polycyclic aromatic hydrocarbons (PAHs), and two types of organobromine compounds used as flame retardants, polybrominated diphenyl ethers (PBDEs) and hexabromocyclododecane (HBCD) in three natural and seven highway sedimentation ponds in Norway. Sediment samples were used to determine source origin of PAHs. The concentrations of organic contaminants were analyzed in dragonfly larvae to investigate their potential role as pollutant vectors across ecosystems. Parent and alkylated PAHs in sediment were measured, and the results were used to characterize the source of PAHs. Distribution patterns of selected PAHs showed similar patterns in all sedimentation ponds, and distinct patterns in natural ponds. Specific PAH ratios indicated that sedimentation ponds are dominated by petrogenic PAHs, whereas natural ponds showed pyrogenic dominance. Moreover, the addition of alkylated PAHs resulted in significant changes in the environmental quality standard values related to sediment pollution. PAHs, PBDEs and HBCD were quantified in sediment, and larval exuvia and tissue. Haemolymph was also analyzed for PAH metabolites. The results indicated that dragonfly larvae accumulate PAHs in the exuvia, but not sufficiently enough to avoid bioaccumulation. 1-hydroxypyrene was detected only in some of the samples and at very low concentrations, and thus it is not clear whether larvae are able to metabolize PAHs at low levels or if the metabolite has come from others sources. Nevertheless, the results suggest that metabolites are not suitable biomarkers for PAH exposure in dragonfly larvae. Levels of BFRs were detected at very low concentrations, and the results were qualified. Overall, there was no indication of bioaccumulation of BFRs." (Author)] Address: not stated

**18511.** Golfieri, B.; Surian, N.; Hardersen, S. (2018): Towards a more comprehensive assessment of river corridor conditions: A comparison between the Morphological Quality Index and three biotic indices. *Ecological Indicators* 84: 525-534. (in English) ["River management and planning of restoration actions require a detailed analysis of stream conditions. However, most biotic and hydromorphological indices that have been developed for implementing the European Water Framework Directive (WFD) are characterized

by limited spatial and temporal scales of application. In addition, the indices based on the biological quality elements defined by the WFD are sensitive to water quality but not to hydromorphological alterations. To overcome these limitations, alternative hydromorphological and biotic indices have recently been developed. In this study we compared the results obtained with the Morphological Quality Index (MQI) to those of three biotic indices, the Odonate River Index (ORI) and two BQE-based indices, in seven rivers of northern Italy. MQI and ORI resulted highly and significantly correlated, and alterations of river functionality and continuity were the most relevant impacts affecting dragonfly assemblages. Conversely, no significant relationships were found between the MQI and both BQE-based indices and assemblages. The significant correlation between MQI and ORI can be explained by the correspondence of the spatial scale of application (i.e. the whole river corridor). In contrast, the lack of correlation between the BQE-based indices and MQI can probably be attributed to the different spatial scales at which the indices work. The results of this study underline the importance of evaluating the lateral dimension of the river corridor and the need to apply reach-scale indices to achieve a comprehensive evaluation of river corridor conditions and to define appropriate management actions." **18512.** Grotz, N.; Roß-Nickoll, M.; Schneider, S. (2018): Der Einfluss von Alter, Struktur und Umweltparametern auf Stillgewässer und ihre Besiedlung durch Amphibien und Libellen im Westen und Südwesten Luxemburgs. *Bulletin de la Société des naturalistes luxembourgeois* 120: 77-106. (in German, with English summary) ["Amphibians are among the most endangered animal classes worldwide. One of the major causes for their decline, besides various diseases, is the disappearance and deterioration of their aquatic habitats. To replace at least some of the lost habitats and to maintain and increase amphibian populations, nature conservation organisations create new semi natural ponds in Luxembourg. The aim of the following study was to evaluate the colonization process of ponds of various ages by amphibians as well as other species and to test for a number of variables that may influence colonization and could be important factors to help improve the design and choice of future ponds. The 36 study ponds were situated in the south-western and western parts of Luxembourg. At each site, a survey of the vegetation, amphibians and dragonflies was undertaken. Furthermore, a number of environmental parameters (e.g. age, shape, distance to nearest watercourse or forest, ...) and water analysis (pH, O<sub>2</sub>, temperature, conductivity) were recorded and statistically tested in order to determine the parameters with the most significant influence on the colonization process of the ponds. The study shows that pond age has an effect on a number of the environmental factors. Pond age also directly influences the colonization by dragonflies. Colonization by amphibians, however, was not explained by pond age alone, which in this case seems to be only one of many factors influencing the process. For plants, a clear succession from pioneer communities to more specialized

reed communities was observed. Overall, the study shows a great heterogeneity of the ponds. The heterogeneity is reflected by the colonisation of the ponds. Because of this it is important to create new ponds of different types and especially in groups so that different succession stages are available for the various species during the time." **18514.** Hajdukiewicz, H.; Wyzga, B.; Amirowicz, A.; Oglecki, P.; Radecki-Pawlik, A.; Zawiejska, J.; Mikus, P. (2018): Ecological state of a mountain river before and after a large flood: Implications for river status assessment. *Science of the Total Environment* 610–611: 244-257. (in English) ["Assessment of the ecological status of rivers is key to monitoring the achievement of the environmental goal of the EU-Water Framework Directive and the success of restoration projects. In summer of 2009 and 2010, repeated assessments of physical habitat conditions and of fish and benthic invertebrate communities were performed at low-flow conditions in 10 unmanaged and 10 channelized cross-sections of the Bia³a River, Polish Carpathians. Between the two surveys, an 80-year flood occurred, significantly affecting habitat characteristics and river communities. In unmanaged cross-sections, active channel width increased, whereas the degree of cross-sectional variation of flow velocity decreased. In channelized cross-sections, the increase in active channel width and the cross-sectional variation of flow velocity was accompanied by a decrease in bed-material grain size. Before the flood, the unmanaged cross-sections hosted 2.3 times more benthic invertebrate taxa than the channelized ones, whereas after the flood, the number of taxa they supported was so reduced that the taxonomic richness of benthic invertebrate assemblages in both cross-section types became similar. In comparison to pre-flood conditions, the abundance of fish juveniles (YOY) in unmanaged cross-sections was reduced nearly by half;

before the flood they hosted 5 times more juvenile individuals than channelized cross-sections and only twice as many after the flood. Finally, a differing assessment of flood impact on the ecological river quality was obtained with the invertebrate-based BMWP-PL index and the European Fish Index, with the former indicating a significant reduction of the quality in unmanaged cross-sections and the latter pointing to no such change. The results indicate that assessments performed before or after a major flood may yield significantly different results for the quality of abiotic and biotic elements of the river ecosystem. Final assessment should thus be based on repeated surveys to balance the effect of extreme hydrological events." **18516.** Haubrock, P.J.; Balzani, P.; Johovic, I.; Inghilesi, A.F.; Nocita, A.; Tricarico, E. (2018): The diet of the alien channel catfish *Ictalurus punctatus* in the River Arno (Central Italy). *Aquatic Invasions* 13(4): 575-585. (in English) ["The North American channel catfish *Ictalurus punctatus* has been widely introduced to Europe, but no in-depth studies on its ecology and potential impacts in the introduced European range have been carried out. In 2016, 248 specimens of *I. punctatus* were collected from the Arno river, Florence (Central Italy), and analysed for their length, weight, size, sex, and stomach contents to assess their diet. Specimens < 30 cm total length (TL) represented the majority of the sampled population. Detritus and phytoplankton dominated the diet, while in larger fish ( $\geq 30$  cm TL) two invasive alien species, the topmouth gudgeon *Pseudorasbora parva* and the red swamp crayfish *Procambarus clarkii*, were dominant prey items. Diet composition of *I. punctatus* significantly varied among size classes, but not between sexes. The results indicate an opportunistic but gape size limited feeding behaviour, suggesting an intra-specific competition avoidance mechanism." (Authors) The diet includes "Odonata".]

**18517.** Hefler, C.; Qiu, H.; Shyy, W. (2018): Aerodynamic characteristics along the wing span of a dragonfly *Pantala flavescens*. *Journal of Experimental Biology* 221 (19): jeb-171199: 14 pp. (in English) ["We investigate the characteristics of inter-wing aerodynamic interactions across the span of the high-aspect-ratio, flexible wings of dragonflies under tethered and free-flying conditions. The effects of the interactions on the hindwings vary across four spanwise regions. (I) Close to the wing root, a trailing-edge vortex (TEV) is formed by each stroke, while the formation of a leading-edge vortex (LEV) is limited by the short translational distance of the hindwing and suppressed by the forewing-induced flow. (II) In the region away from the wing root but not quite up to midspan, the formation of the hindwing LEV is influenced by that of the forewing LEV. This vortex synergy can increase the circulation of the hindwing LEV in the corresponding cross-section by 22% versus that the hindwing in isolation. (III) The region about half way between the wing root and wing tip is there is a transition dominated by downwash from the forewing resulting in flow attached to the hindwing. (IV) An LEV is developed in the remaining, outer region of the wing at the end of a stroke when the hindwing captures the vortex shed by the forewing. The interaction effects depend not only on the wing phasing, but also the flapping offset and flight direction. The aerodynamics of the hindwings vary substantially from the wing root to the wing tip. For a given phasing, this spanwise variation in the aerodynamics can be exploited in the design of artificial wings to achieve greater agility and higher efficiency." **18518.** Heinloth, T.; Uhlhorn, J.; Wernet, M.F. (2018): Insect responses to linearly polarized reflections: Orphan behaviors without neural circuits. *Front. Cell. Neurosci.* | doi: 10.3389/fncel.2018.00050 : 13 pp. (in English) ["The e-vector orientation of linearly polarized light represents an important visual stimulus for many insects. Especially the detection of polarized skylight by a growing number of many navigating insect species is known to improve their orientation skills. While great progress has been made towards describing both the anatomy and function of neural circuit elements mediating behaviors related to navigation, relatively little is known about how insects perceive non-celestial polarized light stimuli, like reflections off water, leaves, or shiny body surfaces. Work on different species suggests that these behaviors are not mediated by the 'Dorsal Rim Area', a specialized region in the dorsal periphery of the adult compound eye, where ommatidia contain highly polarization-sensitive photoreceptor cells whose receptive fields point towards the sky. So far, only few cases of polarization-sensitive photoreceptors have been described in the ventral periphery of the insect retina. Furthermore, both the structure and function of those neural circuits connecting to these

photoreceptor inputs remain largely uncharacterized. Here we review the known data on non-celestial polarization vision from different insect species (dragonflies, butterflies, beetles, bugs, and flies) and present three well-characterized examples for functionally specialized non-DRA detectors from different insects that seem perfectly suited for mediating such behaviors. Finally, using recent advances from circuit dissection in *Drosophila melanogaster*, we discuss what types of potential candidate neurons could be involved in forming the underlying neural circuitry mediating non-celestial polarization vision." **18519.** Holtmann, L.; Juchem, M.; Brüggeshemke, J.; Möhlmeier, A.; Fartmann, T. (2018): Stormwater ponds promote dragonfly (Odonata) species richness and density in urban areas. *Ecological Engineering* 118: 1-11. (in English) ["Highlights: •Determine the importance of stormwater ponds for dragonflies in urban areas. •Strong differences in environmental conditions between stormwater and control ponds. •Overall species richness greater at stormwater ponds than at control ponds. •Higher species richness and densities of threatened species. •High habitat quality of stormwater ponds compensated for low landscape quality. Abstract: The loss of global biodiversity is one of the major challenges of our time and urbanisation is seen as a main cause of this. The aim of this study was to determine whether artificial stormwater ponds, designed to control water flow, can act as refuges for Odonata in urban areas. Moreover, we analysed the influence of habitat and landscape quality on dragonfly species richness and density of 35 stormwater ponds (STOPON) in comparison to 35 control ponds (CONTROL). Our study revealed significant differences in environmental conditions between STOPON and CONTROL. At the habitat level, STOPON were larger, had a warmer microclimate, and lower concentrations of phosphate. STOPON were predominantly situated in suburbs, while CONTROL occurred mostly in rural areas. Accordingly, at the landscape level, STOPON had greater cover of built-up area as well as a lower cover of arable land and woodland. In line with this, the dragonfly assemblages at STOPON and CONTROL differed. Overall species richness was greater at STOPON than at CONTROL, and indicator species were only identified for STOPON. Especially threatened species benefited from STOPON, having higher species richness as well as higher adult and exuviae densities than CONTROL. In conclusion, our study shows that stormwater ponds in urban areas play an important role in the conservation of dragonflies in general and threatened species in particular. At STOPON, as a result of regular management, the habitat quality was high and compensated for the low landscape quality stemming from significant urbanisation effects." The list includes 9 species of ciliate (Ciliophora), 20 species of flatworms (Platyhelminthes), 10 species of mollusks (Mollusca), and 470 species of arthropods, of them 29 species of crustaceans and 441 species of insects. The most species-rich insect orders of the boundary are Hymenoptera (214 species), Diptera (117 species), Lepidoptera (54 species), and Coleoptera (32 species). Some characteristics (habitat, area of distribution within the local landscape boundaries) are given for each species. For the territory of the local landscape 'Theophania' 12 species of insects, included in the 'Red Book of Ukraine', were recorded: *Calopteryx virgo*, *Anax imperator*, ..."] (Authors)] Address: not stated

**18521.** Hossie, T.J.; MacFarlane, S.; Clement, A.; Murray, D.L. (2018): Threat of predation alters aggressive interactions among spotted salamander (*Ambystoma maculatum*) larvae. *Ecology and Evolution* 8(6): 3131-3138. (in English) ["Intraspecific aggression represents a major source of mortality for many animals and is often experienced alongside the threat of predation. The presence of predators can strongly influence ecological systems both directly by consuming prey and indirectly by altering prey behavior or habitat use. As such, the threat of attack by higher level predators may strongly influence agonistic interactions among conspecifics via non-consumptive (e.g., behaviorally mediated) predator effects. We sought to investigate these interactions experimentally using larval salamanders (*Ambystoma maculatum*) as prey and dragonfly nymphs (*Anax junius*) as predators. Specifically, we quantified salamander behavioral responses to perceived predation risk (PPR) from dragonfly nymphs and determined the degree to which PPR influenced intraspecific aggression (i.e., intraspecific biting and cannibalism) among prey. This included examining the effects of predator exposure on the magnitude of intraspecific biting (i.e., extent of tail damage) and the resulting change in performance (i.e., burst swim speed). Salamander larvae responded to PPR by reducing activity and feeding, but did not increase refuge use. Predator exposure did not significantly influence overall survival; however, the pattern of survival differed among treatments. Larvae exposed to PPR experienced less tail damage from conspecifics, and maximum burst swim speed declined as tail damage became more extensive. Thus, escape ability was more strongly compromised by intraspecific aggression occurring in the absence of predation risk. We conclude that multitrophic indirect effects may importantly modulate intraspecific aggression and should be considered when evaluating the effects of intraspecific competition."] (Authors)] Address: Hossie, T.J., Dept Biol., Trent Univ., Peterborough, ON, Canada. (2018): Biodiversity of the Sebangau tropical peat swamp forest, Indonesian Borneo. *Mires and Peat* 22, Article 05: 1-50. (in English) ["The importance of Southeast Asia's tropical peat swamp forests for biodiversity is becoming increasingly recognised. Information on species presence within peatland areas is scant, however, limiting our ability to develop species conservation strategies and monitor responses to human activities. We compile species presence records for the Sebangau forest in Indonesian Borneo since 1993 and present the most complete Bornean PSF biodiversity inventory yet published. Including morpho-species that are likely to represent true species, this list comprises 215 tree, 92 non-tree flora, 73 ant, 66 butterfly, 297 spider, 41 Odonata, 55 fish, 11 amphibian, 46 reptile, 172 bird and 65 mammal taxa. Of these, 46 species are globally threatened and 59 are currently protected in Indonesia; 22 vertebrate species are Borneo endemics. Because our sampling is both biased and incomplete, the true number of species found at this site is likely to be much higher. Little is known about many of these taxa in Sebangau and peat swamp forests elsewhere. Many of these species are considered forest dependent, and the entire community is expected to be important for maintaining the resilience of the peat swamp forest ecosystem and the environmental services that it provides. This highlights the need for urgent conservation of Sebangau and its diverse biological community."] (Authors)] Address: Dow, R.A., 6 Bramley Av., Coulsdon, Surrey, CR5 2DP, UK. **18525.** Islam, S.U.; Qasim, M.; Ali, H.; Islam, W.; Arif, M.; Dash, C.K.; Lin, W.; Du, Z.; Wu, Z. (2018): Genetic diversity of the families Aeshnidae, Gomphidae and Libellulidae through COI gene from South China. *Acta Tropica* 185: 273-279. (in English) ["Highlights: • The present study had covered the region of South-China, which presented 16 species from three families. • Cytochrome oxidase subunit I (COI) was used to identify all species. • Trithemis genus presented maximum genetic divergence (18.69%) from all collected samples. • Maximum diversity was recorded from the sequences of Orthetrum genus. • Trithemis genus was dominated in the entire collection, with 28 sequences. Abstract: Adult dragonflies (Anisoptera) were collected from different localities of South China covering eight provinces. Representative sequences were sixty-one, including 16 species, 11 genera and three families (Aeshnidae, Gomphidae and Libellulidae), under cytochrome oxidase subunit I (COI) gene. After alignment of sequences by BioEdit v6, genetic interaction and divergence were computed by MEGA 7 whereas all the indices of genetic diversity were calculated by DnaSP v5 software. Phylogenetic trees were constructed through Neighbor-Joining method under Jukes-Cantor model, and all species of respective families were assembled with each other into individual groups. Maximum divergence was observed by Trithemis genus (18.69%), followed by Orthetrum genus (18.16%), whereas a minimum value of divergence was noted for Pantala genus (0.31%). On the other hand, maximum genetic diversity was recorded for Orthetrum genus up to 142 mutations, followed by Trithemis genus (126 mutations), while the minimum value (two mutations) was observed for Pantala genus. Genetic diversity for overall and Libellulidae family sequences was much higher, up to 404 mutations and 344 mutations, respectively. Current results suggest a high diversity of odonates in the South China region and results are valuable in gaining a total obligation of the diversity of Asian odonates and conservation measures of this insect group." It is the first record of this sp. in this mountain range. There are no habitats suitable for *S. alpestris* in this region that is why the observed specimen probably came from another area. Tatra Mts.

and their foot-hills are the most likely sources of the population of that species." (Author)] Address: Jankowska, Bogusława, ul. Przyjemna 8/1, 40-470 Katowice, Poland. E-mail: berta01@interia.pl

**18527.** Jinguji, H.; Ohtsu, K.; Ueda, T.; Goka, K. (2018): Effects of short-term, sublethal fipronil and its metabolite on dragonfly feeding activity. *PLoS ONE* 13(7): e0200299. 22 pp. (in English) ["Dragonflies, *Sympetrum* spp., are indispensable to agriculture and are a central element of culture in Japan. However, *S. frequens* populations in rice paddy fields have declined in recent decades. Dragonfly larvae are predatory aquatic insects that feed on other organisms found in habitats with slow-moving or standing water. The increasing use of fipronil and neonicotinoid insecticides in agriculture is also increasing exposure to *Sympetrum* spp. in larval stages through paddy soil and water. The role of fipronil insecticides in the decline of dragonflies is of concern, and we here examine the sublethal effects of this insecticide on the feeding behaviors of two *Sympetrum* spp. Based on the quantity of prey items consumed and the time to capture prey items, feeding inhibition was determined to be a potential mechanism of the decline of *Sympetrum* spp. following 48-h exposure to fipronil and fipronil sulfone. Prey consumption by *S. infuscatum* was significantly reduced for fipronil sulfone at all concentrations (0.01–1000 µg/L). *S. frequens* exposed to 1, 10, 100 and 1000 µg/L fipronil sulfone had significantly longer prey capture times. Fipronil sulfone was 2.8, 9.7 and 10.5 times more toxic to *S. infuscatum* than fipronil in terms of acute toxicity, feeding inhibition and delayed toxicity, respectively. In addition, fipronil sulfone was 6.6, 2.9 and 9.1 times more toxic, respectively, to *S. frequens* than fipronil. Our findings suggest that sublethal effects on feeding inhibition lead to severe mortality at realistic paddy soil and water concentrations. Our results provide the first demonstration that short-term exposure to fipronil and fipronil sulfone can consequently cause significant harm to dragonfly larvae survival due to feeding inhibition. These findings have implications for current pesticide risk assessment and dragonfly protection." **18528.** Karlsson, T. (2018): Grön flodtrollsända *Ophiogomphus cecilia* i Pite älv – inventering inom biogeografisk uppföljning 2018. Länsstyrelsen Östergötland, rapport 2018:13: 30 pp. (in Swedish, with English summary) ["The member countries in the European Union are obliged to report the conservation status for species listed in the Habitat directive every 6th year. To gather information about population sizes and trends for the species in Sweden, the County Administrative Board of Östergötland has been assigned by the Swedish Environmental Protection Agency to coordinate monitoring of dragonflies (Odonata) and diving beetles (Dytiscidae) listed in the Habitat directive in Sweden. This report presents a survey of *O. cecilia* in the river Piteälven. *O. cecilia* is in Sweden restricted to a few rivers in the very northeastern part. It is red listed as "Near threatened" in Sweden due to small distribution area. *O. cecilia* was searched

for as exuviae and imago at 17 localities in Piteälven from the river mouth and 100 km upstream. The survey was performed during the period 1-2 August 2018. The species could for the first time ever be found in Piteälven. Exuviae of the species were observed at five localities between Sikfors in the south and Vidsel in the north. No imago were observed despite sunny and very warm weather. The survey demonstrates that searching for exuviae is the best method for detecting the species in Sweden. The difficulty to observe imagos of the species indicates that it has a wider distribution in Sweden than previously known. Some of the surveyed localities in Piteälven should be monitored continuously. The distribution in northern Sweden of other species in the family Gomphidae was studied. *Gomphus vulgatissimus* is not recorded in this area, while there are five records of *Onychogomphus forcipatus* as larvae. Furthermore, *O. forcipatus* is reported from the province Norrbotten in some literature. Four of records have been checked out, but showed to be misidentified larvae. The occurrence of *O. forcipatus* in Norrbotten could neither be confirmed nor denied." (Author)] Address: Karlsson, T., Opphems-gatan 2, 58237 Linköping, Sweden. E-mail: tommy.karlsson@e.lst.se

**18529.** Karlsson, T. (2018): Biogeografisk uppföljning av grön mosaikslända *Aeshna viridis* – inventering och metodiktest 2017. Report, Swedish Environmental Protection Agency: 14 pp. (in Swedish, with English summary) ["The member countries in the European Union are obliged to report the conservation status for species listed in the Habitat directive every 6th year. To gather information about population sizes and trends for the species in Sweden, the Swedish Environmental Protection Agency funds "Biogeographical monitoring". The County Administrative Board of Östergötland has been assigned to coordinate the biogeographical monitoring of Odonata and diving beetles (Dytiscidae) listed in the Habitat directive in Sweden. This report aims to function as a basis document for a national monitoring programme for the dragonfly *Aeshna viridis*. The species is mainly restricted to waters with the plant *Stratiotes aloides*, where it lays its eggs and where the larvae lives. It is red listed as "Near threatened" at the European and EU-level, and listed in the annex 4 in the Habitat directive. In Sweden it is red listed as "Least concerned", but is considered to have unfavourable conservation status. During 2017 a survey was performed which aimed to test netting for larvae as survey method and to search for the species at new potential sites. The species was surveyed at 20 sites with *S. aloides* along the northern Baltic coast and in the middle east Sweden. *A. viridis* was found at nine localities of which five were previously unknown. One of these is of special interest since it together with other recent observations indicates that the species have a wider distribution in northern Sweden than previously known. The survey shows that netting for larvae is an appropriate method for monitoring *A. viridis* in Sweden. The larva is quite easy to identify and big advantages with surveying larvae compared to adults is that it is not dependent of the weather and that records of larvae confirm reproduction of the species. A suitable sample design for biogeographical monitoring of *A. viridis* in Sweden would be to

select a number of localities from a previous study of the species (Anderson et. al. 2016) and survey these once every 6 year-period." (Author)] Address: Karlsson, T., Opphems-gatan 2, 58237 Linköping, Sweden. E-mail: tommy.karlsson@e.lst.se

**18530.** Kassner, Z.; Ribak, G. (2018): Role of side-slip flight in target pursuit: blue-tailed damselflies (*Ischnura elegans*) avoid body rotation while approaching a moving perch. *Journal of Comparative Physiology A* 204(6): 561-577. (in English) ["Visually guided flight control requires processing changes in the visual panorama (optic-flow) resulting from self-movement relative to stationary objects, as well as from moving objects passing through the field of view. We studied the ability of the blue-tailed damselfly, *Ischnura elegans*, to successfully land on a perch moving unpredictably. We tracked the insects landing on a vertical pole moved linearly 6 cm back and forth with sinusoidal changes in velocity. When the moving perch changed direction at frequencies higher than 1 Hz, the damselflies engaged in manoeuvres that typically involved sideways flight, with minimal changes in body orientation relative to the stationary environment. We show that these flight manoeuvres attempted to fix the target in the centre of the field of view when flying in any direction while keeping body rotation changes about the yaw axis to the minimum. We propose that this pursuit strategy allows the insect to obtain reliable information on self and target motion relative to the stationary environment from the translational optic-flow, while minimizing interference from the rotational optic-flow. The ability of damselflies to fly in any direction, irrespective of body orientation, underlines the superb flight control of these aerial predators." (Authors)] Address: Ribak, Gal, 2. Sagol School of Neuroscience, Tel Aviv University, Tel Aviv, Israel

**18534.** Klostermann, L. (2018): Kartierung von Libellen und Entwicklung eines Pflegekonzeptes zur optimalen Lebensraumentwicklung der neu angelegten Gewässer auf der Fläche der Deichrückverlegung Langenlonsheim. Mapping of dragonflies and elaboration of a management concept for optimal habitat development of the new created water bodies on the area of the dike relocating Langenlonsheim. BSc. thesis, Department 1 – Life Sciences & Engineering, Univ. of Applied Sciences Bingen: 92 pp. (in German, with English summary) ["In the course of flood protection on the Nahe river, a retention area was created 3 years ago on a former arable land as part of the dike relocating Langenlonsheim. New water bodies were created in order to promote habitat connectivity. The paper presented deals with the dragonfly colonisation of these waters. Small waters were completely scanned for dragonflies and their exuvias while larger ones were mapped by transects. The occurring dragonfly species and

their number of individuals were gathered by abundance classes. The investigations showed that all water bodies were populated by dragonflies. Silt up waters showed less numbers of individuals as waters of earlier successional stages. A high diversity of differently structured water bodies benefits a high diversity of dragonfly species, including species classified as near-threatened. Based on the habitat requirements of the occurring endangered dragonfly species, a management concept was developed for all water bodies. This includes the restoration of earlier successional stages as well as the creation of periodically water-bearing areas." **18535.** Kömer, A.; Rieckh, C.; Holzinger, W.E. (2018): Die Vogelazurjungfer (*Coenagrion ornatum*) am Laabach (Grazer Feld, Steiermark): Bestandsgröße und Biologie einer EU-geschützten Libellenart. *Entomologica Austriaca* 25: 145-155. (in German) [The Laabach is an approx. 9.4 km long stream in the southern Graz field. It is the site of what is probably Austria's most important occurrence of the protected European species *C. ornatum*. As part of a Master's thesis, data on the biology of the species was collected at this water body in early summer 2017 and the population size was estimated. For this purpose, selected stretches of the watercourse were walked in a two-day rhythm from 11 May to 17 July and all individuals of *C. ornatum* encountered were individually marked and recorded. In addition, data on diurnal activity at the watercourse were recorded. In total, about 1,800 individuals were observed on 35 days and 732 individuals (538 males, 194 females) were marked. The total population amounts to several thousand individuals, although only relatively short sections of the stream are more densely populated. The occurrence of the species depends largely on the water flow of the stream and the presence of submerged vegetation. The phenomena known from the literature of the very short diurnal occurrence at the breeding site and the equally short flight time of the species could be confirmed. Translated with www.DeepL.com/Translator (free version)] Address: Rieckh, Christina, Institut für Zoologie der Karl-Franzens-Univ. Graz, Universitätsplatz 2, 8010 Graz, Austria. **18536.** Korkeamäki, E.; Elo, M.; Sahlén, G.; Salmela, J. (2018): Regional variations in occupancy frequency distributions patterns between odonate assemblages in Fennoscandia. *Ecosphere* 9(4) e02192. doi:10.1002/ecs2.2192: 15 pp. (in English) ["Odonate (damselfly and dragonfly) species richness and species occupancy frequency distributions (SOFD) were analysed in relation to geographical location in standing waters (lakes and ponds) in Fennoscandia, from southern Sweden to central Finland. In total, 46 dragonfly and damselfly species were recorded from 292 waterbodies. Species richness decreased to the north and increased with waterbody area in central Finland, but not in southern Finland or in Sweden. Species occupancy ranged from 1 up to 209 lakes and ponds. Over 50% of the species occurred in < 10% of the waterbodies, although this proportion decreased to the north. In the southern lakes and ponds,

none of the species occurred in all lakes, whereas in the north many species were present in all of the studied waterbodies. The dispersal ability of the species did not explain the observed species occupancy frequencies, but generalist species with a large geographical range occurred in a higher percentage of the waterbodies. At Fennoscandian scale, we found that the unimodal satellite pattern was predominant. However, at smaller scale, we found geographical variations in odonate species SOFD patterns. The most southern communities followed the unimodal satellite-dominant pattern, whereas in other regions communities fitted best with the bimodal core- satellite patterns. It seems that the richer species pool in the southern locations, and the larger distribution range of the northern species, skewed the unimodal pattern into a bimodal satellite dominant pattern." **18539.** Lhundup, K.; Dorji, U. (2018): Macro-invertebrate diversity and its relationship with environmental variables in Adha Lake between monsoon and post-monsoon seasons. *Bhutan Journal of Natural Resources & Development* 5(1): 13-24. (in English) ["Lentic water bodies are amongst the most threatened wetland habitat types as anthropogenic disturbances have significantly influenced the structure and function of aquatic ecosystems. This study compared the

seasonal variations of macro-invertebrate diversity and analysed the physiochemical parameters to study the influence of surrounding land use on the lentic ecosystem of Adha Lake. Macro-invertebrate abundance in the lake was used as an indicator to assess the effect of surrounding land use. The lake was categorised into four major zones namely agriculture zone, forest east zone, catchment zone, and forest west zone. Sampling was carried out along the littoral zone of the lake. Physio-chemical variables were collected for both the seasons. Chironomidae and Baetidae families were the most dominant macro-invertebrates in the lake. The least families encountered were Acrididae, Aeshnidae, Tabanidae, Hydrophilidae, and Libellulidae during monsoon season, and Simuliidae and Culicidae for post-monsoon season. There was no significant difference in Shannon Wiener's Diversity Index for monsoon and post-monsoon seasons,  $p > .05$ . pH, salinity, conductivity, total dissolved solid, and water temperature had negative correlation with diversity and richness; however, total dissolved solid, water temperature, and pH had positive association with taxon evenness. The HKH-bios index and NHBL index indicated that the lake is polluted which could be attributed to discharge from the paddy fields. Restoration and protection of Adha Lake as White-bellied heron's habitat may need significant conservation and advocacy measures." **18540.** Lin, C.-P.; Yang, I.H. (2018): Correlation between larger body mass, smaller wing and alternative reproductive tactics in *Psolodesmus mandarinus* damselflies. MSc. thesis, Faculty of Science, Dept of Life Sciences, Biological Agriculture, Biological Science, National Taiwan Normal University: 96 pp. (in English, with Chinese summary) ["Males of the many animal species use alternative reproductive tactics (ARTs) to obtain mating opportunity and reproductive success. In odonate species, adult males employ various genetically or conditionally based mating tactics (territoriality, non-territoriality/wandering/sneaking, or switching between the two). The evolution of different ARTs via sexual selection in recently diverged odonate species may have facilitated their speciation process. However, the relative effects of the ARTs between closely related but phenotypically divergent odonate species is poorly known. This study investigated the causes and consequences of the ARTs in two parapatrically distributed subspecies of Taiwanese *Psolodesmus mandarinus*, *P. m. mandarinus* and *P. m. dorothea*. The observations indicate that the males of both subspecies employ the same three mating tactics, including territorial, switching, and non-territorial. In *P. m. mandarinus* population of Fusan, an increase in body mass and decrease in hindwing area is associated with an increase in territoriality. Compared to non-territorial males, territorial and switching *P. m. mandarinus* males have higher mating opportunity (i.e. to engage in at least one mating). However, only switching but not territorial *P. m. mandarinus* males have higher mating success than non-territorial males. In contrast, none of the body size indicators are associated with territoriality in *P. m. dorothea* population of Lianhuachi. Only the switching

but not territorial *P. m. dorothea* males had higher mating opportunity than non-territorial males. The mating tactics of *P. m. dorothea* males had no significant effect on their mating success. In both *P. mandarinus* subspecies, the switching males instead of territorial males, appear to have the highest fitness. These results suggest that the ARTs of the two *P. mandarinus* subspecies were different in their associations of morphological traits and fitness consequences, which may be due to habitat differences or observer effects." **18541.** Lozano, F.; Muzón, J.; Anjos-Santos, D.; Pessacq, P. (2018): Chapter 14.6. Superfamily Coenagrionoidea. Thorp and Covich's Freshwater Invertebrates (Fourth Edition). Volume 3: Keys to Neotropical Hexapoda: 475-494. (in English) ["The superfamily Coenagrionoidea with approximately 170 genera and more than 1,700 species is the largest superfamily within the Zygoptera. Recent molecular studies and classificatory schemes suggest that it is composed of three families: Isostictidae, Platycnemididae, and Coenagrionidae; from these only the Coenagrionidae is represented within the Neotropics. Besides, these proposals imply the non monophyly of long recognized families such as Protoneuridae and Pseudostigmatidae which are now included within Coenagrionidae. The knowledge on Neotropical coenagrionid larvae is still very incomplete, currently it is restricted to 34 genera (48.57%) and approximately 210 species (31.81%). Few ordinal level keys exist that include larvae of Coenagrionoidea, and they are limited to certain regions or countries; this together with the fact that larval morphology is strikingly uniform makes larval identification very difficult. Here we present a key to the genera of final instar larvae of Coenagrionidae." **18542.** Maloney, E.M.; Liber, K.; Headley, J.V.; Peru, K.M.; Morrissey, C.A. (2018): Neonicotinoid insecticide mixtures: Evaluation of laboratory-based toxicity predictions under semi-controlled field conditions? *Environmental Pollution* 243, Part B: 1727-1739. (in English) ["Highlights: •Chronic toxicity of neonicotinoids and mixtures was evaluated for wetland insects. •Contrary to predictions, mixtures were not more toxic than single neonicotinoids. •Some neonicotinoids/mixtures had greater-than-predicted effects on emergence and biomass. •Lab-derived mixture models did not adequately predict field-based mixture effects. Abstract: Neonicotinoid insecticide mixtures are frequently detected in aquatic environments in agricultural regions. Recent laboratory studies have indicated that neonicotinoid mixtures can elicit greater-than-additive toxicity in sensitive aquatic insects (e.g. *Chironomus dilutus*). However, this has yet to be validated under field conditions. In this study, we compared the chronic (28. and 56-d) toxicity of three neonicotinoids (imidacloprid, clothianidin, and thiamethoxam) and their mixtures to natural aquatic insect communities. Using experimental in-situ enclosures (limnocorrals), we exposed wetland insects to

single-compounds and binary mixtures at equitoxic concentrations (1 Toxic Unit under the principle of Concentration Addition). We assessed the composition of all emerged insect taxa and cumulative Chironomidae emergence and biomass over time. In all treated limnocorrals there were subtle shifts in community composition, with greater proportions of emerged Trichoptera and Odonata. Cumulative emergence and biomass increased over time and there was a significant interaction between time and treatment. At 28 days, cumulative Chironomidae emergence and biomass were not significantly different between neonicotinoid treatments and controls. However, cumulative emergences in imidacloprid, clothianidin, and clothianidin-thiamethoxam treatments were 42%, 20%, and 44% lower than predicted from applied doses. At 56 days, imidacloprid, clothianidin, and the clothianidin-thiamethoxam mixture elicited significant declines in cumulative emergence and biomass. However, contrary to laboratory predictions, greater-than-additive mixture toxicity was not observed under semi-controlled field settings. Furthermore, only clothianidin significantly shifted sex-ratios towards female-dominated populations. Results showed that the responses of natural Chironomidae populations to neonicotinoids and their mixtures cannot be adequately predicted from laboratory-derived single-species models, and that reductions in Chironomidae emergence and biomass can occur at neonicotinoid concentrations below some current water quality guidelines (albeit effects may have been attenuated by occasional overdosing). Therefore, these neonicotinoid guidelines should be reviewed and amended to ensure that Chironomidae and other sensitive aquatic insects inhabiting agricultural wetlands are adequately protected." **18543.** Marques Pires, M.; Périco, E.; Renner, S.; Sahlén, G. (2018): Predicting the effects of future climate change on the distribution of an endemic damselfly (Odonata, Coenagrionidae) in subtropical South American grasslands. *Journal of Insect Conservation* 22: 303-319. (in English) ["Climate change is predicted to affect the distribution of freshwater taxa, and stronger impacts are expected on endemic species. However, the effects of future climates on freshwater insects from the Neotropical region have been generally overlooked. In this study, the distribution of *Cyanallagma bonariense* endemic to the subtropical South American grasslands (Pampa) was modelled in relation to future scenarios of high greenhouse gas emissions (RCP 8.5) for 2050 and 2070. For this purpose, ecological niche models were developed based on assumptions of limited dispersal and niche conservatism, and the projected distribution of *C. bonariense* was contrasted with the location of current protected areas (PAs) in the Pampa. A broad potential distribution of *C. bonariense* was indicated throughout the Pampa, and projections predicted a predominance of range contractions rather than range shifts in climatically suitable areas for *C. bonariense* in 2050 and 2070. Projections of suitable areas overlapped in central Argentina and southernmost Uruguay

in these periods. Our results indicated a potential resilience of *C. bonariense* to future climate change, which is likely related to the low restrictions in habitat use of *C. bonariense*. In every projection, however, most PAs were expected to lose effectiveness, as by 2070 most PAs fall outside the range of the predicted distribution of *C. bonariense*. Thus, the creation or enlargement of PAs in these areas is recommended and these results represent an important information for the conservation of endemic freshwater insects under global warming scenarios in an overlooked Neotropical landscape." **18544.** Marques Pires, M.M.; Stenert, C.; Maltchik, L. (2018): Drivers of beta diversity of Odonata along a forest–grassland transition in southern Brazilian coastal ponds. *Freshwater Science* 37(2): 357-366. (in English) ["Assessment of  $\beta$  diversity patterns in relation to environmental and spatial drivers can provide useful insights into the underlying mechanisms structuring communities (deterministic and dispersal limitation). However, the relative importance of each mechanism and driver of  $\beta$  diversity patterns in freshwater communities is assumed to change with ecosystem type, scale of observation, and among groups with different dispersal abilities. We assessed  $\beta$  diversity patterns of assemblages of odonate larvae in relation to geographical distances and scale-specific environmental drivers in southern Brazilian coastal ponds along a latitudinal gradient. We expected to find similar contributions of deterministic and dispersal limitation mechanisms to odonate assemblages and distinct patterns of  $\beta$  diversity between suborders Anisoptera and Zygoptera. We found low values of  $\beta$  diversity (probably related to distribution of generalist taxa and environmental conditions constituted by temporary ponds). Mantel and partial Mantel tests detected distinct relationships between dissimilarity in scale-specific drivers and geographical distances with  $\beta$  diversity of Odonata. Zygoptera was influenced by dissimilarity in local. (presence of riparian vegetation and connectivity) and regional-level (climate) variables, whereas Anisoptera was influenced by geographical distances. Our results supported our hypothesis that changes in the composition of assemblages of odonate larvae in temporary ponds were jointly driven by deterministic and dispersal limitation mechanisms. Furthermore, the similar contributions of nestedness and replacement components and the differing responses of Anisoptera and Zygoptera to local. and regional-level environmental drivers and geographical distances indicate that the relative importance of environmental and spatial drivers to  $\beta$  diversity patterns in ponds is scale-specific." (2018): Timing of adult emergence and flight periods of the Odonata of the Gallecs Rural Area (Barcelona, Catalonia, NE Spain). *Boletín de la Sociedad Entomológica Aragonesa (S.E.A.)* 62: 235-242. (in English, with Spanish summary) ["This article presents the results of a field study carried out in the Gallecs Rural Area (Barcelona, Catalonia, NE Spain) in 2015 in order to determine the emergence and flight periods of the dragonflies inhabiting a group of four small permanent and temporary man-made ponds set up through an amphibian breeding habitat project. In total fifteen taxa were recorded, most of which are common and well distributed throughout the Iberian territory. Exuviae collection provided valuable information on their life cycle, voltinism and sex ratios at emergence. In general, biotope characteristics influenced the timing of emergence and the composition of larval and adult communities, which differed between ponds, although less markedly in the case of the latter. There were also within-pond differences between larval and adult assemblages. While exuviae collection provided accurate information on the taxa breeding at each pond, records of adults reflected the diversity and composition of species at a broader landscape level due to dispersal movements between ponds." **18547.** Mendonça, F.Z.; Bernardy, J.V.; Oliveira, C.E.K.; Oliveira, P.B.G.; De Marco, P. (2018): Temperature effect on the development of tropical dragonfly eggs. *Neotropical Entomology* 47: 484-491. (in English) ["Physiological constraints in insects are related to several large-scale processes such as species distribution and thermal adaptation. Here, we fill an important gap in ecophysiology knowledge by accessing the relationship between temperature and embryonic development time in four dragonfly species. We evaluated two questions (1) what is the effect of temperature on the development time of Odonata eggs, and (2) considering a degree-day relationship, could a simple linear model

describe the dependence of embryonic development time on temperature or it is better described by a more complex non-linear relation. Egg development time of *Erythrodiplax fusca*, *Micrathyria hesperis*, *Perithemis mooma*, and *Micrathyria simplex* were evaluated. We put the eggs at different temperatures (15, 20, 25, and 30°C) and counted the number of hatched larvae daily. A nonlinear response of the development to the temperature was found, differing from the expected pattern for standard degree-day analysis. Furthermore, we observed that there is a similar process in the development time and hatching synchronization between species, with all species presenting faster egg development at high temperatures. Species-specific differences are more evident at lower temperatures (15°C), with no egg development in *M. simplex*. Only *E. fusca* was relatively insensitive to temperature changes with similar hatching rates in all treatments." **18548.** Mitchell, F.L.; Lasswell, J.L. (2018): Population characteristics of the dragonfly *Pantala flavescens* (F.). colonizing small constructed ponds. *Southwestern Entomologist* 43(4): 833-839. (in English) ["A series of small ponds was constructed to determine whether dragonflies would oviposit in them. Four pond sizes . 0.3, 0.6, 0.9, and 1.2 m<sup>2</sup> . were replicated and randomized in each of six blocks. Ponds in three of the blocks were planted with cattail (*Typha* sp.) and three with spike rush (*Juncus* sp.). Sampling revealed that of 273 nymphs collected, 267 were *P. flavescens* and six were *Orthemis ferruginea*, although adults of 15 other dragonfly species were seen in the study area. Dragonfly nymphs were not found in any of the smallest size of pond. Significantly more nymphs were found in ponds planted with cattail than rush (215 vs 52), but the nymphs grew larger in ponds with rushes. The mean number of nymphs was larger in the 1.2-m<sup>2</sup> ponds (21.8) than in the 0.6-m<sup>2</sup> ponds (8.7), while 0.9 m<sup>2</sup> was intermediate (15.0). However, when the number of nymphs per unit area was compared, there were no differences between any of the pond sizes within a vegetation class -. cattail or rush. Between classes, more nymphs per unit area were in ponds planted with cattails. Because the one species of dominant dragonfly was not representative of distribution of dragonfly species in normal-sized ponds and probably was the only dragonfly found in any similar experiment, use of small reference ponds of these sizes was not feasible for assessing dragonfly diversity and abundance." (Authors)] Address: Mitchell, F.L., Texas A&M AgriLife Res., 1229 North Highway 281, Stephenville, TX 76401, USA

**18549.** Mitchell, Z. (2018): Dragonfly locomotion: Ecology, form and function. PhD thesis, Faculty of Biological Sciences, School of Biology, University of Leeds: XIX, 166 pp. (in English) ["The Odonata is a charismatic insect order remarked for their flight ability. They are a useful model system for ecological and evolutionary processes, but in particular their strong and unique flight abilities make them a model taxon

to study the biomechanics of flight. Movement is fundamental to a range of processes in biology, including population spatial dynamics. With increasingly urgent demands to understand and predict the impacts of climate change, uncovering the processes driving the movement of populations is paramount. Currently the macroecological patterns caused by climate change are reasonably well documented – particularly for the Odonata. However the mechanisms driving population movements are less clear. Despite considerable advances in our knowledge of the biomechanics of insect flight, little of this has been applied in an ecological context. This thesis aims to identify the gaps in our knowledge of macroecological processes and how biomechanical techniques can advance the field. I have set out a number of methods demonstrating how the biomechanics of flight in Odonata impacts ecological patterns. Range shifts are perhaps one of the best detailed impacts of climate change. At some level they must be driven by the movements of individuals, yet many studies have found little evidence to correlate flight ability and dispersal in insects. Using laboratory measures of flight performance I show that climate induced range shifts in the Odonata are limited by flight efficiency. This has important implications for conservation, as knowing how flight ability is able to restrict a species' range shift will aid reserve design and future ecosystem predictions. The possible reason behind the lack of evidence linking flight ability and dispersal is the use of proxies for flight performance, and the assumptions of the relationship between these measures and actual flight performance. Indeed, in the literature there are a host of different often mutually exclusive assumptions regarding the role of morphology in shaping flight ability. I provide empirical evidence of how wing morphology affects flight performance, showing that a large proportion of assumptions made within the literature are not supported, or are only weakly supported. This calls into question how prevalent the effects of flight performance on dispersal are, given the use of misleading assumptions. In many systems the state of adult organisms is strongly dependent on the experience of juveniles. For the Odonata, a number of mass and size carry-over effects exist between larva and adult forms, but whether locomotory performance is linked in this way is as yet unknown. Here I show that there is no correlation between larval and adult locomotory performance, suggesting that muscle development mechanisms are different for larvae and adults. Except for existing mass and size effects, flight performance should not be strongly affected by larval conditions. Finally, various behaviours have the capacity to affect dispersal in a species. One of the behaviours recently empirically confirmed in the Odonata is that of reversible polarotaxis: initial repulsion from polarised light sources as immature adults and the attraction back to polarised light as mature adults. I predicted that reversible polarotaxis would help aid dispersal, repelling insects from natal habitats and encouraging them to find new ones. However, the individual-based model of dispersal that I developed shows that reversible polarotaxis is more important in speeding up the progression through life stages, reducing the time taken to reach feeding habitats and to return to breeding sites. Individuals without polarotaxis would experience

higher mortality and lower rates of energy uptake (taking longer to find food) and also higher mortality rates taking longer to return to breeding sites (including lower reproductive success from potentially spending less time at breeding sites). All the work here is then synthesised to create a comprehensive description of Odonata flight morphology (form), its effects on flight performance (function) and the ecological patterns it generates (ecology). I demonstrate that biomechanics can provide important insights into ecological processes – in this case, that flight performance is an important limiting factor for range expansions, where other limitations are perhaps not present. In addition flight morphology is strongly linked with flight performance, suggesting that up to 74% of studies have used incorrect assumptions regarding the links between morphology and performance." (Author) 1.6 Thesis Outline: The purpose of this thesis is to provide a much-needed evidence base to link form, function, and ecology in a model insect taxon. In the following chapters I demonstrate methods to build this body of evidence and demonstrate how it advances our mechanistic understanding of species' movements: 1.6.1 – Chapter 2: In this chapter I measure quantitatively the flight mechanics of a range of UK Odonata species, comparing flight mechanics data to observed range shifts during a period of warming. This comparison will help to demonstrate that population level movements are affected by the flight ability of the species, and to ascertain what specific aspect of flight performance drives macroecological patterns. Alongside providing baseline descriptions of flight performance for several Odonata species, I demonstrate the function of flight performance in influencing ecological movements. 1.6.2 – Chapter 3: Our theoretical understanding of how wing morphology affects flight performance is good, but empirical evidence is lacking. Further, a host of often mutually exclusive assumptions regarding links between morphology and flight performance have been made in the literature. Here I demonstrate empirically the effect of different wing shapes across the same range of Odonata species as in chapter 2, on their flight performance. From describing the detailed form of wing morphology I can demonstrate its function in driving flight performance and following back up through chapter 2, driving ecological range shifts. 1.6.3 – Chapter 4: Odonata like many insects have a complex life cycle, so the adult is very much dependent on the larval stage. Several previous studies have found 'carry-over' effects from larva to adult, but few have looked for an effect in locomotory performance. In this chapter I look for 'carry-over' effects of locomotory performance in Odonata from larva to adult by measuring swimming performance and subsequent flight performance when the larva emerges. It is still not known exactly how the form of flight morphology is produced, so here I demonstrate the potential function of larval form in affecting adult flight morphology, and the ecological basis of larval variation in swimming performance. 1.6.4 – Chapter 5: The previous chapters aim to establish a mechanistic understanding of locomotory performance, relating form to function and understanding its effects on Odonata ecology. They do not take into account how behaviour might modulate this process. In this chapter I provide a spatially explicit individual based

model of Odonata movement to investigate the potential impact of reversible polarotaxis, a behaviour seen in Odonata, on dispersal. Through my work, I aim to demonstrate the emergent macroecological effects from individual behaviours, informed in part from the dispersal mechanisms outlined in the previous chapters. 1.6.5 – Chapter 6: Here I describe how the preceding chapters link to form a comprehensive explanation of the form and function of Odonata biomechanics and its effects on individual and population level ecological patterns, starting from potential larval influences through to adult flight morphology. I then compare the work here to our current understanding of biomechanics and ecology and how it amends or adds to current theory. Finally I suggest the best direction for future work, looking to improve and expand on the work I have carried out here. 1.7 Conclusion: The flight biomechanics and ecological patterns in the Odonata are well described within those two respective fields. However, the underlying processes are still unclear in some cases and links between the two areas of work are few and often tenuous, due to conflicting evidence and potentially poor proxies of the properties involved being used. In the following chapters I attempt to bring together biomechanics and macroecology to explain underlying processes. I will first look at the links between quantitative flight performance data and climate induced range shifts across a range of Odonata species, followed by an empirical demonstration of the effects of wing morphology on flight performance in the Odonata. I will also look for ontogenetic carry-over effects of biomechanical performance across the odonate life cycle, to see if larval performance has an impact on macroecological patterns seen in the adults. Finally using an individual based dispersal model I test the effect that certain behaviours might have on odonate dispersal. I will give a brief discussion in each of these chapters on the results obtained, followed by an in depth discussion and synthesis in chapter 6.] Address: not stated

**18550.** Moore, M.P.; Martin, R.A. (2018): Trade-offs between larval survival and adult ornament development depend on predator regime in a territorial dragonfly. *Oecologia* 188(1): 97-106. (in English) ["Trade-offs between juvenile survival and the development of sexually selected traits can cause ontogenetic conflict between life stages that constrains adaptive evolution. However, the potential for ecological interactions to alter the presence or strength of these trade-offs remains largely unexplored. Antagonistic selection over the accumulation and storage of resources could be one common cause of environment-specific trade-offs between life stages: higher condition may simultaneously enhance adult ornament development and increase juvenile vulnerability to predators. We tested this hypothesis in an ornamented dragonfly (*Pachydiplax longipennis*). Higher larval body condition indeed enhanced the initial development of its intrasexually selected wing coloration, but was opposed by viability selection in the presence of large aeshnid predators. In contrast, viability selection did not oppose larval body condition in pools when aeshnids were absent, and was not affected when we manipulated cannibalism risk. Trade-offs between larval survival and ornament

development, mediated through the conflicting effects of body condition, therefore occurred only under high predation risk. We additionally characterized how body condition influences several traits associated with predator avoidance. Although body condition did not affect burst distance, it did increase larval abdomen size, potentially making larvae easier targets for aeshnid predators. As high body condition similarly increases vulnerability to predators in many other animals, predator-mediated costs of juvenile resource accumulation could be a common, environment-specific limitation on the elaboration of sexually selected traits." **18551.** Móra, A.; Boda, P.; Mauchart, P.; Perneckner, B.; Csabai, Z. (2018): Hydrobiological state of Fehér-tó near Kardoskút based on the physico-chemical characteristics and the aquatic macroinvertebrate assemblages in 2015. *Crisicum* 10: 143-167. (in Hungarian, with English summary) [The Fehér-tó is one of the most important astatic soda pans in the Carpathian basin. The pond is separated by a dam to eastern and western basins, which are different in hydrological regime and extension of macrovegetation. In 2015 physico-chemical parameters were measured and quantitative and faunistic samplings of aquatic macroinvertebrate assemblages were carried out to reveal the potential differences in the hydrobiological state of the two basins. The chemical parameters (Na<sup>+</sup>, K<sup>+</sup>, Ca<sup>2+</sup> ions, pH, conductivity, total dissolved solid) show that both basins are polyhalobous soda pans. Based on nutrient contents (N and P forms) the whole Fehér-tó is hypertrophic, especially the western basin. Altogether 6937 specimens belonging 60 aquatic macroinvertebrate taxa [including *Lestes macrostigma*] were collected. In the eastern basin 45, in the western basin 25 taxa were found, the number of taxa occurring in both basins was 20. Significantly higher number of species and specimens were found in the assemblages of the riparian zone (with vegetation cover) than in the open water areas in both basins. The differences between the basins were less obvious; although more species and specimens were collected in the eastern basin and the assemblages were more diverse here, the differences were not statistically significant. These results were confirmed by multivariate analyses (ANOSIM, NMDS) too. In both basins the chironomid *Cricotopus ornatus* was the dominant species, while the number of subdominant species were different (7 in the eastern and 3 in the western basin). The species composition (fewer species and specimens with the dominance of tolerant species) in the western basin suggests heavy organic matter load (the influence of aquatic birds) and regular dry periods. The more diverse macroinvertebrate fauna in the eastern basin might be due to the higher habitat heterogeneity, the more stable hydrological regime and the lower nutrient load." **18553.** Muzon, J. (2018): Chapter 14.5. Superfamily Lestoidea. Thorp and Covich's Freshwater Invertebrates (Fourth Edition). Volume 3: Keys to Neotropical Hexapoda: 469-473. (in English) [The Lestoidea, known also as Lestinoidea (Bybee et al., 2008; Rehn, 2003), is a small taxon composed of medium to large damselflies encompassing approximately 21 genera and 210 species distributed worldwide (Dijkstra et al., 2013). It includes four families: the monotypic and Australian endemic Hemiphlebiidae, the speciose and cosmopolitan Lestidae and Synlestidae, and the Neotropical endemic Perilestidae (Dijkstra et al., 2014). In the Neotropical region three families, five genera, and 62 species are reported, but this number is very likely to increase (Garrison et al., 2010). The Lestoidea has been proposed as the sister group of all the remaining Zygoptera (Bybee et al., 2008; Carle et al., 2008; Dumont et al., 2010; Davis et al., 2011). In this group, larval caudal appendages are lamellate and held in a vertical plane. Most species occupy fast to moderate streams, except *Lestes*, which prefer temporary lentic environments." **18554.** Neiss, U.G.; Fleck, G.; Pessacq, P.; Tennessen, K.J. (2018): Chapter 14.3 . Odonata: Superfamily Libelluloidea. Thorp and Covich's Freshwater Invertebrates (Fourth Edition). Volume 3: Keys to Neotropical Hexapoda: 399-447. (in English) [Libelluloidea is the second most diverse and speciose group of Odonata just behind the Coenagrionoidea. It includes almost 1,500 species in 195 genera, of which approximately 450 species and 58 genera are represented in the Neotropical region. The Libelluloidea have a cosmopolitan distribution and are present in all kind of environments. The monophyly of the superfamily is strongly supported but inner arrangement is still unresolved. In this work, four families are acknowledged: Synthemistidae (one genus in the Neotropical region: Gomphomacromia); Macromiidae (a broad genus not considered generally neotropical but present in northern Mexico: Macromia); Corduliidae (sensu stricto with six genera in the Neotropical region, but including also here for practical reasons the probable closely related incertae sedis *Lauromacromia* and *Neocordulia*), and Libellulidae (48 genera in the Neotropical region). Except for Libellulidae, with 40 genera with known larvae, all remaining genera larva are known. Here, we present a key to the families and genera of ultimate stadium larvae of Libelluloidea." **18555.** Norling, U. (2018): Constant and shifting photoperiods as seasonal cues during larval development of the univoltine damselfly *Lestes sponsa* (Odonata: Lestidae). *International Journal of Odonatology* 21(2): 129 -150. (in English) ["Larvae were reared at 21.5°C from eggs from southernmost Sweden, and fed ad libitum to emergence in four different photoperiodic treatments, intended to represent increasing levels of time stress: constant LD 16:8, corresponding to late April (or August) conditions, a shift after about two weeks from LD 16:8 to 19.5:4.5, coarsely simulating late spring, constant LD 19.5:4.5, corresponding to the summer solstice, and a shift from LD 19.5:4.5 to 16:8, coarsely simulating late summer. Mean larval development time significantly decreased in this series: 47.5, 45.2, 43.0 and 39 days (n = 11–13 larvae), respectively. This suggests an ecologically relevant integration of absolute photoperiods and changes in photoperiod, allowing larvae to distinguish if LD 16:8 represented spring or late summer, depending on earlier experience. Thus, rapid development, a long day response during spring conditions, is further speeded up by shorter days during late summer. In early stadia, moulting intervals were uniform, but long days may to some extent have programmed young larvae to develop with fewer moults, thereby increasing development rate. In the last four stadia the principal effect was variation in moulting intervals. Adult size was little affected. Homogeneous conditions and low genetic diversity produced a remarkably synchronous development within treatments, with an emergence span of 5–10 days. Due to low numbers of larvae, derived from a single female, and problems with a switch, the generality of these results would need confirmation." **18559.** Pestana, G.C.; Caromano, T.G.; Guillermo Ferreira, R. (2018): Sexual ornamentation triggers rival aggressiveness in the Neotropical damselfly *Hetaerina longipes* (Odonata: Calopterygidae). *Odonatologica* 47(1/2): 121-132. (in English) ["Coloration is associated with male quality in various animal species. These secondary sexual characters are a result of selective pressures that favor males able to cope with the physiological costs of production and maintenance of the ornament. Males of the Neotropical damselfly *Hetaerina longipes* exhibit red wing pigmentation, which is considered a sexual ornament. We tested the hypothesis that territorial males assess the quality of sexual ornamentation of rival males and respond with aggressive or neutral behaviors according to the quality of the opponent. Since wing pigmentation is an indicator of male quality, influencing contest outcome and territory acquisition, we expected that territorial males would decrease their aggressiveness when facing opponents with experimentally enhanced wing pigmentation, assuming that males should avoid conflicts with stronger males. The results suggest that territorial males are in fact more aggressive against rivals with increased pigmentation, contrary to our initial hypothesis. We discuss the cognitive ability of odonates in the assessment of opponents and suggest three hypotheses to explain the observed patterns." **18560.** Plan, L.; Stöger, T.; Draganits, E.; Gier, S. (2018): A Pleistocene landslide-dammed lake indicated by karren features (Eastern Alps, Austria). *Geomorphology* 321: 60-71. (in English) ["Highlights: •Documentation and morphometric measurements of rare röhrenkarren. •These karst features have formed due to water table fluctuation of a palaeolake. •A previously unknown palaeo-landslide body is identified. •A landslide dammed lake is reconstructed. Abstract: Numerous enigmatic tube-shaped holes in the limestone ceilings of overhangs and small caves in a restricted area north of the village St. Aegydt am Neuwalde (Lower Austria) have been known at least since 1933, but so far, no detailed study concerning their origin has been conducted. The vertical holes occur in Middle Triassic limestone and they are almost perfect cylinders tapering gently to a rounded apex. Their diameters are up to 5.5 cm and their depths reach 45 cm. They occur on both sides of the Unrechtraisen valley located in the north-eastern part of the Northern Calcareous Alps. Almost identical features were described from the shores of lakes in western Ireland and termed röhrenkarren or tube karren (Simms, 2002). According to Simms' model, they have formed by condensation corrosion within air pockets trapped in limestone overhangs by rising water levels during floods. The occurrence of these features is surprising, because presently, there is no lake and so far, no palaeolake has been known from this area. Based on high-resolution airborne laser scanning data and detailed field observations, a landslide deposit was identified in a narrow section of the valley, downstream of the röhrenkarren sites. Fine-grained, partly laminated sediments with abundant Anisoptera or flatworm (*Turbellaria*) eggs, indicative of lacustrine sediments, up to ca. 100 m above present river bed. These data indicate that a landslide had dammed the Unrechtraisen River resulting in a ca. 100 m deep lake. The röhrenkarren have formed due to fluctuations of the lake level, resulting from differences in river run-off and seepage through the landslide dam. Since <sup>230</sup>Th/U-dating of calcite crusts covering some röhrenkarren was not successful, the age is not well constrained." **18563.** Ramírez, Y.P.; Giraldo, L.P.; Zúñiga, M.; Ramos, B.C.; Chará, J. (2018): Influencia de la ganadería en la comunidad de macroinvertebrados acuáticos en microcuencas de los Andes centrales de Colombia. *Revista de Biología Tropical* 66(3): 1244-1257. (in Spanish, with English summary) ["Influence of cattle ranching on the community of aquatic macroinvertebrates in watersheds of central Andes, Colombia. In order to measure the impact of cattle ranching and riparian corridors on the composition and diversity of benthic macroinvertebrates in Andean watersheds, nine headwater streams were selected in the municipality of Villamaría (Caldas, Colombia), five of them with riparian corridors and four without protection. In July (2013) in each stream, macroinvertebrate samples were collected using D and Surber nets, and streams were characterized according to water quality, channel metrics and habitat quality score. In total 98 934 individuals were collected, distributed in nine classes, 17 orders, 56 families and 92 genera. Veneroidea was the most abundant order followed by Trichoptera, Diptera, Tubificida and Ephemeroptera. Coleoptera was the order with highest richness with 28 genera, followed by Diptera with 18, Trichoptera with 11, Ephemeroptera with 10 and Odonata with 8. Streams with riparian corridors were deeper, had higher proportion of coarse substrates and Habitat Quality Score and presented higher genus diversity than those unprotected ( $p < 0.05$ ). The genera *Ferrisia*, *Eurygerris*, *Heleobia* and *Pisidium*, total nitrogen, ammonia nitrogen and silt proportion on the streambed were correlated with unprotected streams, whilst the genus *Rhagovelia*, the subfamily Chironominae, the Habitat Quality Score and the proportion

of coarse substrates were correlated with streams with riparian corridors. This information confirms that riparian corridors help reducing the negative impact generated by cattle ranching practices and improve the provision of environmental services, and therefore it is recommended to maintain the strip of riparian vegetation in streams that possess it and allow the establishment of this in streams devoid of forest on its slopes." (Author)] Address: Ramírez, Yuly Paulina, Centro para la Investigación en Sistemas Sostenibles de Producción Agropecuaria -CIPAV, Carrera 25 No. 6-62, Cali, Colombia. **18564.** Rangel-Sánchez, L.; Nava-Bolaños, A.; Palacino-Rodríguez, F.; Córdoba-Aguilar, A. (2018): Estimating distribution area in six *Argia* damselflies (Insecta: Odonata: Coenagrionidae) including *A. garrisoni*, a threatened species. *Revista Mexicana de Biodiversidad* 89: 921-926. ["Odonata are currently facing a number of threats. One tool to provide a straightforward assessment of risk is distribution area. Here we have used ecological niche modeling to estimate distribution range for 6 species of *Argia* damselflies distributed in North America: *A. cuprea*, *A. funcki*, *A. garrisoni*, *A. harknessi*, *A. munda*, and *A. rhoadsi*. These species are not included in the International Union for the Conservation of Nature (IUCN) Red List, except for *A. garrisoni* which has been categorized as Least Concern. Our results indicated large distribution areas for all species, except for *A. garrisoni*, (8,038 km<sup>2</sup> after a refinement analysis looking for suitable habitat). Large distribution can be explained by similar niche properties shared by all study species. This is not the case for *A. garrisoni* whose situation seems worrying. This species was found in the Mexican state of San Luis Potosí in 1999 and there have been no further observations so it deserves further inspection to see whether populations are at risk. In the meantime, and according to the IUCN criteria, *A. garrisoni* should be placed under a vulnerable category." (Authors)] Address: Rangel-Sánchez, Laura, Grupo de Investigación en Odonatos de Colombia-Grupo de Investigación en Biología, Depto Biol., Univ. El Bosque, Av. Cra 9 No. 131A-02 Bogotá, Colombia

**18565.** Rathod, D.M.; Parasharya, B.M. (2018): Odonate diversity of Nalsarovar Bird Sanctuary - a Ramsar site in Gujarat, India. *Journal of Threatened Taxa* 10(8): 12117-12122. (in English) ["Odonate diversity of Nalsarovar Bird Sanctuary, a Ramsar site in Gujarat, was studied between January 2015 and July 2017. A total of 46 species belonging to six families, and 27 genera were recorded, which included 14 species of Zygoptera and 32 species of Anisoptera. Out of the 46 species, 40 species are new records for the Nalsarovar Bird Sanctuary. The record of *Enallagma cyathigerum* in Gujarat needs verification. Need to monitor changes taking place in Odonata species composition after influx from Narmada canal at Nalsarovar is emphasized." **18566.** Relyea, R.A. (2018): The interactive effects of predator stress, predation, and the herbicide Roundup. *Ecosphere*

9(11):e02476. 16 pp. (in English) ["As the number of studies examining the effects of contaminants grows, ecologists are becoming increasingly aware that contaminants can interact with natural stressors (e.g., competition and predator cues) in their effects on nontarget animals. In amphibians, predator cues can make contaminants more lethal under laboratory conditions, but the opposite outcome has been observed under more natural conditions with stratified water columns; stratification causes more pesticide to be present near the surface while predator cues scare spring-breeding amphibians down to the benthos. I examined whether this phenomenon also occurs in three species of summer-breeding amphibians (*Hyla versicolor*, *Rana clamitans*, and *Rana catesbeiana*) that were raised in outdoor mesocosms. Specifically, I asked how amphibian survival was affected by multiple concentrations of a common herbicide (glyphosate; commercial name: Roundup), the herbicide combined with chemical cues from predators (caged larval *Anax junius*), and the herbicide combined with lethal predators. Environmentally relevant concentrations of the herbicide caused high rates of tadpole mortality, but this outcome was substantially reversed by the addition of predator cues. With lethal predators, the tadpoles experienced such high mortality that the herbicide caused no additional effect. Roundup also induced morphological changes in *Hyla versicolor*, and the induced traits were different from those induced by predators. Collectively, these results suggest that while predator cues can make pesticides less lethal when thermal stratification occurs, highly lethal predators can overwhelm these effects. Thus, the impacts of such contaminants can be dramatically different in environments that do or do not contain high-risk predators." (Author)] Address: Relyea, R.A., Dept Biol. Sci., Darrin Fresh Water Inst., Rensselaer Polytechnic Inst., Troy, New York 12980 USA. E-mail: relyer@rpi.edu

**18567.** Remm, L.; Sushko, G. (2018): Dragonfly fauna in rewetted mires in Belarus: diverse but different from natural sites. *Wetlands Ecology and Management* 26(6): 1173-1180. (in English) ["Mire specialist species are under strong anthropogenic pressure. In areas where the exploitation of their habitat has been temporary or unsuccessful, restoration frequently has risen as an objective. The results of the restoration activities for habitat specialists, however, are unclear. In this work we investigated whether raising the water level ca. 10 years ago in degraded bogs has brought back a characteristic group of fauna, and mire specialists therein. Dip-netting for Odonata larvae, together with habitat description, was carried out in restored, unrestored, and natural sites. We found almost no larvae at unrestored sites. The restored sites provided habitat for diverse Odonata fauna, including lagg zone species. Bog specialists only occurred at a former pit-mining site. Based on the study, we suggest three means to support the biodiversity of mire Odonata: (i) protecting the remaining natural mires, (ii) using pit-mining instead of milling for peat extraction, and (iii) creating special pools in former milled sites that have been designated for mire restoration." **18569.** Riaz, M.A.; Riaz, A.; Ijaz, B.; Rasool, M.S.; Rahat, S.; Un Nisa, Z. (2018): Environment friendly management of mosquito: a short review. *Bangladesh Journal of Scientific and Industrial Research* 53(3): 169-178. (in English) ["Despite the large scale use of insecticides, capacity building, municipality, community and metropolis awareness, and preventive measures to counter vector borne diseases which are mounting day-by-day, new tools are now being introduced to prevent the spread of mosquito transmitted diseases. The low efficacy status of chemical pesticides have led to the interest of researchers in search of fresh and even more practicable vector control methodologies to be applied. In this regard, multiple alternatives have been monitored to develop control practice measures for the eradication, observation and control of mosquitoes at larval level by the use of a sustainable biological monitoring and control by an ordinary constructive predator, to exercise monitoring and practical control measures over parasites at larval stages in environmental and eco-friendly techniques. In particular, bio-control measures to monitor and control practical practices, context predatory larvivorous fish, dragonfly nymph, frogs, copepods, turtle, Entomopathogenic bacillus, *Bacillus sphaericus* and *Bacillus thuringiensis israelensis* are being tried in different regions of world. The available research on the subject recommends that there exist multiple direct and indirect growth factors that could play a dynamic role in prey and predator's survival. Species controphic that have an impact on concerned eco-relation reflect significant effect. In addition to this, certain eco-relations represent positive stimuli for the control of vector borne viral diseases. As a bio-control achieving feasible agent for vector monitoring, pointing, management and control predatory larvivorous fish, dragonfly nymph, frogs, copepods, turtle, Entomopathogenic bacillus, *Bacillus sphaericus* and *Bacillus thuringiensis israelensis* are not only considered as a liberated intervention for disease vector control of practices and mechanical

control cost deterrents as well. Further research has been suggested on the subject so as to find out even more practicable and effective mosquito monitoring and practical control practices." **18570.** Rieckh, C. (2018): Die Libellenfauna des Laabachs im Grazer Feld (Insecta: Odonata). MSc. thesis, Ökologie und Evolutionsbiologie, Karl-Franzens-Universität Graz: VIII, 121 pp. (in German, with English summary) [Austria; "For this Master's thesis, the Odonata fauna of the rivulet "Laabach" in the "Grazer Feld" south of Graz (Styria) was examined. The small stream has a length of 9,2 km and runs through predominantly agricultural landscape, but also partly through residential areas. For the survey of Odonata fauna it was divided in 59 widely homogeneous sections. All sections of the Laabach were surveyed at least four times in 2017, during the flying period of Odonata from May to September. In addition, in 2016 data were collected in some of the sections in August and September. Data collection was carried out on a semiquantitative basis, by observation of adult dragonflies and damselflies. To verify the impact of the surrounding habitat the rivulet sections were characterized by their morphology and by mapping the surrounding habitat at a distance of up to 30 m on both sides. Some sections of the Laabach were rich in structure, others were strongly anthropogenically affected (channelled) and/or dried out at least temporarily. A total of 27 Odonata species were identified, from which 14 species were considered autochthonous. 6 species showed a mass occurrence, among them the critically *Coenagrion ornatum*. The occurrence of *Somatochlora meridionalis* and *Lestes barbarus* are also remarkable records regarding nature conservation. Dried sections were significantly poorer in species diversity and population densities than sections with permanent water. The presence/absence of some species showed a significant dependence on the character of the surrounding landscape." **18571.** Ries, L.; Neupane, N.; Baum, K.A.; Zipkin, E.F. (2018): Flying through hurricane central: impacts of hurricanes on migrants with a focus on monarch butterflies. *Animal Migration* 5(1): 94-103. (in English) ["Hurricanes are becoming more frequent and intense, so understanding the consequences for biodiversity, including migratory species, has become critical. Studies suggest that migrants may avoid most of the direct harm of hurricanes by shifting their flight trajectories to less-impacted regions, but the majority of this research has focused on birds. We review the literature on migratory bird responses to hurricanes and also describe other taxa likely to be affected. We then focus on the monarch butterfly (*Danaus plexippus*), whose fall migratory pathway goes through Texas during hurricane season. Like birds, monarchs may be able to avoid direct damage from hurricanes. However, it may be more important to determine how they respond to shifts in availability of critical resources during migration. In

fall, when a storm-triggered flush of out-of-season vegetation growth is especially likely, hurricanes could reasonably cause indirect impacts that could be positive (increased nectar) or negative (out-of-season host plants that could disrupt migration), or both. The monarch butterfly is an especially good target for this research because of its distinct migratory phases, the importance of hurricane-impacted zones to its annual cycle, and the large quantity of data available through an extensive network of citizen science programs. ... There are also five species of migratory dragonflies (*Anax junius*, *Tramae lacerata*, *Sympetrum corruptum*, *Pantala flavescens*, and *P. hymenea*), which have both solely residential and solely migratory populations throughout their ranges [24]. Although little is known about their migration, the migratory timing of these species through Texas also coincides with peak hurricane season so there is potential for both direct and indirect effects." **18572.** Román-Heracleo, J.; Springer, M.; Ramírez, A. (2018): The larva of *Perissolestes remotus* (Williamson & Williamson, 1924) (Zygoptera: Perilestidae). *International Journal of Odonatology* 21(3-4): 173-179. (in English) ["The larva of *P. remotus* is described for the first time based on Costa Rican specimens collected in forested streams with abundant organic matter. It is characterized by a slender, elongated body, with lateral keels on abdominal segments 1–9, and a middorsal row of spines on segments 4–10. We also provide additional notes on the larvae of *P. magdalenae* using material from Panama. The larva is similar to the only other species of *Perissolestes* present in Mexico and Central America, *P. magdalenae*, but can be separated by the articulation of the prementum-postmentum reaching the metacoxa (reaching the mesocoxa in *P. magdalenae*) and the female gonapophyses exceeding past the posterior margin of S10 (just reaching posterior margin in *P. magdalenae*). At the generic level, *Perissolestes* can be differentiated from *Perilestes* by the presence of abdominal keels on segments 1–9 (from 4–9 in *Perilestes*) and by having caudal gills with small spines along the medial trachea (spines absent in *Perilestes*)."] (Authors)] Address: Ramírez, A., Dept Applied Ecology, North Carolina State Univ., Raleigh, NC 27603, USA. **18573.** Rudolf, V.H.W.; Roman, A. (2018): Trophic structure alters consequences of environmental warming. *Oikos* 127(11): 1646-1656. (in English) ["Climate warming can directly affect traits and demographic rates of organisms. However, individuals are embedded in complex networks of ecological interactions with other members of the community, allowing for a range of direct and indirect effects that depend on the trophic structure of the community. Here we show that effects of warming (i.e. increase in mean temperature) on a given species can strongly depend on the community context and trophic complexity of the system. Specifically, we manipulated the presence/ absence of two competing tadpole species and their dragonfly predators to simulate different food webs of increasing complexity that

were exposed to ambient or warmed conditions. We found that warming dramatically reduced herbivore (tadpole) survival in the absence of strong interspecific competition and predation, but it had no measureable effect on demographic rates on the dominant competitor in more complex communities where it was exposed to interspecific competition and predation. Conversely, our results also indicate that warming reduced the strength of interspecific competition and predation in our system. These results suggest that trophic complexity could potentially buffer climate change effects on populations and emphasize that we often cannot predict the effects of changes in abiotic conditions on a given population without accounting for the community context." **18574.** Rumrill, C.T.; Scott, D.E.; Lance, S.L. (2018): Delayed effects and complex life cycles: How the larval aquatic environment influences terrestrial performance and survival. *Environmental Toxicology and Chemistry* 37(10): 2660-2669. (in English) ["Species with complex life cycles are susceptible to environmental stressors across life stages, but the carryover and latent effects between stages remain understudied. For species with biphasic life histories, such as pond-breeding amphibians, delayed effects of aquatic conditions can influence terrestrial juveniles and adults directly or indirectly, usually mediated through fitness correlates such as body size. We collected adult southern toads (*Anaxyrus terrestris*) from two source populations – a natural reference wetland and a metal-contaminated industrial wetland – and exposed their offspring to two aquatic stressors – a metal contaminant, copper (Cu), and a dragonfly predator cue – in outdoor mesocosms (n = 24). We then reared metamorphs in terraria for five months to examine delayed effects of early life stage environmental conditions on juvenile performance, growth, and survival. Larval exposure to Cu, as well as having parents from a contaminated wetland, resulted in smaller size at metamorphosis – a response later negated by compensatory growth. Although Cu exposure and parental source did not affect larval survival, we observed latent effects of these stressors on juvenile survival, with elevated Cu conditions and metal-contaminated parents reducing post-metamorphic survival. Parental source and larval Cu exposure affected performance at metamorphosis through carryover effects on body size but, one month later, latent effects of parental source and larval predator exposure directly (i.e., not via body size) influenced performance. The carryover and latent effects of parental source population and aquatic Cu level on post-metamorphic survival and juvenile performance highlight the importance of conducting studies across life stages and generations." **18575.** Rushbrook, B. (2018): Habitat enhancement opportunities for southern damselfly. Itchen Valley Country Park. Arcadian Ecology & Consulting Ltd, Curdridge.: 50 pp. (in English) ["Executive Summary: Arcadian Ecology was

appointed by Eastleigh Borough Council to conduct a walk over visit of Itchen Valley Country Park and, based on this and information provided by Kevin Young (formerly of Eastleigh Borough Council and who has an in-depth knowledge of the species at this site), identify habitat enhancement and creation opportunities for southern damselfly (*Coenagrion mercuriale*) at the site. The historic water meadow network at Itchen Valley Country Park forms part of the River Itchen Site of Special Scientific Interest (SSSI) / Special Area of Conservation (SAC), and supports a population of *C. mercuriale* considered to be of national importance. However, recent studies have indicated a potential decline in the strength of the population at Itchen Valley Country Park, and it is considered that urgent conservation action for this species is required at this site. It is therefore the specific intention of this report to outline habitat enhancement and creation opportunities identified at Itchen Valley Country Park and assess them in terms of their: a. relative or site-specific value in increasing the distribution, robustness and resilience of the *C. mercuriale* population at Itchen Valley Country Park, and b. habitat enhancement and creation potential in the context of the wider Itchen Valley metapopulation as set out in the recently published strategic conservation plan for *C. mercuriale* with in and adjacent to Eastleigh Borough boundary. Habitat enhancement opportunities were identified for 16 of the 26 watercourses assessed, with a further two infrastructure improvement opportunities identified, considered to provide benefits for both *C. mercuriale* and for the management / ecology of the wider Itchen Valley Country Park. It was not considered appropriate to make recommendations for habitat creation at Itchen Valley Country Park, due to the complexity of the historic network of floodplain meadow carrier streams and ditches. It is therefore considered that a detailed hydrological study would be necessary before any notable alterations are made to water level management at the site such as the re-connection of paleo-channels or defunct elements of the historic water meadow network. It was considered more appropriate and valuable to base the recommendations of potential implementation options on the results of the site-specific prioritisation assessment (rather than strategic assessment) since: \* there is no evidence of an imminent delivery of the recently published strategic conservation plan for southern damselfly with in and adjacent to Eastleigh Borough boundary; and \* there was limited variability between options in the strategic assessment with 16 of the 18 assessed to have a high current potential of being delivered. Four different options for the suite of opportunities that should be included in the future management of Itchen Valley Country Park are provided below, representing the preferred option, preferred (within site) option, an alternative sub-optimal option, and a strongly recommended 'minimum' option. It is emphasised that these recommendations are provided on the basis that they are delivered in parallel with the general management recommendations provided. Furthermore, irrespective of what programme of works is selected, its delivery must not be unduly rigid, but be subject to continual assessment and responsive to the current habitat characteristics of the relevant watercourse(s). Specifically, where cattle grazing is already creating suitable conditions, it is not

recommended that rotational clearance is undertaken, and could instead be re-assigned to another (sections of) watercourse where it is required at that time. Finally, it is considered that there would be three distinct, but not disconnected, elements of any programme of habitat enhancement and infrastructure improvement works in order to maximise the resulting increase in the distribution, robustness and resilience of the *C. mercuriale* population at Itchen Valley Country Park. Specifically this will include measures that: 1. maintain and strengthen *C. mercuriale* numbers in the important hub in the north of site; 2. provide two-fold benefits for the wider population through works in the centre of the site; and 3. maintain and strengthen *C. mercuriale* numbers supported in the south of the site. In conclusion, it is strongly recommended that any future programme of works is designed to encompass all three elements outlined above (i.e. as included within the two preferred options outlined in Section 4.2.1). However, where there are insufficient resources and / or it is not feasible to deliver a programme of works that meets all three of these criteria, the programme should be designed to include works that deliver in line with the three elements as prioritised above." **18576.** Samanmali, C.; Udayanga, L.; Ranathunge, T.; Perera, S.J.; Hapugoda, M.; Welivitiya, C. (2018): Larvicidal potential of five selected dragonfly nymphs in Sri Lanka over *Aedes aegypti* (Linnaeus) larvae under laboratory settings. *BioMed Research International* Volume 2018, Article ID 8759459: 10 pp. (in English) ["Introduction. Limitations in breeding source reduction practices, development of insecticide resistance in mosquitoes, and ill effects of chemical controlling methods on human and ecosystem health have motivated Sri Lankan authorities working for dengue control to seek for alternative, ecofriendly, and sustainable approaches for controlling of *Aedes* vectors, to manage dengue epidemics. The present study attempted to investigate the predation efficiency of locally available dragonfly nymphs over *Aedes aegypti* under laboratory conditions, aiming to evaluate the potential of using dragonflies as biocontrol agents against dengue. Methods. Nymphal stages of five locally abundant dragonfly species were collected from different stagnated water bodies in Belihuloya area. After morphological identification, a well grown individual of each species was starved for 12 hours and introduced into a glass tank containing 1L of pond water with 200 larvae (4th instar) of *Aedes aegypti*. Number of larvae survived in the tank was enumerated hourly up to 48 hours. In case where >75% of larvae are consumed by dragonfly nymphs, additional *Ae. aegypti* larvae were introduced into such tanks. Experiment was repeated for five times. Same procedure was followed with different stages of growth of the dragonfly nymphs characterized by the highest predation rate. General Linear Model followed by Tukey's pairwise comparison was used for statistical analysis. Results. The predation rates of different dragonfly species varied significantly ( $p < 0.05$ ), whereby *Anax indicus* ( $110 \pm 7.14$  per day) indicated the highest, followed by *Pantala flavescens* ( $54.07 \pm 5.15$ ) and *Gynacantha*

dravida (49.00±11.89), while *Tholymis tillarga* (23.47±2.48) had the lowest. Further, significant variations in the larval predation were found among different maturity stages (10–20; 25–35; and 35–45 mm in body length) of *Ana. indicus* ( $p < 0.05$ ). Regardless of statistical significance, a relatively higher larvicidal activity was observed at dusk than in dawn. Conclusion. *Ana. indicus*, which is characterized by the highest predation rate, and *P. flavescens* that has the widest geographical distribution within Sri Lanka along with a notable predation efficacy could be recommended as potential candidates for field trials in biological control of dengue outbreaks via suppression of *Ae. aegypti* larvae." **18578.** Schiesari, L.; Sgambatti Monteiro, A.; Ilha, P.; Pope, N.; Tadeu Corrêa, D. (2018): The ecology of a system of natural mesocosms: Rock pools in the Atlantic Forest. *Freshwater Biology* 63(9): 1077-1087. (in English) ["1. The methodological trade-off between the realism of natural systems and the tractability of artificial systems has led ecologists to praise the qualities of natural micro. and mesocosms as an ideal means for investigating the processes that organise biological communities. Among the different types of naturally occurring micro. and mesocosms, clusters of rock pools combine a global distribution with the simplicity, replicability, tractability and structural homogeneity that are desirable in model experimental systems. However, critical geographical data gaps in the study of rock pools must be filled if ecologists are to use these as global model systems in community ecology. 2. In a year-long study of a cluster of 181 rock pools in the Atlantic Forest of eastern Brazil, we conducted the first study on the ecology of freshwater rock

pool communities in the entire Neotropical region, to the best of our knowledge. Building on published descriptions of the factors that drive community assembly within rock pools, we tested the hypotheses (1) that the effects of environmental factors prevail over those of spatial factors and (2) that pool volume and secondarily species interactions between consumers (anuran larvae), resources (leaf litter) and predators (dragonfly larvae) have a dominant role in driving species patterns of occurrence and abundance. 3. Our hypotheses were generally supported as community structure was clearly influenced by the environmental characteristics of individual pools, and not to the spatial relations among them. Pool volume had a consistent, positive influence on the probability of occurrence of dragonflies and tadpoles of three anuran species, possibly through the influence of volume on hydroperiod. However, the species most strongly associated with larger pools were not those with longer times until metamorphosis, but those with larger egg clutches. In addition, species occurrences were positively associated with resource availability as measured by leaf litter mass (significantly so for *Rhinella* and dragonflies). These observations suggest that within these severely confined freshwater systems, indicators of environmental stability and reduced intraspecific competition could be important ultimate criteria for oviposition site selection. 4. The ease of sampling and manipulating the rock pools at our Atlantic Forest site combined with the observation that these pools are governed by some of the same factors influencing community organisation in other rock pool systems around the world reinforces the merit of the system as a means to conduct global comparative studies of the ecology of communities and meta-communities." **18579.** Schmidt Dalzochio, M.; Périco, E.; Renner, S.; Sah-lén, G. (2018): Effect of tree plantations on the functional composition of Odonata species in the highlands of southern Brazil. *Hydrobiologia* 808: 283-300. (in English) ["Changes in biodiversity have mainly been assessed using taxonomical diversity indices. Although these approaches contribute to the scientific understanding of species richness and composition patterns, trait-based metrics may be more useful for detecting responses to land use change. We used odonates as a model system to compare traits composition in mixed ombrophilous forest (MOF) and tree plantations: exotic species (*Pinus* sp.) and native species (*Araucaria angustifolia*). Our goal was to understand and compare how each vegetation type affects the selection of species traits, and which factors are responsible for the presence of the species in the environment. We recorded 36 Odonata species distributed across 14 functional groups. The functional composition varied between MOF and exotic tree plantations and was similar between these two habitats and native tree plantations. Native forest favoured specialist traits. Our results suggest that the conversion of MOF to tree plantations, especially exotic ones, results in a shift to less specialized Odonata communities with altered functional group composition. This result highlights the negative impact

associated with the conversion of native forests into exotic plantations. Our results show that odonates with specialist traits are limited to natural forest sites, which makes the conservation of such areas crucial." **18581.** Schröder, R.; Linkem, C.N.; Rivera, J.A.; Butler, M.A. (2018): Should I stay or should I go? Perching damselfly use simple colour and size cues to trigger flight. *Animal Behaviour* 145: 29-37. (in English) ["Highlights: •We examined how flying insects respond to visual stimuli in a natural environment. •*Megalagrion xanthomelas* damselflies used colour and size cues to trigger pursuit. •They attacked small beads of socially relevant colours and avoided large beads. •The retina spatial resolution is  $0.82^\circ$ , but the object detection threshold is  $0.34^\circ$ . •The damselfly's stereopsis range is estimated to be  $\sim 17.5$  cm. Abstract: How do flying insects correctly respond to visual stimuli in complex natural environments? The spectacular coloration of some orders suggests that colour cues are important. Size may contain useful information as well, but insects are limited in resolving fine spatial detail due to the structure of their compound eyes. Although there have been many studies of experimentally altered body colour and pattern, we know surprisingly little about simple, isolated cues that insects use to take off after objects. Specifically, whether it is colour, size or some combination that triggers pursuit. We presented artificial bead stimuli of varying colours and sizes to perching males of the Hawaiian orangeblack damselfly *Megalagrion xanthomelas* in their natural forested stream habitat. Damselflies were most vigorously responsive to conspecific colours – attacking red (males) and tracking brown (females). Other colours with lesser biological relevance inspired lower response rates. Interestingly, size strongly modulated responses, whereby attack responses towards the smallest bead sizes transitioned to tracking or avoidance at the larger bead sizes. Although small beads are inherently more difficult to see, they triggered responses from greatest distances, even beyond the calculated stereopsis range of 17.5 cm. Damselflies had an object detection threshold of  $0.34^\circ$  within a high-resolution frontally directed acute zone with an interommatidial angle of  $0.82^\circ$ . We found evidence that size and colour serve as discrimination filters to efficiently identify

objects of interest while ignoring visual noise. Simple schemes for object discrimination may help to explain how insects can differentiate among prey and conspecifics, and why multiple species can exist in the same community despite being similar in colour. We discuss implications for visual capabilities, and how visual systems that can readily discriminate size and colour can contribute to extraordinary phenotypic diversity." **18584.** Seehausen, M.; Pinto, R.M.; Trainor, C.R.; Potenzo Lopes, J. (2018): Further records of Odonata from Timor Island, with the first photographs of living *Nososticta impercepta* (Odonata: Platycnemididae) and additional records from Rote and Romang Islands. *Faunistic Studies in Southeast Asian and Pacific Island Odonata* 25: 1-73. (in English) ["We present an annotated list of 28 Odonata species (19 Anisoptera, 9 Zygoptera) from Timor Island based on 464 records via photographs and 56 specimens held in collections at the Museum and Art Gallery of the Northern Territory, Darwin, Australia and the Museum Wiesbaden, Germany. Additionally 43 records of eight species (7 Anisoptera,

1 Zygoptera) from Rote Island and one record from Romang were reported. Most Timorese records are from Oecusse Special Administrative Region/Timor-Leste, a region which to date was "terra incognita". Further records from Timor-Leste are predominantly from Lautem Municipality and Baucau Municipality as well as from the Indonesian Kupang Regency. Four species are new records for Timor Island increasing the checklist to 40 species: *Brachythemis contaminata* (Fabricius, 1793), *Tholymis tillarga* (Fabricius, 1798), *Gynacantha* sp. cf. *dobsoni* Fraser, 1951 and *Ischnura aurora* (Brauer, 1865). We provide the first photographs of live *Nososticta impercepta* Seehausen & Theischinger, 2017 as well as some descriptions of habitats in Oecusse. At Rote Island five species were reported for the first time as well: *B. contaminata*, *Crocothemis servilia* (Drury, 1773), *Rhyothemis phyllis* (Sulzer, 1776), *Macrodiplax cora* (Brauer, 1867) and *Potamarcha* congener (Rambur, 1842). The record of *Orthetrum testaceum* (Burmeister, 1839) from Romang Island appears to be the first Odonata documented from this island. The status of *Rhyothemis phyllis* is discussed with regard to the ssp. *ixias* Lieftinck, 1953 from the islands of Sumba and Flores. We provide distribution maps of each species as well as suggestions for targeted field research in the future. All historical records of *Nososticta selysii* (Förster, 1896) from Timor are now assigned to *N. impercepta*." University of Sindh Journal of Animal Sciences 2(4): 20-25. (in English) ["Research article should aim to observed morphometric study of dragonflies which inhabited in district Matiari. During study period many surveys were conducted from 02 talukas included (Saeedabad and Hala) district Matiari is an extravagant amount of minute district of Sindh that's why it is withal included in taluka as well. Survey were commenced from monsoon season which is commences from August up to mid of September. During survey total 381 specimens comprising 213 males and 168 females were amassed. All specimens exhibiting some key transmutations in their morphological description." (Authors)] Address: Shaikh, J., Dept of Zoology, University of Sindh, Jamshoro, Pakistan

**18586.** Shkëmbi, E.; Gerken, B.; Pepa, B.; Këçaj, H.; Misja, K.; Paparisto, A. (2018): Contribution to the knowledge of Odonata from Vjosa catchment. Acta Zoo.Bot. Austria 155: 239-250. (in English, with German summary) ["The Vjosa River in Albania carries pan-European and global significance. It represents one of the last intact large river systems in Europe, hosting many different types of ecosystems, from the narrow gorges in the upper part, to the wide, braided river sections in the middle part, to the near natural delta in the Adriatic Sea. These ecosystems include aquatic, semi-aquatic and semi-terrestrial habitats, and also include vital terrestrial foraging habitats near the river, in the still predominantly traditionally cultivated landscape. Imagines of

Odonata act as ecosystemconnecting faunal elements – a fact which enhances their meaning as bioindicators. Very few studies for the area exist so far, but these few underscore the importance of the river valley as Albania's biodiversity hotspot, providing ideal aquatic habitats for numerous species. Here, we will discuss the Odonata species based on the analysis of existing research data and on the results of our expeditions to the Vjosa habitats during 2015–2017. In total, 22 Odonata species were found, 9 belonging to the Zygoptera and 13 to the Anisoptera. The species were recorded both as imagines and partly as exuviae. 10 species (*Pyrrhosoma nymphula*, *Ceriagrion tenellum*, *Coenagrion ornatum*, *Sympecma fusca*, *Sympetrum fonscolombii*, *S. vulgatum*, *S. striolatum*, *Aeshna mixta*, *Crocothemis erythraea*, *Libellula quadrimaculata*) are reported for the first time in this area. Based also on data reported in the literature, the total checklist now increases to 28 species known for the Vjosa watershed so far; all 28 species belong to Annex II (IUCN, 2010); *Cordulegaster heros* is classified as NT (Near Threatened) according to the IUCN, the EU27 red list and the European red list, and as VU (Vulnerable) according to the Mediterranean red list. *Caliaeschna microstigma* and *C. ornatum* are classified as very rare and endangered at all current sites (according to Annex II they are considered strictly protected faunal elements, are listed as LC (Least Concern) according to the IUCN, but as NT according to the EU27 red list, European red list, and the Mediterranean red list. *Calopteryx splendens* is classified as VU according to Mediterranean red list and as LC according to the others. The total number of species recorded for the Vjosa watershed is nearly half of the Odonata species found in Albania (70 species based on our data). The Vjosa floodplain system is therefore one of the richest ecosystems regarding Odonata of Albania and the Balkan region." (Authors)] Address: Shkëmbi, Enilda, Tirana Univ., Fac. Nat. **18587.** Siepielski, A.M.; McPeck, S.J.; McPeck, M.A. (2018): Female mate preferences on high dimensional shape variation for male species recognition traits. Journal of Evolutionary Biology 31(8): 1239-1250. (in English) ["Females in many animal species must discriminate between conspecific and heterospecific males when choosing mates. Such mating preferences that discriminate against heterospecifics may inadvertently also affect the mating success of conspecific males, particularly those with more extreme phenotypes. From this expectation, we hypothesized that female mate choice should cause *Enallagma* females (Odonata: Coenagrionidae) to discriminate against conspecific males with more extreme phenotypes of the claspers males use to grasp females while mating – the main feature of species mate recognition in these species. To test this, we compared cerci sizes and shapes between males that were captured while mating with females to males that were captured at the same time but not mating in three *Enallagma* species. In contrast to our hypothesis, we found only one of forty comparisons of shape variation that was consistent with females discriminating against males with more extreme cerci shapes. Instead, differences in cerci shape

between mating and single males suggested that females displayed directional preferences on 1-4 aspects of cerci shape in two of the species in our samples. These results suggest that while some directional biases in mating based on cerci shape occur, the intraspecific phenotypic variation in male cerci size and shape is likely not large enough for females to express any significant incidental discrimination among conspecifics with more extreme shapes." **18588.** Sigutova, H.; Sigut, M.; Dolny, A (2018): Phenotypic plasticity in specialists: How longspined larval *Sympetrum depressiusculum* (Odonata: Libellulidae) responds to combined predator cues. *PLoS ONE* 13(8): e0201406. 15 pp. (in English) ["Phenotypic plasticity is a common defensive strategy in species experiencing variable predation risk, such as habitat generalists. Larvae of generalist dragonflies can elongate their abdominal spines in environments with fish, but long spines render larvae susceptible to invertebrate predators. Long-spined specialists adapted to fish-heavy habitats are not expected to have phenotypic plasticity in this defence trait, but no empirical studies have been undertaken. Moreover, in comparison to prey responding to multiple predators that induce similar phenotypes, relatively little is known regarding how species react to combinations of predators that favour opposing traits. We examined plasticity of larval dragonfly *Sympetrum depressiusculum*, a long-spined habitat specialist. In a rearing experiment, larvae were exposed to four environments: (i) no predator control, (ii) fish cues (*Carassius auratus*), (iii) invertebrate cues (*Anax imperator*), as well as (iv) a combination of (ii) and (iii). Compared with the control, fish but not invertebrate cues resulted in longer spines for two (one lateral, one dorsal) of the six spines measured. Interestingly, the combined-cue treatment led to the elongation of all four dorsal spines compared with the fish treatment alone, whereas lateral spines showed no response. Our experiment provided evidence of morphological plasticity in a long-spined specialist dragonfly. We showed that nearly all spines can elongate, but also react differently under specific predator settings. Therefore, while spine plasticity evolved in direct response to a single predator type (fish), plasticity was maintained against invertebrate predators as long as fish were also present. Selective spine induction under the combined condition suggests that *S. depressiusculum* can successfully survive in environments with both predators. Therefore, phenotypic plasticity may be an effective strategy for habitat generalists and specialists. Although more studies are necessary to fully understand how selection shapes the evolution of phenotypic plasticity, we demonstrated that in dragonflies, presence or absence of a specific predator is not the only factor that determines plastic defence responses." (2018): Immature Odonata community in streams: diversity, season variation and habitat preference in different levels of degradation. *North-Western Journal of Zoology* 14(2): 232-236. (in English) ["The immature Odonata community is used to diagnose and monitor impacts on aquatic environments. Degraded environments, with a wide range of environmental variables, usually present highly resilient species. Here we present a highly diverse immature Odonata community, collect with great sample effort. In doing so, we were able to show that these altered and natural environments have similar immature Odonata communities, and pH was the only abiotic variable affecting the system and the community. The community also changes with seasonal variation, because rains modify the river flow. Furthermore, the ecological integrity of the streams was influenced by anthropogenic activities, changing the dynamics of the Odonata communities. Two genera, *Brechmorhoga* and "Unidentified genus 1", are indicators of altered environments, so they can be used as bioindicator in others monitoring environmental evaluations." **18590.** Silva Mendonça, S.; Alcântara Santos, A.C.; Marques Martins, M.; Gerson Araújo, F. (2018): Size-related and seasonal changes in the diet of the non-native *Cichla kelberi* Kullander & Ferreira, 2006 in a lowland reservoir in the southeastern Brazil. *Biota Neotropica* 18(3): 8pp. (in English, with Portuguese summary) ["We examined size-related and seasonal changes in the diet of the peacock bass *Cichla kelberi* in a tropical lowland reservoir in southeastern Brazil over three hydro-climatic seasons: summer (high rainfall and temperature), winter (low rainfall and temperature), and late spring (increasing rainfall and temperature) during two years (2006-2007). The tested hypothesis is that this non-native predator fish changes diet during the subadult and adult phases and among seasons to adapt in new colonized environment. Fishes of the families Clupeidae (*Platanichthys platana*), Characidae (*Astyanax* spp.) and Cichlidae (*Cichla kelberi*) were the most important food items, followed by insects of the order Odonata. Cannibalism was also recorded for the largest individuals. A significant size-related change in diet was found with the smallest individuals (Total Length, TL < 20 cm) preying mainly on fishes, whereas the larger individuals (TL > 30 cm) preyed mainly on Odonata. The niche breadth increased during growth, with the largest individuals having a diet more evenly distributed among the available resources. No significant seasonal differences in diet composition were found, but stomachs with higher degree of volume occupied by food were more frequent in late spring than in summer. Conversely, the highest niche breadth was found during the summer compared to the other seasons. Together, these observations suggest an efficient use of the available resources by this top predator in this new colonized system." (Authors)] Address: Alcântara Santos, A.C., Univ. **18592.** Starr, S.M. (2018): The effects of land use and climate change on Playa wetlands and their invertebrate communities. Ph.D.thesis, Biology, Dept Biological Sciences, Texas Tech University: XIII + 129 pp. (in English) ["Climate and land-use changes are the primary threats to playa wetlands and their invertebrate communities. Playas are ephemeral, depressional wetlands that are the primary form of surface water in the Southern High Plains of North America, an area that has experienced recent land-use changes that may affect playas. I used remotely sensed imagery to assess changes in land use in five categories (agriculture, rangeland/grassland, fallow, developed, and water) and playa inundation in Texas on six dates during the late growing season over 23 years. A decrease in the number of wet playas was observed over that span, and significant differences among land uses were found between and within years around dry and wet playas. Mean patch size and overall area of rangeland/grassland increased over time, possibly due in part to conservation efforts in the area. Other land-use types consequently decreased, but agriculture remained one of the dominant land-use types throughout. Because playas are crucial habitats, these changes have likely

affected regional biodiversity. Playa-associated biodiversity is largely comprised of birds, amphibians, and invertebrates. *Enallagma civile* was selected as a model organism to study the effects of environmental changes on playa invertebrates. Odonates are good model organisms to study ecological and evolutionary concepts because of their amphibious life history, which makes them sensitive to both aquatic and terrestrial environmental changes. *Enallagma civile* is a habitat generalist with a widespread distribution throughout the New World that has been underutilized in research. I summarized its life history and described lab husbandry techniques in an overview of the species as a potential model organism for studies on environmental subjects like climate change effects on elevated water temperature. Current climate change predictions estimate increased air temperatures across the Southern High Plains, putting many organisms at risk from environmental changes affecting nymph and adult life stages. Increased air temperatures can lead to elevated water temperatures, but experiments are lacking on responses in terms of development or survival. *Enallagma civile* was used to examine these effects. Eggs were collected and reared under four water temperature regimes (26, 32, 38, and 41°C). Nymph body measurements after molts, development rate, and deaths were recorded daily. Nymphs in the two hotter treatments were smaller and had lower survivorship whereas individuals in the cooler temperatures generally survived to adulthood and were larger. Individuals reared at 32°C emerged the quickest, going from egg to adult in 26 days. Elevated temperatures can thus be both advantageous and detrimental, causing concern for aquatic invertebrates in the future. In conclusion, these studies have demonstrated how land-use and climate changes are threats to playa wetlands and biota. With rangeland/grassland increasing over time, the frequency of playa wetland inundation may continue to decrease due to interactions between land use and overland water flow during precipitation events. With decreases in playa inundation frequencies and effects of climate change, playa invertebrate communities are threatened due to infrequent standing water and elevated water temperatures. By understanding how land-use and projected climate changes are currently effecting playa wetlands, it will allow for better comprehension and management of current and future alterations." **18593.** Start, D.; McCauley, S.; Gilbert, B. (2018): Physiology underlies the assembly of ecological communities. Proceedings of the National Academy of Sciences 115(23): 6016-6021. (in English) ["Significance: Ecology aims to understand the distribution of species and the processes that assemble communities. One common strategy is to use species traits to predict interaction with the abiotic and biotic environment, thus gaining an understanding of ecological communities. Here, we show that considering causal relationships among physiological and behavioral traits can help elucidate patterns of species distribution and community assembly in larval dragonflies across ponds differing in predation risk. Beyond a conceptual understanding of trait causality,

we also show a striking ecological pattern: the activity of two biomolecules accounts for >80% of the variation in community composition. Together, our conceptual framework and demonstration of a strong ecological pattern suggest that causal relationships are key to advancing trait-based community ecology. Abstract: Trait-based community ecology promises an understanding of the factors that determine species abundances and distributions across habitats. However, ecologists are often faced with large suites of potentially important traits, making generalizations across ecosystems and species difficult or even impossible. Here, we hypothesize that key traits structuring ecological communities may be causally dependent on common physiological mechanisms and that elucidating these mechanisms can help us understand the distributions of traits and species across habitats. We test this hypothesis by investigating putatively causal relationships between physiological and behavioral traits at the species and community levels in larvae of 17 species of dragonfly that co-occur at the landscape scale but segregate among lakes. We use tools borrowed from phenotypic selection analyses to show that physiological traits underlie activity rate, which has opposing effects on foraging and predator avoidance behaviors. The effect of activity on these behaviors ultimately shapes species distributions and community composition in habitats with either large-bodied fish or invertebrates as top predators. Remarkably, despite the inherent complexity of ecological communities, the expression of just two biomolecules accounts for a high proportion of the variation in behavioral traits and hence, dragonfly community composition between habitats. We suggest that causal relationships among traits can drive species distributions and community assembly." **18594.** Stauer, M.; Pöchlacker-Florian, H. (2018): Erste aktuelle Reproduktionsnachweise der Östlichen Moosjungfer (*Leucorrhinia albifrons*) und der Zierlichen Moosjungfer (*Leucorrhinia caudalis*) aus Wien mit Beiträgen zur Phänologie in Ostösterreich (Odonata: Libellulidae). Beiträge zur Entomofaunistik 19: 95-110. (in German, with English summary) ["Since the turn of the millennium there have been single records of adult males of the Dark Whiteface *Leucorrhinia albifrons* (Burmeister, 1839) and the Lilypad Whiteface *Leucorrhinia caudalis* (Charpentier, 1840) in Eastern Austria. In May 2018 the reproduction of both species could be proved at an oxbow in the Lobau, the Viennese part of the Donau-Auen National Park (Natura 2000 Danube Floodplains). Earlier findings indicate that the first population of *L. caudalis* throughout Austria for about hundred years already colonized the Lobau in 2015. For *L. albifrons* the Mühl. and Tischwasser complex currently represents the only breeding site outside Carinthia. Furthermore the Yellow-spotted Whiteface *Leucorrhinia pectoralis* (Charpentier, 1825) has spread significantly in the area in recent years. From May 8th to June 23rd 2018, 97 exuviae of *L. albifrons*, two of *L. caudalis* and one of *L. pectoralis* were collected on a shore length of about 15 meters. Within the emergence of *L. albifrons* the sex ratio was female dominated with only 42.1 %

male exuviae. First adult imagines of *L. caudalis* and *L. pectoralis* appeared already on May 6th and May 7th, respectively, followed by *L. albifrons* from May 12th onwards at the reproduction site. The phenology of these species in Eastern Austria, possible migration routes and potential threats are discussed." (Authors)] Address: Pöchlacker-Florian, Helga, Arneithgasse 85, 1160 Wien, Austria. **18595.** Stewart, S.S. (2018): Phenotypic plasticity: temporal, spatial, and behavioral effects on wing morphology of damselflies in Central Texas. Ph.D. thesis, Baylor University. Dept. of Biology: XIV, 90 pp. (in English) ["In winged animals, flight morphology must be adapted for optimum behavioral efficiency. Behaviors such as foraging, predator avoidance, and mating are strongly influenced by wing morphology and influenced by environmental conditions in many species. Geometric morphometric methods analyze and visualize subtle variations in wing shape. This study examined environmental and behavioral effects on wing shape and wing size in both sexes of multiple damselfly species over several flight seasons in central Texas. Wing size is a proxy for body size of damselflies. For *Argia sedula*, comparisons were made 1) between adults collected early in the season versus those collected late in the season, 2) between adults collected at different locations, and 3) among adults collected during several flight seasons at the same locations. Significant differences in wing shape and size occurred between seasons and between years, but not between locations. Using these findings, I broadened this study to examine temporal effects on wing size and wing shape of both sexes in eight damselfly species. Analyses indicated significant differences in wing shape and wing size between early and late flight seasons in every comparison, including seven populations of four species. Damselflies emerging early in the flight season were significantly larger than those emerging later in the flight season. In contrast, significant shape and size differences between years occurred in only one of six species. Finally, I examined wing morphology associated with gender by comparing 1) mated and unmated damselflies of both sexes from three species, and 2) males and females from ten species. Significant differences in wing shape and size occurred between mated and unmated damselflies in one of nine populations sampled. As expected, significant differences in wing shape and wing size occurred between males and females in nineteen of the twenty comparisons made from ten species. These results suggest that differences in seasonal and annual environmental conditions frequently influence wing shape and body size in both sexes of multiple damselfly species. This work presents an original, comprehensive study of environmental and behavioral effects on wing morphology using geometric morphometric techniques." 21(3-4): 189-203. (in English) ["Well-adapted flight morphology must allow for efficient behavioral activities. Wing shape has been shown in a variety of species to be influenced by environmental conditions. Analysis of wing shape using geometric morphometrics provides a visualization of wing shape variations. This study examined the effects of varied environments on wing shape and wing size of the damselfly *Argia sedula* in central Texas. Comparisons were made (1) between populations collected early in the flight season versus those collected late in the flight season; (2) between populations collected at different locations, and (3) among populations collected from the same locations during several annual flight seasons. We found widespread differences in both wing shape and body size in males and females among most environments examined. Male and female damselflies collected early varied significantly from those collected late in the flight season for all locations and years sampled. Damselflies emerging early in the flight season were significantly larger than those emerging late in the season. Significant differences in wing shape and size occurred in comparisons of male and female damselflies collected in different years at the same location. In comparing damselflies collected at different locations, neither females nor males varied significantly in wing shape. Size varied in only one male comparison between locations. Our results suggest that differences in seasonal and year-to-year environmental conditions, but not geographical location, frequently influence wing shape and wing size in *A. sedula*, and quite possibly in other damselfly species." **18597.** Sugita, N.; Agemori, H.; Goka, K. (2018): Acute toxicity of neonicotinoids and some insecticides to first instar nymphs of a non-target damselfly, *Ischnura senegalensis* (Odonata: Coenagrionidae), in Japanese paddy fields. *Applied Entomology and Zoology* 53: 519-524. (in English) ["Systemic insecticides such as neonicotinoids and fipronil are widely applied in rice production. These insecticides have been suspected of reducing biodiversity in paddy ecosystems and reducing wild dragonfly populations in Japan. Conventional ecotoxicological risk assessment could not confirm this, as it has not considered interspecific variation in sensitivity to insecticides. We estimated the median effect concentration (EC50) of 15 systemic insecticides to first instar nymphs of a Japanese damselfly, *Ischnura senegalensis*, commonly found in rice paddy fields. Damselflies were found to be highly sensitive to pyrethroid pesticides, less so to phenylpyrazole, organophosphates, and carbamates, and least sensitive to neonicotinoids, nereistoxin, and diamide. Given the acute toxicity data, the sensitivity of the damselfly to neonicotinoids was considered to be lower than that of other aquatic insects, whereas the EC50 values of the damselfly were 2–3 orders lower than that of *Daphnia magna* Straus (Diplostraca: Daphniidae), which is a standard test species. These results indicate that the conventional ecological risk assessment based on acute toxicity data of *D. magna* would underestimate the impact of neonicotinoids on Odonata diversity in paddy ecosystems. We

therefore recommend using the paddy-dwelling damselfly as a new test species for insecticide bioassay." (Authors)] Address: Sugita, N., Center for Environmental Biology and Ecosystem Studies, National Institute for Environmental Studies, Tsukuba, Japan

**18598.** Sun, Z.; Brittain, J.E.; Sokolova, E.; Thygesen, H.; Saltveit, S.J.; Rauch, S.; Meland, S. (2018): Aquatic biodiversity in sedimentation ponds receiving road runoff – What are the key drivers? *Science of the Total Environment* 610–611: 1527-1535. (in English) ["Highlights: • Investigated the impact of environmental factors on aquatic biodiversity in ponds. • Used multivariate statistical methods on data collected in twelve ponds over a year • The most important factors were metals, chloride, phosphorus, and pond size. • Larger sedimentation ponds host more taxa than smaller ponds. • Sedimentation ponds have the potential to contribute to aquatic biodiversity. Abstract: Recently, increased attention has been paid to biodiversity conservation provided by blue-green solutions such as engineered ponds that are primarily established for water treatment and flood control. However, little research has been done to analyse the factors that affect biodiversity in such ponds. The purpose of this study was to evaluate the influence of environmental factors on aquatic biodiversity, mainly macroinvertebrate communities, in road sedimentation ponds in order to provide a foundation for recommendations on aquatic biodiversity conservation. Multivariate statistical methods, including unconstrained and constrained analysis, were applied to examine the relationships between organisms and the water quality as well as physical factors (including plant cover). Stepwise multiple regressions indicated that the most important variables governing the variation in the biological community composition were pond size, average annual daily traffic, metals, chloride, distance to the closest pond from study pond, dissolved oxygen, hydrocarbons, and phosphorus. The presence of most taxa was positively correlated with pond size and negatively correlated with metals. Small ponds with high pollutant loadings were associated with a low diversity and dominated by a few pollution tolerant taxa such as oligochaetes. A comprehensive understanding of impacts of various environmental factors on aquatic biodiversity is important to effectively promote and conserve aquatic biodiversity in such sedimentation ponds. Our results indicate that road sedimentation ponds should be designed large enough, because large ponds are likely to provide a more heterogeneous habitat and thus contain a species rich fauna. In addition, larger ponds seem to be less contaminated due to dilution compared to smaller ponds, thereby maintaining a higher biodiversity. Finally creating some additional ponds in the vicinity of the sedimentation ponds in areas with few water bodies would increase the connectivity that facilitates the movement of invertebrates between ponds." insectphobia. Research Bulletin of Kindai University Kyushu Junior College 48: 65-76. (in Japanese, with English summary) ["Influence on the grade of organism form cognition by the insectphobia was investigated in early childhood course students. The definite decline of the organism form cognition grade in the three insects (ant, dragonfly, spider) was not seen in five years. On the other hand, in same five years, the ratio of students of the insectphobia increased. The organism form cognition grades of the students of the insectphobia tended to lower, and it was shown that the grades of organism form cognition became higher so that the kinds of the insect to touch increased. To train childminders being able to do appropriate correspondences when a child met an insect, it is necessary to change the negative consciousness for the insect of the students and to let students acquire the power of observation to notice small points.] Address: not stated

**18600.** Tennesen, K. (2018): Dragonfly nymphs of North America . An identification guide. Springer: 816 pp. (in English) ["This monograph is the first of its kind devoted entirely to the dragonfly nymphs of North America north of Mexico, the focus being accurate identification of the 330 species of Anisoptera that occur in the region. Nymphal external morphology is described and illustrated in detail, and all terms needed to navigate the dichotomous keys are defined. Species are tabulated with references that provide the most detailed, accurate descriptions for each; species that are inadequately described are so indicated. The key separating the seven families in the region contains several new characters. The families are then covered separately: Aeshnidae (13 genera), Gomphidae (17 genera), Petaluridae (2 genera), Cordulegastridae (2 genera), Macromiidae (2 genera), Corduliidae (7 genera), and Libellulidae (29 genera). Each family is further characterized, followed by a generic key. A drawing of the habitus and diagnostic details for each genus are provided, along with additional diagnostic remarks and notes on habitat and life cycle; for each genus, a map shows its geographic distribution in North America. Full-grown nymphs of all known species of each genus are keyed and diagnosed; characters that apply to earlier instars are noted. Morphological variation in character states was analyzed in order to assess the reliability of previously utilized characters and to discover new characters. Most of the characters used to distinguish all levels of taxa are illustrated; a total of 702 figures, comprising 1,800 original drawings, along with selected photographs where necessary for clarity, accompany the keys. Measurements of total length, head width, and other variables for each species are provided in tables. Difficulties with past keys and descriptions, including errors, omissions and other shortcomings, are addressed. The importance of nymph characters in helping solve generic and specific distinctions and their role in phylogenetic studies is emphasized. Methods for collecting, rearing, and preserving dragonfly nymphs and exuviae are presented. The final chapter discusses research opportunities on North American Anisoptera nymphs, including taxonomic needs, studies on structure and function, life history and microhabitat, water quality indices and conservation efforts. The habitus

drawings of all genera are arranged according to family in five plates (Appendix I); although the book is intended as a lab manual, these plates conveniently allow for comparison based on nymph shape making field identification to genus possible in many cases. Appendix II contains a brief history of dragonfly nymph studies in North America. A glossary and an index to scientific names are included." **18602.** Tippler, C.; Wright, I.A.; Davies, P.J.; Evans, C.R. (2018): Are Odonata nymph adversely affected by impaired water quality in urban streams. *Austral Ecology* 43(8): 890-902. (in English) ["Globally 10% of all dragonfly species are threatened by extinction that can be primarily attributed to a loss of natural habitat. Urban expansion and the associated urban stream syndrome has established that the extent and intensity of urban development is directly linked to a range of adverse physical, chemical and ecological changes. Urban waterways typically experience degraded water quality and are occupied by impaired communities of aquatic invertebrates which are mostly dominated by rapid colonizing insects. Odonata are a diverse insect group and their tolerance or sensitivity to urban waterway degradation is unclear. This research examined the response of aquatic macroinvertebrate communities and specifically the Odonata nymph community to impaired water quality and degraded riparian vegetation condition in streams of the Georges River catchment, Sydney, across an urban development gradient. Unlike the overall macroinvertebrate community, Odonata nymph species assemblages were not strongly linked to the urban development gradient nor the degree of degradation in water quality. This result diverges from many aquatic macroinvertebrate studies that have reported a correlation between the response of Odonata taxa to degraded water quality. Our findings conclude that Odonata nymph community alone are not a suitable indicator of urban stream degradation as measured by water quality or catchment imperviousness and that the conservation of urban dragonflies should place a greater focus on the conservation and creation of suitable habitats." **18603.** Tumilovich, O.A. (2018): Formation of odonata-fauna in a pond of the Kaliningrad region. *Scientific journal "News of KSTU"* 51: 35-42. (in Russian, with English summary) ["Dragonflies are amphibiotic insects. Their existence is closely connected with waterbodies suitable for their

reproduction. Newly created artificial ponds serve as new habitats for hydrobiontic and amphibiotic organisms that allow exploring their development dynamics. Dragonflies belong to those insects, which species diversity and abundance strongly depend on the appearance of new waterbodies. Dynamics of dragonflies' colonization in ponds can be considered in both faunistic and ecological aspects. In this way it becomes apparent that formation of the dragonfly fauna of this pond goes through three stages. The first stage is a pioneer. The second stage is stabilization. The third stage is the reduction of the fauna. By the frequency of occurrence within first two years the following three species dominate: *Enallagma cyathigerum*, *Erythromma najas* and *Lestes virens*. Within the third year, the occurrence of *E. cyathigerum* and *L. virens* declines with simultaneous appearance in waterbodies of *Libellula* dragonfly larvae. In addition, the frequency of occurrence of *Aeshna* dragonflies was increasing. Eight years later, we again found a sharp increase in the occurrence of dragonfly larvae *E. cyathigerum*, *L. quadrimaculata*, *Ae. cyanea* and *Ae. grandis* against the background of the phytocenosis that was greatly changed in the direction of simplifying the composition and an increase in aquatic vegetation coverage." **18604.** Ubhi, R.; Matthews, P.G.D. (2018): The transition from water to air in aeshnid dragonflies is associated with a change in ventilatory responses to hypoxia and hypercapnia. *Journal of Insect Physiology* 106(3): 172-178. (in English) ["Highlights: •Dragonflies transition from breathing water as nymphs to breathing air as imagoes. •Nymph ventilation is insensitive to aquatic hypercapnia up to 10% CO<sub>2</sub>. •Aquatic hypoxia elicits hyperventilation. •Air-breathing adults show ventilatory responses to both hypoxia and hypercapnia. Abstract: Dragonflies are amphibiotic, spending most of their lives as aquatic nymphs before metamorphosing into terrestrial, winged imagoes. Both the nymph and the adult use rhythmic abdominal pumping movements to ventilate their gas exchange systems: the nymph tidally ventilates its rectal gill with water, while the imago pumps air into its tracheal system through its abdominal spiracles. The transition from water to air is known to be associated with changes in both respiratory chemosensitivity and ventilatory control in vertebrates and crustaceans, but the changes experienced by amphibiotic insects have been poorly explored. In this study, dragonfly nymphs (*Anax junius*) and imagoes (*Anax junius* and *Aeshna multicolor*) were exposed to hypoxia and hypercapnia while their abdominal ventilation frequency and amplitude was recorded. Water-breathing nymphs showed a significant increase in abdominal pumping frequency when breathing hypoxic water (< 10 kPa O<sub>2</sub>), but no strong response to CO<sub>2</sub>, even in severe hypercapnia (up to 10 kPa CO<sub>2</sub>). In contrast, both species of air-breathing imago increased their abdominal pumping amplitude when exposed to either hypoxia or hypercapnia,

but did not show any significant increase in frequency. These results demonstrate that aquatic dragonfly nymphs possess a respiratory sensitivity that is more like other water breathing animals, being sensitive to hypoxia but not hypercapnia, while their air-breathing adult form responds to both respiratory challenges, like other terrestrial insects. Shifting from ventilating a rectal gill with water to ventilating a tracheal system with air is also associated with a change in how abdominal ventilation is controlled; nymphs regulate gas exchange by varying frequency while imagoes respond by varying amplitude." **18605.** Underhill, L.; Lofie-Eaton, M.; Navarro, R. (2018): Odonata of the Kruger National Park. *Biodiversity Observations* 9.11: 1-16. (in English) ["The number of species of Odonata recorded in the Kruger National, South Africa, was 103 in April 2018. This figure was based on a database containing 2,817 records of Odonata, made since 1980, from the 52 quarter degree grid cells which intersect with the Kruger National Park. Records were available for 41 of the 52 grid cells. The most frequently recorded species were *Trithemis arteriosa* (167 records) and *T. kirbyi* (144 records), both recorded in 33 grid cells, and *Brachythemis leucosticta* (175 records) and *Broad Scarlet* (141 records) both in 29 grid cells. Based on records up to April 2018, the median date of the most recent record for species was September 2017, so that half of the 103 species had been recorded during summer 2017/18. This report could be used to motivate the proclamation of the river and wetland systems of the Kruger National Park as a "Wetland of International Importance" in terms of the Ramsar Convention. Two-thirds of the Odonata of South Africa, and one-eighth of the Odonata of Africa, have been recorded in the Kruger National Park." (Authors)] Address: Les G. **18606.** Vajda, C.; Szabó, L.J.; Cserhádi, C.; Dévai, G. (2018): Analysing the European genera of family Lestidae (Odonata: Zygoptera) with special emphasis on the status of *Chalcolestes* based on the morphological characteristics of male adults. *International Journal of Odonatology* 21(3/4): 241-259. (in English) ["Lestidae is a heterogeneous family with more than 150 species worldwide. There are many debates concerning its resolution. One of them is whether the genus *Chalcolestes* should be recognized as a genus or considered as a synonym of *Lestes*. We compared male characteristics of eight Hungarian species of three genera (*Lestes*, *Chalcolestes* and *Sympecma*) of the family Lestidae to get closer to the answer. We analysed the morphometry of genital and non-genital characteristics and the morphology of the secondary genitalia, especially the ligula. The morphometric analyses showed that two *Chalcolestes* species were the biggest in the most of the cases while *Sympecma fusca* (Vander Linden, 1820) and *Lestes virens* (Charpentier, 1825) were the smallest. The genera were separated mainly by the genitalic traits in the morphometric analyses.

The differences in the secondary genitalia strengthen the generic status of *Chalcolestes*." **18607.** Valente-Neto, F.; Rodrigues, M.E.; Roque, F. (2018): Selecting indicators based on biodiversity surrogacy and environmental response in a riverine network: Bringing operationality to biomonitoring. *Ecological Indicators* 94(1): 198-206. (in English) ["Highlights: •We assessed cross-taxon congruence between adult dragonflies and groups of aquatic insects. •We evaluated groups responses to environmental and spatial predictors. •We developed a set of criteria that avoid arbitrariness in the selection of the best indicator group. •EPT was selected as the best indicator group for monitoring the effects of riparian vegetation loss. Abstract: An efficient indicator group should fulfill operational and performance-related criteria, including reasonable taxonomic knowledge, costs, response to environmental changes and strong proxy-capacity for biodiversity groups. However, in the real world many trade-offs are involved in the selection of an indicator group, and a single group rarely satisfies all criteria. We investigated cross-taxon congruence of assemblage composition patterns using both quantitative and qualitative data between adult dragonflies and aquatic insects (midges, Ephemeroptera-Plecoptera-Trichoptera (EPT), beetles and entire aquatic insects assemblage). Also, we tested whether environmental and spatial variables were important drivers for cross-taxon congruence. Finally, we developed a set of guiding criteria that avoid arbitrariness in the selection of the best indicator group. We sampled adult dragonflies and aquatic insects in 41 streams and rivers along a riparian vegetation loss gradient in a Neotropical riverine network. We used Procrustes analyses to verify surrogacy between groups and the association of each group with environmental and spatial predictors. The criteria used involves both operational and performance aspects to select an indicator group. Our results showed that adult dragonflies were weakly congruent with the entire aquatic insects assemblage and aquatic insect subgroups were moderate (beetles) to strongly (EPT and midges) congruent with the entire assemblage. Comparisons between EPT, midges and beetles were also weakly congruent, with the exception of midges-EPT. The association between assemblage patterns and overall environmental predictors was significant for all groups, while with spatial patterns, only midges and entire assemblage showed significant results. Numerical resolution slightly improved the congruence results. Incidence data could be used instead of abundance, due to higher congruence values compared to abundance data. Based on cost-benefit, EPT was selected as the best indicator group for monitoring the effects of riparian vegetation loss on aquatic biodiversity, and its use could be viable in biomonitoring programs." **18609.** Vanacker, M.; Wezel, A.; Oertli, B.; Robin, J. (2018): Water quality parameters and tipping points of dragonfly diversity and abundance in fishponds. *Limnology* 19(3): 321-333. (in English) ["Fishponds are often enriched with nutrients in order to increase phytoplankton and zooplankton populations to support fish production. This eutrophication often leads to a global decrease of biodiversity. This biodiversity shift may be identified by a tipping point, the value of an environmental parameter above which a significant change of species richness and abundance occurs. A total of 110 eutrophic to highly eutrophic fishponds were studied in two areas in France to investigate parameters governing dragonfly species richness and species abundance by determining tipping points. Parameters investigated were chlorophyll a (CHL), water transparency, total N (TN), total P (TP), aquatic plant richness and coverage, adult dragonfly richness and abundance, and fish harvest. A high species richness of dragonflies was found in fishponds, with a total of 34 species, including six species of conservation concern. Dragonfly richness and abundance was shown to be negatively influenced by higher degrees of eutrophication. A high diversity of dragonflies occurred in the fishponds with CHL concentrations below 127 µg/l, water transparency above 67 cm, TN concentrations below 2.30 mg/l, and a fish harvest smaller than 253 kg/ha. A minimum of 5% of aquatic plant cover and the presence of a minimum 9 aquatic plant species seem to promote the richness and abundance of dragonflies. According to tipping points, 19 dragonfly species could be determined as indicator species for water quality in fishponds." (2018): The life cycles of *Boyeria irene* and *Onychogomphus uncatus* (Odonata: Aeshnidae, Gomphidae) in western Spain: A biometric study. *Eur. J. Entomol.* 115: 684-696. (in English) ["Co-occurrence of species with similar trophic requirements, such as odonates, seems to depend both on them occupying different microhabitats and differing in their life-cycles. The life cycles of the dragonflies *Boyeria irene* and *Onychogomphus uncatus* were studied in two consecutive years, mainly by systematic sampling of larvae in seven permanent head courses that constitute the upper basin of the River Águeda, western Spain, in the central part of the ranges of these two species. The size ranges of the last five larval stadia of both species were established based on biometric data. The eggs of the egg-overwintering aeshnid hatched in late spring and early

summer and for the gomphid hatching peaked in middle-late summer. Both species showed mixed voltinism with "cohort splitting". *B. irene* had a dominant three-year development (partivoltinism), with some developing in two years (semivoltinism). *O. uncatus* requires four, sometimes three years to complete development (all partivoltine). *B. irene* larvae spent the winter before emergence in the last three, maybe four stadia, as a "summer species". *O. uncatus* mainly behaved as a "spring species", most larvae spending the last winter in the final larval stadium." **18611.** Villalobos-Jiménez, G.; Dunn, A.M.; Hassall, C. (2018): Environmental noise reduces predation rate in an aquatic invertebrate. *Journal of Insect Conservation* 21: 839–847. (in English) ["Noise is one of a wide range of disturbances associated with human activities that have been shown to have detrimental impacts on a wide range of species, from montane regions to the deep marine environment. Noise may also have community-level impacts via predator–prey interactions, thus jeopardising the stability of trophic networks. However, the impact of noise on freshwater ecosystems is largely unknown. Even more so is the case of insects, despite their crucial role in trophic networks. Here, we study the impact of underwater noise on the predatory functional response of damselfly larvae. We compared the feeding rates of larvae under anthropogenic noise, natural noise, and silent conditions. Our results suggest that underwater noise (pooling the effects of anthropogenic noise and natural noise) decreases the feeding rate of damselflies significantly compared to relatively silent conditions. In particular, natural noise increased the handling time significantly compared to the silent treatment, thus reducing the feeding rate. Unexpectedly, feeding rates under anthropogenic noise were not reduced significantly compared to silent conditions. This study suggests that noise per se may not necessarily have negative impacts on trophic interactions. Instead, the impact of noise on feeding rates may be explained by the presence of nonlinearities in acoustic signals, which may be more abundant in natural compared to anthropogenic noise. We conclude by highlighting the importance of studying a diversity of types of acoustic pollution, and encourage further work regarding trophic interactions with insects using a functional response approach." **18614.** Wildermuth, H.; Borkenstein, A.; Jödicke, R. (2018): Verhaltensgesteuerte Thermoregulation bei *Leucorrhinia pectoralis* und *L. rubicunda* (Odonata: Libellulidae). *Libellula* 37(3/4): 97-134. (in German, with English summary) ["Behavioural thermoregulation in *Leucorrhinia pectoralis* and *L. rubicunda* (Odonata: Libellulidae). Libellulids are perchers that control their body temperature. in contrast to the endothermic fliers. during their activity periods at sunny sites mainly by perch selection and body posture. Hitherto, thermoregulation in Libellulidae was studied only in a few species applying an experimental-invasive method to measure the thoracic temperature. As to *Leucorrhinia* spp. nothing has been published in this respect. Aiming to learn more about the behavioural thermoadaptation of this cool and cold temperate Holarctic genus, we studied *Leucorrhinia pectoralis* and *L. rubicunda* in peat bogs of the Swiss Plateau and Lower Saxony in northwestern Germany. All data were collected by Observation, photo documentation and measures of

temperature without capture and Intervention. The breeding water and its terrestrial environment turned out to be a richly structured thermal landscape with vast differences varying up to 25°C between diverse sites, which were preferred or avoided by the dragonflies depending on the given Situation. For a spontaneous takeoff from a shaded roost, *L. rubicunda* needed a minimum temperature of ca 17°C. In the morning and after cloudy periods both species first flew to a sunlit site where they pressed their body with spread legs and wings against the Substrate ('dorsally exposed warm-up posture') and thus assimilated the direct and indirect radial heat as well as most probably also heat conduction from the Substrate. A 'warm-up obelisk posture' was seen rarely and only in *L. rubicunda*. The insects preferred light bark and deadwood but also flat parts from green herbs and bushes for basking. *L. rubicunda* preferentially basked directly on the ground in wind-sheltered grooves. With rising temperatures they gave up their close link to the ground but remained within the ground Vegetation. On sunny days mature males of *L. pectoralis* arrived at ca 17°C at the water, those of *L. rubicunda* at ca 14°C. Both species sat there at ambient temperatures between 20 and 30°C in a horizontal or oblique body posture on an elevated, sunlit perch above the water or on the water's edge, always with free view of the open water. From time to time they took off for a patrol flight and occasionally they flew ashore for basking. On hot days with an ambient temperature above 30°C most individuals left their sunlit sites to seek out shade, which was especially obvious in *L. rubicunda*. All males remaining at the water changed their posture and sun exposure for heat avoidance: They either directly faced the sun ('sun-facing heat posture') or they adopted the 'heat Obelisk posture', the abdominal tip pointing to the sun, the wings holded V-shaped and the legs stretched. In both postures the sunlit body surface was reduced to a minimum. For fine adjustment of the body temperature they controlled the heat input by turning the abdomen or the whole body in all three spatial axes. Heat release by convection resulted from wind effects on elevated, wind-exposed perches. In hot conditions *L. rubicunda* preferred frontal exposure to the sun and adopted the obelisk posture only in extremely hot periods when there was no compensating cooling by wind. All forms of behavioural thermoregulation are of great adaptive importance. The effective warm-up enables young *L. rubicunda* individuals optimal use of the hours of sunshine that may be scarce during cold April days. Thus, the species is able to feed, escape and disperse at low air temperatures. During hot conditions mature males of both species use behavioural heat avoidance to remain at water for reproductive activities instead of withdrawal into the shade of the terrestrial habitat. It remained unclear to what extent wing whirring and flapping played a role in warming up. Both *Leucorrhinia* species have demonstrated that they are able to apply it in extreme situations but we have never observed this to be performed systematically during diurnal hours." **18615.** Willink Castro, B. (2018): The descent of damselflies and variation in relation to sex. PhD. Thesis, Evolutionary Biology, Lund University, Faculty of Science, Department of Biology: 84 pp. (in English) ["Sexual conflict over mating shapes the interactions between males and females in many animals and is also responsible for dramatic adaptations in both sexes. In some species of pond damselflies (Odonata: Coeangrionidae), sexual conflict maintains discrete female-limited colour morphs over multiple generations and within populations. One of the female morphs is typically male-coloured and considered a male mimic. This is because their male-like appearance provides a frequency-dependent advantage against excessive male mating attempts. In this thesis, I investigate three major questions regarding the evolutionary consequences of this pervasive sexual conflict. First, how is phenotypic variation in ecological traits distributed among heritable female colour morphs? Second, how does sexual conflict shape phenotypic variation within the lifespan of females? Finally, how, where and why do female-limited morphs arise in the first place? In *Ischnura elegans*, female morphs differ in multiple phenotypic traits. My results uncover further phenotypic associations between the two most common morphs of the Common Bluetail in Sweden. One morph is more resistant to infections by parasitic mites, whereas the other is instead more tolerant. These morphs also differ in their developmental sensitivity to temperature, which in turn influences how morph frequencies are distributed across European populations. Moreover, my findings provide some insights as to how these profound phenotypic differences are produced over the course of adult development, and suggest that male mimics and non-mimics differ in the regulation of important developmental processes. Females of the Common Bluetail undergo dramatic colour changes as they become sexually mature. My thesis shows that immature colour patterns in non-mimic female morphs reduce male pre-mating harassment, and may have evolved by co-opting male colour signals to be expressed as immature signals of reproductive unsuitability. These results suggest that female colour patterns might be highly evolutionarily labile. Yet, a large-scale phylogenetic framework is required to gain a full understanding of the macroevolutionary consequences of sexual conflict on the evolution of female-limited colour variation. I inferred a multi-locus phylogeny for the damselfly superfamily Coeangrionoidea. I then used this phylogeny to show that female-limited colour polymorphisms have arisen repeatedly in this clade, and in association with ecological conditions that foster sexual conflict over mating. Finally, my results uncover a stark contrast between the consequences of sexual conflict at micro and macroevolutionary scales. While sexual conflict promotes diversity within populations by maintaining alternative female morphs, the presence of these morphs is also associated with increased extinction risk and a fast lineage turnover. Together, my results reveal how sexual conflict can influence the origin, distribution and loss of diversity." **18617.** Worthen, W.B. (2018): Confirming the relationship between body size and perch height in tropical odonates (Odonata: Libellulidae): wet-season contrasts and experimental tests. *International Journal of Odonatology* 21(3/4): 229-239. (in English) ["In a previous study conducted during the dry season at La Selva Biological Station, Costa Rica, mean perch height of libellulid dragonfly species (Odonata: Libellulidae) correlated with male body size, and interactions between species suggested a size-dependent competitive hierarchy. Here, I report on a wet-season study that examined whether seasonal changes in community composition affect these patterns. Males were captured, photographed, and marked, perch heights among individuals and species on natural and artificial perches (25, 50, and 100 cm) were compared, and the frequencies of aggressive interactions between species were analyzed. I also examined the responses of *Micrathyria atra* and *Micrathyria mengeri* males to decoys of these species placed in their territory at different heights (50 or 100 cm). Although the wet season community differed from the dry season community (Jaccard dissimilarity = 0.778), there was still a significant correlation between species perch height and body size, on both natural and artificial perches. Interspecific interactions supported the size-dependent competitive hierarchy hypothesis: smaller species that perched low avoided attacks by larger species. These patterns were confirmed in the decoy experiment. The larger *M. atra*, which perches at ~100 cm, attacked decoys at 100 cm almost exclusively, and attacked decoys of the smaller *M. mengeri* more than conspecifics. In contrast, *M. mengeri* (which perches at 50 cm) only attacked decoys placed at 50 cm. Although community membership changed, the correlation between body size and perch height was maintained by a size-dependent competitive hierarchy in both dry and rainy seasons." **18618.** Worthen, W.B.; Hoke, L. (2018): Pseudoreplication in species comparisons: do individual differences matter?

*Notulae odonatologicae* 9(1): 18-25. (in English) ["Pseudoreplication occurs in many behavioral studies of odonates, because a few unmarked individuals are sampled repeatedly and are used as estimators of the species' behavior. This can confound individual differences with species differences. Here, we tallied perches of marked and unmarked male libellulids on artificial perches of seven heights (10–120 cm). We estimated the effect of pseudoreplication on species-level contrasts of mean male perch height by comparing the results of four different analyses: 1) a nested ANOVA (analysis of variance) evaluating individual and species effects on perches by marked individuals; 2) a one-way ANOVA comparing species using mean perch heights of the same marked individuals; 3) a one-way ANOVA comparing species without regard to individuals (pseudoreplication of these marked individuals); and 4) a one-way ANOVA using perches by unmarked individuals observed at the same time (pooling across pseudoreplicated individuals in a larger independent data set). Species differences were qualitatively similar across all analyses, and mean perch heights computed on individual means, pooled (pseudoreplicated) data on marked individuals, and data on unmarked individuals were highly correlated. Pseudoreplication altered patterns slightly, but these effects were overcome in the larger data set on unmarked individuals." (Authors)] Address: Worthen, W.B., Biology Department, Furman University, Greenville, SC 29613, USA. E-mail: wade.worthen@furman.edu

## 2019

**18619.** Alves-Martins, F.; Brasil, L.S.; Juen, L.; De Marco Jr, P.; Stropp, J.; Hortal, J. (2019): Metacommunity patterns of Amazonian Odonata: the role of environmental gradients and major rivers. *PeerJ* 7:e6472. 26 pp. (in English) ["Background. We identified and classified Zygoptera and Anisoptera metacommunities in Brazilian Amazonia, relating species distribution patterns to known biological gradients and biogeographical history. We expected a random distribution of both Zygoptera and Anisoptera within interfluves. At the Amazonian scale, we expected Anisoptera metacommunities to be randomly distributed due to their higher dispersal ability and large environmental tolerance. In contrast, we expected Zygoptera communities to exhibit a Clementsian pattern, limited by the large Amazonia rivers due to their low dispersal ability. Methods. We used a dataset of 58 first-to-third order well-sampled streamlets in four Amazonian interfluves and applied an extension of the Elements of Metacommunity Structure (EMS) framework, in which we order Zygoptera and Anisoptera metacommunities by known spatial and biogeographic predictors. Results. At the Amazonian scale, both Zygoptera and Anisoptera presented a Clementsian pattern, driven by the same environmental and biogeographical predictors, namely biogeographic region (interfluve), annual mean temperature, habitat integrity and annual precipitation. At the interfluve scale, results were less consistent and only partially support our hypothesis. Zygoptera metacommunities at Guiana and Anisoptera metacommunities at Tapajós were classified as random, sugges-

ting that neutral processes gain importance at smaller spatial scales. Discussion. Our findings were consistent with previous studies showing that environmental gradients and major rivers limit the distribution of Odonata communities, supporting that larger Amazonian rivers act as barriers for the dispersal of this group. In addition, the importance of habitat integrity indicates that intactness of riparian vegetation is an important filter shaping metacommunity structure of Amazonian stream Odonata." **18620.** Cherpitel, T.; Filipe, M. (2019): Observations de pontes de *Sympetrum striolatum* sur un estran rocheux atlantique (Odonata: Libellulidae). *Martinia* 34(1/2): 57-58. (in French) [Verbatim: *S. striolatum* is a eurytopian species whose larvae live in fresh, permanent, stagnant to slightly flowing water but can also live in temporary or brackish water (e.g. HEIDEMANN H. & SEIDENBUSCH R., 2002: Larvae and exuviae of dragonflies from France and Germany (except Corsica). *Société française d'odonatologie*, Bois-d'Arcy, 416 pp.) When laying eggs, the eggs of this species are deposited freely in the water or sometimes on the exposed banks (GRAND D. & BOUDOT J.-P., 2006: *Les Libellules de France, Belgique et Luxembourg*. Biotope [Coll. Parthénope], Mèze, 480 pp). During a low-water tide on 28-IX-2018, during a survey in search of continental invertebrates taking refuge in the diachases of the rocky foreshore of the Pointe de Penchâteau (Le Pouliguen [44]), our attention was drawn to the presence of numerous tandems of *S. striolatum*. We then observed, on about 15 occasions, spawning in the numerous tidal pools of the mediolittoral. Up to three tandems were noted laying eggs in one of them (Fig. 1). Spawning took place in open water, sometimes in the algal clusters that were outcropping on the surface (*Fucus* sp., *Ulva* sp., etc.). No copulatory hearts were observed that day. As this was seawater, these observations seem atypical. Most Odonata live in fresh to brackish water and their larvae are unable to perform hypo-osmotic regulation and thus to survive in water with too much salt. The only counter-example is the American Libellulidae *Erythrodiplax berenice* (Drury, 1773) whose larvae are able to live in water saltier than sea water, i.e. over 35 g/L (CORBET P.S., 2004: *Dragonflies: behaviour and ecology of Odonata* (Revised Edition). Harley books, Colchester, 829 pp.). The larvae of *S. striolatum* tolerate a salinity of 2 to 3 g/L (AGUESSE P., 1968: *Les Odonates de l'Europe Occidentale, du Nord de l'Afrique et des Îles Atlantiques*. Faune de l'Europe et du Bassin méditerranéen, 4. Masson, Paris, 258 pp.). These spawning sites observed in sea water therefore have no chance of allowing the larvae that might hatch to develop properly. However, this type of egg-laying behaviour, and others whose reproductive success is just as predictable, have already been cited for this species, notably at the level of "puddles of sea water at low tide, car windscreens or bonnets, paths, roads or tarmac car parks, puddles of diesel fuel in a petrol station, dog bowls or metal sheets" (JOURDE P. & MONTENOT J.-P., 2009.

*Sympetrum striolatum* (Charpentier, 1840). In: Poitou-Charentes Nature (ed.). *Libellules du Poitou-Charentes*. Poitou-Charentes Nature, Fontaine-le-Comte: 198-199). Many other examples are known, involving various species in egg-laying behaviour in a woollen jumper, a rubber boot, a carpet in a house, etc. (CORBET, 2004: op. cit.). The choice of an oviposition site in a tidal pool, like several other cases cited above, is probably due to the species' polarotaxis. Indeed, to find their oviposition sites, many Odonata are guided by horizontally polarised light (e.g. WILDERMUTH H., 1998: Dragonflies recognize the water of rendezvous and oviposition sites by horizontally polarized light: a behavioural field test. *Naturwissenschaften*, 85: 297-302). This visual response of species with exophytic oviposition is also assumed to be universal by CORBET (2004: op. cit.). Here, the ecological trap represented by oviposition in sea water is linked to the chemical properties of the water, which the females of *S. striolatum* do not seem to have detected. Odonates with endophytic oviposition have taste sensilla on the ovipositor (e.g. REBORA M. et al., 2013: The gustatory sensilla on the endophytic ovipositor of Odonata. *Arthropod Structure & Development*, 42: 127-134). If *S. striolatum* also possesses them, this would tend to show that these sensilla are totally inoperative in assessing the salinity of the water when the apex of the abdomen is in contact with it. However, it should be remembered that Libellulidae laying eggs at random in all potentially favourable areas are the Odonata with the widest distribution on the planet, while presenting important numbers (AGUESSE, 1968: op. cit.); an efficient strategy that accommodates some ecological traps. **18624.** Gorb, S.N. (2019): Body temperatures in *Sympetma paedisca* (Zygoptera, Lestidae) in the autumn in the Central Ukraine. *International Journal of Odonatology* 22(2): 95-100. (in English) ["This short communication reports on the warming ability of the damselfly *S. paedisca*, which is known for its winter hibernation and tolerance to low temperatures. The data were collected using an infrared camera in late September on two sunny days (air temperature 15–17°C) in the vicinity of Kyiv, Central Ukraine. The obtained data show that the thorax was almost always the warmest part of the body (up to 21°C in comparison to 17–18°C of the substrates damselflies were resting on and surrounding living plants). This indicates that the animals, in addition to sun, use their thoracic musculature to warm their bodies up. There was a clear correlation between thorax temperature

and the temperature of both the head and abdomen, which means the warmed up thorax can transport part of its heat to other parts of the body by using their circulatory system." **18625.** Krieg-Jacquier, R.; Baux, V.; Cornuel-Willermoz, A. (2019): Mortalité importante à l'émergence chez *Libellula depressa*: impact du pâturage sur une pozzine de Corse (Odonata: Libellulidae). *Martinia* 34(1-2)(2020): 26-28. (in French) [Verbatim: The pozzine is a flat acidic peat bog dotted with water holes connected by channels and owes its name to the term pozzini (plural of pozzo) which means "well" in Corsica (BRIQUET J., 1910: *Prodrome de la flore corse: comprenant les résultats botaniques de six voyages exécutés en Corse sous les auspices de M. Emile Burnat*, tome I. Georg, Geneva, 656 + LVI pp). More precisely, it is a "set of hygrophilous or mesohygrophilous grasslands developed around glacial lakes or water holes which result from their fragmentation" (GAMISANS J., 2010. *Le paysage végétal de la Corse*. Albiana, 348 pp). The observation was made on 27 May 2017 at about 3 pm on a pozzo in the commune of Casamaccioli (42.25806°N | 8.93667°E [WGS84]) at an altitude of 1,745 m, on the Ninu pozzine in the immediate vicinity of the eponymous lake. This water body is vaguely kidney-shaped and its surface area is about 135 m<sup>2</sup> (20 × 10 m in its maximum dimensions). Like various pozzies on the site, it is not directly connected to the main stream, which flows 6 m from the nearest bank, but gives rise to a small tributary circulation that feeds 6-7 smaller pozzies. The depth was not probed, but the visible bottom areas did not appear to support macrophytes. Unlike other pozzos at the site, this pozzo did not have a steep bank and the water came into direct contact with the bank vegetation which is mainly Poaceae like the surrounding grassland. As the water levels and the connection between the different pozzini can fluctuate rapidly (Cyril Berquier, pers. com.), the configuration we describe here is variable over time, particularly according to the seasons. When we arrived at the edge of the pond, we spotted numerous *Libellula depressa* Linnaeus, 1758 teneral floating on the surface; they were in various stages of decomposition, indicating that some individuals had been dying for several days. Other specimens were observed completing their emergence, wings and abdomen in the water. About ten individuals managed to complete their emergence during our observation but sometimes had poorly developed wings. We estimate that we saw about 100 individuals (emergent, dead, exuviae) and it is likely that less than 5% of the emergences allowed an imago to fly. The only other odonate species we observed on the site today was an agonising female of *Sympetrum fonscolombii* (Selys, 1840). Three types of impact of grazing on emergence can be identified (THOMPSON D.J. et al. 1985. Horses as a major cause of mortality in *Coenagrion puella* (L.) (Zygoptera: Coenagrionidae). *Notul. Odonatol.* 2(6), pp. 104–105): (i) accidental consumption of emerging larvae and

adults during grazing or their eventual fall; excessive mowing of vegetation which (ii) reduces the number of supports on which larvae can climb to emerge (larvae then attempt to emerge on insufficiently high plant supports and fail to complete emergence) and (iii) allows greater accessibility of the emergence site to birds, predators of emerging larvae and individuals. In the case of the observation area under consideration, cattle and horses share the meadow and after prolonged grazing of the bank, there is no longer enough support on which the larvae can climb to emerge. As a result, emergence takes place on insufficiently high vegetation (about 10 cm). A significant number of individuals fail to complete emergence, either because they are exposed to wind-generated ripples, or because they remain partly in the water, or because they fall. It is possible that avian predation is also facilitated here, but we have not observed it. It seems to be negligible on the site, frequented only by a few *Spioncelle* Pipits *Anthus spinoletta*, Clumped Wheatears *Oenanthe oenanthe* and various passerines, mainly granivorous, such as the Corsican Venturon *Carduelis corsicana* or the Tree Finch *Fringilla coelebs* (Cyril Berquier, in litt. 29 November 2018). The presence of vegetation that is not very appealing to livestock, which generally surrounds water bodies (rushes, sedges, reeds), often preserves a ring of riparian vegetation that allows for emergence with less risk. Here, the absence of this ring encourages grazing right up to the water's edge. At some distance from the pozzo studied, Lake Ninu offers a more varied vegetation on its banks (helophytes and hydrophytes) which preserves more areas suitable for the emergence of Odonata. The consequences of pastoral practices on the pozzines of Corsica should be studied in greater depth and the mortality of other Odonata species should be assessed (the observation reported here being fairly early). These studies would make it possible to envisage measures for the conservation of Odonata that are consistent with traditional activities and respect for the landscape characteristics of pozzines. One of these measures could be the enclosure of part of their banks, which would maintain a riverine vegetation of sufficient height and structure that the larvae could select during emergence (e.g. WORTHEN W. B., 2010: Emergence-site selection by the dragonfly *Epitheca spinosa* (Hagen). *Southeastern Naturalist*, 9 (2): 251-258; GROF-TISZA P. et al., 2017: Plant structural complexity and mechanical defences mediate predator-prey interactions in an odonate-bird system. *Ecology and Evolution*, 7(5): 1650-1659) without prohibiting livestock access to drinking water. **18626.** Patten, M.A.; Barnard, A.A.; Smith, B.D. (2019): Geographic variation in a restricted-range endemic dragonfly *Gomphurus ozarkensis* (Odonata: Gomphidae), with description of a new subspecies. *Journal of Insect Biodiversity* 13(2): 15-26. (in English) ["The geographic distribution of *G. ozarkensis*, a species described to science only four de-

caes ago, is confined to a four-state area in the central United States: southeastern Kansas, eastern Oklahoma, western and northern Arkansas, and southern Missouri. Its small range has led some to classify it a species of conservation concern. We examined geographic variation in the species, which despite its small range exists in three distinct subpopulations: one in the Ouachita Mountains of western Arkansas and southeastern Oklahoma; one on the Ozark Plateau of northeastern Oklahoma, southeastern-most Kansas, southern Missouri, and northern Arkansas; and one in the Osage/Flint hills of southeastern Kansas and northeastern Oklahoma. Clinal variation is evident in the extent of yellow on the terminal abdominal segments and the extent to which certain thoracic stripes are fused. A population in a separate watershed basin in the southern Osage Hills of Oklahoma is taxonomically distinct, with some phenotypic characters tending toward *G. externus* (Hagen, 1858). We describe this population as a new subspecies of *G. ozarkensis*." (Authors)] Address: Patten, M.A., Oklahoma Biological Survey, Univ. Oklahoma, Norman, Oklahoma 73019, USA

**18627.** Payette, W.I.; Sullivan, A.M. (2019): The effect of predator kairomones on caudal regeneration by Allegheny Mountain dusky salamanders (*Desmognathus ochrophaeus*). *Canadian Journal of Zoology* 97(6): 502-509. (in English) ["Many prey utilize autotomy as an antipredator mechanism. Rapid regeneration of autotomized appendages is beneficial because forfeited tissues may serve as organs for energy storage, accessories for locomotion, or indicators of social status. We monitored levels of caudal regeneration by Allegheny Mountain dusky salamanders, *D. ochrophaeus* (Cope, 1859) exposed to kairomones from predatory eastern garter snakes, *Thamnophis sirtalis* (L., 1758). After the induction of autotomy, salamanders were exposed to one of three treatment regimens: blank (water), or an acute (30 min per week) or chronic (constant) exposure to predator kairomones during a 12-week study period. Overall, the average volume of regenerated tissue, as a percentage of original tail volume, was highest for individuals exposed to the blank versus predator kairomones. When the combined effects of time elapsed since the induction of caudal autotomy and the different treatment regimens were considered, we found that the average volume of regenerated tissue was significantly greater for control salamanders beginning eight weeks after autotomy. The mechanism contributing to the differential rates of regeneration among individuals in our treatment groups is unknown, but previous work suggests that elevated stress related to predation threat can have detrimental effects on wound healing and growth in amphibians." (Authors) The paper includes references to Odonata.] Address: Sullivan, A.M., Dept Biol., Houghton Coll., Houghton, NY 14744, USA. E-mail: aaron.sullivan@houghton.edu

**18628.** Rahaman, M.M.; Stout, M.J. (2019): Comparative efficacies of next-generation insecticides against yellow stem borer and their effects on natural enemies in a rice ecosystem. *Rice Science* 26(3): 157-166. (in English) ["The efficacies of some next-generation insecticides against the rice yellow stem borer (YSB), *Scirpophaga incertulas*

(Walk.), and their compatibilities with natural enemies were investigated during 2014 and 2015. Three newer insecticides, chlorantraniliprole 0.4%G, dinotefuran 20% SG, and methoxyfenozide 24% SC, and two older, commonly used insecticides, carbufuran 5G and quinalphos 25 EC, were evaluated in the field for their efficacies against YSB and their non-target effects on natural enemies. Application of chlorantraniliprole 0.4%G at 10.96 kg/ha resulted in the greatest reduction in YSB infestation (deadhearts and whiteheads) and greatest increase of yield over control, followed by methoxyfenozide 24% SC at 0.41L/ha, dinotefuran 20% SG at 0.15 kg/ha, carbufuran 5G at 10.96 kg/ha, and quinalphos 25EC at 1.5 L/ha. All the insecticides reduced the numbers of predators' viz., lady bird beetles, wolf spiders, carabid beetles, earwigs, green mirid bugs, damselflies. Numbers of adults of the egg parasitoids *Trichogramma* sp., *Telenomus* sp., and *Tetrastichus* sp. were significantly reduced in insecticide-treated plots compared to untreated control plots. In all field trials, chlorantraniliprole 0.4%G was found to be least harmful and quinalphos 25EC was found most harmful to natural enemies, with their harmful effects in the following rank order (least harmful to most harmful): chlorantraniliprole 0.4% G <carbufuran5G <dinotefuran 20% SG <methoxyfenozide 24% SC <quinalphos 25EC. On the basis of reduction in YSB infestation, increase in grain yield, and compatibility with natural enemies, chlorantraniliprole 0.4% G proved the best of all the insecticides for the YSB management system, although the study suggested minimizing its retail price for enhancement of cost effectiveness in farmers' fields." **18629.** Ryazanova, G.I. (2019): Odonata and anthropogenic salinization of inland waters. *Moscow University Biological Sciences Bulletin* 74(1): 33-39. (in English) ["The anthropogenic salinization of inland waters and its effect on freshwater biota are current environmental problems. This salinization leads to changes in the natural environment that are ecologically undesirable and not indifferent to humans. The widespread use of agents for road deicing has become one of the three most important factors of anthropogenic salinization of fresh water (along with agricultural activities and mining) in countries with temperate and cold climate. Today, the main components of these agents are Na and Ca chlorides—cheap and easily available natural materials. Their mixture with sand, used in deicing practice, is usually stored in bulk in special open-air areas all year round. The impact of atmospheric precipitation makes this mixture a source of salinization of the surrounding soils and waters. In 2015, 2016, and 2018, the salinity of inland waters was recorded near the long-term open storage of antiicing agents in Kaluga oblast. The anthropogenic nature of salinization of the investigated water bodies is established. The main components of salinization of water bodies in the study area are Na and Ca chlorides. The maximum degree of salinization in the studied conditions is 4‰ (ppm); the degree of salinity depends on the distance of the water body from the road-salt storage. The influence of anthropogenic salinity on dragonflies, mainly of the species *Coenagrion puella* L., is studied. It is found

that the negative effect of high water salinity is expressed only in the slowdown of the development of individuals with a high level of fluctuating asymmetry, the number of which in the population is not determined by water salinity. High water salinity leads to changes only in the timing of emergence of imagoes with high FA. It is assumed that dragonflies as a mass object of freshwater biota are obviously not significantly exposed to anthropogenic salinization. Russian Text © The Author(s), 2019, published in *Vestnik Moskovskogo Universiteta, Seriya 16: Biologiya*, 2019, Vol. 74, No. 1, pp. 42–49.] Address: Ryazanova, G.I., Dept of Biology, Moscow State University, Moscow, Russia. **18630.** Serrano-Meneses, M.A.; López-García, K.; Carrillo-Muñoz, A.I. (2019): Assortative mating by size in the American Rubyspot Damselfly (*Hetaerina americana*). *Journal of Insect Behavior* 31(6): 585-598. (in English) ["Assortative mating refers to the non-random nature of mating patterns between certain males and females. Thus, males and females may associate negative. or positively, based on different traits. Amongst these associations, assortative mating by size is one of the most common patterns found in natural populations of animals. Two main hypotheses have been proposed to account for the occurrence of assortative mating by size. First, it may be the result of mechanical, temporal, or physiological constraints. Second, it may occur in response to direct or indirect selection on mating preferences. Here we investigate whether the American rubyspot damselfly exhibits true assortative mating by size. Males of this species exhibit high levels of male-male competition, as they compete over territories, to which females are attracted for copulation. There is a documented large male body size advantage: the largest males are better able to hold their territories and thus secure more copulations. Our major results show that i) mated males are more likely to be larger than unmated males, whereas mated and unmated females tend to have similar body sizes; ii) *H. americana* exhibits true assortative mating by size; as such, this pattern is not driven by seasonal changes in the body sizes of males and females. We suggest that this mating pattern occurs in this species given the advantages of large male size, and the advantages of large female body size (i.e. higher fecundity). We believe that males may be able to evaluate a female's reproductive value and exert mate choice." **18631.** Sniegula, S.; Golab, M.J.; Johansson, F. (2019): Size-mediated priority and temperature effects on intra-cohort competition and cannibalism in a damselfly. *Journal of animal ecology* 88(4): 637-648. (in English) ["1. A shift in the relative arrival of offspring, e.g., a shift in hatching time, can affect competition at the intraspecific level through size-mediated priority effects, where the larger individuals gain more resources. These priority effects are likely to be affected by climate warming and the rate of intraspecific predation, i.e., cannibalism. 2. In a laboratory experiment, we exa-

mined size-mediated priority effects in larvae of the univoltine damselfly, *Lestes sponsa*, at two different temperatures (21°C and 23°C). We created three size groups of larvae by manipulating hatching time: early hatched with a large size (extra-advanced), intermediate hatched with an intermediate size (advanced) and late hatched with a small size (non-advanced). Thereafter we reared the larvae from these groups in non-mixed and mixed groups of 12 larvae. 3. We found strong priority and temperature effects. First, extra-advanced larvae most often had higher survival, growth and development rates than non-advanced larvae in mixed groups, compared to groups that consisted of only extra-advanced larvae. Second, temperature increased growth and development rates and cannibalism. 4. However, the strength of priority effects did not differ between the two experimental temperatures, because there was no statistical interaction between temperature and treatments. That is, the mixed and non-mixed groups of non-advanced, advanced and extra-advanced larvae showed the same relative change in life history traits across the two temperatures. 5. Non-advanced and advanced larvae had similar or higher growth rate and mass in mixed groups compared to non-mixed groups, suggesting that predation from advanced larvae in the mixed group released resources for the non-advanced and advanced larvae that survived despite cannibalism risk. Thus, a thinning effect occurred due to cannibalism caused by priority effects. 6. The results suggest that a shift in the relative arrival of offspring can cause temperature-dependent priority effects, mediated through cannibalism, growth and development, which may change the size distribution and abundance of emerging aquatic insects." **18632.** Trueman, J.W.H.; Rowe, R.J. (2019): The wing venation of Odonata. *International Journal of Odonatology* 22(1): 1-16. (in English) ["Existing nomenclatures for the venation of the odonate wing are inconsistent and inaccurate. We offer a new scheme, based on the evolution and ontogeny of the insect wing and on the physical structure of wing veins, in which the veins of dragonflies and damselflies are fully reconciled with those of the other winged orders. Our starting point is the body of evidence that the insect pleuron and sternum are foreshortened leg segments and that wings evolved from leg appendages. We find that all expected longitudinal veins are present. The costa is a short vein, extending only to the nodus, and the entire costal field is sclerotised. The so-called double radial stem of Odonatoidea is a triple vein comprising the radial stem, the medial stem and the anterior cubitus, the radial and medial fields from the base of the wing to the arculus having closed when the basal sclerites fused to form a single axillary plate. In the distal part of the wing the medial and cubital fields are secondarily expanded. In Anisoptera the remnant anal field also is expanded. The dense crossvenation of Odonata, interpreted by some as an archdictyon, is secondary venation to support these expanded fields. The evolution of the odonate wing from the palaeopteran ancestor – first to the odonatoid condition, from

there to the zygopteran wing in which a paddle-shaped blade is worked by two strong levers, and from there through grade Anisozygoptera to the anisopteran condition – can be simply explained." (Authors) ] Address: Trueman, J., Res. School Biol., Australian National Univ., Canberra, Australia

**18633.** Veselý, L.; Boukal, D.S.; Buric, M.; Kuklina, I.; Fort, M.; Yazicioglu, B.; Prchal, M.; Kozák, P.; Kouba, A.; Sentis, A. (2019): Temperature and prey density jointly influence trophic and non-trophic interactions in multiple predator communities. *Freshwater Biology* 64(11): 1984-1993. (in English) ["Environmental changes such as global warming can affect ecological communities by altering individual life histories and species interactions. Recent studies focusing on the consequences of environmental change on species interactions highlighted the need for a wider, multi-species context including both trophic and non-trophic interactions (e.g. predator interference). However, the effects of biotic and abiotic factors on trophic and non-trophic interactions remain largely unexplored. To fill this gap, we combined laboratory experiments and functional response modelling to investigate how temperature and prey density influence trophic and non-trophic interactions in multiple predator communities. The system under study consisted of predatory dragonfly larvae (*Aeshna cyanea*) and omnivorous marbled crayfish (*Procambarus virginalis*) preying on common carp fry (*Cyprinus carpio*). We estimated the functional response of each predator in single-predator experiments and used this information to disentangle the trophic and non-trophic interactions and their dependence on environmental conditions in multiple predator trials. We found that consumer identity, prey density, and temperature all affect the magnitude of trophic and non-trophic interactions. Non-trophic interactions mostly decreased predator feeding rates, corroborating previous observations that interference prevails in aquatic communities. Moreover, trophic interactions depended primarily on the environmental variables whereas non-trophic interactions depended mainly on consumer identity. Our results indicate that non-trophic interactions among true predators and omnivores can be substantial and that biotic and abiotic conditions further modify the magnitude and direction of these interactions, which can affect food web dynamics and stability." **18635.** Mendes, T.P.; Amado, L.L.; Barbosa Ribeiro, R.A.; Juen, L. (2020): Morphological diversity of Odonata larvae (Insecta) and abiotic variables in oil palm plantation areas in the Eastern Amazon. *Hydrobiologia* 847: 161-175. (in English) ["Our aim was to investigate whether there is a relationship between abiotic factors and the morphological diversity (MD) of Odonata larvae by building an ecomorphological index in oil palm plantation areas with riparian vegetation in the Eastern Amazon. We hypothesised that the MD of Odonata larvae might be affected by oil palm plantation since changes in the landscape might cause the loss of microhabitats that are essential for the larval life cycle. A total of 950 Odonata larvae were collected in 11 streams located in a continuous forest area (inside the legal reserve) and 18 streams located in oil palm streams surrounded by riparian vegetation. There was a significant difference in the MD of the larvae between the oil palm and forest areas. When we compared the results obtained using traditional measures of biodiversity (estimated species richness) with those obtained using the measure of MD, MD was more efficient. The RLQ tests showed a significant relationship between genus abundance and environmental variables, and between genera and morphological traits. We believe that the suppression or change in riparian vegetation might increase the sediment load input and decrease the amount of plant substrate available in the system, leading to the simplification of morphological traits. Therefore, such traits might be used as indicators of environmental impact." **18636.** Pinto, A.P.; de Araujo, B.R. (2020): A new damselfly of the genus *Forcepsioneura* from the Atlantic Forest of south-eastern Brazil (Odonata: Coenagrionidae). *Odonatologica* 49(1/2): 107-123. (in English) ["A new Brazilian Protoneurinae damselfly, *Forcepsioneura lopii* sp. nov. (holotype male deposited in DZUP: Brazil, São Paulo State, Cananéia, Ilha do Cardoso State Park) is described, and diagnosed based on two males and one female. This small dark yellow-orange *Forcepsioneura* Lencioni, 1999, inhabits typical restinga-like formations in southern Brazil. The coloration and short ventrobasal process of the male cercus of *Forcepsioneura lopii* sp. nov. make it similar to the larger

montane species of the orange-black group, i.e., *F. grossiorum* Machado, 2005, *F. itatiaiae* (Santos, 1970), *F. janeae* Pimenta et al., 2019, *F. lucia* Machado, 2000, and *F. serabonita* Pinto & Kompier, 2018. However it occurs in lowlands and the cercus is slender as in the light blue group, i.e., *F. gabriela* Pimenta et al., 2019, *F. garrisoni* Lencioni, 1999, *F. haerteli* Machado, 2001, *F. regua* Pinto & Kompier, 2018, and *F. sancta* (Hagen in Selys, 1860). The very acute, spur-like process on the mediobasal process of male cercus is unique. This is only one of several undescribed species recently discovered in *Forcepsioneura*, and it reaffirms the necessity for additional investigations to understand the richness and diversification of this genus." **18637.** Schröder, N.M.; Rippel, C.G.; Walantus, L.H.; Zapata, P.D.; Pessacq, P. (2020): Odonata assemblages as indicators of stream condition – a test from northern Argentina. *North-Western Journal of Zoology* 16(2): 117-124. (in English) ["The increasing consumption of natural resources due to population growth, and the expansion of agricultural activity have a major impact on freshwater ecosystems. The aim of this study was to verify if possible changes in habitat condition and physical-chemical variables due to different land uses are reflected by changes in Odonata assemblages. In order to do that, we evaluated the conservation status of the riparian zone and the physicochemical parameters of stream waters affected by different degrees of anthropogenic impact, and assessed richness and variation in species composition, testing for potential indicator species of habitat quality. The riparian index allowed the differentiation of three habitat condition categories: conserved, intermediate and degraded. No significant differences were found in species richness between the three conservation states, but it was possible to discriminate between the communities present. Four species showed potential as habitat quality indicators that can serve as biomonitors in future strategies of stream management and conservation." **18638.** Starr, S.M.; McIntyre, N.E. (2020): Effects of water temperature under projected climate change on the development and survival of *Enallagma civile* (Odonata: Coenagrionidae). *Environmental Entomology* 49(1): 230-237. (in English) ["Current climate projections for the Great Plains of North America indicate markedly increased air temperatures by the end of the current century. Because the Great Plains contains >80,000 intermittent wetlands that serve as irreplaceable wildlife habitat, this projected warming may have profound effects throughout a continental-scale trophic network. However, little research has been done to determine how projected warming may affect the growth, development, or survival of even common species in this region. We conducted laboratory warming experiments, using

an abundant amphibious predatory insect, *Enallagma civile* (Hagen, 1861), as a model organism, to determine whether projected warming may affect development or survival. Eggs were collected and reared under four water temperature regimes representing current (26°C) and projected future conditions (32, 38, and 41°C). Nymph body size after each molt, development rate, and deaths were recorded. Elevated water temperatures were found to significantly affect the survivorship of *E. civile* eggs and nymphs as well as adult body size at emergence: an increase in temperature incurred a decrease in survival and size. Nymphs in the two hotter treatments were smaller and had low survivorship whereas individuals in the cooler temperatures generally survived to adulthood and were larger. Nymphs reared at 32°C experienced accelerated ontogenetic development compared with the other temperatures, going from egg to adult in 26 d. Projected elevated temperatures may, thus, be both advantageous and detrimental, causing concern for aquatic invertebrates in this region in the future." (Authors) ] Address: McIntyre, Nancy, Dept Biological Sciences, Texas Tech University, Lubbock, TX 79409-3131, USA. E-mail: nancy.mcintyre@ttu.edu

## 2021

**18639.** Agnes Deepa, A.; Selvarasu, P.; Gunasekaran, C.; Shobana, G. (2021): Odonata fauna in adjoining areas of Amirthi Zoological Park in Vellore District, Tamilnadu, India. *Acta Entomology and Zoology* 2(1): 12-18. (in English) ["The objective of the present study is to explore the diversity of Odonata in Amirthi Forest Division, Vellore District. Dragonfly watching and recording has been done in each line transect during a week. A total of 37 species belonging to 29 genera and 6 families viz. Lestidae, Platycnemididae, Coenagrionidae and Libellulidae were recorded. The maximum number of Odonates were found in Libellulidae (n=20 species), followed by Coenagrionidae (n=11), Aeshnidae (n=2), Lestidae (n=3), Platycnemididae (n=1) and Gomphidae (n=1). Out of the Site -1 Urban areas, Site -2 Agricultural areas, Site -3 wet land areas and Site. 4 Amirthi park areas are selected study sites, the highest number of Odonate species (28) was recorded in S3 and S2 ranked second with 24 species. Species richness was comparatively low in the remaining Study sites: S4 with 21 species and S1 with 18 species. The result of high species richness in the particular study sites (S3 and S2) may be due to the intensity and duration of longer surveys, rather than true ecological species richness. Among the selected Sites the diversity of dragonflies was high in Agricultural areas and wet land areas. Out of the 37 Odonates recorded from the district, 35 species come under the IUCN Red List of Threatened Category. Among them 37 species comes under Least Concern (LC) Category, one species under Data Deficient (DD) and three species is not evaluated. The present study is to encourages the wide range conservation of dragonfly species in the study area." (Authors)] Address: Agnes Deepa A., Unit Conserv. Biol., Dept Zool., Bharathiyar Univ., Coimbatore, Tamil Nadu, India

**18640.** Archibald, S.B.; Cannings, R.A. (2021): The head

of Cephalozygoptera (Odonata). *Zootaxa* 5047(1): 97-100. (in English) ["Conclusions: We know of no force acting before or during diagenesis that might change the conservative zygoteran head shape to the diagnostic Cephalozygoptera shape. We conclude that the evidence from the specimens discussed by Nel & Zheng (2021), and those further examined and discussed here and by Archibald et al. (2021) supports the proposal that the head shape ascribed to the Cephalozygoptera by Archibald et al. (2021) is their actual shape, and that the Cephalozygoptera is a valid taxon. Note: We maintain that the Cretaceous genera *Palaeodysagrion* Zheng et al., *Electrodysagrion* Zheng et al., and *Burmadyagrion* Zheng et al. are not members of the Dysagrionidae and that the Paleocene genus *Valerea* Garrouste et al. is tentatively a member of the Dysagrionidae for reasons given by Archibald et al. (2021, pages 20 and 42)." (Authors)] Address: Archibald, S.B., Dept of Biological Sciences, Simon Fraser Univ., 8888 University Drive, Burnaby, British Columbia, V5A 1S6, Canada. E-mail: sba48@sfu.ca

**18641.** Busmachi, G. (2021): New record of *Leucorrhinia pectoralis* (Charpentier, 1825) (Insecta: Libellulidae) in the Republic of Moldova. Sustainable use and protection of animal world in the context of climate change. *Editia 10, 2021 Conferința "Sustainable use and protection of animal world in the context of climate change"*. Chisinau, Moldova, 16-17 septembrie 2021: 161-163. (in English) ["The paper includes new record of rare and protected species of Odonata – *L. pectoralis* in the Republic of Moldova. The species was cited firstly in 2009 from the Cioburciu village. In June, 2021 one adult male was identified on the palustral vegetation in the Plaiul Fagului Reserve. This is the second record of this species in the Republic of Moldova." (Author)] Address: Busmachi, Galina, Institute of Zoology, Chisinau, Republic of Moldova. E-mail: bushmakiu@yahoo.com

**18642.** Curtean-Bănăduc, A.; Burcea, A.; Mihub, C.-M.; Bănăduc, D. (2021): The benthic trophic corner stone compartment in POPs transfer from abiotic environment to higher trophic levels — Trichoptera and Ephemeroptera pre-alert indicator role. *Water* 2021, 13, 1778. 17 pp. (in English) ["Persistent organic pollutants (POPs) have been at the forefront of environmental contamination research even before their ban in 2001 at the Stockholm Convention. Their relation to different compartments of the environment (biotic and abiotic) has been thoroughly investigated. This article aims to identify whether the benthos could represent a reliable indicator of environmental contamination with POPs and to highlight its potential transfer role between abiotic and upper trophic compartments—benthos feeders. In this regard, we determined that the Ephemeroptera samples have higher concentrations ( $p < 0.05$ ) of  $\Sigma$ PCB,  $\Sigma$ HCH, and  $\Sigma$ DDT than sediment samples while Trichoptera samples have higher concentrations ( $p < 0.05$ ) only in the case of  $\Sigma$ PCB and  $\Sigma$ DDT. This, along with the fact that the frequency of detection for POPs is similar between the sample types (sediments, Trichoptera, and Ephemeroptera), makes the benthos samples valuable indicators of contamination with sediment samples working as complementary information about how recent the

contamination is." (Authors) At sampling point M14, Odonata contributed with 10,31% to the benthic macroinvertebrate community.] Address: Curtean-Bănăduc, Angela, Applied Ecology Res. Center, Lucian Blaga Univ. of Sibiu, 550012 Sibiu, Romania. E-mail: angela.banaduc@ulbsibiu.ro

**18643.** Dasrat, C.M.; Maharaj, G. (2021): Biological control of mosquitoes with odonates: A case study in Guyana. *Nusantara Bioscience* 13: 163-170. (in English) ["Mosquitoes have plagued the lives of tropical residents as pests. However, due to their role as vectors of life-threatening diseases, controlling their population is necessary, especially in areas of prevalence – the Caribbean and Equatorial regions. In Guyana, we employ chemical treatments sub-regionally to eradicate mosquitoes. However, this treatment has limited success and is harmful to the environment. Therefore, our study focused on an environmentally friendly method such as biological control. This study was conducted at the University of Guyana, Turkeyen campus, where we exploited Odonata; Anisoptera, and Zygoptera as natural predators of mosquitoes of the genus *Culex*. The feeding efficiency and behaviors of naiads from the families of Libellulidae and Coenagrionidae were assessed during April – May of 2018. Each naiad was fed three *Culex* pupae and larvae, then observed for 60 minutes. We found that both groups pursue soft-bodied larvae and Libellulidae naiads are more efficient predators due to the higher feeding rate than Coenagrionidae. This finding is related to a behavioral study where we observed Libellulidae as active hunters that masticate and consume faster than Coenagrionidae, which are lay and wait, opportunistic predators that swallow their prey. We concluded that Libellulidae is an efficient predator for mosquito larvae of the *Culex* genus, and we found that there is a link between morphologic characteristics and feeding behaviors. We hope to use these results as a baseline study to develop mosquito biological control in Guyana. These can be used to reduce mosquito populations and the occurrence of vector diseases as well as improve integrated pest and vector management." (Authors)] Address: Dasrat, Cindy, Dept Biol., Univ. Guyana. Turkeyen Campus, Turkeyen, Georgetown, Guyana. Email: cindrina@gmail.com

**18644.** De Almeida, M.V.O.; Pinto, Â.P.; Carvalho, A.L. (2021): Digitizing Primary Data on Biodiversity to Protect Natural History Collections Against Catastrophic Events: The type material of dragonflies (Insecta: Odonata) from Museu Nacional of Brazil. *Biodiversity Information Science and Standards* 5: e75284: 3 pp. (in English) ["Conference Abstract: Natural history collections (NHC) are guardians of biodiversity (Lane 1996) and essential to understand the natural world and its evolutionary processes. They hold samples of morphological and genetic heritages of living and extinct biotas, helping to reconstruct the timeline of life over the centuries (Gardner 2014). Primary data from specimens in NHC are crucial elements for research in many areas of biological sciences, considered the "bricks" of systematics and therefore one of the pillars for evolutionary studies (Troudet

2018). For this reason, studies carried out in NHC are essential for the development of the scientific knowledge and are pivotal for the scientific-technological progress of a nation (Camargo 2015). The digitization and availability of primary data on biodiversity from NHC represents a inexpensive, practical and secure means of exchanging information, allowing collaboration between institutions and researchers. In this sense, initiatives such as the Sistema de Informação sobre a Biodiversidade Brasileira (SiBBR), a country-level branch of the Global Biodiversity Information Facility (GBIF) platform, aim to encourage and establish ways for the informatization of biological collections and their type specimens. Known for housing one of the largest and oldest collections of insects in the world focused on Neotropical fauna, the Entomological Collection of the Museu Nacional of Federal University of Rio de Janeiro (MNRJ) had more than 3,000 primary types and approximately 12,005,000 specimens, of which about 96% were lost in the tragic fire occurred at the institution on September 2, 2018. The SiBBR project was active in that collection from 2016 to 2019 and enabled the digitization and preservation of data from the type material of many insect orders, including the charismatic order Odonata. Due to the end of the agreement between SiBBR and the Museu Nacional, most of the obtained primary data are pending full curation and, therefore, are not yet available to the public and researchers. The MNRJ housed the biggest and most important collection of dragonflies among all Central and South American institutions. It assembled most of the physical records of neotropical dragonfly fauna gathered over the last 80 years, many of which are of undescribed taxa. Unfortunately, almost all material was permanently lost. This study aims to gather, analyze and publicize primary data of the type material of dragonflies housed in the MNRJ, ensuring the preservation of its history, as well as providing data on the taxonomy and diversity of this marvelous group of insects. A total of 11 families, 50 genera and 131 species were recorded, belonging to the suborders Anisoptera and Zygoptera with distributional records widespread in South America. The MNRJ housed 105 holotypes of dragonflies' nomina representing 11.7% of the richness of the Brazilian Odonata fauna (901 spp.), a country with the highest number of species of the biosphere. The impact of the loss of this collection to studies of these insects is unprecedented, since some enigmatic and monotypic genera such as *Brasiliogomphus*, *Fluminagrion* and *Roppaneura* lost 100% of their type series, while others most diverse such as *Lauromacromia*, *Oxyagrion* and *Necordulia* lost 50%, 35% and 31% of their holotypes. Therefore, due to the registration and preservation of primary biodiversity data, this work reiterates the importance of curating and digitizing biological scientific collections. Furthermore, it shows extreme relevance for preserving information on existing biodiversity permanently and providing support for future research. Digitization and interconnecting digital extended specimen data proves to be one of the main and most effective ways to protect NHC heritage and their primary data against catastrophic events." **18646.** Ensaldo-Cárdenas, A.S.; Rocha-Ortega, M.; Schneider, D.; Robertson, B.A.; Córdoba-Aguilar, A. (2021): Ultraviolet polarized light and individual condition drive habitat selection in tropical damselflies and dragonflies. *Animal Behaviour* 180: 229-238. (in English) ["Highlights: • We examined effects of ultraviolet polarized light (UVPL) on aquatic insects. • We measured odonates' preference for UVPL vs visible range polarized light. • Sexual behaviours were performed in association with the UVPL. • UVPL-associated insects had reduced lipid reserves and body size. • UVPL is both a cue that animals use for habitat selection and an evolutionary trap. Abstract: Artificial objects can polarize ultraviolet light sources to a higher degree than natural objects like water bodies. This can induce a strong attraction response by insects that use such cues as proxies of habitat suitable for reproduction. Visible range polarized light (VRPL) can create evolutionary traps for aquatic insects, but it remains unclear whether insects can use ultraviolet polarized light (UVPL) as a habitat selection cue or if UVPL pollution can create evolutionary traps for aquatic insects like VRPL can. Odonate insects require an aquatic habitat to perform their mating and egg-laying behaviours yet they also perform such behaviours on artificial surfaces (i.e. metal pieces). We measured the preference for UVPL versus VRPL via exposing three species of odonates (*Enallagma praevarum*, *Ischnura denticollis* and *Sympetrum illotum*) to experimental test surfaces differing in these visual cues and assessing behavioural preference via differences in mating behaviour, body condition (i.e. lipid and protein content and body size) and visual acuity (based on eye width size). *Ischnura denticollis* performed more diverse mating behaviours in association with the VRPL treatment, while *S. illotum* preferentially exhibited these behaviours in association with the UVPL. *Ischnura denticollis* individuals associated with the preferred habitat had lower lipid reserves, smaller body size and larger eyes, while habitat preference was unrelated to individual condition and morphology in *E. praevarum* and *S. illotum*. These results suggest intra- and interspecific variation

in trap preferences, which are related to individual condition. They also show that UVPL is a cue that odonates use in habitat selection that has the potential to create evolutionary traps, suggesting conservation problems for aquatic insects that rely upon it to locate water bodies." **18650.** McLoughlin, S.; Prevec, R.; Slater, B. (2021): Arthropod interactions with the Permian Glossopteris flora. *Journal of Palaeosciences / The Palaeobotanist* 70: 43-133. (in English) ["An extensive survey of literature on the Permian floras of Gondwana reveals over 500 discrete arthropod–herbivory–damage/plant–taxon/stratigraphic–unit associations spanning all regions of the supercontinent from the earliest Asselian to the latest Changhsingian. Margin– and apex–feeding damage is the most common style of herbivory but hole– and surface–feeding, galling, and oviposition damage are locally well represented. Evidence for skeletonization and mucivory is sparse and that for leaf mining is equivocal. Wood and root boring is recognized widely but only where depositional conditions were conducive to the permineralization of plant axes. Wood boring and detritivory may have been especially favoured arthropod feeding strategies in Permian high latitudes where living foliage was scarce during the polar winters. Herbivory damage is most strongly apparent on glossopterid remains; other groups of broad–leafed gymnosperms and sphenopsids host moderate levels of damage. Damage features are under–represented on lycophytes, ferns and spine– and scale–leafed conifers. A survey of insect body fossils from the Gondwanan Permian reveals that most records are from a small number of rich assemblages that are dominated by Blattodea, Hemiptera, Grylloblattida, Mecoptera and Protelytroptera, accompanied by significant representations of Coleoptera, Glosselytrodeia, Miomoptera, Neuroptera, Odonata, Protorthoptera, Palaeodictyopteroidea, Paoliida, Paraplecoptera, Plecoptera, Psocoptera, Thysanoptera and Trichoptera, which collectively adopted a broad range of feeding styles. Oribatid mites and collembolans appear to have been important components of the wood–boring and detritivorous communities. Although temporal trends in herbivory styles and diversity are difficult to resolve from mostly incidental observations and illustrations of plant damage across Gondwana, the results of this study provide a baseline of qualitative data for future studies that should adopt a quantitative approach to the analysis of herbivory, spanning the shift from icehouse to hothouse conditions through the Permian of the Southern Hemisphere." (Authors)] Address: McLoughlin, S., Dept of Palaeobiology, Swedish Museum of Natural History, Stockholm, Sweden

**18651.** Outomuro, D.; Golab, M.J.; Johansson, F.; Sniegula, S. (2021): Body and wing size, but not wing shape, vary along a large-scale latitudinal gradient in a damselfly. *Scientific Reports* volume 11, Article number: 18642 (2021): 11pp. (in English) ["Large-scale latitudinal studies that include both north and south edge populations and address sex differences are needed to understand how selection has shaped trait variation. We quantified the variation of flight-related morphological traits (body size, wing size, ratio between

wing size and body size, and wing shape) along the whole latitudinal distribution of the damselfly *Lestes sponsa*, spanning over 2700 km. We tested predictions of geographic variation in the flight-related traits as a signature of: (1) stronger natural selection to improve dispersal in males and females at edge populations; (2) stronger sexual selection to improve reproduction (fecundity in females and sexual behaviors in males) at edge populations. We found that body size and wing size showed a U-shaped latitudinal pattern, while wing ratio showed the inverse shape. However, wing shape varied very little along the latitudinal gradient. We also detected sex-differences in the latitudinal patterns of variation. We discuss how latitudinal differences in natural and sexual selection regimes can lead to the observed quadratic patterns of variation in body and wing morphology via direct or indirect selection. We also discuss the lack of latitudinal variation in wing shape, possibly due to aerodynamic constraints." (Authors)] Address: Outomuro, D., Dept of Biol. Sciences, Univ. **18652.** Pahari, P.R.; Jana, G.C.; Mandal, S., Maiti, S.; Bhattacharya, T. (2021): A study on the impact of brick embankment on aquatic entomofauna. *Uttar Pradesh Journal of Zoology* 42(19): 59-68. (in English) ["Shrinkage of the littoral zone due to brick embankment around a pond caused an adverse effect on the floral & faunal composition. A brick embanked pond (BEP) had lower number of macrophytes and entomofauna as compared to a natural pond (NP). Index of similarity suggests that both the ponds were strongly dissimilar in their floral and entomofaunal composition. Hemiptera was the most predominating insect order (96.73%) in BEP while Odonata (41.14%) and Coleoptera (39.02%) were the common orders in NP. Lower diversity, equitability, signal, ASPT, BMWP indices/scores and higher dominance & FBI indices in BEP as compared to NP indicates that BEP provided a less equitable habitat with poor quality of water for the existence of lower diversity of entomofauna." **18654.** Polizeli, L.; Pinto, A.P. (2021): Taxonomy and conservation concerns of the critically endangered *Roppaneura beckeri*, a phytotelm-breeding damselfly in the southern Brazilian Atlantic Forest. *Bulletin of Insectology* 74(1): 91-101. (in English) ["Phytotelm-breeding Odonata are rare: from the 6,300 known species of these charismatic freshwater organisms, only a small number of about 50 develop in phytotelmata habitats. Mainly members of the Zygoptera are dependent on this special type of environment. The small coenagrionid *R. beckeri*, a damselfly endemic to the Brazilian Atlantic Forest, is the only known Odonata breeding in the terrestrial umbellifers of *Eryngium floribundum* (Cham. et Schltdl.). This is a species-specific association with a host-plant unparalleled in the order. It also is the only species within the subfamily Protoneurinae to occupy phytotelmata habitats. Here, we report on a population of *R. beckeri* re-discovered after 42 years and recorded for the first time from the southern Atlantic Forest from the state of Paraná. The morphology and the distribution of this species is reviewed and based on these primary data future conservation strategies are discussed. We suggest including *R. beckeri* as a priority species for dragonfly conservation policies due to its exclusive biological characteristics, evolutionary relevance, and occurrence in urban to peri-urban landscapes." (Authors)] Address: Polizeli, L., Undergraduate course of Ciências Biológicas, Univ. Fed. Paraná, Curitiba, Paraná, Brazil

**18655.** Sabeder, N. (2021): Popis kačjih pastirjev in dvoživk ob avtocestnem odseku Šentjakob–Blagovica - Inventory of dragonflies and amphibians by the motorway section Šentjakob–Blagovica. M.Sc. thesis (Master Study Programmes – Ecology and Biodiversity, Biotechnical Faculty, Ecology and biodiversity studies, University of Ljubljana. VIII, 52 pp. (in Slovenian, with English summary) ["The primary objective of the thesis was to gather data on the presence of dragonflies (Odonata) and amphibians (Amphibia) along the highway section between Šentjakob and Blagovica on the A1 Šentilj-Koper. We compared the species richness of dragonflies and amphibians between the sampling sites with a direct influence of the highway and those without. We registered 33 species of dragonflies and 9 species of amphibians. We found that water bodies with the direct impact of the highway had a lower diversity of dragonflies and amphibians compared to those without direct impact, however the difference was not statistically significant. On the other hand, we recorded significantly more dragonfly species that completed their life cycle on water bodies without direct impact of the highway than on sites impacted by highway. We also found a positive correlation between the size of the water body and extent of riparian vegetation on the number of recorded dragonflies on sampling sites. We could not confirm the impact of closeness to the highway on dragonfly species richness. The role of water bodies with the direct impact of highways is not yet completely known. In any case, they likely perform an important connecting function between better preserved habitats and therefore require proper management." **18656.** Šigutová, H.; Harabiš, F.; Šigut, M.; Jiří Vojar, J.; Choleva, L.; Dolný, A. (2021): Specialization directs habitat selection responses to a top predator in semiaquatic but not aquatic taxa. *Scientific Reports* | (2021) 11:18928. 11pp. (in English) ["Habitat selectivity has become an increasingly acknowledged mechanism shaping the structure of freshwater communities; however, most studies have focused on the effect of predators and competitors, neglecting habitat complexity and specialization. In this study, we examined the habitat selection of semiaquatic (amphibians: Bufonidae; Libellulidae) and aquatic organisms (true bugs: Notonectidae; diving beetles: Dytiscidae). From each family, we selected one habitat generalist species able to coexist with fish (*Bufo bufo*, *Sympetrum sanguineum*, *Notonecta glauca*, *Dytiscus marginalis*) and one species specialized in fishless habitats (*Bufotes viridis*, *Sympetrum danae*, *Notonecta obliqua*, *Acilius sulcatus*). In a mesocosm experiment, we quantified habitat selection decisions in response to the non-consumptive presence of fish (*Carassius auratus*) and vegetation structure mimicking different successional stages of aquatic habitats (no macrophytes; submerged and floating macrophytes; submerged, floating, and littoral-emergent macrophytes). No congruence between habitat specialists and generalists was observed, but a similar response to fish and vegetation structure defined both semiaquatic and aquatic organisms. While semiaquatic generalists did not distinguish between fish and fishless pools, specialists avoided fish-occupied pools and had a preferred vegetation structure. In aquatic taxa, predator presence affected habitat selection only in combination with vegetation structure, and all species preferred fishless pools with floating and submerged macrophytes. Fish presence triggered avoidance only in the generalist bug *N. glauca*. Our results highlight the significance of habitat selectivity for structuring freshwater ecosystems and illustrate how habitat selection responses to a top predator are dictated by specialization and life history." **18657.** Willink, B.; Blow, R.; Sparrow, D.J.; Sparrow, R.; Svensson, E.I. (2021): Population biology and phenology of the colour polymorphic damselfly *Ischnura elegans* at its southern range limit in Cyprus. *Ecological Entomology* 46(3): 601-613. (in English) ["1. Geographically widespread species provide excellent opportunities to investigate how phenotypes change across large-scale environmental gradients. Temperature is a fundamental environmental variable and an important determinant of insect fitness. However, field research is often geographically restricted, and typically concentrated in northern latitudes. Basic population biology and phenotypic clines in relation to temperature therefore remain poorly known across the entire geographic range, even in otherwise well-studied taxa. 2. We surveyed populations of the trimorphic damselfly *Ischnura elegans* in Cyprus, which is the southern range limit in Europe of this widespread insect species. Females of *I. elegans* occur in three discrete and heritable colour morphs, which vary in suites of phenotypic traits. One of these female morphs is a male-mimic that avoids excessive male-mating harassment

by its male-like appearance, and which is more cold-tolerant than the two other morphs. 3. In contrast to the situation in northern Europe, these male-mimicking females are the minority morph in Cyprus, representing only about 5% of all females. Male mimics also have lower mating rates than alternative female morphs. 4. Individuals in Cyprus are relatively small in comparison to the reported European range for body size, consistent with Bergman's rule. 5. Finally, populations of *I. elegans* on the island have the longest flight period known in Europe, and there is only partial evidence for seasonality in flight activity. 6. These results underscore the benefits of considering the entire range of environmental conditions encountered by insect species when conducting evolutionary ecology research." **18658.** Wu, G.; Tang, S.; Han, J.; Li, C.; Liu, L.; Xu, X.; Xu, Z.; Chen, Z.; Wang, Y.; Qiu, G (2021): Distributions of total mercury and methylmercury in dragonflies from a large abandoned mercury mining region in China. *Archives of Environmental Contamination and Toxicology* 81: 25-35. (in English) ["Odonata are often considered to be biosentinels of environmental contamination. Dragonflies (n = 439) belonging to 15 species of eight genera were collected from an abandoned mercury (Hg) mining region in China to investigate the bioaccumulation of total Hg (THg) and methylmercury (MeHg). The THg and MeHg concentrations in dragonflies varied widely within ranges of 0.06–19 mg/kg and 0.02–5.7 mg/kg, respectively. THg and MeHg were positively correlated with bodyweight (THg:  $r^2 = 0.10$ ,  $P = 0.000$ ; MeHg:  $r^2 = 0.09$ ,  $P = 0.000$ ). Significant variations were observed among species, with the highest MeHg value (in *Orthetrum triangulare*) being 5-fold higher than the lowest (in *Pantala flavescens*). These variations were consistent with those of nitrogen isotope ( $\delta^{15}N$ ) values. A health risk assessment found hazard quotients for specialist dragonfly-consuming birds of up to 7.2, which is 2.4 times greater than the permissible limit of 3, suggesting a potential health risk of exposure." **18659.** Zatkos, L.; Ivan Arismendi, William J. Gerth (2021): Diet of *Octogomphus specularis* (Hagen in Selys, 1859) (Odonata: Gomphidae) nymphs in western Oregon, U.S.A. with incidental information on the diet of *Cordulegaster dorsalis* Hagen in Selys, 1858 (Odonata: Cordulegastridae) nymphs. *The Pan-Pacific Entomologist* 97(2): 75-79. (in English) ["Of the 84 *O. specularis* specimens collected, 39 had empty guts or contained unidentifiable remains of prey and debris. However, stomachs of the remaining 45 contained a diverse composition of prey items. Because the prey in *O. specularis* guts were often damaged or partially digested, insects were mainly identified to order or family (53% identified to order, 45% to family, 2% to genus); non-insects were identified to order or coarser levels. Dipterans were the most common prey found in these specimens. In fall and spring, almost 90% and 70% of the stomachs contained Diptera, respectively

(and 30% in winter). Ephemeroptera (20% and 8%) and Trichoptera. Frequency of occurrence (%F) of prey items by season for *O. specularis* and *C. dorsalis*. (10% and 14%) were also common prey in winter and spring, respectively, whereas Coleoptera made up only 12% of diet contents in the fall. Incidental prey items occurred only in spring and included Coleoptera, Plecoptera, Acariformes, Ostracoda, Oligochaeta, and Psocodea. No statistically significant differences in the composition of individual diets existed among seasons. The results of the PERMANOVA support the null hypothesis that the stomach contents of these opportunistic predators do not vary significantly by season ( $p = 0.13$ ). Nevertheless, this is a relatively small p value, and a larger analysis with more specimens may illuminate seasonal trends not observed here. Because only three *C. dorsalis* specimens were collected, analyses could not be conducted." **18660.** Zhang, H.; Ning, X.; Yu, X.; Bu, W.-J. (2021): Integrative species delimitation based on COI, ITS, and morphological evidence illustrates a unique evolutionary history of the genus *Paracercion* (Odonata: Coenagrionidae). *PeerJ* 9:e11459. DOI 10.7717/peerj.11459: 22 pp. (in English) ["*Paracercion* are common 'blue and black' colored damselflies. We explore the species boundaries of *Paracercion* (Odonata: Coenagrionidae) using ABGD, bPTP, GMYC and Distance-based clustering. We finally got the molecular data of all nine species of *Paracercion*. *P. hieroglyphicum* and *P. melanotum* were combined into one putative species based on cytochrome c oxidase I (COI). However, they were separated into two putative species based on the nuclear segment including ITS1-5.8S-ITS2 (ITS). This suggests the introgression of mtDNA in *Paracercion*. *Paracercion barbatum* and *Paracercion melanotum* can be separated into two species based on COI, whereas they were combined into one putative species based on ITS, which suggests a hybridization event between them. The lower interspecific divergence (COI: 0.49%) between *P. barbatum* and *Paracercion v-nigrum* indicates a recent speciation event in *Paracercion*. *Paracercion sieboldii* and *P. v-nigrum* can be separated into two putative species based on COI, while they were frequently merged into the same putative species based on ITS. This can be explained by incomplete lineage sorting in nDNA. Besides, *P. pendulum* and *P. malayanum* were synonymized as junior synonyms of *P. melanotum*. *P. luzonicum* was confirmed not to belong to *Paracercion*. The possibility of introgression, hybridization, recent speciation and incomplete lineage sorting makes species delimitation, based on molecular data, difficult and complicates understanding of the evolutionary history of *Paracercion*. The discordance in COI and ITS also indicates the value of using markers from different sources in species delimitation studies." **18665.** Shugart, M.M. (2010): In pursuit of dragonflies: protein sources in Balinese rice fields. MSc thesis, University of Colorado, Boulder, CO, USA: 98 pp. (in English) ["Agricultural systems can provide more to the farmers and their communities than simply the production of domesticated plants. This project considers how rice farms can also support a variety of edible insects and small wild animals that can be harvested for protein. In this thesis, I analyze the farmer knowledge, capturing techniques, and cooking methods for small animals and insects from organic rice fields in Bali, Indonesia. Information was gathered from formal surveys with farmers and participant observation. Considering the rich source of protein and fats found in these insects and animals, I argue that production and harvesting of small protein resources may provide a more sustainable approach

to dealing with global food shortages, particularly in places such as Africa, where livestock husbandry is not practical." (Author)] Address: not stated

**18666.** Stübing, S.; Hill, B.T.; Roland, H.-J. (2010): Jahresbericht Hessen 2009. Libellen in Hessen 3: 4-36. (in German) ["The Hessian dragonfly year 2009 was marked by several "records": Never before was the flight season so long, were so many data reported to us and were so many informative photos and manuscripts available as in 2009. For the third annual report on dragonflies, 11,191 data sets were reported by 83 observers from all Hessian districts. 7,924 reports were for the year 2009, which is an increase of about 60 % compared to the previous year's data collection, which was by far the most comprehensive to date. The other data is made up of highly welcome follow-up reports as well as miscellaneous registrations. All in all, the total data stock in Hesse has thus been increased by one third! For reasons of space, the reports of the more common species are therefore presented in tabular form. 26 new first and 24 last observation records are not only due to increased observer activity, but also a result of the climatic conditions in 2009. After the occasionally unusually cold winter of 2008/09 with lows around -26 °C, March and April were remarkably warm and sunny. Already on 1.4. the first winter dragonflies *Sympetma fusca* appeared at the water body and on 5.4. the first early *Pyrrhosoma nymphula* hatched. October and November were very mild, so that on 25.11. *Sympetrum striolatum*, *S. vulgatum* were still on the move. Unusually late flying were *Libellula depressa* and *Crocothemis erythraea*. Remarkable observations were made of the following species, among others: *Leucorrhinia caudalis* (proof of ground-level occurrences of nationwide importance), *Sympetrum meridionale* (large ground-level population for the first time), *Ophiogomphus cecilia* (numerous new water bodies, also among the other gomphids), *Somatochlora arctica*. (confirmation of both occurrences), *S. flavomaculata* (new discovery at two sites) and *Aeshna isocetes* as well as *Libellula fulva* (both remarkably frequent, as last year). *Brachytron pratense* also appeared remarkably often. On the other hand, *Erythromma viridulum* and *Ischnura pumilio* were conspicuously rare, as was probably also *Orthetrum brunneum*. The other southern species did not show any effects of the cold winter." (Authors; DeepL)] Address: Stübing, S., Im Feldchen 1a, 61209 Echzell, Germany. E-mail: stefan.stuebing@gmx.de

**18670.** Blaho, M.; Herczeg, T.; Kriska, G.; Egri, A.; Szaz, D.; Farkas, A.; Tarjanyi, N.; Czinke, L.; Barta, A.; Horvath, G. (2014): Unexpected attraction of polarotactic water-leaving insects to matt black car surfaces: Mattness of paintwork cannot eliminate the polarized light pollution of black cars. PLoS ONE 9(7): e103339. doi:10.1371/journal.pone.0103339: 12 pp. (in English) ["The horizontally polarizing surface parts of shiny black cars (the reflection-polarization characteristics of which are similar to those of water surfaces) attract water-leaving polarotactic insects. Thus, shiny black cars are typical sources of polarized light pollution endangering water-leaving insects. A new fashion fad is to make car-bodies matt black or grey. Since rough (matt) surfaces depolarize the reflected light, one of the ways of reducing polarized light pollution is to make matt the concerned surface. Consequently, matt black/grey cars may not induce polarized light pollution, which would be an advantageous feature for environmental protection. To test this idea, we performed field experiments with horizontal shiny and matt black car-body surfaces laid on the ground. Using imaging polarimetry, in multiple-choice field experiments we investigated the attractiveness of these test surfaces to various water-leaving polarotactic insects and obtained the following results: (i) The attractiveness of black car-bodies to polarotactic insects depends in complex manner on the surface roughness (shiny, matt) and species (mayflies, dolichopodids, tabanids). (ii) Non-expectedly, the matt dark grey car finish is much more attractive to mayflies (being endangered and protected in many countries) than matt black finish. (iii) The

polarized light pollution of shiny black cars usually cannot be reduced with the use of matt painting. On the basis of these, our two novel findings are that (a) matt car-paints are highly polarization reflecting, and (b) these matt paints are not suitable to repel polarotactic insects. Hence, the recent technology used to make matt the car-bodies cannot eliminate or even can enhance the attractiveness of black/grey cars to water-leaving insects. Thus, changing shiny black car painting to matt one is a disadvantageous fashion fad concerning the reduction of polarized light pollution of black vehicles." (Authors) The paper includes references to Odonata.] Address: Horvath, G., Environmental Optics Laboratory, Dept of Biological Physics, Physical Institute, Eötvös Univ., Budapest, Hungary. **18671.** Boda, P.; Horváth, G.; Kriska, G.; Blahó, M.; Csabai, Z. (2014): Phototaxis and polarotaxis hand in hand: night dispersal flight of aquatic insects distracted synergistically by light intensity and reflection polarization. *Naturwissenschaften* 101: 385-395. (in English) ["Based on an earlier observation in the field, we hypothesized that light intensity and horizontally polarized reflected light may strongly influence the flight behaviour of night-active aquatic insects. We assumed that phototaxis and polarotaxis together have a more harmful effect on the dispersal flight of these insects than they would have separately. We tested this hypothesis in a multiple-choice field experiment using horizontal test surfaces laid on the ground. We offered simultaneously the following visual stimuli for aerial aquatic insects: (1) lamplit matte black canvas inducing phototaxis alone, (2) unlit shiny black plastic sheet eliciting polarotaxis alone, (3) lamplit shiny black plastic sheet inducing simultaneously phototaxis and polarotaxis, and (4) unlit matte black canvas as a visually unattractive control. The unlit matte black canvas trapped only a negligible number (13) of water insects. The sum (16,432) of the total numbers of water beetles and bugs captured on the lamplit matte black canvas (7,922) and the unlit shiny black plastic sheet (8,510) was much smaller than the total catch (29,682) caught on the lamplit shiny black plastic sheet. This provides experimental evidence for the synergistic interaction of phototaxis (elicited by the unpolarized direct lamplight) and polarotaxis (induced by the strongly and horizontally polarized plastic-reflected light) in the investigated aquatic insects. Thus, horizontally polarizing artificial lamplit surfaces can function as an effective ecological trap due to this synergism of optical cues, especially in the urban environment." **18672.** Catil, J.-M. (2014): Une femelle de *Gomphus pulchellus* morte empalée sur une tige de *Juncus inflexus* (Odonata: Gomphidae). *Martinia* 30(2): 46. (in French) [Verbatim: On 14 June 2013, an odonate caught my attention at the edge of a small pond in the commune of Monfort (Gers [32]). This one, a female of *G. pulchellus*, was impaled on the top part of a stem of *Juncus inflexus* L., 1753 by the left forewing. The individual had obviously been dead for a relatively short

time, its relatively intact body not having been damaged by weather conditions or predators. Several cases of accidental capture by plants have been reported, one of which is quite similar (Lambret, P., 2010: Un mâle de *Lestes macrostigma* prisonnier de *Juncus maritimus*. *Martinia*, 26 (1): 49-51). Various hypotheses were put forward at the time. Amongst these, the influence of the wind is plausible, as there had been strong gusts of wind on the previous days (11 and 12 June). In addition, the individual in question had crumpled and still relatively shiny wings, suggesting that it had emerged shortly before the incident and that the wings were fragile. This factor, whether or not combined with the windy episode, could explain a flight accident. However, we cannot exclude other causes, although less likely, such as flight from a predator or from fellow birds (Lambret, op. cit.) and only direct observations, although unlikely, could shed light on this very unusual mortality. I would like to thank Pierre-Olivier Cochard for his help in determining *J. inflexus*. (DeepL)] Address: Catil, J.-M., CPIE Pays Gersois, Au Château, 32300 L'Isle-de-Noé, France. **18674.** Charashika, Z. (2014): An assessment of infestation by parasitic water mites on dragonflies at Marsh along Mwenje dam, Mazowe district, Zimbabwe. BSc. thesis, Bindura University of Science Education: 30 pp. (in English) ["This study was done to determine the infestation levels by water mites (Hydrachnidae) on dragonflies (Anisoptera) that are found at a marsh along Mwenje Dam in Mazowe District, Zimbabwe. A total of 111 dragonflies comprising Aeshnidae (31.5%) and Libellulidae (68.5%) were collected over a period of four months (January to April 2014). The total length and gender of each individual was recorded, as well as number and attachment sites of the parasitic mites. Overall, a total of 28.8% insects were infected. Among the Aeshnidae, the proportion of males that were infected were significantly greater than the females (Chisquare,  $x^2$ ,  $p < 0.05$ ). However, for Libellulidae there was no significant difference in the proportions of infected males and females (Chi-square,  $x^2$ ,  $p > 0.05$ ). A significantly greater proportion of Aeshnidae was parasitized as compared to Libellulidae (Chi-square,  $x^2$ ,  $p < 0.05$ ). For both taxa, the parasites were attached on either the thorax or abdomen, with no significant

difference in the number of parasites between the two attachment sites (ANOVA,  $p > 0.05$ ). (Author) Regrettably, all odonate taxa are misidentified.] Address: not stated

(2014): DRAGONFLY ASSOCIATION INDEX: Bewertung der Morphologie von Fließgewässern der Bioregion Östliche Flach- und Hügelländer durch libellenkundliche Untersuchungen. Bundesministerium für Land- und Forstwirtschaft, Umwelt und Wasserwirtschaft Stubenring 1, 1010 Wien: 43 pp. (in German) ["The aim of this dragonfly study was to develop a water type-specific, index-based approach to assess the hydromorphology of small and medium-sized watercourses in the Eastern Plains and Hills bioregion. Based on the ecological requirements of 57 dragonfly species (potentially) occurring in the bioregion, seven dragonfly associations were described. The ecological requirements of these associations were correlated with the water typological characteristics. The result is the definition of water body type-specific associations. In the Dragonfly Association Index, any deviation of the respective status quo from these reference states is calculated and expressed in one of the five classes of ecological status according to the Water Act (WRG). The method is to be applied in particular to those water bodies and water body types where the informative value of the standard methods according to the WRG is limited or not given due to the water body typological characteristics. Furthermore, the use of the method is recommended for the evaluation of local hydraulic engineering interventions, in particular reconstruction measures." **18676.** Chovanec, A.; Schindler, M.; Rubey, W. (2014): Assessing the success of lowland river restoration using dragonfly assemblages (Insecta: Odonata). *Acta ZooBot Austria* 150/151: 1-16. (in English, with German summary) ["The ecological status of straightened and restored stretches of a small river system ("Weidenbach") in the lowland areas of eastern Austria was assessed based on dragonfly surveys. Restoration measures were carried out to varying extent, ranging from measures aimed at the main channel (increasing sinuosity and in-stream habitat heterogeneity) to river-type-specific restoration (RTSR) focusing also on the lateral connectivity of the system (e.g., by river widening and constructing backwaters). The assessment, which is in compliance with the EU Water Framework Directive (WFD), is based on a comparison between the current situation ("status quo") and a river-type-specific reference condition. The key elements of the assessment are species composition and the Odonata Habitat Index (OHI). Stretches of the Weidenbach subjected to RTSR were characterised by higher species numbers and a broader range of OHIs than in the other areas of the same river, indicating a wider spectrum of relevant habitats. In RTSR areas, autochthonous populations of sensitive and threatened species such as *Coenagrion scitulum* and *Aeshna isosceles* were found. These areas were ranked as class II ("good dragonfly-related ecological status"), which represents the second best class and the quality

target in the 5-tiered WFD classification scheme." (Authors)] Address: Chovanec, A., Krotenbachgasse 68, 2345 Brunn am Gebirge, Austria. E-mail: andreas.chovanec@bmlfuw.gv.at

**18679.** Denis, A. (2014): Evaluation de l'état de conservation de la population de Gomphes à pattes jaunes *Gomphus flavipes* (Charpentier, 1825) sur le fleuve Adour. Rapport de stage de Master 2, Université de Toulouse: 38 pp, app. (in French) [*G. flavipes* is a relatively rare species of Odonate that is restricted to slow, undeveloped streams in the alluvial valleys of the plains. This species, protected in France and Europe, is classified as "Least Concern" on the Red List of European Odonates and "Endangered" on the provisional Red List of French Odonates. A priority species of the Regional Action Plan for Odonates (PRAO) in Aquitaine, effective since 2013, *Gomphus flavipes*, mainly present on the Adour river, benefits from an action dedicated to it. Indeed, the objective of action A.7 of the PRAO is to improve knowledge on the distribution and ecology of *G. flavipes* in order to assess the conservation status of the regional population. The results of this study made it possible to identify certain basic characteristics of the habitat favourable to larval emergence on the banks of the Adour, namely a wooded riparian vegetation and a rather steep slope. The presence of grass beds in beach areas seems to be a limiting factor for the emergence of this species on these sectors. The study also showed that the majority of emergences took place between 0 and 50 centimetres above the water level and that the most commonly used emergence supports are root hairs and roots plunging into the water. As the study took place under particular meteorological and hydrological conditions, only partial conclusions could be drawn as to the conservation status of the population of *G. stylurus* on the Adour River. However, the study did highlight the difficulties and limitations of the proposed protocol. Proposals for improving the protocol and suggestions for future studies were therefore submitted. In addition to these recommendations, this report highlights

the fact that the Adour River is a favourable environment for the species in ecological conditions that are poorly documented in the bibliography. Finally, the pressures and threats weighing on the population appear to be low. The regional population therefore does not seem to be threatened in the medium term. (in German, with English summary) ["*S. paedisca* at the westerly Lake Constance: new findings on population fluctuations and reproduction habitats – Data from surveys carried out in seven years during the period from 2004 to 2013 indicate a correlation between the water level fluctuations of Lake

Constance between April and September, the period of oviposition, larval development and emergence, and the population sizes of the summer generation of *S. paedisca*. It can be assumed that falling water levels during the summer lead to the death of many larvae in their shallow water habitats. Knowledge regarding the larval habitats of *S. paedisca* is still insufficient. We observed reproductive activities at nearly natural shallow shore zones of Lake Constance within the nature reserve "Wollmatinger-Ried-Untersee-Gnadensee" and at an artificially created pond on the Mettnau peninsula. Only at the latter location *S. fusca* occurred syntopically." (Authors)] Address: Hunger, H., INULA, Wilhelmstr. 8, 79098 Freiburg, Germany. E-mail: holger.hunger@inula.de

**18686.** Jeanmougin, M.; Leprieur, F.; Loïs, G.; Clergeau, P. (2014): Fine-scale urbanization affects Odonata species diversity in ponds of a megacity (Paris, France). *Acta Oecologica* 59: 26-34. (in English) ["Highlights: •There was no influence of pond localization along the urban gradient on Odonata assemblages. •There was no influence of pond localization along the urban gradient on Odonata  $\alpha$ -diversity. •Fine-scale urbanization has negative effects on Odonata  $\alpha$ -diversity. •The environmental conditions were similar among the studied ponds. •Exuviae are important for understanding the response of Odonata to urbanization. Abstract: Current developments in urban ecology include very few studies focused on pond ecosystems, though ponds are recognized as biodiversity hotspots. Using Odonata as an indicator model, we explored changes in species composition in ponds localized along an urban gradient of a megacity (Paris, France). We then assessed the relative importance of local- and landscape-scale variables in shaping Odonata  $\alpha$ -diversity patterns using a model-averaging approach. Analyses were performed for adult (A) and adult plus exuviae (AE) census data. At 26 ponds, we recorded 657 adults and 815 exuviae belonging to 17 Odonata species. The results showed that the Odonata species assemblage composition was not determined by pond localization along the urban gradient. Similarly, pond characteristics were found to be similar among urban, suburban and periurban ponds. The analyses of AE census data revealed that fine-scale urbanization (i.e., increased density of buildings surrounding ponds) negatively affects Odonata  $\alpha$ -diversity. In contrast, pond localization along the urban gradient weakly explained the  $\alpha$ -diversity patterns. Several local-scale variables, such as the coverage of submerged macrophytes, were found to be significant drivers of Odonata  $\alpha$ -diversity. Together, these results show that the degree of urbanization around ponds must be considered instead of pond localization along the urban gradient when assessing the potential impacts of urbanization on Odonata species diversity. This work also indicates the importance of exuviae sampling in understanding the response of Odonata to urbanization." Insect Sci.* 14(275): 2014; DOI: 10.1093/jisesa/ieu137: 9 pp. (in English) ["Farm ponds help maintain diversity in altered landscapes. However, studies on the features that drive this type of property in the Neotropics are still lacking, especially for the insect fauna. We analyzed the spatial and temporal distribution of odonate larval assemblages in farm ponds. Odonates were sampled monthly at four farm ponds from March 2008 to February 2009 in a temperate montane region of southern Brazil. A small number of genera were frequent and accounted for most of the dominant fauna. The dominant genera composition differed among ponds. Local spatial drivers such as area, hydroperiod, and margin vegetation structure likely explain these results more than spatial

predictors due to the small size of the study area. Circular analysis detected seasonal effect on assemblage abundance but not on richness. Seasonality in abundance was related to the life cycles of a few dominant genera. This result was explained by temperature and not rainfall due to the temperate climate of the region studied. The persistence of dominant genera and the sparse occurrence of many taxa over time probably led to a lack in a seasonal pattern in assemblage richness." **18691.** Mercer, E.; Mercer, T.; Sayok, A.K. (2014): Effects of forest conversions to oil palm plantations on freshwater macroinvertebrates: A case study from Sarawak, Malaysia. *Journal of Land Use Science* 9(3): 260-277. (in English) ["Oil palm plantations in Malaysia are expanding rapidly due to global oil and biofuel demand. This is of particular concern, as the conversion process of forested land to oil palm plantations and the maintenance of a plantation can significantly alter freshwater ecosystems. This is a result of the initial loss of a forested catchment, particularly the riparian vegetation, changes to the bed and banks of streams, sedimentation and changes to detrital inputs. In addition, various chemicals used on the plantations leach into the nearest waterways and can potentially affect freshwater macroinvertebrates. In the Malaysian region, these are largely endemic and generally incompletely known. This study assesses the impact of oil palm plantations on stream macroinvertebrates, by comparing four streams flowing through undisturbed rainforest and four streams flowing through oil palm plantations in Sarawak, Malaysia. Freshwater macroinvertebrates were sampled using the standard three minute kick sample method with accompanying chemical measurements. Although there were no distinct differences between the control and oil palm streams in the chemical data, the invertebrate communities provided a different interpretation of stream quality. Invertebrates were more abundant, species rich and diverse in rainforest streams than in oil palm ones. Most noticeably, two whole orders of insecta, Coleoptera and Hemiptera, were absent from the oil palm streams. This may be the result of the disappearance of natural bank habitats, the sensitivity to the pesticides targeted at the Rhinoceros beetle (*Oryctes rhinoceros*), or a combination of both." **18692.** Mousseau, T.A.; Møller, A.P. (2014): Genetic and ecological studies of animals in Chernobyl and Fukushima. *Journal of Heredity* 105(5): 704-709. (in English) ["Recent advances in genetic and ecological studies of wild animal populations in Chernobyl and Fukushima have demonstrated significant genetic, physiological, developmental, and fitness effects stemming from exposure to radioactive contaminants. The few genetic studies that have been conducted in Chernobyl generally show elevated rates of genetic damage and mutation rates. All major taxonomic groups investigated (i.e., birds, bees, butterflies, grasshoppers, dragonflies, spiders, mammals) displayed reduced population sizes in highly radioactive parts of the Chernobyl Exclusion Zone. In Fukushima, population censuses of birds, butterflies, and cicadas suggested that abundances were negatively impacted by exposure to radioactive contaminants, while other groups (e.g., dragonflies, grasshoppers, bees, spiders) showed no significant declines, at least during the first summer following the disaster. Insufficient information exists for groups other than insects and birds to assess effects on life history at this time. The differences observed between Fukushima and Chernobyl may reflect the different times of exposure and the significance of multigenerational mutation accumulation in Chernobyl compared to Fukushima. There was considerable variation among taxa in their apparent sensitivity to radiation and this reflects in part life history, physiology, behavior, and evolutionary history. Interestingly, for birds, population declines in Chernobyl can be predicted by historical mitochondrial DNA base-pair substitution rates that may reflect intrinsic DNA repair ability." (Authors)] Address: Mousseau, T.A., Dept Biol. Sciences & the Environment & Sustainability Program, Univ. of South Carolina, Columbia, SC 29208, USA. E-mail: mousseau@sc.edu

**18693.** Mugwenhi, E. (2014): The impact of gold panning to macroinvertebrate communities along the Nyazvidzi river. BSc. thesis, Dept of Biological Science, Fac. Science of Education, Bindura University of Science Education: 28 pp. (in English) ["Gold panning have affected negatively the diversity of macroinvertebrates along the Nyazvidzi river as evidenced by the results. The main objective of this research was to assess the impact of gold panning on the diversity of macroinvertebrates along the Nyazvidzi river. Site1 was up the stream and at this site panning was less because 3 to 5 were seen on daily basis. Site 2 was 2 kilometres down from Site 1 and panning at this site was medium. Site 3 was 2.5 kilometres from Site 2 and panning was more as 30 to 40 panners were seen on daily basis. Species richness was computed using the Shannon Weiner index and abundance was calculated using one way analysis of variance (ANOVA) and determine aquatic macroinvertebrates diversity. Results show that diversity decreased down the stream as more macroinvertebrates were seen at site 1 than site 3. A total of 26 families from 9 orders were recorded. The three main orders were the Odonata (40.8%), Ephemeroptera (26.3%) and the Trichoptera (14.8%). The order Odonata of class Hexapoda had the highest abundance (40.8% of total) and highest richness (9 families). Baetidae (9.8%) was the most persistent and the most abundant macroinvertebrate taxa

followed by Libellulidae (8.4%). Almost all taxa were represented in upper stations, except for Potamidae, which were limited to downstream station. Macroinvertebrate taxa richness, total abundance and diversity were significantly higher at Sites 1 and 2 compared to Site 3. Results show that gold panning have some negative impacts on the diversity, taxa richness and abundance of macroinvertebrates communities." (Author)] Address: not stated

**18694.** Myint, W.W. (2014): A study on some Odonate species in Hinthada University Campus. Hinthada University Research Journal 5(1): 38-47. (in English) ["This study was to identify the some Odonates and to add more information on damselflies and dragonflies. A total of 14 species of odonates from Hinthada University Campus, Myanmar were collected and identified. The study period lasted from September, 2011 to October, 2013. Zygoptera and Anisoptera, four families, 12 genera and 14 species of odonates were recorded. Among these 10 species of family Libellulidae is the large family in this study period. Detail morphological structures such as head, thorax, abdomen, body colour and measurements of high wings and abdomen length had also been described. The percentages of recorded odonate species were 71.42% family Libellulidae, 14.28% family Coenagrionidae and 7.15% of families Platynemididae and Aeshnidae. The Odonate species are beneficial to man as biological control agents and as food and traditional medicine in some countries." (Authors)] Address: Dept Zool., Hinthada University, Myanmar

**18698.** Renner, S. (2014): Composição de Libélulas (Odonata) em diferentes ambientes da floresta nacional de São Francisco de Paula, Rio Grande do Sul, Brasil. *Dissertação (Mestrado) – Curso de Ambiente e Desenvolvimento, Centro Universitário Univates, Lajeado: 59 pp.* (in Portuguese, with English summary) ["The human development brings several consequences to the environment, being the most remarkable the fragmentation of natural systems, resulting in ecological imbalance, biodiversity loss and degradation of the watershed. One of the richest biomes of this planet is the Atlantic Forest, which still poorly known in many animal groups, one example is the Odonata order. Actually this biome remains, under pressure in a fragmented mosaic. The forest formation occurring in the South of Brazil is the Mixed Ombrophilous Forest (MOF), a subtype of the Atlantic Forest. In the state of Rio Grande do Sul, this biome covered the high regions and the slopes of the Atlantic Ocean, occurring mostly in the northern half of the state. The MOF is remarkable by the presence of the Brazilian Pine (*Araucaria angustifolia*). Nowadays the remnants of the MOF are disperse in open fields, agriculture or urban matrix. In this context, the species inventory can play a key role in the conservation of these forest remnants. The present study was developed in a big forest fragment, in which exists an ecologic reserve: the Floresta Nacional de São Francisco de Paula, RS. The dragonfly species inventory was performed by sampling 30 aquatic sources distributed in 4 vegetation types and 3 types of aquatic systems. Were registered 47 species scattered in eight families. The Odonata assemblages found in all the types of water (rivers, lakes and swamps) and vegetation types (MOF, araucaria forest, pinus forest and open fields) were statistically compared. In the pinus areas was found the richest assemblage, being composed mainly by generalist species. Was applied and adapted a known methodology for the selection of potential indicator species. The poor knowledge of the Odonata order was improved in the Atlantic Forest/MOF, contributing for future conservation measures and definition of priority protection areas." (Author)] Address: Renner, S., Laboratório de Ecologia e Evolução, Universidade do Vale do Taquari – UNIVATES, Rua Avelino Tallini, 171 Bairro, Universitário, Lajeado RS 95900-00, Brazil. **18700.** Schiel, F.-J. (2014): Eine Fang-Wiederfang-Studie an *Sympetrum depressiusculum* in Mittelbaden (Odonata: Libellulidae). *Libellula* 33(3/4): 217-231. (in German, with English summary) ["A mark-recapture study of *Sympetrum depressiusculum* in the Upper Rhine Valley, Germany (Odonata: Libellulidae) – In a mark-recapture-study conducted in 2007 at two surveyareas in the central part of the upper Rhine Valley (119-129 m a.s.l., MTB 7214, 7313, German federal state of Baden-Württemberg) all in all 713 specimens of *S. depressiusculum* were individually marked to find out if there is an exchange between the two selected survey areas and between the different breeding sites within each area. With 69 recaptures, the recapture rate amounted to 9.7 %. Both, recapture rates from males (14.4 %) and females (4.4 %) and those of mature (10.3 %) and immature marked (6.9 %) individuals differed significantly. 13 individuals (1.8 %) were recaptured on two dates, three on three dates and one on four dates. The median time span between marking and recapture was 14 days. Seven males and two females were recaptured 28-42 days after marking. Altogether 23 individuals (3.2 %) were recaptured 30-550 m away from the marking sites. 14 of these were movements between reproduction sites and foraging sites or resting sites, respectively. The results suggest a small activity range and a metapopulation structure in both survey areas. Even though an exchange between the two study areas, which are separated by a 14 km gap without records of *S. depressiusculum*, could not be evidenced by recapture dates, an exchange is nevertheless very probable. This may be assumed by own accidental observations of *S. depressiusculum* at unsuitable reproduction sites at distances up to 6 km away from the next known breeding site and by records in literature with observations at distances up to 40 km around reproduction sites.] Address: Schiel, F.J., INULA, Turenneweg 9, 77880 Sasbach, Germany. **18702.** Svensson, E.I.; Runemark, A.; Verzijden, M.N.;

Wellenreuther, M. (2014): Sex differences in developmental plasticity and canalization shape population divergence in mate preferences. *Proceedings of the Royal Society B: Biological Sciences* 281: 9 pp. (in English) ["Sexual selection of high-quality mates can conflict with species recognition if traits that govern intraspecific mate preferences also influence interspecific recognition. This conflict might be resolved by developmental plasticity and learned mate preferences, which could drive preference divergence in populations that differ in local species composition. We integrate field and laboratory experiments on two calopterygid damselfly species with population genetic data to investigate how sex differences in developmental plasticity affect population divergence in the face of gene flow. Whereas male species recognition is fixed at emergence, females instead learn to recognize heterospecifics. Females are therefore more plastic in their mate preferences than males. We suggest that this results from sex differences in the balance between sexual selection for high-quality mates and selection for species recognition. As a result of these sex differences, females develop more pronounced population divergence in their mate preferences compared with males. Local ecological community context and presence of heterospecifics in combination with sex differences in plasticity and canalization therefore shape population divergence in mate preferences. As ongoing environmental change and habitat fragmentation bring formerly allopatric species into secondary contact, developmental plasticity of mate preferences in either or both sexes might facilitate coexistence and prevent local species extinction." **18703.** White, E.L.; Hunt, P.D.; Schlesinger, M.D.; Corser, J.D.; deMaynadier, P.G. (2014): A conservation status assessment of Odonata for the Northeastern United States. *New York Natural Heritage Program, Albany, NY: VI + 44 pp.* (in English) ["Executive Summary: Odonates are valuable biological indicators of freshwater ecosystem integrity and climate change. Approximately 18% of odonates in the US are considered rare and vulnerable to extirpation or extinction. Northeastern North America hosts a rich and ancient odonate fauna, especially for a temperate region. Recognition of northeastern North America as both a hotspot of odonate diversity, and a region of historical and growing threats to freshwater ecosystems, highlights the urgency of developing a comprehensive conservation assessment of the Northeast's resident odonate species. Here, we develop and apply a prioritization framework for 228 species of Odonata occurring in the northeastern US (Virginia to Maine). Specifically, we offer a modified version of NatureServe's methodology for assessing conservation status ranks by assigning a single, regional vulnerability metric (R-rank) reflecting each species' degree of relative extinction risk in the northeastern US. We combine this newly formulated vulnerability assessment with an updated analysis of the degree of endemism (% of the species' US and Canada range within the Northeast) as a proxy for regional responsibility, thereby deriving a list of species of combined vulnerability and regional management responsibility. In so doing our goals are two-fold:

a) to develop a credible list of odonate species of conservation concern in northeastern North America, and more generally, b) to invite scrutiny of a science-based species prioritization methodology that might be applied to assess other diverse taxa that have not yet received adequate conservation attention. We compiled all confirmed, county-level odonate data from all years. This dataset contained 248,059 records, with data from all NEAFWA states. We calculated a single vulnerability rank (R-rank) based on five factors: three rarity factors (range extent, area of occupancy, and habitat specificity), one threat factor (vulnerability of occupied habitats), and one trend factor (relative change in range size). This yielded a regional vulnerability rank (R-rank) for each species, ranging from R1 (most vulnerable) to R5 (least vulnerable). We calculated regional responsibility as the proportion of the US & Canadian range occurring within the Northeast US. Odonate species fell into three categories based on their responsibility calculation: „Primary“ responsibility species were those for which  $\geq 50\%$  of their range fell in the Northeast; „Significant“ responsibility species were those for which 25-50% of their range fell in the Northeast; and „Shared“ responsibility species were those for which  $< 25\%$  of their range fell in the Northeast. We created a matrix of species in three vulnerability categories (High: R1 and R2, Medium: R3, and Low: R4 and R5) and three responsibility categories (Primary, Significant, and Shared). We also present results on habitat associations for northeastern Odonata along with all metric components of our conservation assessment. Overall, 18% of our region's odonate fauna is imperiled (R1 and R2) and peatlands, low gradient streams and seeps, high gradient headwaters, and larger rivers that harbor a disproportionate number of these species should be considered as priority habitat types for conservation, monitoring, and management. We recommend that our assessment be used to inform the strategic allocation of limited state and federal conservation resources and help foster collaborations across state lines to implement similar goals for conserving regionally at-risk Odonata. We also anticipate our products will help guide and standardize conservation assessments of Odonata, and potentially other invertebrate taxa, at the statewide level in the Northeast. Finally, we recommend that a regional Odonata conservation working group be formed to help guide protocols for surveys, monitoring, research, habitat protection, and education, and thereby develop a framework for a coordinated comprehensive conservation plan for northeastern Odonata." **18704.** Wildermuth, H.; Schneider, B. (2014): Der Eisvogel *Alcedo atthis* als Libellenjäger (Aves: Alcedinidae; Odonata). *Libellula* 33(3/4): 127-148. (in German, with English summary) ["The Kingfisher *Alcedo atthis* as dragonfly hunter – The Common Kingfisher mainly feeds on small fish and to a lesser extent on aquatic arthropods caught by plunge-diving. As little is known about the Kingfisher's insect nutrition we investigated the captured prey on photos and video films and analysed the contents of pellets collected between March

and May in the years 2010-2014 at four riverine breeding sites along a 20 km stretch of the River Töss in the Swiss Plateau. Altogether we identified 273 insect prey items from more than 1,000 small cuticle fragments, comprising water bugs (Notonecta spp. and *Iliocoris cimicoides*, 62 %), Anisoptera (38.5 %) and Zygoptera (1.5 %). *Anax imperator* (mainly F0-stadia) constituted 49 %, *Orthetrum cancellatum* 31 % (mainly F1-stadia) and *Aeshna cyanea* 11.5 % (mainly F1-stadia) of the odonate prey, while *Calopteryx* sp., *Brachytron pratense*, *Onychogomphus forcipatus*, *Cordulegaster boltonii*, and *Libellula depressa* were only sporadically found. The number of odonate species and prey items differed greatly between the four sites, due to the availability of prey in the surroundings of the breeding burrows. The recorded insects mainly originated from ponds near the river (water bugs, five odonate spp.) and to a lesser extent from the river itself (*Calopteryx* sp., *O. forcipatus*, *C. boltonii*). The results are discussed with respect to the applied methods and identification problems as well as to the season and the local availability of food, the prey recognition of the Kingfisher, and the behaviour of the odonate larvae preyed on." **18705.** Yen, A.L. (2014): Insects as food and feed in the Asia Pacific region: current perspectives and future directions. *Journal of Insects as Food and Feed* 1(1): 33-55. (in English) ["Western cultures currently struggle to have insects accepted as a human food. This barrier is not as high in many parts of the Asia Pacific region because entomophagy is (or was until recent times) a part of their accepted diets. The region is comprised of many different cultural groups and the degree to which they embraced entomophagy has been determined by dietary needs, cultural considerations, and the availability of insects. While entomophagy has decreased in westernised societies, the demand for edible insects has increased in parts of Asia in association with rising standards of living. An assessment of the use of insects as food and feed in the Asia Pacific region is provided and important knowledge gaps are identified. Edible insects are sourced by three main strategies: wild harvesting, semi-domestication of insects in the wild, and farming. Semi-domestication and farming have the potential to provide a more sustainable food supply, but globally 92% of species are wild harvested. The harvested insects come from all trophic levels, although most of the terrestrial edible insect species are herbivores and most species of edible aquatic species are predators. The increased demand for edible insects puts pressure on the source populations because new technologies are now used to harvest insects more efficiently and to store them safely for longer periods, facilitating the harvesting of greater amounts of insects. This, in combination with either loss of natural habitats or changes to the environment, puts even more pressure on insect populations. The over harvesting of edible insects from different trophic levels could have long term adverse implications for ecosystem processes in Asia Pacific and other regions. ... For example, fish can indirectly facilitate terrestrial plant reproduction by reducing larval dragonfly abundances in ponds, leading to

fewer adult dragonflies nearby. Adult dragonflies consume insect pollinators and alter their foraging behaviour. As a result, plants near ponds with fish have more pollinators than plants near fish-free ponds. There could also be subtle ecological interactions between human and wildlife use of insects. In Thailand," (Author)] Address: Yen, A.L., Dept Economic Development, Jobs, Transport & Resources, Biosciences Research Division, AgriBio, 5 Ring Road, Bundoora, Victoria 3083, Australia. **18706.** Allen, B.T. (2015): Proximate behavioral and morphological mechanisms that may mediate intraguild predation stability in the Anisoptera. Ph.D., University of Texas at Arlington: 189 pp. (in English) ["Intraguild Predation (IGP) is a form of interference competition characterized by an intraguild predator consuming interspecific competitors, the intraguild prey. This interaction is extremely common in nature, but mechanistic and descriptive models usually predict that it is unstable with either the IG prey or IG predator becoming locally extinct, dependent on initial conditions. Only intermediate shared prey availability leads to IGP stability in these models, and this condition is not common. In this work, I used dragonfly nymphs to examine behavioural and morphological aspects of consumptive competition and predator avoidance that may act to stabilize IGP, particularly in systems with more than two predators. There are two primary hypotheses in this treatment. The first is that prey capture is morphologically mediated and that this leads to differences in diet composition that can promote IGP stability by allowing prey specialization. The second is that there is a behavioural tradeoff that leads to disproportionate feeding on competitively superior IG prey by an IG predator that may lead to IGP stability. This tradeoff was hypothesized to exist in terms of direct prey capture as well as movement and space use patterns. Both of these mechanisms were found to exist, with species variation in mortality being explained by their behaviour, in spite of morphological defenses compensating for the lack of behavioural defenses in some species. While effect of this possible mechanism on IGP stability was not directly examined, further long-term study should elucidate it." **18707.** Andem, A.B.; Esenowo, I.K.; Bassey, D.O. (2015): Application of biotic indices and pollution Tolerance Index in assessing macro-invertebrate assemblage of Ediba River, Cross River State, Nigeria. *Environmental & Analytical Toxicology S7*: 007. doi:10.4172/2161-0525.S7-007: 5 pp. (in English) ["The study of the macro-invertebrates community of Ediba River in Cross River State was carried out from October to December, 2014 using Pollution Tolerance Index (PTI). Macro-invertebrate fauna were sampled with sweeping net using kick sampling methods. 16 genera, belonging to 9 orders and a total of 289 individuals were encountered. The dominant groups in the order were Oligochaeta

(29.1%)>Diptera (24.62%)>Odonata (20.3%), showing insignificant difference between the three stations at  $p>0.05$ . Taxa richness was highest in Station 1 (2.985) and least in Station 3 (1.008) showing insignificant differences across station ( $p>0.05$ ). Evenness ranges from 0.337 to 0.369 showing significant difference across stations ( $p<0.05$ ). Station 1 had a PTI value of 39 indicating good quality water status, while Stations 2 and Station 3 had PTI values of 6 and 4 respectively indicating poor quality water status. The abundance of pollution tolerance species of the orders, Odonata Zygoptera, Oligochaeta, Diptera and the absence of pollution sensitive species of the orders, Ephemeroptera and Trichoptera in Stations 2 and 3 indicated the poor waters quality, coupled with the low PTI values in both stations, hence need for proper management of the river." **18708.** Beadle, J.M.; Brown, L.E.; Holden, J. (2015): Biodiversity and ecosystem functioning in natural bog pools and those created by rewetting schemes. *WIREs Water* 2015. doi: 10.1002/wat2.1063: 20 pp. (in English) ["Anthropogenic drainage and cutting over of peatlands have historically occurred worldwide leading to erosion, issues with water quality, loss of biodiversity, and reduced rates of carbon accumulation. In recent years, rewetting measures have attempted to address these issues. Creating dams to block drainage ditches on peatlands is a common restoration tool, yet the ecological consequences of such management interventions are poorly understood. In particular, knowledge about the ecology of the thousands of pools created by drain blocking is limited even though they potentially provide valuable new habitat for aquatic species and food and water sources for terrestrial organisms. More research is needed to assess the suitability of these artificial pools as surrogates for naturally occurring peat pools with regard to the flora (e.g., bryophytes, algae, and macrophytes) and fauna (e.g., invertebrates and amphibians), which utilize them. Evidence suggests that (1) to maximize benefits to aquatic biota, land managers should consider creating an array of differently sized pools behind the dams as a broader size range would facilitate colonization by a wider range of taxa, (2) prioritizing landscapes close to existing water bodies would encourage faster colonization, and (3) even newly created pools with low macrophyte cover may be able to sustain substantial populations of larger fauna via algal primary production, consumption of detritus, and microbial processing of humic substances and methane. Ongoing programs of peatland restoration worldwide also afford unique opportunities to study how pool communities assemble and change over time." (Authors) The study includes references to Odonata.] Address: Beadle, Jeannie, School of Geography, University of Leeds, Leeds, UK, School of Geography, University of Leeds, Leeds, UK. e-mail: ill2jmb@leeds.ac.uk

**18709.** Bechly, G. (2015): Fossile Libellennachweise aus Deutschland (Odonoptera). *Libellula Supplement* 14: 423-464. (in German, with English summary) ["Fossil odonate records from Germany (Odonoptera) – A historical

sketch of the research on fossil dragonflies from Germany is provided, together with a commented list of all localities and discovered taxa, supplemented by a complete bibliography. The deposition of the fossil material is specified as well. The oldest fossils stem from the Carboniferous, and the youngest ones from the Pleistocene. The largest number of fossil dragonflies was found in Jurassic and Tertiary sediments. Only from the Cretaceous and the Paleocene have no fossils yet been discovered." **18710.** Biodrawersity (2015): Relicensing Study 3.3.10. Assess operational impacts on emergence of state-listed odonates in the Connecticut River. Interim Study Report. Northfield Mountain Pumped Storage Project (No. 2485) and Turners Falls Hydroelectric Project (No. 1889). Prepared for: FirstLight: 26 pp. [3.1 Odonate Survey Results: 3.1.1 Species Assemblage: Table 3.1.1-1 lists the genera and species collected at each site. *Epithea princeps*, a species common in lentic habitats, was the most common species collected at Sites 1-3. These sites in the lowermost portion of the Turners Falls Impoundment (Barton Cove) contain mostly lentic habitat with submerged and emergent vegetation. Sites 4-8 were generally more lotic; dominant taxa in these samples included *Gomphus* sp. (mostly *G. vastus*), *Ophiogomphus* (mostly *G. rupinsulensis*), *N. yamaskenensis*, *Boyeria vinosa*, and *Macromia illinoensis*. There was very little variation in the odonate assemblage among sites 4-8. Species-level identification of some of the Gomphidae, especially *Gomphus* sp. and *Ophiogomphus* sp., is incomplete; this interim report will be updated when these data become available. Most of the target state-listed species for Sites 4-8 were in the genus *Gomphus*. Based on historic survey data, which were generally more complete for the Turners. 3.1.2 Emergence and Eclosure: Approximately 250 exuviae were collected across the eight survey sites. These were found on emergent aquatic vegetation only at sites 1 and 3, as this type of emergence substrate was not available at the other sites. Elsewhere, exuviae were found primarily on terrestrial herbaceous vegetation, soil, trees, coarse fallen wood, and rock (Table 3.1.2-1). They were found as high as nine feet above the water's surface (mean = 4.4) and as far as 42 ft from the edge of the water (mean = 12.7). Since these surveys were qualitative and only occurred during the month of June, these distances above the water and from the water's edge are biased, but do provide a range to consider in the next phase of work. 3.2 Habitat Characterization: Habitat parameters recorded at each site are provided in Table 3.2-1, and representative photographs are provided in Appendix A. The most common habitat feature of nearshore areas and streambanks was a muddy slope of varying steepness, with lesser and variable amounts of sand, gravel, or cobble. Upslope, this mud transitioned into the riparian zone that was typically vegetated with trees (especially silver maple), low terrestrial herbaceous vegetation, moss, and vines, and contained varying amounts of large woody debris and detritus. The odonate surveys were typically done during periods of low flow, therefore relatively large amounts of the

muddy bank were exposed and the distance from the water line to the interface between aquatic and terrestrial habitat was relatively great. Less common nearshore habitat types included aquatic emergent vegetation and rock. Aquatic emergent vegetation was prevalent only in the more lentic habitats of Barton Cove (Site 1) and on the other side of Campground Point (Site 3). Elsewhere, aquatic emergent vegetation was either absent, or existed as a very sparse fringe of species that can tolerate daily exposure. Submerged aquatic vegetation, especially *Vallisneria*, was common in some areas but typically only as a narrow band in deeper waters. Bare rock, an emergence substrate for odonates, is uncommon in the Connecticut River between the Deerfield River confluence and Route 116 Bridge. There are some isolated ledge outcrops, and the bridge abutments and areas near bridges often contained higher amounts of "unnatural" rock. The most "natural" rock is located in the Turners Falls bypass reach." (Author)] Address: not stated

**18711.** Blanckenhagen, B. von (2015): Die Arktische Smaragdlibelle *Somatochlora arctica* (Zetterstedt, 1840) im Burgwald: Verbreitung und Anmerkungen zur Ökologie. Libellen in Hessen 8: 39-52. (in German) [The distribution of *S. arctica* in the Burgwald (Hessen, Germany) was mapped in summer 2014 with the help of exuviae collections and supplementary larval surveys. The survey focused on six FFH sites and adjacent areas with fens and transitional bogs as well as dystrophic ponds and their siltation zones. Ten subpopulations were documented with a total of 125 exuviae. The Lange Grund, the Franzosenwiesen and the Christenberger Talgrund are the distribution centres of *S. arctica* in the Burgwald. In addition, the habitats occupied, the association with other dragonfly species and possible predators are described. The occurrence has a nationwide significance and a high value in the context of the disjunct Central European occurrences north of the Alps." **18713.** Burmester, T. (2015): Evolution of respiratory proteins across the Pancrustacea. *Integrative and Comparative Biology* 55(5): 792-801. (in English) [Respiratory proteins enhance the capacity of the blood for oxygen transport and

support intracellular storage and delivery of oxygen. Hemocyanin and hemoglobin are the respiratory proteins that occur in the Pancrustacea. The copper-containing hemocyanins evolved from phenoloxidases in the stem lineage of arthropods. For a long time, hemocyanins had only been known from the malacostracan crustaceans but recent studies identified hemocyanin also in Remipedia, Ostracoda, and Branchiura. Hemoglobins are common in the Branchiopoda but have also been sporadically found in other crustacean classes (Malacostraca, Copepoda, Thecostraca). Respiratory proteins had long been considered unnecessary in the hexapods because of the tracheal system. Only chironomids, some backswimmers, and the horse botfly, which all live under hypoxic conditions, were known exceptions and possess hemoglobins. However, recent data suggest that hemocyanins occur in most ametabolous and hemimetabolous insects. Phylogenetic analysis showed the hemocyanins of insects and Remipedia to be similar, suggesting a close relationship of these taxa. Hemocyanin has been lost in dragonflies, mayflies, and Eumetabola (Hemiptera + Holometabola). In cockroaches and grasshoppers, hemocyanin expression is restricted to the developing embryo while in adults oxygen is supplied solely by the tracheal system. This pattern suggests that hemocyanin was the oxygen-transport protein in the hemolymph of the last common ancestor of the pancrustaceans. The loss was probably associated with miniaturization, a period of restricted availability of oxygen, a change in life-style, or morphological changes. Once lost, hemocyanin was not regained. Some pancrustaceans also possess cellular globin genes with uncertain functions, which are expressed at low levels. When a respiratory protein was again required, hemoglobins evolved several times independently from cellular globins. ... Hemocyanin has been lost in dragonflies, mayflies, and Eumetabola (Hemiptera + Holometabola). ... 2). No Hc was found in Protura, Diplura, Ephemeroptera (mayflies), Odonata (dragonflies and damselflies), or Eumetabola (Hemiptera and Holometabola)" (Author)] Address: Burmester, T., Inst. **18714.** Chavez, M.Y.; Mabry, K.E.; McCauley, S.J.; Hammond, J.I. (2015): Differential larval responses of two ecologically similar insects (Odonata) to temperature and resource variation. *International Journal of Odonatology* 18(4): 297-304. (in English) ["How species respond to shifting environmental conditions is a central question in ecology, especially because ecosystems are experiencing rapidly changing climatic conditions. However, predicting the responses of species interactions and community composition to changing conditions is often difficult. We examined the effects of rearing temperature and resource level on larval survival of two ecologically similar dragonflies, *Erythemis collocata* and *Pachydiplax longipennis*. Within high and low (26 and 21°C) temperatures, we crossed species and resource level and reared larvae individually. We predicted that warmer temperatures would reduce survival and increase growth rate, that higher resource availability would increase survival and growth rate, and that the two species would respond similarly. We

found that increased temperature reduced survival for both species. There was also an interaction between temperature and species: *E. collocata* had higher survival at the lower temperature, but lower survival at the higher temperature when compared to *P. longipennis*. Resource level did not affect survival. In general, *P. longipennis* grew more than *E. collocata*, with no effects of temperature or resource level. These results suggest that these species respond dissimilarly to changing thermal conditions, that increased food availability cannot always compensate for the negative effects of higher temperatures, and that climate change may affect interactions between these two sympatric, ecologically similar species, with potential consequences for community composition." (Authors)] Address: Hammond, J.I., Dept of Biology, University of New Mexico, Albuquerque, NM, USAEmail: jhammo02@unm.edu

**18715.** Chovanec, A. (2015): Bewertung der Renaturierungsmaßnahmen in den Mündungsbereichen von Leitenbach und Sandbach sowie an der Aschach (Oberösterreich) aus libellenkundlicher Sicht. Im Auftrag des Amtes der Oberösterreichischen Landesregierung, Abt. Oberflächengewässerswirtschaft: 73 pp. (in English) ["In the present study, the ecological status of the renaturalised estuary sections of the Leitenbach and Sandbach as well as the Aschach in this area was assessed from a dragonfly point of view, with special consideration of the morphological conditions. This was done on the basis of the Dragonfly Association Index and was based - in accordance with the requirements of the Water Framework Directive and the Water Act - on a comparison between a water body type-specific reference condition and the status quo. A total of 25 species were detected in the study area, which corresponds to 32 % of the spectrum of 78 species occurring in Austria; 21 species were native to the soil. On the Leitenbach 23 species were found (20 of them native), on the Sandbach 16 (14) and on the Aschach also 16 (11). The high number of rheobiont and rheophilous species (*Calopteryx splendens*, *Calopteryx virgo*, *Platycnemis pennipes*, *Gomphus vulgatissimus*, *Ophiogomphus cecilia*, *Onychogomphus forcipatus*, *Orthetrum brunneum*) should be emphasised. *G. vulgatissimus*, *O. cecilia* and *O. forcipatus* are "endangered" according to the Red List for Austria. *O. cecilia* is listed in Annexes II and IV of the EU Habitats Directive. All three stretches of water were classified in class 1 "very good dragonfly ecological status". **18716.** Coccia, C. (2015): Invasion biology of *Trichocorixa verticalis* in Doñana, SW Spain . PhD dissertation, Univ. of Seville: 208 pp. (in English, with Spanish summary) ["Biological invasions are one of the top threats to biodiversity and ecosystem functioning worldwide, and fresh waters are among the most invaded ecosystems in the world. To be successful, an invader must possess qualities that allow invasion in the new habitat, but besides these qualities its success also depends on the interactions between its traits, the traits of the invaded community, and many other contingent

factors. A recent addition to the list of alien invertebrate species in European fresh waters is the North American *Trichocorixa verticalis* (Hemiptera: Corixidae). To date, *T. verticalis* is the only established alien waterbug in these ecosystems. In the 18 years since its first detection in the Iberian Peninsula, *T. verticalis* has increased its area of distribution in and around Doñana, in the Guadalquivir delta, and also in other areas of conservation interest including Ramsar wetlands and Nature Reserves in Andalucía. In general, it is highly dominant and abundant in permanent saline waters, where native Corixidae are rare, but it is rare in fresh waters, where native Corixidae dominate. This thesis focuses on four main determinants of successful invasions (plasticity, resource competition, parasites and facilitative interactions among invaders) to investigate why *T. verticalis* dominates in saline waters while it is rare in fresh waters. In addition, we explored the success of a restoration project for macroinvertebrates in new ponds where *T. verticalis* is known to be an abundant breeder. In addressing these topics, we apply an invasive-native comparative approach to both experimental and field data collected in Doñana. In Chapter 1 we show experimentally that *T. verticalis* possesses broader physiological plasticity than native corixids when exposed to different conditions of temperature and salinity, and its physiological tolerance to both heat and freezing increases following exposure to high conductivities. In Chapter 2 we investigate the niche partitioning between native and invasive corixids from different ecosystems by means of carbon (C) and nitrogen (N) stable isotopes. We reveal strong resource partitioning between species in permanent ponds, but also some degree of niche overlap in unstable temporary sites. In Chapter 3 we describe the role of parasite infections during the invasion. *T. verticalis* show higher total parasite (water mite) prevalence, mean total abundance infection and mean infection than native corixids in low salinity waters, whereas mites are not present in saline waters. In Chapter 4 we examine experimentally the role of facilitative interactions among invaders. *T. verticalis* invasion does not seem to be promoted by a lower predation rate by alien predators compared to native corixids. In contrast, owing its smaller size it suffers higher predation rates by Odonata larvae. Finally, in Chapter 5 we investigate the value of the Caracoles restoration project in supporting aquatic macroinvertebrates. *T. verticalis* is known to be an abundant breeder in these ponds. We find that, although new ponds differ from reference sites in abiotic conditions, they become representative and even surpass the levels of local invertebrate richness, diversity and abundance 6-7 years after restoration. However, differences in the abundance and distribution of invasive species between waterbody types and inundation periods may have strong effects on the patterns of species composition, especially for the Hemiptera. The integration of these results sheds light on the role of salinity for the invasion success of *T. verticalis*, and helps to elucidate why it is still rare in fresh waters. In addition, we also provide important insights on the potential impacts that *T. verticalis* may have on native Corixids in the future. ... Using laboratory experiments, we compared the predation rates by the two exotic fish and native Odonata larvae on *Trichocorixa* and the native *Sigara*

*lateralis*. We found no evidence to suggest that *T. verticalis* suffers lower predation rates. However, when both corixids were mixed together, predation of *T. verticalis* by Odonata larvae was higher. Odonata larvae were size-limited predators and the proportion of corixids ingested was positively correlated with mask length. Since *T. verticalis* is smaller than its native competitors, this may explain their higher susceptibility to predation by Odonata. This may be one of various factors explaining why *T. verticalis* is particularly dominant in saline habitats where Odonata are rare, while it is still scarce in fresh waters." **18717.** Crucitti, P.; Brocchieri, D.; Bubbico, F.; Castelluccio, P.; Emiliani, F.; Francioni, G.; Tringali, L. (2015): Check-list di gruppi selezionati dell'entomofauna dell'area "Arcipelago Mentanese-Comicolano" (Lazio). Bollettino della Società Entomologica Italiana 147(1): 3-29. (in Italian, with English summary) ["A check-list of the species of certain groups of insects - Odonata [26 species, including *Trithemis annulata*, *Sympetrum meridionale*, *Somatochlora meridionalis*, *Coenagrion castellani*], Mantodea, Orthopteroidea, Coleoptera and Lepidoptera - observed in the so called "Mentanese-Comicolano Archipelago" a district of the Roman Campagna, north-east from Rome city area (Latium, Central Italy), a relic of mesoxerophilous woods with cultivated land, urban and suburban areas penetrated by infrastructures, is presented. Typical physiographical aspects of the landscape are hilly areas with small valleys of clayey volcanic terrains or limestone rocks with karstic features. Notwithstanding conservation measures - two protected areas administered by the Province of Rome, the Natural Reserve "Nomentum" and the Natural Reserve "Macchia di Gattaceca and Macchia del Barco", exist - little is known about its invertebrate fauna, especially insects. Irregular observations lasted for over ten years followed by intensive researches between 2009 and 2013 with the utilization of many, direct and indirect, collecting tools - nets, aspirators, pitfall and aerial traps, light sheets - together with bibliographical data, allowed the authors to survey 422 species. Biogeographical analysis has been limited to Odonata and Coleoptera Carabidae well represented in the samples, especially in comparison with the insect fauna of the Rome city area restricted by the Grande Raccordo Anulare ring freeway. Species of particular interest from conservational viewpoints are discussed. This check-list is necessarily incomplete and lacking of quantitative analysis, notwithstanding the results of collecting efforts suggest that species richness has been strongly reduced in recent time. From conservational viewpoint, the situation of the Natural Reserve "Nomentum" may be considered middling while the situation of the Natural Reserve "Macchia di Gattaceca and Macchia del Barco" may be considered moderate (Macchia di Gattaceca) or fairly good (Macchia del Barco). The current inadequacy of protection measures is critical, considering the relevant entomological importance of some patches of this landscape." (Authors)] Address: Crucitti, P., Soc. **18720.** Fulan, J.; Rodrigues dos Anjos, M. (2015): Predation by *Erythemis* nymphs (Odonata) on Chironomidae (Diptera) and Elmidae (Coleoptera) in different conditions of habitat complexity. *Acta Limnologica Brasiliensia* 27(4): 454-458. ["Aim: The goal of this study was to analyze the effects of predation by nymphs of *Erythemis* Hagen, 1861 on Elmidae and Chironomidae and to check if the presence and the architecture of aquatic macrophytes may mediate this interaction. Methods: All prey as well as nymphs were captured near macrophytes in a small lagoon alongside a highway near Humaitá, Amazonas, Brazil. Twelve buckets were used in three different treatments: with *Pistia stratiotes* Linnaeus, 1753, with *Salvinia auriculata* Aublet and without macrophytes. Results: We found a mortality rate of 100% of Chironomidae and Elmidae larvae in the treatment without macrophytes. There was a greater survival of Elmidae compared to Chironomidae in the treatments with *P. stratiotes* and *S. auriculata*; however, there was a greater survival of both preys on treatment with *P. stratiotes*. Conclusions: We conclude that the presence of macrophytes decreased the efficiency of predation of *Erythemis* nymphs under experimental conditions. The architecture of macrophytes affected

predation as macrophytes with longer roots and with greater habitat complexity promoted a greater survival of prey." (Authors)] Address: Fulan, J.A., Universidade Federal do Amazonas – UFAM, Rua 29 de agosto, 786, CEP 69800-000, Humaitá, AM, Brazil. E-mail: joaofulan@hotmail.com

**18723.** Gomez-Anaya, J.A.; Novelo-Gutierrez, R. (2015): A case of successful restoration of a tropical wetland evaluated through its Odonata (Insecta) larval assemblage. *Rev. Biol. Trop.* 63(4): 1043-1058. (in English, with Spanish summary) ["Wetlands are important wildlife habitats that also provide vital services for human societies. Unfortunately, they have been disappearing due to human activities such as conversion to farmland, pollution, habitat fragmentation, invasion of alien species, and inappropriate management, resulting in declines in species diversity, wildlife habitat quality, and ecosystem functions and services. In some countries,

many programs and actions have been undertaken to reverse the rate of wetland loss by restoring, creating and constructing new wetlands. We report on the assessment of Odonata larvae from a tropical and putatively restored wetland located in the La Mancha Biological Station, CÍCOLMA (LM, Ramsar site #1336), Veracruz, Mexico. Larval surveys were performed during the 2010 and 2011 dry and rainy seasons in both LM and a reference site, Cansaburro (CB), located approximately 2 km South of LM. Twelve samples were collected during each survey using a D-frame aquatic net (0.2 mm mesh size), sweeping 1 m<sup>2</sup> areas along shorelines using a random design. The effect of site, season and year on Odonata larval abundance was explored and diversity and abundance patterns of the assemblages were compared. A total of 3 718 larvae from 25 species (five Zygoptera and 20 Anisoptera) in 14 genera and three families were collected from both wetlands. Species number was equal in both wetlands although abundance was significantly higher in LM. Renyi's diversity profiles and species abundance patterns (rank abundance curves) in both sites were similar, suggesting an apparent recovery at LM. Differences in species composition (sites shared 13 species), and species dominance between both assemblages were observed and were related to differences in the aquatic plant structure between both wetlands as a result of extensive plant management in LM and cattle grazing in CB. Most evidence derived from this work shows that the LM wetland may be recovered." **18724.** Happel, A.; Lafountain, J.; Creque, S.; Rinchard, J.; Höök, T.; Bootsma, H.; Janssen, J.; Jude, D.; Czesny, S. (2015): Spatio-temporal description of spottail shiner (*Notropis hudsonius*) fatty acid profiles in Lake Michigan's southern basin Austin. *Journal of Great Lakes Research* 41: 179-184. (in English) ["On-going ecosystem alterations within Lake Michigan have drastically transformed species interactions and food-web assembly. Description of trophic interactions across broad spatial regions is likely necessary to fully appreciate the structure of this emerging food web. Spottail shiners, *Notropis hudsonius*, are numerically abundant in the nearshore zone of Lake Michigan, but their trophic interactions are under-described. To that end, we described fatty acid profiles of spottail shiner through spring, summer, and fall across western and eastern shorelines of Lake Michigan's southern basin. Fatty acids, used as dietary tracers, suggested a shift from benthic-based diets in spring to more pelagic-associated diets in summer and a reversal in fall. When time lag of fatty acid accumulation is accounted for in interpretations, diets likely follow spring plankton and summer/fall benthic invertebrate maxima. Fatty acid profiles also indicated differences in diet composition based on geographic location, with benthic tracers more prevalent among spottail shiner inhabiting the western shoreline. These interpretations were generally supported by stomach content data, with high Chironomidae consumption in spottail shiners

from western waters. The presence of Coleoptera, Hymenoptera, and Odonata in spottail shiner stomach contents throughout the lake highlights its reliance on nearshore and potentially inshore areas. This study offers one of the most spatially broad depiction of spottail shiner foraging habits in Lake Michigan." The concept is inspired by blood circulation in insect wings. The blood flowing in veins induces Coriolis forces in the flapping wings. The Coriolis forces acting on veins are of opposite directions when blood flows in and out. The opposite Coriolis forces generate torsional moment to the wing, especially in the leading-edge part. To estimate the time-varying torque induced by the blood circulation, a simplified U-tube model is designed. A three-dimensional finite element model of the wing is developed to analyze the dynamic behaviors under this torque. The dragonfly wing is in favor of torsional deformation because the corrugated structure is of high flexural rigidity in the spanwise direction but is of low torsional rigidity in the chordwise direction. In both the downstroke and upstroke, the twist of the leading-edge part causes the sections to camber spontaneously. Such a kind of deformation is found to be of great importance to improve aerodynamic efficiency. In addition, it also compensates for the disadvantageous bending deformation caused by air pressure in flapping flight. These results are important for better understanding of the multifunctional structures of dragonfly wings and may give some inspiration to the bionics of flapping-wing micro air vehicles (FMAVs)." **18729.** Jisha Krishnan, E.K.; Sebastian, C.D. (2015): Evolutionary divergence and phylogenetic relationships of selected dragonflies using cytochrome oxidase I gene. Proceedings of International Conference on Biodiversity & Evaluation: Perspectives and Paradigm shifts 2015: 227-229. (in English) ["Dragonflies are candidates among ancient flying insects existed in the carboniferous period. Libellulidae is the largest and cosmopolitan dragonfly family of the order Odonata. Here we assessed the phylogenetic relationships of 5 dragonfly members (*Rhyothemis variegata*, *Acisoma panorpoides*, *Orthetrum sabina*, *Anaciaeschna jaspidea* and *Trithemis pallidinervis*) using cytochrome oxidase I (COI) marker. The partial PCR product of this gene yielded 450bp, 479bp, 500bp, 591bp and 580bp DNA respectively. The nucleotide BLAST analysis confirmed the taxonomic identity of these entire species. Phylogenetic tree constructed by Neighbour joining method showed that Libellulidae members are having a monophyletic ancestry due to the divergence from a common ancestor. Among these members, *Orthetrum sabina* is sharing a sister clade relationship with *T. pallidinervis* which remained in the same clade and *R. variegata* with *A. jaspidea* in another clade. The average A+T content of all these species is 66.26% while G+C content is 33.74% showing a strong A+T bias. The nucleotide substitution analysis states that *A. panorpoides*, has the highest substitution rate followed by *R. variegata*, *A. jaspidea*, *O. sabina* and *T. pallidinervis*. The high A+T content along with second codon change reflects evolutionary divergence of all these species. Thus the present study concluded that cytochrome oxidase I is an effective tool for predicting phylogenetic relationships and evolutionary divergence of closely related species." **18730.** Korichi, R.; Bouzid, A.; Zehani, A.; Hammadi, Z.; Korichi-Almi, A. (2015): La diversité de l'odonatofaune dans deux biotopes sahariens. 2eme Seminaire International sur la Biodiversite Faunistique en Zones Semi arides Et Arides, 29 & 30 Novembre 2015: 29-30. (in French) [Verbatim

translated to English: "The objective of research on biotic indicators is to provide tools that allow the characterisation of the evolution of the ecological state of ecosystems over time. At the ecosystem level, we can examine the structure of communities or look at processes, structures and the landscape. These are known as ecological indicators. Odonates are useful and usually protected ecological indicators and any attempt to address them should take this special status into account and therefore only take from nature what is strictly needed in a rational approach. However, few studies have taken this group of predatory insects into account, even fewer have taken the trouble to establish temporal monitoring in Saharan regions and in all seasons. The objective of the present study is to characterise the population of odonates (Insecta) in some Saharan biotopes. The draft addresses the specific inventory in a spatio-temporal context through several stations, disturbed or not, reflecting the wetland but especially the palm grove in two regions, Djamaa and Ouargla (northern Sahara) known for these two particular ecosystems. The survey and inventory continued for 11 months at a monthly rate in 6 stations including 2 wetlands (Chott d'Ain Beida in Ouargla and Lake Ayata in Djamaa), 4 palm groves (Chemora, Ain Choucha, Chriâa in Djemâa and the I.T.A.S. palm grove in Ouargla). The trapping of adults or imagos is done with a mowing net and similar tools, whereas the trapping of larvae is done with a net. In addition, the diet is analysed by recovering the faeces when the individuals are captured. Finally, some bioecological aspects are discussed. The inventory reveals the presence of 22 species of odonates in the two biotopes, the majority of which are found in the palm grove. The species inventoried are divided into two suborders: 15 Anisoptera (dragonflies) and 7 Zygoptera. The values of the Shannon-Weaver diversity index fluctuate between 1.52 bits and 2.58 bits and those of the equitability are close to 1. With regard to diet, it should be noted that the total richness of the prey species examined shows the presence of 14 orders of insects." (Authors; DeepL)] Address: Korichi, R., Dép. **18731.** Kovács, T.; Horváth, R.; Juhász, P. (2015): Study of dragonflies and caddisflies (Insecta: Odonata, Trichoptera) on Batanta Island (Indonesia, West Papua). *Annls Mus. hist.-nat. hung.* 107: 269-288. (in Bilingual in Hungarian and English) ["Research of water insects on Batanta Island of the Raja Ampat archipelago in Indonesia started in 2010 with UV light trapping of caddisflies. Soon it turned out that the fauna of the island is extremely rich and many species are still need to be described. In 2014 the research continued with new methods and the scope had been widened to mayflies and dragonflies. In this article the authors summarize their experience and results. The data confirm that Batanta Island is a unique area of freshwater endemism." **18732.** Lewis, T.L.; Lindberg, M.S.; Schmutz, J.A.; Bertram, M.R.; Dubour, A.J. (2015): Species richness and distributions

of boreal waterbird broods in relation to nesting and brood-rearing habitats. *The Journal of Wildlife Management* 79(2): 296-310. (in English) ["Identification of ecological factors that drive animal distributions allows us to understand why distributions vary temporally and spatially, and to develop models to predict future changes to populations—vital tools for effective wildlife management and conservation. For waterbird broods in the boreal forest, distributions are likely driven by factors affecting quality of nesting and brood-rearing habitats, and the influence of these factors may extend beyond single species, affecting the entire waterbird community. We used occupancy models to assess factors influencing species richness of waterbird broods on 72 boreal lakes, along with brood distributions of 3 species of conservation concern: lesser scaup (*Aythya affinis*), white-winged scoters (*Melanitta fusca*), and horned grebe (*Podiceps auritus*). Factors examined included abundance of invertebrate foods (Amphipoda, Diptera, Gastropoda, Hemiptera, Odonata), physical lake attributes (lake area, emergent vegetation), water chemistry (nitrogen, phosphorus, chlorophyll a concentrations), and nesting habitats (water edge, non-forest cover). Of the 5 invertebrates, only amphipod density was related to richness and occupancy, consistently having a large and positive relationship. Despite this importance to waterbirds, amphipods were the most patchily distributed invertebrate, with 17% of the study lakes containing 70% of collected amphipods. Lake area was the only other covariate that strongly and positively influenced species richness and occupancy of scaup, scoters, and grebes. All 3 water chemistry covariates, which provided alternative measures of lake productivity, were positively related to species richness but had little effect on scaup, scoter, and grebe occupancy. Conversely, emergent vegetation was negatively related to richness, reflecting avoidance of overgrown lakes by broods. Finally, nesting habitats had no influence on richness and occupancy, indicating that, at a broad spatial scale, brood distributions are largely driven by the presence of quality brood-rearing lakes, not nesting habitats. Our findings are relevant to generating conservation plans or management goals; specifically, boreal lakes with abundant amphipods and surface areas >25 ha are important habitat for waterbird broods and merit conservation, especially given the patchy distribution of amphipods. Moreover, these high quality brood-rearing lakes are much rarer, and thus more constraining, than are quality nesting habitats, which are likely abundant in the boreal." **18733.** Li, Y.-y.; Zhang, D.-z. (2015): The species diversity and fauna of Odonata in Ningxia Lingwu Baijitan National Nature Reserve. *Journal of Environmental Entomology* 37(3): 492-497. (in Chinese, with English summary) ["From 2010 to 2013, the Odonata diversity were surveyed in Ningxia Lingwu Baijitan National Nature Reserve. A total of 305 specimens were collected. 13 species of 9 genera in 3 families were identified. 9 species of 6 genera in 2 families were belonged to Anisoptera and 4 species of 3 genera in one family were belonged to Zygoptera. Coenagrionidae (3 genera and

4 species) and Libellulidae (5 genera and 7 species) were dominant families. *Ischnura elegans*, *Sympetrum frequens* and *Pantala flavescens* were dominant species. The ratio of total genera and species was 0.692, monotypic genus accounted for 66.67% of total genera. Most species markedly presented the characters of Palaearctic Region in world geographical distribution. Palaearctic Region species accounted for 46.15% of total species and Polytopic species accounted for 30.77%. In the zoogeographic of China, the fauna can be divided into 8 distribution patterns. The seven type distribution was predominant type (accounted for 38.46%), followed by the four type distribution and five type distribution. The six type distribution had only one. The single type distribution, two type distribution and three type distribution were absent. It was showed that the relationship and composition of fauna of Odonata were more complicated in Ningxia Lingwu Baijitan National Nature Reserve." (2015): Evolution of endemism on a young tropical mountain. *Nature* 524: 347-350, Suppl.. (in English) ["Tropical mountains are hot spots of biodiversity and endemism1–3, but the evolutionary origins of their unique biotas are poorly understood4. In varying degrees,

local and regional extinction, long-distance colonization, and local recruitment may all contribute to the exceptional character of these communities<sup>5</sup>. Also, it is debated whether mountain endemics mostly originate from local lowland taxa, or from lineages that reach the mountain by longrange dispersal from cool localities elsewhere<sup>6</sup>. Here we investigate the evolutionary routes to endemism by sampling an entire tropical mountain biota on the 4,095-metre-high Mount Kinabalu in Sabah, East Malaysia. We discover that most of its unique biodiversity is younger than the mountain itself (6 million years), and comprises a mix of immigrant pre-adapted lineages and descendants from local lowland ancestors, although substantial shifts from lower to higher vegetation zones in this latter group were rare. These insights could improve forecasts of the likelihood of extinction and 'evolutionary rescue'<sup>7</sup> in montane biodiversity hot spots under climate change scenarios." **18736.** Mikolajczuk, P. (2015): The next new sites and ecological data of *Nehalennia speciosa* (Charpentier, 1840) (Odonata: Coenagrionidae) from Central Eastern Poland. *Odonatrix* 11(1): 1-20. (in Polish, with English summary) ["The paper discusses the records of 10 new sites of *Nehalennia speciosa* in east-central Poland. Sites 4–6 and 7 are located in the landscape more or less agriculturally transformed converted and do not have continuous forest buffering zone. In Poland, the habitat of *N. speciosa* without the typical continuous forest buffering zone have been previously known only from a few sites so far. Data in this study indicates that their number is probably higher in Poland than previously thought. A relatively low trophy of peat bog and pools despite the agricultural use of their catchment area probably results from the presence of aeolian/poor fluvioglacial sands in the ground. Identified habitats of *N. speciosa* mostly refer to acidic fens with abundant *Sphagnum* (sites 1–3, 5, 7, 10), and acidic fens without or small amount of *Sphagnum* (sites 4, 6, 8, 9). Particular fragments of habitats occupied by *N. speciosa* were situated near open surface of water bodies (sites 1, 3, 4, and probably a few more) as well as far from the influence of water bodies, as a shallow flooded peat bog (sites 2, 5, 6–10 and probably at others at some places). Water bodies at sites 1–3, 6, 7 and probably 5 had peat excavation origins. Formations of helophytes inhabited by *N. speciosa* (with probable or confirmed larval development) can be divided into two groups – monospecies formations: *Juncus effusus* (sites 3, 4, 5, 10), *Carex rostrata* (sites 1, 4), *Carex elata* (sites 6, 9), *Carex lasiocarpa* (site 6), *Carex vesicaria* (site 9); and mixed ones (where space structure is formed by two helophyte species): *J. effusus* + *C. rostrata* (sites 2, 4), *J. effusus* + *C. vesicaria* (site 10), *C. elata* + *C. lasiocarpa* (sites 6, 9), *C. lasiocarpa* + *J. effusus* (site 7), *C. rostrata* + *C. lasiocarpa* (site 2), *C. lasiocarpa* + *Eriophorum angustifolium* (site 8). The formation of *J. effusus* with larval development has been found for the first time in Poland. *C. elata* as the leading plant element was known so far only from two sites discovered after 2009 as well as *C. vesicaria*.

Data in this paper and other recent records of *N. speciosa* in old glacial areas show that the elements different than *Carex limosa/lasiocarpa* are more often inhabited in Poland than it was given in older data. Secondary habitats as well seem to be inhabited more often. The occurrence of imagines was also found within shallow and temporarily flooded marginal zones of peat bogs; at site 3 also at land. Larval development was not found in those zones. Vegetation used by imagines at the discussed marginal zones consisted of *J. effusus*, *Eriophorum vaginatum*, *Carex canescens*, however, mainly: *Molinia caerulea*, *Glyceria fluitans* as well as short grass unidentified to the species level. At sites 1–3, 4, 9, imagines at marginal zones occurred at higher densities than in the zones of larval development (maximum: up to 20 individuals per 1 m<sup>2</sup> at site 3). Perhaps it is caused by favourable microclimatic conditions at temporarily flooded marginal zones as well as the presence of suitable structure of vegetation. Dispersion of imagines towards the marginal zones is in several cases certainly enhanced by the increase in water level, which causes thinning of vegetation on the actual surface of the peat bog (where larval development takes place) and shallow flooding of vegetation in the marginal zone. It is possible that the dispersion towards the marginal zones may be increased at sites 3 and 4 by not entirely suitable spatial structure of swamps of *J. effusus* in the development zones. Existence of imagines aside of larval habitats may occur more frequently than it was suggested by previous data, especially in habitats with greater fluctuations of water level." **18738.** Nico, L.G.; Englund, R.A.; Jelks, H.L. (2015): Evaluating the piscicide rotenone as an option for eradication of invasive Mozambique tilapia in a Hawaiian brackish-water wetland complex. *Management of Biological Invasions* 6: 83-104. (in English) ["Mozambique tilapia *Oreochromis mossambicus* were recently discovered in 'Aimakap. Fishpond, a 12-hectare brackish-water wetland complex in Kaloko-Honokohau National Historical Park, on the Island of Hawaii'. As a possible eradication method, we evaluated rotenone, a natural piscicide used in fish management and the active

ingredient in plants traditionally used by indigenous Hawaiians for capturing fish. To assess rotenone's efficacy in killing tilapia and effects on non-target species, laboratory toxicity tests involved exposing organisms to various concentrations of liquid CFT Legumine (5% rotenone) in static trials of 48-h to 72-h duration. Test organisms included: Mozambique tilapia, non-native guppy *Poecilia reticulata*, the non-native odonate *Ischnura ramburii*, native feeble shrimp  *Palaemon debilis*, and native *ōpae'ula* shrimp *Halocaridina rubra*. All organisms and water used in tests were obtained from 'Aimakap. (12.6 - 12.7 ppt salinity), or, for *H. rubra*, an anchialine pool (15.0 - 15.2 ppt salinity). Survival analyses indicated CFT Legumine concentrations  $\geq 3$  ppm ( $>0.15$  mg/L rotenone) achieved 100% mortality of tilapia and 93% of guppies within 24 h, with most tilapia killed by 6 h and most guppies by 2 h. Little or no mortality was observed among invertebrate exposed to 1 to 5 mg/L CFT Legumine: 0% mortality for *ōpae'ula* shrimp, 4% for feeble shrimp; and 16% for odonate larvae. The 48 h LC50 values for Mozambique tilapia and guppy were 0.06 and 0.11 mg/L rotenone, respectively. Results demonstrate rotenone's potential for non-native fish eradication in brackish-water habitats, with benefit of low mortality to certain macro-invertebrates. High rotenone tolerance displayed by *ōpae'ula* shrimp is noteworthy. Invasive fish are common in anchialine pools, threatening existence of shrimp and other invertebrate fauna. Although rotenone's effects on freshwater organisms have been well studied, our research represents one of only a few controlled laboratory experiments quantitatively assessing rotenone tolerance of brackish or marine fauna." **18742.** Rivas, A. (2015): Co-existence of calopterygid damselfly species: neutrality or negative frequency dependence? MSc. thesis, Department of Biology, Lund University. (in English) ["Closely related species often share the same local environment and use similar resources. Local diversity could then be maintained through some frequency-dependent species maintenance mechanism, fulfilling the inviability criterion. Alternatively, and according to the neutral theory of biodiversity, different species should randomly go extinct over time. Here, I studied two closely related and congeneric damselfly species (*Calopteryx splendens* and *C. virgo*) to investigate if, how and why species with similar ecology could coexist. Through an experimental investigation in large outdoor cages, I investigated if there was any evidence for either species neutrality or coexistence via negative frequency dependent survival advantages of rare species. I quantified the longevity of both species under several different density and frequency treatments, where the

number and species composition in the cages was manipulated in a fully factorial experimental design. My results suggest that longevity of these two species was similar over a large range of densities and frequency treatments, except when total male density was low and the frequency of *C. splendens* males was high. In this situation, *C. virgo* males showed evidence of a negative frequency-dependent survival advantage. I also present data on species-specific territoriality and discuss how territorial plasticity might contribute to coexistence between the two species. I found that *C. virgo* was significantly more likely to be territorial in two out of six density -and frequency treatments than was *C. splendens*. Overall, my results are consistent with species neutrality across most density and frequency-environments, although there is also evidence for negative frequency dependent fitness advantage of *C. virgo* at low density and when *C. splendens* was common. Therefore, different outcomes would be expected when these two ecologically similar and congeneric damselflies come in to contact with each other in nature, depending on environmental context." Popular Abstract: How two similar damselfly species can co-exist? Nowadays, one can not a priori assume that each and every species found together in a local community need to coexist in the long run. Instead, local community composition might follow a neutral community dynamics, whereby species are expected to randomly go to extinct. However, ecologically equivalent species cannot coexist infinitely, so there needs to exist some coexistence mechanism (-s) if two or more species are going to continue to coexist locally. The aim of my project was experimentally investigate and search for potential co-existence mechanisms between two ecologically similar damselfly species within the same genus (*C. splendens*, *C. virgo*). In particular, I investigated the importance of neutrality or coexistence through negative frequency dependence mechanisms (i.e. that a species does better when it is rare than when it is common). In addition, I also investigated how territoriality behaviour of these two species changed in relation to local community composition in the form of density and frequency of interacting species. In order to examine the coexistence mechanism (-s) I estimated longevity of individually marked damselflies of these two species in different density and frequency-environments in large outdoor cages, where the total number of individuals and damselfly species composition was experimentally manipulated. My study demonstrate experimental data suggesting that a mixture of neutrality and negative frequency dependent shape the coexistence of these two ecologically similar damselflies. These results also suggest that these two damselfly species use different degree of territoriality (i.e. more probability to holding a territory or less probability to holding a territory) depending on the other species territorial behavior. This study is one of few experimental studies of this kind, where species composition (frequency) and density (total number of individuals) are simultaneously manipulated with the aim to understand the roles of species neutrality vs. negative frequency-dependent coexistence mechanisms. To understand local species composition, these results can help us to get a better understanding about the ecological causes of global species distributions." (Author)] Available

**18744.** Rychla, A.; Sniegula, S.; Karasek, T.; Golab, M.J.; Zurek, R. (2015): Distribution and habitat characteristics of *Sympecma fusca* (Vander Linden, 1820) and *Sympecma paedisca* (Brauer, 1877) in oxbows of the upper Vistula River. *Odonatrix* 11(1): 21-30. (in Polish, with English summary) ["*Sympecma fusca* and *S. paedisca* occur in a wide spectrum of habitats within standing waters. However, the knowledge of these species distribution in oxbows is poor in Poland. In this study, new sites of *S. fusca* and *S. paedisca* along the Vistula River valley, between Jawiszowice and Otałęż in the Małopolska Region (the Lesser Poland), are presented and the importance of oxbows for the species distribution is discussed. Habitat conditions concerning hydrological and physico-chemical (12 parameters) water properties are analysed with a focus on nutrient contents (phosphate –  $\text{PO}_4^{3-}$ , ammonium –  $\text{NH}_4^+$ , and nitrate –  $\text{NO}_3^-$ ). A total of 22 UTM 10x10 km squares were investigated and *S. fusca* was recorded in 17, while *S. paedisca* in 11 UTM squares. In total, 51 and 25 new sites of *S. fusca* and *S. paedisca*, respectively, were recorded. The species coexisted at 22 (43%) sites. The reproductive behaviour was observed at 29 sites for *S. fusca* and at 16 ones for *S. paedisca*. Both species preferred oxbows that during high water periods were temporarily connected with the river, i.e. those situated inside rather than outside of the levees. Specifically, 63% sites of *S. fusca* and 76% sites of *S. paedisca* were located between the levees of the Vistula River. With respect to hydrochemical conditions, both species occurred in habitats with wide ranges of all measured water parameters and there

was no significant difference between their preferences in this matter. Regarding nutrients, both species were found at concentrations reaching  $1,5 \text{ mg L}^{-1} \text{ PO}_4^{3-}$  and  $1,6 \text{ mg L}^{-1} \text{ NH}_4^+$ . Nevertheless, a comparison between inhabited and uninhabited waters revealed preferences of both species to relatively low contents of phosphate and ammonium. With respect to nitrate, *S. paedisca* occurred at their low concentrations, whereas *S. fusca* did not show any pattern. We conclude that oxbows, particularly those seasonally flooded due to the river proximity, are important habitats for *S. fusca* and *S. paedisca*. Thus, special attention should be paid on biotopes situated in great river valleys in Poland. Although both species tolerate broad ranges of physico-chemical water parameters, oxbows with relatively low nutrient concentrations are preferred." (Authors)] Address: Rychla, Anna, ul. Osiedlowa 12, Płoty, 66-016 Czerwieńsk, Poland. E-mail: an.rychla@gmail.com

**18745.** Salazar Cespedes, S.A.; Castrillon Andrade, G.; Valenzuela-Rojas, J.C.; Amortegui Cedeno, E.F. (2015): Dragonfly (Insecta - Odonata) diversity in the Center for Environmental Research and Education "La Tribuna", Vereda Tamarindo (Neiva-Huila-Colombia). *Entomologia Mexicana* 2: 619-627. (in Spanish, with English summary) ["The main objective of this work was to analyse the composition of dragonflies in the Centro de Investigación y Educación Ambiental (CIEA) "La Tribuna" Vereda Tamarindo (Neiva-Huila-Colombia), in terms of richness and abundance of local communities, by lotic and lentic environment, in the dry and rainy seasons; in a sampling between 2013 and 2014. In total, 543 individuals were collected, including 57 Anisoptera and 486 Zygoptera; distributed in seven families and 19 genera. In Anisoptera, the only family collected was Libellulidae, while in the suborder Zygoptera, the most abundant family was Calopterygidae with 178 individuals. Sampling effort was 73.5%, a value that represents a valid sample of odonate biodiversity in the IARC; alpha diversity ( $\alpha$ ) was low, with dominance in the rainy season of 0.2274 and in the dry season of 0.1933, based on the Shannon-Wiener index which indicates that regardless of the season, the species are constant; for beta diversity ( $\beta$ ), the Jaccard Similarity index was used, this value was 41% which means that the two seasons are similar in terms of species richness." **18747.** Soler Monzo, E. (2015): Estructura de comunidades de Odonata en sistemas mediterráneos. Dissertation, Universitat de València: 193 pp. (in Spanish) ["In ecology, a community is an assemblage of species coexisting at the same time and place (Mittelbach 2012) but the way ecological communities have been conceptualised has changed over time. In the early 20th century, the community was seen as a discrete entity primarily regulated by environmental factors, leading to the debate between Clementsian and Gleasonian views of communities. Later, the debate focused on the mechanisms that allowed species to coexist depending on the way in which different species exploited available resources. This was the time when Hutchinson (1957) enunciated his niche theory. Along these lines, Diamond (1975) described the formation of a community as an "assemblage of species" that follows a series of rules, mainly determined by interspecific relationships (competition for resources), the differential response of species to exploit those resources and their respective dispersal rates. The community was considered a closed entity until McArthur & Wilson (1967) enunciated their Theory of Island Biogeography in which, in addition to possible interactions between species and environmental effect, they outlined the possibility that extinction and colonisation events were also involved in the formation of a community. In this new context in which a community is neither isolated nor closed, Ricklefs (1987) stressed the importance of explicitly recognising a regional scale and a local scale, in which different processes are at work in the assembly of a local community. A local community is now recognised as the result of the interaction of local and regional processes. Local processes are related to abiotic and biotic factors while regional processes are related to species dispersal capacity and their demographic processes. Consequently, the concept of metacommunity (communities that interact through the dispersal of at least part of the species that form them) has become the new scenario for approaching the study of communities and in the literature local processes are called deterministic processes while regional processes are assimilated to spatial processes. There are basically two approaches to the study of metacommunity structure. The first one focuses on the description of patterns while the second approach tries to unravel the processes underlying these patterns. In addition, communities change in their composition and/or structure. Discerning whether these patterns or changes in composition and structure

occur randomly or are driven by specific mechanisms is one of the current challenges in ecology. The underlying processes have been classified into two broad groups: deterministic processes and stochastic processes. Deterministic processes are those related to niche theory and act at the local level. Stochastic processes relate to mechanisms that are regional in scope and can be intrinsic to the organism (dispersal capacity, size, trophic position) or extrinsic (landscape configuration, extinction or colonisation phenomena). Within the study of metacommunities, freshwater ecosystems have received considerable attention. On the one hand, the hydroperiod represents a wide abiotic gradient which, in turn, conditions the biotic component of the sites. On the other hand, they provide an ideal framework for establishing the role of regional processes in the assembly of communities of organisms with different dispersal capacities. Furthermore, elucidating the mechanisms underlying their structure is no longer of mere theoretical interest, but of vital importance for their proper management and conservation, as these systems are among the most threatened by anthropogenic action. This is especially true in Mediterranean freshwater ecosystems, which not only have a great variety of endemic species, but some of these habitats are considered to be of priority protection. Odonata are an important group in inland water communities, as they need these ecosystems to complete their life cycle. They are a suitable group for the study of community assemblages, as many aspects of their distribution, biology and habitat requirements are known, and not all species have the same dispersal capacity. Due to the interest in restoring aquatic habitats, it has been used to assess the consequences of anthropogenic disturbances. Dragonfly communities have also been studied in a metacommunity context, although work in which this conceptual framework prevails is scarce. Moreover, larvae and adults have received uneven attention and this makes it difficult to agree on the prevailing patterns and dynamics. In Mediterranean ecosystems, despite being a well-studied group, Odonata communities have only been described in terms of the main abiotic factors influencing their assemblage structure. There is some knowledge of their dynamism but the only works in which they are studied from a metacommunity point of view are those in which they have been included as part of macroinvertebrate communities. Consequently, it is convenient to establish the metacommunity as a conceptual framework for Odonata communities, especially if we take into account that in the Mediterranean area, one out of five species is threatened with extinction at regional level. Thus, this PhD thesis aims to contribute to this change of perspective and to increase the knowledge of the patterns and dynamics associated with Odonata communities. This general objective is specified in four specific objectives: (1) to establish the factors that determine dragonfly species richness in temporary wetlands, (2) to establish the structure observed in dragonfly metacommunities and their stability over time, (3) to assess what is the temporal beta diversity of dragonfly communities and (4) to analyse how dragonfly community assembly occurs in newly created habitats. To achieve each objective, fieldwork was carried out in two very different study areas, the island

of Menorca (within the Balearic Islands archipelago) and the Banyoles wetland (Girona, Catalonia). In Menorca, the fieldwork included, on the one hand, the monitoring of adult communities in temporary pools and, on the other hand, the monitoring of larval communities in different types of habitats. In the Banyoles wetland, only adult communities linked to permanent and semi-permanent habitats were studied. The methodology used to monitor larvae included the capture, conservation and identification of specimens according to their size. Two different methodologies were used to monitor adults in Menorca (adaptive sampling) and in Banyoles (SLIC). In neither of them was the capture of individuals included, except in cases of doubtful identification. For fieldwork with adult communities, surveys consisted of sightings of adults (males and females) at or near water points. These surveys are carried out weekly or fortnightly in the central hours of preferably sunny and not too windy days in the period between approximately March and November. For the sampling carried out in temporary ponds, the observer walked along transects or used count points and for each new species recorded, an additional 20 minutes of survey time was added. This work was carried out in 2008. To survey the newly created ponds, the SLIC method (*Seguiment de Libèl·lues de Catalunya*), developed by the naturalist group *Oxygastra*, was used. In this case, observers make weekly counts of adult insects along a linear transect and when it is impossible to access some of the lake habitats, counting points consisting of 5-minute sessions from a fixed point are added. Counts of adults in the Banyoles wetland were made over seven years. For larval sampling, each site was visited twice to ensure that larvae of both spring and summer species were captured in their most advanced stages of development, so the sampling period began in late winter and ended in early summer. A methodology similar to that described by other authors was followed in which larvae are captured with a 1 mm light net for at least 3 minutes, trying to cover all existing mesohabitats. The larval sampling was a replica of the work carried out by García-Avilés et al. (1995) 22 years earlier. The environmental characterisation of the sites studied was done by including the variables most commonly measured in this type of study, i.e. physico-chemical parameters of the water, vegetation, connectivity or characteristics of the environment of the sites. The analysis methods used in this thesis included descriptive statistics, hypothesis testing and multivariate statistics. Specific programmes were also used to quantify beta diversity, establish metacommunity patterns and analyse community rarity and dynamics. In addition, the DBI (Dragonfly Biotic Index) was used to test whether the measure of creating new lagoons had improved the odonatological diversity of the Banyoles wetland. The most important results of this doctoral thesis can be grouped according to each objective. In the case of the adult communities of temporary ponds (Objective 1) it was found that regional factors such as area and connectivity played a relevant role in the species richness of the communities. These assemblages, consisting of generalist and rare species, contribute significantly to regional diversity despite the fact that only a low percentage (around 20%) have specific mechanisms to resist desiccation. Larval

communities showed a quasi-nested metacommunity pattern in 1988 and a random pattern in 2010 (Objective 2). These patterns could be caused by differences in dispersal ability and degree of habitat specialisation. Larval communities showed a high variability in composition in both 1988 and 2010 (Objective 3) and, although no direct relationship could be established, it was found that the different habitats included in the study represented an important environmental heterogeneity. In fact, together with distance to the sea and temperature, habitat type was the most influential variable in the differentiation of assemblages in both 1988 and 2010 (Objective 3). Odonata larval communities are highly dynamic and after 22 years, a variability in their composition of about 75% was recorded. This dynamism could not be related to the degree of environmental change and was negatively correlated with the species recorded at each station in 1988. Despite this, the number of species recorded at each locality remained more or less constant after this time period (Objective 3). In newly created habitats the adult Odonata communities did not follow successional but rather stochastic dynamics (Objective 4). This type of dynamics was also observed in assemblages of more mature habitats. In both types of assemblages, a spatial variability close to 50% was recorded. This percentage was very similar to their inter-annual variability, although species richness remained more or less constant (Objective 4). According to the DBI values, the newly created ponds seem to have improved the odonatological diversity of the area. The main conclusions of this PhD thesis show that Odonada communities can be influenced by both local and regional factors, especially in the case of highly fluctuating habitats. In larval communities, the observed metacommunity pattern may be related to the trade-off between dispersal ability and degree of habitat specialisation and is not stable over time. There is great variability in the composition of Odonata communities (adult and larval) at both local and regional scales, especially when different habitat types are taken into account. Odonata communities are highly dynamic at both the adult and larval stages, but the number of species within them remains stable. The mechanisms underlying these dynamics seem to have a strong stochastic component." (Author; DeepL)] Address: not stated

**18749.** Takhelmayum, K.; Gupta, S. (2015): Aquatic insect diversity of a protected area, Keibul Lamjao National Park in Manipur, North East India. *Journal of Asia-Pacific Entomology* 18(2): 335-341. (in English) ["Highlights: •Presence of tolerant orders like Odonata, Hemiptera and Coleoptera. •Absence of sensitive orders of aquatic insects in all the sites of the floating park. •Shannon H' values are less than 1 in all the sites. •Very low DO concentration in water of the park. •Lead and mercury concentrations were found beyond the desirable level of WHO and BIS. Abstract: Keibul Lamjao National Park, only home of Brow-Antler Deer, (*Rucervus eldii eldii*) is the unique floating park of the world. It is a part of the Loktak Lake, Manipur (Ramsar site). The lake gets major share of water from seven feeder rivers. In this paper an attempt has been made to study aquatic insect diversity of the five sites of the national park area which will indicate the health of the unique but deteriorating ecosystem and at the same time reduce aquatic insect data deficiency of the area. The study recorded 3 orders, 12 families and 23 species of aquatic insects. Besides inventorying the aquatic insect taxa, their relationships with several environmental variables including heavy metals were also investigated. The low Shannon Weiner Diversity Index values of aquatic insects (Shannon H' less than 1 in all the sites) indicated perturbed condition of the water of the National Park area. The study revealed very low dissolved oxygen (DO) in all the sites. All the three heavy metals in most of the sites were found beyond the desirable level of BIS (IS 10500: 1991). Different biological monitoring scores and Canonical correspondence analysis (CCA) have been used for discussion and interpretation. This study found that although protected areas are meant for protecting biodiversity,

management of outside protected area particularly catchment area should be given priority for minimizing land use disturbance, altered hydrology and other related factors." (Authors) The following taxa (including probable misidentifications) are listed: *Sympetrum* sp., *Tramea* sp., *Rhodothemis* sp., *Orthetrum* sp., *Crocothemis servilia servilia*, *Potomarcha* sp., *Zyxomma petiolatum*, *Leucorrhinia* sp. [sic] (Libellulidae), *Aeshna* sp., *Anax* sp., (Aeshnidae); *Pseudagrion* sp., *Ischnura* sp., *Ceriagrion* sp. **18751.** White, S.; Smith, S.P.H. (2015): Dragonflies of Lancashire and North Merseyside. Lancashire & Cheshire Fauna Society 118: 104 pp. (in English) ["Just published in full colour, the Dragonflies of Lancashire and North Merseyside provides a comprehensive of all 24 species seen there. The distribution and breeding status of each species are mapped and details of flight periods illustrated, with particular emphasis on changes brought about by climate change. Lancashire lies on the north-western edge of the breeding range of several British dragonflies but, presumably driven largely by climate change, it has been colonised by six new species within the past 20 years during which period the ranges of several established species have also shown dramatic northward shifts. Of the 24 species recorded (8 damselflies and 16 dragonflies), 19 now breed annually with one other, Red-veined Darter, now apparently lost after breeding successfully for several years. The current distribution and breeding status of each species is mapped together with the progression of colonisation by the recently-arrived species. In contrast to most other species groups in Lancashire, the county's dragonflies appear to be thriving, in part due to the creation of a number of large wetlands by the conservation bodies, but other environmental factors have also played a part. Climatic amelioration is undoubtedly the most important of these but improvements in water quality, due especially to the clean-up of industrial pollution, has also figured. The most dramatic example of this is the exponential spread of *Calopteryx splendens* which expanded its breeding range

from a single site in the mid-1990s to its present range covering 25% of the county; like several other species *C. splendens* have moved northwards but their main range change has been to the east along the previously polluted waterbodies of Lancashire's historic cotton-mill towns. Dates of annual first and last sightings have also changed significantly during the past 30 years with the flight period of several species increasing by three or more weeks. This is partly simply a result of the increased number of dragonfly recorders but there is little doubt that major changes in phenology have taken place. For example, the date when the first 25% of annual sightings of Common Darters have been recorded has advanced by a fortnight or more, while there is no evidence of a similar change at the other end of the year. Interestingly, these phenological changes appear to be confined to the lowlands - the flight periods of Lancashire's three predominantly upland species, Golden-ringed Dragonfly, Common Hawker and Black Darter have remained stable. The county supports a wide range of dragonfly habitats which are summarised in the book's introduction - from the sand dunes of the Sefton Coast in Merseyside, the swathe of arable land in the south-west and pastures in the centre of the county, to the uplands of the Pennines and the Forest of Bowland. All contain important dragonfly sites, some perhaps warranting SSSI status, but, perhaps surprisingly, the county's premier site is located on the ex-industrial land of Heysham and Middleton near Lancaster, where all but three of the county's 24 species have been recorded with 16 breeding in recent years."] Address: <https://www.northwestinvertebrates.org.uk/document/the-dragonflies-of-lancashire-and-north-merseyside/>

## 2016

**18752.** BioDrawversity (2016): Assess operational impacts on emergence of state-listed odonates in the Connecticut River: 2014–2016. Study report. Northfield Mountain Pumped Storage, Project No. 2485 and Turners Falls Hydroelectric Project No. 1889. Leverett, MA. 118 pp. (in English) ["Pumped Storage Project (Northfield Mountain Project, FERC No. 2485) and the Turners Falls Hydroelectric Project (Turners Falls Project, FERC No. 1889). FirstLight has initiated with the Federal Energy Regulatory Commission (FERC, the Commission) the process of relicensing the Northfield Mountain and Turners Falls Projects using FERC's Integrated Licensing Process (ILP). The current licenses for the Northfield Mountain and Turners Falls Projects were issued on May 14, 1968 and May 5, 1980, respectively, with both set to expire on April 30, 2018. This report documents the results of Study No. 3.3.10: Assess Operational Impacts on Emergence of State-Listed Odonates in the Connecticut River. The study goal was to assess potential effects of Project operations on emerging dragonflies (Insecta: Odonata; hereafter called "odonates") in the Connecticut River. To meet this goal, field surveys were conducted to characterize the habitat, assemblage structure, and emergence and eclosure behavior of odonates in the Project area. This information was compared with existing data on odonates and water surface elevation (WSEL) collected throughout the Project

area. Three phases of fieldwork were completed. Phase 1, completed in 2014, included qualitative surveys of odonate larvae and exuviae at eight sites in the Connecticut River to determine species assemblage structure and to collect habitat data. For teneral or exuviae, biologists recorded the vertical and lateral distance from the water's edge, and the substrate that each was collected on. Phase 2, completed in 2015, included quantitative odonate surveys, observations of emergence and eclosure behavior, and concurrent collection of WSEL and water temperature data. Surveys for emerging larvae, exuviae, and teneral were conducted at five sites, with six transects per site, during eight biweekly sampling periods from late May to early September. Biologists looked for larvae exiting the water or crawling on land, and attempted to track and record the time it took for individuals to complete eclosure and fly away. For each exuvia and teneral, the vertical height above the water's surface, the distance from the water's edge, and its eclosure substrate was recorded. Phase 3, completed in 2016, was intended to increase sample sizes for eclosure duration for state-listed odonates and to collect additional data on the vertical heights and horizontal distances traveled prior to eclosure. The speed for all or part of the eclosure process was recorded for 180 specimens, with nearly 90% of these observed in 2016. Surveys for emerging and eclosing larvae were conducted at eight sites in the Turners Falls Impoundment (TFI) and downstream from the Turners Falls Dam, on warm sunny days during peak emergence from late May through mid-July. A total of 17 species were collected from 2014 to 2016, including the state-listed *Gomphus abbreviatus*, *Gomphus vastus*, *Gomphus ventricosus*, *Neurocordulia yamaskanensis*, and *Stylurus amnicola*. Species found most frequently in the riverine environments in the bypass reach and downstream from Cabot Station in the Connecticut River included *Gomphus vastus*, *Boyeria vinosa*, *Stylurus spiniceps*, *Ophiogomphus rupinsulensis*, *Neurocordulia yamaskanensis*, *Dromogomphus spinosus*, *Gomphus abbreviatus*, and *Macromia illinoensis*. The lower TFI (Barton Cove) was inhabited by several species more tolerant of lentic conditions, such as *Epithea princeps*, *Perithemis tenera*, and *Libellula* sp. For all species combined, larvae crawled a median vertical height of 5.5 ft from the water's surface, and a median distance of 12.5 ft from the water's edge. Among the riverine species, crawl height was greatest for *Macromia illinoensis*, *Gomphus abbreviatus*, and *Gomphus vastus*; each of these species crawled a median height of near or above 7 ft. Riverine species that crawled the shortest height from the water's surface included *Stylurus amnicola* (median = 2.2 ft), *Stylurus spiniceps* (median = 3.4 ft), and *Ophiogomphus rupinsulensis* (median = 3.5 ft). The more lentic species collected in Barton Cove crawled shorter distances from the water's surface than the riverine species. Average horizontal crawl distance was usually 10-15 ft for most species, with maximum distances often 3-4 times greater than the average. Shortest crawl distance was for *Perithemis tenera* (a lentic species that prefers to emerge on aquatic vegetation) and *Stylurus amnicola*. Considering crawl height and crawl distance together, the riverine species that tended to

eclose closest to the water were *Stylurus amnicola*, *Stylurus spiniceps*, and *Ophiogomphus rupinsulensis*. In general, species eclosed on a wide variety of available substrates. The time elapsed from when a larva stopped to when it completed metamorphosis ("Start to Free") ranged from 7 to 30 minutes (average = 18 minutes). The time elapsed from completion of metamorphosis to flight ("Free to Flight") ranged from 7 to 96 minutes (average = 39 minutes). Together, these two time periods comprise the critical time period from when a larva stops to eclose to when it flies away ("Start to Flight"). A total of 170 specimens were observed for the entire critical time period. The average duration was 58 minutes and ranged from 24 to 126 minutes. In terms of understanding potential effects of water level fluctuations, the concern is for those species that tend to remain close to the water's edge, especially in areas of the river where water level fluctuations and rates of change are greatest. For the analysis, Critical Protective Rates (CPR) (ft/hr) were computed for species and species groups, using climbing height quantiles divided by a conservative eclosure duration of 2.0 hrs. CPR values were compared to the 95th percentile of the maximum hourly rates of change (MHR-95%) at several representative sites in the TFI and downstream from Cabot Station, derived from the hydraulic models for the daily period from 4am to 5pm, from May 15 to August 15. The hydraulic model for the TFI was based on data from 2000-2015 (excluding 2010 due to the extended outage at Northfield Mountain), and the hydraulic model for downstream was based on data from 2008-2015 (excluding 2010). For the bypass reach, empirical water level data from 2014-2015 was used. This provided a means of assessing the potential impacts to species or species groups, based on their behavior (climbing height and eclosure time) and the rate of water level changes at locations throughout the Project area. Water level fluctuations and rates of change may affect odonate emergence in areas of the Connecticut River closest to Cabot Station during the seasonal (May 15-August 15) and daily (4am to 5pm) periods evaluated, which correspond to peak emergence periods for odonates. State-listed odonate species documented in these areas include *Gomphus abbreviatus*, *Gomphus vastus*, *Neurocordulia yamaskanensis*, and *Stylurus amnicola*. Predicted effects were highest for *Stylurus amnicola*; at least 30% of the population, and closer to 50% near Cabot Station, were at risk of inundation based on the MHR-95%. Only a small percentage of the population of *N. yamaskanensis*, *G. vastus*, and the *Gomphus* Group were potentially affected by inundation based on MHR-95%, and these effects were most pronounced close to Cabot Station. Among co-occurring riverine species, *S. spiniceps*, *O. rupinsulensis* and *D. spinosus* were likely most affected by water level fluctuations, based on the tendency of these species to eclose closer to the water." (Authors) Address: Biodrawiversity LLC, Ethan Nedau, Leverett, MA 01054, 206 Pratt Corner Road, USA

**18753.** Kaya, M.; Sargin, I.; Al-jafa, I.; Erdogan, S.; Arslan, G. (2016): Characteristics of corneal lens chitin in dragonfly compound eyes. *International Journal of Biological Macromolecules* 89: 54-61. (in English) ["Highlights: •Chitin in the

corneal (ommatidial) lenses of dragonfly compound eyes was isolated. •The chitin content of the corneal lenses was determined to be quite high ( $0.85 \pm 20.3\%$ ). •The FT-IR analysis showed that corneal lens chitin was in the  $\alpha$ -form. •The maximum degradation temperature of the lens chitin was observed at  $369.2^\circ\text{C}$ . •Corneal lens chitin consist of nanofibrils. Abstract: Chitin in the compound eyes of arthropods serves as a part of the visual system. The quality of chitin in such highly specialised body parts deserves more detailed examination. Chitin in the corneal (ommatidial) lenses of dragonfly (*Sympetrum fonscolombii*) compound eyes was isolated by using the classical chemical method. The chitin content of the corneal lenses was determined to be quite high ( $20.3 \pm 0.85\%$ ). The FT-IR analysis showed that corneal lens chitin was in the  $\alpha$ -form as found in all arthropod species where mechanical strength is required. The surface morphology analysis by scanning electron microscopy revealed that the outer part of corneal lenses consisted of long chitin fibrils with regular arrays of papillary structures while the smoother inner part had concentric lamellated chitin formation with shorter chitin nanofibrils. Chitinase enzymatic digestion studies, elemental analysis results and the degree of acetylation value showed the purity of chitin samples from corneal lens. The maximum degradation temperature value of the corneal lens chitin was observed at  $369.2^\circ\text{C}$ . X-ray analysis revealed that corneal lens chitin has high crystallinity index; 96.4%. Identification of chitin found in ommatidia of insect compound eyes can provide insights into insect vision and chitin-based optical material design studies." **18754.** Kaya, M.; Baublys, V.; Sargin, I.; Šatkauskienė, I.; Paulauskas, A.; Akyuz, B.; Bulut, E.; Tubelyte, V.; Baran, T.; Seyyar, O.; Kabalak, M.; Yurtmen, H. (2016): How taxonomic relations affect the physicochemical properties of chitin. *Food Biophysics* 11: 10-19. (in English) ["Chitin specimens from 16 arthropod species (13 of Insecta and 3 of Arachnida) were isolated for the first time using the same method. Fourier Transform Infrared Spectrometry (FTIR), Thermogravimetric Analysis (TGA), X-ray diffraction (XRD), Scanning Electron Microscope (SEM) and elemental analysis have been applied to determine how physicochemical properties of chitin specimens are affected by taxonomic relationship. The characterisation studies revealed that physicochemical nature of the chitin specimens differed greatly and were found partially specific to taxa. Significant differences in the surface morphologies of chitin specimens were observed even in the same order. However, the chitin contents were recorded to be specific to the order in the class Insecta. The highest chitin content was observed in Coleoptera (18.2–25.2 %) followed by Hemiptera (10.6–14.5 %), Odonata (9.5–10.1 %), Hymenoptera (7.8–9.3 %), Diptera (8.1 %), Blattodea (4.7 %). In addition, the crystalline index (Crl) values of chitin specimens from Coleoptera were found to be higher than the other orders in Insecta. This study revealed that the chitin contents and Crl values can be related

to taxonomical relationships." **18755.** Tsubaki, Y.; Okuyama, H. (2016): Adaptive loss of color polymorphism and character displacements in sympatric *Mnais damselflies*. *Evolutionary Ecology* 30(5): 811-824. (in English) ["A geographical survey of two *Mnais damselfly* species in the Kinki area of Japan showed evidence for character displacements when the two species were found in sympatry. *Mnais costalis*, a species that has polymorphic male mating types of orange-winged territorial and clear-winged non-territorial morphs (hereafter abbreviated to orange and clear morphs respectively) in allopatry often shifted to having monomorphic orange morphs in sympatry. The mean body size of orange morphs was consistently larger than that of clear morph in allopatry. The mean body size of the sympatric orange morphs was even larger than that of allopatric orange morphs. By contrast, *Mnais pruinosa*, a species that also has two morphs of large orange and small clear morphs in allopatry, shifted to having monomorphic clear morphs in sympatry. The mean body size of the sympatric clear morphs was smaller than that of allopatric clear morphs. Divergence was also detected in the preference for habitat insolation conditions between sympatric *Mnais damselflies*. Both species in allopatric regions prefer half-light forest habitats, while in sympatric regions they showed diversified habitat preference: *M. costalis* preferred sunny habitats while *M. pruinosa* preferred shady habitats. Multiple character displacements in signal traits and habitat preference emerged in heterogeneous forest light environments are likely to have synergistic effects on the reproductive isolation of the two species." **18756.** Gomez-Llano, M.A.; Bensch, H.M.; Svensson, E.I. (2018): Sexual conflict and ecology: Species composition and male density interact to reduce male mating harassment and increase female survival. *Evolution* 72(4): 906-915. (in English) ["Sexual conflict is a pervasive evolutionary force that can reduce female fitness. Experimental evolution studies in the laboratory might overestimate the importance of sexual conflict because the ecological conditions in such settings typically include only a single species. Here, we experimentally manipulated conspecific male density (high or low) and species composition (sympatric or allopatric) to investigate how ecological conditions affect female survival in a sexually dimorphic insect, the banded demoiselle (*Calopteryx splendens*). Female survival was strongly influenced by an interaction between male density and species composition. Specifically, at low conspecific male density, female survival increased in the presence of heterospecific males

(*C. virgo*). Behavioral mating experiments showed that interspecific interference competition reduced conspecific male mating success with large females. These findings suggest that reproductive interference competition between con- and heterospecific males might indirectly facilitate female survival by reducing mating harassment from conspecific males. Hence, interspecific competitors can show contrasting effects on the two sexes thereby influencing sexual conflict dynamics. Our results call for incorporation of more ecological realism in sexual conflict research, particularly how local community context and reproductive interference competition between heterospecific males can affect female fitness." **18757.** Svensson, E.I.; Gómez-Llano, M.A.; Torres, A.R.; Bensch, H.M. (2018): Frequency dependence and ecological drift shape coexistence of species with similar niches. *The American Naturalist* 191(6): 691-703. (in English) ["The coexistence of ecologically similar species might be counteracted by ecological drift and demographic stochasticity, both of which erode local diversity. With niche differentiation, species can be maintained through performance trade-offs between environments, but trade-offs are difficult to invoke for species with similar ecological niches. Such similar species might then go locally extinct due to stochastic ecological drift, but there is little empirical evidence for such processes. Previous studies have relied on biogeographical surveys and inferred process from pattern, while experimental field investigations of ecological drift are rare. Mechanisms preserving local species diversity, such as frequency dependence (e.g., rare-species advantages), can oppose local ecological drift, but the combined effects of ecological drift and such counteracting forces have seldom been investigated. Here, we investigate mechanisms between coexistence of ecologically similar but strongly sexually differentiated damselfly species (*Calopteryx virgo*, *C. splendens*). Combining field surveys, behavioral observations, experimental manipulations of species frequencies and densities, and simulation modeling, we demonstrate that species coexistence is shaped by the opposing forces of ecological drift and negative frequency dependence (rare-species advantage), generated by interference competition. Stochastic and deterministic processes therefore jointly shape coexistence. The role of negative frequency dependence in delaying the loss of ecologically similar species, such as those formed by sexual selection, should therefore be considered in community assembly, macroecology, macroevolution, and biogeography." ## 2020

**18759.** Acquah-Lampsey, D.; Brändle, M.; Brandl, R.; Pinkert, S. (2020): Temperature-driven color lightness and body size variation scale to local assemblages of European Odonata but are modified by propensity for dispersal. *Ecology and Evolution* 10(16): 8936-8948. (in English) ["Previous macrophysiological studies suggested that temperature-driven color lightness and body size variations strongly influence biogeographical patterns in ectotherms. However, these trait–environment relationships scale to local assemblages and the extent to which they can be modified by dispersal remains largely unexplored. We test whether the predictions of the thermal melanism hypothesis and the Bergmann's rule hold for local assemblages. We also assess whether these trait–environment relationships are more important for species adapted to less stable (lentic) habitats, due to their greater dispersal propensity compared to those adapted to stable (lotic) habitats. We quantified the color lightness and body volume of 99 European Odonata and combined these trait information with survey data for 518 local assemblages across Europe. Based on this continent-wide yet spatially explicit dataset, we tested for effects temperature and precipitation on the color lightness and body volume of local assemblages and assessed differences in their relative importance and strength between lentic and lotic assemblages, while accounting for spatial and phylogenetic autocorrelation. The color lightness of assemblages of odonates increased, and body size decreased with increasing temperature. Trait–environment relationships in the average and phylogenetic predicted component were equally important for assemblages of both habitat types but were stronger in lentic assemblages when accounting for phylogenetic autocorrelation. Our results show that the mechanism underlying color lightness and body size variations scale to local assemblages, indicating their general importance. These mechanisms were of equal evolutionary significance for lentic and lotic species, but higher dispersal ability seems to enable lentic species to cope better with historical climatic changes. The documented differences between lentic and lotic assemblages also highlight the importance of integrating interactions of thermal adaptations with proxies of the dispersal ability of species into trait-based models, for improving our understanding of climate-driven biological responses." **18760.** Amann, G.; Puchta, A.; Burtscher, B. (2020): Monitoring im Hochmoor. Das Götzner Moos vor und nach seiner Renaturierung. *inatura – Forschung online* 75: 42 pp. (in German, with English summary) ["A drained and therefore partially disturbed bog with *Pinus uncinata* at the edge of the Rhine Valley in Vorarlberg (Austria), called Götzner Moos, was renaturalised in 2013. In the following six years we monitored the water balance and vegetation as well as selected insects (dragonflies, butterflies) in the bog and adjacent fens to evaluate the restoration measures (clearing shrubs and trees, installing plank dams and clay bunds, restart of the autumnal haymaking in the fens). The water table varied from near the surface to 20 cm under normal weather condition in summer, but fell well beyond 20 cm in dry periods. Cleared but otherwise undisturbed vegetation showed positive effects on special bog plants (e. g. *Vaccinium oxycoccus*), but also contrary effects on wetter and dryer places (e. g. increase or decrease of *Sphagnum magellanicum*, thinning or thickening of heath vegetation). *Molinia caerulea* increased and thereby reflects the still partially unfavorable water balance. As a result of restoration activities, open peat was densely overgrown within two years mainly by *Juncus effusus*, in little ponds mainly by *Carex rostrata*, where also rarer moss species (e. g. *Sphagnum cuspidatum*) flourished. Conspicuous mats of *S. magellanicum* developed later in the period on wet peat, or as small hummocks at the edge of the ponds. The moss flora as well as the vegetation as a whole today still points to a bog forest rather than to a raised bog with current peat growth. Yet it is unclear if *Pinus uncinata*, conveniently a protected property, or *Picea abies* will be the winner of this hypothetic competition. Compared with the studies before the restoration, the number of species of dragonflies has increased. After the restoration 15 species of dragonflies were registered. 6 species reproduced in the investigated area using the new ponds as reproduction site. Whereas most of the detected species are common, *Somatochlora arctica* is endangered and associated with bogs. 41 species of butterflies were found, none of them is especially associated with bogs. However, the adjacent fens and wet grassland are important habitats for butterflies - the clearing and the restart of the autumnal haymaking were a contribution to their conservation. It could be interesting to continue the monitoring to keep an eye on the development of the area, especially in view of climate change and the increase of unusual warm and dry periods." **18762.** Bakker, G. (2020): Zadellibellen in Rotterdam. *Stratgras* 32(1): 16-17. (in Dutch) [*Anax ephippiger*: "Back to Rotterdam After the sighting by Schrijvershof and Hak in 2013, it remained quiet for five years as far as saddle dragonflies in Rotterdam are concerned. Following the spectacular developments elsewhere in the Netherlands, Paul Schrijvershof travelled to Hoek van Holland on 10-X- 2018 and found and photographed Rotterdam's second saddle dragonfly. That was all that remained that year. On 14-VI- 2019, both Johan van 't Bosch and Jaap Engberts saw a male saddle dragonfly in - not entirely coincidentally - the dunes of Hoek van Holland. Johan managed to take photos. Because the observations were made at two different pools, the suspicion arose that there must be more specimens present. In the following days this proved to be the case. At a quickly drying pool, several dozen people reported up to six specimens at the same time. Mating and egg deposition were often observed. On 18 June the pool had almost dried up and only one specimen was seen. Until 25 June a few specimens were seen at the nearby dune pond. Meanwhile, elsewhere in the municipality of Rotterdam, some sightings were also made: on 17-VI- 2019, les Goedbloed saw one along the Schiedamseweg in Oud-Mathenesse ("While running, suddenly a saddle dragonfly!") and on 20 June Merijn Loeve saw one at the Veilingterrein in Crooswijk. **18763.** Batista Calvão, L.; Paiva, C.K.; Brito, J.; Fares, A.L.; Maia, C.; Michelan, T.S.; Montag, L.; Juen, L. (2020): Influence of biotic and abiotic factors on adult Odonata (Insecta) in Amazon streams. *Animal Biology* 71(1): 67-84. (in English) ["Abiotic and biotic factors play an essential role in the structuring of natural communities. Aquatic ecosystems have complex interaction networks, encompassing predator/prey relationships and structural support. Among aquatic organisms, the order Odonata is a model group for understanding those relationships since they can be both predators and prey. Our hypotheses were that Zygoptera are (i) influenced positively by Ephemeroptera, Plecoptera and Trichoptera (EPT) and the Habitat Integrity Index (HII), and negatively by fish and macrophytes; and (ii) Anisoptera are affected positively by EPT and macrophytes, and negatively by fish and HII. We found that Zygoptera were affected by the fish functional trophic groups, while Anisoptera were affected by macrophytes, EPT, fish and HII. Macrophytes affected anisopterans positively because they provide perching sites for adults. The results for EPT and HII may be related since these organisms are also sensitive to environmental changes. More open areas have lower HII values and the negative relationship with Anisoptera may be explained by physiological constraints. The negative relationship between EPT and Anisoptera could be explained by the low occurrence of EPT in open sites, which are the sites that were highly rich in Anisoptera. Finally, the dominance of specific functional trophic groups of fish influences Odonata

suborders in different ways. In conclusion, the results show the importance of ecological interactions for Odonata in Amazonian streams in both direct and indirect ways." **18765.** Buffagni, A. (2020): The lentic and lotic characteristics of habitats determine the distribution of benthic macroinvertebrates in Mediterranean rivers. *Freshwater Biology* 66: 13-34. (in English) ["(1) The importance of flow-related factors to benthic organisms, as well as the role of habitat conditions in shaping aquatic communities during low-flow periods, have been recognised. Despite this, the preferences of macroinvertebrates to the ratio of lentic to lotic habitats at the reach scale have not been accurately quantified in most instances. (2) Aquatic invertebrates and habitat features in a range of temporary rivers in Sardinia were investigated. The investigation focused on the flow-related characteristics that contribute to defining the lentic-lotic condition of the river reaches. The relation of habitat features to benthic taxa distributions was assessed using multidimensional scaling. The main aim of the paper was to quantify the responses of taxa to the different lentic and lotic habitat conditions by applying hierarchical logistic regressions. Finally, taxon optima were aligned along the lentic-lotic gradient and the responses of different taxonomic groups compared. (3) Unbroken waves and imperceptible flow were correlated with benthic taxa variability, suggesting local hydraulics and turbulence have a major role in regulating community composition. The overall lentic-lotic character of the river reaches was also clearly related to the benthic taxa distribution. More than 80% of taxa were significantly related to the lentic-lotic gradient, and an asymmetrical response curve was the predominant model. (4) Benthic groups showed taxon optima clustered in different ranges of the lentic-lotic gradient. Odonata, Coleoptera, Hemiptera, and Mollusca preferred clearly lentic con-

ditions. Diptera mainly ranged on the lotic side of the gradient, while Trichoptera were relatively uniformly distributed across the gradient. Ephemeroptera taxa clustered in intermediate lentic-lotic conditions, with two species preferring extremely lentic habitats. In general, optima converged at intermediate and extremely lentic conditions, presumably due, respectively, to the coexistence of different lentic and lotic features and to the highly diverse environmental characteristics under extremely lentic situations. (5) These results support the conclusion that dissimilar ecological factors act on benthic taxa along the lentic-lotic range and species favouring different lentic-lotic conditions are subjected to pressures of different nature. This should not be ignored when defining species preferences and studying community structure or relationships between species in Mediterranean rivers, which cyclically vary their habitat composition. In addition, the uneven distribution of optima of different groups along the lentic-lotic gradient might affect macroinvertebrate metrics when assessing ecological status or establishing reference conditions under variable climatic conditions." (Author) Taxa are treated at family level.] Address: Buffagni, A., Water Res. Inst., Nat. Res. Council (CNR-IRSA), Via del Mullno, 19,1-20861, Brugherio (MB), Italy. Email: huffagnl@Irsa.cnr.it

**18766.** Chelli, A.; Moulai, R.; Djemai, A. (2020): Does the Tichi Haf dam construction affect dragonfly and damselfly (Odonata: Insecta) assemblages of the Boussellam watercourse (central north Algeria)? A preliminary study. *Zoology and Ecology* 30(1): 37-47. (in English) ["This paper reports a pioneer study dealing with the impact of dam construction on Odonata communities, because no similar study has been undertaken in Algeria and the consequences of this artificialization on the Odonata assemblages have rarely been studied elsewhere. The main purpose of this study was to determine if the Tichi Haf dam is really having a negative effect on the Odonata communities living on the Boussellam watercourse, as there has hitherto been a lack of knowledge about its odonatofauna and aquatic microinvertebrates. This study showed that changes due to the construction of this dam, involving riparian vegetation, bank aspect and water parameters, affected the Odonata assemblages inhabiting both sides of the dam wall. The richness and abundance of Odonata found upstream from the dam is quite different from those found downstream from the dam. The survey also identified four new species for the Bejaia region. Among these, we report on the rediscovery of the critically endangered (EN) *Calopteryx exul* in Algeria, recorded in the nineteenth century and deemed to have been extinct after an absence of more than a century. The presence of an extant population *C. exul* in this location does not correspond to any historical locality reported for this species." **18767.** Chung, H.-Y.; Yeom, C.-M.; Kim, J.H.; Park, S.; Lee, Y.-W.; Pyo, G.; Kim, S.H. (2020): Species diversity and com-

munity characteristics of benthic macroinvertebrates from irrigation ponds in the western CCZ area, Korea. *Korean Journal of Ecology and Environment* 53(2): 173-184. (in Korean, with English summary) ["Irrigation ponds, 'dumbeong', which are artificially constructed water resources for traditional farming, serve as a biological shelter connecting seasonally created rice paddy fields to local freshwater ecosystems. This 2018 study surveyed 143 irrigation ponds in the western Civilian Control Zone (CCZ) area from August to September, revealing species diversity and community characteristics of benthic macroinvertebrates. A total of 13,454 individuals of macroinvertebrates were captured and classified into 3 phyla, 5 classes, 17 orders, 59 families, 192 species. Among Insecta, the most frequently recorded order was Odonata, 55 spp. (33.7%), followed by Coleoptera, 52 spp. (31.9%), Hemiptera, 34 spp. (20.8%), Diptera, 17 spp. (9.8%), Ephemeroptera, 3 spp. (2.4%), Trichoptera, 1 spp. (0.6%) and Lepidoptera, 1 spp. (0.6%). Taxon of non-Insecta consisted of Mollusca, 14 spp. (48.2%), Annelida, 11 spp. (37.9%) and Arthropoda, 4 spp. (3.4%). The analysis of Diversity Index (H'), Species Richness Index (RI), Dominance Index (DI) and Evenness Index (J') revealed the general stability of communities in the study sites. A total of 28 rare species were found in 98 study sites, including three endangered species designated by the Ministry of Environment. These results showed that the species diversity and rarity of macroinvertebrates in the study area were greater than those of previous research on lentic wetlands (lake, etc.) and national conserved wetlands (Upo-swamp, etc.) in Korea. A conservation planning of aquatic ecosystems in the western CCZ area, therefore, should focus on conservation of irrigation ponds." (Authors)] Address: Kim, S.H., DMZ Ecology Res. **18768.** Dias de Oliveira, F. (2020): Impact du castor sur les populations d'odonates en Ardenne belge. MSc. thesis, Faculté des sciences, Université catholique de Louvain: 103 pp. (in French, with English summary) ["The beaver is back in Belgium for a few years and today it is an integral part of the Belgian biodiversity. Many studies highlight the positive influence that the beaver can have on other groups of organisms, including dragonflies, by creating a dam that creates heterogeneity in the environment. Dragonflies are known to be insects that are highly dependent on aquatic environments. Consequently, a few studies have already linked the creation of a water retention by the dam to an increase in dragonfly populations. And that's what my work is based on. Throughout this work, I have tried to assess whether there is an apparent change in dragonfly populations since the appearance of the beaver in Wallonia. The first part of the work consisted of finding the year of construction of each dam in order to know the approximate time when a change in dragonflies could have been measured. In the second part I tried to evaluate a change in dragonfly richness and community by comparing dragonfly observations at two periods, namely before and after the appearance of the dam. This work has thus shown that the response of dragonflies is not obvious and that it depends strongly on the influence of the dam on the environment. In other words, not all dams seem

to impact dragonflies in the same way, which has an impact on the results of the analysis. In addition, the size of the impoundments created by the dams appears to be correlated with the size of the standing water present at the sites, which further complicates the assessment of dragonfly responses. Nevertheless, the positive effects of the beaver continue to make it a very useful organism in improving habitat for various organisms, and as a result, we must continue to pay attention to this rodent and its influence on the biodiversity. ... Conclusion: Unfortunately, this thesis could not show a clear-cut response of dragonfly populations to the appearance of dams in the Walloon territory. Nevertheless, I do not believe that this result is due to the fact that dams have no effect on dragonflies but rather to the limitations of the data and the methodology used. Nevertheless, it should be borne in mind that the presence of a beaver or even a dam at a site does not in all cases equate to an increase in the number of dragonfly species or the abundance of a specific species. The dam must clearly have special characteristics and above all have a fairly large effect on the environment (large water reservoir, abundant vegetation, abundant substrates, sunlight, etc.). In this case, not only dragonflies can benefit from the presence of this rodent but also many other species. Over the last 20 years, the beaver has managed to conquer a large part of Wallonia and has drastically changed the waterways. Whether we like it or not, the beaver has clearly become an integral part of Belgian biodiversity once again and I think we should accept this and try to make the most of the benefits to biodiversity. Indeed, it has been clearly proven that the beaver is very beneficial through its ability to create heterogeneity. However, in order to really benefit a large number of organisms, the various natural environments must always be present in the right quantity and distribution, which is unfortunately no longer the case in Wallonia. So I think that if we continue to create wetlands thanks to the various Life projects and if we let the beaver do what it does best, namely create wetlands, we may be able to see a reduction in the decline of dragonflies in certain regions of Belgium, and I hope so." (Author)] Address: not stated

**18769.** Dietrich, S.E. (2020): Habitat, diet, and foraging ecology of Willow Flycatcher in Sierra Nevada Meadows. M.Sc. thesis, Utah State University: XI + 60 pp. (in English) ["The last stronghold of the California Willow Flycatcher (*Empidonax traillii*) population, which exists in the Sierra Nevada, continues to decline, necessitating a clearer understanding of how meadows provide habitat for the species. To gain this understanding, we assessed vegetation type, saturation levels, and invertebrate species at 51 different sites within four meadows located in the Little Truckee River drainage. 17 of these sites were occupied by nesting Willow Flycatcher during the time of the study, 17 sites had been occupied by nesting Willow Flycatcher in annual surveys between 1997 and 2010 but are no longer used, and 17 sites had never been used by nesting Willow Flycatcher. We found that occupied sites were generally far wetter than unused sites. Total saturation varied from 88% to 100% and total inundation varied from 20% to 52%. Sedge vegetation coverage was also

much higher in occupied sites than unused sites and varied from 62% to 90%. Abandoned sites were found to not be suitable for breeding Willow Flycatcher because they were either too dry (low food abundance) or they were too wet (decreased shrub quality). Food items desired by Willow Flycatcher were found to be higher in abundance within wetter occupied sites compared to drier unused sites. In addition to evaluating vegetation coverage, saturation levels, and invertebrates, we examined Willow Flycatcher diet, foraging behavior, and food/habitat relationships by using video footage of nestlings being fed and field observations. Over 75% of the Willow Flycatcher diet was represented by Lepidoptera, Raphidioptera, Ephemeroptera, Odonata, and Hemiptera. Aquatic invertebrate food items composed 42% of the diet and aquatic habitat features such as stream channels and oxbow ponds were found to be important. Overall, gleaning and hawking foraging methods were used relatively equally, 49% and 51% of the time, respectively. Foraging often took place outside of territory boundaries and some food items, such as Raphidioptera, were caught outside of meadow boundaries. Diets and foraging behavior also varied throughout the day with some food items, such as Ephemeroptera and Lepidoptera, being targeted only during certain times of the day." **18771.** Eagles-Smith, C.A.; Willacker, J.J.; Nelson, S.J.; Flanagan Pritz, C.M.; Krabbenhoft, D.P.; Chen, C.Y.; Ackerman, J.T. Campbell Grant, E.H.; Pilliod, D.S. (2020): A national-scale assessment of mercury bioaccumulation in United States National Parks using dragonfly larvae as biosentinels through a Citizen-Science Framework. *Environmental Science & Technology* 54(14): 8778-8790. (in English) ["We conducted a national-scale assessment of mercury (Hg) bioaccumulation in aquatic ecosystems, using dragonfly larvae as biosentinels, by developing a citizen-science network to facilitate biological sampling. Implementing a carefully designed sampling methodology for citizen scientists, we developed an effective framework for a landscape-level inquiry that might otherwise be resource limited. We assessed the variation in dragonfly Hg concentrations across >450 sites spanning 100 United States National Park Service units and examined intrinsic and extrinsic factors associated with the variation in Hg concentrations. Mercury concentrations ranged between 10.4 and 1411 ng/g dry weight across sites and varied among habitat types. Dragonfly total Hg (THg) concentrations were up to 1.8-fold higher in lotic

habitats than in lentic habitats and 37% higher in waterbodies with abundant wetlands along their margins than those without wetlands. Mercury concentrations in dragonflies differed among families but were correlated ( $r^2 > 0.80$ ) with each other, enabling adjustment to a consistent family to facilitate spatial comparisons among sampling units. Dragonfly THg concentrations were positively correlated with THg concentrations in both fish and amphibians from the same locations, indicating that dragonfly larvae are effective indicators of Hg bioavailability in aquatic food webs. We used these relationships to develop an integrated impairment index of Hg risk to aquatic ecosystems and found that 12% of site-years exceeded high or severe benchmarks of fish, wildlife, or human health risk. Collectively, this continental-scale study demonstrates the utility of dragonfly larvae for estimating the potential mercury risk to fish and wildlife in aquatic ecosystems and provides a framework for engaging citizen science as a component of landscape Hg monitoring programs." **18772.** Ekvall, M.T.; Sha, Y.; Palmér, T.; Bianco, G.; Bäckman, J.; Åström, K.; Hansson, L.-A. (2020): Behavioural responses to co-occurring threats of predation and ultraviolet radiation in *Daphnia*. *Freshwater Biology* 65(9): 1509-1517. (in English) ["(1) Organisms in the wild are faced with multiple threats and a common response is a change in behaviour. To disentangle responses to several threats, we exposed two differently sized species of the freshwater invertebrate *Daphnia* to solar ultraviolet radiation (UVR) and predation from either moving pelagic or benthic ambush predators. (2) Using an advanced nanotechnology-based method, we tracked the three-dimensional movements of those mm-sized animals at the individual level. Each behavioural trial was performed both under conditions resembling night (no UVR) and day (UVR) and we examined patterns of the depth distribution and swimming speed by *Daphnia* across three treatments: no predator (control); bottom-dwelling damselfly (*Calopteryx* sp.); and fish (stickleback, *Pungitius pungitius*) predators. We also quantified the actual predation rate by the two predators on the two *Daphnia* species, *D. magna* and *D. pulex*. (3) We show that individual *Daphnia* are able to identify predators with different feeding habitats, rank multiple and simultaneously occurring risks and respond in accordance with the actual threat; complex responses that are generally associated with larger animals. (4) In a broader context, our results highlight and quantify how a cocktail of everyday threats is perceived and handled by invertebrates, which advances our understanding of species distribution in space and time, and thereby of population dynamics and ecosystem function in natural ecosystems." (Authors)] Address: Hansson, L.-A., Aquatic Ecology, Dept of Biology, Ecology Building, Lund University SE-223 62 Lund, Sweden. Email: lars-anders.hansson@biol.lu.se

**18773.** Emiliyamma, K.G.; Palot, M.J.; Charesh, C. (2020): A new species of *Platylestes* Selys (Odonata: Zygoptera):

Lestidae) from the coastal area of Kannur District, Kerala, India. *Journal of Threatened Taxa* 12(13): 16854-16860. (in English) ["The genus *Platylestes* Selys, 1862 is known from India, by only one species, *P. platystylus* from eastern India, West Bengal, and recently from Kerala. Here, we describe a new species *Platylestes kirani* from the coastal tracts of the northern part of Kerala, southern India. The new species differs from all other known species of the genus by its unique coloration, distinct marking on synthorax, and the shape of anal appendages." **18774.** Epp, L.J. (2020): Assessing the effect of *Bacillus thuringiensis* var. *israelensis* on nontarget Chironomidae emergence. MSc. thesis, Department of Biology, Faculty of Science, University of Ottawa: xvi + 220pp. (in English) ["*Bacillus*-derived larvicides, which selectively target mosquito (Diptera: Nematocera: Culicidae) populations to reduce nuisance and health risks, were applied in the South March Highlands Conservation Forest near residential neighbourhoods in Ottawa, Ontario. The objective was to assess effects of application on the nontarget mosquito relative, Chironomidae (Diptera: Nematocera: Chironomidae), and other nontarget aquatic taxa captured using emergence traps. A secondary objective was to assess physicochemical variables that influence Chironomidae emergence. Study ponds received an application of *Bacillus thuringiensis* var. *israelensis*, a subset also received an application of *Bacillus sphaericus*, and a group of control ponds were left untreated over 3 years (2016-2018). Weekly sampling included trap collections and measurements of water temperature, pH, water depth, conductivity, dissolved oxygen, ammonia, nitrate, and sulphate. Drought in 2016, high precipitation throughout 2017, and seasonal precipitation in 2018 influenced variable physicochemical conditions. Principal component analyses identified differences between sampling groups and between years. Redundancy analyses correlated insect emergence with pond pH, average water depth and water temperature and indicated a strong relationship between Chironomidae emergence and average water depth. Although significantly less Chironomidae annual emergence was observed at treated sites in 2017 and 2018, zero-inflated negative binomial generalized linear mixed modelling failed to detect a significant Bti treatment effect when controlling for within group variation. Rather, variations in pH, mean water depth and water temperature were identified as drivers of Chironomidae emergence. Culicidae emergence was reduced to zero briefly following treatment in 2017 and 2018. The model detected a marginal negative treatment effect on Culicidae in 2017 only, and a positive treatment effect in 2018 at the onset of a secondary hydroperiod, in the absence of treatment. Variations in pH and water temperature were also identified to be drivers of Culicidae emergence. Modelling failed to detect treatment effects on any of the nontarget taxa abundance, including Diptera, Lepidoptera, Ephemeroptera, Odonata, Coleoptera, Hymen-

optera, and Arachnida. An inverse relationship between insectivore and prey taxa abundance was observed. In 2018, taxa richness increased between years and trended higher at treated sites and a positive relationship between insectivore and prey taxa richness was observed. In 2017, Shannon-Weiner index and Simpson's index of diversity were higher at untreated sites, and in 2018 diversity indices were higher at treated sites, with taxa richness increasing between years and higher evenness trending at treated sites. Our data suggest that treatment effects were potentially shrouded by natural variability of physicochemical variables, especially due to the varying hydroperiod observed over the three years of sampling. Additional work is needed to capture average conditions and separate confounding variables from treatment effects. This study provides an inventory of the current wetland insect community in the South March Highlands Conservation Forest landscape that offers a reference for ongoing mosquito management." (Author)] Address: not stated

**18775.** Geary, M.; von Hardenberg, A. (2020): White-faced Darter distribution is associated with coniferous forests in Great Britain. *Insect Conservation and Diversity* 14(1): 15-25. (in English) ["Understanding of dragonfly distributions is often geographically comprehensive but less so in ecological terms. 2) White-faced darter (*Leucorrhinia dubia*) is a lowland peatbog specialist dragonfly which has experienced population declines in Great Britain. *L. dubia* are thought to rely on peat-rich pool complexes within woodland but this has not yet been empirically tested. 3) We used dragonfly recording data collected by volunteers of the British Dragonfly Society from 2005 to 2018 to model habitat preference for *L. dubia* using species distribution models across Great Britain and, with a more detailed landcover dataset, specifically in the North of Scotland. 4) Across the whole of Great Britain our models used the proportion of coniferous forest within 1km as the most important predictor of habitat suitability but were not able to predict all current populations in England. 5) In the North of Scotland our models were more successful and suggest that habitats characterised by native coniferous forest and areas high potential evapotranspiration represent the most suitable habitat for *L. dubia*. 6) We recommend that future *L. dubia* monitoring should be expanded to include areas currently poorly surveyed but with high suitability in the North of Scotland. 7) Our results also suggest that *L. dubia* management should concentrate on maintaining Sphagnum rich pool complexes and the maintenance and restoration of native forests in which these pool complexes occur." **18776.** Gomes Viana, C.; Reis Campos, I.; Santana Lustosa, G.; Silas Veras, D. (2020): Environmental gradients as filters on the composition of aquatic insect of the Cerrado Caatinga, Brazil. *Acta Brasiliensis* 4(3): 142-148. (in English, with Portuguese summary) ["The patterns of aquatic in-

sect diversity are influenced by landscape structure and environmental gradients that can be altered significantly through changes in land use. The aim of the present study was to verify if the patterns of diversity of the orders Odonata and Trichoptera vary significantly between preserved and altered sites, along a gradient of environmental impact. Data were collected on the structural and environmental characteristics of the stream, and the assemblages of aquatic insects at seven sampling points in a Cerrado-Caatinga ecotone of northeastern Brazil, in the dry seasons of 2018 and 2019. The results indicated that altered streams had higher electrical conductivity and lowest HII (habitat integrity index) values in comparison with the preserved ones, being determinant in the distribution of genera, and low pH values increased genera richness, informations that can guide management strategies for biodiversity conservation. Which supports the conclusion that the diversity of aquatic insects is determined by the influence of environmental filters in the streams." **18777.** Hoffmann U (2020): Ein Leben im Verborgenen – Nachweise der Gestreiften Quelljungfer (*Cordulegaster bidentata*) im Kreis Lippe, NRW. Berichte des Naturwissenschaftlichen Verein für Bielefeld und Umgegend 57: 58-80. (in German) ["With the present work, an essential gap in the state of knowledge on the distribution and population situation of *C. bidentata* at the northern border of its European range could be closed by means of a targeted search from 2017 to 2019. The study shows that the northern Hessian and southern Lower Saxon occurrences find their northern continuation in the district of Lippe and represent a common settlement area. A colonisation via the Weser region can be assumed as very probable for the eastern Lippe source areas, whereas the western occurrences along the Osning chain could be associated with a colonisation from the Rhine catchment area. The well-founded assumption that two different populations meet in the Lippe district would have to be substantiated by genetic tests. Only 20 % of the 201 mapped, potentially suitable spring sites and spring streams were found. Despite the 62 individual sightings, the occurrences in the district must be considered rather poor in individuals. *C. bidentata* remains a rare species whose conservation status of RL 2 (critically endangered) is still justified, especially in view of the high responsibility we bear in Europe for this endemic species. According to various forecasts and observations, the influence that climate change will have on the habitat of springs and spring creeks must be assessed as quite serious (LANUV 2010, 2016). This concerns on the one hand the increase in average temperatures and on the other hand the changing precipitation amounts and their seasonal distribution. In addition, the forced forest conversion will change many of the spring habitats and thus their suitability for colonisation by *C. bidentata* in the future." (Authors; DeepL)] Address: Hoffmann, Ulrike, Prof.-Schacht-Str. 2, 32657 Lemgo, Germany. E-Mail: mahpa@web.de

**18780.** Ilahi, I.; Yousafzai, A.M.; Ul Haq, T.; Rahim, A.; Attaullah, M.; Naz, D. (2020): Toxicity to lead, cadmium and copper in nymphs of three odonate species. *Bioscience Research* 17(4): 2448-2464. (in English) ["The present research aimed to investigate the effect of seven days exposure to lead (Pb), cadmium (Cd) and copper (Cu) on survival and feeding rate of nymphs of three odonate species i.e., *Ischnura elegans*, *Trithemis aurora* and *Pantala flavescens*. During this study, the nymphs of all the three odonate species survived when exposed separately to 40 ppm each of Pb and Cd, and 10 ppm of Cu. Cu appeared most toxic. The

LC50 values of Cu against *I. elegans*, *T. aurora* and *P. flavescens* was 148.2, 101.8 and 173.6 ppm, respectively. The feeding rate of *I. elegans* and *T. aurora* nymphs when separately exposed to sublethal concentration of Pb and Cd (40 ppm each) was not different significantly ( $P>0.05$ ) from control nymphs. However, the feeding rate of *I. elegans* and *T. aurora* nymphs exposed to the sublethal concentration of Cu (10 ppm) was significantly lower ( $P<0.05$ ) from the control nymphs. The feeding rate of *P. flavescens* nymphs when exposure to the sublethal concentration of any of the three metals was significant lower ( $P<0.05$ ) than control nymphs. It is concluded that among Pb, Cd and Cu, the Cu is most toxic to *I. elegans*, *T. aurora* and *P. flavescens* nymphs. It is further concluded that among Pb, Cd and Cu, the sublethal concentration of Cu significantly reduces the feeding rate of *I. elegans*, *T. aurora* and *P. flavescens* nymphs." (Authors)] Address: Ilahi, I., Dept of Zoology, Univ. of Malakand, Chakdara, Dir Lower, Khyber Pakhtunkhwa, Pakistan. E-mail: ikramilahi@uom.edu.pk

**18781.** Jain, A.; Rasmussen, A.K.; Milla, K.A.; Richard, B.A.; Pescador, M.L. (2020): Water chemistry and aquatic insect assemblages of ephemeral ponds in the Munson Sand Hills region of the Apalachicola National Forest, Florida. *Southeastern Naturalist* 19(2): 205-232. (in English) ["Ephemeral ponds in the Munson Sand Hills region (MSH) of Apalachicola National Forest (ANF) are an essential resource in the life cycles of a variety of amphibian species, a number of which are threatened or endangered. Various types of human activities have disturbed some of these ponds threatening their survival. Although extensive research has been done on the biology of amphibians in the ponds, little is known of the invertebrates and to what extent the water quality may be affected by human impacts. We monitored 4 ponds, representing a spectrum of sizes, natural settings, and anthropogenic disturbance, in terms of water chemistry and aquatic insect assemblages seasonally for 2 years. Pond waters were characterized by acidic pH, low ionic strength, low buffering capacity, low nutrient concentrations, and phosphorus-limiting conditions. The water quality of studied ponds was similar to those reported for natural wetlands in west-central Florida. The chemistry, as compared to a nearby sinkhole, indicated that these ponds were mainly recharged with rain and had no connectivity to groundwater. Aquatic beetles (Coleoptera), Odonata, and aquatic bugs (Heteroptera) were the most diverse groups of aquatic insects recorded. Species collected included many common, predatory species adapted to exploit resources in fishless, temporary ponds. Water chemistry and aquatic insect composition showed minor spatial-temporal variations among ponds. The results of this study indicate that human disturbances have not had a significant effect on pond water quality, posing no threat to amphibian and other wildlife species, and the sampled ponds had abundant and diverse aquatic insect fauna. The aquatic insect assemblages documented in this study provide evidence that pond type and the top-down effects of aquatic insects as predators are important determinants of community structure, which is a common theme observed in temporary ponds found in other regions

within temperate biomes." (Authors)] Address: Jain, Amita, Center for Water Resources, College of Agriculture and Food Sciences, Florida A&M University, Tallahassee, FL 32307, USA. E-mail: amita.jain@famou.edu

**18783.** Kawashima, I. (2020): The order Odonata illustrated in Heikuro (Takanori, Jyakuso-an) Yoshida's "Yoshida-O-Chifu (Part 1)" deposited in the Nagoya City Museum. *Tombo* 62: 77-90. (in English, with Japanese summary) ["The author investigated the Odonata illustrated in a manuscript by Goro Oshio (1830-1894) of Heikuro (Takanori, Jyakuso-an) Yoshida (1805—1869)'s "Yoshida-O-Chifu (Part 1)" housed in the Nagoya City Museum. Out of 65 figures, 27 species in 40 figures were identified as follows: Lestidae: *Lestes sponsa*; Calopterygidae: *Calopteryx Comelia*, *Atrocalopteryx atrata*; Coenagrionidae: *Ceragrion melanurum*, *C. nipponicum*; Aeshnidae: *Boyeria maclachlani*, *Aeschnophlebia longistigma*, *A. anisoptera*, *Gynacantha japonica*, *Polycanthygyna melanictera*, *Anax parthenope*, *A. nigrofasciatus*; Gomphidae: *Sinictinogomphus clavatus*; Corduliidae: *Epithea marginata*; Macromiidae: *Epophthalmia elegans*; Libellulidae: *Rhyothemis fuliginosa*, *Sympetrum darwinianum*, *S. maculatum*, *S. risi*, *S. croceolum*, *Pseudothemis zonata*, *Deielia phaon*, *Nannophya pygmaea*, *Crocothemis servilia*, *Pantala flavescens*, *Lyriothemis pachygastra* and *Orthetrum albistylum*. Of the remaining 25 figures the author could not be certain of the species identification as follows: Lestidae: *Sympetma paedisca* ?; *Lestes* spp. (*sponsa*, *temporalis* or *japonica*); Calopterygidae: *Mnais* spp. (*costalis* or *pruinosa* ?); Platycnemididae: *Pseudocopteryx annulata* ?; Coenagrionidae: gen. et sp. (*Ischnura asiatica* ?); Aeshnidae: *Gynacantha* sp. (*japonica* ?) or *Anax* sp. (*nigrofasciatus* ?); Gomphidae: *Asiagomphus* sp. (*melaenops* or *pryeri* ?); *Davidius fujijama* ?; *Trigomphus* sp. (*ogumai* ?); *Shoagomphus postocularis* ?; Macromiidae: *E. elegans* or *Macromia* spp. (*amphigena* or *daimoji* ?); Libellulidae: *Sympetrum* spp. (*parvulum*, *eroticum* or *kunckeli* ?); *Sympetrum* sp. (*risi*, *baccha*, or *eroticum* ?); *Sympetrum* sp. (*risi* ?); *Sympetrum* sp. (*frequens* ?). Many figures are of a quality that makes identification to generic or specific levels possible to be precise. On the other hand, the arrangement was not intended to be carried out from a phylogenetic viewpoint

which was how Western natural history was done at that time." (Author)] Address: Kawashima, I., Nagasawa 1-50-9, Yokosuka-shi, Kanagawa, 239-0842 Japan. Email: itsurok29-@jcom.home.ne.jp

**18784.** Kita, A.; Nakahara, M.; Tokuda, M. (2020): Changes in Odonata abundance between 2000 and 2015–2016 in Saga Plain, northern Kyushu, Japan. *Journal of Insect Conservation* 24: 575-583. (in English) ["The impacts of systemic pesticides on biodiversity are a major ecological concern. Rapid population declines of *Sympetrum* species (Odonata: Libellulidae) have been reported in various localities in Japan beginning in the 2000s. Several studies suggested that nursery box use of fipronil in paddy fields to prevent insect feeding on rice seedlings negatively impacts *Sympetrum* larvae. Although several other Odonata species are suspected to have declined significantly in recent decades, accurate evaluations of their population declines and identification of the causes are difficult due to limited data on population density prior to the declines. In addition, a recent study revealed that herbicide use negatively affects phytophilous species, but positively impacts benthic populations of lentic Odonata by reducing the prevalence of macrophytes. To evaluate the changes in the abundance of Odonata during recent decades, we conducted line transect observation of Odonata populations at one site along the Tafusegawa River in Saga Plain, northern Kyushu, Japan in 2000 and 2015–2016, before and after the use of fipronil in paddy fields in this area. We identified that *Sympetrum eroticum eroticum* (Selys) populations have significantly decreased in recent years. In addition, prevalence of a lotic benthic species, *Asiagomphus pryeri* (Selys), has significantly decreased in this time period. Other lotic benthic species have also declined in this area, suggesting that benthic environments might have degraded in recent years. In contrast to the decrease of the abovementioned species, prevalence of the lentic and benthic species *Orthetrum melania melania* (Selys) and *Rhyothemis fuliginosa* Selys significantly increased. The densities of lentic phytophilous species appear to have decreased, suggesting that reduction of macrophytes in surrounding lentic environments could be involved in these changes." **18785.** Kosterin, O.E. (2020): Odonata of the great Lake Tonle Sap of Cambodia, as examined in 2017/2019. *International Dragonfly Fund - Report 129*: 29-98. (in English) ["Lake Tonle Sap in NW Cambodia is the largest freshwater lake in Southeast Asia and one of the most productive freshwater ecosystems in the world, so its banks are a home for ca 1,5 million people. It serves as a natural reservoir of the excess water of the Mekong River and cyclically changes its area from 2,500 km<sup>2</sup> in May to 16,000 km<sup>2</sup> in October. Its banks are naturally occupied by temporarily inundated forest and scrub, at present mostly replaced by rice fields. The present day semiaquatic vegetation of the lake is to a large extent formed by invasive plant species. The hitherto existing data on Odonata of the lake are very scarce. The

author briefly examined the bank and floodplain at the NW part of the lake in February/March 2017, June and November 2018 and December 2019. Five main localities studied are described and illustrated in detail. In total 41 odonate species of four families (22 in Libellulidae) were found. Most of them are common and widespread lentic species but *Macrogomphus phalantus* is a species hitherto known only by few specimens from swamped forests of Borneo and Sumatra; its Tonle Sap population was earlier described by the author as the subspecies *M. phalantus jayavarman* Kosterin, 2019. The earlier published report by Seehausen et al. (2016) of *Sinictinogomphus clavatus* (not found by the author) was a considerable extension of the known species' range to the south. Six species were found in all main examined localities and ten only in one of them. At any season at the lake immediate bank (that is water front at the lowest level), *Brachythemis contaminata* predominates overwhelmingly, *Orthetrum sabina* and *Crocothemis servilia* are numerous, two damselfly species, *Pseudagrion microcephalum* and *P. rubriceps*, invariably occur at floating vegetation (mostly water hyacinth), and *Trithemis pallidinervis*, *Urothemis signata*, *Rhyothemis phyllis*, *R. variegata* and *Tholymis tillarga* are common at bushes. *Agriocnemis nana*, *Ceragrion praetermissum*, *Ischnura senegalensis*, *Macrogomphus phalantus*, and *Aethriamanta aethra* were occasionally met at the lake bank. Other 26 species were found, with different occurrence and quantity, on the lake floodplain. Variation of the male occiput coloration of *Amphiallagma parvum* is commented." **18788.** Kosterin, O.E. (2020): First data on Odonata of Prey Long Forest in Cambodian Lowland. International Dragonfly Fund - Report 129: 1-28. (in English) ["Prey Long (Prey Lang) Forest is the largest remaining lowland rainforest in Indochina, shared by Stung Treng, Preah Vihear, Kampong Thom and Kratie Provinces of Cambodia, which has been persisted until present because of the lack of roads. It includes patches of unique evergreen swamp forests. Odonata of Prey Long forest, including Cheum Takong forest swamp, was briefly examined in December 2019, while the already deforested area was examined in June 2018. The former examination resulted in 40 species, the latter in 34 species, 60 species in total. Two species, *Copera chantaburii* Asahina, 1984 and *Burmagomphus williamsoni* Förster, 1914, are for the first time reported for Cambodia from the deforested area (Chey Saen District of Preah Vihear Province). The swamped forest of Cheum Takong provided 17 species, 5 of which were not found elsewhere in the considered area, 3 are rare and 4 generally Sondaic. Prey Long Forest should be reexamined in the rainy season soon after the road to Spong village is constructed." (Author) ] Address: Kosterin, O.E., Institute of Cytology & Genetics, Siberian Branch, Russian Acad. Sciences, Lavrentiev Ave 10, 630090 Novosibirsk, Russia. E-mail: kosterin@bionet.nsc.ru

**18789.** Kosuke, N.; Dai, K.; Hiroyuki, Y.; Taku, K.; Takehiko, I.H. (2020): Investigating effect of climate warming on the population declines of *Sympetrum frequens* during the 1990s in three regions in Japan. Scientific Reports 10(1): 9 pp. (in English) ["Climate warming is of concern as a key factor in the worldwide decline in insect populations. In Japan, numbers of a common dragonfly in rice paddy fields, *S. frequens*, decreased sharply in the 1990s. Because *S. frequens* migrates to cooler mountains in summer, climate warming has been suggested as one of the main causes of the population decline in addition to agronomic factors. Here, we analysed the relation between summer temperatures and population densities of *S. frequens* and the related *S. infuscatum*, which does not migrate to mountains in summer, using published population monitoring data and temperature data from three regions (Toyama, Ishikawa, and Shizuoka) in Japan. Decadal differences in summer temperatures lay within the range of fluctuations among years, suggesting that an increase in summer temperatures cannot explain the past sharp population declines. However, regression analyses using monitoring data from Toyama showed that the population dynamics of both species in autumn are negatively correlated with summer temperatures in the same year. These results suggest that high temperatures in summer directly affect adult mortality to an extent that results in a decrease in population growth." **18790.** Krause, M.A.; Koster, T.; MacNeill, B.N.; Zydek, D.J.; Ogburn, N.T.; Sharpin, J.; Shell, R.; Lajeunesse, M.J. (2020): Diversity and abundance of dragonflies and damselflies in Tampa Bay, Florida. Florida Entomologist, 103(3): 392-396. (in English) ["Little is known about the community of Odonata in Tampa Bay, Florida, USA. To address this gap, we conducted 2 longitudinal surveys of adult odonates in a natural floodplain of the Hillsborough River in 2013 and 2017. Along with abundance and species diversity, we also measured intraspecific variation in body size, sexual dimorphism, wing-cell asymmetry, and water mite ectoparasitism. Our first weekly survey from Oct 2013 to Oct 2014 sampled 327 adults (230 female, 97 male) from 8 dragonfly species, with *Erythemis simplicicollis* Say representing 79% of captures, followed by the second most abundant (14%), the Florida non-native and neotropical *Miathyria marcella* Selys. Our second weekly survey from Sept to Dec 2017, which focused on both damselflies and dragonflies and captured 205 adults from 8 species, with *Ischnura posita* Hagen being the most abundant with 70% of captures. Female-biased sexual size dimorphism was found in both *E. simplicicollis* and *I. posita*; however, both sexes were equally variable in size and symmetric in a meristic trait. Female and male *M. marcella* were equally variable, monomorphic, and symmetric. Combining symmetry data from each sex, only *I. posita* damselflies were asymmetric overall. Finally, we did not observe any parasitism by larval water mites in either survey. We aim to continue surveys to track seasonal and climate-driven changes in dragonfly diversity and phenology in this region." **18791.** La Porta, G.; Goretti, E. (2020): Movement and demography of Southern damselfly (*Coenagrion mercuriale*, Odonata) in a Mediterranean lotic ecosystem. Ethology Ecology & Evolution 32(2): 107-121. (in English) [*Coenagrion castellani*; "Home range, routine movement, and dispersal are key factors affecting the population distribution, thus playing a crucial role in spatial dynamics and gene flow. In this regard, detailed investigations on insects require the capture of the specimens and subsequent manipulation. The movement and the abundance of a population of the damselfly *Coenagrion mercuriale* were monitored using the mark-recapture method at a breeding site located in a Mediterranean watercourse in Central Italy. The study area was a transect of 250 m along a ditch, subdivided into five stretches varying from 40 to 70 m each. A total of 849 adults was captured and 210 specimens of them were recaptured on a 17-day survey (from mid-June to early July 2018), corresponding to an estimation of population size of 5,600 specimens. Recapture and survival probabilities revealed no significant effect ensuing from handling and marking with different colours. Specimens of different stretches showed different sedentary rate. The recaptured individuals had a low vagility, with a high proportion of individuals which are incline to philopatry." **18796.** Mogali, S.M.; Saidapur, S.K.; Shanbhag, B.A. (2020): Behavioral responses of tadpoles of *Duttaphrynus melanostictus* (Anura: Bufonidae) to cues of starved and fed dragonfly larvae. *Phyllomedusa* 19(1): 93-98. (in Defense behavior, dietary cues, kairomones, *Pantala flavescens*, predator-prey interactions, tadpoles, Wandering Glider.) ["Tadpoles of *Duttaphrynus melanostictus* use chemoreception to detect kairomonal cues and excretory metabolites from predatory anuran tadpoles (*Hoplobatrachus tigerinus*) that consume them. We describe here the behavioral responses of tadpoles of *D. melanostictus* to predatory dragonfly larvae (*Pantala flavescens*). The predator's kairomones (water conditioned by the starved predator) or its diet-derived metabolites released in excreta of predator after consumption of conspecific prey tadpoles were used to simulate predation risk. The tadpoles of *D. melanostictus* had no behavioral response to predator kairomones. However, the larvae reduced swimming movements and overall time spent in swimming, and had a higher burst speed/swimming velocity in response to water borne cues released from the excreta of predators fed conspecific prey. Thus, just the presence of dragonfly larvae does not elicit defense behaviors in tadpoles of *D. melanostictus*, but when predation risk is recognized as real (i.e., when tadpoles are exposed to excretory metabolites of predators fed conspecific tadpoles), defense behaviors are activated." **18797.** Moon, M.Y.; Chang, W.J.; Lee, D.-S.; Lee, D.-Y.; Hwang, S.J.; Noh, S.-Y.; Kwak, I.-S.; Park, Y.-S. (2020): Characterizing responses of biological trait and functional diversity of benthic macroinvertebrates to environmental variables to develop aquatic ecosystem health assessment index. *Korean Journal of Ecology and Environment* 53(1): 31-45. (in Korean, with English summary) ["The biological indices based on the community structure with species richness and/or abundance are commonly used to assess aquatic ecosystem health. Meanwhile, recently functional traits-based approach is considered in ecosystem health assessment to reflect ecosystem functioning. In this study, we

developed a database of biological traits for 136 taxa consisting of major stream insects (Ephemeroptera, Plecoptera, Trichoptera, Coleoptera, and Odonata) collected at Korean streams on the nationwide scale. In addition, we obtained environmental variables in five categories (geography, climate, land use, hydrology and physicochemistry) measured at each sampling site. We evaluated the relationships between community indices based on taxonomic diversity and functional diversity estimated from biological traits. We classified sampling sites based on similarities of their environmental variables and evaluated relations between clusters of sampling sites and diversity indices and biological traits. Our results showed that functional diversity was highly correlated with Shannon diversity index and species richness. The six clusters of sampling sites defined by a hierarchical cluster analysis reflected differences of their environmental variables. Samples in cluster 1 were mostly from high altitude areas, whereas samples in cluster 6 were from lowland areas. Non-metric multidimensional scaling (NMDS) displayed similar patterns with cluster analysis and presented variation of taxonomic diversity and functional diversity. Based on NMDS and community-weighted mean trait value matrix, species in clusters 1-3 displayed the resistance strategy in the life history strategy to the environmental variables whereas species in clusters 4-6 presented the resilience strategy. These results suggest that functional diversity can complement the biological monitoring assessment based on taxonomic diversity and can be used as biological monitoring assessment tool reflecting changes of ecosystem functioning responding to environmental changes." **18799.** Motta, L.; Barrios-Garcia, M.N.; Ballari, S.A.; Rodriguez-Cabal, M.A. (2020): Cross-ecosystem impacts of non-

native ungulates on wetland communities. *Biological Invasions* 22: 3283-3291. (in English) ["Herbivory by non-native species can create strong direct and indirect effects on plant and arthropods communities that can potentially cross ecosystem boundaries. Yet, the cross-ecosystems impacts of non-native species are poorly understood. We took advantage of ongoing invasions by non-native ungulates in Patagonia, Argentina, to examine their cross-ecosystem impacts on water parameters, littoral vegetation and aquatic macroinvertebrate assemblages in wetlands. We found a gradient of invasion by non-native ungulates from intact (non-invaded) to highly invaded wetlands. These highly invaded wetlands had ~ 24% less vegetation cover, which was 72% shorter in height than vegetation in intact wetlands. As a result, the abundance of predatory macroinvertebrates such as Odonata was reduced by ~ 90%; while Diptera were ~ 170% more abundant, and Oligochaeta were recorded mostly at invaded sites. In contrast, we did not find evidence that non-native ungulates altered water parameters. Understanding the indirect consequences of invasive non-native species is crucial for quantifying the real impacts of global change. Our results show strong cross-ecosystem impacts of non-native ungulates on macroinvertebrate wetland communities, highlighting the importance of indirect interactions beyond ecosystem boundaries." **18801.** Ngo, C.D.; Le, P.L.T.; Nguyen, H.D.; Truong, P.B.; Hoang, N.T.; Ngo B.V. (2020): Diet of the Bronze Skink *Eutropis macularius* (Reptilia: Squamata: Scincidae) from Thua Thien Hue Province, Central Vietnam. *Russian Journal of Herpetology* 27(4): 209-216. (in English) ["In this study, we examined the diet of 149 males and 147 females of *Eutropis macularius* from Thua Thien Hue Province, central Vietnam

using a nonlethal stomach-flushing technique. The prey items of *E. macularius* composed of Araneae, Insecta (Blattodea, Coleoptera, Hymenoptera, Isoptera, Odonata, and Orthoptera), Mollusca (Philomycidae), and plant materials. The most important prey items were insect larvae, hymenopterans (including ants), grasshoppers, and termites, for both sexes in three populations. Plant materials were also found in the stomach of *E. macularius* with an index of relative importance of 7.19%, suggesting that *E. macularius* is an omnivorous species. However, the dominant prey categories of *E. macularius* were insects, including insect larvae, hymenopterans, grasshoppers, and termites, with many small, sedentary, clumped prey items. Simpson's heterogeneity index of skinks from three populations from Bach Ma National Park as well as from Aluoi and Huong Tra districts were 10.07, 7.85, 3.94, respectively. *Eutropis macularius* showed significant positive correlations between mouth width (MW) and prey width ( $P = 0.001$ ) and between MW and prey volume ( $P < 0.0001$ ). There are significant positive correlations between snout-vent length (SVL) and prey sizes consumed: between SVL and prey length,  $P < 0.0001$ ; SVL and prey width,  $P < 0.0001$ ; and between SVL and prey volume,  $P < 0.0001$ . These results indicated that SVL and MW are the limiting factors on the size of prey consumed in this skink." **18802.** Okude, G.; Fukatsu, T.; Futahashi, R. (2020): Interspecific crossing between blue-tailed damselflies *Ischnura elegans* and *I. senegalensis* in the laboratory. *Entomological Science* 23: 165-172. (in English) ["*Ischnura* species are among the most common damselflies in the world, which often exhibit female color polymorphisms. One morph, called androchrome, is similar to males in its color pattern, whereas the other morphs, generally referred to as gynochromes, exhibit female-specific colors. In several *Ischnura* species, the female polymorphism is heritable, although molecular and genetic mechanisms remain largely unknown. The dominant-recessive patterns of the female color morphs may differ between species. For example, androchromic females are dominant to gynochromic females in *Ischnura elegans*, whereas androchromic females are recessive in *Ischnura senegalensis*. Here we report a case of interspecific hybridization between a gynochrome female of *I. elegans* and a male of *I. senegalensis* in the laboratory. We obtained 61 hybrid adult offspring, of which all 31 females were of gynochrome morph. DNA analyses of the hybrids confirmed that nuclear DNA sequences were derived from both parent species, whereas mitochondrial DNA sequences were maternally inherited. In the hybrids, the postocular spots of female heads, the shape of male appendages, and the color of female's cerci resembled those of *I. elegans*, whereas the size of abdominal blue spots was similar to that of *I. senegalensis*. The shape of prothorax and basal abdominal markings were intermediate in females. The larval developmental traits and the morphological changes in the final larval instar of the hybrids were similar to those of *I. senegalensis*. To our knowledge, this is the first

report of hybrids between two damselfly species with different dominant-recessive patterns of female color morphs." (Authors)] Address: Futahashi, R., Bioproduction Res. Inst., National Institute of Advanced Industrial Science and Technology (AIST), Central building 6th, 1-1-1 Higashi, Tsukuba, Ibaraki 305-8566, Japan. Email: ryo-futahashi@aist.go.jp

**18804.** Palacino-Rodríguez, F.; Altamiranda-Saavedra, M.; Palacino, D.A.; Penagos, A.C. (2020): Ecology of *Mesamphiagrion laterale* (Odonata: Coenagrionidae): abundance, reproduction and interactions with co-occurring species. *International Journal of Odonatology* 23(2): 165-182. (in English) ["The behavior of *M. laterale* (Selys, 1876) is described based upon 2430 hours of observation. A total of 2820 individuals were observed for 270 days from 2014 to 2015 using mark-recapture. Probabilities of resight, highest reproductive activity, time-perch and time of perch-temperature were statistically analyzed. *Mesamphiagrion laterale* is not a territorial species, the individuals perch on grass, trees, garbage, ground, and rocks, they feed on hemipterans, mosquitoes, spiders and other damselflies, and are prey to spiders and birds. Conspecific siege and interspecific interactions by perch were observed. No courtship was observed. During tandem, which lasted for 3–90 min, the ventral side of the male's abdominal segment 2 was in contact with the female's abdominal segments 8–10 until a wheel was formed. We observed three tandem pair combinations: sexually mature males and females, immature males with mature females, and immature males and females. While copulation lasted from 7 to 20 min, oviposition lasted from 12 to 15 min. Irrespective of male presence, oviposition occurred in submerged or emerged areas of *Eichornia crassipes*. We recorded the highest reproductive activity between 12:00 and 12:35 (Colombia Time-COT, UTC-5). Above 20°C, a larger perching area close to the water allows more reproductive events. However, a more extensive canopy cover impedes achieving optimal reproductive temperatures. Species interactions within this community may be explained by temporal and spatial niche partitioning." **18807.** Pinkert, S.; Zeuss, D.; Dijkstra, K.-D. B.; Kipping, J.; Clausnitzer, V.; Brunzel, S.; Brandl, R. (2020): Climate–diversity relationships underlying cross-taxon diversity of the African fauna and their implications for conservation. *Diversity and Distributions* 26(10): 1330-1342. (in English) ["Many taxa show remarkable similarities in their diversity patterns, and these similarities are commonly used to define large-scale conservation priorities. Here, we investigated the relative importance of contemporary climate and climate change since the Last Glacial Maximum for determining the species richness and rarity patterns of four animal taxa. We assessed the extent to which diversity patterns are congruent across taxa because of similar responses to these climatic aspects, and we identify regions that are disproportionately diverse due to their palaeoclimatic stability. Location: Sub-Saharan Africa. Time period: LGM–contemporary. Major taxa studied: Mammal, bird, amphibian and dragonfly species. Methods: Diversity patterns were predicted based on their relationships with contemporary climate and Quaternary climate change, respectively. Climate–diversity relationships were modelled with and without accounting for spatial autocorrelation. For raw and predicted diversity patterns, cross-taxon congruence and the coverage of diversity hotspots by protected areas were determined. Results: Species richness and rarity of all taxa increased with increasing temperature and precipitation, but also with increasing palaeoclimatic stability. Cross-taxon congruence was higher for predictions based on contemporary climate than for predictions based on Quaternary climate change. Protected areas covered 17%–37% of the species richness and rarity hotspots and approximately 6% fewer hotspots of the underlying signatures of Quaternary climate change (i.e. biodiversity refugia). Main conclusions: Both contemporary climate and past climatic changes strongly affect species richness and rarity patterns. However, whereas contemporary climate–diversity relationships are largely congruent across

taxa, signatures of Quaternary climate change differ among taxa. Furthermore, protected areas emphasize regions with high species richness and rarity but fewer biodiversity refugia—even less than expected by random placement (<21%). Our results highlight the importance of historical factors for shaping large-scale diversity patterns and the potential of using palaeoclimatic stability–diversity relationships for identifying important conservation areas at the global scale." **18808.** Pires, A.; Drumm Müller, N.F.; Stenert, C.; Maltchik, L. (2020): Influence of different riparian vegetation widths and substrate types on the communities of larval Odonata (Insecta) in southern Brazilian streams. *Acta Limnologica Brasiliensia* 32 e301: 16 pp. (in English, with Portuguese summary) ["Aim: We assessed the influence of substrate type and categories of riparian vegetation widths on the community structure of Odonata (Insecta) in southern Brazilian streams. Methods: Sampling took place in twelve stream reaches differing in their riparian vegetation widths (from more than 40 m up to less than 5 m). Larval odonates were collected in inorganic (stone and gravel) and organic (leaf litter) substrates at each stream reach. Differences in Odonata composition among substrates and categories of riparian vegetation width were tested using PERMANOVA and visualized with ordination diagrams. In addition, we assessed the influence of riparian vegetation width taking into account two levels of resolutions: fine (four categories: > 40 m, 30-15 m, 15-5 m and < 5 m) and coarse (narrower and broader than 15 m). Results: Odonata composition differed more strongly according to substrate type regardless of the level of resolution. Organic substrate (litter) had different composition and higher richness than inorganic ones. Odonata composition significantly differed between riparian vegetation widths at the coarser level of resolution (narrower and broader than 15 m); at the coarser level, the interaction between substrate and riparian widths was significant, with the composition from litter substrate in broader widths differing from stone and gravel in narrower widths. Conclusions: The composition of odonate larvae responded to the major reductions in riparian widths (above > 15 m), indicating that reductions above this level are enough to affect the community structure of Odonata. Additionally, the different composition of Odonata in organic substrates in broader riparian vegetation widths compared to inorganic substrates in narrower widths indicate a complex relationship between riparian vegetation and substrate in the assembly of insect communities in southern Brazilian forest streams. The interaction between riparian vegetation widths and substrate suggests that the effects of reductions in riparian widths on Odonata composition are not similar across substrate types." (Authors)] Address: Pires, M.M., Laboratório de Ecologia e Conservação de Ecossistemas Aquáticos, Universidade do Vale do Rio dos Sinos – UNISINOS, Av. **18809.** Potapov, G.S.; Kolosova, Y.S.; Gofarov, M.Y.; Bolotov, I.N. (2020): Dragonflies and damselflies (Odonata) from Flores Island, Lesser Sunda Archipelago: New occurrences in extreme environments and an island-level checklist of this group. *Ecologica Montenegrina* 35: 5-25. (in English) ["Although the Odonata are common inhabitants of various extreme environments such as geothermal springs, brackish wetlands, mangroves, and volcanic lakes, the assemblages of this group associated with extreme habitats in Australasia are rather poorly known. Here, we combine museum collection data and published reports on Odonata from extreme habitats on Flores Island, Lesser Sunda Archipelago. The highly acidic Sano Nggoang Crater Lake (mean pH = 3.17) on Flores houses seven species as follows: *Agriocnemis pygmaea*, *Xiphiagrion cyanomelas*, *Neurothemis ramburii*, *Orthetrum pruinatum pruinatum*, *O. sabina*, *O. testaceum soembanum*, and *Anax gibbosulus*. A coastal marsh site with slightly brackish water on Flores harbors at least five dragonfly species as follows: *Diplacodes trivialis*, *Neurothemis intermedia excelsa*, *N. terminata*, *Pantala flavescens*, and *Rhyothemis phyllis ixias*. The migratory dragonfly *Pantala flavescens* was a single species recorded on the waterless Kanawa Island near the western edge of Flores. Our findings suggest that extreme habitats in eastern Indonesia primarily colonized by widespread generalist Odonata species. Finally, an updated checklist of Odonata species recorded from Flores Island was compiled. Our survey of museum specimens recovered two species not found on existing species lists for Flores: *N. intermedia excelsa* and *P. flavescens*." (Authors)] Address: Potapov, G.S., N. Laverov Federal Center for Integrated Arctic Research of the Ural Branch of the Russian Academy of Sciences Russian Federation

**18810.** Pouillon, J.-M.; Nel, A. (2020): The oldest representative of the modern clade Aeshnodea from the Lower Cretaceous Crato Formation, Araripe Basin, NE Brazil (Odonata: Anisoptera). *Cretaceous Research* 116, 104580: (in English) ["The hawker dragonfly *Primumaeshna britta* gen. et sp. nov., type genus and species of the new family *Primumaeshnidae*, is described from the Lower Cretaceous Crato Formation in Brazil, corresponding to the oldest record of the clade Aeshnodea. The previously described representatives of the Aeshnoptera from this formation belonged to extinct families or to the *Gomphaeschnidae*. Otherwise the oldest Aeshnodea were previously only known from the Cenomanian. This new discovery confirms that the diversification of the modern lineages of hawker dragonflies occurred during the Early Cretaceous." (Authors)] Address: Nel, A., Lab. Ent., Mus. Natn. Hist. **18811.** Pramual, P.; Thane, I.; Uttaruk, Y.; Thajjarern, J.; & Wongpakam, K. (2020): Efficiency of DNA barcodes for identification and documenting aquatic insect diversity in rice fields. *Tropical Natural History* 20(2): 169-181. (in English) ["Rapid and accurate identifications are crucial for biodiversity assessment. Yet, traditional methods for species identification have some limitations. In this study, we tested

the efficiency of mitochondrial cytochrome c oxidase I barcoding sequences for species identification and documenting diversity of aquatic insects in the rice fields of Thailand. Considerable success rate (80%) for species identification was found among the species of the order Odonata. Unidentifiable specimens of immatures were successfully associated with conspecific adults or by matching with reference sequences in the public DNA barcoding library. However, some specimens were ambiguous, possibly due to incomplete lineage sorting of closely related species or erroneous identification of the sequences in the public database. The technique was less successful for other insect orders because a lack of reference sequences in the DNA barcode library limits the utility of DNA barcoding. The Poisson tree process and Automatic Barcode Gap Discovery species delimitations revealed that the number of species recognized is more than twice that based on morphological identification. Therefore, DNA barcoding has potential for use in species identification and biodiversity assessment of the aquatic insects in the rice field ecosystem." (Authors)] Address: Pramual, P., Department of Biology, Faculty of Science, Mahasarakham University, Maha Sarakham 44150, Thailand

**18812.** Prasad, P.K.; Shinad, K.; Sherin, C.; Arusha, K. (2020): Studies on the life cycle of *Pleurogenoides wayanadensis* Shinad & Prasad, 2018 (Digenea: Pleurogenidae) from the Western Ghats, India. *Journal of Helminthology* 94 e196: 10 pp. (in English) ["The life cycle of *Pleurogenoides wayanadensis* Shinad & Prasad, 2018, infecting the frogs *Hoplobatrachus tigerinus* and *Euphlyctis cyanophlyctis*, is elucidated in this study. All the life cycle stages from egg to egg-producing adults were elucidated under natural conditions and successfully established in the laboratory. The life cycle took about 58 to 65 days for completion. Miracidia were released by teasing the eggs with fine needles. Sporocysts were found in the freshwater snail, *Bithynia (Digoniostoma) pulchella*, collected from paddy fields at Payode, Western Ghats, Wayanad region, in the months of October and November 2019. Cercariae were of the virgulate xiphidiocercous type. Metacercariae were recovered from the eyes of the damselfly naiads of the species *Ischnura* sp. and *Copera* sp., and the thorax and abdomen of the dragonfly naiads, *Orthetrum* sp. The metacercariae showed progenetic development. The growth and development of the metacercariae in the naiads that were exposed to cercariae, and development of the trematode in frogs that were force-fed with encysted metacercariae, have been studied at regular intervals. The prepatent period is 14–19 days. The present life cycle study of a *Pleurogenoides* spp. forms the seventh report from the world, fourth report from India and the third from Kerala." **18813.** Rafael, J.A.; Limeira-de-Oliveira, F.; Hutchings, R.W.; (74 authors) (2020): Insect (Hexapoda) diversity in the oceanic archipelago of Fernando de Noronha, Brazil: updated taxonomic checklist and new records. *Revista Brasileira de Entomologia* 64(3):e20200052, 2020: 27 pp. (in English) ["Hexapods, commonly known as insects, are a neglected

taxonomic group in the Fernando de Noronha archipelago, with unanswered questions about their species richness and the ecological processes in which they are involved (e.g., colonization, introduction, establishment, and extinction). Herein, we provide an updated Hexapod checklist with current nomenclatural combinations. The entomofauna of the Fernando de Noronha archipelago is currently composed of 453 species in 21 orders. The orders, and their respective number of species, are: Blattaria (9), Coleoptera (118), Collembola (29), Dermaptera (3), Diplura (1), Diptera (134), Embioptera (1), Hemiptera (29), Hymenoptera (59), Isoptera (2), Lepidoptera (25), Mantodea (1), Neuroptera (3), Odonata (5), Orthoptera (11), Phasmatodea (1), Phthiraptera (6), Psocoptera (3), Siphonaptera (1), Thysanoptera (10), and Zygentoma (2). The archipelago has 263 new taxon records (family + genera + species). Thirty-eight species (3.39%) were described from local specimens and most of them are likely endemic species. This study more than doubles our knowledge (from the previous 190 records) of the entomofauna in this large Brazilian archipelago. This study also provides a baseline for studies on its conservation status and for implementing future environmental management programs." (Authors) Odonata [Responsible: A.P. Pinto] are represented by *Ischnura capreolus* (Hagen, 1861), *Erythemis vesiculosa* (Fabricius, 1775), *Miathyria marcella* (Selys in Sagra, 1857), *Pantala flavescens* (Fabricius, 1798), *Tremea basalis* (Burmeister, 1839). "Remarks. *Libellula basalis* Burmeister, 1839 is currently considered a synonym of *Tremea abdominalis* (Rambur, 1842). The identity of the species cited by Kirby (1890) as *Tremea basalis* (Burmeister, 1839) and transcribed by Alvarenga (1962) cannot be ascertained without examination of specimens from Ridley's expedition housed in the NHMUK, due to nomenclatural confusion and ambiguities about the identity of at least three current valid species, i.e., *T. abdominalis*, *T. binotata* (Rambur, 1842) and *T. cophysa* Hagen, 1867 (Calvert, 1906a; Ris, 1913). They are all widespread species in the Western Hemisphere. Furthermore, a species described in the 19th century, *Libellula basalis* Burmeister, 1839, was a homonym of two other species, and later on *L. basalis* Burmeister was synonymized with *T. cophysa* (Calvert, 1906a; but see Calvert, 1906b). In his revision of Libellulidae, Ris (1913) synonymized *Libellula basalis* Burmeister with *T. abdominalis* and mentioned the material from Fernando de Noronha as a synonym for *T. cophysa* (due to a misidentification by W. Kirby) based on the study by Kirby (1897). Decades later, De Marmels and Racenis (1982) included Kirby's (1897) *T. basalis* in the synonymy of *Tremea calverti* Muttkowski, 1910. Therefore, because neither Ris (1913) or De Marmels and Racenis (1982) cited Kirby's (1890) original study, and it is unclear if they examined those specimens, this Fernando de Noronha record is left identified only to genus level until the original material can be studied." ] Address: Rafael, J.A., Instituto Nacional de Pesquisas da Amazônia, Coordenação de Biodiversidade, Manaus, AM, Brazil. fauna of district Swabi Khyber Pakhtunkhwa, Pakistan. *Sarhad Journal of Agriculture* 36(2): 675-684. (in English) ["Current study was conducted in order to explore the dragonflies fauna in District Swabi of Khyber Pakhtunkhwa, Pakistan. A comprehensive field survey was conducted to collect dragonfly adults using aerial nets. 19 sites of District Swabi were surveyed during summer seasons of 2015 and 2016. The study revealed 23 species from 15 genera under 3 families. Libellulidae comprised of 19 species belonging to 11 genera, Gomphidae included 3 species belonging to 3 genera and Aeshnidae included one species. Detailed description of each species, valid scientific names, their habitat, ecological observation, collection date and distributional range for all recorded species are provided. ... *Ictinogomphus angulosus*, *Burmogomphus sivalikensis*, *Zygomma petiolatum* were recorded for the first time from district Swabi as well as Khyber Pakhtunkhwa" (Authors)] Address: Rehman, A., Department of Entomology, Faculty of Crop Protection Sciences, Univ. of Agriculture Peshawar, Khyber Pakhtunkhwa, Pakistan

**18815.** Reis dos Santos, M.; Saito, V.S.; Zaitune Pamplin, P.A.; Pereira, A.A.; Fonseca-Gessner, A.A. (2020): Pollution tolerance, flight capacity and natural history explain meta-community structure in high-altitude stream insects. *Acta Limnologica Brasiliensia* 32: 14 pp. (in English, with Portuguese summary) ["Aim: To test how different taxonomic and functional groups of aquatic insects from high-altitude streams respond to environmental and spatial gradients at multiple scales in Southeast of Brazil. Methods: Specimens were collected in 26 high-altitude streams distributed over a gradient of previously defined environmental quality. The taxonomic identification was made at the genus level and the functional classification was based on traits of flight capacity and pollution tolerance compiled from specific literature. We obtained local in situ data (limnological, sediments, and organic matter), as well as calculated land use at the riparian and drainage basin scale. A variation partitioning approach was used to explain species composition based on different response matrices deconstructed by both taxonomic groups and functional traits. The explanatory matrices encompassed environmental variables at three spatial scales and spatial variables extracted from Principal Components of Neighbor Matrices analysis. A linear model was applied to verify the possible correlation between spatial and environmental components." (2020): Odonate species occupancy frequency distribution and abundance–occupancy relationship patterns in temporal and permanent water bodies in a subtropical area. *Ecology & Evolution* 10(14): 7525-7536. (in English) ["This paper investigates species richness and species occupancy frequency distributions (SOFD) as well as patterns of abundance–occupancy relationship (SAOR) in Odonata (dragonflies and damselflies) in a subtropical area. A total of 82 species and 1983 individuals were noted from 73 permanent and temporal water bodies (lakes and ponds) in the Pampa biome in southern Brazil. Odonate species occupancy ranged from 1 to 54. There were few widely distributed generalist species and several specialist species with a restricted distribution. About 70% of the species occurred in <10% of the water bodies, yielding a surprisingly high number of rare species, often making up the majority of the communities. No difference in species richness was found between temporal and permanent water bodies. Both temporal and permanent water bodies had odonate assemblages that fitted best with the unimodal satellite SOFD pattern. It seems that unimodal satellite SOFD pattern frequently occurred in the aquatic habitats. The SAOR pattern was positive and did not differ between permanent and temporal water bodies. Our results are consistent with a niche-based model rather than a metapopulation dynamic model." (Authors)] Address: Renner, S., Lab. **18822.** Ruiter, E.; Mulder-Milderij, G.; Bunskoek, M.; Huijzinga, A. (2020): *Libellen in Overijssel*. ISBN: 9789050117739. Uitgeverij Knv: 348 pp. (in Dutch) [Bohre, P. (2021): *Prachtig boek over libellen in Overijssel*. <https://www.rootsmagazine.nl/blog/dieren/prachtig-boek-over-libellen-in-overijssel/>: "Already in 2005 an overview of the dragonflies in Overijssel was published with preliminary distribution maps up to 2003. The prelude to the enormous book of 30×30 centimetres that is now before us. Evert Ruiter, main author of *Libellen van Overijssel*: "One of the reasons that this book was not published earlier, was the fact that almost every year a new species of dragonfly was discovered in Overijssel. *Erythromma lindenii*, *Leucorrhinia caudalis*, *Sympetrum depressiusculum*, *Leucorrhinia albifrons*, to name but a few. And of course, they had to be included in the book. In the end, we cut the Gordian knot and started writing. By now, 65 species have been identified within the provincial borders, from extremely rare to very common. "And that puts us in second place as a province behind Limburg. The species richness in Overijssel is mainly due to the exceptionally large diversity of wetlands," says Ruiter. "There are small streams here, but also large rivers, bogs, low moors, a range of other wetlands such as canals, ditches, fens, pools and sand drifts. And not forgetting the local height differences, such as the Salland Ridge and the lateral moraines in north-east Twente. They provide seepage-rich environments on the flanks. All ideal factors for a very diverse dragonfly fauna. Another important factor is the increased interest in observing dragonflies. "I remember well that about twenty years ago I first came to the Woldlake forest to make an inventory. I walked around all alone, the area was still totally undiscovered. And I was pleasantly surprised by the surprisingly large number of species that could be found here. Now thousands of dragonflies fly around here on a beautiful day and you come across photographers everywhere who want to capture these flying gems. The interest in dragonflies has grown enormously in the last twenty years. This is also thanks to *Waarneming.nl*, where dragonfly enthusiasts are increasingly posting their sightings and photos. Naturally, the Woldlake forest is therefore included in the book as a walking route." Critical species Dragonflies occupy an important place in wetland ecosystems. Their presence or absence says a lot about the quality of the biotope and the water in which they occur. This preference is therefore determined to a very large extent by the larvae, as they live in the water. "Some species only thrive in nutrient-poor water and disappear when acidification or enrichment occurs. Other, less critical species appear and are thus a direct indication of deteriorating water quality", explains Ruiter. Industrial discharges in the previous century had heavily polluted the Vecht and the Regge. Thanks to water purification and nature development, many vulnerable species such as the meadow creek juggernaut, blue broad-headed damselfly and brook hawk have fortunately returned. However, dragonflies also appreciate favourable conditions

around the water, such as shelter provided by riparian vegetation, upright trees and shrubs. All of this has led to the exceptionally rich dragonfly population in Overijssel. Magnificent book *Libellen in Overijssel* is a beautiful publication for every nature lover who wants to discover the dragonflies and the landscape while walking. This book, richly illustrated with brilliant photographs, highlights and describes all of the dragonfly species found in the 'garden of the Netherlands'. Distribution maps show where they occur. And by means of 8 special dragonfly routes, you can also find all that beauty yourself while walking. The book is intended for both beginners and experienced dragonfly lovers." (Author; DeepL)]

**18823.** Salami, E.; Ward, T.A.; Montazer, E.; Nik Ghazali, N.N. (2020): Nanoindentation analysis comparing dragonfly-inspired biomimetic micro-aerial vehicle (BMAV) wings. *International Journal of Bio-Inspired Computation* 16(2): 111-120. (in English) ["Biomimetic micro-aerial vehicle (BMAV) are micro-scaled, unmanned aircraft based on flying biological organisms, generating thrust and lift by flapping their wings. This study investigates and compares the nano mechanical mechanical properties of four sets of fabricated, dragonfly inspired BMAV wings and compares them to actual dragonfly wings used as a baseline reference. The BMAV wings were fabricated using a 3D printer, based on these simplified models. Different 3D printer filament materials were used for each of the four wing sets: acrylonitrile butadiene styrene (or ABS), polylactic acid (or PLA), high impact polystyrene (or HIPS) as well as Ultrat. Nanoindentation tests of the actual dragonfly wings and the BMAV wings were conducted to measure their hardness and Young's modulus. The test result demonstrates the feasibility solution in the development of strong, practical and low cost BMAV wings, this work is a stepping-stone on the path to flying robotic dragonfly." **18824.** Sánchez-Herrera, M.; Beatty, C.D.; Nunes, R.; Salazar, C.; Ware, J.L. (2020): An exploration of the complex biogeographical history of the Neotropical banner-wing damselflies (Odonata: Polythoridae). *BMC Evolutionary Biology* 20(74) (2020): 14 pp. (in English) ["Background: The New World Tropics has experienced a dynamic landscape across evolutionary history and harbors a high diversity of flora and fauna. While there are some studies addressing diversification in Neotropical vertebrates and plants, there is still a lack of knowledge in arthropods. Here we examine temporal and spatial diversification patterns in the Polythoridae, which comprises seven genera with a total of 58 species distributed across much of Central and South America. Results: Our time-calibrated phylogeny for 48 species suggests that this family radiated during the late Eocene (~ 33 Ma), diversifying during the Miocene. As with other neotropical groups, the Most Recent Common Ancestor (MRCA) of most of the Polythoridae genera has a primary origin in the Northern Andes though the MRCA of at least one genus may have appeared in the Amazon Basin. Our molecular clock suggests correlations with some major geographical events, and our biogeographical modeling (with BioGeoBEARS and RASP)

found a significant influence of the formation of the Pebas and Acre systems on the early diversification of these damselflies, though evidence for the influence of the rise of the different Andean ranges was mixed. Diversification rates have been uniform in all genera except one—Polythore—where a significant increase in the late Pliocene (~ 3 mya) may have been influenced by recent Andean uplift. Conclusion: The biogeographical models implemented here suggest that the Pebas and Acre Systems were significant geological events associated with the diversification of this damselfly family; while diversification in the tree shows some correlation with mountain building events, it is possible that other abiotic and biotic changes during our study period have influenced diversification as well. The high diversification rate observed in Polythore could be explained by the late uplift of the Northern Andes. However, it is possible that other intrinsic factors like sexual and natural selection acting on color patterns could be involved in the diversification of this genus." (Authors)] Address: Sánchez-Herrera, Melissa, Dept Biology, Faculty of Natural Sciences, Univ. del Rosario, Bogotá, DC, Colombia; Fed. Dept of Biol. Sciences. **18827.** Schmidt, K.J. (2020): Developing eDNA techniques for the endangered Hine's Emerald Dragonfly (*Somatochlora hineana*) and its symbiont the Devil Crayfish (Camba-

rus [=Lacunicambarus] diogenes): Mesocosm and field studies. M.Sc. thesis, Department of Biology, University of South Dakota: V, 18 pp. (in English) ["Detection of environmental DNA (eDNA) has become a commonly used surveillance method for threatened or invasive vertebrates in both aquatic and terrestrial environments. However, use of eDNA methodologies for the detection of aquatic invertebrates (e.g., crayfish and insects) has been limited. Environmental DNA protocols can be especially useful for endangered invertebrates such as *S. hineana* where conservation efforts have been greatly hindered by the training, time, overall costs, and environmental impacts associated with conducting surveys in the calcareous fens occupied by this species. An essential step in developing such a protocol is to evaluate the dynamics of eDNA concentration under controlled and field conditions. In this study we examined the persistence and accumulation of eDNA from captive *S. hineana* larvae in experimental mesocosms at temperatures (5.0°C and 16.0°C) that reflect seasonal variation in their natural habitat, and we evaluated the usefulness of eDNA protocols for studying the distribution and abundance of invertebrates by assessing patterns of eDNA distribution for the Hine's emerald dragonfly and its symbiont the devil crayfish, in the field over several months. In mesocosms, *S. hineana* eDNA persisted longer at 5.0°C but accumulated more readily at 16.0°C. In the field, life-history events affected seasonal variations in eDNA more significantly and consistently than temperature for both species. These data can be used to aid in conservation efforts for *S. hineana* and similar aquatic invertebrates." (Author)] Address: Schmidt, Kristie, Univ. of South Dakota, Vermillion, SD, USA. Email: Kristie.Schmidt@uky.edu

**18828.** Schmidt Dalzochio, M.; Périco, E.; Dametto, N.; Sahlén, G. (2020): Rapid functional traits turnover in boreal dragonfly communities (Odonata). *Scientific Reports* 10, (15411) (2020): 12 pp. (in English) ["All natural populations show fluctuations in space or time. This is fundamental for the maintenance of biodiversity, as it allows species to coexist. Long-term ecological studies are rare, mainly due to logistics, but studies like the one presented below recognize the dimensionality of temporal change and the ecological processes that lead to shifts in community composition over time. Here, we used three sampling occasions from a dataset spanning 20 years where dragonflies in central Sweden were monitored. Our aim was to investigate how the prevalence of ecological and biological species traits varied over time measured as Community-level Weighted Means of trait values (CWM). Most CWM values varied significantly between years. Most of the traits changed between the second and the last sampling occasion, but not between the two first ones. These changes could be linked to major changes in species abundance. Our work indicates that fundamental shifts in community structure can occur over a short time, providing environmental drivers act on species turnover. In our case, Climate change and pH levels in lakes are most likely the most important factors." **18829.** Shrimali, S.; Rathore, A.S. (2020): Efficacy of neem oil for the eradication of aquatic insects in fish nurseries. *Uttar Pradesh Journal of Zoology* 41(8): 104-112. (in English) ["Generally, the survival rate of carp spawn during the nursery phase is very low due to the presence of harmful aquatic insects in fish nursery pond, which prey heavily upon the spawn and early stages of fry. Insects usually found in large numbers in ponds over the greater part of the year especially during and after rains. They injure the spawn and some of them prey upon spawn. Insects should be eradicated prior to stocking to ensure maximum survival of the spawn. Aquatic insects and their larvae compete for food with the young fish and also cause large scale destruction of hatchlings in nurseries. A study was carried out by the authors to investigating the possible use of natural chemical Neem Oil for the control of aquatic insects in nursery ponds. Bioassay studies were conducted in 5 glass aquaria and using four concentration 0.003, 0.004, 0.005, 0.006 ppm of Neem Oil (natural chemical) on four experimental insects Notonecta (Backswimmer), Dragonfly nymph, Eretes (Small beetle), Nepa (Water Scorpion). The LC50 value of Neem Oil for the experimental insects ... ranged 0.0033 ppm for Eretes and Nepa at 6 hrs and 0.0040 for Notonecta at 5 hrs. Further, the results on toll rate showed that Backswimmer, Small beetle, Water Scorpion killed within 6hrs when exposed to a concentration of 0.004 ppm Neem oil. This was the lowest dose of Neem oil which killed the predatory insects within the desired period of 6 hrs and the death rate of fish seed at this dose is zero. Therefore, the use of Neem oil @0.004 ppm is recommended for the eradication of predatory insects from fish nursery ponds." (Authors)] Address: Shrimali, S., Wildlife Research Laboratory, Dept of Zoology, Bhupal Nobles' University, Udaipur, India

**18830.** Silva-Hurtado, J.D.; Márquez, J.; Escoto-Moreno, J.A.; Martínez-Falcónx, A.P. (2020): Odonate fauna (Insecta: Odonata) from a locality in San Marcos River in the Sierra Norte of Puebla, Mexico. *International Journal of Odonatology* 23(4): 327-336. (in English) ["Odonates have been recognized as an important group for evaluating ecosystems since they are used as bioindicators of the conservation status of the habitat they occupy, in addition to being generalist predators feeding on invertebrates and small vertebrates. In this work, the biodiversity of adult odonates from a locality near the San Marcos River, in Puebla, Mexico, is analyzed through systematic sampling performed during 2018. Species richness and composition patterns were analyzed and compared between the rainy and dry seasons; the results were also compared with those of similar studies at the regional level. There were six families, 21 genera and 37 species that represent about 40% of the 95 species registered in Puebla. Coenagrionidae, with *Argia*, was the best representative of the Zygoptera, and Libellulidae was the best for the Anisoptera. Three of the species collected in the San Marcos River increased the species number from 95 to 98 for Puebla, making it currently placed 14th of 32 Mexican states in terms of the species richness of odonates nationwide. According to the Chao2 and Bootstrap estimators, the completeness of the inventory varied from 61% to 67% in the

dry season, from 73% to 83% in the rainy season, and from 74% to 86% for the annual completeness. There were no significant differences in species richness and composition between the rainy and dry seasons. The species richness of odonates in this locality is the second highest known for Puebla and can still provide important data for this group." **18831.** Simonsen, T.J.; Olsen, K.; Djernæs, M. (2020): The African-Iberian connection in Odonata: mtDNA and ncDNA based phylogeography of *Aeshna cyanea* (Müller, 1764) (Odonata: Aeshnidae) in Western Palaearctic. *Arthropod Structure & Development* 78(2): 309-320. (in English) ["We explore the phylogeography and inter-population relationships of *A. cyanea* in the Western Palaearctic region based on 603 bp Cytochrome Oxidase Subunit 1 (COI) mtDNA and 732 bp Internal Transcribed Spacer region (Internal Transcribed Spacer 1, 5.8S ribosomal RNA gene and Internal Transcribed Spacer 2, ITS region) ncDNA with an increased sampling from Europe compared to a previous study. Both DNA fragments recover a remarkable and compatible pattern: the recently described *Aeshna vercanica* Schneider et al. is the sister group of *A. cyanea*, which in turn comprises three distinct populations. These populations are: a population in the Caucasus region; a North African population; and a European population. When analysed alone, the ITS fragment recovered *A. vercanica* and the Caucasus *A. cyanea* population as separate units, but the North African and European *A. cyanea* populations were recovered as inter-mixed. FST population genetic analyses of COI data revealed high degrees of isolation between all populations as all inter-population values were between 0.818 (North Africa – Europe) and 0.944 (Europe – *A. vercanica*). Average pairwise distance in COI (uncorrected p) between populations followed this pattern and was lowest between Europe and North Africa and highest between North Africa and *A. vercanica*, and between Europe and *A. vercanica*. Within population pairwise distance values were approximately an order of magnitude lower. Pairwise distance values between populations for the ITS region were much lower than for COI, but followed the same pattern. Our results therefore support the full species status for *A. vercanica*, and clearly indicate that the current Western European *A. cyanea* population originated from a North African glacial refugium and dispersed to Europe (the Iberian Peninsula) prior to the Holsteinian interglacial period. While the North African and European populations likely remained in contact initially, the European population was probably isolated in the Iberian Peninsula during the Holsteinian interglacial period, and subsequently spread throughout Europe in late Pleistocene – early Holocene." of Southern India. *Indian Journal of Ecology* 47(3): 869-871. (in English) ["Order Odonata includes important aquatic insect groups such as dragonflies and damselflies. They help to assess the ecosystem health and serves as pollution indicators. Studies of Odonata were conducted in Alagar hills of South India state of Tamilnadu from August 2018 to January 2019. Odonate species abundance was high in October to November (7 to 8 species) and their abundance was low in the January and December (6 species.) Among all months, the abundance of libellulid species was comparatively high. Shannon index values were between 1.6094-1.9792 and it shows that these sites had critical position and they might have sensitive habitat status. The results of Simpson index complement with the results of Shannon index. Higher air and water temperature was in August and causes less diversity of organisms. DO was low in January (1.65) and it directly influences the abundance. This study interpreted that diversity of Odonates was directly and indirectly influenced by climatic change and anthropogenic impacts." **18833.** Svensson, E.I.; Willink, B.; Duryea, M.C.; Lancaster, L.T. (2020): Temperature drives pre-reproductive selection and shapes the biogeography of a female polymorphism. *Ecology Letters* 23(1): 149-159. (in English) ["Conflicts of interests between males and females over reproduction is a universal feature of sexually reproducing organisms and has driven the evolution of intersexual mimicry, mating behaviours and reproductive polymorphisms. Here, we show how temperature drives pre-reproductive selection in a female colour polymorphic insect that is subject to strong sexual conflict. These species have three female colour morphs, one of which is a male mimic. This polymorphism is maintained by frequency-dependent sexual conflict caused by male mating harassment. The frequency of female morphs varies geographically, with higher frequency of the male mimic at higher latitudes. We show that differential temperature sensitivity of the female morphs and faster sexual maturation of the male mimic increases the frequency of this morph in the north. These results suggest that sexual conflict during the adult stage is shaped by abiotic factors and frequency-independent pre-reproductive selection that operate earlier during ontogeny of these female morphs." **18834.** Swaegers, J.; Spanier, K.I.; Stoks, R. (2020): Genetic compensation rather than genetic assimilation drives the evolution of plasticity in response to mild warming across latitudes in a damselfly. *Molecular ecology* 29(4): 4823-4834. (in English) ["Global warming is causing plastic and evolutionary changes in the phenotypes of ectotherms. Yet, we have limited knowledge on how the interplay between plasticity and evolution shapes thermal responses and underlying gene expression patterns. We assessed thermal

reaction norm patterns across the transcriptome and identified associated molecular pathways in northern and southern populations of *Ischnura elegans*. Larvae were reared in a common garden experiment at the mean summer water temperatures experienced at the northern (20°C) and southern (24°C) latitudes. This allowed a space-for-time substitution where the current gene expression levels at 24°C in southern larvae are a proxy for the expected responses of northern larvae under gradual thermal evolution to the predicted 4°C warming. Most differentially expressed genes showed fixed differences across temperatures between latitudes, suggesting that thermal genetic adaptation will mainly evolve through changes in constitutive gene expression. Northern populations also frequently showed plastic responses in gene expression to mild warming, while southern populations were much less responsive to temperature. Thermal responsive genes in northern populations showed to a large extent a pattern of genetic compensation, i.e. gene expression that was induced at 24°C in northern populations remained at a lower constant level in southern populations, and were associated with metabolic and translation pathways. There was instead little evidence for genetic assimilation of an initial plastic response to mild warming. Our data therefore suggest that genetic compensation rather than genetic assimilation may drive the evolution of plasticity in response to mild warming in this damselfly species." **18837.** Twardochleb, L.A.; Treacle, T.C.; Zametske, P.L. (2020): Foraging strategy mediates ectotherm predator-prey responses to climate warming. *Ecology* 101(11). e03146: (in English) ["Climate warming and species traits interact to influence predator performance, including individual feeding and growth rates. However, the effects of an important trait—predator foraging strategy—are largely unknown. We investigated the interactions between predator foraging strategy and temperature on two ectotherm predators: an active predator, the backswimmer *Notonecta undulata*, and a sit-and-wait predator, the damselfly *Enallagma annexum*. In a series of predator-prey experiments across a temperature gradient, we measured predator feeding rates on an active prey species, zooplankton *Daphnia pulex*, predator growth rates, and mechanisms that influence predator feeding: body speed of predators and prey (here measured as swimming speed), prey encounter rates, capture success, attack rates, and handling time. Overall, warming led to increased feeding rates for both predators through changes to each component of the predator's functional response. We found that prey swimming speed strongly increased with temperature. The active predator's swimming speed also increased with temperature, and together, the increase in predator and prey swimming speed resulted in two-fold higher prey encounter rates for the active predator at warmer temperatures. By contrast, prey encounter rates of the sit-and-wait predator increased four-fold with rising temperatures as a result of increased prey swimming speed. Concurrently, increased prey swimming speed was associated with a decline in the active predator's capture success at high temperatures, whereas the sit-and-wait predator's capture success slightly increased with temperature. We provide some of the first evidence that foraging traits mediate the indirect effects of warming on predator performance. Understanding how traits influence species' responses to warming could clarify how climate change will affect entire functional groups of species." **18838.** Udayanath, S.; Yashaswi, N. (2020): Impact of mining activities on odonates diversity in adjacent villages of Balaram open cast project, Talcher, Angul, Odisha, India. *Journal of Entomological Research* 44(3): 449-454. (in English) ["In the present study an attempt has been made to

study the regimen of Odonates in peripheral villages of Balaram Open Cast Project (OCP), Talcher, Angul, Odisha. A total number of 1604 Odonates belonging to 6 families and 34 species under two sub-orders (Anisoptera and Zygoptera) were recorded during the entire study period. Shannon-Weiner index ( $H'$ ) was 2.65 in Bhalugadia village, followed by 2.73 in Malibandha village, 2.62 in Natada village and 2.68 in Nakeipasi village. Margalef's richness ( $D_{mg}$ ) index found to be 3.62 in Bhalugadia, 3.52 in Malibandha, 4.43 in Natada and 2.68 in Nakeipasi village. The presence of Odonates is easily perceived from this study that shows that ecosystem health is proportionate to Odonate diversity. Swap nets and dragonfly traps were used for sampling in the revegetation and un-mined area, but the variation in abundance and diversity among the four areas was statistically insignificant. Hence revegetation can restore the biodiversity and also the population of Odonates belonging to various families. In toto, mined areas should be ecologically restored, so that rich diversity of these elegant insects can be conserved." **18839.** Vega-Sánchez, Y.M.; Lorenzo-Carballa, M.O.; Vilela, D.S.; Guillermo-Ferreira, R.; Koroiva, R. (2020): Comment on Islam et al. (2020) "Molecular identification of seven new Zygopteran genera from South China through partial cytochrome oxidase subunit I (COI) gene". *Meta Gene* 25, September 2020, 100759: (in English) ["This letter to the editor aims to address the issues that we have found in an article recently published in *Meta Gene* by Islam et al. (2020) on the molecular identification of Odonata specimens from eight provinces of southern China. We conducted a review on the literature regarding the distribution of *Hetaerina* (Calopterygidae) and *Nesobasis* (Coenagrionidae), and analyzed the genetic sequences deposited by Islam et al. (2020) in molecular data repositories. *Hetaerina* is a genus endemic to the New World, with most species confined to the Neotropical region. Islam et al. (2020) reported *H. vulnerata* Hagen in Selys, 1853, *H. titia* Drury, 1773 and *H. capitalis* Selys, 1873 for southern China. The genus *Nesobasis* is endemic to the Fiji Islands. The referred authors reported *N. longistyla* also in southern China. All these species had never been registered before by any other study conducted in Asia. The sequences of these species deposited by Islam et al. were analyzed by us and identified as dipteran DNA, fitting cytochrome oxidase I sequences of the Ephydriidae, Chironomidae and Drosophilidae families. Furthermore, few sequences deposited in data repositories matched with the molecular analyses made by Islam et al. (2020). We suggest that the authors must reassess the morphological and molecular identification of the specimens collected for their study. There might be morphological misidentifications of voucher specimens and/or sequences deposited as *Hetaerina* and *Nesobasis*. Aiming to clarify the results, we recommend the authors to include photographs of the species and redo their analyses. Considering the aforementioned problems, we strongly suggest the authors a review of their other results, which may also present flaws that we are not aware of at

the moment." (Authors)] Address: Vega-Sánchez, Yesenia Margarita, Inst. de Investigaciones en Ecosistemas y Sustentabilidad, Universidad Nacional Autónoma de México, Antigua carretera a Pátzcuaro #8701, Morelia, Michoacán 58190, Mexico. E-mail: yvega@cieco.unam.mx

(2020): Differences in land use modify Odonata assemblages in the Cerrado-Caatinga ecotone. *Acta Limnologica Brasiliensia* 32, e15: 11 pp. (in English, with Portuguese summary) ["Aim: The present study tested the hypothesis that the composition of the odonate assemblages in environments with greater habitat integrity is significantly different from that of areas with reduced habitat integrity. Methods: The samples were collected between April 2017 and November 2017 in eight streams in Caxias, in the Brazilian state of Maranhao. The habitat integrity index was used to quantify habitat integrity. The odonate specimens were collected by the fixed area scanning method. Results: The habitat integrity index ranged from 0.265 to 0.915 at the different localities. A total of 229 specimens were collected, representing 19 odonate species. Species composition varied among streams that presented different degrees of conservation, with some species being typical of specific habitats. However, this variation had no effect on the number of taxa or the abundance of odonates, which may reflect the local substitution of extinct specialist species by generalists. Conclusions: Evidence indicates that the reduction of habitat integrity is an important predictor of changes in the biodiversity of aquatic insects in streams such as those of the Cerrado-Caatinga ecotone." **18841.** Wang, Y.; Yin, Y.; Zheng, G.; Yao, H. (2020): Driving mechanism of dragonfly's wing flapping pattern for liquid circulation inside wing. *Animal Biology* 71(1): 85-101. (in English) ["Flying animals can inspire practical approaches to a more advanced way of flying. Dragonflies demonstrate a special flapping pattern in which their wings perform torsional movement while flapping, which is different from that of birds. This flapping pattern is referred to as nonsynchronous flapping in this article. We present a hypothesis that nonsynchronous flapping provides a driving force for enhancing the haemolymph circulation inside dragonfly wings. To support this hypothesis, a controlled experiment was designed and conducted with living dragonflies. By observing the liquid motion inside the vein within free flapping wings and restricted wings of living dragonflies, this hypothesis was supported. A mathematical model of the flapping wing was built and numerically studied to further support the function of the nonsynchronous flapping pattern in driving the circulation. With these studies, a theoretical explanation for the mechanism of enhancing the haemolymph circulation by nonsynchronous flapping was provided." **18842.** Wildermuth, H. (2020): Als Larvenhabitate von *Orthemtrum coerulescens* (Odonata: Libellulidae) im Hinblick auf sporadische Sommertrockenheit optimierte Flachmoorgräben. *Entomo Helvetica* 13: 107-116. (in German, with English and French summaries) ["Larval habitats of *Orthemtrum coerulescens* (Fabricius, 1798) optimized in fenland ditches by counteracting sporadic aestival desiccation (Odonata: Libellulidae). - In 1981–82, 1.5 ha of overgrown fenland were cleared in a nature reserve on the eastern Swiss plateau. The drainage ditches at the site were rebuilt, thus converting the fenland back into a traditional litter meadow. In order to retain water, six controllable weirs were installed, slowing desiccation of the ditches during hot periods with low or no precipitation. Maintenance of ditches was staggered in both space and time. During systematic success monitoring from 2006 to 2019, a total of 26 species of Odonata were recorded, eleven of which were either permanently or temporally indigenous. The study focused specifically on *O. coerulescens*. Up to 150 territorial males were located simultaneously at the ditches and successful reproductions were recorded every year. Due to water retention by the weirs, the ditches did not dry out even during long, dry summer periods. In extreme cases, larvae survived in the moist layer of the peat mud." **18843.** Worthen, W.B.; Chamlee, M.G. (2020): Determinants of adult odonate community structure at several spatial scales: effects of habitat type and landscape context. *International Journal of Odonatology* 23(4): 365-379. (in English) ["Odonata use both aquatic and terrestrial ecosystems, and the abundance and diversity of odonates should be good indicators of habitat integrity. To determine which environmental variables affect odonates, we sampled adult dragonflies three times at 12 sites in Pickens and Greenville Counties, SC, USA, in different habitats, at different spatial scales, across a landscape gradient from intact forest to urban locations. At each site, we established two 2 m × 20 m plots along the shoreline of each aquatic habitat. We sampled dragonflies in ten 2 m × 2 m subplots/plot, described the vegetation and substrate in these subplots and adjacent aquatic subplots, and measured the percent cover of different landforms within 500 m of each plot center. Using nested ANOVA and Akaike information criteria models, habitat type and correlating environmental variables (substrate type and bank vegetation) were the best predictors of community structure at all spatial scales. Streams and rivers had fewer individuals and species than lakes, and had a nested subset of species found in lake communities. Landscape elements were also important, with indices declining as barren land and grasslands increased. At the largest scale, anthropogenic changes to the landscape had mixed effects. Small habitats isolated in urban areas had a significantly depauperate, nested subset of species found in communities inhabiting larger natural areas. However, odonate abundance and diversity was highest at human-made lakes and ponds, suggesting that these anthropogenic features help maintain odonate communities." (Authors)] Address:

**18844.** Alves, N.P.; Andrade da Silva, R.; Calvão Santos, L.B.; Barbosa de Oliveira Junior, J.M. (2021): Variação morfológica de caracteres em *Oligoclada walkeri* Geijskes, 1931 (Anisoptera: Libellulidae) em relação a integridade ambiental de Igarapés da Amazônia oriental. Tópicos Integrados de Zoologia 3: 58-70. (in Portuguese, with English summary). [ "Morphological variation of characters in *O. walkeri* in relation to the environmental integrity of eastern Amazonian streams: This work aims to evaluate the effect of environmental integrity on morphological characteristics in population samples of *O. walkeri*. The collections were carried out in the municipalities of Santarém, Mojuí dos Campos and Belterra, in the state of Pará, between 10 and 14 h, in 48 streams with 150 m sections, subdivided into 10 sections of 15 m, separated by margin to margin transections. The adult individuals of *O. walkeri* were collected with an entomological network (40 cm in diameter, 65 cm in depth and 90 cm in length) and 50 specimens were selected (25 of preserved areas and 25 of altered areas) to obtain the measures of the characters. With the use of digital caliper, the morphological characters CT (total length), CTA (anterior wing length), LAA (anterior wing width), CAP (anterior wing length), LAP (posterior wing width), LAPB posterior wing at the base), CA (abdomen length), CTO (chest length), LT (chest width) were measured and P (weight) was measured by means of an analytical balance with an accuracy of 0.00005g. To evaluate the effect of environmental integrity on the total length of the *O. walkeri* specimens, simple linear regression was performed. Among the morphological variables, only the posterior wing width at base height was affected by environmental integrity ( $r^2 = 0.075$ ;  $p = 0.050$ ), the result suggests that the more preserved the stream, the greater the Wing Width at Base Height. With the increase of 0.01 in integrity there is an increase of approximately 0.06 mm in the Rear Wing at Base Height. Odonata wing size may be affected by a combination of factors such as: sexual selection, agonistic interactions, intersex cut-offs, migration, and reproductive behavior. In addition, the increase in the width of the posterior wing at base height in *O. walkeri* specimens in the preserved environment may have been due to the main activities carried out by the species in these places, where they do not have to travel long distances to find food. corroborates with the study, because in preserved places the species tend to spend less energy, facilitating the maintenance of a flight with less energy expenditure." **18845.** Batucan Jr, L.S.; Hsu, Y.-H.; Maliszewski, J.W.; Wang, L.-J.; Lin, C.-P. (2021): Novel wing display and divergent agonistic behaviors of two incipient *Psolodermus* damselflies. The Science of Nature 108, 49. (in English) [„Sexual selection via male competition is a strong evolutionary force

that can drive rapid changes in competitive traits and subsequently lead to population divergence and speciation. Territorial males of many odonates are known to use their colorful wings as visual signals and to perform agonistic displays toward intruders. *P. mandarinus dorothea* and *P. mandarinus mandarinus* are two parapatrically distributed sister damselflies that share similar ecological characteristics but differ markedly in wing coloration. The wings of *P. m. dorothea* are mostly clear, whereas those of *P. m. mandarinus* have a large area of black pigmentation and a central white patch. We investigated whether territorial males of the two damselflies at breeding sites display distinct agonistic behaviors associated with their respective wing colors. Behavioral interactions between territorial and intruder males and their wing kinematics were filmed and analyzed for *P. m. dorothea* in Lienhuachih of central Taiwan, and *P. m. mandarinus* in Tianxiyuan and Fusan of northern Taiwan. We observed that the *P. m. mandarinus* males exhibited a novel set of perched wing displays, which was not only absent in its sister *P. m. dorothea* but also previously unknown in Odonata. At breeding sites, perched rival males of *P. m. mandarinus* with pigmented wings exhibited escalating agonistic wing-flapping and wing-hitting displays toward each other. In contrast, territorial males of *P. m. dorothea* with clear wings engaged only in aerial chase or face-to-face hovering when intruder males approached from the air. These results indicate that the two sister *P. mandarinus* damselflies diverged behaviorally in territorial contests and support the hypothesis of coadaptation on the basis of wing colors and types of wing movement in Odonata. Our findings further suggest that divergent agonistic wing displays may play a pivotal role in the speciation mechanism of *P. mandarinus* damselflies. The sequential analyses of behavioral characteristics and progression suggest that *P. m. mandarinus* damselflies likely use mutual assessment of rivals in territorial contests." **18846.** Bobrek, R. (2021): Odonate phenology recorded in a Central European location in an extremely warm season. Biologia 76(6): 2957-2964. (in English) [“Life history of ectothermic organisms, including odonates, is greatly influenced by environmental temperature. Current increase in temperatures in many areas connected with global climate change may therefore affect many traits of natural populations, especially their phenology. In odonates, this includes, the timing of emergence, flight period and reproductive behaviour of adults. This study describes the phenology of odonates in a single, extremely warm year (2018) at a site located in a Central European city (Kraków, Poland), and compares it with the past data on odonate phenology across the country. 36 species were recorded in the studied site. Comparison with literature revealed that for a quarter of species, the dates of first records were 1–2 ten-day periods earlier than documented in the previous phenological data for the country. In contrast to existing data, in the current study there were summer, not spring species that showed an advanced

phenological pattern of occurrence. This study demonstrates that contemporary data on odonate phenology obtained in a single, extremely warm season, deviates from comparative long-term data from more than a decade ago, potentially as a result of rising temperatures brought on by climate change." **18847.** Boudot, J.P.; Borisov, S.; De Knijf, G.; van Grunsven, R.H.A.; Schröter, A.; Kalkman, V.J. (2021): Atlas of the dragonflies and damselflies of West and Central Asia. *Brachytron* 22, Supplement: 3-248. (in English) ["This atlas presents, for the first time, a detailed overview of the distribution of the damselflies and dragonflies (Odonata) of West and Central Asia, an area covering nearly 8 million km<sup>2</sup>. The region is not only characterized by the presence of several vast arid deserts such as the Arabian desert, Syrian desert and the Karakum but also harbors extensive mountain chains rich in streams, rivers, marshes and lakes including the Caucasus, Zagros and Hindu Kush. These combination of strong geographic differences in combination with its position between the Afrotropical, Oriental and Palearctic realm result in an interesting and diverse odonate fauna. Dragonflies and damselflies are good indicators of the quality of freshwater habitats and are colorful ambassadors for the preservation of freshwater ecosystems. In West and Central Asia the combination of climate change and an ever increasing demand for freshwater for drinking and agriculture will result in increased desertification and habitat degradation. The future of some of the species occurring in the area is therefore gloomy and some might not make it to the end of the century. This Atlas deals with no less than 175 (sub)species, many of which are endemic to the region or occur just marginally outside the region. For each species a distribution map is presented showing its occurrence in the region and adjacent areas. Texts for each species give basic information on the distribution, habitat preferences and, in some cases, taxonomical information. Although this atlas is not an identification guide, it will definitely help to identify most of the species in the region as it contains images of nearly all species, many of which have seldom been depicted in books before. We hope that this book will help to raise local awareness about this group of freshwater species and will contribute in a better protection and management of freshwater ecosystems." **18848.** Gaenzle Schilling, E.; Kardynal, K.J.; Kundel, H.; Crews-Erjaveck, Z.; Zobitz, J.M.; Hobson, K.A. (2021): Phenological and isotopic evidence for migration as a life history strategy in *Aeshna canadensis* (family: Aeshnidae) dragonflies. *Ecological Entomology* 46(2): 209-219. (in English) ["1. Investigating dragonfly migration is important for understanding species' life history strategies, migratory connectivity, terrestrial-aquatic linkages, and for successful species conservation. While migration patterns are well-documented for some species (e.g., *Anax junius*), questions remain

about potential migratory behaviour of others. 2. We investigated the potential for migration of *Aeshna canadensis* (Walker, 1908; Canada damer) using phenological observations in three study ponds in central Minnesota, 2017–2019. We also conducted probabilistic assignment to natal origins by measuring stable hydrogen isotope values of wing tissue ( $\delta^2\text{H}_w$ ) of dragonflies collected in Minnesota and acquired through Canadian museum collections. 3. This species emerged May–June from study ponds in central Minnesota, with a 10–15 week lag after onset of emergence before mature adults were observed flying and ovipositing in late summer. The probabilistic assignment depictions of emerging teneral overlapped with the sampling location, confirming accuracy of isotopic assignments of natal origin. 4. Late-flying mature adults collected at our study ponds likely originated from southern Manitoba, suggesting a north–south migration pathway. We found further evidence for migration by analysing  $\delta^2\text{H}_w$  of adult dragonflies collected in northern Minnesota and south-central Canada. Their likely origins were farther north in central Canada (Manitoba/Quebec) or the northeastern reaches of this species' range in eastern Canada. 5. We provide the first conclusive evidence of *Aeshna* migration in North America and demonstrate a robust approach, combining field observations with probabilistic assignment to origin using stable isotope analysis, which can test for migration in other dragonfly populations." (2021): Behavior of *Pseudomonas aeruginosa* strains on the nanopillar topography of dragonfly (*Pantala flavescens*) wing under flow conditions. *Biointerphases* 16, 051002: 9 pp. (in English) ["Bacterial associated infection is a threat in the medical field. *Pseudomonas aeruginosa*, one of the major causative agents for nosocomial infection, has developed resistance to almost all the classes of antibiotics. Recently, nanopillar-like structures were identified on the wings of insects such as cicada and dragonfly. Nanopillars both on natural surfaces and those mimicked on artificial surfaces were reported to possess bactericidal activity against a wide range of bacteria. An earlier study reported strain specific variation in the viability of *P. aeruginosa* on the nanopillar topography of a dragonfly wing under static condition. Here, we report the behavior of *P. aeruginosa* strains on a dragonfly wing under hydrodynamic conditions. The results of the study indicated that, under hydrodynamic conditions, *P. aeruginosa* PAO1 was attached in higher numbers to the wing surface than *P. aeruginosa* ATCC 9027 but killed in lower numbers. The plausible reason was identified to be the masking of nanopillars by the secreted extracellular polysaccharide. The shear rate of 1.0 s<sup>-1</sup> showed a relatively higher bactericidal effect among the three tested shear rates." **18850.** Kawabe, H.; Aoki, Y.; Nakamura, T. (2021): Cross-

longitudinal reinforcement structure inspired by dragonfly wing. Proceedings of the American Society for Composites — 36th Technical Conference on Composite Materials, DOI 10.12783/asc36/35748. (in English) ["The aim of this study is to establish a novel aircraft design approach replacing the conventional airframe by utilizing biomimetics. This design approach particularly focused on the dragonfly wing, whose reinforcement structures are composed of cross- veins and longitudinal veins. The cross-veins have been emulated by weighted Centroidal Voronoi Tessellation (WCVT) following the out-of-plane displacement on the skin, while the longitudinal veins have been emulated by extracting a centerline from the topology optimization result on the skin to be reinforced, through image analysis of binarization and skeletonization. The longitudinal layout can reduce the compliance distributing the inner load with only essential reinforcement on the skin without increasing the mass. The weighted CVT layout can improve the effectiveness of the reinforced skin against buckling drastically. Thus, the skin reinforced along the cross- longitudinal layout by the topology optimization and weighted CVT pattern increased buckling load 2.7 times higher even with less mass than the conventional layout. **18852.** Madhukar, G.S. (2021): Faunal diversity of Odonata at Rankala Lake, Kolhapur, Maharashtra. Indian Journal of Entomology 83(1): 54-56. (in English) ["Odonates are excellent habitat indicators of present and past environmental conditions in aquatic habitats. The objective of the present study was to check out the diversity and abundance of Odonates around the lentic habitat, Rankala Lake. A total of 81 individuals was recorded from four localities around the Rankala Lake comprising of ten species (1 unidentified) of dragonflies and three species of damselflies. Family Libellulidae was the most represented (nine species) while family Coenagrionidae was represented by three species. Among

four selected sites, Choupati site has shown maximum diversity ( $H=2.187$ ); however, species abundance was found to be more at Padpath Udyan site. This latter site has plenty of aquatic vegetation dominated by *Sacciolepis indica* and *Alternanthera paronychioides* and shallow water. The Shannon-Weiner index ( $H$ ) was 2.187 at Rankala Choupati, followed by 1.858 at Tambat Kaman and Fish Seed Centre and 1.588 at Padpath Udyan. Margalef's richness ( $D_{mg}$ ) index was found to be 3.246, 1.443, 2.148 and 1.406 at localities 1, 2, 3 and 4 respectively. The present study indicates that the aquatic habitat with good vegetation is most suitable for Odonata life and open area is having the high species richness and  $H$  index than in a water body." (2021): Seasonal abundance and distribution of dragonflies in upper Siran valley of District Mansehra Pakistan. Brazilian Journal of Biology 81(3): 785-791. (in English, with Portuguese summary) ["Present study was conducted to study seasonal abundance and distribution of dragonflies in upper Siran valley district Mansehra Pakistan. To collect data, eleven localities were visited for three consecutive years (2016-2018). Results come up with a sum of 300 specimens identified under three families, eight genera and twenty species. Highest seasonal abundance recorded during summer and spring were 80.67% and 13.33% respectively while minimum 6.00% was recorded during early autumn. Dominant species observed were, *Orthetrum chrysis* (14.00%), followed by *O. glaucum* (12.00%), *Palpopleura sexmaculata sexmaculata* (11.33%) and *O. cancellatum cancellatum* (8.00%). However the highest population of dragonflies was found in Munda Gucha with a percentage of 11.33 followed by Jabbar (11.00%) and Sachan (9.67%). The lowest populations were recorded in Suham (6.00%), Dadar (7.67%) and Jabori (7.67%). The surveyed valley showed diverse anisopterous fauna and thus further extensive surveys are recommended that can come up with more important species from the area." **18856.** Mocq, J.; Soukup, P.R.; Näslund, J.; Boukal, D.S. (2021): Disentangling the nonlinear effects of habitat complexity on functional responses. Journal of animal ecology 90(6): 1525-1537. (in English) ["1. Structural complexity of habitats modifies trophic interactions by providing refuges and altering predator and prey behaviour. Nonlinear effects on trophic interaction strengths driven by these mechanisms may alter food web dynamics and community structure in response to habitat modifications. However, changes in functional response, the relationship between prey density and feeding rate, along habitat complexity (HC) gradients are little understood. 2. We quantified functional responses along a HC gradient from an entirely unstructured to highly structured habitat in a freshwater system, using dragonfly larvae (*Aeshna cyanea*) preying on *Chaoborus obscuripes* larvae. To disentangle mechanisms by which changes in HC affect functional responses, we used two different approaches – a population-level and a behavioural experiment–, applied an information theoretic approach to identify plausible links between HC and functional response parameters, and compared our results to previous studies. 3. Functional response shape did not change, but we found strong evidence for nonlinear dependence of attack rate and handling time on HC in our study. Combined results from both experiments imply that attack rate increased stepwise between the unstructured and structured habitats in line with the threshold hypothesis, because the predators gained better access to the prey. Handling time was lowest at an intermediate HC level in the population-level experiment, while the direct estimate of handling time did not vary with HC in the behavioural experiment. These differences point toward HC-driven changes in foraging activity and other predator and prey behaviour. 4. Most previous studies reported stepwise decrease in attack rate in line with the threshold hypothesis or no change with increasing HC. Moreover, changes in the handling time parameter with HC appear to be relatively common but not conforming to the threshold hypothesis. Overall, increased HC appears to respectively weaken and strengthen trophic links in 2D and 3D predator-prey interactions. 5. We conclude that detailed understanding of HC effects on food webs requires complementary experimental approaches across HC gradients that consider predator foraging strategies and predator and

prey behaviour. Such studies can also help guide conservation efforts as addition of structural elements is frequently used for restoration of degraded aquatic habitats." **18857.** Nava-Bolaños, A.; Vrech, D.E.; Peretti, A.V.; Córdoba-Aguilar, A. (2021): Argentinian odonates (dragonflies and damselflies): current and future distribution and discussion of their conservation. Journal of Threatened Taxa 13(11): 19448-19465. (in English, with Spanish summary) ["In terms of conservation, Argentinian odonates have not been assessed using a quantitative approach. One way to achieve this is by modelling their distribution to gather the extent of occurrence. Thus, we modelled the current and future (projected year, 2050) potential distribution of 44 odonate species that occur in Argentina as well as in neighboring countries. Our models of current times indicate a fairly wide distribution for most species but one exception is relevant for conservation purposes: *Lestes dichrostigma* has less than 30,000 km<sup>2</sup> and falls in the 'Near Threatened' category according to the IUCN Red List. Another seven species have less than or close to 100,000 km<sup>2</sup>: *Elasmothermis cannacrioides*, *Erythemis credula*, *E. paraguayensis*, *Heteragrion angustipenne*, *H. inca*, *Lestes forcifera*, and *Mecistogaster linearis*. Future distribution estimates suggest that: a) 12 species will lose or gain around 10%, four species will increase their distribution beyond 10% (up to 2,346%), and 28 species will lose more than 10% (up to 99%). Although current protected areas embrace most odonate species in Argentina, it is still premature to conclude whether this situation will remain in the future given the physiological tolerance and dispersal abilities of the study species among other drivers of distribution." **18859.** Santos, A.A.; Sender, L.M.; Wappler, T.; Engel, M.S.; Diez, J.B. (2021): A Robinson Crusoe story in the fossil record: Plant-insect interactions from a Middle Jurassic ephemeral volcanic island (Eastern Spain). Palaeogeography, Palaeoclimatology, Palaeoecology 583: 12 pp. (in English) [Highlights: • First study of plant-insect interactions from the Ju-

Jurassic of the Iberian Peninsula. • Comparison with other mid-Jurassic plant-insect interactions. • Identification of possible culprits for the different damages. • Discussion on colonization strategies by insects during the Jurassic. Abstract: We present here the first record of plant-insect interactions from an ephemeral volcanic island that was placed 150 km away from the nearest continental mass. The island was formed and destroyed during the Aalenian (Middle Jurassic) in a shallow sea of the southwestern Tethyan realm corresponding today to a place located in eastern Spain. These plant-insect interactions were mainly documented in leaves of Cycadophytes (comprising both Cycads and Bennettitales), and they have been described and classified into different Damage Types (DTs) and Functional Feeding Groups (FFGs). The interactions were assigned to 11 different DTs including different types of hole feeding, margin feeding, surface feeding, piercing and sucking, mining(?), and some putative ovipositional scars. The presence of these interactions implies that the island was colonized by different groups of insects, including orders such as Coleoptera, Hemiptera, Odonata, or Lepidoptera. The low variety and incidence of interactions comparing with other Middle Jurassic plant-insect interactions assemblages indicate that the diversity of insects was not high, possibly due to the difficulty of reaching this island by various lineages, the small size of the landmass of the island, and the limited food availability (mainly Cycadophytes). Possible colonization strategies could be by atmospheric dispersion, using floating remains of plants or pterosaurs as vectors, by active flight for Lepidoptera, or by rafting and floating in marine currents for flightless or other insects." **18861.** Schmidt, K.J.; Soluk, D.A.; Mays Maestas, S.E.; Britten, H.B. (2021): Persistence and accumulation of environmental DNA from an endangered dragonfly. *Scientific Reports* 11(18987) (2021): 8 pp. (in English) ["Detection of environmental DNA (eDNA) has become a commonly used surveillance method for threatened or invasive vertebrates in both aquatic and terrestrial environments. However, most studies in this field favor vertebrate target species. Environmental DNA protocols can be especially useful for endangered invertebrates such as *Somatochlora hineana* where

conservation efforts have been greatly hindered by training, time, overall costs, and environmental impacts associated with conducting surveys in the calcareous fens occupied by this species. An essential step in developing such a protocol is to evaluate the dynamics of eDNA concentration under controlled conditions. We used the quantitative polymerase chain reaction (qPCR) to examine seasonal shifts in the persistence and net-accumulation of eDNA from captive *S. hineana* larvae in experimental mesocosms at temperatures corresponding with their overwintering (5.0 °C) and active (16.0 °C) seasons. Environmental DNA persisted longer at 5.0 °C but accumulated more readily at 16.0 °C. Differences in the accumulation and persistence of eDNA reflect differences in the longevity of eDNA at different temperatures and seasonal differences in larval *S. hineana* behavior. This study highlights the importance of considering how seasonal changes in temperature influence not only the speed of eDNA degradation but also the target species' eDNA shedding rates." **18862.** Sergio, C.; Luca, R.; Olivier, F. (2021): Plasticity and flexibility in the anti-predator responses of treefrog tadpoles. *Behavioral Ecology and Sociobiology* (2021) 75:142: 14 pp. (in English) ["Tadpoles can respond to perceived predation risk by adjusting their life history, morphology, and behavior in an adaptive way. Adaptive phenotypic plasticity can evolve by natural selection only if there is variation in reaction norms and if this variation is, at least in part, heritable. To provide insights into the evolution of adaptive phenotypic plasticity, we analyzed the environmental and parental components of variation in predator-induced life history (age and size at metamorphosis), morphology (tail depth), and behavior of Italian treefrog tadpoles (*Hyla intermedia*). Using an incomplete factorial design, we raised tadpoles either with or without caged predators (dragonfly larvae, gen. *Aeshna*) and, successively, we tested them in experimental arenas either with or without caged predators. Results provided strong evidence for an environmental effect on all three sets of characters. Tadpoles raised with caged predators (dragonfly larvae, gen. *Aeshna*) metamorphosed earlier (but at a similar body size) and developed deeper tails than their fullsib siblings raised without predators. In the experimental arenas, all tadpoles, independent of their experience, flexibly changed their activity and position, depending on whether the cage was empty or contained the predator. Tadpoles of the two experimental groups, however, showed different responses: those raised with predators were always less active than their predator-naïve siblings and differences slightly increased in the presence of predators. Besides this strong environmental component of phenotypic variation, results provided evidence also for parental and parental-by-environment effects, which were strong on life-history, but weak on morphology and behavior. Interestingly, additive parental effects were explained mainly by dams. This supports the hypothesis that phenotypic plasticity might mainly depend on maternal effects and that it might be the expression of condition-dependent mechanisms." (Authors)] Address: Ser-

gio, C., Dept of Life Science and Systems Biology, University of Turin, Via Accademia Albertina 13, 10123 Turin, Italy. E-mail: sergio.castellano@unito.it

**18864.** Swain, P.K.; Dora, S.P.; Battula, S.M.; Barik, A.K. (2021): Numerical investigation of wing–wing interaction and its effect on the aerodynamic force of a hovering dragonfly. *Proceedings of the Institution of Mechanical Engineers, Part G: Journal of Aerospace Engineering* 235(12): 1648-1663. (in English) ["The present research focuses on the timing of wing–wing interaction that benefits the aerodynamic force of a dragonfly in hovering flight at Reynolds number 1350. A 3-D numerical simulation method, called the system coupling, was utilised by implementing a two-way coupling between the transient structural and flow analysis. We further explore the aerodynamic forces produced at different phase angles on the forewing and hindwing during the hovering flight condition of a dragonfly. A pair of dragonfly wings is simulated to obtain the force generated during flapping at a 60° inclination stroke plane angle with respect to the horizontal. The hovering flight is simulated by varying the phase angle and the inter-distance between the two wings. We observe a significant enhancement in the lift (16%) of the hindwing when it flaps in-phase with the forewing and closer to the forewing, maintaining an inter-wing distance of 1.2 cm (where centimetre is the mean chord length). However, for the same condition, the lift of the hindwing reduces by 9% when the wings are out of phase/counterstroke flapping. These benefits and drawbacks are dependent on the timing of the interactions between the forewing and hindwing. The time of interaction of wake capture, wing–wing interaction, dipole structure and development of root vortex are examined by 2-D vorticity of the flow field and isosurface of the 3-D model dragonfly. From the isosurface, we found that the root vortex elicited at the root of the hindwing in counterflapping creates an obstacle for the shedding of wake vortices, which results in reduction of vertical lift during the upstroke of flapping. Hence, at the supination stage, a dragonfly uses a high rotation angle for the hovering flight mode. It

is observed that the system coupling method was found to be more efficient and exhibited better performance. The present numerical methodology shows a very close match to the previously reported results." **18865.** Takemura, M.; Maoka, T.; Koyanagi, T.; Kawase, N.; Nishida, R.; Tsuchida, T.; Hironaka, M.; Ueda, T.; Misawa, N. (2021): Elucidation of the whole carotenoid biosynthetic pathway of aphids at the gene level and arthropodal food chain involving aphids and the red dragonfly. *BMC Zoology* 6(19). 13 pp. (in English) ["Background: Aphids can be positioned as robust pest insects in farming and as ones of the model organisms for arthropods in molecular biology. Carotenoids are pigments that protect organisms from photooxidative damage caused by excessive light. Aphids were shown to possess genes of fungal origin for carotenoid biosynthesis, whereas a little knowledge was available about the functions of the genes and the biosynthetic pathway. Even carotenoid species contained in aphids were not enough understood. Main purpose of this study is to clarify these insufficient findings. Results: The whole carotenoid biosynthetic pathway of the pea aphid (*Acyrtosiphon pisum*) was elucidated at the gene level, through comprehensive functional analysis of its carotenogenic genes, using *Escherichia coli* that synthesized carotenoid substrates, along with structural and quantitative analysis of carotenoids from various aphid species. Four genes were needed to synthesize all carotenoids accumulated in aphids from geranylgeranyl diphosphate. The *tor* gene mediated desaturation reaction from phytoene to 3,4-didehydrolycopene. It was revealed that a gene designated *ApCrYB3*, which was considered to have functionally evolved in aphids, can convert lycopene into uncommon carotenoids with the  $\gamma$ -ring such as (6'S)- $\beta,\gamma$ -carotene and  $\gamma,\gamma$ -carotene. We further demonstrated that the atypical carotenoids work as ecological indicators for estimating the food chain from aphids to predatory arthropods, and showed that aphids contributed with significant levels to the food chain from insect herbivores to several predatory arthropods, i.e., *Sympetrum frequens* (adults), seven-spotted ladybird (*Coccinella septempunctata*), and two spiders, *Oxyopes sertatus* and *Nephila clavata*. Gut microflora of the dragonfly (mature adults) was also found to include endosymbiotic bacteria such as *Serratia symbiotica* specific to the black bean aphid (*Aphis fabae*). Conclusions: We revealed the whole carotenoid biosynthetic pathway of aphids, including functional identification of the corresponding genes. Subsequently, we showed that arthropodal food chain can be estimated using the uncommon carotenoids of aphids as ecological indicators. This result indicated that aphids made significant contributions to the food chain of several predatory arthropods including the red-dragonfly adults. Aphids are likely to be positioned as an important "phytochemicals" source for some predatory insects and arachnids, which are often active under bright sunlight." **18866.** Thongprem, P. (2021): Torix Rickettsia: aspects of diversity, host range and symbiont-host interaction. PhD thesis, University of Liverpool. VII + 185pp. (in English) ["Rickettsia bacteria have traditionally been considered as the aetiologic agent of deadly arthropod-borne diseases in humans and livestock. However, more recent studies have discovered Rickettsia as non-vertebrate pathogens that are actually important to invertebrate evolution as symbionts. Recently, Rickettsia in the 'torix' clade were described from glossiphoniid leeches. This clade has since been observed to infect a wide range of invertebrate species and is thought to be most common in host species associated with freshwater habitats. This leads to a general hypothesis that torix Rickettsia are a common endosymbiont of freshwater taxa. However, this hypothesis is yet to be formally tested. To assess this hypothesis, I firstly investigated in-depth a freshwater-associated insect order, the Odonata, in which torix Rickettsia had not been previously recorded. This study revealed the first incidence of torix Rickettsia in odonates, present in roughly 10% of the screened species. Maternal transmission of this endosymbiont was observed in *Coenagrion puella*, and this strain has likely driven mtDNA introgression between the insect and its sister species (*C. pulchellum*). Then, I expanded the screen to test for torix Rickettsia in other invertebrate taxa and compared the infection frequency between freshwater and terrestrial communities. Fisher's exact test indicated that the proportions of infected species from freshwater community is significantly higher than the terrestrial group in three representative insect orders. In addition to this broad screen, torix Rickettsia in a few blood-feeding insects are recorded for the first time, including mosquitos (*Anopheles plumbeus*), black flies (*Simulium aureum*) and the common bed bug (*Cimex lectularius*). Bed bugs were then established as a model system to study biological impacts of torix Rickettsia carriage. Symbionts in the bed bug were transmitted via matriline only. There were no signs of reproductive parasitism, sex ratio distortion or cytoplasmic incompatibility phenotypes. Torix Rickettsia only express mild parasitic impacts on *C. lectularius* biology by slowing development time and reducing fecundity. Finally, this thesis raises three questions for onward study; i) why torix Rickettsia are abundant in freshwater biomes, ii) how do torix strains transition into terrestrial species and iii) how torix Rickettsia are associated with broad spectrum of eukaryotic hosts. Possible scenarios for these three questions are discussed for future study." (Author) Address: Thongprem, P., University of Liverpool Faculty of Health and Life Sciences, UK

**18867.** Triyanti, M.; Arisandy, D.A. (2021): Keanekaragaman Jenis Capung Famili Libellulidae di Bukit Cogong Kabupaten Musi Rawas - Diversity species of dragonflies family of Libellulidae in Bukit Cogong Musi Rawas. *Biota: Jurnal Ilmiah Ilmu-Ilmu Hayati* 6(1): 44-51. (in Indonesian, with English summary) ["There are many species of dragonflies in Cogong Hill, Musi Rawas Regency, but not yet well recor-

ded, so it is necessary to collect data on species of dragonflies and studies on diversity. Therefore, the research was conducted to study the diversity of dragonflies of the Libellulidae family in Cogong Hill, Musi Rawas Regency. This research uses the technique of exploring transects by determining 3 observation stations. Each station consists of 5 transects with a transect area of 100x100 m. The capture of the Libellulidae family in Bukit Cogong, Musi Rawas Regency using a net net, was identified by observing the morphological characteristics of the dragonflies of the libellulidae family. Five species of dragonflies from the Libellulidae family were found, namely: *Orthetrum sabina*, *Neurothemis fluctuans*, *Bracythemis contaminata*, *Rhodothemis rufa*, and *Onychothemis culminicola*. The highest species composition is *Orthetrum sabina* by 46.34%, while the lowest is *Onychothemis culminicola* by 6.09%. Uniformity index at all stations in high category, stable community, dominance index (C) in low category, and diversity index is low with a value is 1.61." **18868.** Trong, K.H.; Thi, N.D.; Thi Nhu, Y.N.; Thi, H.V.; Thanh Ho, V.T. (2021): Impacts of climate change to the growth and development of the dragonflies of Tram Chim National Park, Tam Nong – Dong Thap, Vietnam. IOP Conference Series: Materials Science and Engineering, Volume 1092, The 2nd International Conference on Innovative Technology, Engineering and Sciences (iCITES 2020) 22nd-23rd December 2020, Pekan Pahang, Malaysia Citation K H Trong et al 2021 IOP Conf. Ser.: Mater. Sci. Eng. 1092 012090. 8 pp. (in English) ["Dragonflies are insects that have an association with wetland ecosystems and sensitive to changes in environmental factors. Therefore, under the increasingly strong impacts of climate change, they exhibit quite pronounced responses. Assessing the growth and development process of dragonflies can contribute positively to assessing and making strategies to cope with the impacts of climate change which is becoming increasingly complicated. The results of the current study showed that the Dragonfly species composition in Tram Chim National Park was remarkably diverse, including 11 species (2008) and 12 species (2019) of larvae belonging to 6 families in Zygoptera and Anisoptera. Based on information from field surveys, the results showed that the presence of dragonflies tended to be earlier than those recorded in the past, and it was often difficult to find them along the survey route, especially nearer to noon. Range, flight speed, and altitude were somewhat reduced, especially for Zygoptera. These environmental factors fluctuated greatly, which might cause pressing impacts on the growth and development of Dragonflies in the Tram Chim National Park area." **18869.** Uyizeye, E.; Clausnitzer, V.; Kipping, J.; Dijkstra, K.-D.B.; Willey, L.; Kaplin, B.A. (2021): Developing an odonate-

based index for prioritizing conservation sites and monitoring restoration of freshwater ecosystems in Rwanda. *Ecological Indicators* 125 (2021) 107586. 18 pp. (in English) ["Land use changes and the ways that natural resources are extracted and used pose severe threats to freshwater ecosystems globally. This is particularly pronounced in developing and densely populated countries, such as Rwanda. In-depth understanding of how ecosystems respond to threats could guide their restoration, conservation, and better management. The advancement of ecological monitoring tools is crucial for freshwater conservation. We developed and implemented an odonate-based tool, the Rwanda Dragonfly Biotic Index (RDBI), tailored to freshwater ecosystems in Rwanda as a metric to identify conservation priority sites and to monitor their restoration. The RDBI is determined based on three sub-indices: Distribution-Based Score (DBS), Threat-Based Score (TBS) and Sensitivity-Based Score (SBS). Species level-DBS increases from those that are widespread across all ecological zones to those that are restricted to only one ecological zone; TBS for a species ranges from those that are of least concern to those that are critically endangered, as per IUCN Red List; Species' SBS increases from those thriving in a highly disturbed habitat to those occurring only in a relatively intact habitat. Using RDBI, we identified hotspot habitats for odonates in Rwanda and benchmark sites for restoration. Hotspots are defined based on species richness, presence of unique species, and RDBI scores. Benchmark sites for restoration are habitats with the highest RDBI in each ecological zone. The value of using RDBI in ecosystem monitoring rests on the fact that it can help identify priority sites for conservation, and it uses organisms that are charismatic and relatively easy to identify. This is essential for citizen engagement and drawing a long-term link between policymaking, on-the-ground practices, and impacts on freshwater ecosystems." **18870.** Vitasse, Y.; Ursenbacher, S.; Klein, G.; Bohnenstengel, T.; Chittaro, Y.; Delestrade, A.; Monnerat, C.; Rebetez, M.; Rixen, C.; Strebel, N.; Schmidt, B.R.; Wipf, S.; Wohlgenuth, T.; Yoccoz, N.G.; Lenoir, J. (2021): Phenological and elevational shifts of plants, animals and fungi under climate change in the European Alps. *Biological Reviews of the Cambridge Philosophical Society* 96(5): 1816-1835. (in English) ["Mountain areas are biodiversity hotspots and provide a multitude of ecosystem services of irreplaceable socio-economic value. In the European Alps, air temperature has increased at a rate of about  $0.36^{\circ}\text{C decade}^{-1}$  since 1970, leading to glacier retreat and significant snowpack reduction. Due to these rapid environmental changes, this mountainous region is undergoing marked changes in spring phenology and elevational distribution of animals, plants and fungi. Long-term monitoring in the European Alps offers an excellent natural laboratory to synthesize climate-related changes in spring phenology and elevational distribution for a large array of taxonomic groups. This review assesses the climatic changes that have occurred across the European Alps during recent decades, spring phenological changes and

upslope shifts of plants, animals and fungi from evidence in published papers and previously unpublished data. Our review provides evidence that spring phenology has been shifting earlier during the past four decades and distribution ranges show an upwards trend for most of the taxonomic groups for which there are sufficient data. The first observed activity of reptiles and terrestrial insects (e.g. butterflies) in spring has shifted significantly earlier, at an average rate of  $-5.7$  and  $-6.0$  days  $\text{decade}^{-1}$ , respectively. By contrast, the first observed spring activity of semi-aquatic insects (e.g. dragonflies and damselflies) and amphibians, as well as the singing activity or laying dates of resident birds, show smaller non-significant trends ranging from  $-1.0$  to  $+1.3$  days  $\text{decade}^{-1}$ . Leaf-out and flowering of woody and herbaceous plants showed intermediate trends with mean values of  $-2.4$  and  $-2.8$  days  $\text{decade}^{-1}$ , respectively. Regarding species distribution, plants, animals and fungi ( $N = 2133$  species) shifted the elevation of maximum abundance (optimum elevation) upslope at a similar pace (on average between  $+18$  and  $+25$  m  $\text{decade}^{-1}$ ) but with substantial differences among taxa. For example, the optimum elevation shifted upward by  $+36.2$  m  $\text{decade}^{-1}$  for terrestrial insects and  $+32.7$  m  $\text{decade}^{-1}$  for woody plants, whereas it was estimated to range between  $-1.0$  and  $+11$  m  $\text{decade}^{-1}$  for semi-aquatic insects, ferns, birds and wood-decaying fungi. The upper range limit (leading edge) of most species also shifted upslope with a rate clearly higher for animals (from  $+47$  to  $+91$  m  $\text{decade}^{-1}$ ) than for plants (from  $+17$  to  $+40$  m  $\text{decade}^{-1}$ ), except for semi-aquatic insects ( $-4.7$  m  $\text{decade}^{-1}$ ). Although regional land-use changes could partly explain some trends, the consistent upward shift found in almost all taxa all over the Alps is likely reflecting the strong warming and the receding of snow cover that has taken place across the European Alps over recent decades. However, with the possible exception of terrestrial insects, the upward shift of organisms seems currently too slow to track the pace of isotherm shifts induced by climate warming, estimated at about  $+62$  to  $+71$  m  $\text{decade}^{-1}$  since 1970. In the light of these results, species interactions are likely to change over multiple trophic levels through phenological and spatial mismatches. This nascent research field deserves greater attention to allow us to anticipate structural and functional changes better at the ecosystem level." **18871.** Walia, G.K.; Katnoria, N. (2021): Chromosome characterization of four calopterygid damselflies with cytogenetic review of family Calopterygidae (Odonata: Zygoptera). *J. Adv. Zool.* 42(1): 107-117. (in English) ["Taxonomically, in family Calopterygidae, 183 species under 21 genera have been reported worldwide. Out of these, cytogenetic data pertains to only 22 species which is only 12% of the known species. In India, 9 species under 6 genera are present, while only 2 species has been studied cytogenetically. The present study has been conducted to linearly characterize the chromosomes of 4 species (*Matrona nigripictus*, *Neurobasis chinensis*, *Vestalis apicalis* and *Vestalis gracilis*) of

family Calopterygidae by conventional staining, C-banding, silver nitrate staining and sequence-specific staining and also compiled the cytogenetic data of the family. The species were collected from Meghalaya, Goa, Kerala, Himachal Pradesh states of India. All the species possess  $2n=25m$  as the diploid chromosome number with XO-XX sex determination except *Neurobasis chinensis* with  $2n=23$ , characterized by the presence of two equal sized large autosomal bivalents originated by the autosome fusion. C-banding and silver nitrate staining results depict the presence of C-bands and NOR's on the terminal positions of autosomal bivalents, while X chromosome and m bivalent show variation in distribution of C-heterochromatin and NOR's. Sequence-specific staining represents the complement of all the species as AT-rich due to more DAPI bright signals. All the cytogenetically studied species have been catalogued including the presently studied species and the list has been updated to 23 species." **18872.** Wallis de Vries, M.F.; Manger, R.; van Grunsven, R. (2021): Trends van Dagvlinders en Libellen in het Drentsche Aa-gebied. Rapport VS2021.010. De Vlinderstichting, Wageningen. 29 pp. (in Dutch) ["Discussion and conclusion: For the dragonflies, only changes after 1990 could be analysed. As with the butterflies, the number of species increased (13) and decreased (15). The decline was particularly marked for species from fens and cooler climates, which are also under pressure elsewhere in the region. The increase was mainly for species from running water and species that have benefited from climate warming. These trends are in line with nationally observed developments. This is also expected for dragonflies as they are generally much more mobile than butterflies and their populations show similar dynamics on a large spatial scale. Nevertheless, these changes also reflect the development in habitat quality within the Drentsche Aa area, where nutrient-poor environments are under pressure, but the oxygen richness of the flowing water seems to have increased (which does not necessarily mean that the water has become less nutrient-rich)." **18873.** Wang, Y.; Liu, J.-j.; Li, B.-l.; Liu, W.; Zuo, Y.-f.; Kong, D.-x.; Zhu, J.-l. (2021): Relationships between characteristics of macrobenthic assemblages and environmental variables in the Heihe River Basin, China. *AQUA — Water Infrastructure, Ecosystems and Society* 70(5): 710-729. (in English) ["To clarify the characteristics of macrobenthic assemblages and their response to the aquatic environment in the upper and middle reaches of the Heihe River, water quality, sediments and macrobenthos measurements were conducted in the summers of 2018 and 2019. The results showed that 50 species of macrobenthos were identified [including 8 odonate taxa not further detailed], belonging to 3 phyla, 7 classes, 15 orders and 32 families, mainly arthropods (37 species) and mollusks (11 species). *Argyroneta*

*aquatica*, *Chlaznius* sp., dragonfly nymphs, *Palaemon modestus*, *Radix auricularia*, *Cyraululus albus* and *Suecinea* sp. were the dominant species in the whole study region; most of these are pollution-tolerant and moderately tolerant species. The macrobenthos density and biomass ranged from 10 to 577 ind./m<sup>2</sup> and from 0.0907 to 50.0562 g/m<sup>2</sup>, respectively, showing high spatial heterogeneity. Predators were the main functional feeding group. One-way analysis of variance clarified that Margalef's index and the Shannon–Wiener index differed significantly among the spatial areas ( $P<0.05$ ). Canonical correspondence analysis showed that the spatial heterogeneity of the macrobenthos was affected by the water temperature and the total nitrogen and total phosphorus in sediments ( $P<0.05$ ). Highlights: • The spatial variation community structures and species diversity of microbenthic in the Heihe River Basin (HRB) of China were investigated. • Analyzed the intensive fluctuations along the way of macrobenthic assemblages and their response relationship with environmental parameters in the HRB. • Natural environment factors and anthropogenic activities maintained the diversity and stability of macrobenthic communities of the HRB." **18874.** Wang, Y.-J.; Sentis, A.; Tüzün, N.; Stoks, R. (2021): Thermal evolution ameliorates the long-term plastic effects of warming, temperature fluctuations and heat waves on predator-prey interaction strength. *Functional Ecology* 35(7): 1538- 1549. (in English) ["(1) How thermal evolution may affect trophic interactions and its implications for trophic system stability remains unstudied. To advance insights in how global warming shapes trophic interactions, we need to consider besides increases in mean temperatures, also daily thermal fluctuations (DTF) and heat waves (HW), and how their effects are modulated by thermal evolution. (2) Using a common-garden approach we tested how each thermal factor affected predator metabolic rate and functional response parameters, and used these responses to predict long-term predator-prey interaction strength between larvae of the damselfly *Ischnura elegans* and the water flea *Daphnia magna*. By using high- and low-latitude predator populations with the latter being exposed to higher mean temperatures, higher DTF and more frequent HW, we assessed the potential impact of thermal evolution at the high latitude using a space-for-time substitution. (3) In line with thermal adaptation, growth rates were faster and handling times shorter in low-latitude compared to high-latitude larvae at 24°C, while the opposite was true at 20°C. Warming weakened the long-term interaction strength, except for the high-latitude trophic system at DTF and HW where plastic responses therefore may not stabilize the high-latitude system. This extends the emerging insight that temperature variation may make ectotherms more vulnerable to warming. The contributions of metabolic rate, search rate and handling time in shaping thermal effects on interaction strength differed between latitudes. A key finding was that thermal evolution may further weaken the long-term interaction strength of the high-latitude trophic system under increases

in mean temperatures, even at DTF and potentially also at HW. (4) Our results underscore the importance of daily thermal fluctuations and heat waves in shaping predator-prey interactions, and may suggest an overall stabilizing contribution of predator thermal evolution ameliorating thermal plastic effects on food web stability." **18875.** Wildermuth, H. (2021): Auswirkungen des trockenheissen Sommers 2018 auf die Libellenfauna eines Wiesenweihers im östlichen Schweizer Mittelland. *Entomo Helvetica* 14: 33-44. (in German, with English and French summaries) ["Impact of the hot, dry summer of 2018 on the Odonata fauna of a meadow pond in the eastern Swiss Midlands. - Dragonflies rely on freshwater for their development. If a pond goes dry for several weeks during hot summer periods, the larvae will die. This was the case in 2018 at numerous small bodies of water in the Swiss Midlands. Questions were raised regarding the impact of pond desiccation on the local dragonfly fauna. The problem was studied at a small meadow pond that was created in 2010. In 2017, 28 odonate species were recorded, 16 of them with observed reproduction activities and 10 with successful development. In 2018 there were 19, 9 and 8 species, respectively, and in the following year 28, 16 and 4 species. In the second year after the hot and dry summer, the values were 25, 13 and 12 species, respectively. Unexpectedly, 4 species successfully developed in 2019: *Ischnura elegans*, *Sympetrum fonscolombii*, *S. sanguineum*, and *S. striolatum*. Their success is explained by their species-specific life histories. Only two years after the extreme weather event, the local odonate community had more or less recovered. Thanks to the species present in adjacent water bodies, the pond was rapidly recolonized. The importance of metapopulations based on dense limnological networks for both conservation and the promotion of local dragonfly fauna is underlined." **18876.** Wonglersak, R. (2021): Insect size and shape responses to temperature: a case study of British Odonata and Chironomidae (Diptera). PhD thesis, University of Southampton. 169pp. (in English) ["This PhD project investigated the response of wing length (as a proxy of body size) of Odonata and Chironomidae, and wing shape of Odonata to temperature and latitude. Three complementary data sources were used: natural history collections, field data, and mesocosm experiments. While natural history collections are valuable resources of specimens collected over long historical time scales, field data provides a modern perspective and mesocosm experiments provide a window on the future, under a predicted climate warming scenario. This PhD project used 5,331 museum specimens of 14 British Odonata species representing different life cycle types to examine the potential drivers of body size and wing shape responses to latitude and temperature (Chapter II and V). To control for latitude a field survey was performed during

the summer of 2018 at Edington, Somerset to compare modern wing length of three species with historical data based on museum specimens of the same species collected at the same locality (Chapter III). Furthermore, to investigate body size responses of chironomids under a future temperature scenario, 1,976 adult specimens of six chironomid species were collected from mesocosm experiments which comprised ponds at ambient temperature and ponds maintained at 4°C higher than ambient (Chapter IV). The results of Chapters II, III and IV showed that species and suborder (within Odonata) were significant factors affecting the magnitude of the temperature-size responses in Odonata and Chironomidae. Wing lengths of Zygoptera and Chironomidae are more sensitive to temperature and collection date than Anisoptera. Zygoptera and Chironomidae tend to get smaller with increasing temperature, likely due to higher temperatures disproportionately increasing developmental rate, resulting in smaller adults. Anisoptera showed no significant correlation with temperature, possibly due to selection for larger individuals in Anisoptera which are strongly territorial species. Adults of Zygoptera and Chironomidae emerging towards the end of the summer tend to be smaller than those emerging earlier in the season, likely due to larval development being time-constrained later in the season and as a result, larvae accelerate their developmental rate which comes at the cost of a smaller adult body size. The results of Chapter V indicated non-significant correlations between environment and wing shape in Anisoptera, while there were significant influences of latitude and mean seasonal temperature on wing shape in Zygoptera species, with broader and shorter wings found at lower latitudes with warmer temperatures. This finding corresponds well with a result of Chapter II which found shorter wing length with increasing temperature in all zygopteran species in the study. Overall, the results of this PhD project show that there are different factors influencing the temperature-size responses of insects, including phylogenetic relationships, sex, behaviour and life cycle types. Although this study found no universal temperature size responses in the focal taxa, Zygoptera and Chironomidae tend to have stronger negative body size responses to warming temperature and emergence date than Anisoptera. In addition, the study shows that wing shape variation in Zygoptera is more sensitive and adaptive to latitude and temperature than in Anisoptera." **18879.** Hord, K. (2010): Numerical investigation of the aerodynamic and structural characteristics of a corrugated wing. MSc. thesis, J.B. Speed School of Engineering, Department of Mechanical Engineering, University of Louisville: 78 pp. (in English) ["Previous experimental studies on static, bio-inspired corrugated wings have shown that they produce favourable aerodynamic properties such as delayed stall compared to streamlined wings and flat plates at high Reynolds numbers ( $Re = 4 \times 10^4$ ). The majority of studies have been carried out with scaled models of dragonfly forewings from the *Aeshna cyanea* [cf.] in either wind tunnels or water channels. In this thesis, the aerodynamics of a corrugated airfoil was studied using computational fluid dynamics methods at a low Reynolds number of 1000. Structural analysis was also performed using the commercial software SolidWorks 2009. The flow field is described by solving the incompressible Navier-Stokes equations on an overlapping grid using the pressure-Poisson method. The equations are discretized in space with second-order accurate central differences. Time integration is achieved through the second-order Crank-Nicolson implicit method. The complex vortex structures that form in the corrugated airfoil valleys and around the corrugated airfoil are studied in detail. Comparisons are made with experimental measurements

from corrugated wings and also with simulations of a flat plate. Contrary to the studies at high Reynolds numbers, our study shows that at low Reynolds numbers the wing corrugation does not provide any aerodynamic benefit compared to a smoothed flat plate. Instead, the corrugated profile generates more pressure drag which is only partially offset by the reduction of friction drag, leading to more total drag than the flat plate. Structural analysis shows that the wing corrugation can increase the resistance to bending moments on the wing structure. A smoothed structure has to be three times thicker to provide the same stiffness. It was concluded the corrugated wing has the structural benefit to provide the same resistance to bending moments with a much reduced weight." (Author)] Address: not stated

**18881.** Baker, L.F.; Ciborowski, J.J.H.; MacKinnon, M.D. (2012): Petroleum coke and soft tailings sediment in constructed wetlands may contribute to the uptake of trace metals by algae and aquatic invertebrates. *Science of the*

Total Environment 414: 177-186. (in English) ["The fate of trace metals in pore water collected from wetland sediments and organisms exposed to petroleum coke were evaluated within in situ aquatic microcosms. Oil sands operators of Fort McMurray, Alberta, Canada produced 60 million tonnes of petroleum coke by 2008, containing elevated concentrations of sulphur and several trace metals commonly seen in oil sands materials. This material may be included in the construction of reclaimed wetlands. Microcosms were filled with a surface layer of petroleum coke over mine-waste sediments and embedded in a constructed wetland for three years to determine how these materials would affect the metal concentrations in the sediment pore water, colonizing wetland plants and benthic invertebrates. Petroleum coke treatments produced significantly elevated levels of Ni. We also found unexpectedly higher concentrations of metals in "consolidated tailings" waste materials, potentially due to the use of oil sands-produced gypsum, and higher background concentration of elements in the sediment used in the controls. A trend of higher concentrations of V, Ni, La, and Y was present in the tissues of the colonizing macrophytic alga *Chara* spp. Aeshnid dragonflies may also be accumulating V. These results indicate that the trace metals present in some oil sands waste materials could be taken up by aquatic macroalgae and some wetland invertebrates if these materials are included in reclaimed wetlands." **18883.** Fiebrich, M. (2012): Die Libellen der Stillgewässer der Halbinsel Bodanrück - Ein Vergleich verschiedener Erfassungsmethoden. Diplomarbeit. Universität zu Trier: 165 pp. (in German) ["In the context of this diploma thesis, the dragonfly fauna of 17 stillwaters on the Bodanrück [Baden-Württemberg, Germany] peninsula was investigated. Different recording methods were used, which were compared with regard to their resulting species compositions. In the course of this study, 44 dragonfly species were recorded in 7 inspections, 28 of which are considered to be native on the basis of exuviae findings. The results were analysed for their similarity in terms of species composition, phenological differences and development trends over the last 25 years, in order to develop necessary management and protection measures at the end. The study showed that the recording methods are not equivalent and do not reflect the same species composition, which is why dragonfly mapping based on only one recording method is highly questionable. There is therefore no "best" method. This was also found by Raebel et al. (2010) and Giugliano et al. (2012) and supports this

hypothesis. A survey of dragonfly species should accordingly be linked to the goal of mapping. Recording the imagines provides the most representative results with regard to the species diversity of a water body. In order to obtain information on the water quality, it is also advisable to search specifically for exuviae, even if this method is associated with a higher workload. Adult individuals, on the other hand, do not necessarily provide information on aquatic conditions (water quality, presence of predators, etc.). The recording of indicators of ground conditions should still be integrated, but this does not always provide a reliable indication of ground conditions. Standardised methods are indispensable for future surveys. For this purpose, the duration, period, area, etc. of surveys must be standardised in the future in order to make the results spatially and temporally comparable." **18886.** Schmidlin, S.; Schmera, D.; Baur, B. (2012): Alien molluscs affect the composition and diversity of native macroinvertebrates in a sandy flat of Lake Neuchâtel, Switzerland. *Hydrobiologia* 679(1): 233-249. (in English) ["The spread of alien molluscs is a serious threat to native biodiversity in fresh waters. Alien freshwater molluscs may deplete the resources of native species and alter the physical structure of the habitat through their shell mass. These changes might have both positive and negative effects on

native community members. We investigated the native macroinvertebrate community in relation to the densities of four alien mollusc species (*Corbicula fluminea*, *Dreissena polymorpha*, *Potamopyrgus antipodarum* and *Lithoglyphus naticoides*) in a sandy flat of Lake Neuchâtel, Switzerland. The habitat examined was dominated by these alien mollusc species. The abundance of the alien molluscs did not directly impact the native community assembly. However, *C. fluminea* and *D. polymorpha* influenced the composition and diversity of native macroinvertebrates by transforming the sandy substratum into a partly hard substratum habitat. Substantial differences in community composition between shallow (<3.5 m) and (=5 m) deep sites were recorded. At shallow sites, the abundance of *D. polymorpha* was significantly reduced as a result of depth-selective feeding of ducks. A controlled shell decay study revealed that shells of alien molluscs (*C. fluminea*, *D. polymorpha*) persist for a longer period in the sediment than those of native molluscs. Consequently, shells of alien molluscs have a long-lasting impact by modifying the sandy habitat. This form of ecosystem engineering favours the occurrence of several native taxa, but is disadvantageous for other taxa with specific habitat requirements, and thus can be regarded as an indirect impact of competition." (Authors) The list of macrozoobenthos includes "Ischnura sp.".] Address: Schmidlin, Stephanie, Section of Conservation Biology, Dept of Environmental Sciences, University of Basel, St. Johanns-Vorstadt 10, 4056, Basel, Switzerland

#### 2014

**18887.** Dayaram, A (2014): Discovery of novel circular replication-associated protein encoding single-stranded DNA viruses in ecosystems using viral metagenomic approaches. PhD. thesis, School of Biological Sciences, University of Canterbury: 293 pp. (in English) ["The introduction of next-generation sequencing (NGS) technologies has dramatically changed the field of virology, with many significant discoveries of novel circular replication-associated protein (Rep) encoding single-stranded (CRESS) DNA viruses. Traditionally, most research into CRESS DNA viruses has often focused on investigating plant and animal pathogens that are of significant economic importance. This research has led to the discovery and establishment of three different CRESS DNA families including Geminiviridae, Nanoviridae and Circoviridae, which infect eukaryotes. CRESS DNA viruses can have single or multicomponent genomes, with the latter requiring all components for infection. CRESS DNA viruses have circular single-stranded DNA (ssDNA) genomes with at least one protein encoding a Rep which is responsible for viral replication. It has been shown that CRESS DNA viruses are able to evolve rapidly with nucleotide substitution rates that are similar to those observed in RNA viruses. The Rep gene has conserved regions known as motifs which are often used to determine relatedness between CRESS DNA virus. NGS has expanded our knowledge on the diversity of novel CRESS DNA viruses. Viral genomes are now routinely recovered from different sample types without any prior knowledge of the viral sequence.

This has led to the development of the field of viral ecology. This field places an emphasis on viruses being one of the most abundant organisms on earth, and are therefore likely to play a major role in ecosystems. Environmental metagenomic studies have isolated CRESS DNA viruses from sea water, freshwater, faecal matter from various animals, soil, the atmosphere, sediments and sewage; dramatically increasing the known CRESS DNA viral genomes in the public domain. These studies are shedding light on the distribution of CRESS DNA viruses, as well as providing baseline data for future studies to examine virus-host interactions, community structure and ultimately viral evolution. Vector enable metagenomics (VEM) is another novel approach utilising NGS techniques for discovering CRESS DNA viruses. As many plant-infecting CRESS DNA viruses such as geminiviruses and nanoviruses are vectored by insects, this approach exploits this mechanism by using insect vectors as a surveillance tool to monitor and survey these viruses circulating in ecosystems. Recent studies have used these methods to identify known viral plant pathogens as well as novel viruses circulating in insect vectors such as whiteflies and other higher order insects such as mosquitoes and dragonflies. These approaches successfully demonstrated that VEM can be used as a unique method, with the first mastrevirus discovered in the new world being recovered from dragonfly species *Erythrodiplax fusca* using this approach. The research in this thesis uses metagenomics to survey CRESS DNA viral diversity in different organisms and environments. Two hundred and sixty eight novel CRESS DNA viruses were recovered and verified in this study from a range of sample types (adult Odonata, Odonata larvae, Mollusca, benthic sediment, water, Oligochaeta and Chironomidae) collected in the United States of America, Australia and New Zealand. All viral genomes isolated had two major proteins encoding for a putative Rep and coat protein (CP), with major Rep motifs identified in most Reps. Phylogenetic analysis of the Reps encoded by the viral genomes highlighted that most were extremely diverse falling outside of the previously described ssDNA viral families. A top-down approach was implemented to recover CRESS DNA viruses and possible viral pathogens from Odonata and their larvae. Thirty six viral genomes were recovered from terrestrial adult dragonflies as well as the twenty four from aquatic larvae. Dragonfly cycloviruses were isolated from the some adult Odonata species which were closely related to the isolates previously described by Rosario et al. (2012). The viruses isolated in the aquatic and terrestrial ecosystems differed substantially indicating that different CRESS DNA viromes exist in both land and water. The diversity of CRESS DNA viruses in seven different mollusc species (*Amphibola crenata*, *Austrovenus stutchburyi*, *Paphies subtriangulata*, *Musculium novazelandiae*, *Potamopyrgus antipodarum*, *Physella acuta* and *Echyridella menziesi*) from Lake Sarah and the Avon-Heathcote estuary both in New Zealand, were also investigated. One hundred and forty nine novel viral genomes were recovered. Two CRESS DNA genomes were recovered from molluscs which have Rep-like sequences most closely

related to those found in some bacterial genomes. Sclerotinia sclerotiorum hypovirulence-associated DNA virus 1 (SsHADV-1) was originally isolated from fungal species Sclerotinia sclerotiorum in China and was later found in benthic sediments in New Zealand. As part of this study, SsHADV-1 was recovered from dragonflies (*Erythemis simplicicollis*, *Ischnura ramburii* and *Pantala hymenaea*) collected in Arizona and Oklahoma, USA suggesting a larger distribution of these viruses and not surprising given the near global distribution of *S. sclerotiorum*. Dragonfly larvae-associated circular DNA viruses (DfIaCVs) that were originally isolated in Odonata larvae samples from three New Zealand lakes were later recovered from water, benthic sediment, worms and molluscs from one of the lakes initially sampled, suggesting that these viruses are ubiquitous in freshwater environments. This study has attempted to generate baseline data of CRESS DNA viruses in certain environments using NGS-informed approaches. This data was used to try and establish whether viral distribution in different sample types can potentially be explained by the food web interactions between different sample types. Although the analysis did not show any significant relationships between sample type interactions and viral distribution a few common associations between Odonata larvae and benthic sediment were evident. This was expected as the larvae live within the sediment so it could be assumed that they potentially have similar CRESS DNA viral distribution. Although the distribution of viruses varied across sample types, molluscs proved the best sampling tool for isolating largest numbers of CRESS DNA viruses in an ecosystem with extensive diversity. Overall, this research demonstrates the applications of NGS for investigating the diversity of CRESS DNA viruses. It demonstrates that some sample types such as Odonata in terrestrial systems and molluscs in aquatic environments, can be used as effective sampling tool to determine the diversity of CRESS DNA viruses in different environments as well as detecting previously isolated viruses. The CRESS DNA viruses isolated in this body of work provides baseline data that can potentially be used in future research to investigate hosts of these viruses and their interactions with hosts and potential flow in their environments." **18888.** Garré, A. (2014): Biología de las larvas de *Cyanallagma interruptum* Selys (1876) (Odonata: Coenagrionidae). PhD thesis, Facultad de Ciencias Naturales y Museo, Universidad Nacional de La Plata: 251 pp. (in Spanish) ["The order Odonata is composed of small to large, cosmopolitan, predatory, exopterygous, palaeopterous insects with hemimetabolous development: mostly aquatic larvae (nymphs or naiads) and aerial adults. The suborder Zygoptera consists of gracile, small to large organisms with generally slow flight. The larvae are slender with three conspicuous caudal lamellae at the posterior end of the abdomen. The family Coenagrionidae is one of the most numerous families within the suborder. The genus *Cyanallagma* was established by Kennedy in 1920. In Argentina it is represented by only three species: *C. bonariense* (Ris, 1913), *C. interruptum* (Selys, 1876) and *C. nigrinuchale* (Selys, 1876).

*Cyanallagma interruptum* (Selys, 1876) is typical of Patagonia, generally inhabiting lentic environments of different types, temporary or permanent, (lagoons, ponds and mallines) in both forest and steppe areas. Post-embryonic development is little studied in Argentina and is important to better understand voltinism and seasonal regulation, as well as to identify species from early larval stages, which is a prerequisite for the study of larval ecology. On the other hand, the larval stage is highly specific to the water body it inhabits. The characteristics of the environment limit the survival of one species or another. The different larval stages are distributed differently within the water body, possibly due to the availability of food, the absence and/or presence of predators, or the preference for one or another substrate. The main objective of this thesis is to determine several biological aspects of natural (non-laboratory reared) larval populations of the species *Cyanallagma interruptum* (Selys, 1876) and their relationship with physical-chemical and biotic variables in two lagoons: El Trébol and Los Juncos in the Northern Region of Patagonia, Argentina. Nine larval stages of *Cyanallagma interruptum* (Selys, 1876) were obtained in El Trébol lagoon and 10 in Los Juncos lagoon. *Cyanallagma interruptum* is a summer species according to Corbet (1956, 1999, 2002) and no seasonal synchronisation was observed. In both lagoons the species showed univoltinism. The diapause phenomenon occurs in the winter months and in the large and intermediate size stages. The description of the last larval stage (F-0) differs from the description made by Bulla in 1973. There is sexual dimorphism in the larval stages of *C. interruptum* which is evident from F-4 to F-0 (last larval stage) by the presence of genitalic sketches. A significant difference in the spatial distribution of *C. interruptum* larval stages was observed from the coast towards the centre in both studied lagoons. Substrate preference was observed for the different larval stages of *C. interruptum*, with medium and larger larval stages selecting *Potamogeton* sp., small larval stages preferring *Myriophyllum* sp. and *Potamogeton* sp. Both lagoons exhibited oligotrophic characteristics during the period of this study. However, differences in the distribution and relative abundance of the associated faunal taxa and physico-chemical variables influenced the distribution of larval stages from the coast towards the centre of both studied lagoons. Ambient temperature and concentrations of P-PO<sub>4</sub>, N-NH<sub>4</sub>, N-NO<sub>2</sub> and N-NO<sub>3</sub> ions influenced the relative abundance of the associated fauna and thus the larval cycle of *C. interruptum*." **18889.** Perkin, E.K.; Hölker, F.; Tockner, K. (2014): The effects of artificial lighting on adult aquatic and terrestrial insects. *Freshwater biology* 59(2): 368-377. ["There is a growing concern that artificial light might affect local insect populations and disrupt their dispersal across the landscape. In this study, we investigated experimentally the effect of artificial light on flying insects in the field, with an emphasis on aquatic insects. We asked whether lights prevented the ability of insects to disperse across the landscape, a process

that is crucial in colonising restored habitats. We set up six, c. 3.5 m high downward facing high-pressure sodium street-lights along a permanently connected oxbow in the Spree River of eastern Germany. We collected insects using 12 flight intercept traps, each with trays at three different heights (0.5, 1.5 and 2.5 m), placed at distances 0, 3, 40 and 75 m from the lights and 5, 8 and 80 m from water. The number of emerging aquatic insects in the study area was measured with six emergence traps. We emptied the traps 22 times between June and September 2010; the lights were on for 11 of these nights and off for the other 11. In total, we caught almost 27 times as many insects at traps 0 m from the lights when the lights were on than when they were off. Most insects caught when the lights were on were aquatic, with Diptera being the most common order. Furthermore, the proportion of aquatic insects caught at traps 0, 3 and 40 m from the lights when they were on was significantly higher than when they were off. On lit nights, more aquatic insects were captured per hour and m<sup>2</sup> (area in which flying insects were intercepted) at traps 0 m from the lights than emerged from per square metre per hour from the Spree River. Our results suggest that adult aquatic insects can be negatively affected by artificial light and that city planners should take this into account when designing lighting systems along rivers." (Authors) The study includes a passing reference to odonata.] Address: Perkin, Elizabeth, IGB, Leibniz-Institute of Freshwater Ecology & Inland Fisheries, 12587 Berlin, Germany. **18890.** Berquier, C. (2015): Etude écologique et patrimoniale du peuplement des odonates de Corse appliquée à la conservation des espèces et des zones humides à enjeux. PhD thesis, Ecologie, Environnement, Université de Corse, Pascal Paoli: 311 pp. (in French, with English summary) ["Corsica [France] is home to a great diversity of wetland subject to anthropogenic pressures and threats which have continued to grow and diversify in recent decades. The conservation of these environments with high heritage value and of the original Odonata community that develops in it, today represents significant environmental and societal challenges in order to preserve essential ecological services provided by these key elements of aquatic and terrestrial ecosystems. The applied research project developed as part of this thesis is focused on improving the knowledge available on the corsican dragonfly's community, to propose concrete conservation and management measures for this group and its main insular natural habitats. In this objective, the first part of this work has sought to fill principal knowledge gaps identified by previous studies on the situation of listed species, including by greatly intensifying exploration effort at the regional level. The special features, distribution, habitat requirements and ecological of many dragonflies growing in Corsica have been described with great precision. The information available on some taxa with high heritage value increased particularly as illustrated by the comprehensive definition of eco-bio-geographical situation of *Chalcolestes parvidens*. The second part of this work has sought to evaluate and compare the effectiveness of the

main sampling methods commonly used for the study of dragonfly's populations. In this context, the extensive information collected on the spatial organization and dynamics of the populations studied were especially used to propose and recommend appropriate methods for evaluation and monitoring the species to high conservation issue to main managers of natural areas of the island (Country Councils, PNRC, PMIBB, municipalities ...), including the emblematic and threatened *Lestes macrostigma*. The third part of this work is devoted to the development of tools for monitoring the quality of the main Odonata habitats. It lead to the development of a whole new biological index adapted to assess the ecological status of corsican rivers: "Odonata Community Index – Corsica" (OCIC). This innovative tool, based on the study of characteristics of dragonflies community of watercourses, was particularly effective during its confrontation with other biological indicators (diatoms, macrophytes, benthic macroinvertebrates) currently used on the island. The OCIC index and the Odonata group today appear clearly as a potentially promising alternative solution to improve the efficiency of the ecological quality assessment system of the rivers of Corsica, given the representativeness vulnerabilities which have been highlighted by the tests performed. The fourth and final part of this thesis, based on heritage and environmental assessments of the insular dragonfly's community made with all the information produced, ended with the development and the proposal of several regional conservation devices whose implementation is encouraged by the state services: a first regional actions plan, a first red list of threatened species and an updated list of species determinative for natural areas of ecological, flora and fauna interest (ZNIEFF). These important features are intended to contribute to improve the overall state of conservation of Corsican dragonflies and main wetlands that support them. They should enable the implementation of truly operational management actions and ensure better consideration of the main regional conservation and valuation issues identified. In the end, this thesis work that increased more than triple the previously available data on dragonflies of Corsica, will provide a new framework to develop the insular odonatology." (Author) The study can be downloaded at. <https://tel.archives-ouvertes.fr/tel-01408080>] Address: Berquier, C., Office de l'Environnement de la Corse, Observatoire – Conservatoire des Insectes de Corse, Lieu-dit "Lergie", RN 200, 20250 Corte, France. **18893.** Schneider, W.; Samraoui, B. (2015): Chapter 5. The status and distribution of dragonflies and damselflies (Odonata) in the Arabian Peninsula. In: García, N., Harrison, I., Cox, N. and Tognelli, M.F. (compilers). (2015). The Status and Distribution of Freshwater Biodiversity in the Arabian Peninsula. Gland, Switzerland, Cambridge, UK & Arlington, USA: IUCN. ISBN: 978-2-8317-1706-7: 39-55. (in English) ["The number of dragonflies and damselflies of the Arabian Peninsula and the Socotra Archipelago amounts to 59 taxa with 5 additional species, *Pseudagrion niloticum*, *Anax tristis*, *Sympetrum sinaiticum*, *Trithemis pallidinervis*, and *Tamea basilaris* not evaluated. *Pseudagrion niloticum* has not been assessed because it was only recently discovered in Wadi Hadhramout (Schneider and Nasher 2013). For *Sympetrum sinaiticum* there is only a single record in northern Saudi Arabia at the southernmost border of the species' distribution. Although a female was collected during oviposition, its true status is unknown. The same holds true for the remaining three species: *Anax tristis* and *Tamea basilaris* are common migrants often spotted in the desert plains or far offshore. In Arabia *Trithemis pallidinervis* is only known from a single specimen collected in northern

Oman. It is likely that the occurrence of this Indian species originated from a windborne migration. The species has obviously not established stable populations in Arabia. The validity of some taxa and their precise distribution deserves further investigation, with the larvae of several species insufficiently described or even unknown (Jödicke et al. 2004). The highest diversity of Odonata in the region is concentrated in the southern Arabian Peninsula, including parts of Yemen (67.2%), Saudi Arabia (64.1%) and Oman (64.1%) (Table 5.1, Fig. 5.1). The south-west of Saudi Arabia, a hot-spot of Odonata diversity in the region, contrasts sharply with the much drier rest of the country." **18894.** Valeriano, W.W. (2015): Cores estruturais da asa da libélula: *Chalcopteryx rutilans*. MSc. thesis, Universidade Federal de Minas Gerais: 61 pp. (in Portuguese, with English summary) ["In dragonflies, color has many functions, the most important ones being sex recognition, courtship and territory defense behaviors. In *C. rutilans* - a dragonfly found in the Amazonian rain forest those functions are performed by displaying their strongly iridescent hind wings, whereas the hyaline forewings are used to maintain the flight. The phenomenon of iridescence results from physical optics effects such as diffraction and interference. The aim of this work is to study the structures responsible for the male wing iridescence in *Chalcopteryx*. Visible range reflectance was measured for each different colored region of the wings. In order to determine the internal microstructure of the region that exhibits the same color, Scanning Electron Microscopy SEM was performed in cross-sections of the wings, after cutting in situ by Focused-Ion Beam FIB. Transmission Electron Microscopy TEM images were obtained from ultrathin sections of osmium treated, resin embedded and uranyl-stained wing. The SEM and TEM images revealed that the wings have a multilayered structure alternating different electron density materials. The number and thicknesses of the layers change across the wing, correlating with the local color. The composition of the layers is considered as being of chitin with different levels of melanin pigmentation. The electron density of the SEM cross-section images was assumed as being directly proportional to the optical density, and was used to define the modulation of the refractive indexes in the multilayered structure. The optical reflectance resulting from a structure with such a modulated refractive index was calculated numerically, using the transfer matrix method. A good correlation is obtained between experiment and simulation, thus confirming that in *C. rutilans* male wings colors result from a multi-layer structure, i.e., these wings are natural one dimensional photonic crystals." **18895.** Aideo, S.N.; Mohanta, D. (2016): Limiting hydrophobic behavior and reflectance response of dragonfly and damselfly wings. *Applied Surface Science* 387: 609-616. (in English) ["In this work, through water contact angle (CA) measurements, we explore hydrophobic behavior of different parts of the hind wings of a dragonfly, *Gynacantha Dravida* and of a damselfly, *Pseudagrion Microcephalum*. As we move from the basal to distal region, the contact angle ( $\theta$ ) was found to vary in the range of 120–136° for both the species. Moreover, the wing of the dragonfly was seen to be more hydrophobic than that of the damselfly one. An attempt has also been made to link roughness factor ( $r_\phi$ ) and solid-water fraction ( $\phi$ ) through the simplified Wenzel and Cassie-Baxter models. We noticed that,  $r_\phi$  and  $\phi$  tend to follow a linear relation that gives  $r_\phi = 1.47$  in the limit,  $\Delta\theta < 10.1^\circ$ , latter being recognized as the difference in angle between the measured CA over a surface to that of the CA ( $\sim 105^\circ$ ) known for a smooth surface. Our experimental data, however, revealed empirical relations which predicted higher  $r_\phi$  values, particularly when  $\Delta\theta$  is large. While the overall reflectance response of the distal segment was believed to be stronger than that of the basal part, the edge parts of the dragonfly and damselfly wings exhibited exponential associated growing trends with increasing wavelength. The relative reflectance response, corresponding to  $\sim 494$  nm and 370 nm peaks, gets nearly doubled for the edge specimen as compared to the distal and basal parts. The edge- specimen, which comprises of rectangular shaped, periodic microstructures, displayed carotenoid based two broad peak maxima at  $\sim 422$  nm and  $\sim 494$  nm. The surface roughness which arises through the distribution of oblate-shaped nano-fibrils is believed to be the basis of sub-surface volume scattering. Interrelating nanostructure surface roughness based wettability and reflectance characteristics would provide new insights on structure-property relationship in naturally available soft matter systems including templates of biological origin.] (Authors)] Address: Mohanta, D., Nanoscience and Soft Matter Laboratory, Dept of Physics, Tezpur Univ., Napaam, Tezpur, Assam 784 028, India. **18896.** Liu, X.; Chen, K.; Chen, Q.; Wang, M.; Wang, L. (2016): The community structure of macroinvertebrate and its relationship to the environmental factors in summer and autumn within typical reaches of Iluai River Basin. *Acta Scientiae Circumstantiae* 36(6): 1928-1938. (in Chinese, with English summary) ["Being an important component of river ecosystem, benthic invertebrate is sensitive to the changes of water environment and ecological status. The community structure characteristics of invertebrate can effectively indicate the status of water quality and river ecosystem condition. To assess the ecological health of Huai River system

which is under strong human disturbances, monitoring on water quality, sediment and benthic invertebrate were conducted at 27 sampling sites in summer and autumn of 2014 in Huaihe mainstream and tributaries. Multivariate analysis methods were used to analyze the composition dominant species, biodiversity, temporal and spatial characteristics of macroinvertebrate assemblages, as well as their relationships to environmental factors. The results showed that 4297 macroinvertebrates of 62 taxa collected within two investigations were mainly composed by Mollusca and Insecta. Insecta mainly consisted of Diptera, Ephemeroptera and Odonata, accounting for 33.33%, 21.21% and 18.18% of the total number in Insecta taxa, respectively. Additionally, the average abundance and biomass of macroinvertebrate were 74.21 ind·m<sup>-2</sup> and 7.89 g·m<sup>-2</sup> in summer with the dominant species of Caridina and Bellamya aeruginosa, and were 27.53 ind·m<sup>-2</sup> and 1.13 g·m<sup>-2</sup> in autumn with the dominant species of Caridina, Orthocladus, Baetis and Cricotopus. The results of t-test showed that there was no significant difference ( $p=0.135$ ) on spatial distribution of macroinvertebrate density between summer and autumn, while the spatial distribution of the biomass was significantly different ( $p=0.002$ ). Based on the comparison of two investigations, it was found that the difference in macroinvertebrate abundance was mainly contributed by Mollusca and Crustacea; the individual number of Insecta also appeared the seasonal difference as the number of Trichoptera in summer is significantly higher than that of in autumn, and the numbers of Diptera and Ephemeroptera were obviously lower than that of in autumn. The results of Redundancy analysis (RDA) indicated that the gradient changes of water temperature, pH, total nitrogen, and heavy metals (Hg, Cd, Pb) were the main driving factors for the changes of benthic macroinvertebrate community structure. Furthermore, dam operation, slope solidification, riparian vegetation, and sand mining were major disturbances to habitats and biodiversity of benthic macroinvertebrates." **18897.** Stauer, M. (2016): Erstnachweis der Kleinen Moosjungfer *Leucorrhinia dubia* (Vander Linden, 1825) für das Burgenland (Insecta: Odonata). *Biodiversität und Naturschutz in Ostösterreich - BCBEA 2/1*. BCBEA 2/1 (Oktober 2016): 97-101. (in German, with English summary) ["First record of *L. dubia* from Burgenland (Insecta: Odonata). On July 21, 2013 *L. dubia* was recorded in Burgenland for the first time. In Austria the species inhabits typically pools in raised and transition bogs in montane to subalpine altitudes. A possibly indigenous population of *L. dubia* in Burgenland is discussed." (Author)] Address: Stauer, Martina, Lindenbauer-gasse 13, 1110 Wien, Austria. Email: m\_stauer@web.de

**18898.** Tichanek, F. (2016): Ecology of endangered damselfly *Coenagrion ornatum* in post-mining streams in relation to their restoration. MSc. thesis, Faculty of Science, University of South Bohemia, Ěeské Budějovice, Czech Republic: 53 pp. (in English) ["Summary and synthesis: As the thesis results confirmed, the Radovesická spoil heap represents a

regionally important secondary habitat for endangered *C. ornatum*. Although the high conservation value of the post-mining streams was already suggested (Tichanek & Tropek 2015), various opponents have been sceptical about residency of the threatened headwater species in the post-industrial freshwater sites. According to our results on the population size, the larval occurrence, and the species' spatial ecology, the population is confirmed to be resident. This detailed study of the endangered species shows that at least some of the habitat most specialised species are able to create rich and relatively stable local populations in human-made sites. It also supports indication, that the most interesting and valuable odonate communities are being formed in reclaimed parts of spoil heaps, contrasting thus to threatened terrestrial biota. Similarly, both studying the spatial ecology and detailed habitat requirements revealed the huge importance of small-scaled microhabitats formed by fine-leaved emergent vegetation (*Eleocharis* spp. in our study). Such microhabitats are favoured by both life stages, both sexes, and on both studied spatial scales. The patches without the microhabitat are colonized by fewer specimens which tend to emigrate soon. Supporting such microhabitats is thus extremely useful for the species conservation and should represent one from the main tools in restoration of post-mining flowing freshwaters. Because the species is sedentary, mostly operating within 100 m long sections, all conservation action potentially degrading the habitat from short-term point of view should be provided in maximally 100 meters long sections. Even short-term damage of longer sections via management suggested by the species' habitat preferences (removing sediments or too grown vegetation) could lead to fragmentation of the local population. Moreover, it would be highly desirable to establish good microhabitats at least with the frequency one short section per 100 m long section. This will keep a higher connectivity and thus viability of the population. Our results confirmed that sampling of larvae is still optimal. Larval response slightly differ from adults, mainly because of requiring finer-scale habitat heterogeneity, whereas they are not influenced by the banks characteristics. However, despite this, *C. ornatum* females have still relatively narrow distribution restricted to specific microhabitats which are very important also for larvae. Females and juveniles thus can be monitored as a very accurate proxy of the larval development and species residency. Finally, as number of present juveniles is decreasing shortly after start of the season, sampling should be provided in early species flight period to record sufficient abundances of the generally hardly detectable juveniles." **18899.** Amann, P. (2017): Über das Vorkommen der Helm-Azurjungfer und anderer Libellen im Raum Dornbirn - Hohenems - Lustenau (Vorarlberg, Österreich). *inatura – Forschung online* 36: 21 pp. (in German) ["The aim of the research assignment was to document the dragonfly fauna in the greater Hohenems, Lustenau and Dornbirn area along ditches. One focus of the work was to record the populations of *Coenagrion mercuriale*, which was first recorded in

the study area in 2007 (Hämmerle 2007: 313). In autumn 2015, the water bodies in the study area were surveyed and assessed as potential dragonfly habitats. 14 water bodies were selected for further investigation. From May 2016, the dragonfly fauna of the selected ditches could be examined. Five inspections were carried out per water body. A total of 28 dragonfly species were identified during this study; ten of the species found belong to an endangered category, two are considered to be threatened with extinction according to Hostettler (2001). In the course of the study, a previously unknown autochthonous occurrence of *C. mercuriale* was also discovered. This is the largest known population of this species in Vorarlberg. From a nature conservation perspective, the protection of this occurrence is of Europe-wide importance (*C. mercuriale* is listed in the Habitats Directive, Annex II)." (Authors/DeepL)] Address: Amann, P., Wiesenbachweg 8, 6824 Schlins, Austria. E-Mail: p.amann@aon.at

**18900.** Billqvist, M. (2017): Nya provinsfynd av trollsländor i Sverige 2009-2017 - New provincial records of Odonata in Sweden 2009-2017. *Entomologisk Tidskrift* 138(3-4): 209-225. (in Swedish, with English summary) ["The interest for dragonflies in Sweden have increased dramatically for more than a decade. This has brought on more knowledge and many new province records. Since year 2000 there has even been six new species for the country: *Sympecma padesca*, (in the year 2000), *Anax imperator* (2002), *Erythromma viridulum* (2004), *Aeshna affinis*, (2010), *Anax parthenope* (2010) and *Sympetrum pedemontanum* (2011). The Occurrence Catalogue (formerly known as the Landscape Catalogue) of dragonflies was last updated in March 2009. This article presents 128 new provincial findings made since then, most of them new records but also older reports that was not included in 2009. By 2017, 64 species of dragonflies have been found in Sweden. Out of these, 51 species have been reported from new provinces since 2009. With the sole exception of Lycksele lappmark, new species of dragonflies have been reported from every province." **18901.** Liechti, T. (2017): RKR2020 - Neukonzessionierung Kraftwerk Reckingen. Fachbericht Libellen. Anlage D 7.21. RKR2020 – Umweltplanung Modul 2: 21 pp. (in German) ["Five species of Gomphidae live on the High Rhine. Among them is *Gomphus simillimus*, which in Germany and Switzerland occurs almost exclusively on the Rhine between the outlet of Lake Constance and Breisach. *Ophiogomphus cecilia*, which occurs in low density on the Rhine, is listed in Annex 4 of the Habitats Directive and is thus strictly protected in Germany. Fauna databases of Switzerland and Germany were consulted and the results evaluated. In addition, five representative stretches were searched for exuviae in June 2015. The data and findings show that the Reckingen dam contains a large population of *G. simillimus* of probably several hundred individuals. Also common are *G. vulgatisimus* and *Onychogomphus f. forcipatus*. The latter prefers flowing stretches to backwater stretches with coarser bottom

substrate. *O. cecilia* is rare, but present in the area. On the High Rhine, exuviae of *G. simillimus* were found both on rapidly flowing and almost stagnant stretches. The highest hatching densities were found at sites with low flow velocity and accumulation of fine sediments, such as the boathouse at Rümikon (CH), which is located in a slightly wider section of the Rhine with large sand and silt deposits. The unchanged operation of the power plant is not expected to have any impact on the dragonfly species group. No valuable dragonfly habitats are affected by the construction of the fishway or replacement measures such as the creation of side channels." ## 2018

**18902.** Cook, P.; Rasmussen, R.; Brown, J.M.; Cooper, I.A. (2018): Sexual conflict does not maintain female colour polymorphism in a territorial damselfly. *Animal Behaviour* 140: 171-176. (in English) ["Highlights: •We examined whether male damselflies discriminate between female colour morphs. •We used five populations that varied in male-like female morph frequency (0–86%). •Males approached, inspected and contacted both female morphs at similar rates. •Females experienced more tandem attempts and longer interaction duration than males. •In *Megalagrion calliphya*, there is little evidence of female harassment by males. Female-limited dimorphism is commonly hypothesized to be an adaptation resulting from male harassment or sexual conflict over female mating rate. We examined whether males discriminate between female colour morphs of the beautiful Hawaiian damselfly, *Megalagrion calliphya*, in order to evaluate whether male harassment could explain the existence and/or maintenance of this dimorphism. Previous studies of this species suggest that spatially varying ecological selection maintains the dimorphism, but these hypotheses are not mutually exclusive. Here, we used a common method of measuring male behaviour towards secured females at mating sites under naturally occurring conditions, using five populations that range in male-like female morph frequency from 0 to 0.86. We found very low rates of interaction in a total of 64 one-hour trials, and male behaviour towards females did not differ significantly between colour morphs. By comparing the populations that vary in female morph frequency, we found no evidence of frequency-dependent sexual selection on colour, suggesting that this polymorphism is maintained by selective forces other than sexual conflict." **18903.** Miler, O.; Czarnicka, M.; Garcia, X.-F.; Jäger, A.; Pusch, M. (2018): Across-shore differences in lake benthic invertebrate communities within reed stands (*Phragmites australis* Trin. ex Steud.). *International Revue Hydrobiology* 103: 99-112. (in English) ["The spatial distribution of benthic macroinvertebrates along reed transects was studied in lakes with minimal human disturbances to enable a deeper

understanding of the functioning of reed macroinvertebrate communities and relations to biotic and abiotic environmental variables. The taxonomic and functional macroinvertebrate community composition significantly differed between outer margin, center, and shore locations. At shore locations, higher proportions of Gastropoda, Hydrachnidia and Coleoptera, mobile swimmers/skaters, predators, and shredders were found. However, outer margin locations were characterized by a higher proportion of sessile filter-feeding Bivalvia and mining Diptera. At the outer margins, also greater contributions of taxa preferring pelal habitats and r-strategists typical for more disturbed environments were observed. An indicator species analysis revealed *Asellus aquaticus* (Crustacea) and *Scirtidae* Gen sp. (Coleoptera) as significant indicator taxa for shore locations and *Valvata piscinalis* (Gastropoda), *Tinodes* sp. and *Orthotrichia* sp. (Trichoptera) as significant indicator taxa for outer margin locations. The taxonomic composition of macroinvertebrate communities was significantly related to higher water depth, oxygen content, and pH at outer margin locations. Shore locations were characterized by higher amounts of woody debris, leaf litter, and decaying plant material. In summary, the taxonomic and functional composition of macroinvertebrates varied strongly from shore to outer margin locations and could be related to spatial changes in hydrodynamical and food conditions along the transects." (Authors) The study includes "Odonata" and "Ischnura elegans".] Address: Miler, M., Leibniz Inst. Freshwater Ecology & Inland Fisheries (IGB), Müggelseedamm 301, 12587 Berlin, Germany. **18904.** Seidu, I.; Nsor, C.A.; Danquah, E.; Lancaster, L.T. (2018): Odonata assemblages along an anthropogenic disturbance gradient in Ghana's Eastern Region. *Odonatologica* 47(1/2): 73-100. (in English) ["We assessed the effects of different levels of anthropogenic disturbance on Odonata species richness and assemblage composition in four different habitats in Ghana: mining sites, agricultural fields, human settlements, and primary forest habitat. A total of 992 individual adult Odonata representing 51 species (20 Zygoptera, 31 Anisoptera) in six families were recorded from 16 sites across these habitats. A majority of species (75 %) recorded across all sites were previously classified as habitat generalists, while 20 % represented specialists. The human settlement habitat exhibited the overall highest Odonata abundance (302 individuals), whereas the greatest species diversity was observed in the mining sites ( $D = 4.59$ ). Agricultural fields had lowest abundance ( $n = 196$  individuals), while primary forest sites exhibited the lowest diversity ( $D = 2.75$ ), although these differences were not statistically significant. There was also no significant difference in adult Odonata richness  $D$  ( $F_{3,59.72} = 2.48$ ,  $p = 0.07$ ) among habitats. However, species composition differed significantly among the various habitats (ANOSIM: global  $R = 0.73$ ,  $p = 0.001$ ). A canonical correspondence analysis revealed that river flow rate, percentage of canopy cover and channel width were the key factors influencing Odonata assemblages. Generalist and heliophilic dragonflies dominated in human-altered habitats, while the matured forest habitat included

more specialists and stenotopic damselflies. The results suggest that specialist dragonflies can be used as freshwater habitat quality indicators, and their habitat requirements also support the need to maintain the remnant primary forest in the East Akim District." ## 2019

**18906.** Archibald, S.B.; Cannings, R.A. (2019): Fossil dragonflies (Odonata: Anisoptera) from the early Eocene Okanagan Highlands, western North America. *Canadian Entomologist* 151(6): 783-816. (in English) ["We describe the first dragonflies (Odonata: Anisoptera) from the early Eocene Okanagan Highlands of far-western North America from nine fossils. Six are assigned to five species in four new, named genera of Aeshnidae: Antiquiala snyderaenew genus and species, Idemlinea versatilisnew genus and species, Ypshna brownleeinew genus and species, Ypshna lapennatanew genus and species, and Eoshna thompsonensis new genus and species; we treat one as Aeshnidae genus A, species A; one is assigned to Gomphidae: Auroradraco eosnew genus and species; and we treat a ninth, fragmentary fossil of unknown family affinity as Anisoptera indeterminate genus A, species A, which represents a seventh genus and eighth species. The dominance of Aeshnidae is consistent with other Paleocene and Eocene fossil localities. Auroradraco eos is the only fossil Gomphidae in the roughly 66-million-year gap between occurrences in mid-Cretaceous Burmese amber and the early Oligocene of France. Ypshna appears close to Parabaissaeshna ejerslevense from the early Eocene Fur Formation of Denmark; this is not surprising given Holarctic intercontinental connections at this time and a growing list of insect taxa shared between the Okanagan Highlands and the Fur Formation." **18907.** Bell, T.; Harriss, J.; Ruzaini, A.; Fernando, C.; Guay, P.J.; Weston, M.A. (2019): Flight initiation distance in dragonflies is species-specific, positively related to starting distance and sometimes body length. *International Journal of Odonatology* 22(3-4): 173-179. (in English) ["Predator escape behaviour is a critical component of dragonfly life history. Flight initiation distance is the distance at which escape commences, and is well studied in vertebrates, barely studied in invertebrates, and entirely unstudied in dragonflies. Here we test four principles regarding flight initiation distance as derived from studies of vertebrates to examine if they apply to dragonflies in Sri Lanka: (1) flight initiation distance is a species-specific trait; (2) flight initiation distance increases with starting distance (the distance at which the experimenter begins an approach); (3) larger individuals have longer flight initiation distances; and (4) flight initiation distance varies between the sexes in some species. We collected 105 flight initiation distances from 11 species (known sex and size). Flight initiation distances varied between species and positively with starting distance. In one of three data-rich species (n = 10), flight initiation distance was positively associated with body length. Flight initiation distance did not vary with sex in our sample. Escape responses evoked by standardised human approaches represent a fruitful methodology to study dragonfly escape behaviour in the wild." **18908.** Bielczynska, A. (2019): Wind exposure as a factor influencing the littoral macrozoobenthic community: a methodological approach and preliminary findings. *Limnol. Rev.* 19(3): 113-123. (in English) ["The aim of the work was to analyze the influence of wave activity on invertebrate fauna living in the littoral zone. For this purpose, an algorithm was developed to analyze spatial and meteorological data, calculating the values of fetch and wind exposure. The taxonomic composition of the fauna and the values of selected water quality indicators were analyzed against the background of varied wind exposure, trophy, and various habitats. A significant negative impact of wind exposure on the taxonomic variety of the macrozoobenthic community, the number of Coenagrionidae damselflies and Baetidae mayflies was found. It is difficult to separate the impact of waves on the fauna from the impact of other natural and anthropogenic factors, because those factors may also be affected by water movements. The tool produced as part of this work can also be used to further investigate the issue of impact of waves on all the communities living in the littoral zone." (Authors)] Address: Bielczyńska, Aleksandra, Dept Freshwater Protection, Institute of Environmental Protection – National Research Institute, Kolektorska 4, 01-692 Warsaw, Poland. **18909.** Brasil, L.S.; Silverio, D.V.; Cabette, H.S.R.; Batista, J.D.; Vieira, T.B.; Dias-Silva, K.; de Oliveira-Junior, J.M.B.; de Carvalho, F.G.; Calvao, L.B.; Macedo, M.N.; Juen, L. (2019): Net primary productivity and seasonality of temperature and

precipitation are predictors of the species richness of the Damselflies in the Amazon. *Basic and Applied Ecology* 35: 45-53. (in English) ["Several hypotheses have been proposed to explain the mechanisms that generate temporal and spatial species richness patterns. We tested four common hypotheses (water, energy, climatic heterogeneity and net primary productivity) to evaluate which factors best explain patterns of Zygoptera species richness. Of these, we predicted that climatic heterogeneity would be the most important predictor for Zygoptera richness patterns. We sampled communities of adult Zygoptera in 100 small Amazonian streams. Based on generalized linear mixed models (GLMM), we found that net primary productivity and climatic heterogeneity comprised the best model of Zygoptera species richness in Amazonian streams, with an pseudo  $r^2$  of 39.5%. Results indicate that species richness increases by one species per 1 kg of biomass per square meter in NPP, or with an increase of 2°C in air temperature variability. Our work corroborates a recent study with other taxa in Brazilian Bioms. This suggests that temporal variation in climate and net primary productivity are important predictors of the macroecological patterns of richness for aquatic organisms in tropical regions." (Authors)] Address: Brasil, L.S., Programa de Pós-Graduação em Zoologia - Universidade Federal do Pará e Museu Paraense Emílio Goeldi. Belém, Pará, Brasil. E-mail: brasil\_biologia@hotmail.com

**18910.** Buczynska, E.; Buczynski, P. (2019): Survival under anthropogenic impact: the response of dragonflies (Odonata), beetles (Coleoptera) and caddisflies (Trichoptera) to environmental disturbances in a two-way industrial canal system (central Poland). *PeerJ* 6:e6215: 31 pp. (in English) ["Ecological metrics and assemblages of three orders of aquatic insects (Odonata, Coleoptera and Trichoptera — OCT) in an industrial canal system affected by dredging were studied. Five sites (a river as a control site and canals) along the Vistula River in Central Poland were sampled during six sampling periods (2011 and 2013). Canonical correspondence analyses (CCA) was used to assess the influence of environmental variables on the distribution of 54 insect species in the following system of habitats—a river feeding the canals, river-fed inlet canals and outlet canals with cooling waters. Additionally, before and after control impact (BACI) was used to test for the impact of canal dredging in 2011 on the insect response metrics. Non-metric multidimensional scaling analysis differentiated insect assemblages of the three habitats and similarity percentage (SIMPER) indicated the species most responsible for the faunistic dissimilarities. Temperature was found to be a key factor governing the presence of insects in the outlet canals with cooling water. CCAs revealed that electrolytic conductivity (EC) and salinity had the greatest influence on the OCT fauna in the river and the inlet canals, whilst it was the dissolved oxygen and the level of development of aquatic plants that proved most important in the outlet canals. Modified ANOVAs showed that dredging significantly affected the mean species richness and the dominance in the canals. The changes in OCT species composition were highly informative. The comparison between tolerance patterns of the OCT orders

against the five parameters (temperature, EC, total dissolved solids (TDS), pH and current) revealed that caddisflies are the most sensitive group, followed by Coleoptera while Odonata proved the most resistant. Dragonflies have the greatest potential to serve as bioindicators of industrially heated waters. The OCT fauna responded specifically to different environmental factors and stressors, it is strongly recommended to track the responses on different levels, not only metrics, but above all, species." (Authors)] Address: Buczynski, P., Dept of Zool., Maria Curie-Skłodowska Univ., Akademicka 19, 20-033 Lublin, Poland. E-mail: pawbucz@gmail.com

**18911.** Buczynski, P.; Takowski, A. (2019): Wazki (Odonata) rezerwatu przyrody „Jeziro Obradowskie” (Polesie Zachodnie) - Dragonflies (Odonata) of the nature reserve “Lake Obradowskie” (West Polesie). *Parki Narodowe i Rezerwaty Przyrody National Parks and Nature Reserves (Parki nar. Rez. Przyr.)* 38(3-4): 17-30. (in Polish, with English summary) ["The nature reserve “Lake Obradowskie” near Parczew in the Lublin Region (Central-Eastern Poland) lies in a drainage depression and encompasses: a slightly hypertrophic polyhumic lake, high and transitional peat bogs surrounding the lake and the canal connected to the lake. In 2019, 27 dragonfly species were found here. The fauna of the lake was the qualitatively richest (22 spp.). An assemblage found in the lake was typical of a small eutrophic lake, but poorer in species: lacking species preferring transparent water and the elodeid zone, and with a very poor representation of the fauna typical of the nymphaeid zone. This correlated with very poor development of tall vegetation, constant bloom of cyanobacteria and low oxygen content in the water. In the canal 16 spp. occurred; this was a poorer variant of the lake's fauna with the addition of the habitat disturbance indicator, *Libellula depressa*, which resulted from the almost complete drying out of the canal in the summer. 6-11 species were found on three studied open peat bogs, but they were almost exclusively foraging individuals from other habitats, and regular reproductive behaviour was observed only in *Somatochlora flavomaculata*. The studied nature reserve proved to be of little importance for the protection of dragonflies. (1) Its fauna was not too rich in species, the small size of the populations of most species was also unfavourable, which may reduce their stability. (2) Assemblages of dragonflies in individual habitats were of little value, common eurytopes dominated. The only recorded typhophile is *S. flavomaculata*. Stenotopes of other habitats only flew over the study area. (3) Only one of 16 species of dragonflies protected in Poland (*Sympetma padesca*) was found, it was rare and showed no reproductive behaviour. (4) No species endangered in Poland and in the Lublin Province were found. The state of the fauna described above results from the high productivity of the lake and its dominance by algae but not macrophytes. However, this productivity is probably natural: in the geological base of West Polesie, limestone rocks dominate, which makes the pH of the lake waters high and there are good conditions for the development of bacteria that decompose organic matter. An important factor is also the lack of water bodies in the

peat bogs, which means that dragonflies do not develop on them (and probably valuable assemblages would be formed here, dominated by tyrphobionts and tyrphophiles), nor do they colonize lakes from them. Data from the nature reserve "Lake Obradowskie" indicates in particular that such colonization is crucial for the presence in the fertile lake of species associated with peat bogs. The authors suggest the protection of dragonflies in the studied reserve by manually digging small peat excavations in the peat bogs around the lake. This would create valuable habitats for hydrobionts associated with high and transitional peat bog waters without significantly interfering with water relationships. Such activities may soon be a sine qua non condition for the protection of this organisms in the case of rising air temperatures and drying out of peatlands." **18912.** Cerini, F.; Stellati, L.; Luiselli, L.; Vignoli, L. (2019): Long-term shifts in the communities of Odonata: effect of chance or climate change? *North-western Journal of Zoology* 16(1): 1-6. (in English) ["Global climate change has been causing growing concern among conservationists for its strong implications on biodiversity alteration and loss at different levels of organization. Odonata occur in habitats threatened by global warming, thus they represent an ideal model organism to study the correlation patterns of climate change with taxonomic composition and the ecological functioning of communities. We carried out climate and diachronic faunistic analyses of Odonata community changes in three countries (Tunisia, Mauritania, Sweden) to test if the patterns uncovered for single assemblages as a response to local climate change may resist to the generalization across regions and latitudes. Clear climate warming occurred in the analysed regions during the last five decades. We found three main patterns of diachronic shifts in Odonata assemblage species composition based on correlative evidence: i) Generalists are likely advantaged from warming processes that cause the loss of specific habitats (i.e. temporary wetlands, cool lentic waters) and the formation of new or altered habitats suitable for pioneer species (i.e. warm and intermittent pools), whereas specialists are more likely to go toward local extinctions; ii) In Tunisia and Sweden new colonizers expanded northward from their southern distributions; iii) The Odonata communities inhabiting lentic waters are more prone to show species turnover than communities from standing waters. Our results provide new insights on the possible impact of climate change on Odonata fauna from large areas (i.e. countries) at different latitudes and represent an attempt of a generalization of the effects of climate change on Odonata range shifts and expansions. Despite that Odonata global assessment of conservation status has been completed, insufficient information is available to robustly assess all the main threats affecting their status, and extensive new field surveys are required to test if major changes in fauna composition have occurred during the last decades." **18913.** Chakravorty, J.; Jugli, S.; Boria, M.; Meyer-Rochow, V.B. (2019): Arunachal's Adi and Apatani tribes' traditional knowledge of harvesting and using edible insects. *Journal of Insects as Food and Feed* 5(2): 125-135. (in English) ["At least 65 insect species of 30 families and 9 orders, namely Orthoptera (15 species), Odonata (12), Coleoptera (11), Hymenoptera (10), Hemiptera (9), Lepidoptera (5) and one species each of Ephemeroptera, Isoptera and Mantodea find acceptance as food by Adi and Apatani tribals. Adi use overall more species than Apatani: 53 species of 24 families and 8 orders versus 49 species of 21 families and 8 orders. Odonata are highly appreciated by the Apatani whereas Adi consume more Orthopterans. Various harvesting systems exist and often methods like handpicking or using simple tools are involved with minimal environmental impact. However, depreciation of the environment, increased availability of conventional foodstuffs, rapid population growth and rising influence of westernisation collectively affect diversity, abundance and use of edible insects, leading to a decline of entomophagy among the tribal people." **18914.** Chovanec, A. (2019): Bewertung von Oberflächen-gewässern anhand libellenkundlicher Untersuchungen (Odonata) – Methoden für stehende und fließende Gewässer sowie ihre beispielhafte Anwendung an der Mattig (Oberösterreich). *Zeitschrift der Arbeitsgemeinschaft Österreichischer Entomologen* 71: 13-45. (in German, with English summary) ["Assessment of surface waters based on odonatalogical investigations (Odonata) – methods for standing and running waters with an exemplary application at the river Mattig (Upper Austria). – In recent decades, the importance of odonatalogical studies in water management has greatly increased, since Odonata are good indicators of morphological and hydrological conditions of water bodies. The application of this guideline is intended to ensure the standardisation of dragonfly-based studies and thus the comparability of results. The aim of the field survey method described is to obtain as complete a picture as possible of the species spectrum reproducing at a given site by monitoring and recording adult dragonflies. Sightings of teneral, additional recording of exuviae, estimates of the number of individuals as well as observations of reproductive behaviour serve to determine whether or not species are autochthonous to the site. According to the legal requirements of the EU Water Framework Directive and the Austrian Water Law (Wasserrechtsgesetz, WRG), the assessment is based on a comparison of the water-type-specific dragonfly fauna with the status quo. In accordance with WRG, various methodological approaches have been developed for standing and running waters, to which reference is made in this paper. As an example, the restructuring measures at the hyporhithron stretch of the river Mattig (Upper Austria) near its mouth into the river Inn have been evaluated by means of a study on dragonflies carried out in 2019. The longitudinal classification of the Odonata represents the methodological basis for determining the Odonata reference

species and any deviations." (Authors)] Address: Chovanec, A., Bundesministerium für Nachhaltigkeit & Tourismus, Abteilung Nationale & Internationale Wasserwirtschaft, Marxergasse 2, 1030 Wien, Austria. Email: andreas.chovanec@bmnt.gv.at

**18915.** de Omena, P.M.; Srivastava, D.S.; Romero, G.Q. (2019): Consumptive effects and mismatch in predator-prey turnover rates cause inversion of biomass pyramids. *Oecologia* 190(1): 159-168. (in English) ["The mismatch between the turnover rates of predators and prey is one of the oldest explanations for the existence of inverted trophic pyramids. To date, the hypotheses regarding trophic pyramids have all been based on consumptive trophic links between predators and prey, and the relative contribution of non-consumptive effects is still unknown. In this study, we investigated if the inversion of pyramids in bromeliad ecosystems is driven by (i) a rapid colonization of organisms having short cohort interval production (CPI), and (ii) the prevalence of consumptive or non-consumptive effects of top predators. We used a manipulative experiment to investigate the patterns of prey colonization and to partition the net effects of the dominant predator (damselfly larvae) on biomass pyramids into consumptive (uncaged damselfly larvae) and non-consumptive effects (caged damselfly larvae). Consumptive effects of damselflies strengthened the inversion of trophic pyramids. Non-consumptive effects, however, did not affect the shape of biomass pyramids. Instead, the rapid colonization of organisms with predominantly short CPI sustained the large biomass of top predators found in natural bromeliad ecosystems. Prey colonized bromeliads rapidly, but this high production was never visible as standing stock because damselflies reduce prey densities by more than a magnitude through direct consumption. Our study adds to the growing evidence that there are a variety of possible ways that biomass can be trophically structured. Moreover, we suggest that the strength of biomass pyramids inversion may change with the time of ecological succession as prey communities become more equitable." (2019): A simple developmental model recapitulates complex insect wing venation patterns (A winkle in time). *Bulletin of the American Physical Society, APS March Meeting 2019, Monday–Friday, March 4–8, 2019; Boston, Massachusetts, Session A66: Morphogenesis I, 8:00 AM–11:00 AM, Monday, March 4, 2019, BCEC Room: 261:* (in English) [Verbatim: Geometric patterns in nature have long been a matter of fascination and intrigue. Veins bifurcate insect wings into a diverse and complicated menagerie of shapes. For many insect species, even the left and right wings from the same individual have veins with unique topological arrangements, and little is known about how these patterns form. We present a quantitative study of the fingerprint-like "secondary veins." We compile a dataset of wings from 232 species and 17 families from the order Odonata, a group with particularly elaborate vein patterns. We characterize the geometric arrangements of veins and develop a simple model of secondary vein patterning. Last, we show that our model is capable of recapitulating the vein geometries of species from other, distantly related winged insect clades.] Address: not stated

**18918.** Kärcher, O.; Hering, D.; Frank, K.; Markovic, D. (2019): Freshwater species distributions along thermal gradients. *Ecology and evolution* 9(1): 111-124. (in English) ["The distribution of a species along a thermal gradient is commonly approximated by a unimodal response curve, with a characteristic single optimum near the temperature where a species is most likely to be found, and a decreasing probability of occurrence away from the optimum. We aimed at identifying thermal response curves (TRCs) of European freshwater species and evaluating the potential impact of climate warming across species, taxonomic groups, and latitude. We first applied generalized additive models using catchment-scale global data on distribution ranges of 577 freshwater species native to Europe and four different temperature variables (the current annual mean air/water temperature and the maximum air/water temperature of the warmest month) to describe species TRCs. We then classified TRCs into one of eight curve types and identified spatial patterns in thermal responses. Finally, we integrated empirical TRCs and the projected geographic distribution of climate warming to evaluate the effect of rising temperatures

on species' distributions. For the different temperature variables, 390–463 of 577 species (67.6%–80.2%) were characterized by a unimodal TRC. The number of species with a unimodal TRC decreased from central toward northern and southern Europe. Warming tolerance (WT = maximum temperature of occurrence—preferred temperature) was higher at higher latitudes. Preferred temperature of many species is already exceeded. Rising temperatures will affect most Mediterranean species. We demonstrated that freshwater species' occurrence probabilities are most frequently unimodal. The impact of the global climate warming on species distributions is species and latitude dependent. Among the studied taxonomic groups, rising temperatures will be most detrimental to fish. Our findings support the efforts of catchment-based freshwater management and conservation in the face of global warming." **18919.** Khelifa, R. (2019): Female "assist" sneaker males to dupe dominant males in a rare endemic damselfly: Sexual conflict at its finest. *Bulletin of the Ecological Society of America* 100(4): 1-5. (in English) ["Study Description: One common view in sexual selection is that females select the fittest male. By investigating the reproductive behavior of an endemic damselfly, *Colopteryx exul*, in Northeast Algeria. I showed that this is not always the case. To avoid the costly repeated copulations, the female hosting the sneaker's sperm (low-quality male) tends to avoid the dominant male by landing near another female, which confuses the dominant male who ends up copulating with a different female. Hence, the female indirectly assists the sneaker male. This finding advances our view about the mechanisms underlying the maintenance of phenotypic and genetic variability." **18920.** Khelifa, R.; Zebba, R.; Amari, H.; Mellal, M.K.; Mahdjoub, H. (2019): Field estimates of fitness costs of the pace-of-life in an endangered damselfly. *Journal of evolutionary biology* 32(9): 943-954. (in English) ["Theory predicts that within-population differences in the pace-of-life can lead to cohort-splitting and produce marked intraspecific variation in body size. While many studies showed that body size is positively correlated with fitness, many argue that selection for the larger body is counterbalanced by opposing physiological and ecological selective mechanisms that favor smaller body. When a population split into cohorts with different paces-of-life (slow or fast cohort), one would expect to detect the fitness-size relationship among and within cohorts, that is, (1) slower-developing cohort has larger body size and higher fitness than faster-developing cohort, and (2) larger individuals within each cohort show higher fitness than smaller individuals. Here we test these hypotheses in capture-mark-recapture field surveys that assess body size, lifespan,

survival, and lifetime mating success in two consecutive generations of a partially bivoltine aquatic insect, *Coenagrion mercuriale*, where the spring cohort is slower-developing than the autumn cohort. As expected, body size was larger in the slow-developing cohort, which is consistent with the temperature-size rule and also with the duration of development. Body size seasonal variation was greater in slow-developing cohort most likely because of the higher variation in age at maturity. Concordant with theory, survival probability, lifespan, and lifetime mating success were higher in the slow-developing cohort. Moreover, individual body size was positively correlated with survival and mating success in both cohorts. Our study confirms the fitness costs of fast pace-of-life and the benefits of larger body size to adult fitness." (Authors)] Address: Khelifa, R., Biodiversity Res. Center, Univ. (2019): Evaluating the validity of a simple citizen science index for assessing the ecological status of urban drainage ponds. *Ecological Indicators* 98: 1-8. (in English) [oas 59 ; "•Simple citizen science tool as effective as complex assessments of ecological quality. •Assessment correlated with status established through five ecological indicators. •Assessment consistent across the entire range of scores, •Assessment tool consistent for different invertebrate groups involved. Abstract: Citizen science approaches are valuable tools for biodiversity management and conservation, particularly in urban areas. The OPAL Water Survey is a citizen

science approach to assessing water quality by recording the presence/absence of 13 easily identifiable freshwater invertebrate groups. The survey generates a score (the Pond Health Score) that can usefully inform urban freshwater wildlife conservation, as well as engaging urban residents with nature. The main aim of this study was to investigate the capability of the OPAL Pond Health Score to assess the overall ecological status of urban drainage ponds. We applied linear regression between the OPAL Score from 78 drainage ponds across Scotland and a measure of ecological status obtained by the dimension reduction (Principal Coordinate Analysis) of five widely-used ecological indicators: taxonomic richness of amphibians, macroinvertebrates and macrophytes, and adjacent terrestrial habitat richness and degree of urbanization. The OPAL Pond Health Score was strongly correlated with ponds' ecological status established using the five ecological indicators (Pearson's  $r = 0.86$ ,  $P < 0.0001$ ). Furthermore, this relationship was generally consistent, both across the entire range of OPAL Scores, and in relation to the different invertebrate groups involved. Thus, the OPAL Pond Health Score has great value as a quick stand-alone assessment method, and offers clear opportunities for collaboration between citizen scientists, government agencies and professional researchers." (2019): Detoxifying enzyme complements and host use phenotypes in 160 insect species. *Current Opinion in Insect Science* 31: 131-138. (in English) ["Highlights: • 160 insect genomes screened for esterase, GST and cytochrome P450 genes. • Omnivores and herbivores eating chemically complex tissues have many of these genes. • Species using chemically simpler tissues like sap, nectar and blood have relatively few. • Polyphages have more than other species using the same tissue type. Abstract: We use the genomes of 160 insect species to test the hypothesis that the size of detoxifying enzyme families is greater in species using more chemically diverse food resources. Phylogenetically appropriate contrasts in subsamples of the data generally support the hypothesis. We find relatively high numbers of cytochrome P450, glutathione S-transferase and carboxyl/choline esterase genes in omnivores and herbivores feeding on chemically complex tissues and relatively low numbers of these genes in specialists on relatively simple diets, including plant sap, nectar and pollen, and blood. Among Lepidoptera feeding on green plant tissue and Condylognatha feeding on sap we also find more of these genes in highly polyphagous species, many of which are major agricultural pests. These genomic signatures of food resource use are consistent with the hypothesis that some taxa are preadapted for insecticide resistance evolution." **18927.** Rathod, P.P.; Raja, I.A.; Milind, K. (2019): Contrast behavior by female dragonfly, *Orthetrum sabina* while mating with its territorial male. *Bioscience Biotechnology Research Communications* 12(4): 927-933. (in English) ["There is variation in receptiveness of female dragonfly to male waiting in territorial ponds. The present study reported how a female of *Orthetrum sabina* agreed or not for mating with a male in different situations. In usual or first case after grasping female by male, female helped him for flying at perch and to make copulatory wheel the 'tandem'. But in the second case, a non receptive female denied territorial male for making tandem was also noted. It was observed that non receptive female was evasive to make tandem and appeared to be resisting the males grasp by her wing vibration. She got clung to male's abdomen remained inactive for 7 minutes in motionless pose and appeared like dead. Although she injured her wings by vibrating she tried to escape and got freed from the grasp of male without copulation. One failure of copulation added to account of that territorial male was seen. We conclude that in second case the female may be immature and not ready for mating, or the male was not of her choice, may be the eggs deposition by her would have already been accomplished for the day or female may already have carried the sperms so she rejected that territory owner. The significance of this study is to understand different ways for breeding behavior in selected species to save their future." (Authors)] Address: Raja, I.A., B.S. **18928.** Ribeiro, S.M. (2019): Análise de metais potencialmente tóxicos em ambientes aquáticos (Da Água e dos insetos da ordem Odonata) para biomonitoramento ambiental. Ph.D. thesis, Universidade Federal de São Carlos: 83 pp. (in Portuguese, with English summary) [Analysis of potentially toxic metals in aquatic environments (from water and insects of the order Odonata) for environmental biomonitoring: "Analysis of potentially toxic metals in aquatic environments (Water and Odonata insects) for environmental biomonitoring. Potentially toxic metals are among the most common contaminants in waters and their origin may be both natural and anthropogenic. As soon as they come into contact with the aquatic ecosystem, the metals can be transported to the various compartments of the environment, such as soil, sediment, plants and animals, and may become bioaccumulative. With the increase of activities of anthropic origin and the degradation of water resources, biomonitoring becomes an effective way to expose various types of stress that may occur in the environment, serving as an alarm for declines in the quality of the environment and populations. With the determination of the adverse effects of the presence of contaminants in water bodies, it is becoming increasingly important to indicate environmental disturbances from possible contaminating sources such as agriculture. The objective of this study was to determine the levels of  $Zn^{2+}$ ,  $Cd^{2+}$ ,  $Cu^{2+}$ ,  $Co^{2+}$ ,  $Pb^{2+}$ ,  $Cr^{2+}$ ,  $Mn^{2+}$ ,  $Al^{3+}$  in the water and larvae of the order Odonata in dams 1 and 2, related to the conventional and organic planting of a plantation orange. The collected samples were previously digested

and subjected to the analysis of determination of the potentially toxic metals using the atomic emission spectrometry equipment with microwave plasma (MP-AES). The water samples indicated for some metals a concentration above the limit allowed by CONAMA Resolution n° 357/2005, in the following order  $Cu^{2+}$  >  $Pb^{2+}$  >  $Mn^{2+}$  in both dams near conventional and organic cultivation. Cr ions were observed only in dam 1 (close to conventional planting) and Al ions in dam 2 (close to organic planting). In the Odonata larvae, the presence of metals  $Zn^{2+}$  >  $Cu^{2+}$  >  $Pb^{2+}$  >  $Mn^{2+}$  was observed in both dams close to conventional and organic cultivation. All other metals were found in dams and larvae, even in small concentrations. It is concluded that the insects of the order Odonata absorb considerable concentrations of metals in the organism, the metals found in the Odonata resemble the metals found in the water, and it can be reinforced the concept that the Odonata are important indicators to monitor contaminations of metals in agricultural areas." (2019): Results of the second (2016) Goose Pond fish and wildlife biodiversity survey, Green County, Indiana. *Proceedings of the Indiana Academy of Science* 128(1): 13-27. (in English) ["The Friends of Goose Pond, the Indiana Academy of Science, the Indiana Department of Natural Resources – Division of Fish and Wildlife, the Sassafras Audubon Society, and Duke Energy Foundation hosted the second biodiversity survey or bioblitz at Goose Pond Fish and Wildlife Area, Greene County, on 18–19 June 2016. Over 95 scientists, naturalists, students, and other volunteers on 17 different taxonomic teams observed and reported 883 taxa during the event. The 17 taxonomic teams included aquatic macroinvertebrates, bats, bees, beetles, birds, butterflies, fish, freshwater mussels, herpetofauna, small mammals, moths, fungi and slime molds, non-vascular plants, odonates, singing and non-singing insects, spiders, and vascular plants. State listed animal species included ... the state rare jade clubtail (*Arigomphus submedianus*). ... This manuscript presents both a brief history of the bioblitz sites and a summary overview of the results. Detailed results are available on the Indiana Academy of Science website." (Authors) "33 species of Odonates (22 dragonflies and 11 damselflies); 7 Greene County records plus a visual sighting of *Epiaeschnia heros* (swamp darner); 1 rare species in Indiana, *Arigomphus submedianus* (jade clubtail)." "Odonates (dragonflies and damselflies).— Odonates were surveyed using observation primarily with 83 binoculars and/or photography. This approach allowed the benefit of rapid assessment and more distance covered than collection would have afforded. The methods used in the 2016 bioblitz contrast with those of the 2010 Goose Pond bioblitz (Karns et al. 2012) which used insect nets and dip netting for aquatic larval specimens. Due to more distance covered in a short period of time during the 2016 survey, it is possible that

many Odonate species were not detected. Importantly, the 2016 survey might not include species which are primarily larval at the time of the survey, whereas dip netting may have detected some of these. Despite this impediment, the 2016 survey detected one more species of dragonfly and two more species of damselfly than the 2010 bioblitz. It should be noted that differences in the species counts should not be attributed only to survey methods, as many other differences, such as time of year and weather events, can affect Odonate abundance. Eleven species of damselfly (Zygoptera) and twenty-two species of dragonflies (Anisoptera) were observed during the bioblitz. Most of the common Odonates were ubiquitous throughout the Goose Pond habitat areas. While no endangered, threatened, or rare species were observed, eight potential Greene County records were noted, i.e., Swamp Darter (*Epiaeschna heros*), Illinois River Cruiser (*Macromia illinoensis*), Jade Clubtail (*Arigomphus submedianus*), Plains Clubtail (*Gomphus externus*), Common Sanddragon (*Progomphus obscurus*), Blue-faced Meadowhawk (*Sympetrum ambiguum*), Skimming Bluet (*Enallagma geminatum*), and Slender Bluet (*E. triviatum*) (Curry 2001; Abbott 2006–2016; Karns et al. 2012). In summary, GPFWA produced the diversity and abundance of Odonates that should be expected of a large area of such varied aquatic habitats. With only the two sampling events of the 2010 and 2016 bioblitzes, the Goose Pond complex has an odonate list that includes 28 dragonflies and 13 damselflies. This represents 26% of the Indiana's known dragonflies (Curry 2001; Mauffray 2008), and 30% of the state's known damselflies (Williamson 1917). Undoubtedly, additional odonate surveys, especially in August or September, would add to this list." **18930.** Rychla, A.; Buczynski, P.; Czechowski, P.; Dumanski, J.; Kusal, K.; Lewandowska, E.; Lewandowski, K.; Michalczyk, W.; Niewolnik, J.; Orska, M.; Ostrowski, K.; Pielot, M.; Rauner-Bunczynska, E.; Swiata, D.; Swiata, M.; Tanczuk, A.; Tarkowski, A.; Tonczyk, G.; Wakulski, R.; Wasylk6w, E.; Wereniewicz, K.; Wiszniowska, M. (2019): The earliest records of dragonflies and damselflies (Odonata) in Poland in April and May 2018. *Odonatrix* 15\_4: 10 pp. (in Polish, with English summary) ["In the temperate zone, the beginning of emergence of adult dragonflies and damselflies depends largely on the weather conditions, principally air temperature. High temperatures are conducive to the earlier appearance of adults, while low ones can delay it. In spring 2018, Poland was constantly under the influence of hot, dry air masses arriving from the south, mainly from Africa. This resulted in positive air temperature anomalies throughout the country of as much as 3-6 °C in April and 3-5 °C in May, compared to the long-term average (1971-2000). As such warmer weather could have had affected the phenology of many odonates, we undertook to compile a list of the earliest emergence dates of dragonfly and damselfly species, recorded by a group of volunteers (professionals and amateurs) from the

beginning of the season until the end of May 2018. In addition, we compared our results with the hitherto known flight periods of odonates in Poland (Milaczewska 2010) to see whether any shifts in dates of emergence had occurred in response to climatic changes." **18931.** Start, D.; Gilbert, B. (2019): Trait variation across biological scales shapes community structure and ecosystem function. *Ecology* 100(9). e02769: 9 pp. (in English) ["Trait variation underlies our understanding of the patterns and importance of biodiversity, yet we have a poor understanding of how variation at different levels of biological organization structures communities and ecosystems. Here we use a mesocosm experiment to test for the effects of a larval dragonfly functional trait on community and ecosystem dynamics by creating artificial populations to mirror within- and between-population trait variation observed in our study area. Specifically, we manipulate variation in activity rate, a key functional trait shaping food webs, across three levels of biological organization: within-populations (differences in trait variation in a population), among-populations (differences in population mean trait values), and among-species (species-level differences of co-occurring dragonflies). We show that differences in activity rate alter prey communities, trophic cascades, and multiple ecosystem processes. However, trait variation among populations had much larger effects than differences between co-occurring species or even the presence of a predator, whereas within-population variation had a relatively minor impact. Interestingly, combined with earlier work in the same system, our study suggests that the relative importance of species versus individual level differences for ecosystem functioning will depend on the spatial scale considered. Ecological processes, including biodiversity-ecosystem functioning relationships, cannot be understood without accounting for trait variation across biological scales of organization, including at fine scales." **18933.** Takahashi, M.; Takahashi, Y.; Kawata, M. (2019): Candidate genes associated with color morphs of female-limited polymorphisms of the damselfly *Ischnura senegalensis*. *Heredity* 122: 81-92. (in English) ["Many Odonata species exhibit female-limited polymorphisms, where one morph is similar to the conspecific male in body color and other traits (andromorph), whereas one or more other morphs differ from the male (gynomorphs). Here we investigated the differentially expressed transcripts (DETs) among males and two female morph groups (gynomorphs and andromorphs) using RNA-seq to identify candidate transcripts encoding female-limited polymorphisms in the damselfly *Ischnura senegalensis*. Seven DETs that had significantly different expression levels between males and gynomorphs, but not between males and andromorphs, were identified. The expression levels of four of these candidate genes, doublesex (*dsx*), black, ebony, and chaoptin (*chp*), were selected for further analysis using qRT-PCR. Sequence analysis of the *dsx* amplicons revealed that this gene produced at least three transcripts. Two short transcripts were mainly expressed in males and andromorphs, whereas the long transcript was specifically expressed in both morph female groups; that is, the expression pattern of the *dsx* splice variants in andromorphs was an intermediate between that of males and gynomorphs. Because the *dsx* gene functions as a transcription factor that regulates the sex-specific expression of multiple genes, its splice variants in *I. senegalensis* may explain why the andromorph is female but exhibits some masculinized traits. Because we did not detect different coding sequences of the candidate genes among the different morphs, a diallelic genomic region controlling alternative splicing of *dsx*, thus determining female-limited polymorphism in *I. senegalensis* most likely lies in a non-coding region of the *dsx* gene or in a gene upstream of it." **18934.** Therry, L.; Cote, J.; Cucherousset, J.; Finn, F.; Buoro, Y.; Blanchet, S. (2019): Genetic and environmental contributions to the impact of a range-expanding predator on aquatic ecosystems. *Journal of Animal Ecology* 88: 35-46. (in English) ["1. Global change is altering biodiversity locally and globally and subsequently affecting the dynamics of communities and ecosystems. Biodiversity can be impacted both at the interspecific (i.e., species composition of communities) and at the intraspecific (evolutionary modification of phenotypic traits through selection or plasticity) levels. Changes in intraspecific diversity have been demonstrated to generate evolutionary feedbacks acting on ecological dynamics. Quantifying the role of intraspecific trait variation, global change and their interactions on ecological dynamics is of utmost importance. 2. Here, we used the range-expanding dragonfly *Crocothemis erythraea* as a model species to test the relative effects of intraspecific trait variation in larvae and thermal conditions on the dynamics of freshwater community and ecosystem functioning. Using experimental mesocosms, we manipulated intraspecific trait variation arising from genetic (G), early developmental

environment (Ee) and late developmental environment (EL) contributions in a full factorial design. 3. We showed that intraspecific trait variation arising from genetic effects has the strongest consequences on community and ecosystem dynamics relative to trait variation driven by the thermal environment (Ee and EL). Importantly, the ecological effects of trait variation due to genetic effects were partly modulated by thermal conditions (G \* EL, and to a lesser extent G \* Ee interactions) and varied among ecological response variables. For instance, the strongest G \* EL effects were observed on primary productivity and zooplankton dynamics. Trait variation driven by plasticity related to early or late developmental environments has an overall weak effect on ecological dynamics. 4. Intraspecific trait variation induced by genetic effects can affect ecological dynamics (evo-to-eco dynamics) more strongly than variation induced by the developmental environment. However, they likely interact to modulate the structure of communities and the functioning of ecosystems, highlighting the strong context (environmental) dependency of evo-to-eco dynamics." **18935.** Van Dievel, M.; Janssens, L.; Stoks, R. (2019): Additive bioenergetic responses to a pesticide and predation risk in an aquatic insect. *Aquatic Toxicology* 212: 205-213. (in English) ["Highlights: • Effects of predation risk and chlorpyrifos on life history and physiology were tested. • Only chlorpyrifos was lethal, yet both stressors reduced growth. • Both stressors negatively affected the bioenergetics at organismal and cellular level. • Predation risk and chlorpyrifos consistently interacted in an additive way. Abstract: Ignoring natural stressors such as predation risk may contribute to the failure of ecological risk assessment of pesticides to protect freshwater biodiversity. To better understand combined effects of multiple stressors, bioenergetic responses are important as these inform about the balance between energy input and consumption, and provide a unifying mechanism to integrate the impact of multiple stressors with different modes of action. We studied in *Enallagma cyathigerum* damselfly larvae the single and combined effects of exposure to the pesticide chlorpyrifos and predation risk on life history (survival and growth rate) and bioenergetic response variables at the organismal level (assimilation and conversion efficiency) and the cellular level (cellular energy allocation CEA, energy storage  $E_a$ , and energy consumption  $E_c$ ). Chlorpyrifos exposure almost halved the survival of the damselfly larvae, while predation risk had no effect on survival. Both exposure to the pesticide and to predation risk reduced larval growth rates. This was caused by a reduced conversion efficiency under chlorpyrifos exposure, and by a reduced assimilation efficiency under predation risk. Both chlorpyrifos and predation risk reduced the CEA because of a decreased  $E_a$ , and for chlorpyrifos also an increased  $E_c$ . The lower  $E_a$  was driven by reductions in the fat and glycogen contents. Effects of the pesticide and predation risk were consistently additive and for most variables the strongest response was detected when

both stressors were present. The absence of any synergisms may be explained by the high mortality and hypometabolism caused by the pesticide. Our results indicate that CEA can be a sensitive biomarker to evaluate effects of not only contaminants but also natural stressors, such as predation risk, and their combined impact on organisms." **18936.** Verheyen, J. (2019): Evolutionary-ecotoxicological study of the effects of daily temperature fluctuations on pesticide toxicity in damselfly larvae. PhD thesis, Department of Biology, Ecology, Evolution and Biodiversity Conservation, KU Leuven - University: (in English) ["In natural ecosystems animals encounter several environmental stressors that furthermore can interact with pollutants and potentially increase their toxicity. This is considered one of the underlying reasons why current ecological risk assessment is possibly failing to protect natural ecosystems as it may be lacking realism by being based on pesticide toxicity testing under standard laboratory conditions. While it is widely known that an increase in mean temperature increases the toxicity of pollutants, studies largely ignored the effects of daily temperature fluctuations (DTFs) on pesticide toxicity and never tested pollutant toxicity under both global warming stressors (the more realistic scenario in which both the mean temperature and the DTF increase). Furthermore, how DTFs shape pesticide toxicity is mostly unknown, which asks for an integrated approach including life history and physiology. In this thesis, I tested for the single and combined effects of exposure to the pesticide chlorpyrifos (CPF) and warming (+ 4 °C increase in mean temperature and a + 5 °C increase in DTF) in *Ischnura elegans* damselfly larvae by executing a series of common-garden experiments. I studied effects on life history traits, heat tolerance and candidate underlying physiological mechanisms. Thereby, I used damselfly larvae across a latitudinal gradient (European low- and high-latitude populations) to study the role of thermal adaptation in shaping the sensitivity to pesticides under global warming. The mean summer water temperatures and maximum summer DTFs in shallow freshwater ponds located in southern France (low latitude) are 24 °C with 10 °C DTF, and in southern Sweden (high latitude) are 20 °C with 5 °C DTF. This 4 °C difference in mean temperature and 5 °C difference in maximum DTF also matches the predicted increase in both factors by 2100 under the IPCC RCP 8.5 scenario, which allows for applying a space-for-time substitution to test if gradual thermal evolution in high-latitude populations may buffer for the increased pesticide toxicity under global warming (increase in both mean temperature and DTF). I reviewed the strengths and weaknesses of this approach in chapter I. In the second chapter, I studied the effects of global warming in the absence of the pesticide and I found that DTFs only had negative effects on growth rate under the 4 °C warming treatment. While 4 °C warming was beneficial for larvae of both latitudes, this changed in a negative effect in the presence

of high DTF. These negative effects of DTF were stronger in high-latitude larvae and already occurred at low DTF, indicating local thermal adaptation. This also suggests that if high-latitude populations are able to gradually thermally evolve into 'low-latitude' populations, they would no longer suffer a growth reduction in the presence of DTF under 4 °C warming. When studying the effects of DTFs on pesticide toxicity in chapter III, I found the striking result that while the used chlorpyrifos concentration was not affecting the damselfly larvae's life history at a constant temperature of 20 °C, it did strongly decrease survival and growth in the presence of DTFs around 20 °C. These results suggest that in standard pesticide toxicity tests, which are carried out by current risk assessment, this concentration would have been regarded as safe. Thereby, this highlights it is crucial to integrate DTFs in current risk assessment to reach more realistic predictions about pesticide toxicity in natural systems. In the last three chapters, I studied the effects of pesticides under global warming, thereby including the predicted increases in both mean temperature and DTF. The toxicity of chlorpyrifos was magnified by the increase in both mean temperature and DTF, but especially at their combination. Furthermore, I described in chapter V a novel, likely general mechanism that contributes to the higher chlorpyrifos toxicity under global warming by coupling two general principles: the widespread temperature-size rule and the size-pesticide sensitivity pattern. Larvae got smaller under DTFs, and these smaller larvae were more vulnerable to the pesticide, hence the higher chlorpyrifos toxicity under DTFs was partly mediated through DTF-induced reductions in body size. In terms of physiological variables, I found evidence of chlorpyrifos-induced effects being stronger under DTFs in terms of oxidative damage to lipids, which may contribute to the mortality patterns. Further, in my last chapter, I observed that the chlorpyrifos-induced reductions in bioenergetic response variables (energy availability and net energy budget) were stronger when the high mean temperature was combined with the high DTF. Moreover, I also showed that the bioenergetic responses contributed to the higher chlorpyrifos toxicity under global warming as treatment combinations with lower net energy budgets showed higher mortality and lower growth rates. Although I did not always find evidence that possible gradual thermal evolution in high-latitude damselflies would buffer for the increased chlorpyrifos toxicity under global warming, I did find a strong signal in chapter IV. Latitude-specific thermal adaptation to both mean temperature and DTF buffered for the chlorpyrifos-induced reduction in heat tolerance, meaning that possible gradual thermal evolution in high-latitude populations may buffer for the negative effects of chlorpyrifos on heat tolerance under warming, unless the DTF increase is taken into account. My results indicate that it is crucial to not only consider DTFs, but also their interaction with increasing mean temperatures, and to integrate gradual thermal evolution to make more realistic predictions of pesticide toxicity in the current climate and in a warming world." **18939.** Zou, P.Y.; Lai, Y.-H.; Yang, J.-T. (2019): Effects of phase lag on the hovering flight of damselfly and dragonfly. *Phys. Rev. E* 100, 063102 – Published 4 December 2019: (in English) ["In this work we studied the differences in flight

kinematics and aerodynamics that could relate to differences in wing morphologies of a dragonfly and a damselfly. The damselflies and dragonflies normally fly with the fore wing or hind wing in the lead, respectively. The wing of the damselfly is petiolate, which means that the wing root is narrower than that of the dragonfly. The influence of the biological morphology between the damselfly and the dragonfly on their hovering strategies is worthy of clarification. The flight motions of damselflies and dragonflies in hovering were recorded with two high-speed cameras; we analyzed the differences between their hovering motions using computational fluid dynamics. The distinct mechanisms of the hovering flight of damselflies (*Matrona cyanoptera*) and dragonflies (*Neurothemis ramburii*) with different phase lags between fore and hind wings were deduced. The results of a comparison of the differences of wing phases in hovering showed that the rotational effect has an important role in the aerodynamics; the interactions between fore and hind wings greatly affect their vortex structure and flight performance. The wake of a damselfly sheds smoothly because of slender petiolation; a vertical force is generated steadily during the stage of wing translation. Damselflies hover with a longer translational phase and a larger flapping amplitude. In contrast, the root vortex of a dragonfly impedes the shedding of wake vortices in the upstroke, which results in the loss of a vertical force; the dragonfly hence hovers with a large amplitude of wing rotation. These species of Odonata insects developed varied hovering strategies to fit their distinct biological morphologies." **18940.** Alves, A.F. (2020): Revisão sistemática de autotomia em larvas de Odonata: um método de defesa com alto custo na sobrevivência. BSc thesis, Entomologia – Laboratório de Ecologia Comportamental e Interações (LECI), Universidade Federal de Uberlândia: 41 pp. (in Portuguese, with English summary) ["Autotomy is a phenomenon of predetermined biological rupture, where an animal detaches a part of the body, with the function of defending itself. Thus, the autotomy occurs in response to a perceived threat, acting as a proximal defense strategy for the individual. Thus, the autotomy has evolved at different rates, as in the order Odonata. However, there are consequences caused by such a process, such as loss of mobility and additional energy expenditure. With that, this study carried out a systematic review of studies related to autotomy of caudal lamellae in nymphs of the order Odonata, in order to discuss what knowledge they have of this process, within the taxonomic group (Odonata) and understand what are the possible costs of this defensive process. This review will show that the autotomy of the caudal appendages is beneficial for the individual, as it allows survival, even with the high costs it represents." (Author)] Address: not stated

**18941.** Araujo, B.R. (2020): Taxonomia e diversidade das

libélulas (Insecta: Odonata) do Mananciais da Serra, Município de Piraquara, Estado do Paraná, Brasil. Dissertação (mestrado) - Universidade Federal do Paraná, Setor de Ciências Biológicas, Programa de Pós-Graduação em Ciências Biológicas (Entomologia): 70 pp. (in Portuguese, with English summary) ["Human activities alter the structure, dynamics and energy flow of aquatic environments. For example, damming rivers increases solar incidence, water permanence and temperature, interfering with dragonfly communities (order Odonata). The sensitivity of Odonata species to disturbances makes them model organisms of bioindicator of environmental quality, however, knowledge of dragonfly fauna in Brazil is concentrated close to institutions with specialists and most of the territory is undersampled. The objectives of this research were: (1) to present a comprehensive checklist of Odonata species for the protected area of Mananciais da Serra, (2) to provide taxonomic notes for rare or littleknown species and finally (3) to investigate the influence of the dam on the structure and composition of the Odonata community in a subtropical area. The research was conducted in the threatened Atlantic Forest domain, in the Serra do Mar mountain chain in a well-preserved area in the municipality of Piraquara, state of Paraná, Brazil. The sampling effort took place between 2017 and 2019, using different collection methods in different mesohabitats in which dragonflies occurs from bromeliads and small streams to large reservoirs. Two communities were considered, one from a forested area (local community, MS) and another from a reservoir (homogeneous landscape community, RP). The alpha and beta-diversity of MS and RP were investigated to infer about the homogenization of the landscape. In addition, two bioindicator tools for habitat quality were applied to our data. The amount of 1,627 specimens from 9 families, 42 genera and 83 species were sampled. A total of 53 new occurrence records were detected for Paraná, bringing to 113 the number of dragonfly species reported to the state, while *Micrathyria venezuelae* De Marmels, 1989 is registered for the first time in Brazil. The female from the original description of *Neocordulia mambucabensis* Costa & T.C. Santos 2000 is another species of *Neocordulia*. In addition, two females, four species not described and larvae of the last stage of development of four species were detected. Larvae sampling increased the abundance of rare species and females. Alpha diversity showed the RP community as the most diverse, a result related to the high occurrence of generalist species. The composition of species and typical species configure greater heterogeneity for MS. The high turnover characterizes a Clementsian pattern for the metacommunity, probably due to the conversion and homogenization of the aquatic system, therefore the reservoir has almost no capacity to maintain the local fauna. Finally, the habitat quality bioindication tools were efficient, considering MS as more preserved than RP, however, the Zygoptera / Anisoptera ratio was less accurate than the Libellulidae / other Anisoptera and Coenagrionidae / Zygoptera ratios, respectively. The estimated richness for Mananciais da Serra is over one hundred, corresponding to at least 60% of the species known for Paraná and 10% of Brazilian species, the country richest in species in the world.

The reservoir excludes local species, giving rise to a high diversity of more generalist species; however, its surrounding areas are preserved maintaining part of the natural habitat and local biodiversity, a positive aspect that mitigates the homogenization of the landscape." (Author)] Address: Araujo, B.R., Lab. de Sistemática de Insetos Aquáticos, Depto Zool., Univ. Federal do Paraná, Caixa Postal 19020, 81531-980 Curitiba, PR, Brazil. E-mail: breno.rda94@gmail.com

**18943.** Baaloudj, A. (2020): Aspects of life history of the Afrotropical endangered *Acisoma inflatum* (Selys, 1889) (Odonata: Libellulidae) in Northeast Algeria. *Annales de la Société entomologique de France* (N.S.) 56(2): 180-188. (in English, with French summary) ["*A. inflatum* is a threatened dragonfly in the Mediterranean, where only a few relict populations remain. It is listed as endangered in North Africa, where no data on its biology, behaviour or ecology are available. These latter are important to understand how this species is adapted to local environmental conditions and for establishing effective conservation plans. In this study, the life history of *A. inflatum* is investigated in a north-east Algerian population. By combining field and laboratory investigations on embryonic development and regular collection of exuviae during the emergence season, it is revealed that the species has direct and synchronous embryonic development, with 75% of all eggs hatching after 10 days of oviposition, and a hatching period ranging from 9 to 15 days. Emergences were asynchronous with half of the larval population (EM50) emerging within the first 25 days of a 64-day emergence season, which matches a typical 'summer species' emergence pattern. Sex ratio at emergence was not significantly different from unity. Body size of exuviae did not show a significant pattern across the season. Exuviae males and females did not differ in their vertical stratification. Height of exuviae fixation during emergence was not random, but was rather positively correlated with support height where the relationship was logarithmic. Apparent lifespan of adults was not significantly different between sexes with a mean of  $4.6 \pm 2.9$  days ( $\pm$  SD). Males and females reached their sexual maturity after two days of emergence. The information provided in this study has not been reported before and thus will be helpful in future conservation efforts." (Author)] Address: Baaloudj, Affef, Lab. **18944.** Balázs, A.; Fric, Z.F.; Holuša, O. (2020): Flying activity and population dynamics of *Cordulegaster heros* Theischinger, 1979 (Insecta: Odonata: Cordulegasteridae) in Slovakia. *International Journal of Odonatology* 23(3): 1-9. (in English) ["In 2017, we investigated the population dynamics

and flying activity of the south-east European endemic *C. heros*. This research was conducted in the southern part of Central Slovakia in the Revúcka vrchovina Upland at a sub-mountainous stream called Drienok. The mark-release-recapture method was applied to study the population. *C. heros* was observed 775 times during the midsummer season. We found out that the species has bimodal diurnal activity pattern with a highest peak from 17:00 until 19:00 hours, but the species had a short peak before noon as well. The differences between sexes in the sense of entering new individuals to the population were low during the main flying period. Estimated population size for males surpassed the population size of females. Probability of capture decreased by the end of the flying season without differences in sexes. This article is the first on the flying activity and population dynamics of *C. heros*." **18946.** Bandara, C.D.; Ballerín, G.; Leppänen, M.; Tesfamichael, T.; Ostrikov, K.; Whitchurch, C.B. (2020): Resolving bio-nano interactions of *E. coli* bacteria-dragonfly wing interface with Helium ion and 3D-structured illumination microscopy to understand bacterial death on nanotopography. *ACS Biomaterials Science & Engineering* 6(7): 3925-3932. (in English) ["Obtaining a comprehensive understanding of the bactericidal mechanisms of natural nanotextured surfaces is crucial for the development of fabricated nanotextured surfaces with efficient bactericidal activity. However, the scale, nature, and speed of bacteria-nanotextured surface interactions make the characterization of the interaction a challenging task. There are currently several different opinions regarding the possible mechanisms by which bacterial membrane damage occurs upon interacting with nanotextured surfaces. Advanced imaging methods could clarify this by enabling visualization of the interaction. Charged particle microscopes can achieve the required nanoscale resolution but are limited to dry samples. In contrast, light-based methods enable the characterization of living (hydrated) samples but are limited by the resolution achievable. Here we utilized both helium ion microscopy

(HIM) and 3D structured illumination microscopy (3D-SIM) techniques to understand the interaction of Gram-negative bacterial membranes with nanopillars such as those found on dragonfly wings. Helium ion microscopy enables cutting and imaging at nanoscale resolution while 3D-SIM is a super-resolution optical microscopy technique that allows visualization of live, unfixed bacteria at ~100 nm resolution. Upon bacteria-nanopillar interaction, the energy stored due to the bending of natural nanopillars was estimated and compared with fabricated vertically aligned carbon nanotubes. With the same deflection, shorter dragonfly wing nanopillars store slightly higher energy compared to carbon nanotubes. This indicates that fabricated surfaces may achieve similar bactericidal efficiency as dragonfly wings. This study reports in situ characterization of bacteria-nanopillar interactions in real-time close to its natural state. These microscopic approaches will help further understanding of bacterial membrane interactions with nanotextured surfaces and the bactericidal mechanisms of nanotopographies so that more efficient bactericidal nanotextured surfaces can be designed, fabricated, and their bacteria-nanotopography interactions can be assessed in situ." **18947.** Bastos, R.C. (2020): Respostas ecológicas de espécies de Odonata (Insecta) a um gradiente de múltiplos usos do solo na Amazônia Oriental. Universidade Federal do Pará – UFPA Instituto de Ciências biológicas Embrapa Amazônia Oriental Programa de Pós-Graduação em Ecologia, Belém: 11 + 33 pp. (in Portuguese, with English summary) ["Ecological responses of Odonata species (Insecta) to multiples land uses gradient in the Oriental Amazon: Several factors can influence, jointly or separately, the communities structuration through space and time, such as niche, dispersal ability and evolutionary history of species. For this reason, environmental, morphological and phylogenetic factors are constantly focused in studies about community ecology. In this sense, the goal of this study is to evaluate the response pattern of Odonata adult species to an environmental change gradient in the Amazon, to identify species subgroups that respond to the environmental filter in a similar way. The study hypothesis is that the species subgroups would have similar responses to the environmental gradient will be structured phylogenetically and They will be morphologically similar among themselves than to the other species. The adult Odonata were collected in 98 amazon streams, where 48 streams in the Santarém and Belterra region and 50 in the Paragominas municipality, both in the state of Pará, Brazil. It was used distribution modeling methods jointly with statistical methods to identify the species subgroups that have similar responses, in other words it is the latent classes. Subsequently, it was analyzed the relationship between the structuring patterns of these latent classes and the communities' morphological and phylogenetic factors. Overall 3,588 adult Odonata individuals were sampled, representing 131 species distributed in 49 genera. Of the species sampled, 34 were classified as well-modeled

and formed four latent classes, for each of the regions. The findings show that phylogenetic and morphological factors may influence the latent classes structuring of Odonata species. However, the patterns were not the same for all classes and regions. Furthermore, it is likely that the classes structuring may be related to more complex and/or dynamic processes, not considered in this study, such as intra and/or interspecific relationships, adaptation ability or even differences in the land use historic between the regions studied. Therefore, these results show the importance of more detailed studies in the Amazon using that approach. Thus, it can help to understand better the distribution/response patterns of Odonata species in the face of environmental changes across landscapes in a scenario of multiple land uses." **18948.** Beckstead, R.; Beckstead, R.B.; Anderson, K.; McDougald, L.R. (2020): Oviduct fluke (*Prostogonimus macrorchis*) found inside a chicken egg in North Carolina. *Avian Diseases* 64(3): 352-353. (in English) ["A video received by faculty at NC State University Department of Poultry Science revealed a live parasite inside a chicken egg. The parasite was identified as an oviduct fluke (*Prostogonimus macrorchis*), a trematode with a three host life cycle: the primary host, a galliform bird, then an aquatic snail, and finally a dragonfly larva or adult consumed by the infected bird. The egg was from a „backyard flock“ with access to a watercourse. No other instances of this parasite were seen in eggs from the flock. The presence of this parasite inside an egg suggests that the worms had migrated above the shell gland in the oviduct, to be incorporated inside the egg. Currently, the occurrence of an oviduct fluke inside an egg in the US is rare. Such parasites are not found in eggs from caged layers, as those birds do not have access to watercourses. This case reinforces the view that parasites requiring intermediate hosts may become more common in birds reared under „free range“ conditions." **18949.** Bender Kotzian, C.; Marques Pires, M.; Ubiratan Hepp, L. (2020): Effects of spatial distances on the assemblage dissimilarity of macroinvertebrates with different dispersal pathways and abilities in southern Brazilian streams. *Ecological Research* 35(5): 826-837. (in English) ["The magnitude of distance–decay relationships (DDRs) in stream macroinvertebrates can vary with their preferential dispersal pathways (overland and watercourse) and abilities as well as with environmental dissimilarity. We assessed DDRs in the compositional dissimilarity of macroinvertebrate assemblages in southern Brazilian streams using overland and watercourse distances (WD) as explanatory variables. We conducted additional separate assessments for taxonomic groups and according to a classification that took into account differences in the dispersal abilities and main pathways among macroinvertebrates. Assessments were conducted separately for (a) strong-flying insects with overland

dispersal (Anisoptera), (b) weak-flying insects dispersing preferably through riparian corridors (Chironomidae, Ephemeroptera, Plecoptera, Trichoptera and Zygoptera), and (c) watercourse dispersers (Mollusca, Psephenidae and Elmidae). The environmental dissimilarity associated with spatial extent was accounted for via partial Mantel tests. Overland and WD were positively correlated with the dissimilarity of the total macroinvertebrate assemblage, weak-flying insects, watercourse dispersers, and most taxonomic groups. DDRs were stronger with overland than WD. However, no consistent pattern emerged after accounting for environmental dissimilarity. Strong- and weak-flying insects were correlated with environment, while watercourse dispersers, with geographic distances. Additionally, taxonomic groups were differently related with environment and geographic distances. The distinct responses of each taxonomic group to the environmental specificities of the study area such as substrate composition and land use likely explain the observed results. Thus, our findings indicate that combining taxonomic and natural history information is an effective approach for comprehending the underlying mechanisms generating spatial structure in stream macroinvertebrate assemblages." **18950.** Beukema, J.J. (2020): Is it wise to terminate counting along transects where Odonata can no longer be found? *Brachytron* 21: 3-11. (in Dutch, with English summary) ["Regular counts of the numbers of Odonata during 14 years (2007-2020) along several transects in the dune area Grafelijkheidsduinen near the town of Den Helder (northwest Netherlands) yielded significantly positive correlations between total numbers and numbers in several species as observed at different groups of transects, and with water levels. Significantly negative correlations were found with year numbers. At two transects (along the same lake), numbers declined to (close to) 0 in the course of the years and termination of counting along these transects was considered (but dismissed). From the above correlations, it is concluded that (1) monitoring of part of a large area would generally be sufficient to follow the fluctuations in population sizes in the entire area; (2) water level (resulting from the difference between rain fall and evaporation) is of decisive influence for the numbers of Odonata present; (3) total numbers and numbers in about half of the species showed a significantly declining long-term trend. Long-term local trends deduced from monitoring might be biased by decisions to terminate counting at transects when numbers there decline to very low levels. In the calculations of the national trend this is being corrected for." (Authors)] Address: Beukema, J.J. Email: jan.beukema@outlook.com

**18951.** Billqvist, M. (2020): Nya provinsfynd av trollsländor (Odonata) i Sverige 2018–2020. *Entomologisk Tidskrift* 141 (4): 173-189. (in Swedish, with English summary) ["During the last three years we have seen a further increase in submitted Odonata observations to the Species Observation

System (Artportalen). More than 15 000 observations have been submitted annually 2018–2020. This after the interest for and the knowledge of dragonflies in Sweden already had increased dramatically for more than a decade. The paper presents the 47 new provincial records of 23 species made in 2018-2020. Included is the first ever *Crocothemis erythraea* (Brullé, 1832) in Sweden, which increases the amount of species registered in Sweden to 65. With the sole exception of Lycksele lappmark, new provincial records of dragonflies have been made in every province since 2009. There are still gaps in our knowledge regarding the range of several species. In the northernmost provinces we yet lack observations of even some of the more common species. Since the interest still is on a rise and many dragonflies show a northern expansion shift, we should in the years to come continue to get more new provincial records." **18952.** Bobrek, R. (2020): High biodiversity in a city centre: Odonatofauna in an abandoned limestone quarry. *European Journal of Environmental Sciences* 10(2): 107-114. (in English) ["Limestone quarries are known to be places where the diversity of xerothermophilic organisms is promoting diversity and in some, there are water bodies that potentially support the presence of hydrobionts. These include dragonflies (Insecta: Odonata), which, as amphibiotic insects, use both aquatic and terrestrial habitats. The purpose of this paper was to determine whether there was a high diversity of odonatofauna in an old limestone quarry with well-developed aquatic habitats, located in an urban environment in the Central-European city of Kraków (S Poland). For this purpose, dragonflies in the quarry were monitored regularly, focusing on the reproductive status and relative abundance of each species. In 2017–2018, 37 species belonging to seven families of Odonata were recorded in the quarry, which is 50% of the Poland's odonatofauna. Of these, 33 species were considered indigenous to the quarry. Among them, 30% were moderately urbanophobic or urbanophobic taxa. Habitat specialists made up 39% of the species. Some rare and declining species, i.e. *Leucorhinia pectoralis* and *L. rubicunda*, were abundant at this site. The study shows that a well-preserved secondary habitat, located in the centre of a city and not subject to urban management, can support a high diversity of odonates. Such limestone quarries in highly transformed urban environments can be valuable sites for this indicator group of organisms and should be identified, evaluated and conserved." **18954.** Borisov, S.N.; Iakovlev, I.K.; Borisov, A.S.; Ganin, M.Yu.; Tiunov, A.V. (2020): Seasonal migrations of *Pantala flavescens* (Odonata: Libellulidae) in Middle Asia and understanding of the migration model in the Afro-Asian region using Stable Isotopes of hydrogen. *Insects* 2020, 11, 890; doi:10.3390/insects11120890: 12 pp. ["Simple Summary: Large-distance migrations of insects have been recognized for many years, but many details of this behaviour remain unknown. The globe skimmer dragonfly has the most extensive cosmopolitan range among all dragonfly species. Migrations of these dragonflies are noted on all continents (except Antarctica), over both land and the oceans, but the patterns of their seasonal movements are still poorly understood. We aimed to confirm seasonal latitudinal migrations of the globe skimmer in Middle Asia and to clarify its migration pattern in extended areas. We used stable isotope composition of hydrogen in wings of dragonflies as an intrinsic marker of their places of origin. Combining phenological data and a comparison with published isotopic data on migratory insects, our results suggest that in spring, the already-mature dragonflies arrive in Middle Asia for reproduction from tropical parts of East Africa and/or the Arabian Peninsula, and, in autumn, summer-generation dragonflies migrate to the south. We conclude that in the Afro-Asian region there is an extensive migration circle of the globe skimmer covering East Africa, Central Asia and the Indian subcontinent with a total length of more than 14,000 km." Abstract: In Middle Asia, the dragonfly *Pantala flavescens* makes regular seasonal migrations. In spring, sexually mature dragonflies (immigrants) arrive in this region for reproduction. Dragonflies of the aboriginal generation (residents) develop in about two months, and migrate south in autumn. Residents of Middle Asia have significantly lower  $\delta\text{-H}$  values ( $-123.5$  (SD 17.2)‰,  $n = 53$ ) than immigrants ( $-64.4$  (9.7)‰,  $n = 12$ ), as well as aboriginal dragonfly species from Ethiopia ( $-47.9$  (10.8)‰,  $n = 4$ ) and the Sahel zone ( $-50.1$

(15.5)‰, n = 11). Phenological data on *P. flavescens* in the Afro-Asian region and a comparison with published isotopic data on migratory insects from this region suggest that (i) the probable area of origin of *P. flavescens* immigrants is located in tropical parts of East Africa and/or the Arabian Peninsula and (ii) the autumn migration of Middle Asian residents to the south may also pass through the Indian Ocean. We assume that in the Afro-Asian region, there is an extensive migration circle of *P. flavescens* covering East Africa, Central Asia and the Indian subcontinent with a total length of more than 14,000 km." **18955.** Borisov, S.N.; Iakovlev, I.K.; Borisov, A.S.; Zuev, A.G.; Tiunov, A.V. (2020): Isotope evidence for latitudinal migrations of the dragonfly *Sympetrum fonscolombii* (Odonata: Libellulidae) in Middle Asia. *Ecological Entomology* 45(6): 1445-1456. (in English) ["1. *Sympetrum fonscolombii* dragonflies are believed to migrate seasonally. In the spring and early summer, the already-mature dragonflies arrive in Middle Asia for reproduction. In the late summer and autumn, summer-generation dragonflies migrate to the south. Their wintering places remain unknown. 2. Stable hydrogen ( $\delta^2\text{H}$ ) and oxygen ( $\delta^{18}\text{O}$ ) isotope analyses were conducted to confirm the migration of *S. fonscolombii* and determine the wintering area. Stable isotope composition of carbon ( $\delta^{13}\text{C}$ ) and nitrogen ( $\delta^{15}\text{N}$ ) in wings and legs was used to clarify the habitats in which dragonfly development took place. 3. Three cohorts of dragonflies collected in different regions of Middle Asia were used for analysis: (i) immigrants that arrived in the spring, (ii) residents that developed in Middle Asia, and (iii) transit dragonflies migrating to the south during autumn. 4. The average  $\delta^2\text{H}$  values in the wings were significantly higher in immigrants (-96‰) than in residents (-134‰) and transit individuals (-124‰). High  $\delta^{18}\text{O}$  and  $\delta\text{-N}$  values in the tissue of immigrants confirmed their southerly origin. 5. Based on the species range and the global distribution of annual averages of  $\delta^2\text{H}$  and  $\delta^{18}\text{O}$  values in precipitation, the latitudinal migrations of *S. fonscolombii* were inferred to cover the area from the proposed natal regions of immigrants in South-West Asia (below  $\sim 36^\circ\text{N}$ ) to Southern Ural and the south of Western Siberia in the north ( $54\text{--}55^\circ\text{N}$ ) with a maximum migration distance of more than 4000 km." **18958.** Boudot, J.-P.; Monnerat, C.; Juillerat, L.; Feulner, G.R.; Kunz, B.; Corso, A.; Vigano, M.; Brochard, C. (2020): Range, distribution, field identification, behaviour and exuvia description of *Orthetrum ransonnetii* (Odonata: Libellulidae). *Odonatologica* 49(3/4): 199-244. (in English) ["Based on numerous records of *Orthetrum ransonnetii* from south-eastern Arabia, the Middle East, the Maghreb and the Canary Islands in recent decades, the range of this species is characterised in relation to climate and habitat parameters. The species is mostly found in hot, arid, rocky environments. Its flight period extends year-round, with an apparent bivoltine cycle at lower elevations and in the southernmost part of its range. The range of its known distribution in certain areas, particularly in the mountains of central and western Morocco, is extended. There it was met with, sometimes as permanent reproductive populations, on the northern slopes of the Moroccan High Atlas, a montane area with a heavy winter snow cover, distinct from most of its previously known Saharo-Arabian-Iranian habitats. The absence of earlier records in some regions may be attributable to both difficulties in identification and confusion with the more common and widespread *O. chrysostigma* and *O. brunneum* and also with *O. brevistylum* and *O. taeniolum*, with which *O. ransonnetii* is sympatric in Central Sahara and part of Southwest Asia, respectively. Field identification criteria and the unique behaviour of the species are described. The combination of black antenodal subcostal cross-veins in dorsal view and fully hyaline hind wings is sufficient to differentiate *O. ransonnetii* from all other *Orthetrum* in the Palearctic area. The species can be distinguished in the field from sympatric congeners, particularly *O. chrysostigma*, if good views or photographs are available, on the basis of several readily observable visual characteristics. The identification of the exuviae is difficult but *O. ransonnetii* is unique

among its known West Palaearctic congeners in having more than 10 setae (instead of 3 to 8) at the base of the movable hook on each labial palp of the prementum." (Authors)] Address: Boudot, J.-P., Immeuble Orphée, Apt 703, F-54710 Ludres, France. E-mail: jean.pierre.boudot@numerical.fr

**18959.** Brasil, L.S.; Vieira, T.B.; Andrade, A.F.A.; Bastos, R.C.; Montag, L.F.; Juen, L. (2020): The importance of common and the irrelevance of rare species for partition the variation of community matrix: implications for sampling and conservation. *Scientific Reports* volume 10, Article number: 19777 (2020): 8 pp. (in English) ["In community ecology, it is important to understand the distribution of communities along environmental and spatial gradients. However, it is common for the residuals of models investigating those relationships to be very high (>50%). It is believed that species' intrinsic characteristics such as rarity can contribute to large residuals. The objective of this study is to test the relationship among communities and environmental and spatial predictors by evaluating the relative contribution of common and rare species to the explanatory power of models. Our hypothesis is that the residual of partition the variation of community matrix (varpart) models will decrease as rare species get removed. We used several environmental variables and spatial filters as varpart model predictors of fish and Zygoptera communities in 109 and 141 Amazonian streams, respectively. We built a repetition structure, in which we gradually removed common and rare species independently. After the repetitions and removal of species, our hypothesis was not corroborated. In all scenarios, removing up to 50% of rare species did not reduce model residuals. Common species are important and rare species are irrelevant for understanding the relationships among communities and environmental and spatial gradients using varpart. Therefore, our findings suggest that studies using varpart with single sampling events that do not detect rare species can efficiently assess general distributional patterns of communities along environmental and spatial gradients. However, when the objectives concern conservation of biodiversity and functional diversity, rare species must be carefully assessed by other complementary methods, since they are not well represented in varpart models." **18961.** Cerini, F.; Stellati, L.; Vignoli, L. (2020): Segregation structure in Odonata assemblages follows the latitudinal gradient. *Oecologia* 194: 15-25. (in English) ["Latitude is known to deeply affect life with effects generalizable into ecological rules; the increasing species diversity toward tropics is the most paradigmatic. Several hypotheses tested patterns of biotic interactions' intensity along latitude. Negative interactions (i.e. competition and predation) are expected to be among the processes that produce checkerboard distribution of species. However, no relationship between checkerboardness and latitude has been uncovered. We tested Odonata assemblages worldwide for segregation patterns using a faunistic dataset (395 species arranged in 386 natural communities) spanning a wide latitudinal range (87°). We used co-occurrence analyses (C-score index and Standardized Effect Size) as an estimate of checkerboardness then correlated the occurrence of segregation to latitude. Odonata followed the Latitudinal Diversity Gradient at the regional scale (i.e. country scale) within our analyzed assemblages spanning, whereas local richness (i.e. community scale) did not follow the same pattern. Odonata assemblages structured with segregation are more common going from high to low latitudes, and local species richness have no effect on the pattern. We summarized hypotheses on how biotic interactions or ecological and historical processes can influence the spatial patterns in the checkerboards of assemblages and presented promising ways to help to gain a better mechanistic understanding of the drivers of the Latitudinal Diversity Gradient." **18962.** Chazanah, N.; Muntalif, B.S.; Rahmayani, R.A.; Sudjono, P. (2020): Macrozoobentos distribution as a bioindicator of water quality in the upstream of the Citarum River. *Journal of Ecological Engineering* 21(3): 10-17. (in English) ["This study aims to prove the type and abundance of macrozoobenthos are affected by the physico-chemical condition of the habitat so that it can be used as a bioindicator in assessing river water quality with a case study in

the Upstream of Citarum River. The method used in this study consists of two stages, namely determining the status of river quality with pollution index and determining the components to see the relationship of the water quality parameters to the abundance of macrozoobenthos with principal component analysis. On the basis of these studies, the results were that at the location of the study status of the river quality is slightly polluted and mildly polluted. For the slightly polluted status *Corbicula* sp. was used as the dominant macrozoobenthos parameter with the parameters of dissolved oxygen, organic carbon and N-O in the clay-dominated sediments. In turn, for the river areas with mild pollution, *Enallagma* sp. [sic], *Tubifex* sp., and *Chironomus* sp. were used as bioindicators and they have a relationship with the parameters of nitrate, TSS, and P-total." **18965.** Chitsaz, N.; Marian, R.; Chahl, J. (2020): Experimental method for 3D reconstruction of Odonata wings (methodology and dataset). *PLoS ONE* 15(4): e0232193: 18 pp. (in English) ["Insect wings are highly evolved structures with aerodynamic and structural properties that are not fully understood or systematically modeled. Most species in the insect order Odonata have permanently deployed high aspect ratio wings. Odonata have been documented to exhibit extraordinary flight performance and a

wide range of interesting flight behaviors that rely on agility and efficiency. The characteristic three-dimensional corrugated structures of these wings have been observed and modeled for a small number of species, with studies showing that corrugations can provide significant aerodynamic and structural advantages. Comprehensive museum collections are the most practical source of Odonata wing, despite the risk of adverse effects caused by dehydration and preservation of specimens. Museum specimens are not to be handled or damaged and are best left undisturbed in their display enclosures. We have undertaken a systematic process of scanning, modeling, and postprocessing the wings of over 80 Odonata species using a novel and accurate method and apparatus we developed for this purpose. The method allows the samples to stay inside their glass cases if necessary and is non-destructive. The measurements taken have been validated against micro-computed tomography scanning and against similar-sized objects with measured dimensions. The resulting publicly available dataset will allow aeronautical analysis of Odonata aerodynamics and structures, the study of the evolution of functional structures, and research into insect ecology. The technique is useable for other orders of insects and other fragile samples." **18971.** Cuellar-Cardozo, J.A.; Fonseca-Santanilla, E.B. (2020): Concentración letal (CL50 y CL95) de nitrógeno reactivo en larvas de *Hetaerina caja*. *Revista de toxicología* 37: 101-105. (in Spanish, with English summary) ["Lethal concentration (CL50 and CL95) of reactive nitrogen in larvae *H. caja*. In aquatic ecosystems, the nitrogen is a limiting element inside the environment where minimal variations in its concentration could cause strong alterations in the biodiversity. However, wastes from agricultural processes where is used agrochemicals and fertilizers rich in nitrogen, represent a huge increase in the amount of nitrogen into the water bodies causing alterations in the environment, especially the aquatic food web. In recent years, new researches have promoted the use of Odonata, focused on their aquatic larval growth, as bioindicators of environmental damage, especially in the Neotropical region. The larvae of *H. caja* are strongly associated with aquatic environmental characteristics, as well as being a taxon that has been well studied letting a better discussion on issues such as development and ecological importance. Therefore, our research aims to quantify the lethal concentrations of total nitrogen over *Hetaerina* individuals, facilitating the knowledge of the damages caused by the nitrogen additions. As result, nitrogen CL50 for *H. caja* specimens is 21.8 ppm and CL95 is 28,070.42 ppm until 72 hours after the exposition. Also, this research represents a first step in Colombia to develop the Odonata as an ecotoxicology tool and how this insect group responds to environmental changes." (Authors)] Address:

**18972.** Damm, A.; Bode-Oke, A.T.; Dong, H. (2020): Aerodynamics and wing-wing interaction during the pre-ovipository flight of the damselfly. American Institute of Aeronautics and Astronautics 2020-1780. Published Online: 5 Jan 2020. <https://doi.org/10.2514/6.2020-1780>: (in English) ["Damselflies have four wings that are controlled independently during flight. The fore and hindwings typically beat out of phase, and the interactions which enhance or attenuate flight forces of the wing pairs are phase-dependent. During oviposition, however, there exists a species (*Neurobasis chinensis*) that flies by beating only the forewings while the hindwings are kept outstretched and stationary. Using computational fluid dynamics simulations based on high-speed photography, we examined the aerodynamics of this unique flight behavior. We hypothesized that the hindwings passively benefit from the wake of the forewings without moving. Our findings elucidate the interactions between a flapping and stationary wing and add to our understanding of insect flight, which serves as an inspiration for micro-aerial vehicle design.] Address: Bode-Oke, A.T., Mechanical & Aerospace Engineering, Univ. of Virginia, Charlottesville, VA 22903, USA

**18973.** Deacon, C.; Samways, M.J.; Pryke, P.S. (2020): Determining drivers of dragonfly diversity patterns and the implications for conservation in South Africa. *Biological Conservation* 245 (2020) 108548: 10pp. (in English) ["Highlights: • Climate gradients drive the rich South African dragonfly fauna. • Assemblage composition varies substantially across the region. • Assemblage-turnover boundaries are gradual at the regional scale. • Turnover boundaries are determined by topography and spatial climatic variation. • The conservation network of South Africa represents dragonflies well. Abstract: Knowing where species occur is essential for conservation planning. In South Africa, regional climatic variation is subject to effects of oceanic current systems, which in turn, determine species diversity patterns. We hypothesize that regional climates and topography are important drivers of aquatic insect species richness, endemism, and assemblage composition, and expect strong assemblage-turnover boundaries to be concurrent with topographical features. We also expected that current conservation networks do not represent aquatic insect species richness and endemism. We used generalized linear mixed models and generalized dissimilarity models to determine drivers of South African Odonata species richness and assemblage-turnover, as well as to investigate the extent of assemblage-turnover boundaries. We found that climate gradients were significant drivers, and found significant variation in assemblages between sub-regions. Turnover boundaries were gradual but concurrent with topographical features and/or areas with spatial changes in sub-regional climate. Modern-day climate and topography partially explained dragonfly diversity patterns, but other local factors and past geological events likely both contribute to current dragonfly diversity

patterns. The existing conservation network in South Africa represents areas of high dragonfly species richness and endemism. We recommend additional conservation efforts in areas outside of protected areas with high species richness and endemism levels, but importantly also in areas with high assemblage-turnover rates to ensure protection of as many species as possible. We also propose further searches in areas with high endemism and high assemblage-turnover for possible discovery of unknown species, and further searches in under-represented areas to improve distribution data for known species." **18976.** Dickens, J.K.; Schoenberger, D.; VanCompernelle, M. (2020): Guide to the Odonata of central Ñeembucú, Paraguay: indicator species of wetland habitats. *International Journal of Odonatology* 23(3): 239-289. (in English) ["The department of Ñeembucú, in south-western Paraguay, is home to the virtually unexplored Ñeembucú Wetlands, the second largest wetland system in the country, representing a major gap in biodiversity knowledge. As organisms ubiquitous with wetlands, the Odonata ... have the potential to be effective indicators of wetland habitats in the face of increasing anthropogenic impacts in the region. We therefore comprehensively surveyed the Odonata in central Ñeembucú over a period of two years using a listing method. Here, we present an annotated checklist and identification

key to the species present in central Ñeembucú with details on their habitat preferences, phenology and behaviour. We found 60 species but estimate a total of between 62 and 90 species. Eleven (18%) are new records for Paraguay. Species composition is similar to the Argentine Humid Chaco, with four bioregional endemics, whilst representatives from the Andean-Patagonian subregion are present in open areas. Such partitioning of species from different bioregions into different habitats is typical of ecotonal regions. Two further species are endemic to the Paraná-Paraguay basin and three are highly localised, indicating the high conservation value of the Ñeembucú Wetlands. Eleven species have the potential to be effective indicators of the Paraguay River, large permanent wetlands, grassy temporary wetlands and wooded temporary wetlands, providing an effective tool to identify critical wetland ecosystems in the face of the growing threats from human activities. We also provide recommendations for the protection and management of wetlands in the region." (Authors) ]Address: Dickens, J.K., Fundación Para La Tierra, Centro IDEAL, Pilar, Paraguay. **18977.** Ducotterd, C.; Crovadore, J.; Lefort, F.; Guisan, A.; Ursenbacher, S.; Rubin, J.-F. (2020): The feeding behaviour of the European pond turtle (*Emys orbicularis*, L. 1758) is not a threat for other endangered species. *Global Ecology and Conservation* 23 (2020) e01133: 13 pp. (in English) ["Molecular technologies, such as metabarcoding, have become powerful tools for conservation purposes. Here, we present a non-invasive study analyzing the diet of one population of *E. orbicularis* during its whole activity period and of four other populations during the same period, based on faecal sample, and using for the first time on this species, a long metabarcoding approach. *E. orbicularis* is an emblematic freshwater species of wetlands in Europe. In several countries, this species is endangered and, in Switzerland, *E. orbicularis* is ranked as critically endangered on the Swiss Red List. A national conservation program was created to reintroduce this species and raised the question if this reintroduced species could be a threat for other endangered species. We developed a new method of long metabarcoding analysis, using universal PCR primers to determine prey species occurrence in the faeces. The analysis conducted on 174 faeces collected on 142 individuals revealed 1153 preys from 270 species. *E. orbicularis* consumed plants throughout the year with a more diverse diet during the reproduction period (April-June). This study therefore not only determines precisely the omnivorous and opportunistic diet of the *E. orbicularis*, but also shows that this species is not a threat to its environment, as 85.5% of the consumed species were not list on the Swiss Red List. Moreover, it also demonstrated that the genetic analyses of faeces could be an efficient tool to determine trophic interaction with a high level of precision, yielding promising perspectives for food web ecology." (Authors) Prey items included one *Coenagrion pulchellum*.] Address: Ursenbacher, S., Info Fauna e Centre Suisse de Cartographie de la Faune (CSCF) and Centre de Coordination pour les Reptiles et les Amphibiens de Suisse (Karch), Bellevaux 51, CH-2000, Neuchâtel, Switzerland

**18978.** Ekpah, O.; Kemabonta, A.K.; Ogbogu, S.S.; Fomekong, L.-J. (2020): Records of lost and associated species of Odonata in Cross River National Park, Nigeria. *Odonatologica* 49(3/4): 245-258. (in English) ["A number of species of Odonata in south-eastern Nigeria have not been seen for decades, while others have not been recorded since their description. The Mango River in the Oban division of the Cross River National Park (CRNP) in eastern Nigeria was visited three times every month in September 2019, January and March 2020, to survey species of Odonata. The survey was carried out with a view to rediscovering lost species or species that are hitherto not known to occur in the study area. Micrographs of the thorax and wings of specimens suspected to be relict species of Odonata were taken and compared with data in literature to determine their actual identities. A total of 61 individuals of Odonata belonging to 34 species in nine families were collected. Of the 34 species, three, *Africocypha lacuselephantum* (Vulnerable), the relict *Pentaplebia stahli* (Vulnerable) and *Umma purpurea* (Endangered) are new records for Nigeria. This record of rare and common species provides a preliminary baseline data for a checklist of the Odonata fauna in Oban Hills for possible formulation of conservation strategies for threatened species in the area in particular and south-eastern Nigeria at large." **18979.** Ekpah, O.; Williams, A.B.; Kehinde, K.A. (2020): An inventory of Odonata in relation to water quality in Lekki Conservation Centre, Nigeria. *British Entomological and Natural History Society* 33: 367-382. (in English) ["A survey of the Odonata fauna of Lekki Conservation Centre, southwestern Nigeria was carried out from May to December 2019, to investigate how water quality affects species composition. Two study areas were identified and classified as forest swamp (sampling points SW1 to SW7) and forest grassland (G1 to G7). Adult Odonata were collected once a week throughout the study period using an aerial net. Twenty-five species in seven families were recorded of which *Chalcostephia flavifrons* and *Ceriagrion glabrum* were the most abundant species throughout the survey period. Five families were represented by a single species, namely: *Anax tristis*, *Phyllomacromia contumax*, *Phaon iridipennis*, *Chlorocypha* cf. *curta* and *Copera sikassoensis*. Data analyses revealed that the forest swamp was the marginally richer area with Shannon and Simpson indices of 0.88 and 2.4, respectively. Some species such as *Agriocnemis maclachlani* and *Copera sikassoensis* shared a similar microhabitat. The sum of the African Dragonfly Biotic Index (ADBI) scores for all species in the study was 16 with *Ceriagrion rubelloccerinum* Fraser with the highest ADBI score of 4. Lekki Conservation Centre should therefore be considered an important refuge for Odonata." (Authors)] Address: Ojonugwa, E., Nigerian Conservation Foundation, Lagos, Nigeria. **18980.** Erasmus, J.H.; Malherbe, W.; Zimmermann, S.; Lorenz, A.W.; Nachev, M.; Wepener, V.; Sures, B.; Smit, N.J. (2020): Metal accumulation in riverine macroinvertebrates

from a platinum mining region. *Science of The Total Environment* 703 (2020) 134738: (in English) ["Highlights: • Quantification of Cr, Ni, Cu, Zn, Cd, Pt, Pb in water, sediment and macroinvertebrates. • Metal contamination increased in water and sediment downstream of mining activities. • Metal bioaccumulation was significant in macroinvertebrate families. • Macroinvertebrate families showed different grades of bioaccumulation. • Urban and informal settlements also contributed to metal pollution. Abstract: South Africa is the world's main supplier of Pt. The Bushveld Igneous Complex in South Africa contains 75% of the world's Pt resources. Mining of this precious metal requires large volumes of water for production and removal of waste products. Most of this wastewater is discharged into river systems. Although the source of contamination with Pt in aquatic systems due to mining activities is known, little to no information is available about the impact of Pt on aquatic organisms. Additionally, other metals are released as byproducts of Pt mining, which might also be discharged into the environment. Therefore, concentrations of Cr, Ni, Cu, Zn, Cd, Pt and Pb were determined in water, sediment and macroinvertebrate samples from a reference site (Site 1), a highly impacted site (Site 2) and a moderately impacted site (Site 3) along the Hex River, South Africa. Aquatic invertebrate families representing different functional feeding groups i.e. scraper-grazers (Lymnaeidae), collector-gatherers (Potamonautidae, Hydropsychidae, Tubificidae and Chironomidae), shredders (Baetidae) and predators (Coenagrionidae and Libellulidae) were studied. In the sediments, the concentrations of Cr and Pt were significantly higher at Site 2 than at Sites 1 and 3, respectively, whereas concentrations of Ni, Cu, Cd, and Pb showed no significant differences between the sites. Depending on the metal, the aquatic invertebrate families showed different grades of bioaccumulation. The results from especially Lymnaeidae, Baetidae, Tubificidae and Chironomidae showed great promise for the use of these taxa for biomonitoring of metal contaminations. The macroinvertebrates accumulated metals associated with Pt mining, with epi-benthic dwelling taxa (Tubificidae) accumulating higher concentrations of Pt and Cr than other families (e.g. Potamonautidae, Coenagrionidae and Lymnaeidae). These results provide valuable information on the behavior of metals related to Pt mining in aquatic ecosystems and therefore can contribute to the risk assessment of these intensive mining activities." **18981.** Flechoso, F.; Morales, J.; Lizana, M. (2020): Comunidades de odonatos (Insecta: Odonata) en tramos de diferentes características hidrotérmicas en la cuenca de río Carrión. - Communities of odonata (Insecta: Odonata) along sections of the basin of the river Carrión with different hydrothermic characteristics.. *Munibe, Cienc. nat.* 68: 19-33. (in Spanish, with Euskara and English summaries) ["The diversity of Odonata in the area around Velilla del Río Carrión (NW of Palencia) was analyzed in relation to the water temperature and the modification of the water regime by the

Compuerto reservoir. The communities along the main axis of the Carrión river were compared in three sections with different dynamics with respect to a section of the Besandino river, not influenced by the presence of a large nearby reservoir. The results contributed the presence of 11 species (6 Zygoptera and 5 Anisoptera) in 23 records obtained between June and September during 2014 and 2015. Due to the release of water for irrigation in summer, the temperature and flow in the river Carrión were inverted below the reservoir and were associated with a decrease in the specific richness of Odonata showing evidence of reproduction, indicated by the presence of larvae and exuviae. Downstream from the Compuerto dam, despite being a long and varied section, only one species was found of a specimen observed in flight and with no evidence of reproduction, while in the rest of the areas a larger number of species appeared with signs of reproduction in all of them. The thermal effect of a smaller dam was attenuated and did not restrict the presence of Odonata in the same way." (Authors)] Address: Flechoso, F., Univ. de Salamanca, Dpto. Biología Animal, Campus Miguel de Unamuno, E-37007. Spain. E-mail: fabioflechoso@usal.es

**18982.** Fletcher, D.E.; Lindell, A.H.; Stankus, P.T.; Fletcher, N.D.; Lindell, B.E.; McArthur, J.V. (2020): Metal accumulation in dragonfly nymphs and crayfish as indicators of constructed wetland effectiveness?. *Environmental Pollution* 256, January 2020, 113387: (in English) ["Highlights: • Dragonfly genera differ in levels of metal accumulation, influenced by habitat use. • Dragonfly genera accumulating highest concentrations differ most among sites. • Biomonitor metal accumulation often not reduced downstream of constructed wetland. • Elevated metals in downstream biota despite wetlands reducing total and dissolved metal concentrations at base flow. Abstract: Constructed wetland effectiveness is often assessed by measuring reductions of contaminant concentrations in influent versus departing effluent, but this can be complicated by fluctuations in contaminant content/chemistry and hydrology. We assessed effectiveness of a constructed wetland at protecting downstream biota from accumulating elevated metal concentrations—particularly copper and zinc in effluents from a nuclear materials processing facility. Contaminants distributed throughout a constructed wetland system and two reference wetlands were assessed using six dragonfly nymph genera (*Anax*, *Erythemis*, *Libellula*, *Pachydiplax*, *Tamea*, and *Plathemis*) as biomonitors. Additionally, the crayfish, *Cambarus latimanus*, were analyzed from the receiving and two reference streams. Concentrations of Cu, Zn, Pb, Mn, Cr, Cd, and Al were evaluated in 597 dragonfly nymph and 149 crayfish whole-body composite samples. Dragonfly genera varied substantially in metal accumulation and the ability to identify elevated metal levels throughout components of the constructed wetland. Genera more closely associated with bottom sediments tended to accumulate higher levels of metals with *Libellula*, *Pachydiplax*, and *Erythemis* often accumulating highest concentrations and differing most among sites. This, combined with their abundance and broad distributions make the latter two species suitable candidates

as biomonitors for constructed wetlands. As expected, dragonfly nymphs accumulated higher metal concentrations in the constructed wetland than reference sites. However, dragonfly nymphs often accumulated as high of metal concentrations downstream as upstream of the water treatment cells. Moreover, crayfish from the receiving stream near the constructed wetland accumulated substantially higher Cu concentrations than from downstream locations or reference streams. Despite reducing metal concentrations at base flow and maintaining regulatory compliance, metal fluxes from the wetland were sufficient to increase accumulation in downstream biota. Future work should evaluate the causes of downstream accumulation as the next step necessary to develop plans to improve the metal sequestering efficiency of the wetland under variable flow regimes." **18983.** Gärtner, F.; Joest, R. (2020): Quelljungfern im FFH-Gebiet Arnsberger Wald. Situation und Gefährdung nach dem Dürrejahr 2018. *Natur in NRW* 2/2020: 17-21. (in German) [Nordrhein-Westfalen, Germany "Cordulegastridae are typical representatives of the biocoenosis of near-natural springs and flowing waters. Larval mapping at 13 streams in the Arnsberg Forest FFH area showed that both species were still present here even after the extremely dry summer of 2018. However, in the early summer of 2019, 14 percent of the 223 100-metre segments surveyed, or even five of 13 streams surveyed, fell at least partially dry. With a continuing trend towards a negative water balance, a new hazard factor has thus emerged. In addition, the bark beetle mass reproduction as a result of the drought led to large-scale die-back of spruce stands in the Arnsberg Forest. In particular, the habitats of the rarer striped spring damselfly are strongly altered by the clearing of formerly shaded spring areas and sensitive sites are endangered by forestry work. As protective measures, the careful conversion of spruce forests in the stream valleys into site-appropriate deciduous trees and the renaturation of the watercourses as well as the dismantling of all melioration measures in the forest such as piping, fortifications and shortening of courses as well as the drainage into side ditches of the forest roads are recommended." (Authors(Deepl) Address: Joest, R., Arbeitsgemeinschaft Biologischer Umweltschutz – Biologische Station Soest, Bad Sassendorf-Lohne, Germany. E-mail: r.joest@abu-naturschutz.de

**18984.** Galimberti, A.; Assandri, G.; Maggioni, D.; Ramazzotti, F.; Baroni, D.; Bazzi, G.; Chiandetti, I.; Corso, A.; Ferri, V.; Galuppi, M.; Ilahiane, L.; La Porta, G.; Laddaga, L.; Landi, F.; Mastropasqua, F.; Ramellini, S.; Santinelli, R.; Soldato, G.; Surdo, S.; Casiraghi, M. (2020): Italian Odonates in the Pandora's Box: A comprehensive DNA barcoding inventory shows taxonomic warnings at the Holarctic scale. *Molecular Ecology Resources* 21: 183-200. (in English) ["The Odonata are considered among the most endangered freshwater faunal taxa. Their DNA-based monitoring relies on validated reference datasets that are often lacking or do not cover

important biogeographical centres of diversification. This study presents the results of a DNA barcoding campaign on Odonata, based on the standard 658 bp 5' end region of the mitochondrial COI gene, involving the collection of 812 specimens (409 of which barcoded) from peninsular Italy and its main islands (328 localities), belonging to all the 88 species (31 Zygoptera and 57 Anisoptera) known from the country. Additional BOLD and GenBank data from Holarctic samples expanded the dataset to 1294 DNA barcodes. A multi-approach species delimitation analysis involving two distance (OT and ABGD) and four tree-based (PTP, MPTP, GMYC, bGMYC) methods were used to explore these data. Of the 88 investigated morphospecies, 75 (85%) unequivocally corresponded to distinct Molecular Operational Units, whereas the remaining ones were classified as 'warnings' (i.e., showing a mismatch between morphospecies assignment and DNA-based species delimitation). These results are in contrast with other DNA barcoding studies on Odonata showing up to 95% of identification success. The species causing warnings were grouped in three categories depending on if they showed low, high, or mixed genetic divergence patterns. The analysis of haplotype networks revealed unexpected intraspecific complexity at the Italian, Palearctic, and Holarctic scale, possibly indicating the occurrence of cryptic species. Overall, this study provides new insights into the taxonomy of odonates and a valuable basis for future DNA and eDNA-based monitoring studies." (Authors)] Address: Galimberti, A., ZooPlantLab. **18985.** Garzón-Salamanca, L.L.; Rivera-Rondón, C.A.; Aristizabal, H.; Forero, D. (2020): Exploring the ecology and indicator value of some larvae of Odonata genera in Colombia. *Environmental Entomology* 49(4): 829-837. (in English) ["Bioindication is a method to assess environmental conditions using indicator organisms. In Colombia, water quality evaluation is mostly performed following the Biological Monitoring Working Party/Colombia method (BMWP/Col), which uses aquatic macroinvertebrates at the taxonomic family level. Studies on potential bioindicators are important to produce comprehensive information on the requirements of macroinvertebrates and their value for water quality bioindication. We studied the larval ecology of several common genera of Odonata from Colombian freshwater ecosystems and assigned an indicator value to each genus. The physical and chemical water characteristics of 1,022 sites surveyed in Colombia from 2005 to 2016 were analyzed using a principal component analysis (PCA). The relationship between environmental conditions and Odonata genera found was studied using multiple logistic regressions between sample coordinates of the first three axes of the PCA and occurrence of the respective genus. We assigned an indicator value for each genus using the logistic regression and the water quality of samples. The highest indicator values were assigned to genera, which were mainly explained by the PCA axis associated with water quality, showed a high odds ratio to this axis, and were found in ecosystems with

excellent water quality. The indicator values suggested for each taxon are, *Brechmorhoga* Kirby, 1894, 8; *Macrothemis* Hagen, 1868, 4; *Micrathyría* Kirby, 1889, 4 (*Libellulidae*); *Progomphus* Selys, 1854, 7 (*Gomphidae*); *Acanthagrion* Selys, 1876, 4; and *Argia* Rambur, 1842, 7 (*Coenagrionidae*). Differences in water quality preferences in genera of the same family suggest that higher taxonomic resolution may allow more detailed environmental assessments." **18986.** Genise, J.F.; Sánchez, V.; Poiré, D.G.; González, M.G. (2020): A fossorial petalurid trace fossil from the Albian of Patagonia. *Cretaceous Research* 116, December 2020, 104591: (in English) ["Highlights: • *Maichnus wetkaroae* igen. isp. nov. is a new trace fossil from the Albian of Patagonia. • It is the first trace fossil attributable to Odonata recorded from paleosols. • It is one of the oldest insect trace fossils recorded from paleosols. • It provides the first and unique evidence of ancestral burrowing behavior of petalurids. • This evidence supports some previous theoretical evolutionary scenarios for Odonata. Abstract: *Maichnus wetkaroae* igen. isp. nov., from the Albian of Patagonia, is composed of two or three ellipsoidal oblate chambers connected to shafts that show swellings and concentrically laminated linings. Such laminated linings are also present in chambers, and probably originated by radial backfilling and/or the successive discharges of liquid organic excretions. This unique morphology occurs in paleosols showing evidence of waterlogging. Trace fossil morphology and the occurrence of traces in clusters in waterlogged soils indicate that *M. wetkaroae* igen. isp. nov. represents larval burrows of fossorial petalurids. This is the first record of Odonatan trace fossils from paleosols and also the oldest one. *M. wetkaroae* igen. isp. nov. is one of the oldest insect trace fossils recorded from paleosols. It represents the first and unique paleontological evidence of the ancient origin of the burrowing behavior of petalurids postulated only theoretically until now in evolutionary scenarios of Odonata." **18987.** Gezie, A.; Legesse Mulat, W.; Anteneh, W.; Dejen, E.; Kloos, H.; Mereta, S.T. (2020): Habitat suitability modelling of benthic macroinvertebrate community in wetlands of Lake Tana watershed, northwest Ethiopia. *Wetlands* 40: 853-864. (in English) ["Predictive modelling corroborates decision-making in the development of a standard habitat assessment protocol. In this study, we modelled environmental requirements of benthic macroinvertebrates. Classification and regression tree models (CART) and ordination analysis were performed to identify important variables affecting macroinvertebrate community pattern in the Lake Tana Watershed. A dataset of 95 samples was collected from eight wetlands. Among the modelled taxa, *Coenagrionidae* and *Libellulidae* had substantial predictive performance based

on Kappa statistic ( $\kappa > 0.6$ ) whereas *Baetidae*, *Physidae*, *Tipulidae* and *Hydrophilidae* had moderate predictive model performance ( $\kappa \geq 0.4$ ). Vegetation cover, leather tanning, vegetation clearance and nitrate ion were the topmost selected environmental variables influencing the occurrence of macroinvertebrate taxa. The conditional analysis depicted that the abundance of *Coenagrionidae* and *Libellulidae* increased with the increasing in vegetation cover. Overall, macroinvertebrate taxa have a clear habitat requirement within the habitat gradient studied and hence, could be a potential candidate for biomonitoring and provide valuable information in the development of a standard wetland assessment protocol." (Authors)] Address: Gezie, A., Dept of Biology, Bahir Dar University, Bahir Dar, Ethiopia

**18988.** Gómez-Llano, M.; Narasimhan, A.; Svensson, E. (2020): Male-male competition causes parasite-mediated sexual selection for local adaptation. *The American Naturalist* 196(3): 344-354. (in English) ["Sexual selection has been suggested to accelerate local adaptation and promote evolutionary rescue through several ecological and genetic mechanisms. Condition-dependent sexual selection has mainly been studied in laboratory settings, while data from natural populations are lacking. One ecological factor that can cause condition-dependent sexual selection is parasitism. Here, we quantified ectoparasite load (*Arrenurus* water mites) in a natural population of *Ischnura elegans* over 15 years. We quantified the strength of sexual selection against parasite load in both sexes and experimentally investigated the mechanisms behind such selection. Then we investigated how parasite resistance and tolerance changed over time to understand how they might influence population density. Parasites reduced mating success in both sexes, and sexual selection was stronger in males than in females. Experiments show that male-male competition is a strong force causing precopulatory sexual selection against parasite load. Although parasite resistance and male parasite tolerance increased over time, suggestive of increasing local adaptation against parasites, no signal of evolutionary rescue could be found. We suggest that condition-dependent sexual selection facilitates local adaptation against parasites and discuss its effects in evolutionary rescue." **18991.** Harabiš, F.; Jakubec, P.; Hronková, J. (2020): Catch them if you can! Do traits of individual European dragonfly species affect their detectability?. *Insect Conservation and Diversity* 13(3): 303-312. (in English) ["1. Odonates are an ancient group of freshwater invertebrates that have complex life cycles and highly variable phenotypes and behaviours. These traits make odonates a very attractive model group to study various aspects and phenomena in the fields of ecology, behaviour, and evolutionary biology. 2. Such variability in appearance and behaviour can influence the detectability of individual species under natural conditions; and this variability in detection rates, if not statistically treated, may lead to significant distortions of results and misleading conclusions. 3. In the present study, we used detectability models to predict the time to detection (TTD) of individual odonate species and generalised linear mixed models to analyse the effects of morphological and behavioural traits on the TTD of the first individual of a species. 4. We found that only abundance had a significant effect on the TTD of both Anisoptera and Zygoptera, while the larger Anisoptera were generally detected earlier. No such patterns were observed in Zygoptera; however, dispersal ability was found to have had some influence. 5. Surprisingly, coloration and activity were not found to influence the TTD of odonates. Therefore, although there are considerable differences between species, with the exception of abundance and size, we did not detect any easily measurable traits that would unequivocally explain the differences in the detection rates of individual species." **18992.** Hashimoto, K.; Kasai, A.; Hayasaka, D.; Goka, K.; Hayashi, T.I. (2020): Long-term monitoring reveals among-year consistency in the ecological impacts of insecticides on animal communities in paddies. *Ecological Indicators* 113, June 2020, 106227: (in English) ["Highlights: • The effects of three insecticides on animals in paddies were assessed for three years. • Animal community composition significantly differed among years. • Some taxa were decreased by each insecticide irrespective of year. • These taxa can be used as robust indicators of the effects of each insecticide. • Long-term monitoring may be useful in identifying ecotoxicological effect indicators. Abstract: Semi-natural mesocosm experiments have been proposed as a powerful approach for evaluating the realised rather than potential

ecotoxicological effects of agrochemicals on biological communities. However, there is uncertainty in the results from such experiments due to spatio-temporal variability in various ecological factors, such as community composition. Therefore, long-term studies evaluating such variability are critical for assessing the utility of mesocosm experiments, although few studies have been conducted over multiple years. We conducted a multiple-year (i.e., three-year) mesocosm experiment to examine the effects of three systemic insecticides (clothianidin, fipronil, and chlorantraniliprole) on aquatic animal communities in experimental paddies, and we evaluated the among-year variability in these ecotoxicological effects. We found substantial variation in community composition among years. However, when we controlled for this variability by performing partial redundancy analysis (partial RDA), we found that paddy community composition was significantly different between the three insecticide treatments irrespective of year. Moreover, we identified some taxa that consistently decreased in abundance following exposure to each insecticide and may thus be regarded as indicator taxa of the environmental stress caused by the insecticides (e.g., clothianidin: *Gerris lacustris* (water striders), fipronil: *Orthetrum albistylum speciosum* (dragonflies), and chlorantraniliprole: *Hydroglyphus japonicus* (beetles)). Our study suggests the utility of multiple-year, semi-natural mesocosm experiments not only for evaluating the temporal variability in ecotoxicological effects but also for identifying potential robust indicator organisms that consistently decrease in abundance in response to specific agrochemicals irrespective of the variability in ecological factors under realistic conditions.] Address: Hashimoto, K., Faculty of Agriculture, KINDAI University, Nakamachi 3327-204, Nara 631-8505, Japan. **18993.** Hasik, P. (2020): A macroevolutionary view on extinction risk in Aves, Chiroptera, and Odonata. MSc thesis Arkansas State University: 31 pp. (in English) ["A central goal of conservation biology is to identify and understand the factors that lead to extinction. The Earth is currently undergoing a 6th mass extinction event, in large part because of human activity. In the last century, rates of extinction have increased anywhere from 8-100 times the background rate of 2 extinctions per 10,000 species every 100 years. However, there remains a debate over whether certain species are predisposed to a higher extinction risk. In particular, it is not known if the macroevolutionary history of a lineage is a major contributor to the probability of extinction, nor is it clear whether the current rise in extinction rates is due strictly to anthropogenic activity. Using life history trait information and the International Union for Conservation of Nature (IUCN) Red List rankings for bats, birds, and odonates in combination with a novel diversification method, MiSSE (Missing State Speciation and Extinction), we test if there is an evolutionary signal of extinction susceptibility independent of the influence that traits can have on rates of diversification. Phylogenetic and non-phylogenetic regressions were run to determine if any specific traits correlated with extinction risk ranking. We find that there is no correlation between diversification rates and IUCN extinction risk. However, larger

clutch sizes and range sizes correlated with lower extinction risk and that longer generation lengths for birds did correlate with higher levels of extinction risk. We found no correlation of extinction risk and life history traits in bats and odonates. Our modeling suggests that other factors, such as human-mediated activities, better explain the increased extinction rates." (Author)] Address: not stated

**18994.** Herzog, R. (2020): Global change genomics: comparative genomic analyses on environmental associated speciation and adaptation processes in Odonata. Dissertation, Naturwissenschaftlichen Fakultät der Gottfried Wilhelm Leibniz Universität Hannover: XIX, 154 pp. (in English, with German summary) ["Proceeding global and local environmental changes require innovative conservation concepts and animal model systems which integrate empirical and genomic data. Odonata are a highly suitable model system for the evaluation of ecosystems and on top hold an evolutionary key position at the base of winged insects. The rapid (r)evolution of genetic methods in the last two decades has allowed the transition of traditional ecological field model systems (which cannot or only with difficulty be kept in the laboratory in contrast to traditional genetic model organisms) to model systems of integrative research. This raises the possibility of closing the gap between ecological factors and their genetic consequences and / or causes. Here, the order Odonata plays a prominent role based on the solid foundation of extensive ecological data and now numerous genetic research approaches for dragonflies. Consequently, the presented dissertation deals with two odonate species with very different ecological niches, almost opposing adaptation strategies and distributional dynamics. These are on the one hand *Lestes macrostigma*, an endangered, stenotopic damselfly adapted to temporary, brackish ecosystems with spatially very limited distribution. The other target species is the cosmopolitan, abundant and migratory *Pantala flavescens*, inhabiting all kinds of temporary waters created by local rains as an ecological generalist. Due to their temporary nature, both habitats are particularly prone to climate change, but they differ significantly in their spatio-temporal occurrence. The resulting different adaptation strategies and distributional dynamics of both species were therefore genetically characterized in this work on (i) temporal, (ii) local and (iii) global levels to compare potential "winners" and "losers" in terms of the current insect extinction and rapidly changing environmental conditions: A long-term local monitoring of a population of *L. macrostigma* in southern France revealed highly fluctuating population sizes resulting in genetic bottlenecks. These results were associated with fluctuating precipitation and drought periods and were compared to populations covering the entire distribution range of this species and are discussed in a geographic context. The global comparison approach reveals that the fragmented population structure is reflected in the genetics of this species and that populations are even genetically isolated. Furthermore, two conservation units were discovered in Spain and France requiring the re-evaluation of the conservation status of these populations by the relevant authorities. Finally, a new dispersal model of this species was

proposed, suggesting that this species originated in Asia with a subsequent westward expansion. A first global population study on the cosmopolitan dragonfly species *P. flavescens* surprisingly revealed contradicting geographic structuring based on mitochondrial and nuclear data. Despite their extraordinary migratory potential, island populations of *P. flavescens* show genetic signals of local adaptation processes, going along with phenotypic differences and behavioral adaptations. In particular, the investigated population on Easter Island is genetically isolated and depleted whereas all other populations show remarkably high intraspecific diversity. However, nucleotide and amino acid diversity indicate saturation of the CO1 barcode gene fragment, highlighting the limited suitability of marker for population genetic studies as local adaptations could not be detected. To complement single marker gene analyses and to pave the way for genomic studies on insect migration, the complete mitochondrial genome of an Easter Island individual of *P. flavescens* was characterized and compared to mitogenomes of the key odonate species *Anax imperator*, *Ischnura elegans*, and *Megalopterus caeruleus*. These new mitogenome data are a highly valuable resource for future comparative mitogenome studies on the population level and for insect migration. Migration of flying insects has so far only been studied in detail on two phylogenetically very derived model systems (*Danaus plexippus* and *Locusta migratoria*). Since dragonflies are phylogenetically placed on the base of winged insects, studies on *P. flavescens* open up the possibility of tackling the question of the evolution of migration and its genetic mechanisms." **18995.** Houard, X. (coord.) (2020): 2020 – Plan national d'actions en faveur des « libellules » - Agir pour la préservation des odonates menacés et de leurs habitats 2020-2030. Office pour les insectes et leur environnement – DREAL Hauts-de-France - Ministère de la transition écologique: 66 pp. (in French, with English summary) ["12 actions implemented during 10 years for saving French dragonflies and damselflies endangered species National Action Plans (NAPs) are strategic tools from the French Ministry in charge of biodiversity issues. They are intended to ensure the maintenance or restoration of populations of endangered species or species of special interest in a favorable conservation status. In a legal framework, the NAPs then organize the preservation of these species by implementing a voluntary and structuring approach. The overall objective of this plan and its regional implementations is to safeguard the dragonflies and damselflies through specific measures to stop the direct causes of their disappearance (destruction of their habitat, drying, pollution, damage to dispersal abilities, climate change...) starting with the issues concerning the species considered as the most "patrimonial" (threatened and / or protected). This plan requires the mobilisation of all, both public authorities (State services, local authorities) and rural stakeholders (breeders, farmers, foresters ...), managers of spaces and / or natural resources (quarry operators, owners,

riparians ...) encouraging them to favor appropriate management for the conservation of the target species. Finally, considering the "bioindicator" qualities of dragonflies and damselflies, this plan targets all naturalist citizens wishing to contribute to a better collection of scientific information. Researchers should be also interested in better detailed assessment of practices related to wetlands preservation." **18996.** Huang, D.-Y.; Nel, A.; Ngo-Muller, V. (2020): The sixth species of the damselfly family *Burmacoenagrionidae* (Odonata) endemic to the mid-Cretaceous Burmese amber. *Palaeoentomology* 3(6): 564-568. (in English) ["*Burmagrion azari* sp. nov., sixth species of the small damselfly family *Burmacoenagrionidae*, is described and illustrated. This family is currently only recorded from the mid-Cretaceous Burmese amber and is possibly endemic to this isolated island of the Tethys Ocean at that time. The presence of slender, elongate legs with very long tarsi is a putative synapomorphy of the *Burmacoenagrionidae*, as present in *Burmagrion* and *Burmacoenagrion*. The type specimen of the new genus and species is dislocated together with several fragments of flies, suggesting that these fossils are possibly the result of a regurgitation by a small vertebrate passing aside the fresh resin. The female of *Burmagrion azari* sp. nov. was probably laying its eggs inside plant cuticles. Its ovipositor is described." (Authors)] Address: Nel, A., Lab. Ent. Mus. Natn. Hist. Nat., 45 rue Buffon, F-75005 Paris, France. E-mail: anel@cimrns1.mnhn.fr

**18997.** Jooste, Mi.J.; Samways, M.J.; Deacon, C. (2020): Fluctuating pond water levels and aquatic insect persistence in a drought-prone Mediterranean-type climate. *Hydrobiologia* 847: 1315-1326. (in English) ["In dry areas, natural and artificial ponds experience frequent water level fluctuation, affecting conditions for some aquatic and amphibiotic taxa. Water beetles, bugs, and dragonflies make up much of pond diversity, and are responsive to changes in environmental conditions. Using a drought-prone pondscape within the Greater Cape Floristic Region biodiversity hotspot, we determine (1) the relative extent to which species richness, abundance, and composition are affected by pond water level fluctuation, (2) the effects of environmental variables and vegetation characteristics relative to fluctuating water levels, and (3) make recommendations to improve pondscape conservation. We found that the degree of fluctuation had a significant effect on beetle species richness, but had no significant effect on the other focal taxa. Water temperature, pH, and conductivity, and vegetation cover and composition were drivers of aquatic insect species richness, abundances, and assemblage structures. Habitat heterogeneity supported rich aquatic insect assemblages. We recommend that a range of ponds with various degrees of water level fluctuation should be maintained, along with naturally diverse marginal vegetation. Such

a dynamic pondscape can contribute greatly towards maintenance of local and regional aquatic insect diversity in drought-prone regions and should be considered as a main focus in conservation efforts." (Authors)] Address: Deacon, C., Dept of Conservation Ecol. & Ento., Stellenbosch Univ., South Africa. E-mail: charldeacon@sun.ac.za

**18998.** Kamnananda, H.T.A.R.; Gnnawardena, M.P. (2020): Diversity of Odonata at Ramsar City - Colombo, Sri Lanka. Symposium on Applied Sciences (SAS) 2020: 124-131. (in English) ["Urban wetlands are water-rich natural areas that lie within the boundaries of a city or town known to provide many valuable ecological benefits to urban ecosystems. Wetlands restore drinking water, reduce flooding, play a vital role in filtering waste and also provide urban green spaces. More importantly, the wetlands provide a good feeding and breeding habitat for urban wildlife. The present study investigated the effects of urbanization 011 the diversity of dragonflies and damselflies in major wetlands located in the Ramsar City, Colombo, Sri Lanka. The selected wetlands are 'Diyasanf Wetland Park. 'Baddagana' Wetland Park, 'Pelawatha' Wetland and 'Thalawathugoda' Wetland. Dragonflies and damselflies were used as an indicator species as they are found commonly in wetlands and are very sensitive to any change in the environment. Sampling was conducted at 3 points for a period of 10 minutes at each location. The type of species and the number of individuals observed within a 10m radius were recorded. Opportunistic observations were taken when a dragonfly was encountered in the field other than the time interval. The number of species and individuals recorded at 'Diyasanf, 'Baddagana'. 'Pelawatha' and 'Thalawathugoda' wetlands were 11/75, 8/43. 9/97 and 8/56 respectively. A total of 37 species were found in all four locations (opportunistic species) indicating that these wetlands still have a good diversity of dragonflies and damselflies. However, during the study, garbage and other sewage waste were dumped at all four study sites. These waste materials may increase the environmental pollution potential of the aquatic ecosystem and alter the habitat structure of wetland organisms. Further study is needed 011 communities of Odonata living in differently polluted habitats to understand the impact of pollution loads 011 their diversity and abundance." **18999.** Karube, H.; Terayama, H.; Kaga, R.; Sato, T.; Sakabe, K. (2020): Contamination implications of the neonicotinoid insecticide for the habitat of the endangered dragonfly *Sympetrum maculatum* in the Tonoh area, Gifu Prefecture. *Tombo* 62: 26-37. ["*S. maculatum* Oguma, 1915, which inhabits small reservoirs in hilly areas, is an endemic dragonfly of Japan and ranked as an endangered species in the Japanese Red List. Recently a serious decline in the species has been observed in the Tonoh area, in the southeast part of Gifu Prefecture. The reason for the decline is still not clear, but we presume the decline was initiated by Chemical pollution of neonicotinoid insecticide, and in the autumn of 2018 we reported that acetamiprid in the species habitat

had exceeded the allowable limits set by the Ministry of the Environment (Karube et al., 2019). In 2019, we investigated these insecticides in the habitat of *S. maculatum* in May and July, during the period of the larval stage. As a result, 8 substances of neonicotinoid insecticides were detected from almost all samples, which indicates Chemical pollution has spread widely in this area. Especially notable was the concentration of acetamiprid in the habitat that highly exceeded the allowable limits, in addition to thiacloprid, clothianidin and fipronil that also exceeded allowable limits. The values of the neonicotinoid insecticide were highest in May, compared to other seasons (e.g. imidacloprid: 13.94-41.34 times that of 2018 autumn data; acetamiprid: 11.47-1362.12 times as that of 2018 autumn data). These results suggest that neonicotinoid insecticide is one of the main factors for the dragonflies decline." (Authors)] Address: Karube, H., Kanagawa Prefect. Mus. Nat. Hist., 499 Iryuda, Odawara, Kanagawa, 250, Japan. E-mail: paruki@nh-kanagawa-museum.jp

**19000.** Kaunisto, K.M.; Roslin, T.; Forbes, M.R.; Morrill, A.; Sääksjärvi, I.E.; Puisto, A.I.E.; Lilley, T.M.; Vesterinen, E.J. (2020): Threats from the air: Damselfly predation on diverse prey taxa. *Journal of Animal Ecology* 89(6): 1365-1374. (in English) ["1. To understand the diversity and strength of predation in natural communities, researchers must quantify the total amount of prey species in the diet of predators. Metabarcoding approaches have allowed widespread characterization of predator diets with high taxonomic resolution. To determine the wider impacts of predators, researchers should combine DNA techniques with estimates of population size of predators using mark–release–recapture (MRR) methods, and with accurate metrics of food consumption by individuals. 2. Herein, we estimate the scale of predation exerted by four damselfly species on diverse prey taxa within a well-defined 12-ha study area, resolving the prey species of individual damselflies, to what extent the diets of predatory species overlap, and which fraction of the main prey populations are consumed. 3. We identify the taxonomic composition of diets using DNA metabarcoding and quantify damselfly population sizes by MRR. We also use predator-specific estimates of consumption rates, and independent data on prey emergence rates to estimate the collective predation pressure summed over all prey taxa and specific to their main prey (non-biting midges or chironomids) of the four damselfly species. 4. The four damselfly species collectively consumed a prey mass equivalent to roughly 870 (95% CL 410–1,800) g, over 2 months. Each individual consumed 29%–66% (95% CL 9.4–123) of its body weight during its relatively short life span (2.1–4.7 days; 95% CL 0.74–7.9) in the focal population. This predation pressure was widely distributed across the local invertebrate prey community, including 4 classes, 19 orders and c. 140 genera. Different predator species showed extensive overlap in diets, with an average of 30% of prey shared by at least two predator species. 5. Of the available prey individuals in the widely consumed family Chironomidae, only a relatively small proportion (0.76%; 95% CL 0.35%–1.61%) were consumed. 6. Our synthesis of population sizes, per-capita consumption rates and taxonomic distribution of diets identifies

damselflies as a comparatively minor predator group of aerial insects. As the next step, we should add estimates of predation by larger odonate species, and experimental removal of odonates, thereby establishing the full impact of odonate predation on prey communities." **19001.** Kebede, G.; Mushi, D.; Linke, R.B.; Dereje, O.; Lakew, A.; Hayes, D.S.; Farnleitner, A.H.; Graf, W. (2020): Macroinvertebrate indices versus microbial fecal pollution characteristics for water quality monitoring reveals contrasting results for an Ethiopian river. *Ecological Indicators* 108 (2020) 105759: 10 pp. (in English) ["Awash River is one of the major surface water sources used by millions of people in the central Highlands of Ethiopia. However, numerous pollution sources exert significant pressure on the river. Different approaches for assessing the status of water quality exist, but few studies compared the performance of distinct methods. Therefore, this study aims to evaluate the consistency of fecal indicator bacteria for environmental health assessment of rivers by comparing them to assessments of physicochemical tests as well as newly developed macroinvertebrate indices. Physicochemical, biological (macroinvertebrates) and microbiological (*Escherichia coli* and Enterococci) parameters were assessed at five sites along the upper Awash River. For *E. coli* and Enterococci moderate to strong fecal pollution levels, ranging from  $7.9 \times 10^2$  to  $7.6 \times 10^3$  cfu/100 ml and  $7.6 \times 10^2$  to  $1.1 \times 10^4$  cfu/100 ml, were observed, respectively. The concentrations of both fecal indicator bacteria exceeded the standards set by the European Union and the World Health Organization for safe recreational water. Hence, all sites were categorized as poor for swimming and recreation. In contrast, three African benthic macroinvertebrate indices (South African Scoring System 5, Tanzanian River Scoring System, Ethiopian Biotic Score) indicated a natural or good water quality with slight ecological degradation at the upstream sites, and a moderate to poor ecological status at the downstream sites. While macroinvertebrate communities were able to reflect anthropogenic disturbances, mainly caused by different land uses, fecal indicator bacteria, most likely driven by the high pressure of extensive livestock fecal emission and overgrazing in the whole catchment, did not. This study underpins the necessity of combining different indicator systems to analyze human pressures in Africa in a holistic way, which can serve as a basis for management and sustainable use of fundamental resources such as water from freshwater ecosystems." (Authors) Odonata are treated at the family level.] Address: Kebede, G., Ambo University, Department of Biological Sciences, P.O. Box 95, Ambo, Ethiopia

**19002.** Keetapitchayakul, T.S.; Sripanya, J.; Phlai-Ngam, S.; Tungpairjwong, N. (2020): Description of the final stadium larva of *Bayadera serrata* Davies & Yang, 1996 (Odonata: Euphaeidae) from Thailand. *Zootaxa* 4894(1): 98-110. (in English) ["The damselfly genus *Bayadera* Selys, 1853 comprises 17 species, but the larvae of only four species have been described. Here we describe the final stadium

larva of another species—*Bayadera serrata* Davies & Yang, 1996. Larvae were collected from a headwater stream at Nam Nao National Park, Phetchabun Province, Thailand. The larva of *B. serrata* is distinguished from congener species following the presence of one to three distinct spines on the genae, two pairs of setae on the ligula, one pair of setae on the ventral side of prementum, the presence of three teeth of the distal end of the labial palp, the presence of a plate-like spine on the gonapophyses, the presence of a row of rod-like setae on the distal end of the tibial comb, the presence of a cluster of long simple setae on the abdominal terga S3–9, and the presence of short terminal filament of the caudal gills. The larvae of genus *Bayadera* have been compared with other known larvae from family Euphaeidae. Key is provided to the genera with known Southeast Asian euphaeid larvae: *Anisopleura*, *Bayadera*, and *Euphaea*." **19003.** Khan, M.K.; Herberstein, M.E. (2020): Ontogenetic habitat shifts reduce costly male–male interactions. *Evolutionary Ecology* 34(5): 735-743. (in English) ["Ontogenetic habitat shifts are predicted to increase the fitness and survival of individuals by allowing effective utilization of spatially distributed resources. Evidence supports nutritional requirements and predation pressure as drivers of habitat shifts. Likewise, intraspecific interactions are thought to lead to ontogenetic habitat shifts, however, empirical evidence is lacking. Here, we test if intraspecific male–male interactions are responsible for ontogenetic habitat shifts in *Xanthagrion erythroneurum*, a damselfly that undergoes developmental colour change. The juvenile males are yellow and change colour to red with sexual maturity. Field observations showed that the proportion of juvenile males is higher in adjacent woods than in primary mating arenas by ponds. We measured male–male interactions by the pond and in the woods, predicting the habitat switch would reduce male antagonistic interactions such as male aggression and male–male mating attempts. We showed that juvenile males receive less aggression in woods than at the pond mating arena. We conclude that lower population density and lower male encounter rates in the woods reduce the cost of male aggression for juvenile males. Our study provides evidence that stage-dependent habitat choice resulting from intrasexual antagonistic interactions may drive ontogenetic habitat shifts." (Authors)] Address: Khan, M.K., Dept of Biological Sciences, Macquarie Univ., Sydney, NSW, 2109, Australia

**19004.** Khan, M.K. (2020): Female pre-reproductive colouration reduces mating harassment in damselflies. *Evolution* 74(10): 2293-2303. (in English) ["Conspicuous female colouration can evolve through male mate choice or via female-female competition thereby increasing female mating success. However, when mating is not beneficial, such as in pre-reproductive females, selection should favour cryptic rather than conspicuous colouration to avoid male detection and the associated harassment. Nevertheless, conspicuous

female colouration occurs in many pre-reproductive animals, and its evolution remains an enigma. Here, I studied conspicuous female colouration in *Agriocnemis femina*, in which the conspicuous red colour of the immature females changes to a less conspicuous green approximately a week after their emergence. I measured body size, weight and egg numbers of the female morphs and found that red females are smaller, lighter and do not carry developed eggs. Finally, I calculated the occurrence frequency and mating frequency of red and green females in several populations over a three-year period. The results demonstrate that red females mated less frequently than green females even when red females were the abundant morph in the populations. I concluded that conspicuous female colouration is likely to function as a warning signal of sexual unprofitability, thereby reducing sexual harassment for females and unprofitable mating for males." **19005.** Korkeamäki, E. (2020): Local extinction risk and community structure of Odonata populations in Fennoscandia. *Annales Universitatis Turkuensis Ser. A II* 366: 46 pp. (in English, with Finnish summary) ["A key need in conservation biology is to identify the ecological traits of a species that make it vulnerable. This thesis focuses on population traits and extinction risk of dragonflies and damselflies (order Odonata) in Finland and Sweden. First, I examined whether species occupancy frequency distributions (SOFD) of odonates vary among the lakes and ponds of four geographical regions. Second, I determined the main habitats, species traits, and local population distributions of Odonata in Central Finland. I found that in the southern regions, the SOFD was dominated by species that occur at few sites, while in the northern regions the distribution was bimodal. In the northern parts of the range, rare species inhabited only high-quality sites. Size of the geographical range, breeding habitat requirements, and degree of generalism/specialism largely explained the observed variation in species occupancy frequency. Specialized species with limited distributions had a greater extinction risk than widely distributed generalist species. However, when the effect of species' geographical range sizes was controlled, I found that extinction risk was actually lower for specialist species than for generalist species, probably due to the fact that generalist species occur in both low- and high-quality habitats. In particular, an extremely high extinction rate was found for peatland-associated species and dynamic lotic headwater populations. Taken together, my results indicate that extinction risk is shaped by the relationship between species population size, distribution, specialization, and habitat quality. The results of this thesis are consistent with existing predictions of species vulnerability and source-sink theory. In conclusion, my research highlights the necessity for conservation biologists to study the quality of freshwater habitats, because this is likely to be an important factor affecting the likelihood of extinction for populations in aquatic environments." **19007.** Li, F.; Tokin, J.D.; Haase, P. (2020): Local contribution to beta diversity is negatively linked with community-wide dispersal capacity in stream invertebrate communities. *Ecological Indicators* 108: 9pp. (in English) ["It is increasingly well understood that stream communities are regulated by both local niche and regional dispersal processes, but comprehensive tests of these factors with datasets that cover extensive spatial and temporal scales are rare. Based on 1180 benthic invertebrate community samples from 2005 to 2012 in central low mountain streams of Germany, we tested the hypotheses that: 1) local contribution to beta diversity (LCBD: a measure of the uniqueness of communities) would decline with increasing average community dispersal capacity; and 2) owing to the relatively large spatial extent of the study region, regional dispersal processes would override local niche controls in structuring community composition. We found considerable temporal variation in LCBD and a negative correlation between LCBD and community dispersal capacity. However, no statistically significant correlation between species contribution to beta diversity (SCBD) and species dispersal capacity was observed. The large-scale spatial structure among locations (representative of dispersal limitation) was important in structuring benthic communities. Although much of the variation was explained by the shared effects of local processes and large-scale spatial variables, environmental controls were stronger than regional processes in few cases in the variance partitioning analysis, with the annual mean temperature and mean diurnal range of temperature being the important drivers. Given the highly varied correlates of beta diversity over time, we urge researchers to focus on not only spatial variation in diversity, but also the context of temporal variation." (Authors) The study includes "Odonata".] Address: Li, F., Dept River Ecology & Conservation, Senckenberg Research Inst. & Natural History Museum Frankfurt, 65371 Gelnhausen, Germany

**19008.** Li, X.; Li, Y.; Muzammil, I.; Lei, M. (2020): Antireflection and antiwetting functionalities of plasma-nanotextured polymer surfaces with biomimetic nanopillars. *Plasma Processes and Polymers* 17(11); e2000050: 14 pp. (in English) ["Inspired by the antireflection and antiwetting functionalities of dragonfly wings decorated with random nanopillars and a wax layer, a facile technique to endow the same functionalities has been devised. In this two-step plasma nanotexturing technique, first oxygen plasma treatment is implemented to grow the random nanopillars on the polymethyl methacrylate (PMMA) surfaces, and then C4F8 plasma polymer

deposition is carried out so that the thin fluorocarbon film with a low surface free energy and refraction index covers the random nanopillars. The biomimetic PMMA surfaces exhibit excellent broadband and omnidirectional antireflection properties and robust antiwetting properties under the water droplet impact. The superhydrophobicity at the slippery Cassie state was maintained under the natural oscillation of residual droplets." **19009.** Liu, C.; Zhang, Y.; Liu, X. (2020): Geographical fauna of Odonata in Xiangtoushan National Reserve, Guangdong province. *Forestry and Environmental Science*: 92-99. (in Chinese, with English summary) ["The field investigation of Odonata in Xiangtoushan national nature reserve was carried out from March 2017 to December 2019. The results showed that there were 122 species of Odonata, belonging to 14 families and 74 genera, in the reserve. The species number of Libellulidae (33 species) is the highest, followed by Gomphidae (28 species). The dominant species are *Neurobasis chinensis*, *Mnais mneme*, *Gomphidia kruegeri*, *Asiagomphus hainanensis*, *Macromia calliope*, *Orthetrum glaucum*, *Pantala flavescens* and *Triethemis festiva* etc. The world faunal characteristics of Odonata in this reserve showed that 92 species (occupied 75.41%) are oriental, 28 species (occupied 22.95%) are oriental-palearctic. Meanwhile, all these species construct 10 distribution groups in 7 Chinese Zoogeographic subregions. There are 50 (40.98%) species in South China subregion, 13 (10.66%) species in South and Southwestern subregions, 19 (15.77%) species in South and Central-China subregions, and 20 (16.39) species live in three subregions of South–Central–North China simultaneously. The results of Odonata fauna are consistent with the place of Xiangtoushan national reserve." **19011.** Mafuwe, K.; Moyo, S. (2020): Dragonfly (Odonata) community structure in the Eastern Highlands Biodiversity

Hotspot of Zimbabwe: potential threats of land use changes on freshwater invertebrates. *International Journal of Odonatology* 23(4): 291-304. (in English) ["We examined the diversity and potential drivers of dragonfly distribution in a biodiversity hotspot of Southern Africa (Eastern Highlands, Zimbabwe) by surveying 30 sites (13 lentic and 17 lotic habitats) located within this region. Additionally, we identified the anthropogenic factors that may threaten Odonata diversity and abundance. Our results revealed that 27 odonate species are associated with dams and ponds, one species is associated with streams and four species are associated with swamp forests. Considering odonate diversity between protected and unprotected areas, we found significantly higher diversity of odonates in streams in protected areas compared to non-protected areas. Broadly, we found anthropogenic activities (e.g. commercial exotic tree plantations, mining activities, vegetation clearing) possibly affect Odonata diversity (by decreasing abundance and diversity) compared to those within protected and undisturbed habitats. Our results reveal that several human activities like human encroachment into riverine habitats potentially threaten the existence of freshwater species in this biodiversity hotspot and biodiversity hotspots elsewhere." **19012.** Manasov, S.; Suhling, F. (2020): Hiding among traps? Mortality of early instar odonate larvae in the presence of bladderwort plants. *International Journal of Odonatology* 23(2): 103 -111. (in English) ["We investigated the effects of the presence of bladderwort plants on survival of early instar larvae of one coenagrionid and two libellulids in laboratory experiments. In all three species survival was reduced compared to treatments with a non-carnivorous submerged plant, with effective mortality that could be related to bladderwort being 19–45% dependent on the prey species. Individuals of all species were found in capture bladders. We also recorded the microhabitat use of the early instar larvae and found that the species with highest use of vegetation had highest mortality due to bladderwort. We conclude that bladderwort may have effects on odonate larvae that translate into natural conditions and we discuss factors that may affect predation by bladderwort on odonates in the field." (in German, with English summary) ["Changes in the dragonfly fauna on the island of Wolin (Baltic Sea, Poland) – a case study – Changes in the dragonfly fauna of the Island of Wolin (Baltic Sea) are shown on the basis of two studies at ten selected waterbodies. The first study took place between 1970 and 1976, the second 2018 and 2019. The temporal comparison reveals the immigration of eleven new species, while three species could not be recorded anymore. For each water body the species-exchange-quota is rather high. The findings are discussed

mainly in the light of climatic changes." (Author)] Address: Masius, P., Talstr. 56, 35457 Lollar, Germany. E-mail: patrick\_masius@gmx.de

**19014.** Meijer, A. (2020): Voortplantingspoelen van de gevlekte witsnuitlibel in het duingebied van Kennemerland. Onderzoek naar de verspreiding en voortplantingslocatievoorkeur van de gevlekte witsnuitlibel (*Leucorrhinia pectoralis*) in de Amsterdamse Waterleidingduinen en het Noordhollands Duinreservaat [Reproduction pools of the large white-faced darter in the dune area of Kennemerland. Research on the distribution and reproductive site preferences of *Leucorrhinia pectoralis* in the Amsterdam Water Supply Dunes and the Noordhollands Duinreservaat]. BSc. thesis, Aeres Hogeschool Almere: 31 pp. (in Dutch, with English summary) ["In 2018, *L. pectoralis* was discovered at a number of new locations in the Dutch dunes. Despite the fact that *L. pectoralis* is appointed as a target species for the Noordhollands Duinreservaat area, under the Habitats Directive of the European Union (Natura 2000), not much is known about the habitat preferences of this dragonfly in coastal areas. In this study, it was examined in which specific bodies of water this species reproduced in 2018. Every dune pool with a known observation from 2018 was re-examined in 2020 to find out whether the dragonfly had reproduced. When the species was discovered at a pool in both 2018 and 2020, this pool was designated as a reproductive site. Twenty pools where the dragonfly was not observed in 2018 were also examined. If the dragonfly was not observed in 2020, the pool was designated as a non-reproductive site, and would thus function as a control pool. Subsequently, various characteristics of the reproductive and non-reproductive sites were compared, in order to answer the main question: What are the specific physical and botanical characteristics of the reproductive pools of *L. pectoralis*, in the Noordhollands Duinreservaat and the Amsterdamse Waterleidingduinen? Results indicate that *L. pectoralis* in the dunes of Kennemerland reproduce in, on average, larger pools that are largely sedimentized, and contain a well-developed submersed and riparian vegetation. All examined pools, reproductive and non-reproductive, contained submersed vegetation, with a coverage larger than 50%. Reproductive sites did however contain a higher percentage of riparian vegetation, with no upper limit restrictions, since the dragonfly reproduced in pools with banks covered with vegetation. The sedimentation percentage of the reproductive sites was, on average, greater than that of the non-sedimentized sites, 41.7% and 25% respectively. There was, however, an upper limit to the percentage of sedimentation of 60%. The dragonfly will not recognize a body of water if the percentage of sedimentation is over 60% and thus will not reproduce at this site. To take the dragonfly into account when performing management, it is advisable to make sure the pools are not too deep and to avoid rigorous cleaning, to stimulate sedimentation and the development of riparian vegetation. If the sedimentation process progresses beyond 60% sedimentation, it is advisable to clean the pool, leaving half of the riparian vegetation and a third of the submersed vegetation intact." (Author)] Address: not stated

**19017.** Nakanishi, K.; Koide, D.; Yokomizo, H.; Kadoya, T.; Hayashi, T.I. (2020): Investigating effect of climate warming on the population declines of *Sympetrum frequens* during the 1990s in three regions in Japan. *Scientific Reports* 10:12719: 10 pp. (in English) ["Climate warming is of concern as a key factor in the worldwide decline in insect populations. In Japan, numbers of a common dragonfly in rice paddy fields, *Sympetrum frequens*, decreased sharply in the 1990s. Because *S. frequens* migrates to cooler mountains in summer, climate warming has been suggested as one of the main causes of the population decline in addition to agronomic factors. Here, we analysed the relation between summer temperatures and population densities of *S. frequens* and the related *S. infuscatum*, which does not

migrate to mountains in summer, using published population monitoring data and temperature data from three regions (Toyama, Ishikawa, and Shizuoka) in Japan. Decadal differences in summer temperatures lay within the range of fluctuations among years, suggesting that an increase in summer temperatures cannot explain the past sharp population declines. However, regression analyses using monitoring data from Toyama showed that the population dynamics of both species in autumn are negatively correlated with summer temperatures in the same year. These results suggest that high temperatures in summer directly affect adult mortality to an extent that results in a decrease in population growth." **19021.** Odume, O.N. (2020): Searching for urban pollution signature and sensitive macroinvertebrate traits and ecological preferences in a river in the Eastern Cape of South Africa. *Ecological Indicators* 108 (2020) 105759: 10 pp. (in English) ["Urbanisation of riverine landscapes is a major threat to river ecosystems because of the ecological consequences of the so called urban stream syndrome. Taxonomically, certain macroinvertebrate metrics such as the diversity of species of Ephemeroptera, Plecoptera and Trichoptera (EPT) are known to be sensitive to urban pollution, whereas chironomids and oligochaetes are relatively tolerant. Trait correlates of such taxonomic metrics are yet to be established even though traits are less constrained by geographical differences. Using the Swartkops as a case study of a river receiving urban pollution, the pattern of trait distribution in relation to a gradient of urban pollution was examined, and urban pollution signature and sensitive traits identified. Macroinvertebrates and physico-chemical analysis were undertaken over a period of three years between August 2009 and September 2012 at one control site and three impacted downstream sites. Seven traits resolved into 32 trait attributes including body size, respiration, body shape, mobility, biotope preference, preferred food, and feeding habits were fuzzy coded and analysed using RLQ and fourth-corner analyses. Of the 32 trait and ecological attributes, four, including large body size (> 20 to 40 mm), animal materials as preferred food, predation and a preference for vegetation biotope, which were associated with the impacted sites, and were also significantly positively correlated with at least one physico-chemical indicator of increasing

urban pollution were deemed signature traits. Three traits, swimming, fine particulate organic matter and grazing, associated with the control site, which showed significant negative correlations with at least one physico-chemical indicator of increasing urban pollution were identified as sensitive traits. The results indicate that urban pollution differentially influenced macroinvertebrate traits, with the identification of pollution signature and sensitive traits seen as an important step towards the development of trait-based indices for riverine monitoring of urban pollution effects." (Author) Odonata are treated at the family level.] Address: Odume, O.N., Unilever Centre for Environmental Water Quality, Institute for Water Research, Rhodes University, P.O. Box 94, Grahamstown, South Africa

**19022.** Orda-Dejtz, C. (2020): Besiedelung renaturierter Moorflächen durch Amphibien und Libellen in der Neumarkter Passlandschaft. MSc thesis, Karl-Franzens-Universität Graz: 276 pp. (in German, with English summary) ["This study deals with the Amphibians and Odonata of four revitalized and recultivated peat bog areas in the „Neumarkter Passlandschaft“ (near Murau, Styria, Austria) in 800-900m a.s.l. Field trips were conducted in the year 2016 for Amphibians (26 field days/nights from March to September) and dragonflies (5 visits per site from May to September) to get information about the recultivating success and the species composition and abundance of both groups within the four study sites. In context of this work a positive acceptance was documented for the studied water bodies both by amphibians and dragonflies. Species-specific preferences concerning vegetational cover, habitat structures and aquatic parameters were registered. In total 8 species of Amphibia and 23 of Odonata were detected. The species richness and the abundance of species increased in recultivated areas with increasing age of the sites. The number of aquatic habitats and the size of the water body are limiting factors at the sites. Semi-natural standing water bodies with a high occurrence of vegetational and structural elements are recorded as species rich, but size and depth of the water body do not seem to have great influence on the species composition of the two animal groups. The increasing diversity of vegetation and habitat structures according to increasing age of the peat bog areas has a positive influence on species diversity and abundance. By individual recognition of yellow-bellied toads (*Bombina variegata*), it was possible to document migratory behavior of single individuals. Photographs of 72 toads were made, 11 could be recaptured. A maximum migration distance of 110m was documented." (Author)] Address: not stated

(2020): Macroinvertebrados como bioindicadores de la calidad del agua de la parte céntrica del río Jipijapa - Ecuador. *Recimundo* 4(4): 454-467. (in Spanish, with English and Portuguese summaries) ["The following research was conducted in the city of Jipijapa with the use macroinvertebrates as bioindicators of the water quality of the central part of the Jipijapa river. One of the main problems of the River is the discharge

of untreated domestic wastewater, because it receives a high load of nutrients and organic matter, whose degradation is critical for the water quality that flows through its channel. In this research the evaluation was carried out using benthic macroinvertebrates as bioindicators of water quality, using the following methodology with the application of the Biological Monitoring Working Party (BIPA), the technique used in the study was the Surber to capture the individuals studied, the results showed that the only order found in the study area is Odonata, of which five families and six genera were identified with a total of 93 individuals analyzed, after the field study and laboratory was obtained a total of 34 points which is within the range (16-35), concluding that the water quality in the Jipijapa river is bad and very polluted according to the applied biological index, which evidences effects of contamination." **19024.** Outomuro, D.; Utku Urhan, A.; Brodin, A.; Johansson, F. (2020): Preference for supernormal stimuli tends to override initially learned associations for conspicuous prey traits: implications from a laboratory study. *Journal of Ethology* 38: 365-371. (in English) ["How predators select on conspicuous prey traits is not well understood. We used a laboratory setup to investigate the role of learning in predator choice of conspicuous visual traits. We used a generalist predator, the great tit, and coloured wings of males of two species of damselflies as prey. Wing pigmentation differs between the species in colour (green [*Calopteryx virgo*] vs. blue [*Calopteryx splendens*]) and size (large vs. small). Wing pigmentation is a sexually selected trait that experiences negative selection by avian predators. Inexperienced great tits showed no preference for the colour or the size of wing pigmentation. Great tits were then repeatedly exposed to rewarded wings with either large or small wing patch size. When these experienced birds were exposed to both wing patch sizes for the first time, they tended to prefer the wings with the large patch, irrespective of their previous experience. Our results suggest that the choice of the predator was based on an initial association of the trait to a reward followed by a preference for a supernormal stimulus, probably due to a larger sensory stimulation. We discuss the implications of our laboratory results in the light of previous estimates of damselfly predation risk under field conditions." **19025.** Pastorino, P.; Brizio, P.; Abete, M.C.; Bertoli, M.; Oss Noser, A.G.; Piazza, G.; Prearo, M.; Elia, A.C.; Pizzul, E.; Squadrone, S. (2020): Macroinvertebrates as tracers of rare earth elements in freshwater watercourses. *Science of the Total Environment* 698 (2020) 134282: 9 pp. (in English) [Highlights: • Rare earth elements were detected in

macroinvertebrates from six watercourses. • Higher concentrations were measured in sites affected by anthropogenic activities. • A positive correlation exists between La, Ce, Gd and collector-gatherer density. • Functional feeding guilds of macroinvertebrates influenced REE accumulation. • Macroinvertebrates appear to be good indicators of REEs. Abstract: Rare earth elements (REEs) are emergent contaminants in aquatic ecosystems in parallel with their growing use in science, technology, and industry. In this study we measured the concentration of 16 REEs in freshwater macroinvertebrates from 6 watercourses in northeast Italy to determine their potential use as ecological tracers of REEs in aquatic ecosystems. The total REE concentration at the sampling sites followed this order: site 6 (7.05 mg Kg<sup>-1</sup>) N site 3 (5.76 mg Kg<sup>-1</sup>) N site 4 (3.58 mg Kg<sup>-1</sup>) N site 1 (3.0mg Kg<sup>-1</sup>) N site 5 (2.36 mg Kg<sup>-1</sup>) N site 2 (1.95 mgKg<sup>-1</sup>). There were no significant differences in REE concentrations across the six samplings sites (Kruskal Wallis test, p=0.1773), but two (site 3 and 6) had higher amount of REEs and were classified with the ecological status "Moderate" sensu Water Framework Directive since affected by anthropogenic activities. Light REE were always greater than heavy REE concentrations at all six sites. A positive correlation was observed between certain REEs (La, Ce, Gd) and the density of genera *Caenis* and *Baetis* (Ephemeroptera, collectorgatherers) (pS range 0.795–0.812), suggesting that non-predatory macroinvertebrates accumulate more REEs than predatory organisms and that the intake of sediment is the most effective route of assimilation." **19026.** Pearce-Higgins, J.W.; Chandler, D. (2020): Do surveys of adult dragonflies and damselflies yield repeatable data? Variation in monthly counts of abundance and species richness. *Journal of Insect Conservation* 24: 877-889. (in English) ["There is considerable debate over the most appropriate method for surveying dragonflies and damselflies (odonates). Using data from 62 survey locations nested within 26 waterbodies at 15 sites (discrete parcels of common ownership) in West Suffolk, UK, we show that short (20 m line transects or 3 min duration point counts), monthly counts of adults are repeatable. Correlations between predictions from models accounting for variation in ambient conditions and time of day and 52 separate counts used for validation equalled  $r = 0.87$  for total abundance and  $r = 0.75$  for species richness. Correlation coefficients between observed and modelled abundance exceeded 0.5 for eight of fourteen species modelled individually. Ambient temperature was the most important weather variable that influenced survey results, affecting the abundance of nine species, total abundance and species' richness. Most of the spatial variation in survey results was between waterbodies, rather than between sites or at individual survey locations, suggesting that adult counts may indicate aspects of waterbody quality, although differences in these patterns were observed between Anisoptera and Zygoptera. Encouraging relatively infrequent and rapid counts of flying adults may

therefore be used to increase volunteer participation in citizen (community) science odonate monitoring schemes whilst also providing repeatable abundance and species richness data that can contribute to research and monitoring programmes." **19028.** Pérez, P.; Ruiz-Herrera, A.; SanLuis, A.M. (2020): Management guidelines in disturbance-prone populations: the importance of the intervention time. *Journal of Theoretical Biology* 486, 7 February 2020, 110075: (in English) ["Highlights: • There exists a broad range of management strategies to mitigate the possible damages after a natural catastrophe. However, their efficacy in real situations is not well understood. • We derive management guidelines in disturbance-prone populations regarding the external introduction of individuals and the ecological restoration. • The intervention time plays a critical role in the efficacy of most management strategies. • The presence of disturbance events produces many non-monotone and unexpected behaviours in the populations. • We illustrate our results with real data from three different species, mayfly, dragonfly and ostracod. Abstract: The use of conservation and management practices to buffer possible damages after disturbance events is growing to become popular worldwide. However, little is known about their efficacy in real-life situations. To fill this gap, we will derive management guidelines in disturbance-prone populations regarding the external introduction of individuals and the ecological restoration. We will also discuss the efficacy of these practices in the population dynamics of three species (a fast life-cycle mayfly, a slow life-cycle dragonfly and an ostracod) when their habitat suffers from periodic controlled flooding. One of the main messages of this paper is that the interplay between the inherited parameters of the population and disturbance events is a source of rich and unexpected behaviours. More importantly, intervention time plays a critical role in the performance of many management strategies." **19029.** Pestana, G.C. (2020): Seleção sexual e a ordem

Odonata: uma abordagem teórica e experimental. *Dissertação Universidade Federal de São Carlos, Centro de Ciências Biológicas e da Saúde, Programa de Pós-Graduação em Ecologia e Recursos Naturais*: 73 pp. (in Portuguese, with English summary) ["Sexual Selection theory was proposed by Darwin in 1871 and, thenceforth, has been widely discussed and tested in several taxonomic groups. Complementary hypotheses were formulated by different researchers aiming to understand the mechanisms and evolutionary processes related to sexual secondary characters and reproductive behaviors. Insects of the order Odonata, also known as dragonflies and damselflies, are used as models due to the presence of coloring patterns on the body and wings that act as sexual ornaments, and the diversity of behaviors related to reproduction. Thus, studies on the use of sexual traits before and after copulation, in different mating systems, are carried out with different species in this group. In this context, the present dissertation is focused in evolutionary models of sexual selection in odonates as study models. The first part contains two chapters: the first is a review of the mechanisms, costs and some hypotheses related to sexual selection, mainly related to the presence and function of sexual ornaments in males; and the second chapter, a scientometric analysis of published studies on the role of male sexual ornamentation and the different sperm competition strategies. The results of the scientometric analysis showed a difference in pre- and post-mating studies, in relation to the years in which there is a greatest number of publications with these themes, countries where the studies were developed, species analyzed and main authors. In the second part of this dissertation an observational study was carried out in order to verify the relationship between pre- and post-mating sexual traits, analyzing wing pigmentation proportion, sperm viability, total number of sperm, muscle mass, fat reserve and body size in two species: *H. longipes* and *H. rosea*. The results were discussed based on two hypotheses of sexual selection: the sperm competition game, which proposes a trade-off between sexual traits; and the fertility-linked phenotype, which predicts that the male sexual ornament co-vary with the individual's fertility. The results obtained suggest that both hypotheses can be corroborated, since males of *H. longipes*, presented a trade-off between the traits evaluated, while males of *H. rosea* presented a positive relationship between these traits." **19030.** Piersanti, S.; Rebora, M.; Salerno, G. (2020): The antennal pathway of dragonfly nymphs, from sensilla to the brain. *Insects* 11(12). 10.3390/insects11120886: 15 pp. (in English) ["Simple Summary: The study of the sensory biology in aquatic insects undergoing incomplete metamorphosis, passing from nymphal life in fresh water to adult aerial life, provide great opportunities to understand how Arthropod nervous systems can adapt in response to critical ecological challenges. Here we investigate the antennal sensilla, and the related sensory pathways in the brain, of nymphs of an evolutionarily ancient hemimetabolous aquatic insect,

the dragonfly *Libellula depressa*, and compare them with previous data on adults. While antennal sensilla are dramatically different between *L. depressa* nymphs and adults, responding to the need to perceive different cues in water and air, the general morphology of the brain and the sensory circuitry remain quite similar during development. That suggests that the same brain centers are able to process highly diverging information, provided through different sensory structures adapted to water and air. This is in agreement with developmental plasticity that serves as a mechanism to maintain functionality throughout ontogenesis, when the lack of a pupal stage does not allow metamorphic changes of the nervous system. The present data also advance the knowledge on the biology of Odonata, threatened insects in fragile ecosystems, and thus present important results from an evolutionary and conservation biology perspective. Abstract: Dragonflies are hemimetabolous insects, switching from an aquatic life style as nymphs to aerial life as adults, confronted to different environmental cues. How sensory structures on the antennae and the brain regions processing the incoming information are adapted to the reception of fundamentally different sensory cues has not been investigated in hemimetabolous insects. Here we describe the antennal sensilla, the general brain structure, and the antennal sensory pathways in the last six nymphal instars of *L. depressa*, in comparison with earlier published data from adults, using scanning electron microscopy, and antennal receptor neuron and antennal lobe output neuron mass-tracing with tetramethylrhodamin. Brain structure was visualized with an anti-synapsin antibody. Differently from adults, the nymphal antennal flagellum harbors many mechanoreceptive sensilla, one olfactory, and two thermo-hygroreceptive sensilla at all investigated instars. The nymphal brain is very similar to the adult brain throughout development, despite the considerable differences in antennal sensilla and habitat. Like in adults, nymphal brains contain mushroom bodies lacking calyces and small agglomerular antennal lobes. Antennal fibers innervate the antennal lobe similar to adult brains and the gnathal ganglion more prominently than in adults. Similar brain structures are thus used in *L. depressa* nymphs and adults to process diverging sensory information." (2020): Species diversity of Odonata in Mimbilisan Protected Landscape, Misamis Oriental, Philippines. *Asian Journal of Conservation Biology* 9(2): 280-289. (in English) ["The sensitivity of Odonata to changing ecological conditions makes this group an effective indicator of aquatic and terrestrial health. The present study aimed to determine the species diversity and endemism of Odonata in Mimbilisan Protected Landscape. Sampling activity was conducted on July 18 to 28, 2017, using sweep-netting and handpicking methods in two forested sites and one riparian site. 176 individuals comprising 27 species under 10 families and 18 genera of Odonata were documented. Overall, endemism was recorded at 62.96%, including five species exclusive to Mindanao Island. *Orthetrum prunosum* clelia and *Risicnemis appendiculata* were the most abundant dragonfly and damselfly species, respectively. Findings also revealed highest species richness ( $S=24$ ) and diversity ( $H'=2.732$ ) in the forest stream (riparian site). Even distribution of species was observed in all sampling sites. Human-made disturbances were observed in the area. High level of endemism and moderate diversity of Odonata indicate that Mimbilisan Protected Landscape is a healthy area and conservation measures need to be sustained." **19036.** Rodríguez-Tapia, G.; Rocha-Ortega, M.; Córdoba-Aguilar, A. (2020): An index to estimate the vulnerability of damselflies and dragonflies (Insecta: Odonata) to land use changes using niche modeling. *Aquatic Insects* 41(3): 254-272. (in English) ["We developed an index of vulnerability for odonates (IVO) that occurred predominantly in Mexico to assess land use change. Vulnerability was defined as a function of A) habits of the species and B) ecological niche models. Index validation was done by relating it to rate of vegetation cover change, with the habitat preferences of each species and with species' sensitivity to habitat deterioration. Thus, the most sensitive species would be found in

areas with no change in land use. IVO values ranged from a maximum of three (i.e., the most sensitive) to a minimum of one (i.e., the least sensitive). As it was demonstrated in other studies, odonates did not show a clear preference between conserved and perturbed land uses. Interestingly, the few sensitive species were clearly resilient and can be found in a wide range of land use types, thus they may be more generalist than previously thought." **19038.** Romero-Lebrón, E.; Gleiser, R.M.; Petrulevicius, J.F. (2020): Geometric morphometrics of endophytic oviposition traces of Odonata (Eocene, Argentina). *R. Soc. Open Sci.* 7(12): 201126: 14 pp. (in English) ["The insertion of the Odonata ovipositor in the plant tissue generates a scar that surrounds the eggs (trace). In insects, individual egg traces are known to vary in size, but their variation in individual shape is mostly unknown. 24 specimens were obtained from the Laguna del Hunco (Lower Eocene, Chubut) and Río Pichileufú (Middle Eocene, Río Negro), Argentina, which had 1346 oviposition traces (MEF Collection). For the first time, a study of the shape and size of a large number of individual Odonata endophytic egg traces was carried out using traditional (general and mixed linear models) and geometric morphometrics (Fourier elliptical series) to elucidate whether there are changes in size or shape of the individual endophytic egg traces associated with the substrate used at the time of oviposition, if the Lower Eocene traces have varied in relation to those of the Middle Eocene, and if the ichnological classification (*Paleoovoidus arcuatus*, *P. bifurcatus* and *P. rectus*) reflects such variations. We found differences in size ( $p < 0.05$ ), but not in shape, in relation to the variables studied. This could reflect that the shape of Odonata eggs (inferred from the traces), unlike their size, could have a strong evolutionary constraint already observed since the Eocene." (2020): Value of artificial ponds for aquatic insects in drought-prone southern Africa: a review. *Biodiversity and Conservation* 29: 3131-3150. (in English) ["Artificial ponds assure continuous societal water supply, especially during droughts. Obligate aquatic and amphibiotic insects readily inhabit novel water bodies, as many possess mobility traits for opportunistic colonization. We review here the value of artificial ponds (<2 ha) (and reservoirs; >2 ha) for local aquatic insect diversity in mostly dry and drought-prone southern Africa. We compare these ponds to natural pools, wetlands, and stream deposition pools. The region has a highly varied topography and physiographical zones. Flat, arid areas largely support widespread insect generalists, while the mountainous orographic zones support an additional rich fauna of localized endemics. However, the many ponds (>0.5 million) have greatly changed the local distribution patterns of surface freshwater across the region, increasing the area of occupancy for many aquatic insect species, especially dragonflies. We focus on the extent to which aquatic insect assemblages have benefitted from new ponds and reservoirs. We conclude that these novel ecosystems benefit almost all lentic aquatic insect species, while also enabling population resilience during droughts. However, while these benefits are substantial, these ponds are not a substitute for natural still waters, which are still required to maintain all indigenous lentic aquatic insect diversity.] Address: Deacon, C., Dept of Conservation Ecology & Entomology, Stellenbosch University, South Africa. (2020): The evolutionary history of colour polymorphism in *Ischnura* damselflies (Odonata: Coenagrionidae). *Odonatologica* 49(3/4): 333-370. (in English) ["A major challenge in evolutionary biology concerns how genetic and phenotypic variation is created and maintained. In this study, we investigated the origin(s) and evolutionary patterns of the female-limited colour polymorphism in *Ischnura*. This involves the presence of one to three colour morphs: one androchrome morph with coloration that resembles that of the male, and two gynochrome morphs (*infuscans* and *aurantiaca*) with a female-specific coloration. We documented the colour of 44 and mating system of 36 of the 76 species within *Ischnura* to investigate the ancestral state of both traits and the correlated evolution and to infer directionality of trait-state transitions. The ancestral state reconstructions suggest that the most recent common ancestor of the *ischnuran* damselflies was most likely polymorphic and polyandrous. Our results give some support to the evolutionary correlation between female-limited colour polymorphism and mating system in *Ischnura*. That correlation is consistent with the idea that sexual selection through sexual conflict over the frequency of matings has selected for polymorphic females to reduce the overall intensity of male mating harassment, and our finding that the same phenotypic morphs have evolved multiple times (convergent evolution) suggests that several species in this genus might be experiencing similar selective pressures." **19044.** Schmidt Furieri, K.; Dondoni Colombo, L. (2020): A contribuição da coleção entomológica da Reserva Natural Vale para Odonata (Insecta). *Tópicos Integrados de Zoologia* 2: 10-17. (in Portuguese, with English summary) ["The dragonflies and damselflies (Odonata) are predatory insects that need water to reproduce. The males, sexually active, seek to live near to aquatic environments, and females visit the water, usually for copulation (mating) and laying (egg release). Biological collections are important sources of information. So that collections can, for example, effectively contribute to the construction and updating of the lists of Threatened Species, the specimens deposited therein must be identified at the species level and their data organized in a digital repository of records. This work aims to analyze the information available in the repository of records of the Reserva Natural Vale (RNV) about the Order Odonata. We found 200 specimens of Odonata, of which 18 (9%) are Aeshnidae, seven (3.5%) are Calopterygidae, 15 (7.5%) are Coenagrionidae, one (0.5%) are Dictyodidae, 129 (64.5%) are Libellulidae, four (2%) are Heteragrionidae and 26 are (13%) specimens without any identification. Considering that 45 (21%) of the species registered in Espírito Santo (Brazil) do not have information about the locality of occurrence, identifying all the specimens and performing a biological survey for Odonata in the RNV may contribute significantly to the knowledge about this group of insects and to the analysis of the risk of extinction, as well as to the conservation of the species that inhabit there. Considering that there is no information on the place of occurrence for 21% (45) of the species recorded in Espírito Santo, the identification of the unidentified specimens and a specific survey for Odonata in the RNV may contribute significantly to the knowledge on this group of insects and for the analysis of the risk of extinction, as well as for the conservation of the species that live there. We suggest the increase in the collection of specimens from the RNV, since there is no systematized survey of these insects for this area. Even with few specimens of Odonata identified at the species level, the information available in the book of record of the Vale Natural Reserve (RNV) showed its relevance, because records of two species of dragonflies threatened with extinction were found. Therefore, the identification of the remaining dragonflies (85.5%) recorded in the yearbook may significantly contribute to the understanding of Odonata in Espírito Santo and consequently in Brazil." **19046.** Shah, R.D.T.; Sharma, S.; Bharati, L. (2020): Water diversion induced changes in aquatic biodiversity in monsoon-dominated rivers of Western Himalayas in Nepal: Implications for environmental flows. *Ecological Indicators* 108: 8 pp. (in English) ["Highlights: • Water diversions for irrigation, water mills, and micro-hydropower are prolific. • Effects of water diversions on the macroinvertebrate community composition are significant. • Macroinvertebrates abundance is sensitive metric rather than taxonomic richness. • Stream flow during baseflow season is critical for maintaining aquatic biodiversity. Abstract: Water diversion projects across the world, for drinking water, energy production and irrigation, have threatened riverine ecosystems and organisms inhabiting those systems. However, the impacts of such projects on aquatic biodiversity in monsoon-dominated river ecosystems are little known, particularly in Nepal. This study examines the effects of flow reduction due to water diversion projects on the macroinvertebrate communities in the rivers of the Karnali and Mahakali basins in the Western Himalayas in Nepal. Macroinvertebrates were sampled during post-monsoon (November), baseflow (February) and pre-monsoon (May) seasons during 2016 and 2017. Non-metric Multidimensional Scaling (NMDS) was performed to visualize clustering of sites according to percentage of water abstractions (extraction of water for various uses) and Redundancy Analysis (RDA) was used to explore environmental variables that explained variation in macroinvertebrate community composition. A significant pattern of macroinvertebrates across the water abstraction categories was only revealed for the baseflow season. NMDS clustered sites into three clumps: "none to slight water abstraction (<30% – Class 1)", "moderate water abstraction (>30% to <80% – Class 2)" and "heavy water abstraction (>80% – Class 3)". The study also showed that water abstraction varied seasonally in the region (Wilk's Lambda = 0.697,  $F_{(2, 28)} = 4.215$ ,  $P = 0.025$ ,  $\eta^2 = 0.23$ ). The RDA plot indicated that taxa such as Acentrella sp., Paragenetina sp., Hydropsyche sp., Glossosomatinae, Elmidae, Orthocladiinae and Dimesiinae were rheophilic i.e. positively correlated with water velocity. Taxa like Torleya sp., Caenis sp., Cinygmmina sp., Choroterpes sp., Limonidae and Ceratopogoniidae were found in sites with high proportion of pool sections and relative high temperature induced by flow reduction among the sites. Indicator taxonomic groups for Class 1, 2 and 3 water abstraction levels, measured through high relative abundance values, were Trichoptera, Coleoptera,

Odonata ["Gomphidae"] and Lepidoptera, respectively. Macroinvertebrate abundance was found to be the more sensitive metric than taxonomic richness in the abstracted sites. It is important to understand the relationship between flow alterations induced by water abstractions and changes in macroinvertebrates composition in order to determine sustainable and sound management strategies for river ecosystems." **19047.** Sharma, P.; Kumar, D. (2020): Odonata diversity in and around Vadodara, Gujarat, India. *Entomon* 45(1): 43-51. (in English) ["Investigation on the diversity of Odonates revealed a total of 38 species belonging to two suborders, six families, and 24 genera in and around Vadodara, in Gujarat, which included 15 species of Zygoptera and 23 species of Anisoptera. Out of the 38 species, 10 species are new records for the Vadodara. Most number of species was found in water reservoirs as compared to urban ponds and area around Mahi River. Furthermore, it was observed that areas around the rivers were adversely affected because of nearby sand mining. Amongst damselflies and dragonflies the population of damselflies was richer. Renovation of urban ponds leads to decrease in their diversity due to loss of vegetation indicating anthropogenic pressure on species diversity." **19048.** Sigutova, H.; Šigut, M.; Kovalev, A.; Gorb, S.N. (2020): Wing wettability gradient in a damselfly *Lestes sponsa* (Odonata: Lestidae) reflects the submergence behaviour during underwater oviposition. *R. Soc. Open Sci.* 7: 201258: 11 pp. (in English) ["The phenomenon of hydrophobicity of insect cuticles has received great attention from technical fields due to its wide applicability to industry or medicine. However, in an ecological/evolutionary context such studies remain scarce. We measured spatial differences in wing wettability in *Lestes sponsa*, a damselfly species that can submerge during oviposition, and discussed the possible functional significance. Using dynamic contact angle (CA) measurements together with scanning electron microscopy (SEM), we investigated differences in wettability among distal, middle and proximal wing regions, and in surface nanostructures potentially responsible for observed differences. As we moved from distal towards more proximal parts, mean values of advancing and receding CAs gradually increased from 104° to 149°, and from 67° to 123°, respectively, indicating that wing tips were significantly less hydrophobic than more proximal parts. Moreover, values of CA hysteresis for the respective wing parts decreased from 38° to 26°, suggesting greater instability of the structure of the wing tips. Accordingly, compared with more proximal parts, SEM revealed higher damage of the wax nanostructures at the distal region. The observed wettability gradient is well explained by the submergence behaviour of *L. sponsa* during underwater oviposition. Our study thus proposed the existence of species-dependent hydrophobicity gradient on

odonate wings caused by different ovipositional strategies." (Authors)] Address: Šigutová, Hana, Department of Biology and Ecology/ENC, Faculty of Science, Univ. of Ostrava, Chittussiho 10, 71000 Ostrava, Czech Republic. E-mail: hana.sigutova@osu.cz

**19049.** Silva dos Anjos, C.; Milani, L.R.; Magalhães de Souza, M. (2020): Odonata (Insecta) species richness in the Parque Estadual do Ibitipoca, Southeast Brazil. *Revista Agrogeoambiental* 12(3): 79-90. ["There are few studies on Odonata communities in Brazil, even in its most deeply studied states, such as Minas Gerais. Therefore, it is proposed the presentation of results on the Odonata species richness of Parque Estadual do Ibitipoca (Ibitipoca State Park), located at the Zona da Mata region in the Minas Gerais state, Brazil. This Conservation Unit is considered a priority area for the conservation of the state's invertebrates. The objective of this study was to know the number of species within the area. 100 hours of sampling were carried out, distributed amongst five campaigns of four consecutive days between November 2016 and July 2017. There were recorded 20 different species, including a new record for the state and one potential new species. Species richness was low due to the sampling being focused exclusively on lotic systems, and also to the environment's homogeneity. Despite the low number of species, Parque Estadual do Ibitipoca is relevant to the conservation of the Minas Gerais state's Odonata." (Authors)] Address: Silva dos Anjos, C., Universidade Federal do Paraná, Setor de Zoologia, Programa de Pós-graduação em Entomologia. Discente. **19050.** So, K.Y.K.; Dudgeon, D. (2020): Conservation management of abandoned paddy fields in Asia: Semi-natural marshes with low-intensity bovid grazing have higher biodiversity. *Aquatic Conservation: Marine and Freshwater Ecosystems* 30(1): 1934-1944. (in English) ["1. Semi-natural marshland is becoming increasingly prevalent in Asia as a result of the continuing abandonment of rice cultivation. Although these marshes are important habitats for aquatic animals, they are susceptible to terrestrialization. Large mammalian herbivores that can retard terrestrialization are in decline globally, but domesticated bovids may serve as their surrogates, and could be used for managing semi-natural marshes. Relevant research in Asia is lacking, however. 2. Aquatic macroinvertebrates were sampled in both the wet and dry seasons from 26 freshwater marshes (abandoned paddy fields) across Hong Kong, encompassing 15 sites grazed by feral bovids (yellow cattle and water buffalo) and 11 ungrazed sites. The aim was to investigate seasonal variation in the effects of bovids on macroinvertebrate communities in monsoonal marshes. 3. Four decades after paddy cultivation had been abandoned, semi-natural marshes with low-intensity bovid grazing (0.06–0.14 cattle ha<sup>-1</sup>) had significantly higher (16%) site-scale  $\gamma$ -diversity. Macroinvertebrate communities at grazed sites had more Coleoptera and larval Odonata, and differed markedly from those at ungrazed sites. The effects of grazing on

diversity and composition were unaffected by season, but season itself was a significant predictor of  $\alpha$ - and  $\beta$ -diversity and species composition. 4. This study is the first to record the responses of aquatic macroinvertebrate diversity and composition to large-mammal grazing in Asian marshlands. Given that bovid grazing at low intensity can control plant growth, with concomitant benefits for wetland diversity, it is suggested that targeted grazing of short duration could be used for conservation management of abandoned paddy fields." **19051.** Sowa, A.; Krodkiewska, M.; Halabowski, D. (2020): How does mining salinisation gradient affect the structure and functioning of macroinvertebrate communities?. *Water Air Soil Pollut* (2020) 231: 453: 19 pp. (in English) ["Elevated salinity creates degrading conditions for the development of aquatic biota in different regions of the world. There is a need for research on freshwater salinisation in order to understand how this stressor alters ecosystem function and to predict changes in biodiversity globally. Such data are missing from Central Europe, and therefore, the presented study was performed in inland anthropogenic ponds with different salinity levels located in the second largest European hard coal basin. The researcher indicated a positive correlation between water salinity and the biomass and density of macrozoobenthos as well as the percentage of shredders and the abundance of alien species, whereas there was a decrease in taxa diversity and richness and the abundance of filtering and gathering collectors and predators along with increasing salinity. The survey showed that a high level of nutrients and organic matter were also significantly correlated with the distribution of the macroinvertebrate taxa and functional feeding groups. The conducted research confirmed that mining salinisation acts as a strong filter that shapes the biodiversity because it affects the composition, abundance, biomass and functional traits of benthic macroinvertebrates and significantly contributes to the invasion of alien species." (Authors) Taxa - including Odonata - are treated family wise.] Address: Sowa, Agnieszka, Inst. Biol., Biotech. & Environmental Protection, Faculty of Natural Sciences, Univ. of Silesia in Katowice, Bankowa 9, 40-007 Katowice, Poland. E-mail: agsowa@us.edu.pl

**19052.** Sparrow, D.J.; De Knijf, G.; Smith, M.S.; Sparrow, R.; Michaelides, M.; Konis, D.; Siedle, K. (2020): The circumtropical *Pantala flavescens* is a regular visitor to Cyprus and reproducing on the island (Odonata: Libellulidae). *Odonatologica* 49(3/4): 289-311. (in English) ["Although considered one of the most widespread dragonflies in the world, *Pantala flavescens* is rarely recorded in Europe and only irregularly observed in the eastern Mediterranean. The first published records of *P. flavescens* from Cyprus date back to 1957. There are no further published records from Cyprus until 2010 when a single individual and a copula were observed. The latter is also the first record of reproductive

activity of the species in the eastern Mediterranean. Since the systematic monitoring of Odonata in Cyprus began in 2013, *P. flavescens* has been recorded on the island every year with one to 13 records each year from 2013 to 2017, 45 in 2018, and with a significant increase to 146 records in 2019, giving a total of 237 records. Reproductive behaviour of *P. flavescens* has been observed 19 times on Cyprus and in 2018 we found a larva and a teneral male. Oviposition mode showed high plasticity and was observed in five cases in non-contact guarding behaviour; five times females were ovipositing alone (unguarded oviposition) and oviposition in tandem was seen only once. Our observations are the first proof of successful reproduction of *P. flavescens* in the eastern Mediterranean." (Author)] Address: Sparrow, D.J., Cyprus Dragonfly Study Group, P.O. **19053.** Su, X.; Zhang, K.; Zheng, J.; Zhao, Y.; Han, R.; Zhang, J. (2020): Investigation of high lift force generation of dragonfly wing by a novel advanced mode in hover. *Fluids* 2020, 5, 59: 16 pp. (in English) ["In the paper, a novel flapping mode is presented that can generate high lift force by a dragonfly wing in hover. The new mode, named partial advanced mode (PAM), starts pitching earlier than symmetric rotation during the downstroke cycle of the hovering motion. As a result, high lift force can be generated due to rapid pitching coupling with high flapping velocity in the stroke plane. Aerodynamic performance of the new mode is investigated thoroughly using numerical simulation. The results obtained show that the period-averaged lift coefficient,  $CL$ , increases up to 16% compared with that of the traditional symmetrical mode when an earlier pitching time is set to 8% of the flapping period. The reason for the high lift force generation mechanism is explained in detail using not only force investigation, but also by analyzing vortices produced around the wing. The proposed PAM is believed to lengthen the dynamic stall mechanism and enhance the LEV generated during the downstroke. The improvement of lift force could be considered as a result of a combination of the dynamic stall mechanism and rapid pitch mechanism. Finally, the energy expenditure of the new mode is also analyzed." (Authors)] Address: Su, X., School of Hydraulic Engineering, Dalian University of Technology, Dalian 116024, China. **19054.** Svensson, E.I.; Gomez-Llano, M.; Waller, J.T. (2020): Selection on phenotypic plasticity favors thermal canalization. *Proc. Natl. Acad. Sci. U.S.A.* 117: 29767-29774. (in English) ["Climate change affects organisms worldwide with profound ecological and evolutionary consequences, often increasing population extinction risk. Climatic factors can increase the strength, variability, or direction of natural selection on phenotypic traits, potentially driving adaptive evolution. Phenotypic plasticity in relation to temperature can allow organisms to maintain fitness in response to increasing temperatures, thereby "buying time" for subsequent genetic adaptation and promoting evolutionary rescue. Although many studies have shown that organisms respond plastically to increasing temperatures, it is unclear

if such thermal plasticity is adaptive. Moreover, we know little about how natural and sexual selection operate on thermal reaction norms, reflecting such plasticity. Here, we investigate how natural and sexual selection shape phenotypic plasticity in two congeneric and phenotypically similar sympatric insect species. We show that the thermal optima for longevity and mating success differ, suggesting temperature-dependent trade-offs between survival and reproduction in both sexes. Males in these species have similar thermal reaction norm slopes but have diverged in baseline body temperature (intercepts), being higher for the more northern species. Natural selection favored reduced thermal reaction norm slopes at high ambient temperatures, suggesting that the current level of thermal plasticity is maladaptive in the context of anthropogenic climate change and that selection now promotes thermal canalization and robustness. Our results show that ectothermic animals also at high latitudes can suffer from overheating and challenge the common view of phenotypic plasticity as being beneficial in harsh and novel environments." **19055.** Tang, C.; Zhang, X.; Li, J.; Li, Z.; Huang, M.; Duan, H.; Lu, Z.; Li, Q.; Chen, Y. (2020): Diversity and bioindication of Odonata in the Qinghuahai National Wetland Park in Baoshan City. *Wetland Science* 18(6): 712-718. (in Chinese, with English summary) ["In order to understand the species diversity of Odonata in Baoshan Qinghuahai National Wetland Park, the field surveys were conducted on the adults and larva of Odonata insects in the ecological conservation area, restoration and reconstruction area, rational utilization area of Baoshan Qinghuahai National Wetland Park and Datianba wetlands restored naturally by sweep-net and dipnet methods in July17-27, 2018, October 13-17, 2018, August 7-14, 2019, and June 19-22, 2020. The 205 adult specimens and 670 larval specimens of Odonata were collected, and the diversity of Odonata in 4 different regions of Qinghuahai National Wetland Park was analyzed. The results showed that 205 adult specimens belong to 24 species in 6 families, 8 genera, and 670 larval specimens belong to 25 species (morphological species) in 4 families, including 10 species of Odonata recorded newly in Baoshan city. There was no significant difference in terms of abundance, species richness and adaptive coherence estimator value of adults of Odonata among ecological conservation area, reconstruction and restoration area and rational utilization area in the wetland park, but species richness and adaptive coherence estimator value of larvae of Odonata in the reconstruction and restoration area were significantly lower than those in ecological conservation area and rational utilization area. The community structure of adults of Odonata in ecological conservation area was significantly different from those in reconstruction and restoration area and rational utilization area, there were significant differences in the community structure of larvae of Odonata in the 4 areas. Totally, there were high level of Odonata diversity in ecological conservation area and rational utilization area, there was a low level of Odonata diversity in the reconstruction

and restoration area. The biological indicator effect of larvae of Odonata were better than that of the adults, and the identification of larvae at the morphological species level or the family level could meet the demand to indicate wetland environment quality." **19056.** Tang, Y.; Sun, H.; Qin, Z.; Yin, S.; Tian, L.; Liu, Z. (2020): Bioinspired photocatalytic ZnO/Au nanopillar-modified surface for enhanced antibacterial and antiadhesive property. *Chemical Engineering Journal* Volume 398, 15 October 2020, 125575: (in English) ["Highlights: • ZnO/Au nanopillars are fabricated by hydrothermal and photo-reduction. • PDMS-ZnO/Au shows a mechanical antimicrobial effect in the dark. • A two-fold antibacterial action occurs for PDMS-ZnO/Au under visible light. • The modified PDMS could also function as an antifouling surface. Abstract: Biological contamination of surfaces is a thorny issue that brings series of adverse factors to the daily life and industrial manufacture. A dragonfly-wing-mimicking nanopillar array of ZnO/Au on Polydimethylsiloxane (PDMS-ZnO/Au) with two-fold bactericidal activity as well as the antiadhesive property has been developed. In this process, ZnO nanopillar is obtained using a hydrothermal method followed by the introduction of plasmonic gold nanoparticles (AuNPs) via a photo-reduction protocol. The obtained PDMS-ZnO/Au surface demonstrates physical antibacterial performance, resulting in a killing rate of 65.5% in dark. Furthermore, the surface effectively inactivates bacteria under visible light irradiation, yielding a lethality >99.9% in 30 minutes. The advantages of high lethality rate and short action time are endowed to PDMS-ZnO/Au by a two-fold antibacterial action combining the enhanced photocatalysis upon the introduction of Au nanoparticles and the mechanical property of biomimetic nanostructure. Meanwhile, the nanopillar-modified PDMS can also function as a superhydrophobic surface and efficiently impede bacterial adhesion by over 99.9%. Therefore, the approach presented here holds a promising solution to tackle biological contamination for medical paint, catheter and implant equipment." **19057.** Theodoropoulos, C.; Karaouzas, I.; Vourka, A.; Skoulikidis, N. (2020): ELF – A benthic macroinvertebrate multi-metric index for the assessment and classification of hydrological alteration in rivers. *Ecological Indicators* 108: 11pp. (in English) ["Hydrological alteration prevents unpolluted rivers from reaching acceptable ecological conditions. In Europe, 40% of rivers are degraded due to hydrological alteration but the indices currently used in ecological monitoring cannot quantify the degree of hydrological alteration or discriminate between pollution and hydrological alteration. In this article, we demonstrate the development, calculation and validation of the Hellenic Flow Index (ELF), a new macroinvertebrate-based multi-metric index to assess, quantify and classify hydrological alteration in Greek

streams and rivers. 1351 samples collected throughout Greece were partitioned in reference and test datasets and were pre-classified in varying levels of pollution and hydrological alteration. Optimal flow ranges for benthic macroinvertebrates were calculated and flow sensitivity metrics were developed. We tested the predictive accuracy of 607 versions of the ELF index, that is, 607 combinations of seven hydrologically sensitive macroinvertebrate metrics. The developed index is a combination of two ELF versions that had the highest predictive accuracy on two validation datasets. The index developed can assess, quantify and classify hydrological alteration and is also capable of discriminating between pollution and hydrological alteration. The ELF's overall predictive accuracy was 75% and the index was equally accurate in discriminating between clean, polluted and hydrologically altered sites. Within the regular ecological monitoring, water agencies, managers and decision makers can now use a tool that will quickly flag watercourses that specifically need hydrological restoration instead of pollution mitigation measures and thus apply targeted actions towards the ecological restoration of rivers." (Authors) Odonata are treated at the family level.] Address: Hellenic Centre for Marine Research, Institute of Marine Biological Resources & Inland Waters, 46.7 km Athens – Sounio Ave., 19013 Anavyssos, Greece

**19058.** Tüzün, N.; Debecker, S.; Stoks, R. (2020): Strong species differences in life history do not predict oxidative stress physiology or sensitivity to an environmental oxidant. *Journal of Animal Ecology* 89(7): 1711-1721. (in English) ["Species typically align along a fast-slow life-history continuum, yet it is not clear to what extent oxidative stress physiology can be integrated with this continuum to form a 'pace-of-life syndrome', especially so in invertebrates. This is important, given the assumed role of oxidative stress in mediating life-history trade-offs, and the prediction that species with a faster pace should be more vulnerable to oxidative stress. We tested whether a species' life-history pace, here represented by its growth rate, can predict species-level differentiation in physiology and sensitivity to oxidative stress. Therefore, we exposed four species of *Ischnura* damselflies that strongly align along a fast-slow life-history continuum to different levels of ultraviolet (UV) radiation. We measured an extended set of physiological traits linked to the pace-of-life: standard metabolic rate (SMR), oxidative stress physiology (antioxidant enzymes and oxidative damage), and defence/condition traits (investment in immune function, energy storage, and structural defence). Despite strong species differences in growth rate and physiology, growth rate did not predict species-level differentiation in physiology. Hence there was no support for the integration of metabolic rate, oxidative stress physiology or defence/condition traits into a species-level syndrome. UV exposure affected nearly all traits: it reduced growth rate and increased metabolic rate, affected all oxidative stress physiology traits and increased the two defence traits (immune function, and melanin content). Nevertheless, the pace-of-life based on growth rate did not predict sensitivity to UV. Instead, the observed pattern of investment in structural UV defence (melanin)

might have reduced the need for enzymatic antioxidant defence, this way potentially decoupling the covariation between the life-history pace and oxidative stress physiology. The absence of an integrated axis of life-history and physiological variation indicates no major constraints for the evolution of these traits among the studied damselfly species. Our study highlights that ecological differences between species may decouple covariation between species' life-history pace and their physiology, as well as their sensitivity to environmental stressors." **19059.** Tüzün, N.; De Block, M.; Stoks, R. (2020): Live fast, die old: oxidative stress as a potential mediator of an unexpected life-history evolution. *Oikos* 129(9): 1330-1340. (in English) ["Intraspecific latitudinal patterns in life history are well documented, yet underlying mechanisms of such patterns are poorly understood. To advance our insights in the evolution of latitudinal differences in two key traits, growth rate and lifespan, we evaluated the potential costs of rapid growth in terms of reduced adult lifespan, and the mediatory role of oxidative stress. We studied latitudinal differentiation in routine and experimentally increased (compensatory) larval growth rates, and in adult lifespan under common garden conditions in low- and high-latitude populations of the damselfly *Ischnura elegans*. The low-latitude populations showed not only higher routine growth rates but also a stronger compensatory growth response after a transient food shortage compared to the high-latitude populations. In contrast with a tradeoff scenario, adults of the faster growing low-latitude populations lived longer, had higher levels of antioxidant enzymes, and tended to experience lower oxidative damage. Importantly, these latitudinal patterns were largely mirrored at the treatment level, where experimentally induced compensatory growth rates were associated with neither oxidative damage nor shorter adult lifespans. Moreover, individuals with a higher growth rate after the transient food shortage did not have shorter adult lifespans or higher oxidative damage, but instead showed a stronger antioxidant defense. Our data indicate that an overcompensatory, hormetic response in antioxidant defense, potentially induced by the higher routine growth rates, resulting in less oxidative damage may underlie these unexpected growth-lifespan patterns. Our results highlight the added value of incorporating oxidative stress physiology, and the need to consider multivariate trade-offs in which animals optimize multiple traits, when studying life-history evolution." **19060.** Uboni, C.; Jugovic, J.; Tordoni, E.; Pizzul, E.; Riseriato, E.; Bacaro, G. (2020): Dragonfly (Odonata) diversity patterns in mixohaline coastal wetlands. *Estuaries and Coast* 43: 375-386. (in English) ["Salinity is a limiting factor for many invertebrates, especially for Odonata which are typically associated with freshwater ecosystems. In Europe, 15 Odonata species inhabit brackish wetlands and only few

detailed data on their tolerance towards salinity are available. We investigated Odonata fauna in 11 sampling stations situated in three estuarine areas (northern Adriatic coastline) which differed in salinity conditions (freshwater-polyhaline habitats) in order to assess affinity of Odonata species to brackish habitats and to describe their distribution pattern in coastal wetlands. Adults, exuviae (the remains of the exoskeleton after the last larval instar), and the main chemical and physical water parameters were sampled every 2 weeks for 1 year in each station. In total, 25 species were detected and 56% of them were able to complete their life cycle in brackish water environments. Our results showed that freshwater and oligohaline ponds were the most favorable for dragonflies, with an overall higher species richness. There was a high species turnover along the salinity gradient, with a strong differentiation among the communities along the gradient. Considering the exuviae, we observed a high specificity with respect to the habitat conditions (seven species exclusive of freshwater sites and six of oligohaline ones, respectively). Among the adults, four species were found exclusively in freshwater habitats and no species seemed to be strictly connected with oligohaline habitats. Coastal wetlands are composed by a mosaic of different habitats especially when freshwater and seawater are close together, supporting many Odonata species with different tolerance toward salinity conditions. They also provide useful insights for conservation and management actions. ... In total, we identified 4963 adults and 1907 exuviae belonging to 25 species of Odonata (Zygoptera: 7 spp., Anisoptera: 18 spp.). Considering the different habitat types (freshwater, oligohaline, mesohaline, and polyhaline water), 32% of species (*Coenagrion puella*, *C. scitulum*, *Aeshna isocetes*, *Orthetrum albistylum*, *Libellula depressa*, *Ischnura pumilio*, *Lindenia tetraphylla*, *Anax parthenope*) and 25% of species (*Aeshna cyanea*, *A. affinis*, *Lestes parvidens*, *L. depressa*, *C. scitulum*, *Hemianax ephippiger*, *Brachytron pratense*, *Orthetrum cancellatum*, *O. albistylum*, *Sympetrum fonscolombii*, *S. striolatum*, *S. vulgatum*, *I. pumilio*) were exclusive of only one habitat type for adults and exuviae, respectively. Moreover, 28% of adult species (*Anax imperator*, *O. cancellatum*, *Sympetrum meridionale*, *Erythromma viridulum*, *Ischnura elegans*, *Aeshna mixta*, *S. fusca*) were present in all habitat types, whereas none of all sampled species was breeding all along the gradient (Table S2 of supplementary material). We found a low share of rare species expressed as singletons and doubletons (namely the number of unique species represented by one or two individuals, respectively): one singleton (*L. tetraphylla*) and one doubleton (*A. isocetes*) for adults; for exuviae, four singletons (*I. pumilio*, *B. pratense*, *A. cyanea*, *H. ephippiger*) and no doubletons at all." **19061.** Uyizeye, E. (2020): Developing an odonate-based index for monitoring freshwater ecosystems in Rwanda: Towards linking policy to practice through integrated and adaptive management. Ph.D., Antioch University, Antioch New England: Environmental Studies: 179 pp. (in English)

["Worldwide, the decline of biodiversity in freshwater ecosystems is occurring at an alarming rate, due to anthropogenic threats, which directly impact humans in a variety of ways. Freshwater ecosystems occupy an integral part of political, socio-economic and ecological spheres. Integrated Watershed Management (IWM) and Adaptive Management (AM) conceptual frameworks provide an underpinning holistic platform from which to evaluate the performance of policies and actions on the ground in relation to freshwater ecosystem management. I investigate the extent to which environmental policies and practices embrace IWM and AM frameworks in Rwanda. Furthermore, this dissertation develops an odonate-based ecological monitoring tool, referred to as Dragonfly Biotic Index (DBI). The development of this tool involved surveying adult odonates, water physical-chemical variables, habitat characteristics and weather conditions across the six ecological zones of Rwanda. An average of 16 sites per each ecological zone were surveyed in a short rainy season and revisited in a short dry season. This countrywide survey added 25 new odonate species to the national check list, which increased it to 114 species. The abundance of odonates was significantly different between ecological zones and between seasons. The DBI developed here consists of three sub-indices: distribution-based score, sensitivity-based score and threat-based score as per IUCN Red List categories. To validate DBI, I examined its effectiveness in reflecting habitat integrity. This included using DBI to assess the relationship of land uses (agriculture and mining) and environmental, and physical-chemical variables of freshwater ecosystems. DBI values were significantly lower in agricultural and mining sites than their control sites. Also, significant changes in some environmental variables were associated with the two land uses. These included the degradation of riparian vegetation as associated with both agriculture and mining. While agriculture was significantly associated with higher conductivity, mining exhibited a significant relationship with higher water turbidity and higher sandy substrates than their control sites. In conclusion, not only will DBI enable deeper investigation of the extent to which land uses affect freshwater ecosystems, but also will be instrumental in prioritization for habitats that need crucial conservation. Additionally, this monitoring tool is meant to make data on ecosystem status readily available to facilitate analysis of ecological responses to socio-economic, political and pragmatic interventions. Thus, these data can be used to inform all spheres involved: ecological, political and socio-economic. The use of odonates, which are charismatic insects, will potentially engage and promote citizen-based monitoring. This will ultimately instill pro-environmental attitudes within local communities and set the stage for collaboration between stakeholders." (Author)] Address: not stated

**19062.** Valdivia, F.G.A.; Alves-Silva, E.; Del-Claro, K. (2020): Differences in size and energy content affect the territorial status and mating success of a neotropical dragonfly. *Austral Ecology* 45(6): 748-758. (in English) ["In male odonates, both size and fat content are related to territory defence and mating success. Males that are larger and have

higher energy reserves win relatively more disputes for territory and attract more females. Wing colour has also been regarded as a mechanism that influences agonistic behaviour between males, as wing pigmentation might be regarded as a sign of male quality. In this study, we analysed whether a set of male physical (body size and wing colour), physiological (body fat content) and behavioural (disputes between males) characteristics were involved in the territory defence and mating behaviour of the neotropical dragonfly *Zenithoptera lanei* Santos, 1941 (Anisoptera: Libellulidae). Males were characterised as territorial whenever they ward-off other males and remained in the same place within the pond for two consecutive days. In general, these territorial males were larger and had more abdominal and thoracic fat, engaged in pursuits more frequently, spent more time on sexual behaviour and female guarding, and mated more in comparison to subordinate males. By evaluating whether the percentage of wing area covered by black ink influenced male behaviour, we found that territorial males tended to act aggressively towards other males whose wings were partially painted, and sexually towards females irrespective of wing area painted. In *Z. lanei*, both body size and fat content play a role in defining territoriality. By subduing competitors and dominating preferred locations within high-quality sites, these males are likely to be visited by females and engage in mating." **19063.** Verheyen, J.; Stoks, R. (2020): Negative bioenergetic responses to pesticides in damselfly larvae are more likely when it is hotter and when temperatures fluctuate. *Chemosphere* 243, March 2020, 125369: (in English) ["Highlights: • Chlorpyrifos (CPF) reduced cellular energy allocation (CEA) in *Ischnura elegans*. • CPF had little effect on CEA values under standard test conditions (constant 20°C). • CPF reduced CEA, mainly at the most stressful (hottest) thermal regime. • CPF reduced CEA, mainly by reducing energy availability (fat and sugar declines). • Testing at standard conditions would underestimate the bio-energetic impact of CPF. Abstract: To make more realistic predictions about the current and future effects of pesticides, we need to better understand physiological mechanisms associated with the widespread higher toxicity of many pesticides under increasing mean temperatures and daily temperature fluctuations (DTFs). One overlooked, yet insightful, mechanism are bioenergetic responses as these provide information about the balance between energy gains and costs. Therefore, we studied how the bioenergetic responses to the insecticide chlorpyrifos were affected by a higher mean temperature and a higher DTF in *Ischnura elegans* damselfly larvae. To quantify bioenergetic responses we measured energy availability (Ea), energy consumption (Ec) and total net energy budget (cellular energy allocation, CEA). Exposure to chlorpyrifos considerably reduced CEA values when a high mean temperature was combined with a high DTF (up to -18%). Notably, chlorpyrifos had little effect on CEA at a constant 20°C, meaning that the bioenergetic impact of

chlorpyrifos would have been underestimated if we had only tested under standard testing conditions. The chlorpyrifos-induced reductions in CEA under warming were driven by reductions in Ea (up to -16%, mainly through large reductions in sugar and fat contents) while Ec was unaffected by chlorpyrifos. Treatment groups with a lower CEA value showed a higher mortality and a lower growth rate, indicating bioenergetic responses are contributing to the higher toxicity of chlorpyrifos under warming. Our study highlights the importance of evaluating the effects of pesticides under an increase in both mean temperature and DTF to improve the ecological risk assessment of pesticides under global warming." **19065.** Vorster, C.; Samways, M.J.; Simaika, J.P.; Kipping, J.; Clausnitzer, V.; Suhling, F.; Dijkstra, K.-D.B. (2020): Development of a new continental-scale index for freshwater assessment based on dragonfly assemblages. *Ecological Indicators* Volume 109, February 2020, 105819: 12 pp. (in English) ["Highlights: • A new, continental-scale freshwater assessment tool, African Dragonfly Biotic Index. • 604 African dragonfly species are evaluated. • This index determines deterioration or recovery of a freshwater site. • It also

compares freshwater quality at different sites. • The index is a foundation for developing other national Dragonfly Biotic Indices. Abstract: African freshwater ecosystems are increasingly being impacted by humans, requiring an effective tool to assess these impacts for future conservation action. Such a tool, the Dragonfly Biotic Index (DBI), was earlier developed to assess the quality of South Africa's freshwater ecosystems and is based on combining the scores of three sub-indices (geographical distribution, threat status, and habitat sensitivity) for each South African dragonfly species. The sum of the DBI scores for all the species recorded at assessed sites indicates the relative quality of these sites. The International Union for the Conservation of Nature/Species Survival Commission (IUCN/SSC) has assessed the threat status of certain aquatic taxa in Africa, including dragonflies. These assessments, coupled with the latest information on the geographical distribution of each species, makes it possible here to geographically expand the South African DBI into a continental-scale assessment index (the African Dragonfly Biotic Index (ADBI)) by adapting the South African DBI sub-indices. We develop this continental index here. However, there are challenges when undertaking an assessment at the continental scale compared to a national scale. In particular, the habitat sensitivity sub-index of the South African DBI is a relative, quantitative measure based on numbers of individual dragonflies recorded from natural versus human-modified or artificial freshwater systems. While the data for the two sub-indices, species' geographical distribution and Red List threat statuses, are available across the continent, this is not the case for the habitat sensitivity sub-index at this large spatial scale. This meant that an alternative sub-index measure was required. We overcame this challenge by exploring an alternative sub-index, i.e. the 'species vulnerability sub-index', based on knowledge of the vulnerabilities of the species to certain types of landscape transformation. Then, the species vulnerability sub-index scores were calculated and combined with the geographical distribution and Red List threat status sub-index scores to develop ADBI scores for a core of 604 dragonfly species with adequate data across the African continent. These ADBI scores provide a workable framework and baseline for determining freshwater quality, both lotic and lentic, relative to human disturbance at a continental spatial scale. The ADBI enables the monitoring of quality changes, for better or worse, over the continent in years to come. Overall, the ADBI also has the potential to help identify threats to, and sensitivities of, African freshwater ecosystems, leading to conservation action.] Address: Kipping, J., BioCart Ökologische Gutachten, Taucha/Leipzig, Germany. (in English, with German summary) ["25 species of Odonata were found on two short holiday trips to the southern part of the Dead Sea Basin in May 2018 and April 2019. Occurrence of *O. abboti* and *C. sanguinolenta* in Jordan was confirmed,

many new localities of *O. ransonnetii* in Israel and Jordan were discovered." (Author)] Address: Waldhauser, M., Petrovice 136, Jablonné v Podještědí, 471 25, Czech Republic. Email: martin.waldhauser@nature.cz

**19067.** Walia, G.K.; Devi, M. (2020): Cytogenetic characterization of five species of genus *Coeliccia* of family Platycnemididae (Odonata: Zygoptera) using C-banding, silver nitrate staining and sequence specific staining. *The Nucleus* 64(1): 1-6. (in English) ["Cytogenetic characterization of five species of genus *Coeliccia* of family Platycnemididae has been done by conventional staining, C-banding, silver nitrate staining and sequence specific staining. These species were collected from the localities present in Andretta, Bilaspur (Himachal Pradesh) and Nongkhyllem (Meghalaya), India. All the species possess  $n=13$  as haploid chromosome number, which is the type number of the family with X0-XX sex determining mechanism except *Coeliccia bimaculata* with  $n=12$ , originated by the fusion of two autosome pairs as complement is characterized by the presence of one large bivalent. m chromosomes are absent in all the species. Mostly, light/dark terminal C-bands and NOR's are seen on the autosomal bivalents, while X chromosome shows variations as large terminal C-band on one side of X chromosome is present in all the species except *C. renifera*, it is C-positive. Moreover, X chromosome possesses terminal NOR on one side in *C. chromothorax*, while NOR-positive in *C. renifera* and NOR-negative in *C. bimaculata*, *C. didyma* and *C. fraseri*. In sequence specific staining, autosomal bivalents are homogeneously stained with both DAPI and CMA3 dyes in *C. bimaculata*, *C. renifera* and *C. chromothorax*, while whole chromosome complement of *C. didyma* is CMA3 bright and *C. fraseri* is DAPI bright.] Address: Walia, G.K., Dept of Zoology & Environmental Sciences, Punjabi Univ., Patiala, Punjab, 147002, India

**19068.** Wan, L.; Long, Y.; Hui, J.; Zhang, H.; Hou, Z.; Tan, J.; Pan, Y.; Sun, S. (2020): Effect of norfloxacin on algae-cladoceran grazer-larval damselfly food chains: Algal morphology-mediated trophic cascades. *Chemosphere* 256 (2020) 127166: 11 pp. (in English) ["Highlights: • Without NOR, suppressed grazer density by damselflies promoted algal growth. • NOR increased the positive impacts of damselflies on *C. vulgaris* growth. • NOR reduced the positive impacts of damselflies on *S. quadricauda* growth. • NOR altered trophic cascades and showed species-specific differences. • The above differences depend on algal morphology-mediated indirect interactions. Abstract: Antibiotic norfloxacin (NOR) has recently been demonstrated to affect the swimming behavior of zooplankton species and phytoplankton-zooplankton interactions, which may further affect trophic cascades. To test this hypothesis, two food chains (*Scenedesmus quadricauda*-*Daphnia magna*-larval damselfly and *Chlorella vulgaris*-*D. magna*-larval damselfly) were used to examine the effect of NOR concentrations (0, 0.5, 5, and 25 mg L<sup>-1</sup>) on trophic cascades. In the absence of NOR, larval damselflies reduced grazer density and increased algal density, regardless of algal species. In the presence of NOR, increasing NOR concentration strengthened

the positive effect of larval damselflies on the growth of *C. vulgaris* because larval damselflies suppressed grazer density more efficiently resulting from reduced swimming ability in the grazers. Conversely, increasing NOR concentration reduced the positive effect on the growth of *S. quadricauda* due to inhibited grazer-induced colony formation in *S. quadricauda*. Therefore, exposure to NOR altered the direction and strength of trophic cascades and showed species-specific differences, depending on algal morphology-mediated indirect interactions. These findings provide novel insights into how NOR affects aquatic food chains and reveal the importance of algal traits in determining trophic cascades." **19069.** Wang, Y.-J.; Stoks, R.; Sentis, A.; Tüzün, N. (2020): Support for the climatic variability hypothesis depends on the type of thermal plasticity: lessons from predation rates. *Oikos* 129(7): 1040-1050. (in English) ["Plastic and evolutionary changes in traits related to biotic interactions are crucial for the local persistence of populations under global warming. Yet, how acute and developmental thermal plasticity evolve and shape predation rates has been poorly studied, especially in the context of latitude-driven thermal evolution. A powerful predictive framework is given by the climatic variability hypothesis (CVH) stating that thermal plasticity and acclimation capacity evolve to be higher in high-latitude populations because these are exposed to higher thermal seasonal variability. We tested the CVH for predation rates and evaluated if the support for the CVH depended on the type of plasticity and acclimation metric. We examined effects of developmental temperature (20 and 24°C) and acute changes in mean and extreme temperatures (20, 24 and 32°C) on the predation rates of high- and low-latitude populations of a predatory aquatic insect, the damselfly *Ischnura elegans*. We documented opposing and interactive effects between developmental and acute temperatures, which urges caution when using thermal performance curves to forecast the impact of global warming on biotic interactions. Predation rates were higher in low-latitude than high-latitude predators, especially at the warmer developmental and test temperatures, suggesting thermal adaptation to the higher low-latitude temperatures. The latitudinal patterns in acute and developmental plasticities differed, providing mixed support for the CVH. Moreover, there was no latitudinal pattern in post-acclimation thermal sensitivity, indicative of perfect thermal compensation in predators from both latitudes. Strikingly, the acclimation capacity leading to perfect thermal compensation was ~6 times higher in high-latitude than in low-latitude predators. Our study provides new insights into the climatic variability hypothesis (CVH) by documenting that its support is critically dependent on the type of plasticity and acclimation metric used." (Authors)] Address: Stoks, R., Lab. voor Aquatische Ecologie, K.U.Leuven, De Beriotstraat 32, B-3000 Leuven, Belgium. E-mail: robby.stoks@bio.kuleuven.ac.be

**19070.** Ward, J. (2020): Predator-Prey Interactions between *Paranehrops zealandicus* and Odonata species in semi-natural aquaculture environments. MSc. thesis, University of Otago: 101 pp. (in English) ["Interactions between predator and prey contribute towards shaping food webs and can be responsible for the composition of species in an ecosystem. In semi-natural aquaculture ponds, interactions between predators and competitors can be unfavorable for farmed species as they might reduce biomass in ponds and therefore economic growth. Juvenile farmed species are significantly more vulnerable in pond aquaculture as size is usually the factor that dictates trophic levels in aquatic habitats. Odonata are a family of pond invertebrates that are considered opportunistic predators and are known to feed on the prey of many juvenile vertebrate and invertebrate ponds species. Their ability to successfully capture prey makes them top invertebrate predators and how they interact with farmed species, specifically juveniles in aquaculture pond systems has been speculated. In New Zealand (NZ), semi-natural aquaculture ponds are used to cultivate the freshwater water crayfish species *Paranehrops zealandicus* yet how this species interacts with other pond invertebrates, particularly odonate larvae has not been studied. It was therefore the aim of this thesis to further investigate the predator-prey interactions between NZ odonate larvae and the farmed species *P. zealandicus* in semi-natural aquaculture ponds. This thesis examines predator-prey interactions based on species spatial patterns and habitat use in ponds, as well as stomach content and stable isotope analysis on study species. Results indicate odonate larvae have no significant effect on the abundance of *P. zealandicus* in ponds. Vegetation and the densities of *P. zealandicus* in ponds are more likely to have a greater impact on odonate larvae and juvenile *P. zealandicus* abundance. Desirable habitat was occupied by larger *P. zealandicus* which forced juvenile *P. zealandicus* to seek refuge in areas of the pond that were not attractive for larger territorial individuals. Based on stomach content analysis, odonate larvae were found to primarily feed on small sedentary pond invertebrates such as Chironomidae. *P. zealandicus* tissue was exceptionally low in odonate larvae stomachs. Stable isotope analysis further showed all odonate larvae had lower trophic levels to juvenile *P. zealandicus* indicating odonate larvae are unlikely to be major predators of juveniles. *P. zealandicus* diets reflected their omnivorous nature feeding on both plant detritus and invertebrate tissue, however *P. zealandicus* were highly cannibalistic with adults found to have high volumes of *P. zealandicus* tissue in their stomachs. Stable isotope analysis showed between *P. zealandicus* and juvenile crayfish there was no significant difference in trophic levels. Year 1 crayfish represented much of the *P. zealandicus* sample used for stable isotope analysis and adults were poorly represented in the sample which could be the reason for this result. Therefore Year 1 *P. zealandicus* are unlikely to be feeding on juveniles, however more research needs to be carried out looking at the trophic interactions between adult *P. zealandicus* and year of young. Ultimately, odonate larvae are not likely to be major predators of juvenile *P. ze-*

alandicus, and cannibalism is more likely to be the main factor for low juvenile success in ponds. Future research investigating other pond invertebrates and ways to mitigate cannibalism in ponds is speculated." (Author)] Address: not stated

**19071.** Wildermuth, H.; Monnerat, C. (2020): Fakten und Indizien zum Besiedlungs- und Ausbreitungsverhalten von *Coenagrion scitulum* in der Schweiz (Odonata: Coenagrionidae). *Libellula* 39(3/4): 123-147. (in German, with English summary) ["Colonisation and dispersal behaviour of *C. scitulum* in Switzerland – facts and evidence – In Europe, *C. scitulum* is mainly distributed in the Mediterranean area. Since the 1990s the species has extended its range north- and eastwards successively. In Switzerland, it established itself since 2002. Based on comprehensive faunistic data we tried to reconstruct its immigration from France and dispersal routes in Switzerland. Accordingly, during a first advance through the Burgundy Gate it arrived at the Ajoie region and from there it reached the central and eastern Plateau. The second advance followed from the French Rhone Valley into the Geneva Basin and further on to the western Plateau. In the Valais and the Ticino it firstly appeared in 2020. The colonization of Switzerland proceeded dynamically, in short but occasionally also in long leaps. In many cases, the first newcomers at waters were single specimens or small groups of individuals. According to their behaviour it is inferred that single males and females intensively searched for mates. If they remained unsuccessful, they soon moved on. Frequently, small populations were formed that existed only temporarily. Large and permanent populations occurred very rarely. The dispersal of *C. scitulum* was especially promoted by the availability of suitable habitats, i.e. by freshly created or revitalized water bodies. In addition, the sp. would also have profited from climate warming." (Authors)] Address: Wildermuth, H., Haltbergstr. 43, 8630 Rüti, Switzerland. E-mail: hansruedi@wildermuth.ch

**19072.** Yu, Y.; Pu, G.; Jiang, T.; Jiang, K. (2020): A dragonfly wing inspired biomimetic aerodynamic thrust bearing for increased load capacity. *International Journal of Mechanical Sciences* 176(6): (in English) ["Highlights: • A novel biomimetic aerodynamic bearing is designed. • Five most representative surface structures of dragonfly wings are mimicked on the surface of thrust air bearings. • The load capacity of the five surface structures are compared under various velocity angles. • The optimal surface structure and velocity angle are taken to design the biomimetic bearing. • The designed biomimetic bearing achieves a 46.11% higher load capacity than the optimized conventional spiral grooved bearing, verified by experiments. Abstract: A novel biomimetic aerodynamic thrust bearing is developed and investigated. The surface structure of the bearing is evolved from the micro-grids of dragonfly wings, which presumably aid flying and maneuver ability of dragonflies. The topography of the micro-grids of dragonfly wings was studied and five most representative geometries were extracted before being put on thrust bearings for performance examination. A theoretical model, solved with finite different and finite

volume method, is developed to compare the static load capacity of the bearings under various velocities and flow angles, and the best geometry and velocity angle were selected and manufactured on the bearing surface for experimental tests. The dragonfly wing biomimetic bearing is found to increase load capacity by up to 46.11% in comparison with an optimized conventional spiral grooved bearing by experiments." **19074.** Akindede, E.O.; Adedapo, A.M.; Adu, B.W.; Ogbogu, S.S. (2021): First report of the larva of a vulnerable damselfly in Nigeria, with some ecological notes: A case for umbrella species conservation approach. *Tropical Conservation Science* 14: 1-7. (in English) ["Background and Research: Lack of information on the distribution of threatened aquatic species impedes their conservation, thus predisposing them to extinction risk before being reported. Hence, this study reports in Nigeria, for the first time, the occurrence and habitat specificity of the larva of *Pentaplebia stahli* (Zygoptera: Pentaplebiidae) a vulnerable damselfly. Methods: Samples of *P. stahli* were collected in July and December 2020 from a rural stream situated at the Ekor Waterfalls in the Cross River State of Nigeria and very close to the Nigeria-Cameroon border. Some water quality parameters were also measured in each sampling period. Results: A total of 27 larvae of *P. stahli* and 1 teneral adult emerging from its exuvia were recorded in the two sampling periods. The habitat was a forested stream characterized by rapids, falls, and dark rock substrata. Water flows at a fast rate of 1min 3 or 4 seconds, thus characterizing a riffle and headwater stream. Dissolved oxygen concentration was between 8.05 and 8.09 mg/L, while dissolved oxygen saturation was ~ 98%. Biological oxygen demand was between 1.04 and 1.08 mg/L, while pH ranged from 7.28 and 7.56. Conclusion: The stream could be described as having high ecological integrity as evidenced in its optimum range of values

for the investigated water parameters and the presence of a threatened species. Implications for Conservation: Based on habitat specificity, *P. stahli* is considered an umbrella species required for conserving other co-occurring species in the tropical stream and its riparian forest." (Authors)] Address: Akindede, E.O., Room 1.07, Dept Zoology, Obafemi Awolowo Univ., Ile-Ife, Osun State, Nigeria. Email: eoakindele@oauife.edu.ng

**19075.** Bechly, G.; Garrouste, R.; Aase, A.; Karr, J.A.; Grande, L.; Nel, A. (2021): The damselfly palaeofauna from the Eocene of Wyoming and Colorado, USA (Insecta, Odonata, Zygoptera). *Papers in Palaeontology* 7(3): 1373-1402. (in English) ["A new family, five new genera, and nine new species of fossil damselflies (Insecta, Odonata, Zygoptera, Calopterygida) from the USA are described, seven from the Eocene Fossil Lake deposits and one from Lake Uinta deposits, both from the Green River Formation, and an additional specimen from the Wind River Formation of Wyoming and Colorado. Namely, *Carlea eocenica* gen. et sp. nov. (in Carleidae fam. nov.), *Labandeiraia riveri* sp. nov., *L. browni* sp. nov., *Eodysphaea magnifica* gen. et sp. nov., *Litheuphaea* sp. cf. *coloradensis* Petrulevicius et al., 2007, *Zacallites cockerelli* sp. nov., *Dysagrion integrum* sp. nov., *Tenebragrion shermani* gen. et sp. nov., *Tynskysagrion brookeae* gen. et sp. nov., and *Oreodysagrion tenebris* gen. et sp. nov. *Epallagoidea* and *Amphipterygoidea* are most common while *Calopterygoidea*, *Coenagrionoidae* and *Lestoidea* damselflies are less diverse. Genera of zygopteran *Dysagrionidae* are known from Europe and North America, further supporting the hypothesis of Palaeogene terrestrial interchange. Representatives of *Epallagoidea* and *Amphipterygoidea* in the Green River Formation confirm that warm conditions occurred at the time of deposition." **19078.** Chovanec, A. (2021): Libellenkundliche Bewertung von Restrukturierungsmaßnahmen an einem Fließgewässer in Österreich durch Prae- und Post-Monitoring (Trattnach, Oberösterreich) - Odonatological assessment of river rehabilitation by pre- and post-monitoring (River Trattnach, Upper-Austria). *International Dragonfly Fund - Report* 163: 1-43. (in German, with English summary) ["In 2019, a 500 m section of the River Trattnach, which is situated in the municipality Schlüßberg in the Austrian province Upper Austria, has been ecologically enhanced by restructuring the riverbed. The investigation of the Odonata carried out in 2016 (pre-monitoring) and 2021 (post-monitoring) aimed at the evaluation of the success of these measures. Five field trips at three 100 m stretches situated in this section were performed in both years. The regeneration measures at the river caused an increase of the total species number from five to ten and an increase of the number of the certainly, probably and possibly autochthonous species from four to eight. In 2021, four of the five rivertype-specific target reference species were detected: *Calopteryx splendens*, *Calopteryx virgo*, *Gomphus vulgatissimus*, and *Onychogomphus forcipatus*. The autochthonous occurrence of these rheophilous species and their abundances confirm the river-type specific biocoenotic region of this river section (transition between hyporhithron and epipotamon) and indicate the existence of riverbank vegetation as well as of heterogeneous morphological features causing the formation of a mosaic of different current and sediment conditions. The riverbed restructuring had only little influence on the general course of the river channel, which remained mainly straightened. Therefore, limnophilous accompanying reference species benefited only to a small extent from the regeneration measures. The detection of freshly emerged *G. vulgatissimus* and *O. forcipatus* two years after finishing the measures documented the early colonisation of the modified river section by these species. The assessment of the dragonfly-based ecological status of the whole section subjected to rehabilitation measures and of the individual stretches was based on comparing the current dragonfly fauna with a river-type-specific reference community. The Rhithron-Potamon Concept represented the methodological framework. Possible differences between the status quo of the dragonfly fauna and the reference were assessed by the Odonata-River-Zonation-Index and by a scheme of five classes of ecological status stipulated by the EU Water

Framework Directive: "high ecological status", which corresponds to the reference state, "good ecological status", "moderate ecological status", "poor ecological status" and "bad ecological status". The rehabilitation measures caused an improvement of the dragonfly-based ecological status: According to the results gained in the pre-monitoring, the dragonfly-based ecological status of the whole section was classified as "moderate". The three individual stretches investigated were ranked as "poor" and "moderate". The results of the post-monitoring revealed the "good dragonfly-based ecological status" for both, the whole section and the stretches. Even the ecological status of a regulated control-stretch, which was not subjected to rehabilitation measures, changed from "poor" to "moderate". "Spread effects" from the enhanced section to the still regulated section are assumed to be the reason for this improvement." **19079.** Coram, R.A.; Jarzembowski, E.A. (2021): Immature insect assemblages from the Early Cretaceous (Purbeck/Wealden) of Southern England. *Insects* 2021, 12(10), 942: 23 pp. (in English) ["Simple Summary: The non-marine Lower Cretaceous Purbeck and Wealden rocks of southern England provide an important record of insects that lived alongside the dinosaurs. Most fossil remains are those of adult insects from orders alive today, but immature insects and their trace fossils occur in the same deposits. Terrestrial immatures comprise mostly sessile nymphs of true bugs, whereas the aquatic immature fauna is represented by stoneflies and mayflies (rarely), dragonflies (uncommonly), true bugs and true flies (often common in the Purbeck), and the cases of caddisflies (locally common in the Wealden). These fossils help to shed light on the local palaeoenvironment, such as the salinity of water bodies, as well as on the processes that lead to the fossilization of generally fragile insect remains. Abstract: The record of immature insects from the non-marine Purbeck and Wealden groups (Lower Cretaceous) of southern England is reviewed and expanded. Fossils of adult terrestrial insects are locally common, but terrestrial immature remains are restricted to transported hemipterans, most of which are sessile nymphs or puparia resembling those of extant whiteflies (Aleyrodidae). Remains of immature aquatic insects are more diverse and comprise the extant orders Plecoptera, Ephemeroptera, Odonata, Trichoptera, Hemiptera and Diptera. The Trichoptera are represented by larval cases constructed from a variety of materials corresponding to several ichnogenera. The Wealden immature insects were preserved in predominantly freshwater fluvial settings, whereas the Purbeck ones occur in lagoonal palaeoenvironments, ranging in salinity from brackish to hypersaline. The composition of aquatic immature insect faunas in the latter offers potential for palaeosalinity analysis, although there are complicating factors relating to habitat stability. Uncommon trace fossils such as beetle borings in wood provide evidence of immature insects not represented by body fossils." **19081.** Dow, R.A.; Choong, C.Y. (2021): Previously unpublished Odonata records from Sarawak, Borneo, part VII: Odonata from Limbang Division. *Faunistic Studies in South-East Asian and Pacific Island Odonata* 37: 1-18. (in English) ["Records of Odonata from Limbang Division in Sarawak are presented, based on two surveys. The first survey was made in 2010 by the second author in the Paya Maga area at the border with Sabah. The second survey was made by the first author in 2020, mostly within the Ravenscourt Forest Management Unit, but with two days spent at Paya Maga. 54 species are listed from these two surveys. Several species were recorded from Sarawak for the first time during the surveys reported on: *Devadatta tanduk* Dow, Härmäläinen & Stokvis, 2015 and two as-yet-unnamed species of *Coeliccia*; all of these species were previously known from Sabah. Many of the other records are firsts for Limbang Division. Other particularly significant records include *Indolestes dajakanus*, *Protosticta joepani*, *Telosticta ulubaram*, *Euphaea basalis*, *Rhinoneura caerulea*, *Idionyx montana*, *Procordulia fusiformis*, *Hylaeothemis clementia* and *Orthetrum borneense*. *Xiphiagrion cyanomelas* (form B as discussed in Dow et al. (2021)) is reported using surface tension to perch on the surface of a pond. The identity of the unidentified *Devadatta* species recorded from the Long Seridan area in Miri Division by Dow et al. (2021) is discussed further. With the records presented here 123 species of Odonata have now been recorded from Limbang Division and 312 from Sarawak as a whole." **19083.** Ertas, A., Yasartürk, M., Boz, T.; Kizilkaya, I.T.; (2021): Evaluation of the water quality of Karabal stream (Gediz River, Turkey) and comparative performance of the used indices. *Acta Aquatica Turcica* 17(3): 334-349. (in English, with Turkish abstract) ["We used seven biotic indices to determine the water quality of Karabal Stream (Gediz River) in West Anatolia, Turkey. The indices were based on benthic macroinvertebrate and physicochemical parameters: Saprobic Index (SI), Biological Monitoring Working Party (BMWP), Average Score per Taxon (ASPT), Family Biotic Index (FBI), Belgian Biotic Index (BBI), EPT-Taxa [%] were used as biotic indices and Shannon-Weaver index (SWDI), Simpsons index (SDI) and Margalef index (MDI) for diversity. Ten taxonomic groups were found in Karabal Stream consisting of Crustacea, Oligochaeta, Gastropoda, Ephemeroptera, Plecoptera, Trichoptera, Odonata, Coleoptera, Diptera, and Hemiptera. The water quality along the stream varied from good class in the upstream stations, to moderate in downstream stations according to the most suitable indices. According to canonic correspondence analysis (CCA), the distributions of Diptera, Oligochaeta, and Hemiptera species are positively correlated to EC, Cl, Turbidity, Temperature, NH<sub>4</sub>-N, NO<sub>2</sub>-N, and NO<sub>3</sub>-N while they are negatively correlated to DO, DOS and pH. The distributions of EPT species are positively correlated to DO, DOS and pH. According to Pearson's correlation, the BBI, BMWP (Original), BMWP (Spanish), and EPT-Taxa [%] metrics were sufficient in the estimation of water quality in the examined watercourse. Considering studies in surface waters of Turkey, the BMWP and EPT-Taxa [%] indices reflect the water quality as correctly in all studies we examined, however, BBI did not always show reliable results. Therefore there is a need for the establishment of a Turkish Biotic Index which takes into account country-specific macroinvertebrates, their abundance, biology, and ecology. ] Address: Ertas, A., Ege University, Faculty of Science, Dept of Biology, 35100 Bornova, Izmir, Turkey. **19084.** Ferreira, T. (2021): Odonata da Coleção Entomológica Adalberto Antônio Varela-Freire: inventário, identificação e curadoria. BSc. thesis, Centro de Biociências, Universidade Federal do Rio Grande do Norte, Natal: 31 pp.

(in Portuguese, with English summary) ["Odonata is an insect order with broad geographic distribution, popularly known as dragonflies and damselflies. They are predators associated with water ecosystems, and therefore they are often used for environmental quality studies. The objective of this study was to inventory the odonates from the Coleção Entomológica Adalberto Antônio Varela-Freire and their storage conditions, to identify the specimens and to indicate measures of curatorship to ensure their long term preservation in accordance to practices conventionally adopted by other entomological collections. A total of 3181 specimens was inventoried, most preserved dry, kept in envelopes in varying conditions (2319 specimens) or ethanol (860 specimens). The identified specimens belong to 2 families (Aeshnidae and Libellulidae) and 14 genera, some of which were recorded for the first time in Rio Grande do Norte. Two hundred specimens were curated, with the major changes being the use of polyethylene zipper lock envelopes and printed labels with data obtained through the process of inventory. This study increases to 18 the number of species/genera recorded from the state. Even though the number of localities represented in the collection was limited, it still constitutes an important record of the state's dragonfly fauna, which should be further studied and have its data uploaded to public biodiversity databases, so that it becomes more accessible to researchers and to the general population as well." **19085.** Joshi, V.; Mysa, R.C. (2021): Hydrodynamic analysis of tandem flapping hydrofoils. *International Conference on Ocean, Offshore, and Arctic Engineering (OMAE)*. Vol. 6. Paper No: OMAE2021-62191, V006T06A006: 12pp. (in English) ["Flapping hydrofoils in tandem configuration find applications in wave gliders, dragonfly, dorsal-tail fin interaction in fishes, among others. The flapping motion consists of a combination of heaving and pitching motion. This type of motion involves complex interaction of the vortices shed from the upstream hydrofoil with the downstream hydrofoil, thus influencing the performance of the downstream hydrofoil. A two-dimensional stabilized finite element moving mesh framework is utilized for the current study. The important parameters which influence the flow interactions are the chord size ratio and the gap between the hydrofoils. The size ratio is defined as the ratio of the chord of the upstream hydrofoil to that of the downstream hydrofoil. The size ratio is varied from 0.25 to 1. The gap is varied from one chord length to 3 chord lengths of the downstream foil. The study focuses on the effect of the size ratio, gap and flapping kinematics based on sinusoidal heaving and pitching motion on the detailed flow dynamics of the tandem hydrofoils. The effect on the thrust coefficient and hydrodynamic efficiency is explored and compared with that of an isolated hydrofoil. The results obtained from the study can pave way for a better understanding with regard to engineering designs based on biomimetics." **19086.** Futahashi, R.; Futahashi, H.; Araki, Y.; Negoro, H. (2004): The dragonflies and damselflies of Toyama prefecture, central Honshu, Japan. Spec. Publs Toyama Sci. Mus. 17: ii + 220 pp. (in Japanese, with english summary) ["We investigated the odonata fauna in Toyama Prefecture mainly in the last 10 years. Our investigations were carried out on the largest scale in Japan at the prefecture level for the times of survey, the number of places, and the amount of data. In this report, we listed up the data of the 9,671 specimens of 84 odonate species belonging to 11 families contributed to Toyama Science Museum by Ryo Futahashi, Hiroyuki Futahashi and Yoshimasa Araki. Other original data mostly in Futahashi and Araki's collections were also reported. Consequently, many new records of collection and localities were added for many species. Based on these data, we reported 86 species and 5 hybrids from 11 families recorded in Toyama Prefecture. The characters such as distribution, life cycle, habitat, morphology, behavior were commented for each species. The present condition of Odonata fauna of Toyama Prefecture was comprehensively revealed. Only the following two have not been found in this investigation (the last collection year in parenthesis); Gomphus postocularis (1972) and Onychogomphus viridicostus (1959). Here we show three tables; Habitat, distribution in neighbor prefecture and behavior of 86 species known in Toyama Prefecture (Table 1). All the collection data of Odonata species for every city, town and village in Toyama Prefecture (Table 2). Fluctuation in adult occurrence for each of 86 species and 5 hybrids known in Toyama Prefecture (Table 3). In addition, a map of the distribution in Toyama Prefecture and a graph showing the seasons of occurrence of the adult are presented for each species and hybrids." **19087.** Groenendijk, D. (2004): Mogelijkheden voor monitoring van de rivierrombout. Rapportnummer VS2004.038,

De Vlinderstichting, Wageningen: 14 pp. (in Dutch) ["Introduction and Purpose: Stylurus flavipes belongs to a special dragonfly family. They are often difficult to find as a dragonfly, but the larval skins are often in a conspicuous place. The current situation is therefore that they are not well represented in the National Monitoring Network for Dragonflies, and it is therefore not possible to calculate trends for these species. Yet this is important, because within the Netherlands, two species of dragonflies, *S. flavipes* and *Ophiogomphus cecilia*, are listed on the Habitat Directive. Therefore, the aim of this study was to investigate whether there is a method of using larval skin counts to include the *S. flavipes* and possibly other species of Gomphidae in the dragonfly monitoring network. Method: *S. flavipes* was found again in 1996, after an absence of many years. Since then the species has made a considerable advance and is found in most larger river systems in the Netherlands. In 2004 eight counting routes of about one kilometre were set out in the catchment of the Rhine and Waal in the direct vicinity of Wageningen. These routes were all walked twice between 28 June and 17 July, with all larval skins recorded per groene section. Results: In total, over 80 exuviae of the *S. flavipes* were found on the eight counting routes. Some imago were also found. Along the Rhine routes more larval skins were found in direct comparison to the routes along the Waal. Counting one counting route took on average over an hour. Conclusion: The results show that with a good choice of counting routes, counts of larval scales of the river scrub offer a good opportunity for inclusion in the NEM and then in the future counted by volunteer counters. This method of counting offers the best chance for *S. flavipes* and probably also for *Gomphus vulgatissimus*. It is important that the counting route is shortened to a maximum of 500 metres and that counting is not carried out at wind force 4B and above. About the necessary counting frequency no statements can be made yet." (Author/Deepl)] Address: De Vlinderstichting, Postbus 506, 6700 AM Wageningen, The Netherlands. E.; Gaidagis, G. (2004): Integrative evaluation of the ecological quality of metalliferous streams (Chalkidiki, Macedonia, Hellas). *Environmental Monitoring and Assessment* 91: 59-86. (in English) ["The present study reports on a year-long (November 1997–November 1998) study of water quality in streams of the Olympias and Skouries areas of Chalkidiki (Hellas), subject to past and present mining activities. Benthic macroinvertebrates were collected from 18 sampling sites at five sampling intervals, while several physico-chemical parameters of the water (D.O., pH, temperature, nutrients etc.) were also measured. Five European biotic indices and scores and two multivariate statistical methods (CANOCO, FUZZY) were applied to the macroinvertebrate data. The concentration of various trace metals in the water, sediment, fish and crustaceans were also measured. Most sampling stations exhibited a highly diverse macroinvertebrate fauna during the whole year. However, a slight amelioration of water quality was observed during the high-flow period (winter and early spring), regarding diversity of several invertebrate groups, especially pollution-sensitive families, which decreased. The European biotic indices and scores proved to be relatively ineffective in describing water quality and it is suggested that an Hellenic biotic indice or score should be created. The bioaccumulation studies indicated variable effects of trace metals and organic load on macroinvertebrates according to the degree of load." **19089.** Lill, S. (2004): Die Libellenfauna im Einzugsgebiet der Pfrimm (Pfalz) unter besonderer Berücksichtigung der Indikatorqualitäten der Imagines von *Calopteryx virgo*, *Platycnemis pennipes*, *Orthetrum cancellatum* und *Crocothemis erythraea*. Diplomarbeit. Universität des Saarlandes: 164 pp. (in German) [Rheinland-Pfalz, Germany. "In the years 2001 to 2003 (with a focus on April to October 2003), the occurrence and distribution of the dragonfly fauna in the catchment area of the Pfrimm was investigated. The selected area lies between the source of the Pfrimm southwest of Sippersfeld and the eastern border of the Donnersberg district between Zellertal and Wachenheim. It includes parts of the natural areas Pfälzerwald, Nordpfälzer Bergland and Rheinhesisches Tafel- und Hügelland. The survey of odonates mainly focused on the observation of reproductive and hatching imagines. Dragonflies were searched for at selected flowing and still waters and their surroundings. In addition, larvae and exuviae were also observed. A total of 32 dragonfly species were found in the study area, 29 of which were considered to be native to the area. It is noteworthy that only 3 of the odonates recorded were purely running water species. Of the 32 dragonflies recorded, 21 (= 64 %) are considered endangered according to the Rhineland-Palatinate Red List (EISLÖFFEL et al. 1993), which means that 33 % of the "endangered species" in Rhineland-Palatinate occur in the study area. The detected dragonflies were briefly described with regard to their ecology, and possible reasons for their distribution in the area were discussed. An

essential part of this work was the investigation of the indicator suitability of the imagines of *C. virgo*, *P. pennipes*, *O. cancellatum* and *C. erythraea*. The following results were found for the study area: *C. virgo* is a good indicator for open, sunny stream sections with well-developed vegetation structures in the study area. Monotonous stream sections lined with gallery forest and thus shaded were avoided due to the lack of favourable vegetation conditions here. In the study area, *P. pennipes* is only suitable to a limited extent as an indicator for permanent, sunny still waters with structurally rich vegetation at the edge of the bank and in the direct vicinity of the water body, whereby a preference for ponds is obvious. At less diverse or less vegetated stillwaters, the species flew only in smaller numbers of individuals. *P. pennipes* occurred extremely rarely and in low abundance at the watercourses in the study area; the streams are not suitable or at best suboptimal for the species. *O. cancellatum* has only limited indicator qualities in the study area. All habitats had in common a continuous exposure to sunlight, the size of the water body played a rather subordinate role in the colonisation. A completely free water surface as well as shore areas free of or poor in vegetation could be found predominantly, but not at all water bodies surveyed. However, large abundances on the sparsely vegetated bank sections of the surveyed sampling sites suggest that a lack of vegetation played a corresponding role in the choice of habitat. In the study area, *Crocothemis erythraea* can be regarded as a good indicator for eutrophic, well-sunlit, wind-protected still waters with sufficient shallow water zones in climatically favourable locations. The occurrence of the fire dragonfly in the Pfrimm is probably promoted by the presence of habitat structures that provide wind protection and at the same time cause heat accumulation. The distribution focus of *C. erythraea* in the study area is in the climatically favoured Rheinhesische Tafel- und Hügelland. The findings at the sampling sites in the Pfälzerwald and Nordpfälzer Bergland indicate a possible spread of the dragonfly in these areas as well. Of the proportionate natural areas in the study area, the largest number of dragonfly species was recorded in the Rheinhesisches Tafel- und Hügelland. Due to the favourable climatic conditions of this area, most of the warmth-loving species were observed here, as expected, but the Euro-Siberian species also experienced their strongest distribution here. In the study area, protection and management measures are particularly appropriate along the watercourses. The partly complete shading of the streams by a uniform, monotonous gallery forest only allows colonisation by stream dragonflies in the few open areas. By thinning out sections of the wooded area, which also takes into account the requirements of other species groups, more favourable settlement opportunities could be created for dragonflies of flowing waters." **19090.** Pagel, M. (2004): Maßnahmenkonzept zur Optimierung der Lebensräume von Amphibien und Libellen im

Zollhausried bei Blumberg. Diplomarbeit. Hochschule Nürtingen: 127 pp. (in German) [Baden-Württemberg, Germany. "In the present work, the amphibian and dragonfly species of the Zollhausried nature reserve are first presented and their population trends are shown on the basis of earlier mapping results and extensive current surveys. It becomes clear, especially in the case of amphibians, that a decline in species as well as a decrease in abundance can be observed in the area for all ten species studied. The Great Crested Newt (species of Community interest according to Annex II of the Habitats Directive), the Midwife Toad and the Natterjack Toad could no longer be detected in 2004. The dragonflies of the study area are less specially adapted, but here too a decline can be observed, especially in the Red List species. As a further basis, numerous structural and vegetation-typical features of all reproduction waters were recorded and described in a uniform and comparable manner using various evaluation matrices. The current habitat availability was then compared with the requirements of the amphibian and dragonfly species currently or formerly occurring there. The deficits that became apparent could be compiled in a catalogue, which forms the sound basis for numerous measures, all of which pursue a common goal: The enhancement of the amphibian and dragonfly habitats of the Zollhausried. A particular deficit was identified as the lack of dynamics of the former peat digging, which had a landscape-altering effect and created vegetation-free areas. It is precisely on these sites that the species of the former stream and river floodplains are dependent. By designing several measures, a careful attempt is being made to integrate some dynamic structures into the sensitive lowland moorland. The occurrence of the individual species and the redesign measures are also shown in maps." (Author/DeepL)] Address: not stated

**19091.** Polhemus, D.A.; Helgen, K. (2004): Preliminary studies on the biodiversity of mammals and aquatic insects in East Timor. Report to the Ministry of Environment, Dili, Timor-Leste: 35 pp. (in English) ["Seventeen sampling stations in East Timor, ranging in elevation from 0 to 1585 meters elevation, were sampled for aquatic insects from 11 to 21 November 2003. The sampling stations included sites on the Mt. Ramilau massif, the Baucau Plateau, and the limestone mountain ranges near Lospalos, in the far east. Sampling concentrated on three major groups that had been employed in previous aquatic biodiversity surveys in the Australasian region: Heteroptera (aquatic true bugs), Zygoptera (damselflies), and Gyrinidae (whirlygig beetles), with other aquatic insect taxa also collected on an opportunistic basis. Thirty-eight species in 26 genera of aquatic Heteroptera were collected, of which at least 7 are new to science, and 2 others are described species reported from Timor for the first time. In the Zygoptera, 5 species in 4 genera were collected, all representing species previously reported from the island. In the Gyrinidae, 4 species in 3 genera were collected, all once again representing previously reported species, although many of these had not been collected in over 70 years. Aquatic insect diversity in East Timor was moderately high by regional standards, and similar to that seen in

corresponding elevational zones in western Timor. The richest overall site sampled was the Tchino River south of Lospalos, which supported 17 species of aquatic Heteroptera, 2 species of Gyrinidae, and 2 species of Zygoptera. The richest individual site for Zygoptera was the Irasiquero River east of Lospalos, where 4 species were collected. The richest sites for Gyrinidae were the Tchino River near Lospalos and the upper Eralisau River south of Maubisse, both of which harbored completely different sets of 2 species each; the latter site was also the second richest site for aquatic Heteroptera, supporting 12 species. The site with the highest number of Timor-endemic taxa across these three groups combined was the Tchino River, which supported 11 Timor endemics out of the 21 taxa present, for an local endemism rate of over 50 percent. Throughout East Timor there was clear evidence of catchment degradation due to overgrazing by domesticated ungulates such as goats and banteng in the lowlands and water buffalo in the highlands, which have damaged riparian zones across all elevational ranges. The rivers in best overall condition were those of the far east, in the Lospalos area, where higher rainfall and some degree of local fencing serve to mitigate ungulate impacts. Due to poorly functioning water systems in East Timor at the present time, this catchment degradation has a direct effect on the quality of water supplies being used by local families, and it is suggested that a program of selective fencing around watercourses, coupled with construction of livestock watering troughs at some distance from streams, would benefit both stream ecology and public health." **19092.** Towers, N.M. (2004): Invertebrate community structure along a habitat-patch size gradient within a bog pool complex. Doctor of Philosophy thesis, University of Edinburgh: Vii, 152 pp. (in English) ["This thesis characterises species richness and community structure over a habitat patch size gradient of a typical bog-pool complex, investigating the effect of pool size on aquatic invertebrate communities. In this study, twenty-two pools were surveyed ranging in area from 8.6 m<sup>2</sup> to 280.9 m<sup>2</sup> within a single complex at Forsinard in the north of Scotland. Three different sampling methods were used: baited and unbaited activity traps and a sediment sampler. Univariate and multivariate methods were used to investigate the effects of pool size and pool location within the complex on species richness and community structure. The research expands our knowledge of peatland pool invertebrates by providing a comprehensive survey of the aquatic invertebrate fauna representative of the Flow Country of northern Scotland. Two IUCN British Red Data Book species were recorded: *Coenagrion hastulatum*, and the cased caddisfly, *Nemotaulius punctatolineatus* (Retzius). Three species of aquatic Coleoptera were collected that have Nationally Notable status according to Ball (1986): *Dytiscus lapponicus* Gyllenhal, *Ilybius aenescens* Thomson and *Gyrinus minutus* Fabricius. All these species are typical of, and often restricted to, this habitat type. The three different sampling methods differed in their sampling

efficiency and each gave a different species spectrum. A distinct seasonal change in the samples was also observed. The number of taxa caught per standardised sampling unit (taxon density) was investigated over the pool size gradient. Relationships between taxon density and area were weak or non-existent in both unbaited activity traps and sediment samples. However, the number of beetle species caught in baited activity traps increased significantly with pool size, indicating that the total number of beetle species per pool may also increase over the size gradient. Ratios of the number of predator taxa to prey (non-predator) taxa for each pool ranged from 0.34 to 0.78 with a mean of 0.49 and were not affected by pool area or total taxonomic richness. Taxa displayed a positive abundance-occupancy relationship and the possible underlying mechanisms involved in creating this pattern are discussed. Multivariate techniques showed that pool area, depth, and distance from the centre of the pool complex (periferality) all had a small but significant affect on community composition and that between certain taxa there were distinctly different optima along the pool size gradient. These results are discussed in the context of species area theory." (Author)] Address: not stated

## 2016

**19093.** Andersen, E.; Nilsson, B.; Sahlén, G. (2016): Survival possibilities of the dragonfly *Aeshna viridis* (Insecta, Odonata) in southern Sweden predicted from dispersal possibilities. *Journal of Insect Conservation* 20(2): 179-188. (in English) ["We use public records from 1980 to 2014 to analyse survival of the EU Annex IV species *Aeshna viridis* in Sweden, a dragonfly strongly associated with the plant *Stratiotes aloides*. We clustered localities with *S. aloides* based on assumed dispersal abilities of *A. viridis*, using a dispersing radius of 2–100 km, calculating the proportion of sites with *S. aloides* that *A. viridis* is able to reach. If mean dispersal capability is high (40 km or above) 92.6 % or more of the localities are connected. For a good disperser, the probability of long-time survival is good. We further analysed the species richness of other Odonata and aquatic plants at 98 localities from the dataset. *A. viridis* co-occurred with more Odonata in the presence of *S. aloides* and running water but not in lakes. *S. aloides* sites had a higher number of other aquatic plants. Area had no impact on the occurrence of the species. For the present situation we surveyed 32 localities with known occurrence of the species. Only half of the sites for *S. aloides* contained any specimens while *A. viridis* occurred in the same number of sites. The species co-occurred in only 8 of 32 sites. In four sites *A. viridis* larvae appeared among *Menyanthes trifoliata*, *Phragmites australis*, *Potamogeton natans* and *Sphagnum* spp., indicating that at high latitudes *A. viridis* breeds among other species. Indirect monitoring based only on *S. aloides* would underestimate the number of populations of the dragonfly." **19094.** Banjo, F.M.; Sebiomo, A. (2016): Biodiversity and

seasonal variation of macro invertebrates in four water bodies in Odogbolu Local Government area of Ogun State. *African Journal of Science and Nature* 3: 57-61. ["The biodiversity and seasonal variation of aquatic macroinvertebrates in four different water bodies in Ijagun, Ijele, Odepo and Imaweje in Odogbolu Local Government Area of Ogun State were investigated using modified kick sampling technique between July and December 2014. The aquatic macroinvertebrates were sampled twice in a month using a scoop net (0.5mm mesh size with 0.4m diameter). The collected samples were preserved separately in 10% formalin and later identified. The physical properties (air and water temperature (oC), water current and water depth) of the water bodies were measured. Analysis of variance and spear man analytical tools were used to analyze the collected data. The different aquatic macro-invertebrates encountered belong to the super phylum Arthropoda, and three phylaviz: Mollusca, Annelida and Nematoda. The most abundant macro-invertebrate group was insects belonging to the orders Diptera (*Simulium* sp., *Chironomus* sp., *Anopheles* sp., and *Cricotopus* sp.), Odonata (*Agrocnemis femina*, *Macromia* sp and *Calopteryx* sp.), Coleoptera (*Dysticus marginalis* and *Hydrophilus* sp.), and Heteroptera (*Gerris lacustris*). The correlation coefficients (rho) of water depth, water current, water and air temperature in relation to frequency of occurrence of macro invertebrates were found to be -6.2, -4.2, -4.6 and -2.6 respectively. Water depth was the strongest factor that could determine the abundance of organisms. All physical properties showed inverse relationship with variation of aquatic macro invertebrates in the water bodies." **19095.** Beukema J.J.; Smit, H. (2016): Counts of Odonata in the Zwanenwater nature reserve. *Brachytron* 18(1): 30-37. (in Dutch, with English summary) ["Zwanenwater is a dune area in the northwestern part of the Netherlands. Most of the Odonata in the area occur at small (some tens to a few hundreds of m<sup>2</sup>) and shallow pools. In dry periods, part of these pools dry up completely. At 12 pools, numbers of Odonata were counted 4 to 8 times per year during the 9-year period 2007-2015. A second observer counted independently at the same pools. Due to a slight difference in counting method, he recorded about 15% more individuals. Nevertheless, highly similar long-term fluctuation patterns and local differences in Odonata abundance were found by the two observers. Particularly few Odonata were encountered in 2010 and 2011 after a serious drought at the end of the summer of 2009, causing complete drying up of several pools and serious reduction of the surface area in the remaining pools. Recovery of numbers was a slow process, in particular in Zygoptera. In 2010, individuals of these small-sized species were even fully absent at the pools that had been completely dry in 2009. Only by 2013 (deeper pools) or 2014 (shallower pools) had the numbers and species composition recovered to pre-drought levels. We recommend deepening of the central parts of some shallower pools by about 0.5 m to create more stability in Odonata

abundance." (Authors)] Address: Beukema, J.J. E-mail: Jan.beukema@nioz.nl

**19096.** Billqvist, M. (2016): Genomgång och digitalisering av trollsländor och dykarskalbaggar på Lunds Zoologiska museum. Naturvårdsverket 106 48 Stockholm: 9 pp. (in Swedish) ["The collections of previously unrecorded and in many cases unidentified dragonflies and divers at the Biological Museum, Lund University, have been reviewed, and from the material species occurring in the Habitats Directive have been sorted out. Five of the six species of dragonflies listed in the Directive were found in Sweden: green mosaic dragonfly *Aeshna viridis* (18 records), green river dragonfly *Ophiogomphus cecilia* (9), powdered dragonfly *Leucorrhinia albifrons* (69), broad dragonfly *Leucorrhinia caudalis* (21) and lemon-spotted dragonfly *Leucorrhinia pectoralis* (39). (The sixth species, the Siberian winter dragonfly *Sympetma paedisca*, is only found in Sweden occasionally and is therefore missing from the collections.) ... There is a very large amount of material available, so the mission has focused on recording the records of the species concerned from different localities and landscapes, and those not previously recorded by the Species Data Bank in 1998 (Ragnar Hall 1998). The collections consisted of different types of material; mounted dragonflies and divers, dragonflies in envelopes, animals in spirits, larvae and caterpillar skins. This study was limited to mounted material and material in envelopes. Animals in spirits, larvae and larval skins can be reviewed if necessary. All collections recorded were also individually tagged with museum labels." (Author/DeepL)] Address: Billqvist, M., Länsstyrelsen Östergötland, Postadress 581 86 Linköping, Sweden

**19097.** BioDrawversity (2016): Assess operational impacts on emergence of state-listed odonates in the Connecticut River: 2014–2016. Study report. Northfield Mountain Pumped Storage, Project No. 2485 and Turners Falls Hydroelectric Project No. 1889. Leverett, MA.: 118 pp. (in English) ["Pumped Storage Project (Northfield Mountain Project, FERC No. 2485) and the Turners Falls Hydroelectric Project (Turners Falls Project, FERC No. 1889). FirstLight has initiated with the Federal Energy Regulatory Commission (FERC, the Commission) the process of relicensing the Northfield Mountain and Turners Falls Projects using FERC's Integrated Licensing Process (ILP). The current licenses for the Northfield Mountain and Turners Falls Projects were issued on May 14, 1968 and May 5, 1980, respectively, with both set to expire on April 30, 2018. This report documents the results of Study No. 3.3.10: Assess Operational Impacts on Emergence of State-Listed Odonates in the Connecticut River. The study goal was to assess potential effects of Project operations on emerging dragonflies (Insecta: Odonata; hereafter called "odonates") in the Connecticut River. To meet this goal, field surveys were conducted to characterize the habitat, assemblage structure, and emergence and eclosure behavior of odonates in the Project area. This information was compared with existing data on odonates and water surface elevation (WSEL) collected throughout the Project area. Three phases of fieldwork

were completed. Phase 1, completed in 2014, included qualitative surveys of odonate larvae and exuviae at eight sites in the Connecticut River to determine species assemblage structure and to collect habitat data. For teneral or exuviae, biologists recorded the vertical and lateral distance from the water's edge, and the substrate that each was collected on. Phase 2, completed in 2015, included quantitative odonate surveys, observations of emergence and eclosure behavior, and concurrent collection of WSEL and water temperature data. Surveys for emerging larvae, exuviae, and teneral were conducted at five sites, with six transects per site, during eight biweekly sampling periods from late May to early September. Biologists looked for larvae exiting the water or crawling on land, and attempted to track and record the time it took for individuals to complete eclosure and fly away. For each exuvia and teneral, the vertical height above the water's surface, the distance from the water's edge, and its eclosure substrate was recorded. Phase 3, completed in 2016, was intended to increase sample sizes for eclosure duration for state-listed odonates and to collect additional data on the vertical heights and horizontal distances traveled prior to eclosure. The speed for all or part of the eclosure process was recorded for 180 specimens, with nearly 90% of these observed in 2016. Surveys for emerging and eclosing larvae were conducted at eight sites in the Turners Falls Impoundment (TFI) and downstream from the Turners Falls Dam, on warm sunny days during peak emergence from late May through mid-July. A total of 17 species were collected from 2014 to 2016, including the state-listed *Gomphus abbreviatus*, *Gomphus vastus*, *Gomphus ventricosus*, *Neurocordulia yamaskanensis*, and *Stylurus amnicola*. Species found most frequently in the riverine environments in the bypass reach and downstream from Cabot Station in the Connecticut River included *Gomphus vastus*, *Boyeria vinosa*, *Stylurus spiniceps*, *Ophiogomphus rupinsulensis*, *Neurocordulia yamaskanensis*, *Dromogomphus spinosus*, *Gomphus abbreviatus*, and *Macromia illinoensis*. The lower TFI (Barton Cove) was inhabited by several species more tolerant of lentic conditions, such as *Epithea princeps*, *Perithemis tenera*, and *Libellula* sp.

**19098.** For all species combined, larvae crawled a median vertical height of 5.5 ft from the water's surface, and a median distance of 12.5 ft from the water's edge. Among the riverine species, crawl height was greatest for *Macromia illinoensis*, *Gomphus abbreviatus*, and *Gomphus vastus*; each of these species crawled a median height of near or above 7 ft. Riverine species that crawled the shortest height from the water's surface included *Stylurus amnicola* (median = 2.2 ft), *Stylurus spiniceps* (median = 3.4 ft), and *Ophiogomphus rupinsulensis* (median = 3.5 ft). The more lentic species collected in Barton Cove crawled shorter distances from the water's surface than the riverine species. Average horizontal crawl distance was usually 10-15 ft for most species, with maximum distances often 3-4 times greater than the average. Shortest crawl distance was for *Perithemis tenera* (a lentic species that prefers to emerge on aquatic vegetation) and *Stylurus amnicola*. Considering

crawl height and crawl distance together, the riverine species that tended to eclose closest to the water were *Stylurus amnicola*, *Stylurus spiniceps*, and *Ophiogomphus rupin-sulensis*. In general, species eclosed on a wide variety of available substrates. The time elapsed from when a larva stopped to when it completed metamorphosis ("Start to Free") ranged from 7 to 30 minutes (average= 18 minutes). The time elapsed from completion of metamorphosis to flight ("Free to Flight") ranged from 7 to 96 minutes (average = 39 minutes). Together, these two time periods comprise the critical time period from when a larva stops to eclose to when it flies away ("Start to Flight"). A total of 170 specimens were observed for the entire critical time period. The average duration was 58 minutes and ranged from 24 to 126 minutes. In terms of understanding potential effects of water level fluctuations, the concern is for those species that tend to remain close to the water's edge, especially in areas of the river where water level fluctuations and rates of change are greatest. For the analysis, Critical Protective Rates (CPR) (ft/hr) were computed for species and species groups, using climbing height quantiles divided by a conservative eclosure duration of 2.0 hrs. CPR values were compared to the 95th percentile of the maximum hourly rates of change (MHR-95%) at several representative sites in the TFI and downstream from Cabot Station, derived from the hydraulic models for the daily period from 4am to 5pm, from May 15 to August 15. The hydraulic model for the TFI was based on data from 2000-2015 (excluding 2010 due to the extended outage at Northfield Mountain), and the hydraulic model for downstream was based on data from 2008-2015 (excluding 2010). For the bypass reach, empirical water level data from 2014-2015 was used. This provided a means of assessing the potential impacts to species or species groups, based on their behavior (climbing height and eclosure time) and the rate of water level changes at locations throughout the Project area. Water level fluctuations and rates of change may affect odonate emergence in areas of the Connecticut River closest to Cabot Station during the seasonal (May 15-August 15) and daily (4am to 5pm) periods evaluated, which correspond to peak emergence periods for odonates. State-listed odonate species documented in these areas include *Gomphus abbreviatus*, *Gomphus vastus*, *Neurocordulia yamaskanensis*, and *Stylurus amnicola*. Predicted effects were highest for *Stylurus amnicola*; at least 30% of the population, and closer to 50% near Cabot Station, were at risk of inundation based on the MHR-95%. Only a small percentage of the population of *N. yamaskanensis*, *G. vastus*, and the *Gomphus* Group were potentially affected by inundation based on MHR-95%, and these effects were most pronounced close to Cabot Station. Among co-occurring riverine species, *S. spiniceps*, *O. rupin-sulensis* and *D. spinosus* were likely most affected by water level fluctuations, based on the tendency of these species to eclose closer to the water." **19099.** Caparoso, K.R.; Medina, M.N.D.; Jumawan, K.M.; Villanueva, R.J. (2016): Species composition and status of

Odonata in Malabog, Paquibato District Davao City, Philippines. Univ. of Min. Intl. Mult. Res. Jour. 1(2): 158-163. (in English) ["Despite series of Odonatological expeditions in Mindanao, there are still areas with no Odonata record. The present paper presents the list and status of Odonata fauna in Malabog, Paquibato District, Davao City Philippines. Odonates were captured using hand picking and hand net for illusive species in five (5) sampling sites: Malabog River, Macaduhong River and its tributaries, Malabog spring, and Maglipayan River. A total of 208 individuals collected comprising of 28 species under 19 genera and 9 families. Zygoptera is represented by seven families comprised of 15 species of which 12 (80%) are Philippine endemic and 5 species are found only in selected areas of Mindanao. Anisopteran record composed of 2 families, Gomphidae and Libellulidae where only 3 out of 13 species or 23% are Philippine endemic. Increase of sampling areas and period for further studies and an immediate conservation effort must be conducted to areas with high endemism is recommended."] Address: Medina, M., Research and Publication Center, University of Mindanao, Davao City Philippines, Email: mnd\_medina@umindanao.edu.ph

**19100.** Chelmick, D.; Seidenbusch, R.; Boudot, J.P.; Brochard, C. (2016): The exuviae of the Urothemistinae of the Arabian Peninsula including the first description of the exuvia and final instar larva of *Urothemis thomasi* Longfield 1932 (Odonata: Libellulidae). *Tribulus* 24: 97-108. (in English) ["The exuviae of all four species of Urothemistinae known from the Arabian Peninsula (*Macrodiplax cora*, *Selysiothemis nigra*, *Urothemis edwardsii* and *U. thomasi*) were collected on recent surveys in UAE and Oman. The exuvia of *Urothemis thomasi*, first discovered in 2013, is described here for the first time. This paper, when used in conjunction with Suhling et al. (2014), provides sufficient information for all species of Libellulidae currently known from Arabia to be identified from final instar larvae and/or exuviae. It is hoped that this will encourage local naturalists to collect and identify specimens, which will improve knowledge of this region of which large areas remain little known." **19101.** Chen, G.; Jia, Q.; Hou, L.; Zhang, Y.; Zhao, Y.; Qin, B. (2016): Preliminary survey on the diversity of Odonata in Zhangye National Wetland Park. *Journal of Ningxia University (Natural Science Edition)* 37(4): 470-475. (in Chinese, with English summary) ["The article made field survey on odonata in Zhangye wetland with the method of combining net capturing with visual inspection to understand the species distribution situation of Odonata in Zhangye wetland and collected totally 834 specimens, which belong to, by authenticating, 5 families, 13 genus and 19 species, among which, Anisoptera is identified as 3 families, 9 genera and 14 species and Zygoptera, 2 families, 4 genera and 5 species. Of all the collected species, Libellulidae is richest in categories, the *Sympetrum pedemontanum* of which, has the maximum species individual amount 127 individuals, accounting for 15.23% of overall collected individuals. The

data investigated were under calculation and analysis with quantitative degree structural proportion relation between species, population diversity index and population growth and decline in different seasons. The population structure of Odonata in Zhangye wetland is comparatively stable, the quantitative distribution, however, varies in different living condition; the diversity of dragonfly population varies as the change of seasons, which conforms to the local climatic variation characteristic and the life history of dragonfly as well." (Authors)] Address: Maize Seed Safety Treatment & Research Center, Hexi Univ., School of Agriculture & Biotechnology, Hexi University, China

**19102.** Coulter, J.P.; Bartels-Hardege, H.; Gennard, D.E.; Mill, P.J.; Cowell, A.; John, E.A.; Hayes, W. (2016): *Aeshna grandis* larvae detect chemical cues derived from carrion: evidence of chemically-mediated food detection? (Odonata: Aeshnidae). *Odonatologica* 45(3/4): 191-212. (in English) ["Odonate larvae locate live, moving prey using a range of predominantly visual and mechanical cues. However, this does not explain observations of larval Odonata in association with submerged corpses, i.e., whether larvae are attracted by chemical cues emanating from submerged dead bodies. Hence the chemosensory capabilities of larval *Aeshna grandis* previously fed on living prey were tested under circumstances in which visual and mechanical perception was impossible, using model 'corpses', i.e., solid, homogenised, and dialysed tilapia, in link-tank test chambers. Results indicated that *A. grandis* larvae recognised cues emanating from the 'carrion' responding by moving in the source direction. Larval behavioral choice tests in link-tanks were also carried out on a selection of amino acids known to be released on tissue decomposition. Larvae responded positively to taurine, proline, L-glutamic acid, and glycine by moving in the direction of the source. These amino acid triggers were assessed electrophysiologically by recording from the antennal nerve. Responses depended on both the amino acid and its concentration. A positive electrophysiological response was noted for glycine at concentrations from 10<sup>-4</sup> to 10<sup>-8</sup> g g<sup>-1</sup> and for taurine, proline, and Lglutamic acid at a concentration of 10<sup>-5</sup> g g<sup>-1</sup>. No response was recorded for glutamate over a range of concentrations from 10<sup>-2</sup> to 10<sup>-6</sup> g g<sup>-1</sup>. Therefore *A. grandis* larvae are able to respond to non-visual cues, such as some of the chemicals released during tissue breakdown, suggesting that, in the absence of live prey, their search for food may be chemically-mediated." **19104.** Daemen, F.; Huysmans, M.; Munch, P.; De Knijf, G.

(2016): The Lilypad Whiteface (*Leucorrhinia caudalis*) back in Flanders (Belgium), after an absence of 100 years. *Brachytron* 18(1): 23-29. ["*L. caudalis* has been rediscovered in Flanders after an absence of more than a century. The first individual, a female, was observed on 28 May 2013 at Lommel, soon followed by a second observation of a female on 8 June at Den Diel in Mol. The next year, a male was noted on 12 and 13 June 2014 at the same locality in Mol. This was also the place where on 17 May 2015 a male could be photographed. All these observations over a period of three years, all situated around Den Diel in Mol make it very likely that a (small) population is locally present. The habitat of this locality seems to correspond well with the known habitat preferences of this species." **19105.** Deacon, C.; Samways, M.J. (2016): Conservation of a phenomenon: rapid, reversible colour change in both sexes of one of the world's most threatened damselflies. *Journal of Insect Conservation* 20(3): 497-504. (in English) ["Physiological colour change is rare in insects. Unusually, both the males and females of *Spesbona angusta* (Odonata: Platycnemididae), Red Listed as Endangered, are capable of rapid and reversible colour change. There is only one known population of this species, which occurs in a unique habitat in the Cape Floristic Region, South Africa. Appreciation of this unusual phenomenon of distinct physiological colour change helps us appreciate that we need to conserve phenomena in the insect world as well as the species themselves. Using controlled experiments, we evaluated the importance of ambient temperature as the possible primary cue for physiological colour change. We found that *S. angusta* responds rapidly to short-term changes in ambient temperature, even in the absence of additional environmental stimuli and without the body temperature matching the ambient temperature. Colour change is reversible when temperature returns to its earlier level. The reason why *S. angusta* shows this rapid and reversible colour change may be a combination of reproductive enhancement, competitive advantage and thermoregulation. This colour change appears to have strong selective advantage in a very particular habitat type, meaning that careful conservation of its habitat in all respects is important, and must be considered in any possible future translocations." **19106.** Duong, M.T.T.; McCauley, S.J. (2016): Predation risk increases immune response in a larval dragonfly (*Leucorrhinia intacta*). *Ecology* 97(6): 1605-1610. (in English) ["Predators often negatively affect prey performance through indirect, non-consumptive effects. We investigated the potential relationship between predator-induced stress and prey immune response. To test this, we administered a synthetic immune challenge into dragonfly larvae (*L. intacta*)

and assessed a key immune response (level of encapsulation) in the presence and absence of a caged predator (*Anax junius*) at two temperatures (22°C and 26°C). We hypothesized that immune response would be lowered when predators were present due to lowered allocation of resources to immune function and leading to reduced encapsulation of the synthetic immune challenge. Contrary to our expectations, larvae exposed to caged predators had encapsulated monofilaments significantly more than larvae not exposed to caged predators. Levels of encapsulation did not differ across temperatures, nor interact with predator exposure. Our results suggest that the previously observed increase in mortality of *L. intacta* exposed to caged predators is not driven by immune suppression. In situations of increased predation risk, the exposure to predator cues may induce higher levels of melanin production, which could lead to physiological damage and high energetic costs. However, the costs and risks of increased allocations to immune responses and interactions with predation stress remain unknown." **19107.** Ekena, G.; Isfendiyaroglu, S.; Yenyurt, C.; Levent Erkol, I.; Karatas, A.; Atal, M. (2016): Identifying key biodiversity areas in Turkey: a multi-taxon approach. *International Journal of Biodiversity Science, Ecosystem Services & Management* 12(3): 181-190. (in English) ["Key biodiversity areas (KBAs) are sites of global importance for biodiversity conservation. Their selection is based on standard criteria applied through a bottom-up, iterative process involving local stakeholders. This article presents the results of a study that applied the KBA methodology in Turkey. The KBA method uses four criteria: (1) globally threatened species; (2) restricted-range species; (3) congregations of species that concentrate at particular sites during some stage in their life cycle; and (4) biome-restricted species assemblages. In Turkey, we applied these criteria to 10,214 species of eight taxonomic groups: plants, dragonflies, butterflies, freshwater fish, amphibians, reptiles, birds and mammals. We identified 313 KBAs in Turkey, 303 of which trigger the KBA criteria for one or more taxonomic groups at the global scale. The remaining 10 sites trigger the KBA criteria at the regional scale only. These 303 globally important KBAs in Turkey cover 20,456,884 hectares, 26% of the country. Turkey's natural landscapes, holding globally important biodiversity, are under immense threat and declining rapidly, both in quality and quantity. The nationwide threat assessment of KBAs revealed that dams, irrigation and drainage projects (i.e. water policies) form the main threat to Turkey's biodiversity. Irrigation and drainage projects affect 225 KBAs and dams have an effect on at least 185 sites. KBAs raise attractive possibilities as being core areas where ecologically responsible governance models can be demonstrated, building on scientific and indigenous knowledge." **19108.** Environment Canada (2016): Recovery strategy for

the Rapids Clubtail (*Gomphus quadricolor*) in Canada [Proposed]. Species at Risk Act Recovery Strategy Series. Environment Canada, Ottawa: 21 pp. + Annexes- (in English) ["Executive summary: The Rapids Clubtail is a small, brightly coloured dragonfly which lives in clear, cool, medium to large rivers with wooded shorelines, gravel shallows, and muddy pools. Adult males perch on exposed rocks in the rapids. Adult females inhabit shoreline forests, moving to the rapids when ready to mate. Eggs are laid over the rapids and the nymphs live in quiet, muddy, downstream pools. This species is a globally rare to uncommon dragonfly found throughout Eastern North America, in a range extending from Maine to Minnesota, including southern Ontario. In Ontario it has been found in only four rivers: the Credit, the Thames, the Humber and the Mississippi. The population in the Credit River may be extirpated. The species is listed as endangered on the Species at Risk in Ontario (SARO) List under the Endangered Species Act, 2007. Threats to survival and recovery include dam construction, shoreline alteration, pollution, removal of shoreline forests, exotic predatory species, roadkill and climate change. Limiting factors include low population numbers, limited distribution and apparent sensitivity to specific habitat features. Knowledge gaps include a lack of understanding of the reasons for its limited distribution and for its habitat sensitivity. The recovery goal is to ensure the long-term survival of Rapids Clubtail in the province by protecting existing populations and by restoring populations in appropriate habitat where feasible. The recovery objectives are to: 1. protect, maintain and improve habitat in the four rivers in Ontario where Rapids Clubtail has been found; 2. implement a monitoring program for the locations where Rapids Clubtail is known to exist; 3. conduct additional inventory for Rapids Clubtail in suitable habitat; and, 4. initiate research to address knowledge gaps for Rapids Clubtail. It is important to ensure adequate protection of habitat and water quality for the species' survival and recovery. The locations where the species has been found in the Credit, Thames, Humber and Mississippi Rivers should all be prescribed as habitat in a habitat regulation. At each location, the area prescribed as habitat should include the section of the river containing the rapids and the pools below the rapids, plus the wooded shores on either side extending inland to include any forest which is within 800 metres of the shoreline." (Authors)] Address: not stated

**19109.** Galatowitsch, M.L.; McIntosh, A.R. (2016): Trait flexibility of generalist invertebrates exposed to contrasting predation and drying stressors. *Freshwater Biology* 61(6): 862-875. (in English) ["(1.) How different generalist species are able to exploit heterogeneous landscapes likely depends on whether their life-history strategies confer resilience to multiple environmental selection pressures. (2.) We investigated the life-history strategies of two generalist invertebrates, *Xanthocnemis zealandica* damselflies and *Sigara arguta* waterboatmen, which inhabit ponds varying in drying and predator presence. Using mesocosm experiments with temporary- and permanent-pond nymphs, we determined the flexibility of their predator avoidance and

drying resistance. (3.) *Xanthocnemis zealandica* was most susceptible to predatory fish regardless of natal habitat, with permanent-pond nymphs more likely to have reduced movement, higher refuge use and slower growth than temporary-pond nymphs; growth was, however, not influenced by predator presence. *Xanthocnemis zealandica* had a fixed response to drying stress, with high survival rates (80–90%) during short drying periods (2–8 days), regardless of natal habitat. (4.) In contrast to *X. zealandica*, *S. arguta* had a completely inflexible life-history with no differences in predator avoidance between permanent- and temporary-pond nymphs, and a complete inability to survive drying. (5.) Without flexible traits *S. arguta* may counter potentially high costs of predation in permanent ponds and drying mortality in temporary ponds through rapid development and terrestrial dispersal. *Xanthocnemis zealandica*'s flexible life-history is likely driven by longer nymphal development which requires adaptation to both predator and drying stressors to complete their life-cycle over the range of habitats they occupy. (6.) Overall, these two species exemplify how generalists can strongly differ in their life-history strategies but still persist across a similar range of habitats." **19110.** Ge, Y.; Cao, L. (2016): Transcriptome analysis of *Pantala flavescens* (Fabricius) based on ,qNA-seq. *Sichuan Journal of Zoology* 35(6): 852-859. (in Chinese, with English summary) ["The total transcripts of *Pantala flavescens* (Fabricius) were obtained by ,qNA-seq followed by functional analysis. The head total ,qNA of *P. flavescens* (Fabricius) was extracted and then sequenced by Illumina platform. A total of 47 039 040 reads containing 7 102 895 040 bp were generated. There were 34 406 502 unigenes with GC content of 44. 05% after de novo assembly. All the unigenes were annotated based on different databases and 44 499 unigenes were annotated. In this study all the assembled unigenes could be broadly divided into biological processes cellular components and molecular function categories of 60 branches by gene ontology including metabolic process binding catalytic activity and cellular process. Unigenes were further annotated based on COG category, which could be grouped into 26 functional categories. The results of KEGG prediction suggested that mitochondrial genes were the most abundant in the tested samples. And after KEGG O,qTHOLOGY annotation the most abundant genes were metabolic-related. The genes of mitochondria and metabolism were related with the migration mechanism of *P. flavescens* (Fabricius). **19111.** Gladyshev, M.I.; Popova, O.N.; Makhutova, O.N.; Zinchenko, T.D.; Golovatyuk, L.V.; Yurchenko, Yu.A.; Kalachova, G.S.; Krylov, A.V.; Sushchik, N.N. (2016): Comparison of fatty acid compositions in birds feeding in aquatic and terrestrial ecosystems. *Contemporary Problems of*

*Ecology* 9(4): 503-513. (in English) ["Fatty acid (FA) contents and compositions in the pectoral muscles of 18 bird species from Novosibirsk, Volgograd, and Yaroslavl oblasts were studied. Three groups of birds that had significantly different FA compositions were distinguished based on a multivariate statistical analysis: Passeriformes, Columbiformes, and a group of waterfowl and waterbird species (Charadriiformes, Anseriformes, Podicipediformes, and Ciconiiformes). The highest content of physiologically important docosahexaenoic acid (22:6n-3, DHA), which is considered a marker of aquatic food, was surprisingly found in the biomass of Passeriformes, which are terrestrial feeders, rather than in the biomass of waterfowls and waterbirds. It was suggested that Passeriformes species had the ability to synthesize large quantities of DHA from short-chain omega-3 FAs, which is rare among animals." **19112.** Herrera, L.S. (2016): Identifying the impacts of excess fine sediment on benthic macroinvertebrate communities. MSc. thesis University of Minnesota: VI + 90 pp. (in English) ["Many streams throughout the United States are negatively impacted by excess fine sediments (sand, silt, and clay). Benthic macroinvertebrates are a commonly-used tool to assess stream condition; however, current methodologies typically are not able to distinguish among stressors. Previous studies have correlated macroinvertebrate communities and traits with excess fine sediments, demonstrating that aquatic macroinvertebrates are sensitive to deposited fine sediment and the assemblages will shift in response. Western Lake Superior streams have a wide range of fine sediment amounts due to clay and sand soils, but have low amounts of other stressors, and thus are a good region to investigate relationships between macroinvertebrate traits and fine sediments. Data were collected from 22 stream sites located along the north shore of Lake Superior in 2010. The data collected in 2010 did not have the desired gradient of fine sediment due to wet conditions that year; therefore, the data were supplemented with data collected by NRRRI personnel in earlier years (1997 – 2008). The five sediment stressors used in analyses included percent embeddedness, depth of fine sediments, total percent fine sediments, percent sand, and a combined sediment index created using normalized and transformed embeddedness, depth of fine sediments and total percent fine sediments. Fifty-seven specific taxonomic groups and macroinvertebrate physical and behavioral characteristics (traits) were tested as potential response metrics in linear regressions. In addition, TITAN analyses were used to look for thresholds or sediment stressor values at which a taxon increases greatly, decreases greatly, or disappears from a community. Both the linear regressions and TITAN analyses showed a change in the community structure under conditions of excess sediment in the form of embeddedness, total fines, depth of fines, and/or the combined sediment index. The TITAN analyses also showed a change in the community structure due to increasing proportion sand in the

streambed. Furthermore, the analyses identified potential characteristics that may specifically make a particular macroinvertebrate more or less vulnerable to excess fine sediments." (Author) Taxa - including Odonata - are treated at order-level.] Address: not stated

**19113.** Hesse, L.; Falk, F.; Koch, K. (2016): Inflexible versus flexible: the influence of temperature and photoperiod on pre- and post-eyespot development time in Libellulidae (Odonata). *Physiological Entomology* 41(3): 224-233. (in English) ["Temperature and photoperiod are important environmental parameters for organisms. The present study tests the hypothesis that, during embryogenesis, temperature and photoperiod influence pre- and post-eyespot development time in dragonflies of the family Libellulidae differently. Eggs are used from eight species (five different genera, from Africa/Europe, and lentic/lotic habitat preferences). The eggs are reared under different constant or fluctuating temperature and light conditions. There are no general species-specific degree-days for pre- or the post-eyespot development in these species. In all study species, the variance within and between the treatments of the duration in days and the degree-days of pre-eyespot development is lower than that of post-eyespot development. Pre-eyespot development appears to be less flexible in its reaction to environmental influences. By contrast, post-eyespot development appears to react more flexibly to environmental influences. All eight species show the same pattern. This indicates strongly that this flexibility is a general pattern in Libellulidae that might help the species within this family to cope successfully with variations in environmental conditions. Because eyespot development and katatrepsis occur close to each other, the above-described pattern might also appear in other odonates and in other insect groups that exhibit katatrepsis. For all of them, it is essential for survival to match the time of hatching with adequate external temperature and photoperiodic conditions." **19114.** Holzinger, W.; Zimmermann, P. (2016): Die Vogel-Azurjungfer *Coenagrion ornatum* (Selys, 1850) in Niederösterreich: Ergebnisse einer Habitatmodellierung. Auftraggeber: Amt der Steiermärkischen Landesregierung, Abteilung 13 - Umwelt und Raumordnung, Referat Naturschutz, 8010 Graz, Stempfergasse 7, Austria. GZ: ABT13-56O-26/2013-2. Auftragnehmer: ÖKOTEAM - Institut für Tierökologie und Naturraumplanung, Bergmannngasse 22 • A-8010 Graz, Austria: 35 pp. (in German) [Due to ongoing infringement proceedings, the Republic of Austria and possibly also the province of Lower Austria are required to designate new protected areas for (among others) *Coenagrion ornatum*. In this context, the eco-team was commissioned to prepare the present expert report. The assignment comprises three questions: Are there nationally important populations of the

Common Azure Damselfly within the existing Natura 2000 area in Lower Austria? Is it necessary to expand existing sites and/or designate new sites for this species in Lower Austria? If so, how are the populations of the species to be assessed, what threats might these populations be exposed to and what form might protection and promotion measures take? *C. ornatum* has a ponto-mediterranean distribution and reaches the western limit of its closed range in the Pannonian part of Austria. At altitudes below 400 m, it inhabits fully sunlit, shallow, slow-flowing, silted small streams with relatively dense aquatic vegetation and predominantly herbaceous vegetation close to the banks. Their larvae develop among submerged plants and take 1-2 years to develop. Adults are found between mid-May and the end of June, they are not very migratory and are only flight-active on sunny, windless days. In Austria and in large parts of Central Europe the species is classified as "Critically Endangered", populations in the continental region of Austria are declining, the conservation status of the species is "U1x" ("probably unfavourable-insufficient"). The main threat to the species is the destruction of its habitats. In Lower Austria, the species was specifically searched for by Martina Stauer in 2014 in nine study areas between approx. 5 and 100 km<sup>2</sup> in size and actually detected in a total of 12 streams in the Weinviertel and west of the Leitha Mountains. The first aim of this study is to extrapolate or model the occurrence of the species for the whole of Lower Austria on the basis of these results. For this purpose, the presence data of the species are combined with a lot of other environmental information and the MaxEnt programme is used to estimate the probability of occurrence of the species in Lower Austria. The results show that there are large areas with very high occurrence potential in Lower Austria, although the province of Lower Austria only has concrete occurrence data for a small part of these water bodies. The Pulkau and its tributaries between Retz and Laa an der Thaya have the highest potential, other potentially high quality areas are located along the Zaya and Taschlbach as well as in the vicinity of the Thaya. In the Marchfeld, Weidenbach, Stempfelbach and Rußbach, and south of the Danube, areas along the Fische and Neue Leitha are classified as suitable in sections. In addition, an assessment algorithm for occurrences of the species, a monitoring concept as well as protection and promotion measures are presented.] Address: ÖKOTEAM, Institut für Tierökologie und Naturraumplanung, Bergmannngasse 22, A-8010 Graz, Austria, Austria

**19115.** Ichikawa, Y.; Watanabe, M. (2016): Daily egg production in *Pantala flavescens* in relation to food intake (Odonata: Libellulidae). *Odonatologica* 45(1/2): 107-116. (in English) ["The migratory dragonfly, *Pantala flavescens*, arrives in Japan from tropical regions every spring. Although the population increases as autumn nears, it dies in the winter cold. The adults often form foraging swarms above open grasslands when feeding on small insects, while oviposition occurs at diverse open water bodies throughout the day. Although oogenesis requires a daily intake of nutrition from prey, there has been little consideration of the relationship between food intake and the number of eggs produced. In

the early morning, females of reproductive age were captured from foraging swarms in grasslands. Immediately after capture, an artificial oviposition technique was applied to each female to release all mature eggs loaded. Then, the females were kept until death, up to 5 days, in envelopes in the laboratory. They were starved but hydrated daily, and the dry weight of faeces excreted during 24 h after capture was measured. Females excreted 8.4 mg of faeces within 24 h after capture. Then, they released about 840 mature eggs at 24 h after capture, suggesting that when females take in a sufficient amount of daily food, they can oviposit a large number of eggs every day. The rapid egg production might enable the population of *P. flavescens* to grow. A positive correlation was found between the food intake on the previous day and the number of eggs produced within a 24 h of capture. The act of ingesting fresh nutrients derived from the prey might promote rapid release of reserves in the female fat body, resulting in the oogenesis. Females able to encounter available foraging sites might produce a large number of mature eggs in the subsequent day to be laid." **19116.** Iorio, E.; Noel, F (2016): Première année de suivi de la Grande Aesche *Aeshna grandis* (L., 1758) dans deux étangs du Perche (Orne). Rapport GRETIA réalisé grâce aux financements de l'Europe (fonds FEADER), de l'Agence de l'eau Loire-Bretagne et de l'Agence de l'eau Seine-Normandie, dans le cadre de la déclinaison régionale du PNAO: 19 pp. (in French) ["This report presents the results of the first year of monitoring the exuviae of the Great Aesche *Aeshna grandis* in the Cachot and Gré ponds (Brésolettes, Orne), carried out by means of three passes made on foot/by boat along the banks from the inside, on 27 July, 16 and 31 August 2016. A total of 28 exuviae of *A. grandis* were collected, but only on the Cachot, of which almost 90% were collected on the first pass (n = 25) and none on the third. According to these first data, August does not seem to be a productive month in terms of emergence, as this activity obviously takes place mainly in July; but this impression should be confirmed during the next two years of monitoring. Apart from *A. mixta*, the total absence of anisopteran exuviae at Le Gré is clearly explained by the combination of a prolonged dry spell in 2014-2015 and incomplete surveys due to the inaccessibility of part of the banks. In 2016, *A. grandis* was the best represented anisopteran species in terms of emergences at the Cachot, followed by *Orthetrum cancellatum*. The location of each of its exuviae is mapped. The species richness observed on the two ponds combined is 21, with 13 species recorded on the Cachot and 17 on the Gré. The main biotic and abiotic characteristics of the emergence stations and the conditions for observing the exuviae are described and illustrated by photographs. At the end of this first year, the emergence of *A. grandis* took place on almost half of the perimeter of the Cachot pond, without any habitat or micro-habitat appearing to be more favourable than the others at the current stage.

The eastern bank, however, revealed more than half of their numbers." (Authors/DeepL)] Address: Iorio, E., GRoupe d'ETude des Invertébrés Armoricaux (GRETIA) - Antenne Pays-de-la-Loire – 5 rue Général Leclerc – 44390 Nort-sur-Erdre, France. Email: e.iorio@gretia.org

**19117.** Iorio, E. (2016): Suivi du Leste dryade *Lestes dryas* Kirby, 1890 (2ème année) et du Leste verdoyant *Lestes virens* (Charpentier, 1825) (1ère année) dans les landes de Lessay (Manche). Rapport GRETIA réalisé grâce aux financements de l'Europe (fonds FEADER), de l'Agence de l'eau Loire-Bretagne et de l'Agence de l'eau Seine-Normandie, dans le cadre de la déclinaison régionale du PNAO: 51 pp. (in French) [*L. virens vestalis* de Lessay (50) ; à droite : *L. virens virens* du Var (83).

**19118.** France "This report presents the results of the second year of monitoring the imagoes of *Lestes dryas* and the first year of monitoring those of *Lestes virens* in the Lessay moors, on eleven pre-selected stations. They follow on from the report by GERMAIN (2015) on the same moors and stations. A total of 266 and 49 imagoes were counted for *L. dryas* and *L. virens* respectively, all belonging to the subspecies *vestalis* for the latter. The local phenology of *L. dryas* is thus refined in relation to regional and national knowledge. A synthesis of various biotic and abiotic characteristics common to the stations and habitats of probable autochthony is proposed, by cumulating the data of this year and of 2015. The preferential habitats are more precisely defined in the Lessay moors and more generally at regional level. However, all the data still needs to be confirmed by the third and final year of monitoring, in 2017, for *L. dryas*; and by the next two years of monitoring for *L. virens vestalis*, whose populations appear to be smaller in Lessay for the moment. The future global synthesis that will emanate from this will make it possible to complete or reinforce the recommendations of GERMAIN (2015) with regard to the management of habitats favourable to *L. dryas*, and then to propose some for *L. virens vestalis*, in the long term. Certain factors have already been identified as probably important, or even determining, to be taken into account, such as opening up the environment, sparingly (re)digging to promote late drying and maintaining a selection of appropriate heliophytes (particularly *Eleocharis*)." (Author/deepL)] Address: Iorio, E., GRoupe d'ETude des Invertébrés Armoricaux (GRETIA) - Antenne Pays-de-la-Loire – 5 rue Général Leclerc – 44390 Nort-sur-Erdre, France. Email: e.iorio@gretia.org

**19119.** Jin, L.; Zhang, Y.; Xu, X.; Xiao, X.; Zhang, X. (2016): Identification and phytotoxic activity of fungus QTYC-51 from the gut of *Pantala flavescens* larvae. *Acta Microbiologica Sinica* 56(12): 1869-1875. (in Chinese, with English summary) ["[Objective] To isolate the fungus with phytotoxic activity from the gut of *P. flavescens* larvae. [Methods] Strain QTYC-51 was identified by morphological observation and 5.8S rDNA-ITS sequence analysis. Petri dish bioassay was used to test the phytotoxic activity of fermentation broth and monomer compounds of strain QTYC-51 on *Echinochloa crusgalli* and *Amaranthus retroflexus*. Bioactive

components were isolated from ethyl acetate extracts via chromatographic methods, and the structures were determined by mass spectrum and nuclear magnetic resonance analyses. [Results] QTYC-51 was identified as *Paraconiothyrium* sp.. The fermentation broth had good phytotoxic activity on radical growth of *E. crusgalli* and *A. retroflexus* with the inhibition rates of 76.9% and 56.5%, respectively. Five monomer compounds were purified from the fermentation products, including 1,8-dihydroxyanthraquinone, 1-hydroxy-10-methoxy-dibenz[b,e]oxepin-6,11-dione, hydroxyvertexanthone, globosuxanthone and 1,3,6,8-tetrahydroxyanthraquinone. At the concentration of 100 µg/mL, compound globosuxanthone was found to possess obvious phytotoxic effects on radical growth of *E. crusgalli* and *A. retroflexus* with the inhibition rates of 94.1% and 79.0%, respectively, which were comparable to that of positive control 2,4-dichlorophenoxyacetic acid. Compound 1-hydroxy-10-methoxy-dibenz [b,e] oxepin-6,11-dione showed potent phytotoxic activity against *E. crusgalli* and *A. retroflexus* with inhibition rates of 50.3% and 58.6%, respectively. [Conclusion] Strain QTYC-51 could be potentially developed as a microbial herbicide." **19120.** Kefford, B.J.; Buchwalter, D.; Cañedo-Argüelles, M.; Davis, J.; Duncan, R.P.; Hoffmann, A.; Thompson, R. (2016): Salinized rivers: degraded systems or new habitats for salt-tolerant faunas?. *Biology Letters* 12(3): 8 pp. (in English) ["Anthropogenic salinization of rivers is an emerging issue of global concern, with significant adverse effects on biodiversity and ecosystem functioning. Impacts of freshwater salinization on biota are strongly mediated by evolutionary history, as this is a major factor determining species physiological salinity tolerance. Freshwater insects dominate most flowing waters, and the common lotic insect orders Ephemeroptera (mayflies), Plecoptera (stoneflies) and Trichoptera (caddisflies) are particularly salt-sensitive. Tolerances of existing taxa, rapid adaptation, colonization by novel taxa (from naturally saline environments) and interactions between species will be key drivers of assemblages in saline lotic systems. Here we outline a conceptual framework predicting how communities may change in salinizing rivers. We envision that a relatively small number of taxa will be saline-tolerant and able to colonize salinized rivers (e.g. most naturally saline habitats are lentic; thus potential colonizers would need to adapt to lotic environments), leading to depauperate communities in these environments." **19121.** Kjer, K.M.; Simon, C.; Yavorskaya, M.; Beutel, R.G. (2016): Progress, pitfalls and parallel universes: a history of insect phylogenetics. *J. R. Soc. Interface* 13: 20160363. <http://dx.doi.org/10.1098/rsif.2016.0363>: 29 pp. (in English) ["The phylogeny of insects has been both extensively studied and vigorously debated for over a century. A relatively

accurate deep phylogeny had been produced by 1904. It was not substantially improved in topology until recently when phylogenomics settled many long-standing controversies. Intervening advances came instead through methodological improvement. Early molecular phylogenetic studies (1985–2005), dominated by a few genes, provided datasets that were too small to resolve controversial phylogenetic problems. Adding to the lack of consensus, this period was characterized by a polarization of philosophies, with individuals belonging to either parsimony or maximum-likelihood camps; each largely ignoring the insights of the other. The result was an unfortunate detour in which the few perceived phylogenetic revolutions published by both sides of the philosophical divide were probably erroneous. The size of datasets has been growing exponentially since the mid-1980s accompanied by a wave of confidence that all relationships will soon be known. However, large datasets create new challenges, and a large number of genes does not guarantee reliable results. If history is a guide, then the quality of conclusions will be determined by an improved understanding of both molecular and morphological evolution, and not simply the number of genes analysed." **19122.** Küry, D.; Krieg, R. (2016): Emergenz und Populationsgröße von *Gomphus pulchellus* im Kanton Basel-Stadt sowie Situation und Habitate in schweizerischen Gewässern (Odonata: Gomphidae). *Libellula* 35(1/2): 1-21. (in German, with English summary) ["Emergence and population size of *Gomphus pulchellus* in canton Basel-City plus situation and habitats in Swiss water bodies – *Gomphus pulchellus* is an endangered species of high conservation priority in Switzerland. A study on an isolated population in the Spittelmattponds in Riehen, canton Basel-City revealed a total of 121 exuviae between 22nd May and 24th July 2012. This corresponds to a density of 46 individuals per 100 m of shoreline or 0.6 individuals per m<sup>2</sup>. The adults emerged mainly on the sunlit southwest bank on *Carex* sp. and *Rubus* sp. By sampling the ground three larvae were found in a total of 36 samples. Immediately after the emergence adults were found in the nearby clover field. After maturation several males were found by sunlit places on *Rubus* in the riparian zone, on the adjacent country lane and on the Entenweiher ('duck-pond') 250 m away. *Gomphus pulchellus* developed together with ten other dragonfly species: *Calopteryx splendens*, *Chalcolestes viridis*, *Coenagrion puella*, *Erythromma lindenii*, *Ischnura elegans*, *Pyrrhosoma nymphula*, *Platynemis pennipes*, *Onychogomphus forcipatus*, *Cordulegaster boltonii*, and *Sympetrum striolatum*. A survey of 15 potential breeding sites in the surroundings showed that the species reproduced in the gravel pit Käppelin Weil am Rhein, Germany, (1.2 km distance) and probably in the gravel pit Wyhlen, Germany (7 km distance). A total of 66 known reproductive sites in Switzerland were examined by aerial photography. Of these, 61 % were ponds followed by lakes (23 %), running waters (12 %) and gravel pits (4 %).

The sites had an area between 550 m<sup>2</sup> and 14.5 km<sup>2</sup>. Approximately 50 % were larger than one hectare. Dominant vegetation types were: reeds, rushes, sedges, woody areas, or zones lacking any vegetation. Interviews with experts revealed over 90 % of the reproductive ponds being stocked by fish. The known populations will be monitored for four to six years and additional reproductive sites searched on a regional level. An action plan shall help to manage existing ponds, create new breeding sites and inform the public about the progress of the project." **19123.** Kuhn, W.R. (2016): Three approaches to automating taxonomy, with emphasis on the Odonata (dragonflies and damselflies). Ph.D. thesis, Rutgers, The State University of New Jersey: xi, 177 pp. (in English) ["Taxonomy-the field charged with naming and classifying organisms-forms a foundation for biological research. An understanding of the species on Earth is needed for informing biodiversity research, conservation efforts, management strategies, and global policy. In recent decades, a "taxonomic impediment" has arisen: there is an urgent need to know the millions of yet-undiscovered species, while funding for the science charged with this task, taxonomy, and the number of trained taxonomists are declining. This work aims to provide three software tools for taxonomists that allow them to work more efficiently and effectively, reducing this impediment. First, a system for automatically landmarking images of specimens for geometric morphometric studies was introduced, which could greatly reduce the time required to manually landmark images for these studies while also increasing the possible sample size of such studies. The system's landmarking error, however, was extremely variable on test images of the wings of dragonflies and damselflies (Odonata), and was ultimately too large (300-500 px) to compete with manual landmarking at this time. Second, a method was presented for automatically standardizing and extracting descriptive features from images of insect wings in order to quantify the appearance of the wings. The standardization method was successful in converting scans of odonate wings into consistently-formatted square images, automatically. Then, features describing the color, texture, and shape of the wings were able to be extracted, producing a small set of 663 coefficients that were able to distinguish between species. Finally, a system called Odomatic was presented and tested for automatically identifying Odonata to species from images of their wings, using the feature extraction method combined with machine learning techniques. Odomatic was able to make classifications between 32 species with expert-level (up to 92%) accuracy, making it useful for quickly identifying specimens. The tools presented here will be deployed for use by odonate researchers through the website OdonataCentral.org, but will also be released as open-sourced Python scripts so that they can be customized to be implemented on other taxonomic groups. This work will enable taxonomists and other interested parties to make easier morphological comparisons and faster identifications." (Author)] Address: not stated

**19124.** Labe, M.S.; Fernado, N.C.; Fiegalan, E.R. (2016): Insects associated with organic and inorganic rice farming. *International Journal of Agricultural Technology* 12(7.1): 1347-1367. (in English) ["A study was conducted in organic and inorganic ricefields to identify all insects present in both methods of farming. A total of 34, 957 insects and other arthropods were collected; 17, 549 in organic and 17, 408 in inorganic ricefield, respectively, through net sweeping. The orders of insects represented from the collection include the Odonata, Orthoptera, Thysanoptera, Hemiptera, Homoptera, Coleoptera, Strepsiptera, Diptera, Lepidoptera, and Hymenoptera. Spiders (Araneae) and mites (Acari) in the Class Arachnids were also collected. Among the insects, Diptera and Homoptera had the highest counts in both methods of farming. Both organic and inorganic ricefields had high counts of insect pests. Higher counts of natural enemies were observed in organic ricefield." **19125.** Lutsch, M.; Koch, K. (2016): The probable function of abdominal contractions and liquid drops during the emergence of Zygoptera and Anisoptera (Odonata). *International Journal of Odonatology* 19(4): 199 -205. (in English) ["The transition between larval and adult stage in amphibious insects is called emergence. During emergence abdominal contractions and excretion of liquid drops can be observed in several insect orders. Since the function of these processes is not yet known in odonates, this study examines the probable function of abdominal contractions and excretion of liquid drops in Zygoptera and Anisoptera. By subdividing the emergence into 12 successive stages and counting abdominal contractions as well as the excreted liquid drops during these stages we set up a systematic data collection. In all investigated individuals, both processes began in the middle of the entire emergence. We found that abdominal contractions occurred more frequently at the beginning of the latter half of emergence. The number of excreted liquid drops, however, was higher in the end, shortly before the maiden flight. Concerning the number of excreted liquid drops, we found a significant difference between Zygoptera and Anisoptera. Our findings suggest that there might be a relationship between the two processes, probably explainable by the hemolymph circulation as seen in Lepidoptera. However, abdominal contractions and liquid drops seemed to be crucial for the emergence of Zygoptera and Anisoptera.... Under natural conditions we observed the emergence of *Coenagrion scitulum*: n = 11; *Enallagma cyathigerum* = 24; *Platycnemis pennipes*: n = 17) and *Cordulia aenea*: n = 21; *Libellula quadrimaculata*: n = 25; *Orthetrum cancellatum*: n = 20) in the period from beginning of May to mid-June 2015." **19126.** Martín, R.; Maynou, X. (2016): Dragonflies (Insecta: Odonata) as indicators of habitat quality in Mediter-

anean streams and rivers in the province of Barcelona (Catalonia, Iberian Peninsula). *International Journal of Odonatology* 19(3): 1-18. (in English) ["In a field study carried out in 2011 and 2014 adult dragonflies were identified as a rapid and easy-to-use means of assessing habitat quality and biological integrity of Mediterranean streams and rivers in the province of Barcelona (Region Catalonia, Iberian Peninsula). The study included sampling sites from five different river catchments: Besòs, Foix, Llobregat, Ter and Tordera. Multivariate statistical procedures and indicator species analysis were used to investigate the relationship between river ecological status, study sites and dragonfly species or species assemblages' occurrence. The dragonfly association identified with western Mediterranean permanent streams, i.e. *Cordulegaster boltonii*, *Boyeria irene*, *Onychogomphus uncatus* and *Calopteryx virgo meridionalis*, was found only at the sites with the highest status. All these taxa were identified as indicator species of sites with the best scores for the macroinvertebrate based IBMWP index and for the combined IASPT index, which reflects the sensitivity of the macroinvertebrate families present to environmental changes; besides, *B. irene* and *C. virgo meridionalis* also proved to be indicator species of the riparian forest quality index and *C. boltonii* of the more inclusive ECOSTRIMED, which assesses the overall conservation status of the riverine habitats. The information obtained on habitat preferences and indicator value showed that adults of these taxa may constitute a valuable tool for preliminary or complementary cost-effective monitoring of river status and restoration practices as part of a broader set of indices reflecting biodiversity and ecosystem integrity." **19127.** Matushkina, N.; Lambret, P.; Gorb, S. (2016): Keeping the Golden Mean: Plant stiffness and anatomy as proximal factors driving endophytic oviposition site selection in a dragonfly. *Zoology* 119(6): 474-480. (in English) ["Highlights: •Ovipositor bending stiffness of *Lestes macrostigma* is one of the highest in damselflies. •Most preferred plant for oviposition has intermediate stiffness and specific anatomy characteristics. •Least preferred plants for oviposition have the highest stiffness or large aeriferous cavities. Abstract: Oviposition site selection is a crucial component of the habitat selection in dragonflies. The presence of appropriate oviposition plants at breeding waters is considered to be one of the key habitat determinants for species laying eggs endophytically. For example, *Lestes macrostigma*, a species which is regarded as threatened in Europe because of its highly fragmental distribution, typically prefers to lay eggs in the sea-club rush *Bolboschoenus maritimus*. However, little is known about how the anatomy and mechanical properties of plant tissues associated with their choice by *L. macrostigma* females. We examined green shoots of six plant species used by *L. macrostigma* for oviposition, either in the field (actual oviposition plants) or under experimental conditions (potential oviposition plants), to analyse anatomy and mechanical properties of shoots in a framework of

known preference of plant substrates for oviposition. As expected, anatomy of shoots differed between representatives of two plant families, Cyperaceae and Juncaceae, most essentially in distribution of supporting bundles and presence of large aeriferous cavities that may affect egg placing within a shoot. The puncture force of tested plant samples ranged from 360 to 3298 mN, and their local stiffness ranged from 777 to 3363 N/m. We showed that the most preferred by *L. macrostigma* plant, *B. maritimus*, had intermediate characteristics of both the stiffness and anatomy parameters of shoot. The bending stiffness of the ovipositor in *L. macrostigma* was estimated as 1414 N/m that is one of highest values recorded for zygopteran dragonflies so far. The ecological and behavioural implications of plant-choice mechanisms in *L. macrostigma* are discussed in the context of fragmented areal distribution of this species." **19128.** Mehmood, S.A.; Khan, M.S.; Zia, A.; Shaheen, F.A. (2016): Morphological evaluation of Gomphidae dragonflies of Hazara region Pakistan through principle component analysis. *Journal of Entomology and Zoology Studies* 4(3): 183-188. (in English) ["Current study was conducted on Gomphidae dragonflies in Hazara region of Pakistan. A total 125 specimens were collected and identified in to 8 species and 6 genera. Five morphometric parameters were based to evaluate the variations and similarities among species. The results were obtained using the principle component analysis. Components PC1 and PC2 were observed positive correlated with all variables. Highest Euclidean distance was observed (5.14) between *Platygomphus dolabratus* and *Anormogomphus kiritschenkoi*, while the lowest Euclidean distance was found (0.27) between *Onychogomphus biforceps* and *O. bistrigatus*. Cladogram was showed two groups I and II and result of Line plot highly support the cladogram. Case wise variability showed 6 (75%) and 2 (25%) species were conspired in the same region between (0 to +2.5) and (0 to -2.5) respectively. The component/factors variability plot was observed the cumulative share for PC1 (60.60%) and PC2 (36.82%) respectively. Morphometry and its findings are very important for identification purposes." **19129.** Mikolajewski, D.J.; Scharnweber, K.; Jiang, B.; Leicht, S.; Mauersberger, R.; Johansson, F. (2016): Changing the habitat: the evolution of inter-correlated traits to escape from predators. *Journal of Evolutionary Biology* 29(7): 1394-1405. (in English) ["Burst escape speed is an effective and widely used behaviour for evading predators, with burst escape speed relying on several different morphological features. However, we know little about how behavioural and underlying morphological attributes change in concert as a response to changes in selective predation regime. We studied inter-correlated trait differentiation of body shape and burst-swim-mediating morphology in response to a habitat

shift related reduction in burst escape speed using larvae of the dragonfly genus *Leucorrhinia* [*L. albifrons*, *L. caudalis*, *L. dubia*, *L. pectoralis* and *L. rubicunda*]. Species in this genus underwent a well-known habitat shift from predatory fish lakes (fish-lakes) to predatory fish free lakes dominated by large predatory dragonflies (dragonfly-lakes) accompanied by relaxed selection on escape burst speed. Results revealed that species from fish-lakes that possess faster burst speed have evolved a suite of functionally inter-correlated traits, expressing a wider abdomen, a higher abdominal muscles mass and a larger branchial chamber compared to species from dragonfly-lakes. In contrast, populations within species did not show significant differences in muscle mass and branchial chamber size between lakes types in three of the species. High multi-collinearity among variables suggests that traits have evolved in concert rather than independently when *Leucorrhinia* shifted from fish lakes to dragonfly lakes. Thus, relaxed selection on burst escape speed in dragonfly-lake species resulted in a correlated reduction of abdominal muscles and a smaller branchial chamber, likely to save production and/or maintenance costs. Our results highlight the importance of studying integrated behavioural and morphological traits to fully understand the evolution of complex phenotypes." **19130.** Mwedzi, T.; Bere, T.; Siziba, N.; Mangadze, T.; Bangira, C. (2016): Longitudinal macroinvertebrate assemblages in contrasting discontinuities: the effects of damming in tropical streams. *African Journal of Ecology* 54(2): 183-194. (in English) ["The study assessed the impact of damming on water quality and macroinvertebrate assemblages. It also assessed the response of macroinvertebrate-based indices of water quality to damming. Macroinvertebrate community and physicochemical variables data were collected from 86 sites. Twenty-nine sites downstream of dams were compared with 27 sites above impoundments and 30 sites on nearby unregulated streams. Of the downstream sites, 13 were situated <1 km from a dam while the other 16 were situated >1 km from a dam. A decrease in temperature, dissolved oxygen, conductivity and total dissolved solids was observed in sites immediately downstream of impoundments. Macroinvertebrate community structure and South African Scoring System (SASS) scores closely followed the damming-induced changes in water quality. However, water quality variables, macroinvertebrate community structure and SASS scores reverted back to typical upstream conditions in distances around 1 km from dams. Stream recovery from dam-induced changes was demonstrated with streams recovering at distances around 1 km from the point of regulation in corroboration with predictions of the serial discontinuity concept (SDC). These dam-induced changes also reflected themselves in SASS scores suggesting potential usefulness of SASS in monitoring ecological integrity of tropical rivers following disturbances like damming." **19131.** Palacino-Rodríguez, F. (2016): Two decades of progress in over one hundred years of study: Present status of Odonata research in Colombia. *Odonatologica* 45(3/4): 327-334. (in English) ["This study documents the results of a bibliometric analysis of 135 indexed publications concerning Odonata research in Colombia. A database including publications since 1868 was built through reliable sources on the Web of Knowledge. The publications were classified by time frame, departments (geography), study categories, and origin. All other categories were sub-classified according to the origin of the researcher, except for geographical classification. Contingence tables were constructed and analysed with Pearson's chisquared test in the following analysis: i) number of papers per time frame according to the origin of the researcher; ii) separated number of papers for foreign researchers, network or Colombian authors over time; iii) number of papers per subject in accordance with the origin of the researcher; and iv) national or international publication according to the origin of the researcher. The number of documents per period, department, subject, and international or national publication were analysed by using chi square. The results showed the number of publications highest in Cundinamarca, Antioquia, Magdalena, Meta, and Valle. Departments least studied have been Arauca, Cesar, Guajira, Nariño, and San Andrés. The largest number of publications was taxonomic (83.7 %) and most studies (78.5 %) were published in international journals. The greatest progress in Odonata research in Colombia has been achieved since 2010. Current and future Odonata research in the country should cover more territory and prioritise research to provide information in order to generate conservation strategies in severely threatened Colombian ecosystems." (Author)] Address: Palacino-Rodríguez, F., Grupo de Investigación en Odonatos de Colombia (GINOCO), Grupo de Investigación en Biología (GRIB), Departamento de Biología, Universidad El Bosque Av. **19132.** Panter, C.; Lake, S.; Liley, D. (2016): Southern Damselfly monitoring results 2015/16. *Natural England/ Footprint Ecology*: 48 pp. (in English) ["Natural England has commissioned this survey to provide up to date information on the status of Southern Damselfly *Coenagrion mercuriale* at its main populations in England in order to inform Article 17 reporting on the implementation of the Habitats Directive. This report presents the results of surveys carried out in 2015 and 2016 at sites known to support Southern Damselfly in Hampshire, Dorset and Devon. Single visits were made to 36 sites (nine sites in Dorset, twenty in Hampshire and seven sites in Devon), all of which had records of Southern Damselfly from 2007 or later. Four of the Dorset sites and all of the Hampshire sites were surveyed in 2015, the remainder of the Dorset sites and all six of the Devon sites were surveyed in 2016. At each site one or more transects were walked. The transects covered discrete

parts of the site such as stream branches, stretches of mire etc. In total, 140 transects were walked. Single visits were made to each location and visits were timed to coincide with peak flight periods and favourable weather conditions. In total, 2,267 male Southern Damselflies were recorded. No individuals were recorded at three (marginal) sites, two in Dorset and one in Devon. At four sites (two in Dorset and one each in Hampshire and Devon) only one male individual was recorded. However, most sites had much larger populations - the largest by quite some margin was 569 at Shipton Bottom. The highest density of individuals (males per meter of transect) was recorded at Tor View Moor, with 49 males per meter. The survey is intended to provide an overview and snapshot of the status. Some limited comparison is made to previous surveys. In the New Forest surveys in 2004 used the same transects and overall there was little correlation between the numbers recorded in 2004 and 2015. Numbers were higher in 2015 in 80% of sites, but were markedly lower at two sites. Data from regular Southern Damselfly monitoring was provided to us from surveys at the Devon sites for comparison to our results. These also differed markedly and counts from regular monitoring were consistently higher. This is not unexpected given the regular monitoring is conducted by surveyors that know each site very thoroughly and repeat visits will generate better count data." (Authors)] Address: footprint Ecology, Forest Office, Cold Harbour, Wareham, Dorset BH20 7PA, UK info@footprint-ecology.co.uk

**19133.** Rayan, S.; Chartchumni, B.; Rangsiwivat, A.; Papapim, Y.; Kumla, S. (2016): Diversity and distribution of Odonate larvae in Nam Oun reservoir. *Khon Kaen Agr. J.* 44(4): 623-630. (in Thai, with English summary) ["Diversity and Distribution of Odonate Larvae were investigated in Nam Oun reservoir, Sakon Nakhon province, Thailand. Random Samplings of Odonate Larvae had been conducted in 4 times, total of 6 stations consisted of 159 Odonate larvae from September 2014 to August 2015. These can be classified into 3 suborders with 8 families. The Family Libellulidae had found the most distribution in all time period and all stations. The highest of percentage frequency of occurrence (%F) was found in Family Libellulidae (50.00), Gomphidae (41.67) and Coenagrionidae and Amphiterygidae (8.33), respectively. The experimental of the differences between categories revealed that the species richness and shannon-wiener index of Odonate Larvae (station\*time period) were resulted no significance ( $p > 0.05$ ). The shannon-wiener index of each station was average  $0.41 \pm 0.18$  and the shannon-wiener index of Odonate larvae's time period of was average  $0.45 \pm 0.14$ . Average shannon-wiener index from each station and time period ranged from  $0.18 \pm 0.10$  and  $0.14 \pm 0.23$ . The main factor which has an influence on the distribution of the Odonate larvae in each station and time period was found in the Odonate larvae in Family Protonuridae Amphiterygidae and Chlorocyphidae in water outlet zone. The distribution was found in the water outlet zone particularly in the season changed from Rainy season to Dry season (T1). The Odonate larvae from family Coenagrionidae was found most distribution in the water outlet zone

during the season changed from Dry season to Rainy season (T3) while the Odonate larvae in Family Libellulidae was found the most distribution in the middle of the water zone when the climate changed from Dry season to Rainy season." **19134.** Renner, S.; Périco, E.; Sahlén, G. (2016): Man-made lakes form species-rich dragonfly communities in the Brazilian Atlantic Forest (Odonata). *Odonatologica* 45(3/4): 135-154. (in English) ["One of the forest types occurring in Southern Brazil is the Mixed Ombrophilous Forest (MOF), a subtype of the Atlantic Forest and one of the biodiversity hotspots on Earth. We sampled adult Odonata at 30 locations in the Floresta Nacional de São Francisco de Paula (FLONA-SFP), Rio Grande do Sul, Brazil, a national reserve which is divided into several sectors of MOF, planted *Araucaria angustifolia*, *Pinus elliottii* used for sustainable and financial purposes, and open fields. There are three types of aquatic environments in the reserve: lakes, swamps, and rivers/streams. Our aim was to obtain an overview of the species' distribution patterns in the three types of aquatic environments and to evaluate the species occurring in lakes, an exclusively man-made habitat in this area. We recorded 46 species from seven odonate families; 25 species ( $x = 5.71 \pm 1.77$  SD) occurring in rivers/ streams, 24 in lakes ( $11.57 \pm 2.15$ ) and 21 in swamps ( $5.22 \pm 3.60$ ). Using Non-metric Multidimensional Scaling (NmDS), we showed that the species composition differed clearly between the three types of aquatic habitats. While swamps and rivers/streams had a relatively similar and uniform species composition, species in the lakes were more varied but the total species number was almost as high as that of the rivers/streams. The lake communities also differed distinctly from those of the other habitats, and we assume that the lake species originate from other degraded areas in the vicinity, indicating that the remains of the Atlantic Forest has already been strongly altered by humans. Given the poor knowledge of the Odonata in the Atlantic Forest/MOF, we hope that our study may increase the understanding of the communities, and contribute to the development of conservation measures for this fragmented biome." (Authors)] Address: Renner, S., Centro Universitário Univates, Rua Avelino Tallini, 171, Laboratório de Evolução e Ecologia, sala 104, Prédio 8, 95900-000, Lajeado, RS, Brazil

**19135.** Renner, S.; Périco, E.; Sahlén, G. (2016): Effects of exotic tree plantations on the richness of dragonflies (Odonata) in Atlantic Forest, Rio Grande do Sul, Brazil. *International Journal of Odonatology* 19(4): 207-219. (in English) ["One of the forest types occurring in Southern Brazil is the mixed ombrophilous forest (MOF), a subtype of the Atlantic Forest, which is one of the richest biomes on Earth. This biome currently remains as a highly fragmented mosaic, under pressure from human development. The diversity and ecology of most animal groups in this biome are poorly known. We studied Odonata in a large forest fragment, including an ecological reserve: the Floresta Nacional de São

Francisco de Paula (FLONA-SFP), in Rio Grande do Sul, administrated by the Brazilian government. The reserve is dominated by MOF with sectors of *Pinus elliottii* and *Araucaria angustifolia*. Three surveys of these forest sectors over one year yielded 42 species, with the highest species richness recorded in the *P. elliottii* sector. The odonate species recorded here are all generalist in terms of habitat preferences, but they appeared only in low numbers and were very particular in their occurrence pattern. We therefore assume that the introduction of an alien element in the Atlantic Forest has given rise to a new species assemblage, where the ecology of the species is adapted to the novel habitat of *Pinus* plantations. As expected, the species occurring in the MOF sectors were mainly habitat specialists. The *Araucaria* plantations had an intermediate species composition. Despite the differences observed in habitat preference between generalist and specialist species, such exotic plantation habitats may act as a temporary biodiversity reservoir for further habitat colonization." (Authors)] Address: Renner, S., Centro Universitário Univates, Rua Avelino Tallini, 171, Laboratório de Evolução e Ecologia, sala 104, Prédio 8, 95900-000, Lajeado, RS, Brazil

**19136.** Sanchez Herrera, M. (2016): Why so many colors?. Ph.D. thesis, Rutgers, The State University of New Jersey: XII, 125 pp. (in English) ["The Neotropics is a center of global diversity for many groups of organisms, including the dragonflies and damselflies (Odonata). While the number of biodiversity surveys and new species descriptions for neotropical odonates is increasing, diversity in this region is still under-explored, and very few studies have looked at the genetic and morphological diversity within taxa. Here, I will present an overview of the evolutionary history, species diversity and morphological diversity of the Neotropical damselfly genus *Polythore*. Species in *Polythore* are stunningly colorful; their wings display varying shades of orange, black and white in complex patterns. Despite this color diversity, they lack variation in classical reproductive traits (e.g. male genitalia) commonly used for species description. The genus comprises 21 described morphospecies distributed along the eastern slopes of the Andes cordillera and the Amazon basin, from Colombia to northern Bolivia; they dwell in small, fast flowing streams with highly oxygenated waters. I used novel morphological methods (geometric morphometrics, chromaticity analysis, and Gabor wavelet transformation) to analyze the complexity of the wing color patterns present in this genus. I explored species and population relationships through phylogenetic reconstructions and species delimitation analyses incorporating mitochondrial (COI, ND1, 16S) and nuclear (18S, 28S, PMRT) sequences. I was able to quantify the color polymorphism and detect that wing color is not due to common descent, i.e. not just result of phylogenetic history. I have discovered that the presence of four new cryptic species, which are new to science, are inflating the estimates species diversity within this genus. Furthermore, my phylogenetic reconstruction for the family Polythoridae suggests that *Polythore* has one common ancestor, however, other genera will need to be taxonomically revised. Finally, the divergence time calibration

analyses indicate that important geological events like the Andes Cordillera uplift may have had an impact on the diversification of these Neotropical damselflies." **19138.** Shao, M.; Jin, L.; Zhang, Y. (2016): Phytotoxic metabolite from QTYC01, a fungus residing in the gut of *Pantala flavescens* larvae. *Acta Microbiologica Sinica* 56(9): 1513-1520. (in Chinese, with English summary) ["[Objective] To isolate the fungus with phytotoxic activity from the gut of *Pantala flavescens* larvae and find the phytotoxic lead compound from the fungal metabolites. [Methods] QTYC01 was isolated from the gut of *P. flavescens* larvae by means of spread plate and identified by 5.8S rRNA sequence analysis and morphologic observation. Phytotoxic activities of the fermentation broth and ethyl acetate extracts against the radical growth of weeds as well as the safety of crude extract to the selected crops were tested by Petri dish bioassay. The herbicidal activity of QTYC01 against *Echinochloa crusgalli* seedlings was carried out by potted bioassay. Fermentation product was purified by recrystallization and identified by extensive spectroscopic analysis. [Results] QTYC01 was identified as *Curvularia crepinii*. The fermentation broth of QTYC01 significantly inhibited the radical growth of *E. crusgalli* and *Amaranthus retroflexus* with the inhibition rate of 95.0% and 90.1%, respectively. The fermented liquid showed significant inhibitory activity to the seedling of *E. crusgalli* with the victimization rate of 71.1%. Under the concentration of 100 ig/mL, ethyl acetate extracts exhibited significant phytotoxic activities against the radical growth of *E. crusgalli* and *A. retroflexus* with inhibitory rates of 56.8% and 71.2%, respectively, and showed good security to the selected common crops with the inhibition rate of lower than 33%. Therewith, a bioactive compound was isolated from the ethyl acetate extract and determined as (5Z)-7-oxozeaenol. The compound showed good phytotoxic activity against *A. retroflexus* with the IC<sub>50</sub> value of 4.8 ig/mL. [Conclusion] Strain QTYC01 could be potentially developed as a new microbial herbicide." A(uthors)] Address:

**19140.** Smith-Patten, B.; Patten, M.A. (2016): Status, distribution, and ecology of the Ozark Emerald (*Somatochlora ozarkensis*) and other springtime-emerging dragonflies of eastern Oklahoma. October 1, 2013 through September 30, 2016. Final Performance Report, Federal Aid Grant No. F13AF01188 (T-73-1): 31 pp. (in English) ["This project was focused on determining the status and distribution in Oklahoma of three species of Anisoptera that are regional endemics to the south-central United States, the Oklahoma Clubtail (*Gomphus oklahomensis*), Ozark Clubtail (*G. ozarkensis*), and Ozark Emerald (*Somatochlora ozarkensis*), with a special focus on the last of these species. We conducted a thorough review of extant museum specimens, published literature, and archived photographs to establish baseline information on distribution. We used this baseline to design a series of field surveys to a) confirm continued presence at sites where the species was known, b) obtain information on relative abundance, and c) detect species at sites where it had not been found previously. We effectively doubled the number of known records of the three target species, and we added dozens of localities of occurrence. We found the two clubtails in sufficiently large numbers to conclude that neither species is of high conservation concern in the state. The emerald proved to be rare in the state. Its scarcity, along with its regional endemism and habitat specificity, warrants a high conservation priority. Additional work on this last species, which may be declining range-wide, is needed. We provide information on five other species—the Ouachita Spiketail (*Cordulegaster talaria*), Atlantic Bluet (*Enallagma doubledayi*), Burgundy Bluet (*E. dubium*), Attenuated Bluet (*E. daeckii*), and Westfall's Snaketail (*Ophiogomphus westfalli*)—of conservation interest in

the region. We also make recommendations for future research for these and other species of conservation interest." (Authors)] Address: Patten, M.A., Oklahoma Biological Survey, University of Oklahoma, Norman, OK 73019, USA. E-mail: mpatten@ou.edu

**19141.** Sniegula, S.; Golab, M.J.; Johansson, F. (2016): A large-scale latitudinal pattern of life-history traits in a strictly univoltine damselfly. *Ecological Entomology* 41(4): 459-472. (in English) ["(1.) Variation in thermal conditions and season length along latitudinal gradients affect body size-related traits over different life stages. Selection is expected to optimise these size traits in response to the costs and benefits. (2.) Egg, hatchling, larval and adult size in males and females were estimated along a latitudinal gradient of 2730 km across Europe in the univoltine damselfly *Lestes sponsa*, using a combination of field-collection and laboratory-rearing experiments. In the laboratory, individuals were grown in temperatures and photoperiod simulating those at the latitude of origin, and in common-garden conditions. (3.) The size of adults sampled in nature was negatively correlated with latitude. In all populations the females were larger than the males. Results from simulated and common-garden rearing experiments supported this pattern of size difference across latitudes and between sexes, suggesting a genetic component for the latitudinal size trend and female-biased size dimorphism. In contrast, hatchling size showed a positive relationship with latitude, but egg size, although differing between latitudes, showed no such relationship. (4.) The results support a converse Bergmann cline, i.e. a negative body size cline towards the north. This negative cline in body size is probably driven by progressively stronger seasonal time and temperature constraints towards the higher latitudes and by the obligate univoltine life cycle of *L. sponsa*. As egg size showed no relationship with latitude, other environmental factors besides temperature, such as desiccation risk, probably affect this trait." **19142.** Suvorov, A.; Jensen, N.O.; Sharkey, C.R.; Fujimoto, M.S.; Bodily, P.; Wightman, H.M.C.; Ogden, T.H.; Clement, M.J.; Bybee, S.M. (2016): Opsins have evolved under the permanent heterozygote model: insights from phylotranscriptomics of Odonata. *Molecular ecology* 26(5): 1306-1322. (in English) ["Gene duplication plays a central role in adaptation to novel environments by providing new genetic material for functional divergence and evolution of biological complexity. Several evolutionary models have been proposed for gene duplication to explain how new gene copies are preserved by natural selection but these models have rarely been tested using empirical data. Opsin proteins, when combined with a chromophore, form a photopigment that is responsible for the absorption of light, the first step in the phototransduction cascade. Adaptive gene duplications have occurred many times within the animal opsins gene family, leading to novel wavelength sensitivities. Consequently, opsins are an attractive choice for the study of gene

duplication evolutionary models. Odonata (dragonflies and damselflies) have the largest opsin repertoire of any insect currently known. Additionally, there is tremendous variation in opsin copy number between species, particularly in the long wavelength sensitive (LWS) class. Using comprehensive phylotranscriptomic and statistical approaches we tested various evolutionary models of gene duplication. Our results suggest that both the blue sensitive (BS) and LWS opsin classes were subjected to strong positive selection that greatly weakens after multiple duplication events, a pattern that is consistent with the permanent heterozygote model. Due to the immense interspecific variation and duplicability potential of opsin genes among odonates, they represent a unique model system to test hypotheses regarding opsin gene duplication and diversification at the molecular level." **19143.** Tsubaki, Y.; Samejima, Y. (2016): Hot males live fast and die young: habitat segregation, reproductive output, and lifespan of sympatric *Mnais* damselflies. *Behavioral Ecology and Sociobiology* 70(5): 725-732. (in English) ["The Japanese damselflies *Mnais costalis* and *Mnais pruinosa* show microhabitat segregation in response to forest sunlight conditions in their sympatric habitat: *M. costalis* prefers sunny sites while *M. pruinosa* prefers semi-shady sites. We tested whether sunlight conditions at territorial sites influenced reproductive output, territory occupancy, and/or reproductive lifespan of males of the two species differently. Oviposition duration of females after copulation was used as the measure of reproductive output of individual males. We recorded illuminance at each territorial site on sunny days during the behavioral observation periods. *M. costalis* males at sites with higher illuminance had a higher reproductive output than other territorial males, while *M. pruinosa* males had a relatively lower reproductive output at such sites. During a reproductive season, we performed population censuses in a 500-m area of stream, which contained at least 112 potential territorial sites. Using a fish-eye converter, we took a hemispherical photograph to estimate canopy openness as a measure of insolation at each territorial site and examined whether males incur higher survival costs by holding territories at sunnier sites. Minimum reproductive lifespan, estimated as days between the first and the last sightings, showed that *M. costalis* males that occupied sunnier sites had a shorter lifespan than those occupying shadier sites, while *M. pruinosa* males did not show such a relationship. These results suggest that microhabitat segregation of these two *Mnais* damselflies reflects a species difference in the tradeoff between the benefit of mating rate and cost of survival in the sun. Significance statement: We report a field study on the relationships among thermal environment, temperature tolerance, reproductive success, and character displacement in the mating systems of two species of territorial *Mnais* damselflies. Allopatric populations of these two species are forest dwellers, and males of each species show wing color polymorphism linked to alternative mating behaviors. When these species are sympatric,

males lose their polymorphisms and change their habitat preferences: *M. pruinosa* prefers shady parts of a stream, while *M. costalis* prefers sunnier parts. We showed the costs and benefits of character displacement coupled to microhabitat preference shift. The findings of this study may highlight an underappreciated area of study, namely, the interplay between behavioral and physiological ecology in insects." **19145.** Turnhout, S.; Wasscher, M.; Termaat, T. (2016): The return of the River Clubtail (*Gomphus flavipes*) in the Netherlands. New insights in ecology and research. *Brachytron* 18(1): 38-49. (in Dutch, with English summary) ["After the rediscovery of the River Clubtail (*Gomphus flavipes*) in the Netherlands in 1996, insights in the occurrence and ecology of this rare and critically endangered species changed. In this article we show that new insights like these do not emerge spontaneously. In this case it required the intervention of a new type of actor (a fish researcher, with a sound knowledge of dragonflies) who applied new and unorthodox instruments (the water filter of a power plant) at an unusual place (private terrain, not open to the public) to find a first larva. Only after repeating his discovery two years later the new insights gained a foothold. The example of the River Clubtail shows that our constantly changing knowledge of species can be related to both ecological and social aspects. Besides the improvement of water quality in Dutch rivers at the end of the twentieth century, more people looked for dragonflies more often at more places, with new incentives and using more instruments and more information. Obviously new discoveries should be expected under these circumstances. It is a classical dilemma in ecological monitoring: does this trend show changes in the numbers or occurrence of the species, or does it merely reflect changes in the population of observers? The interconnectedness

of social and ecological aspects shows that biodiversity research is about more than just data. What more precisely, is to be investigated further." (Authors)] Address: Wasscher, M.: marcel.hilair@12move.nl

**19146.** Ubukata, H. (2016): Life history of *Sympetrum frequens* (Selys, 1883) in Hokkaido: are migration and reproductive diapause involved?. *Tombo* 58: 1-26. (in Japanese, with English summary) ["Life history events and spatio-temporal distribution of the imagines of *Sympetrum frequens* (Selys, 1883) in Hokkaido were reviewed and the possibilities of adopting (1) migration between lowland larval habitats and cooler mountainous areas and (2) reproductive diapause were discussed for Hokkaido population. Emergence began in late June in the district where air temperature sometimes exceeded 30°C even in May (i.e., Abashiri District) or in early August in the district with a cool spring (Nemuro District). Precocious adults showed reproductive behavior as early as late July (estimated to be ca. 20 days after emergence), and mass engagements in tandem flight began from late August until early September (estimated to be 40–50 days after emergence) in Ishikari and nearby districts. Individuals performing such a synchronous reproductive behavior 20 days or more after the dates of the earliest reproductive behavior might have undergone reproductive diapause, which could afford a safeguard for avoiding loss from part of their eggs hatching before winter. Many imagines, mostly immature adults, were observed at 400–2,100 m alt. on Mt. Daisetsu during July and early August. They were likely to be those which had emerged from paddy fields, ponds, etc. on the Kamikawa Basin and had flown toward the upper reaches of the mountainous area because the ponds at 1,300–1,700 m alt. were in a condition just after the snow thaws, which should have prevented the larvae from growing and becoming imagines before early August. Actually, no larva of this species was captured during surveys made at various ponds at 1,300–1,700 m alt. in July. Most of the populations emerged on the plains in central Hokkaido was likely to migrate or to move toward mountainous areas and then to fly further toward the upper reaches. But the portion of the Hokkaido population that remained on the plains without migrating to mountains were likely to be much higher than those of the central Honshu populations. As Uéda (1995) predicted, the altitudinal zones utilized by the Hokkaido populations during hot summers were much lower than those of central Honshu, having had no altitudinal gap with the subpopulations remaining on the lowlands. Nevertheless, part of the Hokkaido population is likely to migrate as a habit, if the following observations by Wataji et al. (1997b) in Sapporo city are taken into consideration: at least some imagines of *S. frequens* tended to perch high in the tree canopy around the emergence site on the lowland during the first few days after emergence and then fly rather steadily towards distant mountainous areas. This habit is likely to be an adaptation for long distance (e.g., 10 km) migration across the plain towards mountain areas. Actually Wataji et al. caught several individuals out of several thousands that had been marked at an emergence site, in the middle of the Ishikari Plain. Finally, genetic traits

of reproductive diapause and migration were discussed in the context of adjustments responding to climate and seasonality, followed by speculation on the evolutionary processes of these traits in Hokkaido." (Author)] Address: Ubukata, H., Hokkaido University of Education at Kushiro, Dept Science Education, Shiroyama 1-15-55, Kushiro, 085, Japan. E-mail: ubukata@kus.hokkyodai.ac.jp

**19147.** Westermann, K. (2016): Vorkommen und Schutz der Alpen-Smaragdlibelle (*Somatochlora alpestris*) und der Arktischen Smaragdlibelle (*Somatochlora arctica*) im Oberen Hotzenwald (Südschwarzwald). *Naturschutz südl. Oberrhein* 8: 166-186. (in German, with English summary) ["From 2011 to 2015 I tried to check places together with Elisabeth Westermann in the upper Hotzenwald (southern black Forest) where *Somatochlora arctica* und *S. alpestris* have been found in former times and also tried to find other water bodies where these dragonflies develop. All places where they were found were rated according to the approach described by Sternberg (1995) as stem habitat, secondary habitat or latency habitat based on the regularity and frequency of the recorded exuviae. We found populations of *S. arctica* in 18 bogs and fens; one was a stem habitat, four were secondary habitats and 13 latency habitats. Single populations consisted of observation sites which were at a distance of up to 250 m from each other. in one year the maximum number was 46 exuviae per moor and 103 exuviae in the whole area. *S. alpestris* was significantly less frequent. the populations in ten bogs and fens, one secondary habitat and nine latency habitats, yielded at maximum only ten exuviae per moor and 22 exuviae in the whole area. the lowest observation site of *S. alpestris* was at 878 m NN at the lower limit of the altitudinal distribution of the species in the southern black Forest. *S. arctica* also emerged at all observation sites of *S. alpestris*, sometimes in close spatial vicinity within the same small water body. Approximately two thirds of all exuviae were distributed over small silting gullies of diverse hanging moors which are the most important habitat for the development of both species in the upper Hotzenwald. the populations are highly endangered by long droughts, silting and overgrowth with groves. in the nature reserve „ennersbacher Moor“, one of the scarce stem habitats of both species in the southern and middle black Forest was destroyed within 20 to 30 years. A concept for the protection and optimization of existing stem habitats and secondary habitats as well as for the creation of further habitats for the development, which are effective for the population biology, was outlined." (Author)] Address: Westermann, K., Buchenweg 2, D-79365 Rheinauen., Germany

**19148.** Whispell, A.M. (2016): Physiological color change in the blue-fronted dancer damselfly. Ph.D. thesis, Rutgers, The State University of New Jersey: xi, 141 pp. (in English) ["Several studies have established the existence of temperature-controlled physiological color change (PCC) in Odonata species. Individuals capable of this PCC darken to "dark-phase" (DP) coloration below a temperature threshold and return to "bright-phase" (BP) coloration once above it.

The stimulus controlling PCC in *Argia apicalis* (Say) has been contentious since first studied in the 1960s, as BP and DP males are often present under seemingly identical conditions. In Chapter 1, my goal was to determine if the control of *A. apicalis* male PCC could be attributed to one specific variable or if it is dual-controlled. I first tested whether ambient temperature can be used to predict color phase and found that it is a significant predictor of DP coloration in solitary males only. I next looked for an association between DP coloration and mating status (mating or solitary) and found that DP is far more likely to be exhibited by mating males, thus PCC is also mating-controlled in *A. apicalis* males. Finally, I looked for a relationship between mating stage and color phase and established that mating-controlled PCC is initiated during copulation, further supporting the link between mating and PCC. Additionally, males were darkest during oviposition—the mating stage when males may be most vulnerable to predation. My results indicate that *A. apicalis* males possess dual-controlled PCC. In Chapter 2, my objective was to establish whether DP coloration could be operating as an anti-predator defense strategy in *A. apicalis* males. I first measured the reflectance spectra of DP and BP males and found that BP males are approximately 4.8 times brighter than DP males. I subsequently performed a binary choice experiment to determine whether BP males suffer higher levels of predation than DP males. I tested two predator groups for their color phase preference: avians, *Gallus gallus domesticus* (Linnaeus), and anurans, *Lithobates clamitans melanota* (Rafinesque) and *Lithobates catesbeianus* (Shaw). I found that both groups attacked significantly more BP than DP models, so it is plausible that the mating-controlled PCC exhibited by *A. apicalis* males could be functioning as an anti-predator defense strategy during oviposition." (Author)] Address: not stated

**19149.** Why, A.M.; Lara, J.R.; Walton, W.E. (2016): Oviposition of *Culex tarsalis* (Diptera: Culicidae) differs on water conditioned by potential fish and insect predators. *Journal of Medical Entomology* 53(5): 1093-1099. (in English) ["The response of egg-laying *Culex tarsalis* Coquillett (Diptera: Culicidae) to water conditioned by three fish species used for mosquito control and three predatory aquatic insect species was examined in laboratory binary choice experiments. Oviposition by *Cx. tarsalis* was 72% less on water conditioned with the arroyo chub, *Gila orcutti* (Eigenmann & Eigenmann) (Cypriniformes: Cyprinidae) relative to control cups containing aged tap water, but no significant difference was found in the numbers of egg rafts laid on water conditioned with the fathead minnow (*Pimephales promelas* (Rafinesque), Cypriniformes: Cyprinidae) and the control treatment (water aged 24h). Mosquito oviposition on water conditioned with the predominantly herbivorous/algivorous California Mozambique tilapia hybrid (*Oreochromis mossambicus* (Peters) × *Oreochromis urolepis hornorum* L. (Perciformes: Cichlidae)) or predatory insects (nymphs: *Sympetrum corruptum*; adults: *Thermonectus basillaris* (Harris) or *Cybister fimbriolatus* (Say) (Coleoptera: Dytiscidae)) did not differ significantly relative to that onto water aged for 24h. As compared with water aged 24h and water conditioned with diving

beetles, oviposition by *Cx. tarsalis* was significantly lower (=53%) when live predatory diving beetles were present in oviposition cups. Gravid *Cx. tarsalis* females do not respond equally to putative semiochemicals in water conditioned with the piscine or aquatic insect predators of immature mosquitoes tested here." **19151.** Zhao, Q.; Pan, Y.; Griffin, J.N.; Sun, J.; Sun, S. (2016): Contrasting trophic-cascade effects driven by variation in morphology of the perches used by a larval damselfly. *Freshwater Biology* 61(5): 693-701. (in English) ["(1) The presence of habitat structures (e.g. caves, ledges, branches) has well-documented ecological effects. However, it remains largely unknown how variation in the morphology of particular habitat structures affects ecological interactions. (2) Using an algae-cladoceran grazer-larval damselfly food chain as a model in a series of microcosm experiments, we manipulated food-chain length and the length (long versus short) and diameter (thick versus thin) of vertically orientated damselfly perches (habitat structure) and examined the density of the grazers and algae. Because the larval damselflies are usually more flexible on thinner perches and have broader foraging domains on longer perches, we predicted that when on long and thin perches they would suppress grazer density more efficiently and hence confer a more positive trophic-cascade effect on algal growth. (3) As predicted, larval damselflies occupying long and thin perches most strongly reduced grazer density and increased algal density, illustrating a positive trophic cascade. In all other damselfly treatments, and despite reduced grazer density, algal density declined, showing a negative trophic cascade due to an elevation in grazer foraging efficiency under predation risk. This probably resulted from the increased activity of the grazers and their spatial shift to the lower water column where algal density was higher. (4) In conclusion, perch morphology affected the direction and strength of the trophic cascade by altering both density-mediated and behaviour-mediated indirect interactions. Considering that anthropogenic disturbance is dramatically changing the morphological diversity of habitat structures, we call

for more research into the ecological consequences of such physical diversity at community and ecosystem ." (Authors)] Address: Sun, S., Dept of Biology, College of Life Sciences, Nanjing University, 163 Xianlin Avenue, 210023 Nanjing, China. E-mail: shcs@nju.edu.cn

## 2018

**19152.** Brasil, L.S.; Olivira-Junior, J.M.; Calvao, L.B.; Carvalho, F.G.; Monteiro-Junior, C.S.; Dias-Silva, K.; Juen, L. (2018): Spatial, biogeographic and environmental predictors of diversity in Amazonian Zygoptera. *Insect Conservation and Diversity* 11: 174-184. (in English) ["1. Our objectives were to assess how turnover and nestedness contribute to beta-diversity patterns of the Zygoptera in Amazonian streams, and to relate these components of beta diversity to environmental, spatial and biogeographic predictors. Our first hypothesis is that the turnover is the most important component of beta-diversity patterns due to the historical isolation of all or part of the areas located in the interfluves of the major Amazonian rivers. Our second hypothesis is that the interaction between environmental conditions and the area of endemism (biogeography) would be the most important predictor of beta-diversity patterns. 2. To test these hypotheses, we compiled data on the Zygoptera communities from 172 Amazonian streams. We used three sets of predictor variables: (i) environmental variables, (ii) area of endemism (biogeographic) and (iii) spatial filters. 3. The turnover explained 99.36% of the beta diversity, corroborating our first hypothesis. Together, environmental and biogeographic variables were the best predictors of beta-diversity patterns. For turnover, however, the biogeographic variables were the best predictors, contrary to our second hypothesis. 4. We found high gamma diversity, but low alpha diversity in the Zygoptera communities. This paradox is explained by the high turnover among sites within the study landscape. This pattern of diversity is related to both historical biogeographic factors and the spatial structuring of environmental conditions in the Amazon region. In the light of our results (high turnover and beta diversity), and their correspondence with areas of endemism, adequate conservation of Amazonian Zygoptera diversity will depend on the establishment of so-called mega-reserves throughout the major Amazonian interfluves and, whenever possible, in the areas with adequate environmental conditions for the greatest possible number of species, otherwise, most species may be at a constant risk of extinction." **19153.** Harabis, F.; Dolny, A. (2018): Military training areas as refuges for threatened dragonfly species: Effect of spatial isolation and military activity. *Biological Conservation* 217: 28-35. (in English) ["A long-term decline in habitat quality and freshwater species diversity has forced conservation managers to consider secondary habitats, such as military training areas (MTAs), that were previously overlooked but have conservation potential. Isolation from many negative

anthropogenic influences combined with disturbances associated with military activities can benefit the diversity of terrestrial species. However, little is known about the conservation potential of freshwater habitats that are an integral part of MTAs. In this study, we used Odonata as valuable indicators of habitat quality to compare the diversity of freshwater sites inside and outside MTAs. We randomly selected 16 sites inside four extensive MTAs and 16 reference sites outside MTAs and examined the differences in traits of species occurring inside and outside the MTAs. We found that the diversity and conservation value of dragonfly communities inside MTAs was comparable to that in the most valuable freshwater habitats outside MTAs. Inside MTAs, species were primarily those associated with habitats in the late successional stages, while species associated with early successional stages were absent. Undoubtedly, the conservation potential of MTAs for freshwater invertebrates is in the long-term isolation from negative anthropogenic influences. Paradoxically, the main potential problem in protecting freshwater habitats inside MTAs is the cessation of military activity." (Authors)] Address: Harabiš, F., Dept Ecol., Fac. Environmental Sciences, Czech Univ. Life Sciences Prague, Kamýcká 129, 165 21 Prague 6, Czech Republic

**19154.** Kim, M.J.; Wang, A.R.; Kim, S.S.; An, J.; Kim, I. (2018): Development and validation of microsatellite markers for the tiny dragonfly, *Nannophya pygmaea* (Odonata: Libellulidae), which is endangered in South Korea. *Applied Entomology and Zoology* 53(1): 151-156. (in English) ["The tiny dragonfly, *Nannophya pygmaea* (Odonata: Libellulidae), is listed as a second-degree endangered wild animal in South Korea. The application of molecular markers to assess genetic diversity and population relationships can provide information necessary to establish an effective conservation strategy. In this study, we developed 12 microsatellite markers specific to *N. pygmaea* using the NextSeq 500 platform. Forty individuals of *N. pygmaea* collected from three currently known localities in South Korea were genotyped to validate these markers and to preliminarily assess population genetic characteristics. The observed number of alleles, observed heterozygosity, and expected heterozygosity at a locus ranged from 2 to 9, 0.421–1.0, and 0.508–0.766 in a population with the largest sample size (20 individuals), respectively, thereby validating the suitability of the markers for population analysis. Five of 12 loci showed significant deviation from the Hardy–Weinberg equilibrium in the population. Our preliminary data indicate an absence of inbreeding in all populations and an absence of obvious genetic difference. The microsatellite markers developed in this study will be useful for studying the population genetics of *N. pygmaea* collected from other regions worldwide, including additional sites in South Korea." (Authors)] Address: Kim, Min Jee, Department of Applied Biology, College of Agriculture and Life Sciences, Chonnam National University, Gwangju, Republic of Korea

**19155.** Op de Beeck, L.; Verheyen, J.; Stokks, R. (2018): Strong differences between two congeneric species in sensitivity to pesticides in a warming world. *Science of The Total*

Environment 618: 60-69. (in English) ["Highlights: •Combined effects of warming and chlorpyrifos differed between two damselfly species. •Chlorpyrifos reduced survival and growth more in the large, slow growing species. •Chlorpyrifos reduced heat tolerance only in the more sensitive species. •Differences in sensitivity were not driven by size and life history but physiology. •Trait-based methods to predict sensitivity to pesticides need physiological traits. Abstract: To predict the impact of pesticides in a warming world we need to know how species differ in the interaction pathways between pesticides and warming. Trait-based approaches have been successful in identifying the 'pace of life' and body size as predictors of sensitivity to pesticides among distantly related species. However, it remains to be tested whether these traits allow predicting differences in sensitivity to pesticides between closely related species, and in the strength of the interaction pathways between pesticides and warming. We tested the effects of multiple pulses of chlorpyrifos (allowing accumulation) under warming on key life history traits, heat tolerance (CT<sub>max</sub>) and physiology of two congeneric damselfly species: the fast-paced (fast growth and development, high metabolic rate), small *Ischnura pumilio* and the slow-paced, large *I. elegans*. Chlorpyrifos reduced survival and growth, but contrary to current trait-based predictions *I. pumilio* was 8 × less sensitive than *I. elegans*. The lower sensitivity of *I. pumilio* could be explained by a higher fat content, and higher activities of acetylcholinesterase and of detoxifying and anti-oxidant enzymes. While for *I. pumilio* the effect of chlorpyrifos was small and did not depend on temperature, for *I. elegans* the impact was higher at 20 °C compared to 24 °C. This matches the higher pesticide accumulation in the water after multiple pulses at 20 °C than at 24 °C. The expected reduction in heat tolerance after pesticide exposure was present in *I. elegans* but not in *I. pumilio*. Our results demonstrate that closely related species can have very different sensitivities to a pesticide resulting in species-specific support for the "toxicant-induced climate change sensitivity" and the "climate-induced toxicant sensitivity" interaction pathways. Our results highlight that trait-based approaches can be strengthened by integrating physiological traits." **19156.** Op de Beeck, L.; Verheyen, J.; Stoks, R. (2018): Competition magnifies the impact of a pesticide in a warming world by reducing heat tolerance and increasing autotomy? *Environmental Pollution* 233: 226-234. (in English) ["Highlights: •Competition made the pesticide chlorpyrifos (CPF) become lethal. •CPF exposure led to more autotomy but only at high density under warming. •At high density CPF reduced the heat tolerance (CT<sub>max</sub>). •Competition can increase the toxicity and impact of a pesticide under warming. Abstract: There is increasing concern that standard laboratory toxicity tests may be misleading when assessing the impact of toxicants, because they lack ecological realism. Both warming and biotic interactions have been identified to magnify the effects of toxicants. Moreover, while biotic interactions

may change the impact of toxicants, toxicants may also change the impact of biotic interactions. However, studies looking at the impact of biotic interactions on the toxicity of pesticides and vice versa under warming are very scarce. Therefore, we tested how warming (+4 °C), intraspecific competition (density treatment) and exposure to the pesticide chlorpyrifos, both in isolation and in combination, affected mortality, cannibalism, growth and heat tolerance of low- and high-latitude populations of *Ischnura elegans*. Moreover, we addressed whether toxicant exposure, potentially in interaction with competition and warming, increased the frequency of autotomy, a widespread antipredator mechanism. Competition increased the toxicity of chlorpyrifos and made it become lethal. Cannibalism was not affected by chlorpyrifos but increased at high density and under warming. Chlorpyrifos reduced heat tolerance but only when competition was high. This is the first demonstration that a biotic interaction can be a major determinant of 'toxicant-induced climate change sensitivity'. Competition enhanced the impact of chlorpyrifos under warming for high-latitude larvae, leading to an increase in autotomy which reduces fitness in the long term. This points to a novel pathway how transient pesticide pulses may cause delayed effects on populations in a warming world. Our results highlight that the interplay between biotic interactions and toxicants have a strong relevance for ecological risk assessment in a warming polluted world." **19157.** Tüzün, N.; Stoks, R. (2018): Carry-over effects across metamorphosis of a pesticide on female lifetime fitness strongly depend on egg hatching phenology: a longitudinal study under seminatural conditions. *Environ Sci Technol.* 51, 23: 13949-13956. (in English) ["Current ecological risk assessment of pesticides fails to protect aquatic biodiversity. For the first time, we tested two potential reasons for this failure with regard to carry-over effects across metamorphosis: their dependence on hatching period, and the lack of studies quantifying adult fitness under seminatural conditions. Using the damselfly *Coenagrion puella* sampled from six populations, we designed an outdoor longitudinal one-year study starting from the egg stage. We exposed the aquatic larvae to the pesticide esfenvalerate (0.11 µg/L) during the initial microcosm part. Next, we monitored the lifetime fitness of the terrestrial adults in an insectary. Exposure to the pesticide negatively impacted not only larval traits, but also drastically reduced lifetime mating success of adult females. The impact of this post-metamorphic effect of the pesticide on the population level was three times more important than the effects in the larval stage. Importantly, this carry-over effect was only present in females that hatched early in the season, and was not mediated by metamorphic traits (age and mass at emergence). We provide proof-of-principle under seminatural conditions for two potential pitfalls that need to be considered when improving risk assessment: carry-over effects on adult fitness can (i) be much more important than effects during the larval stage and may not be captured by metamorphic traits, and (ii) be

strongly modulated by egg hatching dates." (Authors)] Address: Stoks, R., Lab. voor Aquatische Ecologie, K.U.Leuven, De Beriotstraat 32, B-3000 Leuven, Belgium. E-mail: robby.stoks@bio.kuleuven.ac.be

**19158.** White, III, H.B.; Moore, M.C. (2018): Forty-five-year record of the Odonata fauna of Lums Pond State Park, New Castle county, Delaware. *Bulletin of American Odonatology* 12(3): 21-33. (in English, with Spanish summary) ["We document the Odonata fauna of Lums Pond State Park in northern Delaware based on 45 years of observations with seasonal and yearly distributions for the 67 species observed. While the species composition has remained fairly stable, periods of drought have resulted in large decreases in the abundance or temporary absence of species associated with vernal pond habitats. Recolonization and population recovery often required several years to more than a decade. Various introduced fauna and flora (e.g. beaver, geese, carp, Phragmites) have altered permanent pond habitats and are associated with changes in the presence of certain Odonata species and their abundance. Disturbance of one shallow water impoundment by carp and beaver resulted in an abundance of cosmopolitan species associated with degraded habitats. Changes in shoreline vegetation resulting from the spread of Phragmites appeared to favor some damselfly species and reduced populations of others." **19159.** Bartosova, M.; Schenková, J.; Polášková, V.; Bojková, J.; Šorfová, V.; Horsák, M. (2019): Macroinvertebrate assemblages of the post-mining calcareous stream habitats: Are they similar to those inhabiting the natural calcareous springs?. *Ecological Engineering* 136: 38-45. (in English) ["Highlights: • Post-mining brooks represent habitats similar to endangered natural spring brooks. • Post-mining brooks harboured spring specialists and red-listed species. • Species compositions of post-mining and natural brooks were distinct. • Differences were caused mainly by extreme environment related to post-mining brooks. Abstract: Surface coal mining severely affects natural ecosystems, though it might also result in an establishment of biologically unique anthropogenic habitats. We studied spontaneously created post-mining calcareous brooks located at the brown coal spoil heap in the Sokolov coal basin (Czechia). Despite their extreme water conditions, linked most to the ionic mixture of dissolved ions (mainly  $\text{SO}_4^{2-}$ ,  $\text{Ca}^{2+}$  and  $\text{Mg}^{2+}$ ), and ferric hydroxide precipitations, we recorded unexpectedly species-rich assemblages there (150 species), including several spring fen specialists (31 species) and eight threatened red-listed species. Macroinvertebrate assemblages of post-mining calcareous habitats were compared with those reported from natural brooks draining Western Carpathians calcareous spring fens. The species richness found in the post-mining calcareous brooks was significantly lower than that of the natural calcareous spring brooks. Although we found 29% of species recorded in the two study systems in common (i.e. 80 species), species composition of their assemblages was systematically distinct. This suggests a

possible role of environmental filtering in the post-mining brooks and/or dispersal limitation of some species typical for natural calcareous spring brooks (e.g. *Trichodrilus strandi*, *Bythinella austriaca*). In contrast, many macroinvertebrates, particularly those of high dispersal capacities (i.e. Odonata, Coleoptera and Diptera), can recognize post-mining calcareous brooks as surrogate habitats for the natural calcareous spring brooks." **19160.** Borisov, S.N.; Malikova, E.I. (2019): Distribution and migration strategy of *Pantala flavescens* (Fabricius, 1798) (Odonata, Libellulidae) near the northern limit of its range in Transbaikalia and in the Far East of Russia. *Eurasian Entomological Journal* 18(3): 155-162. (in English, with Russian summary) ["Data on distribution and phenology of migratory dragonfly *P. flavescens* at the northern limit of the range in Transbaikalia and the Far East of Russia are summarized on the basis of literature sources and collection material. *P. flavescens* flies during May and June from southern territories to the north in order to breed a so-called summer «temperate» generation, and only occurs in that region during the summer and autumn. The northernmost breeding locality registered for the dragonfly is Blagoveshchensk, 50°17'11" N, 127°30'52" E. In September the progeny presumably migrate to the south into a usually warm part of the areal. Hypothetically such a strategy is typical of some individuals while the majority of the population visiting Far East of Russia temporarily do not breed there." **19162.** Devaud, M.; Lebouvier, M. (2019): First record of *Pantala flavescens* (Anisoptera: Libellulidae) from the remote Amsterdam Island, southern Indian Ocean. *Polar Biology* 42(5): 1041-1046. (in English) ["Natural colonization of macroinvertebrates into the Sub-Antarctic area is generally accepted to be a rare event. In February 2017, two live adults of *Pantala flavescens* (Libellulidae) were recorded on the isolated Amsterdam Island (37°50' S, 77°30' E), southern

Indian Ocean [French Southern and Antarctic Lands]. This circumtropical species, common name the Globe Skimmer, can fly several thousand kilometers. This paper analyzes the weather conditions in this sector of the Indian Ocean in February 2017 to assess the probability of arrival of the dragonflies by air from their known migration route at lower latitudes between India and East Africa. The probability that this species could establish and form a permanent population on Amsterdam Island is discussed. Some favorable habitats are present but temperatures are probably too low to allow the dragonflies to complete their development. Odonata have never been observed on Sub-Antarctic islands and reports of natural arrival of insects into these islands mainly concern Lepidoptera. Here we also report observations of *Vanessa cardui* (Nymphalidae) which has established a permanent population on Amsterdam Island and has been observed on several occasions in the Crozet Archipelago." **19163.** Garcia Junior, M.D.N.; Rakes, M.; Pazini, J. de B., Pasini, R.A.; Garcia, F.R.M. & Grützmacher, A.D. (2019): The diversity of Odonata adults's at Pampa Biome from Brazil. *Revista de Biología Tropical* 67(1): 107-117. (in English) ["The growth of humankind has brought with it several environmental problems that have worsened over time, including the loss of insect biodiversity. The Odonata order have been indicated by several authors as relevant bioindicators for assessing and monitoring environmental conditions of specific locations. The main objective of this study was to conduct an inventory of the Odonata diversity in the Pampa Biome, of the Southern region of the state of Rio Grande do Sul, Brazil. The species survey was conducted between November 2014 and October 2015. Adult insects were collected in Capão do Leão, Pelotas and Rio Grande cities. Each location was visited nine times, totalizing 54 samplings. Entomological nets were used for capturing adult insects, which were then kept in entomological envelopes. The identification of the specimens was carried out with taxonomic keys of Lencioni and Heckman. In addition, Chao-1, the Shannon-Wiener and Jackknife indexes were associated with the sampling areas. During the species survey a total of 2 680 Odonata specimens were collected, representing 45 species encompassed in 22 genera and six families. The Libellulidae and Coenagrionidae families were registered in 60 and 30 % of the specimens sampled, followed of the Aeshnidae, Calopterygidae, Gomphidae and Lestidae, of reduced occurrence. The genera *Erythrodiplax*, *Micrathyria* and *Ischnura* were found at least once in all the visited sites. The study resulted in the registration for the first time of the following species: *Progomphus complicatus* Selys, *Lestes minutus* Selys, *Homeoura ambigua* Ris, and *Tauriphila xiphea* Ris. These species were not previously reported in any Odonata study of the Brazilian state of Rio Grande do Sul. In regard to Odonata diversity in the Southern region of Rio Grande do Sul, Libellulidae and Coenagrionidae are the families more abundants. *Erythrodiplax* and *Micrathyria* are the most common genera. *Micrathyria marcella* represented

9.6 % of all collected libellulidae and was the most abundant specie. Capão do Leão has the largest species diversity (wealth), the largest number of collected specimens and more diversity than Pelotas and Rio Grande. However, the results showed that the Odonatofauna in the State are still little known, and new studies are needed to better describe this group in other regions." (Authors)] Address: Garcia, M., Dept of Ecology, Zoology, & Genetics, Inst. of Biology (IB), Federal Univ. of Pelotas, postcode 96010-900, Pelotas, Rio Grande do Sul, Brazil. **19164.** Kemabonta, K.A.; Adu, B.W.; Akanni, N.; Olajide, J.P.; Uche-Dike, R. (2019): Studies on influence of human activities on the species diversity of Odonata in parts of Lagos metropolis. *Nigerian Annals of Pure and Applied Sciences* 1(1): 123-129. (in English) ["This study was conducted to determine dragonfly species diversity in a fish pond in Igbaga, Ikorodu (6.6671°N and 3.5983°E) and a large expanse of farm land in Ipaja (6.6044°N and 3.2660°E), southwestern Nigeria from January, 2016 to July, 2016 to as well as the effect of anthropogenic activities on the dragonflies at both sites. A total of 1002 dragonflies were collected belonging to 20 species, 15 genera, and two families (Libellulidae and Aeshnidae), were found at the two locations. The most dominant species in Site 1 (Ikorodu fish farm) was *Chalcostephia flavifrons* (36%) followed by *Palpopleura lucia* (15%) and the least were *Palpopleura albifrons*, *Gynacantha nigeriensis*, *Diplacodes lefebvrei* and *Trithemis grouti* which were one percent of the total numbers sampled. On the other hand, the most dominant species in Site 2 (Agricultural Farm in Ipaja) was *Pantala flavescens* (92%) and the least was *Urothemis assignata* (1%). Similarity test using Sorensen's quotient revealed a strong dissimilarity in the community structures of the two areas surveyed. The fish pond had a more even distribution of the dragonflies ( $e^H/S = 0.508$ ) and a higher concentration ( $H' = 1.808$ ) of dragonflies than Ipaja agricultural farm." **19168.** Masius, P. (2019): Die Libellenfauna der Ostseeinseln Wollin (NW Polen) und Usedom (NO Deutschland) mit angrenzendem Festland – Frühjahrsaspekt 2018, und Anmerkungen zum Vorkommen von *Coenagrion armatum* (Charpentier, 1840). International Dragonfly Fund Report 130: 1-40. (in German, with English summary) ["In May 2018, 34 dragonfly species were recorded on Wollin (21), Usedom (30) and the adjacent mainland (21). The most frequent spring species in the area were *Coenagrion puella*, *Libellula quadrimaculata*, *C. pulchellum*, *Ischnura elegans*, *Erythromma najas*, *Brachytron pratense* and *Cordulia aenea*. *C. lunulatum* and *Calopteryx virgo* were recorded for the first time on Usedom, while *Anax parthenope*, *Libellula fulva* and *Leucorrhinia caudalis* were recorded for the first time on Wollin. The occurrence of *C. armatum*, which had been recorded in 2016 on Usedom, could not be confirmed. The

quantitative results of the survey are given for different types of water bodies (ditches, pools, ponds, lakes, bog lakes). The average number of species per water body was highest in bog lakes (7.5) and lowest (3.4) in temporary pools. In comparison to older studies from the area, the flight season started 13.7 days earlier in 2018 than in years documented prior to 1989. This might be explained by climatic changes. The species composition, however, has remained rather stable – at least on Usedom and the mainland. On Wollin, climatic factors as well as habitat loss and transformation have led to a species composition that is different from the one recorded in the first half of the 1970s." **19170.** Outomuro, D.; Johansson, F. (2019): Wing morphology and migration status, but not body size, habitat or Rapoport's rule predict range size in North-American dragonflies (Odonata: Libellulidae). *Ecography* 42(2): 309-320. (in English) ["Understanding why species range sizes vary is important for predicting the impact of environmental change on biodiversity. Here we use a multi-variable approach in a phylogenetic comparative context to understand how four morphological, two ecological, and two eco-geographical variables are associated with range size, latitudinal range and longitudinal range in 81 species of North-American libellulid dragonflies. Our results show that: 1) migratory species and species with a more expanded basal hindwing lobe have a larger range size; 2) opposite to Rapoport's rule, latitudinal range is negatively correlated with mid-range latitude; 3) longitudinal range is predicted by wing morphology and migration; 4) body size and larval habitat are not correlated with range size, latitudinal range or longitudinal range. These results suggest that dispersal-related traits, such as wing shape and migratory status, are important factors in predicting the range size of libellulid dragonflies. In addition, the reverse Rapoport's rule suggests that more northern-centred species might be more specialized than more southern-centred species. We suggest that the variables predicting range size are likely imposed by taxon-specific

morphological, ecological, physiological and behavioural traits. Taxon-specific knowledge is thus necessary to understand the dynamics of range sizes and is important to implement successful restoration and conservation plans of threatened species." (Authors)] Address: Johansson, F., Dept of Ecology & Environmental Science, Animal Ecology Group, Umea University, 90187 Umea, Sweden. E-mail: frank.johansson@eg.umu.se

**19171.** Rivas-Torres, A.; Sánchez-Guillén, R.A., Cordero-Rivera, A. (2019): Alternative reproductive strategies in black-winged territorial males of *Paraphlebia zoe* (Odonata, Thaumateuridae). PeerJ 7:e6489: 22 pp. (in English) ["Alternative reproductive strategies are commonly associated with male dimorphism. In *Paraphlebia zoe*, a species of damselfly whose males are dimorphic in wing coloration, black-and-white-winged (BW) males defend territories, while hyaline-winged (HW) males usually play the role of satellites. We found that several BW males can sometimes share a territory, and we hypothesized that within this morph there are two alternative tactics: submissive and dominant. We conducted an experiment to test whether dominant and submissive roles are plastic or stable and fixed on each individual. To this end, we manipulated black and white spots of BW males in four treatments: (i) painting over white and black spots without changing their size, (ii) erasing the white spot using black painting, (iii) increasing the black spot and moving the white spot maintaining its size and (iv) control males. Additionally, we investigated the correlation between some phenotypic variables (wing asymmetry, survival and recapture probabilities) and male behaviour (in terms of quality of the territory). We found that the two behavioural roles (submissive and dominant) were not affected by the manipulative experiments, therefore suggesting that they are stable and fixed. Additionally, we found a positive correlation between body size and survival in both sexes, and a positive effect of territory quality and lifespan on mating success. Moreover, the largest and youngest BW males were the most symmetrical. We conclude that *Paraphlebia zoe* holds high behavioural diversity, with two types of strategies in BW males, dominant and submissive. The occurrence of this intra-morph behavioural diversity might depend on demographic factors such as population density and/or the relative frequency of the different morphs." **19172.** Sakaris, P.C.; Galvez, J.; Callier IV, T.P.; Brown, A. (2019): Ontogenetic and temporal diet shifts of the invasive Asian Swamp Eel in South Florida. North American Journal of Fisheries Management 39(6): 1288-1300. (in English) ["The Asian Swamp Eel *Monopterus albus* is an introduced species in South Florida waters and is considered to be a potential threat to the native biota and ecosystems in the region. As a protogynous hermaphrodite that, under the right climatic conditions, can travel short distances over land and tolerate abrupt shifts in salinity, this species has strong invasive potential. In this study, our main goal was to evaluate the potential effects of the Asian Swamp Eel as a predator

on native fishes and other biota. Our specific objectives were to (1) analyze the stomach contents of introduced Asian Swamp Eels from canals located near Everglades National Park and (2) assess the ontogenetic and temporal shifts in their consumption of prey. We dissected 752 Asian Swamp Eels (107–833 mm TL), and 46.4% (N = 349) of the samples had stomach contents for the analyses. The analyses indicated that amphipods, fishes, dragonfly nymphs, Hemiptera insects, and grass shrimp *Palaemonetes* were the most important prey items for Swamp Eels. Swamp Darters *Etheostoma fusiforme*, juvenile Asian Swamp Eels, and centrarchids were the most common fishes eaten by Swamp Eels. Ontogenetic shifts in diet were apparent, with amphipods and dipteran larvae most often observed in the stomachs of small- to medium-sized Swamp Eels and fish, dragonfly nymphs, and Hemiptera insects more commonly identified in the stomachs of larger eels. The Swamp Eels also became increasingly piscivorous with size. Dragonfly nymphs and grass shrimp occurred more frequently in the Swamp Eel diets in May 2010, while the consumption of fish and amphipods increased in October 2010. Fish were the most important prey item that was consumed during the November–December 2009 period, although other prey items were relatively important during that collection period. As an opportunistic predator that consumes a wide range of prey, the Asian Swamp Eel likely has its greatest effects on native biota and ecosystems as a predator and competitor with native fishes for resources." **19173.** Seidu, I.; Nsor, C.A.; Danquah, E.; Tehoda, P.; Opong, S.K. (2019): Patterns of Odonata assemblages in lotic and lentic systems in the Ankasa Conservation Area, Ghana. International Journal of Zoology Volume 2019, Article ID 3094787: 14 pp. (in English) ["Our study examined Odonata assemblages distribution pattern and the predictive factors that accounted for this in the lotic and lentic water systems within the Ankasa Conservation Area (Ghana). A total of 23 sites with sampling protocol of 2 researchers per hour per sampling site were used to survey Odonata species over two seasons in the three water bodies (streams, rivers, and ponds). Broken stick model, individual-based rarefaction, and Renyi diversity ordering were employed to quantify community assemblages. Ordination technique was also used to determine the Odonata–environmental relationship. A total of 1403 individuals, belonging to 47 species (22 Zygoptera and 25 Anisoptera) in six families, were recorded. Species richness ( $H_c = 3.414$ ,  $p = 0.169$ ) and diversity ( $H_c = 1.661$ ,  $p = 0.44$ ) generally did not differ among the three water systems. However, from individual sites, ponds appeared mostly diverse ( $\alpha\text{-scale} = 0.04$ , Renyi index ( $r = 5.86$  to  $\alpha = 3.5$ ,  $r = 3.12$ ), in spite of their lowest species abundance and richness. At the suborder level, ponds equally exhibited the highest Anisoptera species richness ( $9.90 \pm SE 0.640$ ) compared with Zygopterans ( $0.80 \pm SE 0.291$ ). Overall, Anisopterans ( $K = 16.51$ ,  $p = 0.00026$ ) and Zygopterans richness ( $K = 16.39$ ,  $p = 0.00023$ ) differed

significantly among the three subsystems, while Odonata composition also differed significantly among the various water bodies (ANOSIM: global  $R=0.94$ ,  $p<0.001$ ). Flow rate, water temperature, channel width, and turbidity were the key predictive factors that influence the structure of Odonata species assemblages. The results highlight the need to improve the functional status of the lentic and lotic systems, with the ultimate goal of conserving diverse Odonata fauna and other sympatric freshwater biodiversity." **19174.** Suárez-Tovar, C.M.; Rocha-Ortega, M.; González-Voyer, A.; González-Tokman, D.; Córdoba-Aguilar, A. (2019): The larger the damselfly, the more likely to be threatened: a sexual selection approach. *Journal of Insect Conservation* 23(3): 535-545. (in English) ["In a changing world due to anthropogenic activities, it is increasingly urgent to identify the biological attributes that predispose species to extinction. Using phylogenetic comparative methods and International Union for Conservation of Nature Red List categories as a proxy for vulnerability to extinction, we evaluated whether body size, sexual size dimorphism and/or mating system (territorial or non-territorial) are linked to extinction risk in 139 damselfly (Zygoptera) species. Threatened species of damselflies were, on average, larger than non-threatened species. However, we did not find a relationship between sexual size dimorphism or mating system and extinction risk. Similar to vertebrates and other insects, a large size implies a higher viability costs for damselflies. Other evolutionary mechanisms and not only sexual selection may play an important role in selecting for large body size and rendering larger species more prone to extinction." ## 2020

**19176.** Amado, L.L.; Juen, L. (2020): Glutathione S-transferase activity in *Mnesarete aenea* (Odonata), *Campylocia anceps* (Ephemeroptera), and *Cylindrostethus palmaris* (Hemiptera) from forest and oil palm plantation areas in the Eastern Amazon. *Ecological Indicators* 118, November 2020, 106770: (in English) ["Highlights: • Our results show that *M. aenea* had higher GST activity in oil palm areas. • The high GST activity in *C. anceps* shows the sensitivity of juvenile organisms in environments. • The difference in GST induction in *M. aenea* and *C. palmaris* shows can help the bio-monitoring. The use of aquatic insects in ecological studies of oil palm plantations provides an effective evaluation of biodiversity loss caused by changes in habitat. Approaches at the population or community level associated with biomarker analyses might help in the management and conservation of impacted habitats. Our aim was to assess detoxification responses (Glutathione S-transferase activity) of three aquatic invertebrates (*Mnesarete aenea*, *Cylindrostethus palmaris*, and *Campylocia anceps*) in oil palm plantations and forested areas in the Eastern Brazilian Amazon. A total of 20 streams were sampled during the dry season of 2017, in the municipality of Tailândia, Pará – Brazil. The response of this exposure biomarker was related with water temperature, pH, dissolved oxygen, canopy cover and habitat integrity index. The species *M. aenea* and *C. palmaris* showed differences in detoxification response induction, with higher specific activity in oil palm areas than in forest areas. The conversion of natural landscape and use of agrochemicals in oil palm plantations might affect the dynamics of organisms that are sensitive to changes in habitat quality. We suggest that differences in Habitat Integrity Index between oil palm and Amazon forest areas is a determining factor in increased GST induction in *M. aenea*. This result indicates that this organism might act as a sentinel for biomarker evaluations, providing an early warning signal via its biochemical responses that could help to prevent changes at the population and community levels." **19178.** Bezmaternykh, D.M.; Vdovina, O.N. (2020): Composition and structure of macrozoobenthos of lakes in different natural zones and subzones of Western Siberia. *Limnology* 21: 3-13. (in English) ["In 2003–2016, the composition and structure of macrozoobenthic communities of 49 lakes in three natural zones (taiga, forest-steppe, and steppe) of Western Siberia were investigated. The benthic fauna of the research lakes includes 160 species of nine classes of invertebrates. The trophic structure was characterized, and six major trophic groups were identified. A spatial analysis of the macrozoobenthos of the research lakes showed that from the forest-steppe to the dry steppe subzone, the species diversity decreases on a considerable scale and also dominant taxa of macrozoobenthos change with increasing water salinity. Especially in the forest-steppe and steppe zones, high water salinity is probably a limiting factor in the development of macrozoobenthic communities. In the taiga zone, however, water salinity seems not to have such significance; rather the degree of humification (shown as dark-colored water due to waterlogging) should be taken into account." (Authors)] 12 odonate taxa are listed; most frequent species is *Coenagrion armatum* 13 of 49 lakes were investigated.] Address: Bezmaternykh, D.M., Insti. aquatic & ecological problems, Sibir Branch of the Russian Acad. **19179.** Bibi, S.; Khan, M.F.; Rehman, A. (2020): Dragonfly fauna of district Haripur, Khyber Pakhtunkhwa, Pakistan. *Arthropods* 9(3): 98-103. (in English) ["The present study was conducted from January to September 2018 in district Haripur, KP, Pakistan. A total of 200 specimens were collected and 2 families, 9 genera and 12 species were recorded. Dragonflies of family Libellulidae (170; 94.15%) were present in great abundance while the other two families were less distributed. Minimum number of dragonfly species belong to family Gomphidae (10; 5.85%). *Orthetrum chrysis* was recorded in greater number. We also measured their body length, and length of fore and hind wings. The highest length was found to be in *Pantala flavescens*, with 23.5±0.4, 17.5±0.4, and 16±2.0 mm length of body, fore and hind wings respectively. Further comprehensive study needed on their ecological role." (Authors)] Address: Bibi, Saira, Department of Zoology, Hazara University, Mansehra, KPK, Pakistan. E-mail: sairabibi333@hu.edu.pk

**19180.** Bouhala, Z.; Khemissa, C.; Márquez-Rodríguez, J.; Ferreras-Romero, M.; Samraoui, F.; Samraoui, B. (2020):

Ecological correlates of odonate assemblages of a Mediterranean stream, Wadi Cherf, northeastern Algeria: implications for conservation. *International Journal of Odonatology* 22(3/4): 181-197. (in English) ["We investigated the odonates of Wadi Cherf, a tributary of Wadi Seybouse, and explored the main environmental factors that may be important drivers of the abundance and diversity of Odonata assemblages. PCA analyses demonstrated a significant altitudinal gradient associated with water flow, temperature, vegetation cover, substrate and adjacent land use. Notably, pollution was a dominant structuring factor and the most widespread species, *Ischnura graellsii* and the North African endemic *Platycnemis subdilata*, were the most pollution-tolerant species. Similarly, co-inertia analysis indicated that environmental factors could account for 70% of the co-variation in shaping odonate assemblages. Equally important, threatened species were associated with less degraded but vulnerable habitats, most susceptible to anthropogenic impacts. There is thus a need to develop monitoring tools to assess the ecological integrity of North African rivers and implement a management plan that considers both connectivity and heterogeneity to ensure that Wadi Cherf, a sanctuary to three threatened species *Calopteryx exul* (EN), *Coenagrion mercuriale* (EN) and *Gomphus lucasii* (VU), continues to provide critical ecosystem functions." **19183.** Cerini, F.; Bologna, M.A.; Vignoli, L. (2020): Nestedness-patterns of Odonata assemblages in artificial and natural aquatic habitats reveal the potential role of drinking troughs for aquatic insect conservation. *Journal of Insect Conservation* 24: 421-429. (in English) ["Nestedness patterns including both artificial and natural habitat may represent evidence of such habitats' importance in community assembly and conservation of animals inhabiting those sites. Odonata often colonize drinking troughs (artificial water reservoirs) and thus they are good study models as umbrella species. We investigated if a network of artificial (troughs) and natural (pools) aquatic habitats could create a nested subset pattern for Odonata assemblages. We surveyed all the troughs present in the Castelporziano Estate (Italy, Lazio). Odonata larvae have been collected and identified. Data of a previous paper on 18 natural pools and ponds, and our samplings of 16 troughs were organized into a presence-absence matrix. The Odonata assemblage within natural and artificial habitats is significantly nested with both NODF and T metrics. Odonata species found in the troughs represented 40% of the total species pool. Some troughs interspersed with the natural pools in the nested order: eight troughs were richer in species than some natural pools, despite the big difference in surface area. Pristine water bodies and their area may not represent major constraints for species to oviposit and for larvae to grow. Drinking troughs can be highly relevant for representing refuges in the absence or decline of natural ponds and pools: lacking in top-predators (fishes), they are small "island" habitats that support the generations of Odonata (or other aquatic macroinvertebrates) during dry periods of natural water bodies. The use and focused management of such habitats can be an effective practice for freshwater ecosystems management and Odonata conservation." **19186.** Deepthi, S.; Vengadesan, S. (2020): Role of dipole jet in inclined stroke plane kinematics of insect flight. *Journal of Bionic Engineering* 17: 161-173. (in English) ["The two-dimensional (2D) inclined stroke plane kinematics of insect wing is studied for various stroke plane angles using the Immersed Boundary (IB) solver. The numerical results revealed the dominant lift enhancement mechanisms for this class of flows. The generated dipole was analyzed to find the maximum velocity, inclination and spread. The analysis of these dipole characteristics for the different stroke plane angles exposed the alternate method to study the vertical force variation with the stroke plane angles. Lift enhancement mechanisms and dipole characteristics complement the high vertical force coefficient for the stroke plane angle of 60° commonly used by dragonflies during hover. The location of the dipole identified a region of influence around the wing and demonstrated the role of the dipole jet in multi-body dynamics and wall effects." However, improved habitat heterogeneity often does not lead to natural recolonization by sensitive freshwater macroinvertebrate communities, particularly when the recolonization potential is low and source populations are absent. In preliminary studies we tested whether natural substrate exposures could be used to sample and transport benthic macroinvertebrates. In this pilot study we used these previously tested natural substrate exposures to sample freshwater invertebrates in a donor stream in order to actively (re-)colonize a recipient stream. In the course of three reintroduction campaigns, we were able to accumulate over 350,000 benthic invertebrates, including 25 indicator taxa of the orders Ephemeroptera, Plecoptera and Trichoptera and 30 taxa scoring positive in the German Fauna Index. In total, 45 taxa, which did not occur in the recipient stream before, were reintroduced. They were transported gently within natural substrate exposures and released on a stream bottom area of 500m<sup>2</sup> in the recipient stream. We intended to study if an increase of benthos fauna in a recipient stream is possible, and if this increase will eventually improve the ecological status. So far, the natural substrate exposure-method demonstrated to be an adequate tool to accumulate and transport benthic macroinvertebrates and, in general, has the potential to increase the biodiversity of streams when used as assisted migration measure." (Authors) The study includes a reference to *Calopteryx virgo*.] Address: Kiel, Ellen, Research Group Aquatic Ecology and Nature Conservation, Department of Ecology and Environmental Science, Carl von Ossietzky University of Oldenburg, Germany

**19191.** Escoto-Moreno, J. A.; Márquez, J.; Asiain, J. (2020): New records of Odonata from Central Eastern Mexico. *Proceedings of the Entomological Society of Washington* 122(1): 235-242. (in English) ["A total of 18 new records are provided for four states of central eastern Mexico. For Querétaro, six new records are added, including two species of Phyllogomphoides. According to Paulson & González-Soriano (2019) 61 species are reported from Querétaro but our additions increase that listing to 66 species and is ranked

23rd place for species richness of odonates known in Mexico. However, the position that each state occupies with respect to the richness of species of odonates is a fact that does not take into account the territorial extension or the variety of biogeographical provinces that make up each one, so this should be taken into account when making comparisons between states. In the case of the state of Hidalgo, five new records are added, including the genus *Nehalennia* that was not previously reported in the state. *Nehalennia* includes one species in Eurasia and five in America. The species reported in Mexico has been found mainly in the Gulf of Mexico watershed (Garrison et al. 2010). In Hidalgo, 129 species were reported, according to Escoto-Moreno et al. (2014, 2017a); subsequently, in the update of the Paulson and González-Soriano list (2019) four new records were added (133). The new record of *Megaloprepus caerulatus* (Drury, 1782) (Escoto-Moreno et al. 2018) brings this number to 134 species; adding the five records of our study gives a total of 139 known species for Hidalgo which places the state as seventh in the highest species richness of odonates of Mexico. For the state of Puebla, four new records are provided, including for the first time *Oplonaeschna*, which is a genus that is typical of the Mexican Transition Zone (sensu Halffter and Morrone 2017). The list of Paulson and González-Soriano (2019) reports 93 species; now, however, there are 97, which place the state as 14th in species richness in Mexico. The state of Veracruz had the highest species richness in Mexico with 219 (Paulson & González-Soriano 2019). Now three species of the genus *Argia* are found in an area with elevations greater than 1800 m so there are now 222 recognized species. Until now Veracruz is the only state that exceeds 200 species in Mexico. Finally, some records of precise localities for *Paraphlebia zoe* in Puebla were added when only two locations were known (Escoto-Moreno and Márquez 2013), also for *Rhionaeschna jalapensis* in Hidalgo, which had not been reported in the northwestern part (Escoto-Moreno et al. 2017b), and for *Cordulegaster diadema* in the state of Tlaxcala, where its presence is barely recognized (Paulson & González-Soriano 2019)."] Address: Escoto-Moreno, J., Colección Zoológica, Depto Biología, Centro de Cienc. **19192.** Eslami Barzoki, Z.; Ebrahimi, M.; Sadeghi, S. (2020): Odonata diversity and species assemblages in the Northwest Central Plateau of Iran. *Journal of Insect Conservation* 24: 459-471. (in English) ["Central Iran has been faced with deterioration of water quality and quantity, but yet the biodiversity of freshwater-associated insects in this area remains uncertain and without this information the development of conservation strategies is not possible. Here we explore Odonata diversity patterns and species assemblages in three terrestrial ecoregions of Central Iran. We used the first three Hill numbers and phylogenetic generalizations of these indices to compare the species diversity between the ecoregions. To compare Odonata species composition a PERMANOVA analysis was performed. Alpha-diversity of each

water body was estimated by Hill numbers, taxonomic diversity, taxonomic distinctness and average taxonomic distinctness. The effects of habitat and environmental factors on Odonata diversity indices were modelled using a linear mixed model. About 42% of all Odonata that have been reported in Iran were found during this study. Species richness in the Desert and Steppe ecoregions were almost equal, the same pattern was observed for phylogenetic diversity indices. The Steppe ecoregion also had significantly different Odonata assemblage. Results of the linear mixed model showed that environmental factors have different effects on different diversity indices. Additionally different diversity indices resulted in different outcomes when comparing ecoregions, demonstrating that single measure cannot precisely assess the properties of an assemblage's diversity. The high diversity of Odonata observed in such an arid environment shows the importance of man-made water bodies, as well as the necessity of preparing a conservation plan for these ecosystems." **19193.** Favret, C.; Moisan-De Serres, J.; Larrivé, M.; Lessard, J.-P. (2020): The Odonata of Quebec: Specimen data from seven collections. *Biodiversity Data Journal* 8: e49450: 26 pp. (in English) ["Background: The Odonata, dragonflies and damselflies, constitute one of the more charismatic and better-studied orders of insects. The approximately 6,000 extant species on Earth can be variously found on all continents, except Antarctica. A relatively stable taxonomy, a relative ease of species identification and an aquatic immature stage has made the Odonata a taxon of interest in documenting the symptoms of global environmental change, especially at higher latitudes. The Odonata fauna of the north-temperate Canadian province of Quebec includes 150 species, many of which are at the northern limits of their geographic distribution. New information: Quebec hosts multiple entomological specimen depositories, including seven publicly accessible research collections. One of these, the University of Montreal's Ouellet-Robert Entomological Collection, houses an exceptionally large collection of Odonata. An initial specimen data capture project for this collection gathered 31,595 Quebec Odonata occurrence records, but several Quebec species were missing and geographic coverage was biased towards the Montreal region. To complement this dataset, we undertook to digitise the Odonata records of six other public research collections. They are, in order of Quebec Odonata collection size, the Laval University Entomological Collection, McGill University's Lyman Entomological Museum, the Insectarium of Montreal Research Collection, the Quebec Government's Insect Collection, Bishop's University's Insect Collection and the Laurentian Forestry Centre's René-Martineau Insectarium. Of the 40,447 total specimen occurrence records, 36,951 are identified to the species level, including 137 of the 150 species officially-recorded in Quebec and 2 non-nomotypical subspecies. We here summarise the data and highlight the strengths and weaknesses of the datasets. The complete dataset is available with this publication (Suppl. material 1), whereas the specimen data associated with each collection

are available as Darwin Core archives at Canadensys.net and will be updated as appropriate." (Authors)] Address: Favret, C., University of Montreal, Montreal, Canada. E-mail: colinfavret@aphidnet.org)

**19194.** Fernandez, S.; Rodriguez-Martin, S.; Martinez, J.L.; Garcia-Vazquez, E.; Ardura, A. (2020): How can eDNA contribute in riverine macroinvertebrate assessment? A metabarcoding approach in the Nalon River (Asturias, Northern Spain). *Environmental DNA* 1(4): 385-401. (in English) ["Background: Bioassessment of rivers is a fundamental method to determine surface water quality. One of the groups most commonly employed as bioindicators of aquatic ecosystems are benthic macroinvertebrates. Their conventional assessment is based on morphological identification and entails several limitations, such as being time-consuming and requires trained experts for taxonomic identification. The use of genetic tools to solve these limitations offers an alternative way to evaluate rivers status. The use of environmental DNA (eDNA) metabarcoding has increased in recent years for different purposes, but its use in water quality evaluation is yet to be tested. Here, morphological and eDNA based inventories of macroinvertebrates were compared from the same seven sampling sites in the Upper Nalon River Basin (Asturias, Spain). Materials & Methods: High-Throughput Sequencing (HTS) of the cytochrome oxidase subunit 1 (COI) gene was carried out on DNA from water samples using an Ion Torrent platform. Biotic water quality indices were calculated from morphological and molecular data and compared with independent physicochemical habitat assessment to validate eDNA based approach. Results: Highly positive and significant correlation was found between eDNA metabarcoding and morphological methods (Morphological and eDNA indices,  $r = 0.798$ , 5 degrees of freedom d.f.,  $P = 0.031$ ;) and a highly significant negative correlation was found between molecular and habitat quality indices (Stress score & eDNA,  $\rho = -0.878$  and  $P = 0.009$ ; Stress score & Visual,  $\rho = 0.949$  and  $P = 0.0002$ ). Discussion: The similarity of results from the two approaches and the correlation of eDNA metabarcoding data with the habitat quality indices, suggest that eDNA performs as well as conventional methods for calculating biotic indices in this system, positioning eDNA metabarcoding of macroinvertebrate communities to transform how river bioassessment can be achieved. Conclusion: The usefulness of eDNA metabarcoding to assess rivers water quality based on macroinvertebrates assessment has been demonstrated in a dammed river basin." **19195.** Florencio, M.; Burraco, P.; Rendón, M.A.; Díaz-Paniagua, C.; Gomez-Mestre, I. (2020): Opposite and synergistic physiological responses to water acidity and predator cues in spadefoot toad tadpoles. *Comparative Biochemistry and Physiology Part A: Molecular & Integrative Physiology* 242: (in English) ["Highlights: • Predator cue recognition occurred in both neutral and acidic water, as tadpoles developed anti-predator morphology even at pH = 4. • Predator

presence induced lower levels of plasma corticosterone in tadpoles whereas acidic water increased them. • Predator presence reduced the activity of some antioxidant enzymes, congruent with a decrease in metabolism. • The combination of predator cues and low pH had negative synergistic effects on the redox status of tadpoles. Abstract: Organisms are exposed to multiple environmental factors simultaneously to which they often respond behaviorally, morphologically and/or physiologically. Amphibian larvae are quite plastic and efficiently adjust their phenotype and physiology to the reigning local conditions. Here we tested whether the combination of predator presence and low water pH induces alterations in the morphology and physiology of spadefoot toad tadpoles. We raised *Pelobates cultripes* tadpoles in the laboratory in water at either pH4 or 7, and in the presence or absence of caged dragonfly nymphs, and determined their changes in shape through geometric morphometrics to assess whether predator recognition was impaired or not at low pH. We also measured levels of plasma corticosterone, activity of four antioxidant enzymes, as well as markers of oxidative damage and redox status. We found that tadpoles altered their body shape in response to predator cues even at low pH, indicating that predator recognition was not interfered by water acidity and developmental responses were robust even under abiotic stress. Water acidity was associated with increased corticosterone levels in tadpoles, whereas predator presence consistently reduced corticosterone levels. Predator presence was linked to reduced antioxidant enzyme activity, whereas the combination of both factors resulted in negative synergistic effects on lipid peroxidation and the antioxidant capacity of tadpoles. Here we show that tadpoles detect predators even at low pH but that the development of adaptive anti-predatory morphology can magnify physiological imbalances when other stressors co-occur. These results emphasize the need to understand how multiple environmental perturbations can affect animal homeostasis." **19196.** Funnell, L.; Holmes, R.J.P.; Closs, G.P.; Matthaei, C.D. (2020): Short-term effects of instream habitat restoration on macroinvertebrates and a comparison of sampling approaches. *Limnologica* 80 (2020) 125726: 12 pp. (in English) ["Many streams and rivers worldwide are restored with the intention to mitigate degradation caused by human activities, but these rehabilitation projects often involve physical instream work with diggers or other heavy machinery. The short-term effects of such restoration works on stream ecosystems are rarely investigated. The primary aim of our study was to assess the short-term effects of physical instream restoration works (which likely increased instream fine sediment load temporarily) on the benthic macroinvertebrate community [including *Xanthocnemis zealandica*] in a lowland soft-bottomed stream, and our second aim was to compare the results of semi-quantitative kick-net and quantitative Surber sampling in this assessment. Invertebrates were collected using these two methods from three

Control and three Impact sites, before and two days after recontouring the stream banks and installing instream woody cover features. Three of seven macroinvertebrate community-level indexes suggested positive short-term effects of the restoration works, whereas none indicated negative effects. By contrast, seven of the 14 most common taxa were negatively affected by the restoration works, possibly due to increased fine sediment levels reducing habitat quality for these taxa. These differences imply that taxon-specific invertebrate responses may be more suitable for detecting short-term impacts of instream restoration works than community-level metrics. Community indexes and common taxa were also likely affected by a drought in the spring and summer before restoration, which may have obscured some effects of the restoration works. Finally, kick-net and Surber sampling methods yielded similar findings for the community-level metrics but differed more for the common taxa, probably because the two methods sampled different microhabitats within the stream. Consequently, we recommend that for routine monitoring of macroinvertebrate communities in lowland soft-bottomed streams, the semi-quantitative kick-net sampling method should be used." **19197.** Gao, S.; Zhang, B.; Sun, J.; Liu, W. (2020): A designed method of the surface structure of suspended glass transport device based bionic structure of dragonfly wings. *Industrial Lubrication and Tribology* 72(1): 1245-1250. (in English) ["The purpose of this paper is to design a biomimetic surface structure for use in a glass transport device to enhance the suspension lift of a glass transport unit. Design/methodology/approach: This paper presents a surface structure of a suspended glass transport device based on the principle of bionics. First, a mapping model is constructed based on the wing structure. Second, the optimal structural parameters are given according to genetic algorithm optimization. Finally, the experimental comparison of the test bench verified the feasibility of the theory. Findings: Through experimental comparison, the biomimetic suspension glass transport device saves 20% of air pressure compared with the ordinary suspended glass transport device, which verifies the effectiveness of the theoretical method. Originality/value: This paper proposes a suspended glass transport device based on the principle of bionics, which saves the air pressure required for work. It is expected to be used in suspension glass transport devices." (Authors)] Address: Gao, S., School of Mechatronic Engineering, Changchun University of Technology, Changchun, China

**19198.** Grether, G.F.; Drury, J.P.; Okamoto, K.W.; McEachin, S.; Anderson, C.N. (2020): Predicting evolutionary responses to interspecific interference in the wild. *Ecology Letters* 23(2): 221-230. (in English) ["Many interspecifically territorial species interfere with each other reproductively, and in some cases, aggression towards heterospecifics may be an adaptive response to interspecific mate competition. This hypothesis was recently formalised in an agonistic character displacement (ACD) model which predicts that species

should evolve to defend territories against heterospecific rivals above a threshold level of reproductive interference. To test this prediction, we parameterised the model with field estimates of reproductive interference for 32 sympatric damselfly populations and ran evolutionary simulations. Asymmetries in reproductive interference made the outcome inherently unpredictable in some cases, but 80% of the model's stable outcomes matched levels of heterospecific aggression in the field, significantly exceeding chance expectations. In addition to bolstering the evidence for ACD, this paper introduces a new, predictive approach to testing character displacement theory that, if applied to other systems, could help in resolving long-standing questions about the importance of character displacement processes in nature." **19199.** Grung, M.; Meland, S.; Ruus, A.; Ranneklev, S.; Fjeld, E.; Kringstad, A.; Rundberget, J.T.; Del Cruz, M.; Christensen, J.H. (2020): Occurrence and trophic transport of organic compounds in sedimentation ponds for road runoff. *Science of The Total Environment* 751(Part A):141808: 11pp. (in English) ["Highlights: • Ecosystem in sedimentation ponds for road runoff receives several organic pollutants. • Water, sediment, plants, larvae and fish were analysed for 4 contaminant groups. • Higher levels of pollutants in sedimentation ponds vs. reference were observed. • Bioaccumulation observed for PACs and PBDEs, but all 4 groups detected in fish. • Biomagnification was documented for PBDEs, alkylated PACs important in road runoff. Abstract: Sedimentation ponds have been shown to accumulate several groups of contaminants, most importantly polycyclic aromatic compounds (PACs) and metals. But also, other urban organic pollutants have shown to be present, including polybrominated diphenyl ethers (PBDEs), organophosphate compounds (OPCs) and benzothiazoles (BTs). This investigation aimed at determining the occurrence of these four groups of contaminants in sedimentation ponds and determine their transport from water/sediment to organisms. PACs, including alkylated PACs, PBDEs; OPCs and BTs were determined in water, sediment, plants, dragonfly larvae and fish from two sedimentation ponds and one reference site. Fish were analysed for PAC metabolites. Overall, higher concentrations of all four pollutant groups were detected in water and sediment from sedimentation ponds compared to two natural lakes in rural environments (reference sites). The concentration difference was highest in sediments, and >20 higher concentration was measured in sedimentation ponds (3.6–4.4 ng/g ww) compared to reference (0.2 ng/g ww) for sum BDE6. For PACs and PBDEs a clear transport from water/sediment to organisms were observed. Fish were the highest trophic level organism (3.5–5) in our study, and all four pollutant groups were detected in fish. For PBDEs a trophic biomagnification (TMF) was found both in sedimentation ponds and reference, but higher concentrations in all matrices were measured in sedimentation ponds. TMF was not calculated for PACs since they are metabolised by vertebrates, but a transfer from water/sediment to

organisms was seen. For BTs and OPCs, no consistent transfer to plants and dragonfly larvae could be seen. One OPC and two BTs were detected in fish, but only in fish from sedimentation ponds. It is therefore concluded that sedimentation ponds are hotspots for urban and traffic related contaminants, of which especially PACs and PBDEs are transferred to organisms living there." **19201.** Halabowski, D.; Lewin, I.; Buczynski, P.; Krodkiewska, M.; Plaska &, W.; Sowa, A.; Buczynska, E. (2020): Impact of the discharge of salinised coal mine waters on the structure of the macroinvertebrate communities in an urban river (Central Europe). *Water Air Soil Pollut.* 231:5: 19 pp. (in English) ["The anthropogenic salinisation of rivers causes grave environmental problems that are responsible for the degradation of water quality on a worldwide scale as well as for biological changes in aquatic ecosystems. The objectives of the survey were to analyse the structure of the macroinvertebrate communities in the Bolina River, which is currently the second most anthropogenic salinised river in the world, in relation to various types of instream microhabitats and to determine the environmental factors that have a significant effect on the structure of the macroinvertebrate communities. The result of a canonical correspondence analysis (CCA) showed that electrical conductivity, the temperature of the water and the organic matter content in the bottom sediments were the most important factors (statistically significant) that influenced the macroinvertebrate communities in the anthropogenic salinised river. A total of 77 taxa of macroinvertebrates were recorded in the Bolina River. A Kruskal-Wallis one-way ANOVA and multiple comparison post hoc tests revealed statistically significant differences in the median number of taxa and the median density of macroinvertebrates between the various types of

microhabitats in the salinised river. The anthropogenic salinisation of a river can lead to a decrease in aquatic biodiversity that favours invasive species over native species. The Bolina River, which has a salinity of up to 33.6‰, is an example of a unique habitat for organisms that are salt tolerant (euhaline) or eurytopic. It is a route for the spread of alien and invasive invertebrate species including *Gammarus tigrinus*, *Potamopyrgus antipodarum*, and *Monopylephorus limosus*. ... Odonata, .... was represented by *Ischnura elegans* (density up to 116 individuals m<sup>-2</sup>), *Platycnemis pennipes* (density up to 112 individuals m<sup>-2</sup>), *Orthetrum cancellatum* (density up to 24 individuals m<sup>-2</sup>) and *Chalcolestes viridis* (density up to 16 individuals m<sup>-2</sup>)." **19202.** Hendriks, J.A. (2020): A preliminary study of Odonata communities in a mixed-mosaic habitat structure in Central Kalimantan, Indonesia. BSc thesis, Science and Engineering, Maastricht University: 94 pp. (in English) ["Recent decades have seen an increase in deforestation and fragmentation of forests due to anthropogenic pressures. To assess impacts of degradation, there is an increasing interest in bio-indicator species such as odonates. However, they remain poorly studied in certain areas. Central Kalimantan, Indonesia is one such, where this is the first study investigating odonates in a kerangas dominated mixed-mosaic habitat structure. Line transect method was used to sample 250m – two transects in three habitat types, i.e. riverine/mixed-swamp (RM), kerangas (K), low-pole peat swamp (LP) in KHDTK. Habitat variables were recorded at capture sites and at 25m intervals on each transect. A total of 339 individuals representing 23 species were captured. Highest number of Odonata were captured in LP. Highest species diversity was observed in RM ( $H' = 2.00$ ), and lowest in LP ( $H' = 1.62$ ). Canopy cover had a strong influence on Odonata assemblages and they showed preference for areas with surface water. Anisoptera preferred forest pools and Zygoptera were inclined to flowing water. The greatest lengths in thorax and wing size were observed for Odonata in K. Eco-physiological requirements between sub-orders and habitat variations influenced their distribution and assemblages. This study further explores their potential as bio-indicators for the habitat types discussed." (Author)] Address: not stated

**19203.** Herlinda, S.; Alesia, M.; Susilawati; Irsan, C.; Hasbi; Suparman; Anggraini, E.; Arsi (2020): Impact of mycoinsecticides and abamectin applications on species diversity and abundance of aquatic insects in rice fields of freshwater swamps of South Sumatra, Indonesia. *Biodiversitas* 21(7): 3076-3083. (in English) ["Aquatic insects in rice fields generally are predators of rice insect pests. The application of insecticides may reduce the abundance and species diversity of these predators. This study aimed to determine the impact of mycoinsecticides and abamectin application on species diversity and abundance of aquatic insects in rice

fields. Mycoinsecticides were made from *Beauveria bassiana* s.l., *Metarhizium anisopliae* s.l. and *Cordyceps militaris* s.l. with carrier from shrimp shell flour compost extract, vegetable oil, and Tween®. The treatments were the mycoinsecticides and abamectin. The results showed there were eight aquatic insects species obtained in this study, i.e. unidentified Dytiscidae, *Micronecta* sp., *Mesovelgia* sp., *Ranatra* sp., *Anisops* sp., *Microvelia* sp., unidentified species of Veliidae, and *Orthetrum* sp. belong to 7 families (Dytiscidae, Corixidae, Mesoveliidae, Nepidae, Notonectidae, Veliidae, Libellulidae), and three orders (Coleoptera, Hemiptera, and Odonata). All of the species were predatory insects. The application of mycoinsecticides did not reduce the abundance and species diversity of the aquatic predatory insects, but the application of abamectin reduced the abundance and species diversity of the predators. The highest insect species diversity was in the plots applied with *C. militaris* s.l., followed by the *B. bassiana* s.l. and *M. anisopliae* s.l. plots and the lowest one was found in the abamectin plot. So, the application of mycoinsecticides from *B. bassiana* s.l., *M. anisopliae* s.l. and *C. militaris* s.l. is safe for the aquatic predatory insects and to control rice insect pests than that of abamectin." Raya Palembang-Prabumulih Km 32, Indralaya, Ogan Ilir 30662, South Sumatra, Indonesia

**19204.** Hill, B.; Blanckenhagen, B. von; Adelman, J. (2020): Landesmonitoring 2018 zur Erfassung der Östlichen Moosjungfer (*Leucorrhinia albifrons*) (Art des Anhangs IV der FFH-Richtlinie) in Hessen. Projekt – Nr.: G 18 - 35. Auftraggeber: HLNUG (Hessisches Landesamt für Naturschutz, Umwelt und Geologie), Europastr. 10, 35394 Gießen: 42 pp. (in German) ["*L. albifrons* was recorded in Hesse (Germany) in 2012 after a 100-year hiatus (VON BLANCKENHAGEN 2013). In the following years, further single observations followed, before the first proof of its reproduction was found in the Gehspitzweiher nature reserve in 2015. So far, no nationwide survey of the species' distribution is available. Within the framework of the implementation of the FFH monitoring in Hesse, it was necessary to close this gap. The aim of the present report is to verify the ground stability of already proven occurrences and, if necessary, to localise new sites in the course of a data research. The results will be included in the report to the EU in 2025. The only confirmed and native occurrence within the scope of the state monitoring is located at the Gehspitzweiher near Neu-Isenburg (OF). 65 exuviae were collected, corresponding to a density of 1.3 exuviae/m bank. This justifies a rating of A (excellent) for the main criterion of population status. The habitat quality of the water body is also rated as excellent (value level A), mainly due to the sunlight, the high proportion of submerged vegetation and the location in a forest area. The impairment rating A is also achieved, as there are hardly any substantial threats. In the overall assessment, the Gehspitzweiher receives the value rating A (excellent). Mention should be made of the fact that in the course of the state monitoring of the ornamental damselfly, which was carried out at the same time, a native occurrence

of *Leucorrhinia albifrons* was found at the Langener Waldsee (Mittelgrube). This and the surrounding water bodies at Langener Waldsee should be integrated in the future investigations of the state monitoring." (Authors/DeepL.) Address: von Blanckenhagen, B., Weidenhäuser Str. 34, 35037 Marburg, Germany

**19205.** Hill, B.; Blanckenhagen, B. von; Rehnig, K.; Wurmitzer, C.; Malinger, A. (2020): Landesmonitoring 2018 zur Erfassung der Zierlichen Moosjungfer (*Leucorrhinia caudalis*) (Art des Anhangs II der FFH-Richtlinie) in Hessen. Projekt – Nr.: G 18 - 35. Auftraggeber: HLNUG (Hessisches Landesamt für Naturschutz, Umwelt und Geologie), EuroPastr. 10, 35394 Gießen: 76 pp. (in German) ["The state-wide distribution situation of the *Leucorrhinia caudalis* in Hesse (Germany) was last studied in 2009 (cf. STÜBING & HILL 2010). Within the framework of the implementation of the FFHM monitoring in Hesse, a new monitoring round had to be carried out. The aim of the present report is to check the ground stability of already existing finds and to locate new sites in the course of a data search, if necessary. The results will be included in the report to the EU in 2025. Within the scope of the investigations, the ground stability was determined on the basis of exuviae found at a total of eight water bodies in the Rhine-Main area and one water body in Central Hesse. In addition, there are two study areas with evidence of the Ornamental damselfly from the *L. albifrons* monitoring. The largest occurrence is still in the Gehspitzweiher Nature Conservation Site (OF). In second place comes the water body complex of the Langener Waldsee, where at least four different water bodies are successfully colonised. Of particular importance is the evidence of another native occurrence of *L. albifrons* at Langener Waldsee. Other small occurrences exist in Linden at the Fernie pit (GI), at Lake Linden near Rüsselsheim (GG) and at the Obertshausen fishing lake (OF). Only two exuviae were found in the Enkheimer Ried nature reserve, but the population is estimated to be much larger on the basis of the imagines observed. Observations of adults were made in two other areas. Whereas at the Walldorf bathing lake the presence on the ground is considered less probable, at the Nachtweidensee near Groß-Gerau, due to the larger number of individuals during the flight period, it can be assumed that the species is present on the ground. Overall, occurrences with a good overall rating (value level B) dominate. They make up about half of the water bodies studied. Only the situation at the Gehspitzweiher National Park (value level A) is better. In about one third of the areas with evidence of the species, only a rating of C (medium - poor) could be assigned." (Authors/DeepL.) Address: von Blanckenhagen, B., Weidenhäuser Str. 34, 35037 Marburg, Germany

**19206.** Huang, S.-T.; Wang, H.-R.; Yang, W.-Q.; Si, Y.-C.; Wang, Y.-T.; Sun, M.-L.; Qi, X.; Bai, Y. (2020): Phylogeny of Libellulidae (Odonata: Anisoptera): comparison of molecular and morphology-based phylogenies based on wing morphology and migration. *PeerJ* 8:e8567: 22 pp. ["Background. Establishing the species limits and resolving phylogenetic relationships are primary goals of taxonomists and

evolutionary biologists. At present, a controversial question is about interspecific phylogenetic information in morphological features. Are the interspecific relationships established based on genetic information consistent with the traditional classification system? To address these problems, this study analyzed the wing shape structure of 10 species of Libellulidae, explored the relationship between wing shape and dragonfly behavior and living habits, and established an interspecific morphological relationship tree based on wing shape data. By analyzing the sequences of mitochondrial COI gene and the nuclear genes 18S, 28S rRNA and ITS in 10 species of dragonflies, the interspecific relationship was established. Method. The wing shape information of the male forewings and hindwings was obtained by the geometric morphometrics method. The inter-species wing shape relationship was obtained by principal component analysis (PCA) in MorphoJ1.06 software. The inter-species wing shape relationship tree was obtained by cluster analysis (UPGMA) using Mesquite 3.2 software. The COI, 18S, ITS and 28S genes of 10 species dragonfly were blasted and processed by BioEdit v6 software. The Maximum Likelihood (ML) tree was established by raxmlGUI1.5b2 software. The Bayes inference (BI) tree was established by MrBayes 3.2.6 in Geneious software. Results. The main difference in forewings among the 10 species of dragonfly was the apical, radial and discoidal regions dominated by the wing nodus. In contrast, the main difference among the hindwings was the apical and anal regions dominated by the wing nodus. The change in wing shape was closely related to the ability of dragonfly to migrate. The interspecific relationship based on molecular data showed that the species of *Orthetrum* genus branched independently of the other species. Compared to the molecular tree of 10 species, the wing shape clustering showed some phylogenetic information on the forewing shape (with large differences on the forewing shape tree vs. molecular tree), and there was no interspecific phylogenetic information of the hindwing shape tree vs. molecular tree. Conclusion. The dragonfly wing shape characteristics are closely related to its migration ability. Species with strong ability to migrate have the forewing shape that is longer and narrower, and have larger anal region, whereas the species that prefer short-distance hovering or standing still for a long time have forewing that are wider and shorter, and the anal region is smaller. Integrating morphological and molecular data to evaluate the relationship among dragonfly species shows there is some interspecific phylogenetic information in the forewing shape and none in the hindwing shape. The forewing and hindwing of dragonflies exhibit an inconsistent pattern of morphological changes in different species." **19207.** Huikkonen, I.-M.; Helle, I.; Elo, M. (2020): Heterogenic aquatic vegetation promotes abundance and species richness of Odonata (Insecta) in constructed agricultural wetlands. *Insect Conservation and Diversity* 13(4): 374-383. (in English) ["1. Natural wetlands are among the most

threatened habitat types worldwide. They contain a high diversity of macroinvertebrates, including dragonflies and damselflies (Insecta: Odonata). In agricultural landscapes, new wetlands have been constructed to filter nutrients and solid matter from agricultural runoff. These types of wetlands may also benefit Odonata as new breeding habitats. However, it is not yet clear what environmental characteristics of constructed wetlands are important for Odonata. 2. We studied 20 constructed agricultural wetlands in Central Finland and asked whether Odonata are able to use these wetlands as breeding habitats, and which environmental characteristics (aquatic vegetation, water area, shoreline length, bottom type diversity, water transparency, and pH) of the wetlands affect odonate abundance and species richness. 3. The constructed wetlands hosted altogether 17 odonate species. Odonate abundance was positively associated with the number of aquatic vegetation growth forms of the wetland. Odonate species richness was associated positively with abundance, floating-leaved vegetation, and water transparency. 4. Constructed agricultural wetlands support local diversity of common odonate species. Although protecting the remaining natural wetlands is of primary importance, constructed wetlands can add suitable wetland habitats in the agricultural landscape. From the perspective of Odonata, heterogenic aquatic vegetation and water quality are features worth promoting when constructing and managing agricultural wetlands." (Authors)] Address: Huikkonen, Ida-Maria, Dept of Biological & Environmental Science, University of Jyväskylä, P.O. Box 35, 40014 Univ. Jyväskylä, Finland. E-mail: imma.huikkonen@gmail.com

**19208.** Hunger, H.; Geigenbauer, K.; Fies, R.; Schiel, F.-J. (2020): Abschlussbericht Neubau der B31-West. Fachgutachten Libellen. Im Auftrag des Regierungspräsidiums Freiburg: 91 pp. (in German) ["A total of 40 dragonfly species were recorded at the surveyed water stretches, of which 34 species were certainly to very probably native to at least one survey stretch. Among the species detected, four are on the Baden-Württemberg and / or German list of species at risk, and three species are classified as "endangered" at the national and / or state level. *Coenagrion scitulum* and *Orthetrum albistylum* are considered extremely rare throughout Germany (category R). *Coenagrion mercuriale* is classified nationwide, *Aeshna isocetes* nationwide and *Sympetrum pedemontanum* both nationwide and statewide as critically endangered (RL 2). *Leucorrhinia caudalis* is classified as critically endangered nationwide (RL 1). The detection of *Coenagrion mercuriale*, which is strictly protected under the Federal Nature Conservation Act and listed in Annex II of the Habitats Directive, is relevant in terms of species protection. This species has been found in numerous sections of watercourses. Particularly noteworthy are the large native occurrences in the study sections at the "Riedkanal" (L 13 a-c), as well as at the "Wasenweiler Neugraben (L 12a-d, L 21, L 22)". But the species was also found in the "Merdinger Neugraben" (L 16, L 26), "Krebsbach" (L 31) and in some small ditches in the Wasenweiler Ried (L 08, L 10). In principle, the Helm's damselfly can be expected to occur in all sunny meadow ditches and streams in the study area. The

detection of *Leucorrhinia caudalis*, which is strictly protected under the Federal Nature Conservation Act and listed in Annex IV of the Habitats Directive, is also relevant for species conservation. This species has a native occurrence in the "Murr" fishing lake (L 05). This lake and parts of its surroundings are located within the FFH area "Freiburger Mooswälder", but outside the immediate area of intervention. The larger stillwaters within the study area are also of high importance for *Orthetrum albistylum*, which is strictly protected under Section 44 of the Federal Nature Conservation Act and only occurs in southern Baden and southeastern Bavaria throughout Germany; it has been found on the ground in the fishing lakes between Gottenheim and Wasenweiler." (Authors/DeepL) [https://rp.baden-wuerttemberg.de/fileadmin/RP-Internet/Freiburg/Abteilung\\_4/Referat\\_44/B31-West/19\\_01\\_U\\_VS\\_AnI\\_07-Libellen.pdf](https://rp.baden-wuerttemberg.de/fileadmin/RP-Internet/Freiburg/Abteilung_4/Referat_44/B31-West/19_01_U_VS_AnI_07-Libellen.pdf)] Address: Hunger, H., Institut für Naturschutz und Landschaftsanalyse (INULA), Wilhelmstraße 8, 79098 Freiburg, Germany. **19209.** Hykel, M.; Ruzickova, J.; Dolný, A. (2020): Perch selection in *Sympetrum* species (Odonata: Libellulidae): importance of vegetation structure and composition. *Ecological Entomology* 45(1): 90-96. (in English) ["1. Perching dragonflies are closely associated with the physical structure of vegetation because adults utilise plants when foraging, thermoregulating, and mate-seeking. However, little attention has been given to which structural attribute of vegetation is playing a key role within foraging habitat use. 2. This study focused on the influence of different features of perches on their selection by adult dragonflies. As a model group, a typical percher behavioural guild of *Sympetrum* (*S. depressiusculum*, *S. fonscolombii*, *S. sanguineum*, *S. striolatum*, *S. vulgatum*) was used and experimental plots with artificial perches and different structural properties were established. 3. It was found that adults preferred perch sticks with a wider diameter and larger spacing. It is assumed that these perching sites are advantageous because their base is more stable, they provide the best view for successful foraging, and there is no interference among individuals. 4. This study also revealed significant differences between male and female preferences. Females used less structured vegetation formed by thin perches in high densities. It is suggested that female discrimination is influenced by the higher competitiveness of males, which is related to their agonistic behaviour. 5. These results suggest that the availability of perches in the foraging habitat might be an essential requirement for adults. However, within the terrestrial surroundings of breeding sites, the structure of vegetation providing conditions for perching may be associated only with certain habitats. In intensive landscapes, physically structured vegetation can be limited or completely absent." (Authors)] Address: Hykel, M., Dept of Biology and Ecology, Faculty of Science, Univ. Ostrava, Slezska Ostrava, Czech Republic

**19210.** Johansson, F.; Heino, J.; Coiffard, P.; Svanbäck, R.; Wester, J.; Bini, L.M. (2020): Can information from citizen science data be used to predict biodiversity in stormwater ponds? *Scientific Reports* volume 10, Article number: 9380

(2020): 10 pp. (in English) ["Citizen science data (CSD) have the potential to be a powerful scientific approach to assess, monitor and predict biodiversity. Here, we ask whether CSD could be used to predict biodiversity of recently constructed man-made habitats. Biodiversity data on adult dragonfly abundance from all kinds of aquatic habitats collected by citizen scientists (volunteers) were retrieved from the Swedish Species Observation System and were compared with dragonfly abundance in man-made stormwater ponds. The abundance data of dragonflies in the stormwater ponds were collected with a scientific, standardized design. Our results showed that the citizen science datasets differed significantly from datasets collected scientifically in stormwater ponds. Hence, we could not predict biodiversity in stormwater ponds from the data collected by citizen scientists. Using CSD from past versus recent years or from small versus large areas surrounding the stormwater ponds did not change the outcome of our tests. However, we found that biodiversity patterns obtained with CSD were similar to those from stormwater ponds when we restricted our analyses to rare species. We also found a higher beta diversity for the CSD compared to the stormwater dataset. Our results suggest that if CSD are to be used for estimating or predicting biodiversity, we need to develop methods that take into account or correct for the under-reporting of common species in CSD. ... 29 species of Odonata were found in the 18 studied stormwater ponds." **19211.** Katayama, N.; Osada, Y.; Mashiko, M.; Baba, Y.G.; Tanaka, K.; Kusumoto, Y.; Okubo, S.; Ikeda, H.; Natuhara, Y. (2020): Organic farming and associated management practices benefit multiple wildlife taxa: A large-scale field study in rice paddy landscapes. *Journal of applied ecology* 56(8): 1970-1981. (in English) ["1. Organic farming has potential for the conservation of global biodiversity and associated ecosystem services. Despite this, knowledge of the effects of organic farming systems on farmland biodiversity is limited in Asia, the worldwide leader in rice production. 2. We conducted the first national-scale study to investigate the effects of three different rice farming systems (conventional, low-input, and organic) and specific management practices (e.g. herbicide and insecticide applications, crop rotation, and levee-vegetation management) on species richness and abundance of multiple taxonomic groups (plants, invertebrates, Pelophylax and Hyla japonica frogs, cobitid loaches, and birds) in Japan during 2013–2015. 3. Organic fields supported the highest richness and abundance of several taxonomic groups (native/Red List plants, Tetragnatha spiders, Sympetrum dragonflies, and Pelophylax frogs), followed by low-input and conventional fields. We also found taxon-specific responses to specific management practices. For instance, plant richness and Tetragnatha and Sympetrum abundance increased with reduced herbicide and/or insecticide applications. Sympetrum and Cobitid loach abundance increased in the absence of crop rotation, whereas H. japonica abundance increased with crop rotation. Pelophylax

abundance increased with an increased height of levee vegetation. 4. At spatial scales larger than single fields, waterbird richness and abundance were positively correlated with the proportion of organic rice fields, presumably due to increased prey abundance. Meanwhile, landbird richness and abundance were positively associated with annual precipitation and annual mean temperature, suggesting that such climate increases food availability. 5. Synthesis and applications. We highlight the positive effects of organic and low-input farming for biodiversity relative to conventional farming in rice-paddies. We also provide the scientific basis of the current agri-environmental schemes in Japan, subsidising organic and low-input farming for biodiversity. The taxon-specific associations with management practices indicate that avoiding crop rotation, maintaining levee vegetation, and organic farming at large spatial scales can also be wildlife-friendly. These practices may thus be incorporated into agri-environment schemes for effective biodiversity conservation." **19212.** Kim, M.J.; Kim, J.S.; Kim, S.-S.; Kim, I. (2020): Development and validation of microsatellite markers for an endangered dragonfly, *Libellula angelina* (Odonata: Libellulidae), with notes on population structures and genetic diversity. *International Journal of Odonatology* 23(2): 93 -102. (in English) ["*L. angelina* is listed as an endangered species in South Korea, and is classified as a critically endangered species by the International Union for Conservation of Nature (IUCN). An assessment of the genetic diversity and population relationships of the species by molecular markers can provide the information necessary to establish effective conservation strategies. In this study, we developed 10 microsatellite markers specific to *L. angelina* using the Illumina NextSeq 500 platform. Forty-three samples of *L. angelina* collected from three localities in South Korea were genotyped to validate these markers and to preliminarily assess the population genetic characteristics. The 10 markers revealed 4–11 alleles, 0.211–0.950 observed heterozygosity (HO), and 0.659–0.871 expected heterozygosity (HE) in the population with the largest sample size ( $n = 20$ ), thereby validating the suitability of these markers for population analyses. Our preliminary assessment of the population genetic characteristics appears to indicate the following: presence of inbreeding in all populations, an isolation of the most geographically distant population (Seocheon), and a lower HO than HE. The microsatellite markers developed in this study will be useful for studying the population genetics of *L. angelina* collected from additional sites in South Korea and from other regions." (2020): Composition and diversity of dragonflies (Insecta: Odonata) in Tunan waterfall area, North Minahasa, North Sulawesi, Indonesia. *Pakistan Journal of Zoology* 52(6): 2091-2100. (in English) ["Dragonflies play an important role in an ecosystem and can serve as control agents of agricultural insect pests. Dragonflies can be used as bioindicators for evaluating environmental changes in long-term studies (biogeography) and short-term studies (conservation biology). This research study was aimed to analyse the composition and diversity of dragonflies in Tunan Waterfall area, North Sulawesi, Indonesia. Sampling was conducted from March 2018 to May 2018 at three types of habitat, namely primary forest, secondary forest, and agricultural land. At each habitat type were laid four 300-metre-long transect lines. The lines were placed along the river of each habitat type, and sampling was carried out along the lines using sweep nets. From the research, 7 families, 20 species and 1,750 individuals belonging to 2 suborders, Anisoptera and Zygoptera, were identified. Libellulidae was the family with the most number of species and individuals being found. The species with the highest abundance was *Orthetrum pruinosum*, followed by *Libellago xanthocyana*. The highest dragonfly species abundance was found in the plantation land, while the lowest was found in the primary forest or around the waterfall. The highest dragonfly richness index, species diversity index ( $H'$ ), and species evenness index were found in the secondary forest, followed by the primary forest. The diversity of dragonflies at the observation site was influenced by vegetation cover and temperature." (Authors)] Address: Koneri, R., Department of Biology, Sam Ratulangi University, Indonesia. **19217.** Lewis-Phillips, J.; Brooks, S.J.; Sayer, C.D.; Patmore, I.R.; Hilton, G.M.; Harrison, A.; Robson, H.; Axmacher, J.C. (2020): Ponds as insect chimneys: Restoring overgrown farmland ponds benefits birds through elevated productivity of emerging aquatic insects. *Biological Conservation* 241, January 2020, 108253: 11pp. (in English) ["Highlights: •Farmland pond management strongly enhances emergent insect communities. •Emergent insects abundance increases 18 times following pond management. •Pond management leads to a 25-times increase in emergent insect biomass. •Day-to-day fluctuations in water temperature can predict insect emergences. •Local farmland bird communities are linked to emergent pond insect abundance. Abstract: Farmland bird populations have experienced severe declines across Europe and elsewhere. Ag-

ricultural intensification is believed to be a main factor behind these declines, with losses of non-cropped features, such as farmland ponds, identified as a key driver. Since the 1950s, many European farmland ponds have been in-filled or, through lack of management, become terrestrialised. Restoring terrestrialised farmland ponds has been shown to significantly increase the abundance and diversity of local farmland bird communities. It has been hypothesised that farmland birds are specifically attracted to open-canopy ponds due to increased emergent aquatic insect availability, but this link has hitherto been little explored. This study investigates how farmland pond management influences emergent aquatic insects [including "Odonata"], and how emergent insect abundance and biomass is linked to local bird assemblages. Insect emergences showed an 18-fold higher abundance and a 25-fold higher biomass at managed open-canopy ponds in comparison to their unmanaged overgrown counterparts, with day-to-day fluctuations in pond water temperature a key predictor of insect emergences. Species richness and abundance of birds at farmland ponds were strongly positively linked to the abundance of emergent insects. Furthermore, insect emergence peaks occurred on different days in different restored ponds such that the pond landscape afforded extended feeding opportunities for birds. Our findings suggest that restoring networks of terrestrialised farmland ponds to open-canopy macrophyte-dominated conditions could be a highly effective way of increasing the availability of aquatic insect prey for birds. This study highlights an urgent need to re-evaluate pond restoration and management within agri-environmental schemes in Europe and beyond." (Authors)] Address: Lewis-Phillips, J., Pond Restoration Research Group, Environmental Change Research Centre, Department of Geography, University College London, WC1E 6BT, UK. **19218.** Liu, C.; Zhang, Y.; Liu, X. (2020): Geographical fauna of Odonata in Xiangtoushan National Reserve, Guangdong province. *Forestry and Environmental Science*: 92-99. (in Chinese, with English summary) ["The field investigation of Odonata in Xiangtoushan national nature reserve was carried out from March 2017 to December 2019. The results showed that there were 122 species of Odonata, belonging to 14 families and 74 genera, in the reserve. The species number of Libellulidae (33 species) is the highest, followed by Gomphidae (28 species). The dominant species are *Neurobasis chinensis*, *Mnais mneme*, *Gomphidia kruegeri*, *Asiagomphus hainanensis*, *Macromia calliope*, *Orthetrum glaucum*, *Pantala flavescens* and *Trithemis festiva* etc. The world faunal characteristics of Odonata in this reserve showed that 92 species (occupied 75.41%) are oriental, 28 species (occupied 22.95%) are oriental-palaearctic. Meanwhile, all these species construct 10 distribution groups in 7 Chinese Zoogeographic subregions. There are 50 (40.98%) species in South China subregion, 13 (10.66%) species in South and Southwestern subregions, 19 (15.77%) species in South and Central-China subregions, and 20 (16.39) species live in three subregions of South-Central-North China simultaneously. The results of Odonata fauna are consistent

with the place of Xiangtoushan national reserve." (Authors)] Address: Liu, C., Administration of Guangdong Xiangtoushan National Nature Reserve; Huizhou Forestry Science Research Institute, China

**19219.** Luke, S.H.; Dwi Advento, A.; Dow, R.A.; Aryawan, A.A.K.; Barclay, H.; Eycott, A.E.; Hinsch, J.K.; Kurniawan, C.; Naim, M.; Mann, D.J.; Pujianto; Purnomo, D.; Rambe, T.D.S.; Slade, E.M.; Soeprapto; Ps, S.; Suhardi; Tarigan, R.S.; Wahyuningsih, R.; Widodo, R.H.; Caliman, J.-P.; Snaddon, J.L., Foster, W.A.; Turner, E.C. (2020): Complexity within an oil palm monoculture: The effects of habitat variability and rainfall on adult dragonfly (Odonata) communities. *Biotropica* 52(2): 366-378. (in English) ["Recent expansion of oil palm agriculture has resulted in loss of forest habitat and forest-dependent species. However, large numbers of species—particularly insects—can persist within plantations. This study focuses on Odonata (dragonflies and damselflies): a charismatic indicator taxon and a potentially valuable pest control agent. We surveyed adult Odonata populations biannually over three years within an industrial oil palm plantation in Sumatra, Indonesia. We assessed the effects of rainfall (including an El Niño Southern Oscillation-associated drought), the role of roadside ditches, and the importance of understory vegetation on Odonata populations. To assess the impacts of vegetation, we took advantage of a long-term vegetation management experiment that is part of the Biodiversity and Ecosystem Function in Tropical Agriculture (BEFTA) Programme. We found 41 Odonata species, and communities varied between plantation core and roadside edge microhabitats, and between seasons. Abundance was significantly related to rainfall levels four months before surveys, probably indicating the importance of high water levels in roadside ditches for successful larval development. We found no significant effect of the BEFTA understory vegetation treatments on Odonata abundance, and only limited effects on community composition, suggesting that local understory vegetation structure plays a relatively unimportant role in determining communities. Our findings highlight that there are large numbers of Odonata species present within oil palm plantations and suggest that their abundance could potentially be increased by maintaining or establishing waterbodies. As Odonata are predators, this could bring pest control benefits, in addition to enhancing biodiversity within intensive agricultural landscapes." **19220.** Luttbeg, B.; Hammond, J.I.; Brodin, T.; Sih, A. (2020): Predator hunting modes and predator-prey space games. *Ethology* 126(4): 476-485. (in English) [nv; "Predators and prey are often engaged in a game where their expected fitnesses are affected by their relative spatial distributions. Game models generally predict that when predators and prey move at similar temporal and spatial scales that predators should distribute themselves to match the distribution of the prey's resources and that prey should be relatively uniformly distributed. These predictions should better apply to sit-and-pursue and sit-and-wait predators,

who must anticipate the spatial distributions of their prey, than active predators that search for their prey. We test this with an experiment observing the spatial distributions and estimating the causes of movements between patches for Pacific tree frog tadpoles (*Pseudacris regilla*), a sit-and-pursue dragonfly larvae predator (*Rhionaeschna multicolor*), and an active salamander larval predator (*Ambystoma tigrinum mavortium*) when a single species was in the arena and when the prey was with one of the predators. We find that the sit-and-pursue predator favors patches with more of the prey's algae resources when the prey is not in the experimental arena and that the prey, when in the arena with this predator, do not favor patches with more resources. We also find that the active predator does not favor patches with more algae and that prey, when with an active predator, continue to favor these higher resource patches. These results suggest that the hunting modes of predators impact their spatial distributions and the spatial distributions of their prey, which has potential to have cascading effects on lower trophic levels." (Authors)] Address: Luttbeg, B., Oklahoma State University, Stillwater, OK 74074, USA. Email: luttbeg@okstate.edu

**19221.** Maoka, T.; Kawase, N.; Ueda, T.; Nishida, R. (2020): Carotenoids of dragonflies, from the perspective of comparative biochemical and chemical ecological studies. *Biochemical Systematics and Ecology* Volume 89, April 2020, 104001: 7 pp. (in English) [<sup>13</sup>C carotenoids of 20 species of dragonflies (including 14 species of Anisoptera and six species of Zygoptera) were investigated from the viewpoints of comparative biochemistry and chemical ecology. In larvae,  $\beta$ -carotene,  $\beta$ -cryptoxanthin, lutein, and fucoxanthin were found to be major carotenoids in both Anisoptera and Zygoptera. These carotenoids were assumed to have originated from aquatic insects, water fleas, tadpoles, and small fish, which dragonfly larvae feed on. Furthermore,  $\beta$ -caroten-2-ol and echinenone were also found in all species of larvae investigated. In adult dragonflies,  $\beta$ -carotene was found to be a major carotenoid along with lutein, zeaxanthin,  $\beta$ -caroten-2-ol, and echinenone in both Anisoptera and Zygoptera. On the other hand, unique carotenoids,  $\beta$ -zeacarotene,  $\beta$ , $\psi$ -carotene ( $\gamma$ -carotene), torulene,  $\beta$ , $\gamma$ -carotene, and  $\gamma$ , $\gamma$ -carotene, were present in both Anisoptera and Zygoptera dragonflies. These carotenoids were not found in larvae. Food chain studies of dragonflies suggested that these carotenoids originated from aphids, and/or possibly from aphidophagous ladybird beetles and spiders, which dragonflies feed on. Lutein and zeaxanthin in adult dragonflies were also assumed to have originated from flying insects they feed on, such as flies, mosquitoes, butterflies, moths, and planthoppers, as well as spiders.  $\beta$ -Caroten-2-ol and echinenone were found in both dragonfly adults and larvae. They were assumed to be metabolites of  $\beta$ -carotene in dragonflies themselves. Carotenoids of dragonflies well reflect the food chain during their lifecycle." (Authors)] Address: Maoka, T., Research Inst. for Production Development, 15 Shimogamo-morimoto-cho, Sakyo-ku, Kyoto, 606-0805, Japan. Email: maoka@mbx.kyoto-inet.or.jp

**19222.** McKee, K.M.; Koprivnikar, J.; Johnson, P.T.J.; Arts, M.T. (2020): Parasite infectious stages provide essential fatty acids and lipid-rich resources to freshwater consumers. *Oecologia* 192(2): 477-488. (in English) ["Free-living parasite infectious stages, such as motile cercariae of trematodes (flatworms), can constitute substantial biomass within aquatic ecosystems and are frequently eaten by various consumers, potentially serving as an important source of nutrients and energy. However, quantitative data on their nutritional value (e.g., essential fatty acids [EFA]) are largely lacking. As EFA are leading indicators of nutritional quality and underpin aquatic ecosystem productivity, we performed fatty acid (FA) analysis on an aggregate of ~30,000 cercariae of the freshwater trematode, *Ribeiroia ondatrae*. Individual cercariae contained 15 ng of total FA, and considerable quantities of EFA, including eicosapentaenoic (EPA, at 0.79 ng cercaria<sup>-1</sup>) and docosahexaenoic (DHA, at 0.01 ng cercaria<sup>-1</sup>) acids. We estimated annual EFA production by *R. ondatrae* cercariae for a series of ponds in California to be 40.4–337.0  $\mu\text{g m}^{-2} \text{yr}^{-1}$  for EPA and 0.7–6.2  $\mu\text{g m}^{-2} \text{yr}^{-1}$  for DHA. To investigate viability of cercariae as prey, we also compared growth and FA profiles of dragonfly larvae (nymphs of *Leucorrhinia intacta*) fed equivalent masses of either *R. ondatrae* or zooplankton (*Daphnia* spp.) for 5 weeks. Nymphs raised on the two diets grew equally well, with no significant differences found in their EFA profiles. While zooplankton are widely recognized as a vital source of energy, and an important conduit for the movement of EFA between algae and higher trophic levels, we suggest a similar role for trematode cercariae by 'unlocking' EFA from the benthic environment, highlighting their potential importance as a nutrient source that supports animal health.] Address: Koprivnikar, Janet, Dept of Chemistry & Biology, Ryerson Univ., 350 Victoria Street, Toronto, ON, M5B 2K3, Canada

**19223.** Medupin, C. (2020): Spatial and temporal variation of benthic macroinvertebrate communities along an urban river in Greater Manchester, UK. *Environ Monit Assess* (2020) 192:84. (in English) ["Urban rivers face challenges of increased human activities which also affect river organisms. In order to enhance freshwater biodiversity in urban rivers, it is important to determine how the benthic macroinvertebrate communities are influenced by key abiotic factors. This was investigated in this paper through the study of the spatial and temporal variations of benthic macroinvertebrates and water quality variables at the urban River Medlock in Greater Manchester, UK. Samples were obtained from five sections of the catchment (S1 to S5) over a period of 14 months and the results were compared with the standard requirement of the European Union's Water Framework Directives. Multivariate tests including SIMPER (similarity percentages), PCA (principal component analysis) and BIOENV (biological and environmental) were carried out on the data in order to determine the environmental variables which most influenced the benthic macroinvertebrates. PCA of environmental variables indicated that 34% of the overall variance was heavily weighted on nutrients and catchment area (negatively on altitude and slope), 17% represented ri-

ver substrate and the 12% represented discharge. The BIO-ENV analysis also indicated altitude, slope, catchment area, discharge and conductivity as the variables which influenced the biological communities. SIMPER analysis showed a difference between the upper and lower sections of the river with some sensitive taxa at the upper sites and showed that more organisms are present during spring. Apart from the lowest section of the river, the EU Water Framework Directive classification showed that other sites achieved the 'good ecological status'. While 32 taxa groups [including "Odonata"] were identified, abundant Baetidae, Chironomidae and Oligochaeta were recorded at all sites and seasons. The scores for biotic indices Whalley Hawkes Paisley and Trigg (WHPT) and Biological Monitoring Working Party (BMWP) were found to be similar. By the application of surrogate variables such as percentage urban cover, catchment area and total number of organism, the influence of urbanisation could be seen in the abundance of organisms over time and space." **19224.** Murray, R.L.; Tah, S.; Koprivnikar, J.; Rowe, L.; McCauley, S.J. (2020): Exposure to potentially cannibalistic conspecifics induces an increased immune response. *Ecological Entomology* 45(2): 355-363. (in English) ["1. Within-population infectious disease dynamics depend on multiple factors, including the ability of hosts to mount an effective immune response. These immune responses can be highly plastic, responding to pathogen risk, as well as the ecological context in which pathogens are encountered. 2. High conspecific density can stimulate immune activity, and recent research suggests that predators can cause indirect protective effects in their prey through the induction of increased immune responses. Comparatively little work, however, has investigated whether exposure to potentially cannibalistic conspecifics, representing both increased density and predatory pressures, will have similar effects on immune expression. 3. Using dragonfly larvae, the present study investigated whether exposure to potentially cannibalistic conspecifics altered the melanisation of simulated parasites. 4. Increased levels of melanisation were found in larvae regardless of whether that conspecific had recently engaged in cannibalism or not. Melanisation also increased as conspecific density increased, even if the conspecifics present were small, and therefore unlikely to pose a cannibalism threat. 5. The findings obtained in the present study indicate that conspecific presence is sufficient to affect immune responses in these insects even though they are relatively solitary compared with the phase-polyphenic taxa typically associated with density-dependent prophylaxis. Because melanisation is also important for wound healing, we suggest that the increased melanin response observed with increased conspecific density might act to induce heightened immunity when faced with potentially increased risk of infection, and also facilitate wound healing under threat of predation/cannibalism." **19225.** Murria, C.; Väisänen, L.O.S.; Somma, S.; Wangenstein, O.S.; Arnedo, M.A.; Prat, N. (2020): Towards an Iberian DNA barcode reference library of freshwater macroinvertebrates and fishes. *Limnetica* 39(1): 73-92. (in English, with Spanish summary) ["Freshwater macroinvertebrates and fishes are focal groups in major ecosystem biomonitoring programs in the Iberian Peninsula. Yet, their use as bioindicators is sometimes constrained by the time and cost needed for sorting macroinvertebrates specimens and their challenging taxonomic identification, and the huge sampling procedures for capturing rare or incipient fish species, respectively. Given the increasing cost-effectiveness of metazoan identification based on metabarcoding [i.e., high-throughput sequencing (HTS) of DNA barcodes] and reliability of species-level identification and the high number of samples that can be processed, its use in biomonitoring of freshwater communities can provide an alternative to morphology-based approaches. However, the accuracy of species assignment in metabarcoding approaches relies on the availability of a comprehensive DNA barcode reference library. Because of the high level of endemism in the Iberian Peninsula, current public repositories for DNA barcodes may not be informative enough to identify the Iberian fauna to species level. Here, we compiled the Iberian freshwater macroinvertebrates and fishes taxonomic list (including indigenous and non-indigenous species) and the available molecular data for the cytochrome oxidase I DNA barcode (cox1, COI-5P) in public repositories to assess the extent of DNA barcode coverage. The DNA barcode coverage was reported for DNA fragments within the Folmer region (658 bp). Given that HTS platforms provide DNA sequence in the range of 50-400 bp in length, we also reported the second half of the DNA barcode (313 bp, Leray region) and the first part of the Leray region (285 bp, Leray-285), which are short DNA barcodes useful to assign metabarcoding cox1 data. For macroinvertebrates, the final taxonomic checklist comprises 3348 species including Mollusca (65 species), Crustacea (101 species) and Insecta (3182 species). We present an initial DNA barcode reference library, with an overall coverage of ~ 35 % of the Iberian taxa. Exploring this data, we find a strong taxonomic bias. Based on Leray-285, Odonata (43 of 79 species barcoded, 54.43 %) and Hemiptera (44 of 81 species barcoded, 54.32 %) were the best represented lineages. In contrast, Diptera (393 of 1693 species barcoded, 23.21 %), and Plecoptera (42 of 135 species barcoded, 31.11 %) were underrepresented. For fishes, the available DNA barcode data covered 98.11 % of the indigenous (76) and non-indigenous (30) species. By revealing and quantifying current gaps on the available data (~ 65 %), we aim to improve efficiency in designing the next steps towards the ambitious yet necessary goal of compiling a complete DNA barcode reference library for Iberian macroinvertebrates and fishes." **19226.** Nakanishi, K.; Uéda, T.; Yokomizo, H.; Hayashi, T.I. (2020): Effects of systemic insecticides on the population dynamics of the dragonfly *Sympetrum frequens* in Japan: statistical analyses using field census data from 2009 to 2016. *Science of The Total Environment* 703, 134499: 8 pp. (in English) ["Highlights: • Dragonfly abundance in Japan's agricultural landscapes has decreased. • We monitored the population density of the dragonfly *Sympetrum frequens*. • We estimated systemic insecticide use and analyzed its effect on the dragonfly. • The results suggest a negative effect of systemic insecticide use on population size. • Some agronomic factors need to be further examined as potential confounders. Abstract: Since the mid-1990s, populations of the common Japanese dragonfly *Sympetrum frequens* in rice fields have declined severely. Application of systemic insecticides—especially fipronil—to nursery boxes of rice seedlings is suspected to be the main cause of the decline. However, until now there have been insufficient population data to test the causality. We conducted a dragonfly survey from 2009 to 2016 in four prefectures of Japan and compiled the data to enable the comparison of population growth rates along five main census routes over the years. We also estimated the use ratio of each insecticide applied to nursery boxes in rice fields (i.e., the area exposed to insecticide as a ratio of the total rice field area) by prefecture. We then statistically analyzed the effects of the insecticides on the dragonfly's population growth rates, taking into account the potential confounding factors based on current knowledge. There was a significant negative association between the annual increase in use ratio of the sum of systemic insecticides (e.g., fipronil, imidacloprid, and chlorantraniliprole) and the annual population growth rate of *S. frequens*. This association suggests that systemic insecticide use affected the decrease in population density of the dragonfly, although some agronomic factors need to be further examined as potential confounders." **19229.** Nelson, S.J.; Chen, C.Y.; Kahl, J.S. (2020): Dragonfly larvae as biosentinels of Hg bioaccumulation in Northeastern and Adirondack lakes: relationships to abiotic factors. *Ecotoxicology* 29: 1659-1672. (in English) ["Mercury (Hg) is a toxic pollutant, widespread in northeastern US ecosystems. Resource managers' efforts to develop fish consumption advisories for humans and to focus conservation efforts for fish-eating wildlife are hampered by spatial variability. Dragonfly larvae can serve as biosentinels for Hg given that they are widespread in freshwaters, long-lived, exhibit site fidelity, and bioaccumulate relatively high mercury concentrations, mostly as methylmercury (88%±11% MeHg in this study). We sampled lake water and dragonfly larvae in 74 northeastern US lakes that are part of the US EPA Long-Term Monitoring Network, including 45 lakes in New York, 43 of which are in the Adirondacks. Aqueous dissolved organic carbon (DOC) and total Hg (THg) were strongly related to MeHg in lake water. Dragonfly larvae total mercury ranged from 0.016–0.918 µg/g, dw across the study area; Adirondack lakes had the minimum and maximum concentrations. Aqueous MeHg and dragonfly THg were similar between the Adirondack and Northeast regions, but a majority of lakes within the highest quartile of dragonfly THg were in the Adirondacks. Using landscape, lake chemistry, and lake morphometry data, we evaluated relationships with MeHg in lake water and THg in dragonfly larvae. Lakewater DOC and lake volume were strong predictors for MeHg in water. Dragonfly THg Bioaccumulation Factors (BAFs, calculated as [dragonfly THg]:[aqueous MeHg]) increased as lake volume increased, suggesting that lake size influences Hg bioaccumulation or biomagnification. BAFs declined with increasing DOC, supporting a potential limiting effect for MeHg bioavailability with higher DOC." (Authors)] Address: Nelson, Sarah, School of Forest Resources, Univ. **19231.** Nobles, S.; Jackson, C.R. (2020): Effects of life stage, site, and species on the dragonfly gut microbiome. *Microorganisms* 8(2), 183: 15 pp. (in English) ["Insects that undergo metamorphosis from juveniles to adults provide an intriguing opportunity to examine the effects of life stage, species, and the environment on their gut microbiome. In this study, we surveyed the gut microbiomes of 13 species of dragonfly collected from five different locations subject to different levels of human impact. Juveniles were collected as nymphs from aquatic habitats while airborne adults were caught at the same locations. The gut microbiome was characterized by next generation sequencing of the bacterial 16S rRNA gene. Life stage was an important factor, with the gut microbiomes of dragonfly nymphs differing from those of adult dragonflies. Gut microbiomes of nymphs were influenced by sample site and, to a lesser extent, host species. Neither sample location nor host species had a strong effect on the gut microbiome of dragonfly adults. Regardless of life stage, gut microbiomes were dominated by members of the Proteobacteria, with members of the Bacteroidetes (especially in adults), Firmicutes, and Acidobacteria (especially in nymphs) also being proportionally abundant. These results demonstrate that different life stages of metamorphosing insects can harbor very different gut microbiomes and differ in how this microbiome is influenced by the surrounding environment. ... The number of dragonfly species collected varied by site and life stage and finding a nymph species at a given site did not relate to the later collection of adults (Table 1). Eight different species of adults were collected, and 13 different species of nymphs. One of the more rural sites (Camp Lake Stephens) had the highest number of species collected (eight) with *Erythemis simplicicollis* and *Microorganisms* 2020, 8, 183 4 of 15 *Celithemis elisa* being the most common with four individuals of each collected. The Shelby Farms and former Treatment Pond sites yielded the lowest number of dragonfly species (five). Across all sites, *E. simplicicollis* was the most collected species (19 individuals) followed by *Libellula luctuosa* (15 individuals) and *Pachydiplax longipennis* (13 individuals). Only one individual was collected for each *Erythrodiplax fusca*, *Ladonna deplanata*, and *Tetragoneuria cynosura*." (Authors) The study includes *Anax imperator*, which

must be a misidentification.] Address: Nobles, Sarah, Department of Biology, University of Mississippi, University, MS 38677, USA

**19232.** Ožana, S.; Pyszek, P.; Dolný, A. (2020): Determination of suitable insect part for non-lethal DNA sampling: case study of DNA quality and regeneration capability of dragonflies. *Insect Conservation and Diversity* 13(4): 319-327. (in English) [nv; "1. Genetics has been widely used in insect ecology and conservation. To minimise the effect of DNA sampling on organisms as much as possible, it would be ideal to use non-invasive or non-lethal DNA sources. Therefore, it is also very important to determine the responses of organisms to DNA sampling. 2. In this study, the quality and quantity of genomic DNA samples from three types of insect tissues (exuvia, mid-legs and wings) were evaluated. As model organisms, we used two dragonfly species of different sizes (*Leucorrhinia dubia*, *Anax imperator*). We also tested the regenerative ability of dragonfly larvae as a repair mechanism after mid-leg cut-off, with respect to factors such as size and quantity of diet. 3. We found that DNA of sufficient quality for analyses was obtained from all tested tissues. Nonetheless, isolates from exuviae were conclusively less useful for sequencing than those from the mid-legs and wings. The highest quantity of DNA was obtained from the mid-legs. The survival of larvae is not affected by removing the legs, which can usually regenerate. 4. All the tested tissues could be a source of adequate DNA; however, we concluded that primarily the legs should be used because they provided the best DNA samples in terms of quantity and quality of DNA. Furthermore, their exploitation would not affect individuals seriously if young larvae with sufficient time (at least 6 months) for regeneration are sampled. The exuviae should be used for absolutely non-invasive studies involving endangered or protected species." **19234.** Perron, M.A.C.; Pick, F.R. (2020): Water quality effects on dragonfly and damselfly nymph communities: A comparison of urban and natural ponds?. *Environmental Pollution* 263, Part B, August 2020, 114472: 13 pp. (in English) ["Highlights: • Odonata nymph abundance was lower in stormwater ponds than natural ponds. • Contaminants in stormwater ponds were below guidelines, except for Cl<sup>-</sup>, Cu and TP. • Cl<sup>-</sup> (from road salts) affected dragonfly abundance and assemblages but not damselfly. • A common index of water quality was not useful in predicting habitat quality. • Stormwater ponds can provide suitable habitat for Odonata, if properly designed. Abstract: Cities are increasingly using constructed ponds to mitigate flooding and downstream water pollution from urban runoff. As a result, these stormwater ponds can have poor water quality, yet they can also attract wildlife. In this study, the effects of water quality on Odonata were determined in stormwater ponds (n = 41) and natural reference ponds (n = 10) of similar size across the National Capital Region of Canada. A total of 38 chemical/physical water quality variables along with Odonata nymph abundance and taxonomic composition were sampled at each pond. Chloride concentrations exceeded the guideline for the protection of aquatic life at over two-thirds of the stormwater ponds. Among all the metals tested, only Cu exceeded guidelines at many stormwater ponds. Both dragonfly and damselfly nymphs were on average less abundant in the stormwater ponds in comparison to the natural ponds. Ponds with high concentrations of chloride and metals typically had lower dragonfly abundance. Dragonfly community structure was significantly influenced by high chloride (or conductivity), which likely originates from winter road salting. In contrast, damselfly community structure in the stormwater ponds was similar to that found in natural ponds, with nutrients and metals explaining a small percent of variation in community structure. A water quality index developed to assess habitats for the protection of aquatic life did not significantly explain Odonata abundance or measures of diversity and may not be suitable in assessing pond habitat quality. To improve pond habitats within cities, efforts should be directed at reducing the amount of impervious surface and road salt usage within catchment basins." **19236.** Pires, M.M.; Siegloch, A.E.; Medina Hernandez, M.I.; Petrucio, M.M. (2020): Environmental drivers and composition of assemblages of immature odonates (Insecta) in a subtropical island in southern Brazil. *Acta Limnologica Brasiliensia*, 2020, vol. 32, e2: 10 pp. (in English, with Portuguese summary) ["Aim: Describe the diversity of immature stages of Odonata (Insecta) in streams from a subtropical island in southern Brazil and investigate the influence of environmental variables on the composition of their assemblages. Methods: Eleven low-order streams (1st to 3rd order) were sampled in two conservation units located in the island of Santa Catarina (southern Brazil) between 2010 and 2012. Immature specimens of Odonata were collected using a Surber sampler. The influence of water abiotic parameters and habitat structure (mesohabitats: riffle vs. pool areas, microhabitats: litter vs. stone substrates) on the composition of Odonata was tested through the seasons using ordination diagrams and redundancy analysis. Results: Nine odonate genera from seven families were recorded in the study region. The genera *Desmogomphus*, *Epigomphus* (Gomphidae), *Heteragrion* (Heteragrionidae) and *Perilestes* (Perilestidae) have their first records described for the state of Santa Catarina. Additionally, biological notes are provided for other odonate genera concerning substrate use. The composition of Odonata communities changed over the seasons and they were influenced by water temperature and velocity. Additionally, odonate composition differed significantly between microhabitats (substrate type) and mesohabitats (riffle vs. pool areas) in the streams studied. Conclusions: The lower genera richness of Odonata recorded in the island of Santa Catarina in relation to other Brazilian subtropical streams is probably associated with the insular condition of the study region. This study also demonstrated that substrate (organic and inorganic) and mesohabitat (riffle and pool) types were important drivers of the composition of the fauna of immature odonates, evidencing the role of climate and habitat structure in influencing subtropical stream insect communities." **19237.** Raffard, A.; Therry, L.; Finn, F.; Koch, K.; Brodin, T.; Blanchet, S.; Cote, J. (2020): Does range expansion modify trait covariation? A study of a northward expanding dragonfly. *Oecologia* 192: 565-575. (in English) ["The adaptive value of correlations among phenotypic traits depends on the prevailing environmental conditions. Differences in selection pressures during species range expansions may there-

fore shape phenotypic integration. In this study, we assessed variation in behavioral and morphological traits, as well as their covariations, in replicated southern and northern European populations of the northward expanding dragonfly *Crocothemis erythraea*. Larvae from northern populations were, on average, darker in color, and therefore, better camouflaged than larvae from southern populations. However, there was no difference in activity level. Darkness and activity were positively correlated in larvae from northern populations, whereas this trait covariation was missing in southern populations. This suggests the emergence of alternative strategies in time-limited northern populations, a higher activity level that required better camouflage through darker coloration, while less active larvae benefited from an energy-saving strategy by reducing the investment in costly traits, such as body darkness. We further found that larger larvae emerged into larger adults, with a higher investment in flight morphology. Our findings imply that phenotypic integration is associated with the northward range shift, potentially differentially shaping fitness consequences, and ecological interactions in southern versus northern populations." **19239.** Rivas Torres, A. (2020): Etodiversidad: estudio de la variabilidad del comportamiento sexual en el orden Odonata. PhD. thesis, Departamento de Ecología e Biología Animal, Universidad de Vigo: 195 pp. (in Spanish) ["Nowadays, ethology or the study of animal behaviour seems to have lost the lustre it acquired during its golden age in the 20th century thanks to great naturalists and biologists such as Nikolaas Tinbergen and Konrad Lorenz, not forgetting the perhaps not so well known contribution to ethology of Charles Darwin, who gave value to animal behaviour and included it as another possible adaptation along with anatomical and physiological adaptations. According to Darwin, such adaptations would allow the survival of the individual and its subsequent reproductive success. Although for Dar-

win himself behaviour, together with natural and sexual selection, were fundamental pieces in understanding the adaptation of organisms, it seems that nowadays it seems that the most naturalistic aspect of a biologist, observation, has been lost. Most studies have shifted from a macroscopic to a more microscopic view, focusing on genomic and phylogenetic analysis of organisms. While it is important for the field of biology to move forward, we must not leave behind such important disciplines as ethology, which, together with other disciplines of a more molecular nature, allows us to establish more precise conclusions, hypotheses and theories. Both natural and sexual selection use diversity as a substrate for action, as long as these traits are transmitted through the genetic code. It is therefore important, before going into the objective of this thesis, to talk about biological diversity or biodiversity. The concept of biodiversity can actually be considered a meta-concept, as it encompasses several terms: the genetic diversity within species, the diversity of species in an ecosystem, the diversity of ecosystems of which these species form a part, and the landscape diversity where these ecosystems are found, including evolutionary and ecological processes. Conserving and respecting biodiversity has important social, political, economic and public health consequences: we benefit daily from everything that healthy and stable biodiversity provides, from medicines to food and clothing. In addition, biogeochemical cycles create fertile soil, recycle fresh water and purify the air. However, to complete the complex equation of the biodiversity concept, another variable is missing: ethological diversity, behavioural diversity or etodiversity. There are currently several studies that stress the importance of studying behavioural diversity and its consequences in the fields of ecology, environment and evolution (population dynamics, expansion or reduction of the distribution range of species, trophic cascades). We sometimes overlook the fact that it is not only diversity in physical or physiological traits that is the substrate and driver of evolution, but also behavioural diversity plays a role almost as important, if not more so, as reproductive isolation is often caused by some kind of pre-zygotic behaviour, such as the mating song of frogs. In addition, sexual conflict between males and females, which is just another form of sexual selection, most often uses behaviour as a substrate for reproductive adaptation. Throughout the five chapters that make up this thesis, the aim is to highlight the importance of the study of biodiversity and, in particular, of etodiversity or behavioural diversity, giving the latter an important role at all levels, not only ecosystemic, but also inter- and intraspecific. For this purpose, insects of the order Odonata (dragonflies and damselflies) are used as model organisms, paying special attention to their sexual behaviour. The order Odonata is relatively small in terms of the number of described species (around 6,000), which has facilitated its study and allowed us to obtain a broad knowledge of the distribution and taxonomy of the members of this group. The order is divided into three suborders: Zygoptera, Anisoptera and Anisozygoptera (the latter represented by a single genus, *Epiophlebia*). Anisoptera are usually larger and more robust than Zygoptera and, unlike Zygoptera, they spread their wings when at rest. Anisozygoptera, on

the other hand, are intermediate in appearance between the two previous suborders. Odonates are an ideal group for ethodiversity studies, as they possess a wide variety of behaviours associated with reproduction, each with intraspecific and interspecific variability. Among these behaviours, the encounter between individuals of both sexes and their location, interaction between males and territoriality, intraspecific recognition, tandem formation, copulation and oviposition form are of particular interest. Among these behaviours, the most important for study are encounters between individuals of both sexes and their location, interaction between males and territoriality, intraspecific recognition, tandem formation, copulation and oviposition. Judging from the fossil record, these winged insects have changed little since their origin, suggesting great adaptability of the group. Today, they remain an example of adaptability to their environment, as they are a cosmopolitan group of insects found almost everywhere on the planet, in multiple and varied environments associated with bodies of water. This ability to colonise diverse environments allows us to know the behavioural patterns of individuals at different latitudes, thus being able to establish patterns of ethological diversity in a similar way to the patterns of specific richness observed within the group, with an increase in the number of species from the poles towards the equator. The first chapter of this thesis focuses on the study of alternative reproductive strategies, using the Mexican endemic odonate *Paraphlebia zoe* as a study model. Alternative breeding strategies are commonly associated with male dimorphism and in the case of *P. zoe*, males are dimorphic in wing colour, with black and white-winged males defending territory and hyaline-winged males often acting as satellites. The study was carried out in a population of this species located in runoff habitats in Teocelo, Veracruz region. During the fieldwork period, hyaline-winged males were extremely rare to see, due to the time of year of the study (June-July), so the study focused on black-winged males. Some black-winged males were found to share the same territory, so it was hypothesised that within this morph there might be two territorial (or pre-copulatory) alternatives: dominant and submissive black-winged males. To test whether these two roles were plastic or stable in each individual, an experiment was carried out in which the black and white wing patches of some individuals were manipulated. This experiment included four different treatments: in the first, the black and white spots were painted without changing their size; in the second treatment, the white spot was erased using black paint; in the third treatment, the size of the black spot was increased and the white spot was moved while maintaining its size. Finally, a group of control individuals were included and no modifications were made to them. During a month and a half, focal observations of 10 min per individual were made daily (weather permitting), from 9:00 a.m. to 16:30 p.m., the time frame in which the maximum peak of activity in the individuals of this population took place. To carry out these focal observations, males and females were previously captured with an entomological net, individually marked with a number on the left anterior wing, the date and time of capture were noted, the body size was measured

with a caliper and the marked individuals were released again. An attempt was made to draw the number as far away from the spot as possible so that the marking of individuals did not interfere with the handling experiment. The results of the experiment suggest that the dominant and submissive roles are not affected by the treatment and would therefore be stable and fixed. Not only the plasticity of these roles was studied, but also the possible correlation between some phenotypic variables (wing symmetry, survival and recapture probability) and male behaviour (submissive or dominant) was investigated. In this case, a positive correlation was found between body size and survival in both sexes and roles of black-winged males. In addition, the largest and youngest black-winged males were the most symmetrical. *P. zoe* males possess a high behavioural diversity, with two types of strategies (dominant and submissive) in black-winged males. The occurrence of this behavioural diversity within the same morph could depend on demographic factors, such as population density and/or the relative frequency of different male morphs (hyaline and black-winged) at a given time of the year. Before copulation, male odonates transfer spermatozoa from the testes, located in the 9th abdominal segment, to the seminal vesicle located in the 2nd abdominal segment; a behaviour unique to this group of insects known as sperm translocation. The second chapter discusses how sperm translocation can affect the quality of sperm used by the male to produce sperm. The second chapter analyses how sperm translocation can affect the quality of the sperm used by the male to fertilise the female, and consequently the survival of the progeny (i.e. female fertility). In this case, a European zygopteran species, *Ischnura graellsii*, which is easy to find in Galicia, is used as a model for the study. Some published observations on this behaviour in odonates suggest that sometimes males do not translocate sperm before copulation. The aim of this chapter is to determine the circumstances under which males omit this behaviour and how this affects the viability of their sperm. For this purpose, *I. graellsii* males were allowed to perform a first sperm translocation (interrupting copulation at this time) and then the behaviour of these males in subsequent copulations was studied. Males were randomly assigned to four treatments consisting of allowing these individuals to copulate with a female after 15 minutes, 24 hours, 48 hours or 72 hours. Fertility of mated females was quantified as a proxy for male sperm viability. It was found that all *I. graellsii* males mated 15 minutes after the first sperm translocation used the sperm stored in the seminal vesicle, while the proportion of males repeating sperm translocation increased progressively from 6.7% for the group of males mated after 24 hours to 57.1% for males mated three days after the first translocation. In addition, information was available from field experiments with individuals of the genus *Calopteryx*, which showed that males of this genus also do not repeat sperm translocation less than 24 hours after mating. The fertility of *I. graellsii* females was diminished in cases where the mating males did not perform sperm translocation immediately prior to copulation, suggesting that sperm quality declines over time in *I. graellsii*. Males somehow determine when they can reuse the sperm

stored in the seminal vesicle or when they must discard it and perform a new sperm translocation. The important conclusion of this chapter is that the special anatomical arrangement of male odonates opens up selective pressures aimed at maximising sperm viability through plasticity and variety in sperm translocation behaviour. The third chapter focuses on the comparative study of the survival and behaviour of two populations of *Heteragrion cooki* located in Ecuadorian forest habitats in the locality of Piñas, El Oro region. These populations have been affected in recent years by the felling of riverbank trees. Although the genus *Heteragrion* is one of the most common in South American tropical forests, only 3 of the 46 species described in the genus have been studied by ethologists. The study of their behaviour is important to understand how tropical species are affected by the increasing human-induced deforestation in this region of the planet. For this study, capture, mark-recapture and focal observations of adults were used, similar to the study of *P. zoe* in Mexico. Two distinct stream types in which the target species was present were selected for the study. The first was a stream located next to a teak (*Tectona grandis*) plantation that retains small remnants of forest and riparian vegetation and is right on the border of a nature reserve. As it retains remnants of riparian forest, the environment was shadier in this population. The second stream was located 7.6 km from the first, and was located between crops of sugar cane (*Saccharum officinarum*), pineapples and other agricultural crops, so large areas of the stream were exposed and suffered from high insolation during the central hours of the day. As *H. cooki* is a shade-preferring species, the latter stream is expected to be of lower quality for *H. cooki* individuals. Similar densities of males (but not females) were found in both the less human-affected stream and the sunnier stream. Recapture rates were similar in both populations; higher for males (50%) than for females (20%). Body size was also affected, with individuals in the shady stream being significantly smaller than those in the sunnier stream. Males in the shady stream survived longer than females. Males in the shady stream survived longer than females, while in the sunnier stream daily survival was similar between sexes, but variable over time. Furthermore, in the sunny stream, body size was negatively correlated with survival. The study of *H. cooki* breeding behaviour revealed a peak of activity between 13:00 pm and 16:00 pm. Males arrived earlier than females at the stream and defended small patches of territory in the stream, exhibiting high territory fidelity and aggressive behaviour towards other males of the same species. Copulation duration is around 6 minutes and oviposition takes place in tandem male and female on roots and vines, and lasts an average of 45 minutes. Despite the loss of riparian vegetation in the sunniest population, similar densities of *H. cooki* individuals are maintained, probably due to small remnants of native forest found near the stream that may act as refuges for these individuals. The fourth chapter studies the function of an anatomical structure present in females of several odonate species, the vulvar spine. The European zygopteran *Enallagma cyathigerum* was selected as the target species for this chapter. The females of this species, like

many others within the family Coenagrionidae, possess a vulvar spine on the eighth abdominal segment, the function of which is unknown. This chapter tests three possible hypotheses to explain the presence of the vulvar spine: the first is that the vulvar spine serves as a structure to facilitate endophytic oviposition; the second hypothesis is that the vulvar spine is used by females as an organ to stimulate males to release sperm; and the third and final hypothesis is that the vulvar spine has evolved as part of male-female sexual conflict, to inflict damage on the male and shorten the duration of copulation. To test these hypotheses, a series of experiments were carried out using a colony of *E. cyathigerum* individuals captured in the field and subsequently maintained in the laboratory. To test whether the vulvar spine of the female is used to inflict damage on the male during copulation, 12 mature males were randomly selected. Four of these males copulated only once, 4 were allowed to copulate twice on consecutive days and the remaining 4 males were allowed to copulate 3 times, also on consecutive days. To examine whether the vulvar spine caused any effect on male survival, females were separated into two groups, one group where the vulvar spine was severed with dissecting scissors, and another group where the vulvar spine was left intact. Finally, to test whether the vulvar spine facilitates endophytic oviposition, females from the previous experiment (with and without vulvar spine) were placed inside glass jars with moist filter paper as artificial oviposition substrate. Each female was allowed to lay eggs for 15-20 minutes, a total of two times on different days. During oviposition, each time the female stopped laying, the timer was stopped. With these clutches we can also test whether the vulvar spine has a role as a stimulatory organ for the males (causing them to transfer more sperm or sperm-associated nutritional fluids), since in that case we would expect an increase in fertility in the case of males mated with spined females. The results of the experiments conducted did not support any of the hypotheses proposed for the existence of the vulvar spine, however, scanning electron microscopy analysis of the seminal vesicle of *E. cyathigerum* males showed a series of fold-like structures in their seminal vesicle, which were more or less pronounced depending on the degree of maturation of the male and which seem to correlate with the number of matings. Structures similar to these folds were found in other odonate species whose females have a vulvar spine, but were not observed in species whose females do not have a vulvar spine. In light folds may have evolved as a counter-adaptation to copulatory injury inflicted by females. Further research focusing on comparative morphological analyses of the size and shape of the vulvar spine and seminal vesicle folds is needed and should be correlated in case these structures evolved as a result of sexual conflict between males and females. If this hypothesis is proven, it would be the first case within this group of insects. In the last chapter, a review of the scientific literature was carried out to examine the variation in sperm translocation behaviour in the order Odonata and the evolutionary implications of this variation. In the second chapter, some of the important implications of this behaviour are already mentioned, but only one variant of this behaviour is

considered. In this chapter, information about sperm translocation in 176 species of Odonata is presented and the existence of a wide variety of sperm translocation types is highlighted. The variant of translocation performed once per mating and after tandem formation is the most common (66%), but other variants were found: sperm translocation with a previous genital touch (10%), sperm translocation performed by the male alone before tandem (16%) or after copulation (5%) and repeated translocation during the same copulation (3%). The information obtained from the literature review was used to investigate the evolution of this behaviour within the group through a comparative phylogenetic study. From this study it is possible to elucidate from which evolutionary scenarios the different variants of sperm translocation observed in odonates today originated. Thus, pre-copulation genital contact may have evolved to detect female receptivity; pre-tandem and solo male translocation may be favoured when mating opportunities are scarce and copulations are brief, while post-mating sperm translocation may be favoured in cases where males need to be ready to mate quickly. The possible origin of the characteristic mating behaviour of odonates, the so-called "copulatory wheel" and its relation to sperm translocation behaviour, is discussed. It is suggested that the most plausible scenario for the evolution of sperm translocation behaviour could be one in which odonate ancestors produced a spermatophore and attached it to the body. This would lead to the evolution of a secondary genitalia in males and thus to the formation of the "copulatory wheel". This chapter emphasises the role of behavioural diversity in understanding the evolution of both physical and behavioural traits associated with reproduction. Throughout the different chapters of this thesis, I have been able to demonstrate the importance of the study of animal behaviour and the implications of behavioural diversity or etodiversity for the conservation and study of biodiversity. It confirms the need for more integrative studies that bring together taxonomy, ecology, behaviour and molecular biology in order to establish more effective protocols to avoid species extinctions and thus contribute to the maintenance of biodiversity. I would like the general public reader, at the end of this thesis, to have realised the importance of the ecological processes occurring in our environment and how they affect us. I would also like all of us who are dedicated to basic science, evolutionary ecology and more specifically to ethology, to be aware of the potential that the study of animal behaviour has as a tool for empathising with the general public and transmitting knowledge of evolutionary ecology. In the case of the reader more closely linked to the area of research in evolutionary ecology, I would like them to begin to include the study of behaviour in their projects, in order to establish more complete conclusions, since, as has been seen throughout this thesis, the etodiversity or diversity of behaviour has a notable influence on the adaptation and evolution of species." **19240.** Sabagh, L.T.; Piccoli, G.C.; Viana, L.A.; Rocha, C.F.D. (2020): Predation and parasitism on bromeligenous

Snouted Treefrogs (*Oloolygon* spp.). *Herpetology Notes* 13: 271-279. (in English) ["Among the hypotheses as an advantage for the use of bromeliads by frogs both as refuge and breeding site, is that these plants would constitute a "safe place" and/or a "predator-free environment". Here we present some new records of antagonistic interactions involving bromeligenous Snouted Treefrog species of the genus *Oloolygon* in a coastal Brazilian Rainforest. We report records of predation on *Oloolygon* spp. tadpoles by damselfly larvae (*Leptagrion*) and by the spider *Corinna demersa*, and also predation on adults of the frog by a snake (*Bothrops jararaca*) and spiders. We also report the occurrence of parasitism of *O. perpusilla* adults by ticks (*Ornithodoros* sp.) and the register of a protozoan parasite (*Isospora cruzi*) in *O. littorea* faeces. We conclude that aside from the advantages for bromeligenous treefrogs to live in the bromeliads, living inside these plants does not result in a habitat free of predation and parasitism. Just as bromeligenous frogs evolved in association with bromeliads, so can other groups like predators and parasites. We still need consistent data on both predation and parasitism to better allow to infer to what extent bromeliads habitats are or not more or less safe for bromeligenous and/or bromeliculous amphibians." (2020): DISPERSE, a trait database to assess the dispersal potential of European aquatic macroinvertebrates. *Scientific Data* 7:386: 9 pp.- (in English) ["Dispersal is an essential process in population and community dynamics, but is difficult to measure in the field. In freshwater ecosystems, information on biological traits related to organisms' morphology, life history and behaviour provides useful dispersal proxies, but information remains scattered or unpublished for many taxa. We compiled information on multiple dispersal-related biological traits of European aquatic macroinvertebrates [including Odonata] in a unique resource, the DISPERSE database. DISPERSE includes nine dispersal-related traits subdivided into 39 trait categories for 480 taxa, including Annelida, Mollusca, Platyhelminthes, and Arthropoda such as Crustacea and Insecta, generally at the genus level. Information within DISPERSE can be used to address fundamental research questions in metapopulation ecology, metacommunity ecology, macroecology and evolutionary ecology. Information on dispersal proxies can be applied to improve predictions of ecological responses to global change, and to inform improvements to biomonitoring, conservation and management strategies. The diverse sources used in DISPERSE complement existing trait databases by providing new information on dispersal traits, most of which would not otherwise be accessible to the scientific community." **19242.** Schlemmer Brasil, L.; Luiza-Andrade, A.; Calvão, L.B.; Dias-Silva, K.; Justino Faria, A.P.; Shimano, Y.; Oliveira-Junior, J.M.B.; Cardoso, M.N.; Juen, L. (2020): Aquatic insects and their environmental predictors: a scientometric study focused on environmental monitoring in lotic environmental. *Environmental Monitoring and Assessment* volume 192, Article number: 194 (2020): (in English) ["Since early studies about aquatic ecology, it has been found that changes in environmental conditions alter aquatic insect communities. Based on this, the combined study of environmental conditions and aquatic insect communities has become an important tool to monitor and manage freshwater systems. However, there is no consensus about which environmental predictors and facets of diversity are more useful for environmental monitoring. The objective of this work was to conduct a scientometric analysis to identify the main environmental predictors and biological groups used to monitor and manage lotic freshwater systems. We conducted a scientometric study on the Web of Science platform using the following words: stream, river, aquatic insect, Ephemeroptera, Plecoptera, Trichoptera, Odonata, Heteroptera, Chironomidae, bioindicator, environmental change, anthropic, and land use. Although most of the environmental predictors employed are local, intrinsic of freshwater systems using local environmental and associated landscape variables is a better strategy to predict aquatic insect communities. The facets of diversity most used are composition and richness of species and genera, which are not efficient at measuring the loss of ecosystem services and extinction of phylogenetic lineages. Although very important, these functional and phylogenetic facets are poorly explored for this purpose. Even though tropical regions are the most diverse globally and are experiencing major losses of native vegetation, these ecosystems are the least studied, a knowledge gap that needs addressing to better understand the effect of anthropogenic activities on the diversity of aquatic insects." **19246.** Sharma, S.; Shera, P.S.; Sangha, K.S. (2020): Species composition of parasitoids and predators in two rice

agro-farming systems—effect of ecological intensification. *International Journal of Tropical Insect Science* 40: 233-238. (in English) ["Ecological intensification through organic farming is known to have an influence on plant communities and diversity of insects associated with them. The comparative abundance of natural enemies was studied in organically as well as conventionally (chemical control) grown aromatic rice at farmer's field during 2015–2016 and 2016–2017. Different life stages, i.e., egg, larvae and pupae of rice stem borer, and leaf folder, were collected and brought to the laboratory to record natural parasitism in both organic and conventional fields. The population of predators was recorded through sweep nets. The population of spiders was recorded using pitfall traps and sweep net. A total of nine parasitoid species including 3 egg parasitoids (*T. chilonis*, *T. japonicum*, and *Telenomus* sp.), 3 larval parasitoids (*Stenobracon nicevillei*, *Bracon* sp., and *Cotesia* sp.), and 3 pupal parasitoids (*Tetrastichus* sp., *Brachymeria* sp., and *Xanthopimpla* sp.) were recorded. However, the natural parasitism by these parasitoids was significantly higher in organic than conventional rice. Similarly, the population of predators like spiders, *Pantala flavescens*, and *Agriocnemis femina* was significantly higher in organic fields than in conventional fields. The study highlights the significance of conservation of these natural enemies for a sustainable system of rice insect pest management." **19248.** Shumway, N.; Gabryszuk, M.; Laurence, S. (2020): The impact of dragonfly wing deformations on aerodynamic performance during forward flight. *Bioinspiration & Biomimetics* 15(2):026005: (in English) ["Bulk wing kinematics and wing deformations of free-flying dragonflies of the species *Pachydiplax longipennis* were measured in a controlled

environment. Both upright and inverted straight flights were recorded and analyzed. The inverted dragonflies exhibited similar bulk kinematics to the upright specimens in the global frame, but wing deformations were generally consistent in the body-relative frame. The deformations primarily comprised camber during the body-relative downstroke and twist during the body-relative upstroke. Based on these data, models were developed to incorporate the measured kinematics and deformations into computational fluid dynamics simulations. Both isolated and tandem wings were simulated (rigid and deforming in each case), allowing the effects of deformations and wing-wing interactions to be examined independently. During the upstroke the addition of deformation reduced flow separation on the outboard sections of the wing, whereas the impact of the deformation during the downstroke was found to be dependent on the wing kinematics. The simulations of tandem wings indicated that they produce more force than isolated wings, but the wing deformations reduced the impact of this wing-wing interaction. The changes in average lift and thrust induced by the wing deformations were relatively minor and dependent on the flight orientation, but the aerodynamic efficiency of the deforming wings was significantly higher than that of the rigid wings for all examined cases, including the inverted flights for which the deformations were in the opposite (global) sense to the upright flights." **19249.** Siepielski, A.M.; Hasik, A.Z.; Ping, T.; Serrano, M.; Strayhorn, K.; Tye, S.P. (2020): Predators weaken prey intraspecific competition through phenotypic selection. *Ecological Letters* 23(6): 951-961. (in English) ["Predators have a key role shaping competitor dynamics in food webs. Perhaps the most obvious way this occurs is when predators reduce competitor densities. However, consumption could also generate phenotypic selection on prey that determines the strength of competition, thus coupling consumptive and trait-based effects of predators. In a mesocosm experiment simulating fish predation on damselflies [*Enallagma signatum*], we found that selection against high damselfly activity rates – a phenotype mediating predation and competition – weakened the strength of density dependence in damselfly growth rates. A field experiment corroborated this finding and showed that increasing damselfly densities in lakes with high fish densities had limited effects on damselfly growth rates but generated a precipitous growth rate decline where fish densities were lower – a pattern expected because of spatial variation in selection imposed by predation. These results suggest that accounting for both consumption and selection is necessary to determine how predators regulate prey competitive interactions." **19250.** Smith, L.A.; Lancaster, L.T. (2020): Increased duration of extreme thermal events negatively affects cold acclimation ability in a high-latitude, freshwater ectotherm (*Ischnura elegans*; Odonata: Coenagrionidae). *Eur. J. Entomol.*

117: 93-100. (in English) ["Instances of heat waves and cold snaps are becoming more frequent and of increasing duration worldwide. It is well established that short exposure to high or low-temperatures, such as during extreme weather events, often results in adaptive (acclimation/hardening) or maladaptive plastic changes in tolerance of organisms to subsequent thermal stressors. However, little information is available about how the duration of a prior stressful thermal event mediates future organismal thermal responses. Understanding durational effects of thermal conditioning can help predict ectothermic survival in response to novel extreme weather patterns. We assessed the effect of stressful temperature duration on tolerance to subsequent cold exposure in a widespread freshwater invertebrate species in Britain. Following a week-long acclimation period at 15°C, wild-caught *Ischnura elegans* larvae were held at stressful thermal extreme (2°C or 30°C) temperatures for varying durations designed to mimic a range of extreme to plausible durations of heat waves or cold snaps in the wild (30 min, 2 h, or 24 h). After a period of re-equilibration to ambient temperatures (15°C), we then experimentally assessed CT<sub>min</sub>, the temperature which renders an individual unresponsive, as an index of cold tolerance. Prior exposure to 2°C, simulating a cold snap, improved future cold tolerance, but only when individuals experienced very brief prior exposures to these conditions (30 min up to 2 h), and this benefit was lost following 24 h prior exposure. Prior exposure to 30°C, simulating a heat wave, consistently worsened the subsequent cold tolerance of individuals, with the detrimental effect of prior heat exposure increasing linearly as a function of duration. The research indicates that cold snaps can provide beneficial hardening effects against future cold exposures, but only when these (priming) extreme weather events are of very short duration (here, 30 min or 2 h). Longer durations of exposure to either extreme heat or cold weather events can reduce the ability of individuals to beneficially react to subsequent cold stresses, and may have deleterious effects on future thermal tolerance. The results suggest that increasing durations of extreme temperature events will reduce cold hardening ability of freshwater invertebrates, and that the duration of extreme weather events, or durational changes in freshwater thermal regimes resulting from changes in snowmelt dynamics, is an important parameter to consider when studying organismal responses to climate change." **19251.** Start, D. (2020): Phenotypic plasticity and community composition interactively shape trophic interactions. *Oikos* 129(8): 1163-1173. (in English) [Epitheca Anax "Trait variation defines and underpins biodiversity, yet we are only beginning to understand how processes acting across biological scales (individuals to whole communities) interact to produce trait differences and their consequences, particularly over short time scales. First, species often differ widely in their mean phenotype, meaning that changes in community composition can alter average trait values of a guild.

Second, phenotypic plasticity alters the trait values of individuals, and the net effect of plasticity can also shift the average trait values of a specific species or of whole communities. However, community assembly, phenotypic plasticity, and their effects on biological patterns are not independent. The expression of phenotypic plasticity tends to be species-specific, meaning that differences in species' relative abundances will shape trait change and resulting ecological patterns and processes. I test this idea using mesocosms and simulations of communities of dragonfly larvae that differ in activity rate. Some but not all species reduced their activity rate in response to predation risk, causing larger trait-mediated changes in trophic interactions in experimental communities dominated by plastic versus astatic species. Using surveys and simulations of natural ponds, I demonstrate that community composition will shape patterns of phenotypic plasticity, with likely consequences for ecological dynamics in the wild. The interactive effects of trait differences across scales of biological organization necessitates an integrated view of diverse biological processes, including plasticity and community assembly, in order to understand ecological interactions." **19252.** Sushko, G. (2020): Spatial variation in assemblages of Odonata (Insecta) within habitat gradients in large, pristine peat bogs in Belarus. *Biologia* 76: 575-583. (in English) ["The variation in environmental conditions in peat bogs can be expressed by odonate assemblage composition among habitats or by differences in species richness, abundance and diversity among study sites in a regional context. The adult Odonata of large, pristine peat bogs in Belarus were examined. Adult Odonata were counted along fixed transects in main peat bog habitats under favorable weather conditions. The odonate diversity showed clear differences, affected by distance to the water body, wind speed, and bog water level. The highest diversity was recorded along lakeshores. This study detected distinct odonate assemblage variations among habitats such as lagg zones, lakeshores and hollows. The large areas occupied by pine bogs and open bogs had a very similar species composition and lower diversity. On the other hand, the Shannon diversity index ( $H' = 1.433-2.295$ ) and Pielou's evenness index ( $J' = 0.468-0.507$ ) values were relatively high compared to those of terrestrial insects. The main differences among adult odonate assemblages were driven by cold-adapted, highly specialized species such as *Leucorrhinia albifrons*, *Leucorrhinia dubia*, *Sympetrum danae* and two abundant generalist species such as *Sympetrum sanguineum* and *Sympetrum vulgatum*. Peat bog specialists are among the most rapidly declining insects and, therefore, relatively intact Belarusian peat bogs are refuges for many threatened species and have considerable conservation potential." **19254.** Trudelle, L.; Witté, I.; Happe, D.; Antonetti, P.; Lemarchand, C.; Lolive, N.; Gigot, G. (2020): Priorités de conservation des espèces en Auvergne: l'apport des Listes rouges régionales. *Naturae* 2020 (1): 1-29. (in French, with English summary) ["Species conservation priorities in Auvergne: the contribution of Subnational Red Lists Using subnational Red Lists from the former Auvergne region and available occurrence data, multigroup cross-analyses were carried out to provide a synthesis of the conservation status of species of Auvergne and to illustrate the main trends as well as the main issues for local biodiversity. The results show there are a large number of threatened and near threatened species, including more than half of amphibians, bryophytes and birds. The highest proportions of unknown species concern certain vertebrates (amphibians and mammals) and flora. There is a lack of public policy framework or regulatory statutes for more than 170 species listed under the 'Data Deficient' category and for as many endangered species. There is also strong geographic variation in the distribution of declining species and species 'Data Deficient' that focus on the Allier River axis and the mountain ranges. Moreover, there is a marked endemism in the area of the Dore Mountains, the Cantal Mountains and the Mezenc Massif. In the context of regional conservation strategies and knowledge priorities, special attention should be paid to the endemic species of Auvergne currently threatened and a series of remarkable species among vascular flora. Although other factors exist, the main threats are related to the deterioration of habitats. The development of subnational Red Lists, a decision-making tool, must be maintained in order to continue monitoring and conservation of the regional biodiversity." **19256.** Tseng, H.-Y.; Chen, Y.-H.; Chen, R.-Y.; Yang, H. (2020): Reversibly erasable broadband omnidirectional antireflection coatings inspired by inclined conical structures on Blue-tailed forest hawk dragonfly wings. *ACS Appl. Mater. Interfaces* 12.9: 10883-10892. (in English) ["Blue-tailed forest hawk dragonfly (*Orthetrum triangulare*) wings, covered with inclined conical structures, are studying for their high transparency and low reflectance for large viewing angles. However, limited by existing technologies, the exquisite inclined structures are not replicated easily or applied adequately. Here, we combine a shear-induced self-assembly approach and a colloidal lithography technology to create omnidirectional antireflection structures that inspired by dragonfly wings. Non-close-packed colloid crystals are spin-coated and serve as structural templates in a plasma etching procedure to pattern subwavelength inclined conical structures directly on shape memory polymer-coated substrates. The dependence of the antireflection functionality on the shape and inclination of conical structures is systematically investigated in this research. Compared with a featureless substrate, the structure-covered substrate can display a approximately 8% higher average transmittance in the visible wavelength range at normal incidence and even approximately 23% higher average transmittance as the incident angle increases to 75°. Moreover, the reconfigurable structures composed of shape memory polymers can be repeatedly deformed and recovered as a result of external stimuli at ambient conditions, and the corresponding broadband omnidirectional antireflection functionality is therefore reversibly erased and restored." **19257.** Tüzün, N.; Stoks, R. (2020): Lower bioenergetic costs but similar immune responsiveness under a heat wave in urban compared to rural damselflies. *Evolutionary*

Applications 14(1): 24-35. (in English) ["There is mounting evidence that the widespread phenotypic changes in response to urbanization may reflect adaptations caused by rapid evolutionary processes driven by urban-related stressors. Compared to increased habitat fragmentation and pollution, adaptations towards another typical urban-related stressor, i.e. higher and longer lasting very high temperatures (heat waves), are much less studied. Notably, the sensitivities to heat waves of life history traits and important fitness-related physiological traits such as immune responsiveness and bioenergetic variables (energy availability, energy consumption, and their balance) have never been contrasted between urban and rural populations. By conducting a laboratory common-garden experiment, we compared effects of a simulated heat wave on life history (survival and growth rate), immune responsiveness, and bioenergetic variables between three urban and three rural populations of *Coenagrion puella*. Because energy-mediated trade-off patterns may only be detected under energetically costly manipulations, all larvae were immune-challenged by simulating ectoparasitism by water mites. As expected, the simulated heat wave caused negative effects on nearly all response variables. The immune responsiveness, on the other hand, increased under the heat wave, consistent with a trade-off pattern between immune function and growth, and this similarly between urban and rural populations. A key finding was that urban larvae suffered less from the simulated heat wave compared to the rural larvae in terms of a lower heat wave-induced depletion in energy availability. This suggests an adaptation of urban populations to better cope with the stronger and more frequent heat waves in cities. Notably, this urbanization-driven evolution in the bioenergetic variables was not apparent in the absence of a heat wave. Given that changes in energy budgets have strong fitness consequences, our findings suggest that the evolved higher ability to cope with heat waves is fundamental for the survival of urban damselfly populations." **19258.** Tye, S.P.; Blaske, B.K.; Siepielski, A.M. (2020): Population-level variation of digestive physiology costs of mounting an immune response in damselflies. *Ecological Entomology* 45(3): 635-643. (in English) ["1. Trade-offs are often predicted to occur between energetically costly activities, such as somatic growth and eliciting immune responses to parasites. Although parasitism frequently reduces growth via lowered consumption, it remains unclear if the energetic demands of generating immune responses also affect the digestive physiological processes necessary for growth. Moreover, as local environmental conditions affect energetic investment towards growth and immune responses, the extent of any digestive-immune response trade-offs may vary among populations and not be fixed at the species-level. 2. To test these ideas, melanisation – a general innate immune response – was first induced in damselfly larvae (*Enallagma vesperum*) from two populations. The

study then quantified growth and consumption rates, assimilation and production efficiencies, and daily metabolic rates to determine if digestive-immune response trade-offs were present and, if so, whether they differed between populations. 3. There was no evidence of any trade-offs between immune responses and digestive physiology components in either population. However, the results did show that populations differentially allocated energy towards different digestive physiology components after an immune response was elicited: one population increased their relative consumption and daily metabolic rates, while the other population had lower assimilation efficiencies and consumption rates. 4. Although researchers lack a mechanistic understanding of the observed population-level differences, these results suggest that accounting for population-level variation in digestive physiology and immune responses is critical to inferences about how immunological defences to parasitism may affect the ability for organisms to both acquire and utilise resources." **19259.** Vaikre, M.; Remm, L.; Rannap, R. (2020): Forest ditch maintenance impoverishes the fauna of aquatic invertebrates: Opportunities for mitigation. *Journal of Environmental Management* 274, 15 November 2020, 111188: 9 pp. (in English) ["Highlights: • Ditch network maintenance (DNM) regularly disturbs local communities in ditches. • One of the first studies evaluating the effect of DNM on macroinvertebrates. • Mitigation pools were constructed in conjunction with DNM. • DNM reduces habitat availability, abundance and diversity of aquatic invertebrates. • Mitigation pools add new native species but do not replace natural forest pools. Abstract: One of the main factors causing biodiversity loss in wetlands is drainage, nevertheless, even drained areas may provide habitat for aquatic fauna in the form of drainage ditches. Assemblages in ditches are regularly disturbed by ditch maintenance, but the extent of these disturbances and mitigation possibilities are poorly documented. We conducted an experimental study in three commercially managed forest plots in eastern Estonia, aiming to find out how ditch network maintenance (DNM) affects the diversity and assemblages of aquatic macroinvertebrates in ditches and remnant pools, and whether this effect can be alleviated by constructing mitigation waterbodies. For comparison we also collected data from natural pools in three undrained forest plots. Before DNM, ditches supported greater number of higher taxa compared to remnant and natural pools and more strictly aquatic taxa, whereas natural pools in undrained plots supported more Trichoptera shredders. After DNM, the diversity in remnant pools decreased. Moreover, majority of the pools dried out, which resulted in further reduction of the richness and abundance of macroinvertebrates. In ditches the diversity dropped immediately after DNM, but recovered in two to three years. Nevertheless, plot-scale richness and abundance did not completely recover. Assemblage shift in ditches took place right after DNM and remained distinct after the four year survey pe-

riod. Mitigation pools provided habitat for several taxa (especially Odonata) uncommon in other waterbodies in drained and undrained plots. Our results show that DNM in forests substantially impoverishes habitat availability and reduces the abundance and diversity of aquatic macroinvertebrates. We recommend retaining uncleaned sections in ditches and constructing mitigation pools as tools for supporting wetland biodiversity in drained forests." **19260.** Vallat, A.; Monnerat, C.; Tschanz-Godio, S.; Juillerat, L. (2020): Retablisement des communautés de libellules (Odonata) dans les tourbières du Jura neuchâtelois (Suisse). *Alpine Entomology* 4: 99-116. (in French, with English summary) ["Restoration of dragonfly communities (Odonata) in the peatlands of the Jura Mountains of Neuchâtel (Switzerland). Over the course of the 20th century, the peatlands of the valleys of La Brevine and Les Ponts-de-Martel lost over 90% of their surface area due to the industrial exploitation of peat. Restoration work undertaken between 1996 and 2018 increased the number of bodies of water in these areas from 240 to 341 and their surface area from 1.3 to 10.1 hectares. Odonates have been regularly monitored in several of these wetland areas since 2005. In 2017 and 2018, an intensive monitoring program identified 38 species. Observations made between 1938 and 2018 included a total of 52 species, or over two-thirds of Swiss Odonata fauna. Nine of these species are found on the national Red List. Species strictly associated with peatlands benefitted from restoration measures; their numbers have increased since 2005. *Leucorrhinia pectoralis* is now established in twelve peatlands out of fifteen and *L. albifrons*, one of the rarest dragonflies in Switzerland, currently reproduces in a peatland that was the subject of intensive restoration. Discoveries of *Aeshna subarctica* and *Ceriagrion tenellum* may hint at future colonization of this region by these species. Given such positive results, the canton of Neuchâtel will continue its restoration program for at least the next five years. Only the coordinated management of diverse types of wetland habitats will allow for the survival of the most demanding species." **19261.** Van Dievel, M.; Janssens, L.; Stoks, R. (2020): Effects of pesticide exposure and predation risk on nutrient cycling and primary production. *Science of The Total Environment* 705, 25 February 2020, 135880: (in English) ["Highlights: • Pesticide and predation risk are omnipresent in aquatic ecosystems. • Predation risk and chlorpyrifos additively shaped body and egesta stoichiometry. • The pesticide chlorpyrifos increased egestion of C, without an impact on algae growth. • Predation risk caused higher egestion of N, resulting in an increased algae growth. • This indicates predation risk can shape primary production via nutrient recycling. Abstract: Understanding how pesticides and natural stressors shape ecosystem functions remains

a major challenge. A largely overlooked way how stressors may affect nutrient cycling and primary production is through effects on body stoichiometry and the egestion of elements. We investigated how exposure to the pesticide chlorpyrifos and to predation risk, an abundant natural stressor in aquatic systems, altered the stoichiometry of the bodies and the egested faecal pellets of *Enallagma cyathigerum* damselfly larvae and how this further cascaded into effects on primary production (algae growth). Chlorpyrifos exposure reduced egestion rates while predation risk had no effect. Chlorpyrifos exposure and predation risk affected both elemental composition of bodies and faecal pellets, and this in an additive way. Chlorpyrifos exposure increased body C(carbon), N(nitrogen), and P(phosphorous) contents, and increased the C content of the faecal pellets. Predation risk induced an increase of the N content, resulting in a decreased C:N ratio, of both the bodies and faecal pellets. The changes in the composition of the faecal pellets caused by predation risk but not by chlorpyrifos exposure increased algae growth under control conditions. This indicated that algae growth was N limited. Our results provide an important proof-of-principle how a stressor may shape nutrient cycling and subsequently primary productivity." **19262.** Vieira da Silva, C.; Henry, R. (2020): Aquatic macroinvertebrate assemblages associated with two floating macrophyte species of contrasting root systems in a tropical wetland. *Limnology* 21: 107-118. (in English) ["Aquatic macrophytes play an important role in structuring biotic communities. A comparative study of macroinvertebrate community structures associated with *Salvinia auriculata* Aublet and *Eichhornia crassipes* (Mart.) Solms was conducted in a Brazilian wetland (São Paulo State) during two periods. Our working hypothesis is that the aquatic macrophyte with the highest root system biomass and volume (*E. crassipes*) will result in the highest abundance and richness of associated macroinvertebrates. There were significant differences in the taxa richness and density of macroinvertebrates between macrophytes and sampling periods. The density of macroinvertebrates was higher in *S. auriculata* than in *E. crassipes* during both sampling periods, but there was little difference in mean taxa richness. Negative correlations between the macrophyte root biomass and volume and macroinvertebrate density were found. Insecta, Crustacea and Annelida were the most numerous groups of invertebrates sampled during the study, and Diptera (Insecta) dominated in the root systems of both macrophytes. Macroinvertebrates associated with *E. crassipes* roots may have undergone a vertical gradient of decreased oxygen concentration in the water, as well as of the available periphyton biomass, because of the low penetration of light in the region of the root system, which resulted in a lower density of macroinvertebrates." (Authors) Taxa are treated at the order level including Odonata.] Address: Vieira da Silva, Carolina, Institute of Biosciences, São Paulo State University (UNESP), Botucatu, SP, Brazil. **19266.** White III, H.B.; Moore, M.C.; White Jr., J.F.; Cheicante, R. (2020): Conservation by minimal intervention: Odonata refuge in Idylwild Wildlife Management Area, Caroline County, Maryland. *Northeastern Naturalist* 27(1): 1-24. (in English) ["Over the past decade, 84 species of Odonata have been found in an area <0.6 km<sup>2</sup> (<0.25 mi<sup>2</sup>) within Idylwild Wildlife Management Area in Caroline County, MD. 18 of these species are species of conservation concern in both Maryland and nearby Delaware. This high level of Odonata diversity exceeds that of any other known location on the Delmarva Peninsula. We attribute this to the presence of a variety of pond, marsh, and bog habitats resulting from the unimpeded natural succession of an abandoned sand- and gravel-mining operation. This site has provided a refuge for locally rare species in a heavily agricultural region where draining of swamps and channelization of streams destroyed otherwise suitable wetland habitats for many now rare and endangered Odonata species. Deliberate planning resulted in the decision not to interfere with the ongoing natural succession in the Idylwild Wildlife Management Area, enabling colonization and persistence of Odonata species of conservation concern." (Authors)] Address: White III, H.B., Dept Chem. & Biochemistry, Univ. Delaware, Newark, DE 19716, USA. E-mail: halwhite@udel.edu.

**19267.** Zhou, Y.; Wang, X.; Zhang, S.; Yang, Z. (2020): Spatio-temporal variations of benthic macroinvertebrates and the driving environmental variables in a shallow lake. *Ecological Indicators* 110, March 2020, 105948: (in English) ["Highlights: •Spatio-temporal variation of a shallow lake benthic community was investigated. •Correlations bet-

ween environmental variables and biotic metrics were determined. •Assemblages of disturbed habitat shifted to be less diverse and more tolerant. •Lestidae and Gammaridae were sensitive indicators for water pollution in the lake. Abstract: Shallow lakes widely distributed in middle and lower reaches of watershed are easily multi-stressed by natural forces and human activities. Here, spatio-temporal variations of macroinvertebrate community and their influential variables in a typical large macrophyte-dominated shallow lake—Baiyangdian Lake were studied, using three-year in-situ observational data of spring, summer, and autumn. In total, ten environmental variables and five biological indices were measured for the six sites from each of the two habitat types, semi-natural habitat and disturbed habitat divided by their different exposures to human activities. Disturbed habitat had deeper mean water depth, lower mean transparency, and higher mean concentrations of DO, TN, NH<sub>4</sub>-N, NO<sub>3</sub>-N, and COD than that of semi-natural habitat regardless of seasons. Biological metrics indicate lower family-level richness but higher community tolerance level in disturbed habitat in spring and summer, but the results were close in autumn. The present of Lestidae and Gammaridae was a significant determination of semi-natural habitat. Redundancy analyses showed community temporal distribution was mainly driven by temperature, water depth, and pH that greatly influenced by natural forces, while spatial distribution was mainly driven by TN and transparency that greatly influenced by human activity. Regarding averaged data over the same year, season, and habitat, richness and Shannon-Weiner index had significant Pearson linear correlation with transparency ( $r = 0.521$  and  $r = 0.541$ ,  $p < 0.05$ , respectively), family biotic index significantly correlated with TP ( $r = 0.495$ ,  $p < 0.05$ ), and NO<sub>3</sub>-N ( $r = 0.592$ ,  $p < 0.01$ ), and percentage of tolerant individuals significantly correlated with pH ( $r = 0.667$ ,  $p < 0.01$ ), temperature ( $r = -0.640$ ,  $p < 0.01$ ) and NO<sub>3</sub>-N ( $r = 0.522$ ,  $p < 0.05$ ). Those variables are likely responsible for the major variations of community characteristics. High concentrations of nitrogen and phosphorus nutrients probably encourage the thriving of tolerate assemblage in the lake. Our results reveal that the macroinvertebrate community can shift to be more monotonous and pollution-tolerant under the stress of eutrophication and organic pollution. Disturbance and pollution, in general, can diminish the benefit of habitat-scale protection in certain location." **19268.** Deng, J., Assandri, G.; Chauhan, P.; Futahashi, R.; Galimberti, A.; Hansson, B.; Lancaster, L.T.; Takahashi, Y.; Svensson, E.I.; Duploux, A. (2021): Wolbachia-driven selective sweep in a range expanding insect species. *BMC Ecol Evo* (2021) 21:181: 17 pp. (in English) ["Background: Evolutionary processes can cause strong spatial genetic signatures, such as local loss of genetic diversity, or conflicting histories from mitochondrial versus nuclear markers. Invest-

igating these genetic patterns is important, as they may reveal obscured processes and players. The maternally inherited bacterium *Wolbachia* is among the most widespread symbionts in insects. *Wolbachia* typically spreads within host species by conferring direct fitness benefits, and/or by manipulating its host reproduction to favour infected over uninfected females. Under sufficient selective advantage, the mitochondrial haplotype associated with the favoured maternally-inherited symbiotic strains will spread (i.e. hitchhike), resulting in low mitochondrial genetic variation across the host species range. Method: *Ischnura elegans* has recently emerged as a model organism for genetics and genomic signatures of range expansion during climate change. Although there is accumulating data on the consequences of such expansion on the genetics of *I. elegans*, no study has screened for *Wolbachia* in the damselfly genus *Ischnura*. Here, we present the biogeographic variation in *Wolbachia* prevalence and penetrance across Europe and Japan (including samples from 17 populations), and from close relatives in the Mediterranean area (i.e. *I. genei*: Rambur, 1842; and *I. saharensis*: Aguesse, 1958). Results: Our data reveal (a) multiple *Wolbachia*-strains, (b) potential transfer of the symbiont through hybridization, (c) higher infection rates at higher latitudes, and (d) reduced mitochondrial diversity in the north-west populations, indicative of hitchhiking associated with the selective sweep of the most common strain. We found low mitochondrial haplotype diversity in the *Wolbachia*-infected north-western European populations (Sweden, Scotland, the Netherlands, Belgium, France and Italy) of *I. elegans*, and, conversely, higher mitochondrial diversity in populations with low penetrance of *Wolbachia* (Ukraine, Greece, Montenegro and Cyprus). The timing of the selective sweep associated with infected lineages was estimated between 20,000 and 44,000 years before present, which is consistent with the end of the last glacial period about 20,000 years. Conclusions: Our findings provide an example of how endosymbiont infections can shape spatial variation in their host evolutionary genetics during postglacial expansion. These results also challenge population genetic studies that do not consider the prevalence of symbionts in many insects, which we show can impact geographic patterns of mitochondrial genetic diversity." **19269.** El-Harche, H.; Chavanon, G.; Fegrouche, R.; Berady, K.; Zouaki, N.; Dahmani, J.; Fadli, M. (2021): Comparative Study of Insect Biodiversity in Cultivated and Natural Steppes in the Region of Sidi Kacem of Northwest Morocco. *Tropical Journal of Natural Product Research*: 1766-1774. (in English) ["Insects represent the most species-rich taxa of the animal kingdom. They are extremely important ecosystem components and help to perform various activities which are necessary for an ecological balance. They play a major role in maintaining the structure and function of the ecosystems. In Morocco, no scientific exploitation of resources regarding insect fauna has taken place in the agroecosystems. This study was aimed at creating the first inventory of insects collected from both cultivated and natural

steppes in the region of Sidi Kacem of Northwest Morocco. An entomological investigation was carried out in 5 stations situated on 3 different soil types in the region of Sidi Kacem. Three stations were cultivated fields, and two were natural steppes. Sampling was done during spring and summer in 2020, using sweep net, sight hunting, and pitfall traps methods. Shannon-Weaver, Simpson, and equitability indexes along with Hill indexes were calculated. Seventy-eight species were identified which were distributed into 7 orders, belonging to 29 families. The results obtained showed a richness of Coleoptera by 44 species, Hemiptera by 9 species, Diptera by 6 species, Lepidoptera, Orthoptera, and Odonata [*Ischnura graellsii*, *Sympetrum fonscolombii*, *Trithemis annulata*, *T. kirbyi*, *Crocothemis erythraea*] by 5 species each, while Hymenoptera aggregating in the final place with 4 species. Furthermore, the diversity and abundance of insects were highest in Station 3 and lowest in Station 5. Soil texture and abundance of vegetation seemed to be the major drivers influencing species abundance and richness." **19272.** Gkenas, C.; Magalhães, M.F.; Campos-Martin, N.; Ribeiro, F.; Clavero, M. (2021): Desert pumpkinseed: diet composition and breadth in a Moroccan river. *Knowl. Mag. Aquat. Ecosyst.* 2021, 422, 34: 6 pp. (in English, with French summary) ["The widely invasive North American pumpkinseed sunfish, *Lepomis gibbosus*, is currently established in desert rivers in Morocco. The success of

pumpkinseed in novel ecosystems has been associated with its generalist diet, but this trait remains unevaluated in arid regions. Desert rivers are harsh environments with limited water and prey availability which may adversely constrain the diet of fish. Here we studied the diet of pumpkinseed across 4 sites in the Draa River, embracing a 450 m elevational gradient covering from extremely dry lowlands to relatively humid highlands. We described pumpkinseed diet through the analysis of stomach contents of 82 individuals, collected in the fall of 2013. Pumpkinseed diet was dominated by Chironomidae in dry lowlands, while Ephemeroptera, Heteroptera, Trichoptera and Odonata were relevant prey in more humid highlands. Population diet breadth expanded with elevation, but individual specialization in diet was low among all sites. Our results highlight considerable changes in diet composition and breadth with aridity, suggesting that feeding plasticity and use of exclusive, locally abundant prey rather than generalized feeding may be associated with the success of pumpkinseed in most arid areas in desert rivers." **19273.** Higuera Gómez, M.; Gómez Pinzón, R. (2021): Comunidades de insectos acuáticos en el arroyo de Cabuyita, provincia de Panamá, Panamá. - Communities of aquatic insects in a stream in Cabuyita, province of Panama, Panama. *Revista Colón Ciencias, Tecnología y Negocios* 8(2): 105-113. (in Spanish, with English summary) ["Insects contribute to the conservation of ecosystems. They also have attributes who consider them as indicators of the quality of habitats. When they are in the development phase of larvae or nymph, they are shredders degrading the leaf, that favors other microorganisms, and that way collaborate with the food web. This work had the purpose to determine the dominance and spatial and temporal wealth of the community of aquatic insects associated with leaf, between January to June 2019 in the stream of Cabuyita, Tocumen county, province of Panama. Five sample stations were established, in each station 2 samples of leaf were collected one each month. The Margalef and Simpson indexes were then calculated. They collected 1645 individuals, 6 orders, 17 families and 24 genera. The most abundant orders in descending form are: Diptera, Ephemeroptera, Odonata [taxa are treated at genus level], Trichoptera, Coleoptera and Megaloptera. The most abundant subfamilies were Chironominae, Tanytopodinae, Orthoclaadiinae and Tanytarsini. The most abundant genera are *Caenis* sp, *Ischnura* sp, *Farrodes* sp, *Macrelmis* sp and *Phylloicus* sp. It concluded that the stream of Cabuyita has the appropriate conditions for the community of aquatic insects associated to leaf and there had more wealth of organisms in dry season, than in the rainy season." **19274.** Kristensson, D. (2021): Wing shape variation in a damselfly: Effects of range margins and latitude. BSc. thesis, Uppsala University, Disciplinary Domain of Science and

Technology, Biology, Biology Education Centre: 17 pp. (in English) [nv; "An optimal wing shape is necessary for the survival of winged insects since it enables different survival strategies and is expected to vary between environments due to different selection pressures. However, few studies have explored wing shape variation across the whole range of a species. In this study, geographic variation in wing shape in male *Lestes sponsa* was examined from 14 localities along a latitudinal gradient in Europe. The wings were analyzed using a comparative geometric morphometric approach, where the different shapes were digitized, statistically analyzed, and visualized on thin spline deformation grids. The results showed significant differences in wing shape in both the fore- and hindwings between locations. Wings at some localities showed a slender appearance with a narrow tip, and wings from other localities showed a broader appearance with a convex tip. A significant trend in wing shape was found from the central populations to the northern one. However, no continuous trend in wing shape was found across the latitudinal range suggesting that local abiotic or biotic factors might drive the difference observed." **19275.** Lai, Y.-H.; Lin, Y.-J.; Chang, S.-K.; Yang, J.-T. (2021): Effect of wing-wing interaction coupled with morphology and kinematic features of damselflies. *Bioinspiration & Biomimetics* 16(1) 016017: (in English) ["We investigated the effect of the wing-wing interaction, which is one key aspect of flight control, of damselflies (*Matrona cyanoptera* and *Euphaea formosa*) in forward flight that relates closely to their body morphologies and wing kinematics. We used two high-speed cameras aligned orthogonally to measure the flight motions and adopted 3D numerical simulation to analyze the flow structures and aerodynamic efficiencies. The results clarify the effects of wing-wing interactions, which are complicated combinations of biological morphology, wing kinematics and fluid dynamics. As the amplitude of the hindwing of *Matrona cyanoptera* is larger than that of *Euphaea formosa*, the effect of the wing-wing interaction is more constructive. Restricted by the body morphology of *Euphaea formosa*, the flapping range of the hindwing is below the body. With the forewing in the lead, the hindwing is farther from the forewing, which is not susceptible to the wake of the forewing, and enables superior lift and thrust. Because of the varied rotational motions, the different shed direction of the wakes of the forewings causes the optimal thrust to occur in different wing phases. Because of its biological limitations, a damselfly can use an appropriate phase to fulfill the desired flight mode. The wing-wing interaction is a compromise between lift efficiency and thrust efficiency. The results reveal that a damselfly with the forewing in the lead can have an effective aerodynamic performance in flight. As an application, in the design concept of a micro-aircraft, increasing the amplitude of the hindwing might enhance the wing-wing interaction, thus controlling the flight modes." **19277.** Lima, D.V.M.; Teixeira de Almeida, M.; Vicente, J.X. (2021): Effects of seasonality on the composition and richness of odonate larvae in urban lakes, Rio Branco (AC), Brazil. *Multidisciplinary Sciences Reports* 1(1): 1-16. (in Portuguese, with English summary) ["Odonata are insects with great ability to fly during adult, inhabiting places with the presence of water such as lakes and rivers or even small pool. During the larval stage, these organisms inhabit the aquatic environment, making up the important group of aquatic insects. The knowledge of the composition and richness of these insects is of fundamental importance for us to understand how they organize themselves in a community. The aim of this study was to analyze whether seasonality influences Odonata larvae assemblages. The work was carried out in the Piaba and Viveiro lakes of the Zoobotanic Park of the Federal University of Acre. Samples were taken in winter 2015 and summer 2016. Biological samples were identified down to the genus level. In this study we confirm the hypothesis of the influence of seasonality on the Odonata fauna and the importance of riparian vegetation for the preservation of aquatic species in urban areas." **19278.** Liu, Y.-E.; Luo, X.-J.; Liu, Y.; Zeng, Y.-H.; Mai, B.-X. (2021): Bioaccumulation of legacy and emerging organophosphorus flame retardants and plasticizers in insects during metamorphosis. *Journal of Hazardous Materials* 406(17): 8pp. (in English) [Aeshnidae "Highlights: • Different insect taxa showed different contaminant concentrations and patterns for PFRs and plasticizers. • Grasshopper larvae exhibited a greater biomagnification potential for PFRs than moth larvae. • Negative linear correlations were frequently observed between Ln(adult/larva) and log KOW. • Ecdysis was identified as an important pathway by which dragonflies remove contaminants. Abstract: Seven insect taxa belonging to five different orders were collected from a

former Chinese e-waste dumping site to investigate the occurrences of organophosphorus flame retardants (PFRs) and plasticizers. The total PFR and plasticizer concentrations were in the ranges of 2.3–91 ng/g ww (median: 20 ng/g ww) and 420–15600 ng/g ww (4040 ng/g ww), respectively. The contaminant patterns varied greatly among different insect taxa owing to their specific habitats and feeding habits. The larvae of litchi stinkbugs and grasshoppers exhibited significantly higher PFR concentrations than their adult counterparts. In contrast, the adults of butterflies, moths, and dragonflies exhibited significantly higher PFR concentrations than their larvae. Additionally, negative linear correlations were frequently observed between the ratios of PFR and plasticizer concentrations in adult to larva (A/L) and log KOW in the four studied insect taxa, which were different from those corresponding to persistent organic pollutants. Notably, the contaminant concentrations of dragonfly ecdysis were significantly higher than those of dragonfly larvae, indicating that ecdysis is an important pathway by which dragonflies remove PFRs and plasticizers." Transactions of the Illinois State Academy of Science 114: 1-5. (in English) ["Habitat enhancement projects are commonly used for augmenting fisheries in lakes and reservoirs, but a dearth of research exists regarding how habitat enhancements influence lower trophic levels. Structures used for habitat enhancement may be comprised of a range of natural and artificial materials and thus present different substrates for macroinvertebrates. We examined whether motile, grazing macroinvertebrates from the genera *Baetis*, *Ischnura*, *Pachydiplax*, and *Trichocorixa*

exhibited different selection for substrates commonly used in fisheries habitat enhancement projects. Substrates evaluated included natural pine wood with bark, polyvinyl chloride plastic (PVC; a common frame material for artificial fish cribs), and the composite plastic of a commercial fish attractor. Counts of individuals on each substrate were recorded at one-minute intervals for 30 minutes in a common garden style aquarium experiment where all substrate types were equally available. Substrate selection differed among the macroinvertebrate taxa tested. Natural wood was not selected more often than artificial substrates. *Trichocorixa* rarely selected for the wood substrate over artificial substrates. *Ischnura* selected the light colored PVC substrate most often and *Pachydiplax* selected the darker artificial composite most often. Our results suggest that selection of different substrates may be taxon specific and not heavily influenced by material composition." **19290.** Kolozsvári, I. (2016): Characterization of the dragonfly fauna of the Tisza in the section between Tiszaujálak and Huszt. PhD thesis, Debrecen: 169 pp. (in Hungarian) ["During my research, first of all I tried to collect and systematize the odonatologic, faunistic literatures referring to Transcarpathia, as well as I tried to get an overall picture of the dragonfly fauna's species composition, their occurrence and quantitative proportions in the Tisza section between Tiszaujálak and Huszt in main, side and dead channels based on the data of my larvae and exuviae collections. Besides I tried to compile a natural habitat survey field method in a form of a data sheet that can be helpful in the objective and targeted surveying of dragonfly habitat background variables.

My dragonfly larvae and exuviae field samplings were carried out at Tiszaújlak, Tiszaújhely, Tiszabökény, Nagyszolos and Huszt, altogether on 13 main, 2 side and 3 dead channel sampling sites, on 30 m long channel and riverside stretches between 2010 and 2012. According to my research results the specimen of *G. vulgatissimus* species are connected with the plant coverage of the river bank, the rate of foliage closure and the characteristics of the river bank; the specimen of *O. forcipatus* species are associated with water depth, channel deepening tendency, type of plant coverage on the river bank and water temperature; the exuviae data of *G. flavipes* and *O. cecilia* are related to the mosaic-like bottom of the channel, the intensity of water flow near the river banks, the rate of foliage closure, and the rate of plant coverage of the river bank. In the Tisza sections at Tiszaújlak, Tiszaújhely, Tiszabökény, Nagyszolos and Huszt 8 dragonfly species were identified (*G. vulgatissimus*, *G. flavipes*, *O. forcipatus*, *O. cecilia*, *S. metallica*, *C. splendens*, *P. pennipes*, *S. fusca*). In the sections of the main, side and dead channels of the Tisza at Tiszaújlak, Tiszaújhely, Tiszabökény, Nagyszolos and Huszt I found significant differences between the quantity and composition of the dragonfly fauna. The results of the statistical data processing based on the dragonfly assemblages showed clear characteristic signs between the main, side and dead channel habitat types. The dragonfly species composition data from the dead channels at Tiszaújlak and Nagyszolos are different from the similar data of the main and side channels. In case of the dead channels, contrary to the main and side channels' Anisoptera dominance, the larval data marked the presence of particular Zygoptera. In the main and side channel sections mostly the typical flowing water species appeared while in the dead channels the proportion of those species were prominent too, which are typical in slow-flowing water and in standing water." **19291.** Martina, S.; Höttinger, H. (2016): Die Libellen (Insecta: Odonata) eines Serpentinit-Steinbruches im Südburgenland, Österreich, unter besonderer Berücksichtigung ökologischer und naturschutzfachlicher Aspekte. Beiträge zur Entomofaunistik 17: 109-125. (in German, with English summary) ["Odonata of a serpentinite-quarry in southern Burgenland, Austria, with special focus on ecology and conservation. – Today secondary habitats like quarries, gravel-, sand-, and clay-pits are important refuges for many species of plants and animals. The abandoned serpentinite-quarry Bienenhütte, near Bernstein in southern Burgenland is inhabited by a species-rich flora and fauna and therefore has a very high value for nature conservation. 27 species of Odonata (45 % of all species listed for Burgenland) have been recorded there so far. Particularly notable among these are the first records of *Leucorrhinia dubia* from Burgenland and of *L. pectoralis* from southern Burgenland, some individuals of *Sympetrum danae*, which is very scarce in Burgenland, and a population of *Coenagrion scitulum* at an unusually high altitude. Serpentinite contains high concentrations of

specific heavy-metals, especially nickel, chromium, iron and cobalt. The potential influence on the development of Odonata larvae is discussed. The importance of this quarry from a nature conservational view is presented, and suggestions for further conservation and management options are given." **19293.** Naraoka, H. (2016): Effects of weather conditions on the diurnal variation of perch height of adult *Ischnura elegans* (Vander Linden, 1820). Tombo 58: 61-66. (in Japanese, with English summary) ["The selection of perching site is important for reproduction, physiology and survival of Odonata. The author researched the diurnal change of perching height of *I. elegans*, in relation to weather conditions, which inhabits reed and sedge communities, at Obuchi-pond, in Aomori prefecture, Japan. Results showed that species perched lower in daytime, but sit higher from evening to next morning. On windy days, they generally perched lower, while on non windy days, they sit lower in the following order, rainy, cloudy to clear weather, and tend to perch lower according to higher temperature, lower humidity, and stronger sunshine. In addition, the height of perching was different between reed and sedge communities. Therefore, this species, which inhabits relatively uniform environment such as grassland, delicately changes the perching height according to time and weather condition, so that they may regulate their body temperature, prevent drying, escape from enemies and increase reproductive success." **19294.** Palatova, D.M.; Chertoprud, M.V.; Frolov, A.A. (2016): Fauna and types of soft-bottom macrozoobenthic assemblages in watercourses of mountainous regions on the eastern Black Sea coast. Inland Water Biology 9(2): 150-159. (in English) ["The species composition and communities of soft-bottom macrozoobenthos of the eastern Black Sea coast have been described based on an original collection of 132 quantitative and over 700 qualitative samples. More than 150 species and supraspecific taxa have been registered; 10 types of communities, each having a specific complex of dominants, have been singled out. Regional features of the pelophilic communities in mountainous regions on the eastern Black Sea coast and their altitude and temperature-dependent variability, as well as analogy with other Palaearctic regions, have been discussed.... The material of study involves 132 quantitative and >700

qualitative samples of pelophilic macrobenthos collected in watercourses of the eastern Black Sea region (Fig. 1) in 2003–2014. 86 quantitative samples were additionally collected in the watercourses of western Transcaucasia (including Abkhazia and West Georgia), 22 samples on the Armenian Highlands, 27 on the Anatolian Highlands, and 10 in the Talysh Mountains; single samples were collected from Crimea, as well as from republics of North Caucasus and Lowland Azerbaijan. ... 1. Odonata. Larvae of two dragonfly families on the eastern Black Sea coast are in some way connected with the soft grounds of watercourses. Gomphidae have burrowing and mainly rheophilic larvae-inhabiting pebbles, sand, and silt accumulations. We registered *Ophiogomphus cecilia* in the piedmont watercourses of the Black Sea coast of Asia Minor, *Gomphus schneiderii* in the lowland river of Adjara [Georgia] and North Turkey, *G. vulgatissimus* in piedmont rivers of Crimea, and *Onychogomphus forcipatus* in large rivers at the territory of the entire region (including highlands). Cordulegastridae are represented with five species indistinguishable based on larvae...; they inhabit the soft bottom of small brooks and forest springs. They were found throughout the region, except for Crimea." (Authors)] Address: Palatova, D.M., Moscow State Univ., Moscow, 119992 Russia. Email: ametropus@gmail.com

**19295.** Raab, B. (2016): Kieseintrag verbessert Paarungs- und Larvalhabitate der Grünen Keiljungfer. ANLiegen Natur 38(1): 49-58. (in German, with English summary) ["Gravel Improves Mating and Larval Habitats of the Green Club-tailed Dragonfly: The LIFE+-Project "Optimization of flowing waters in Middle Franconia for the Green Gomphid (*Ophiogomphus cecilia*)" was conducted by the Bavarian Society for the Protection of Birds (LBV) from 2010 to 2014. The project area is located in Bavaria, in the Central Franconian Basin. By dumping gravel into river beds hydromorphological processes should be initiated in order to increase the diversity of flow rates and bed structures, both important habitat prerequisites for *O. cecilia*. For this purpose an average of 70 tons of fine gravel were introduced at 14 river sections. More than 500 tons of gravel were introduced at a site at the river Rednitz. The gravel originated from nearby quarries and sand pits, to ensure geological autochthony. The introduction of gravel had varying effects: gradual drifting of gravel structures down the river, increased formation of rills and ridges and a high diversity of flow rates. At smaller rivers like the Aurach and Zenn, the gravel covered the whole cross section on a long stretch. At bigger rivers, for example at the Rednitz, this is only possible with enormous amounts of gravel. At sections with low flow rates (up to 0,75 m/s) the gravel remains in the river bed and reduces the flow rates even more. The gap system in the gravel body is clogged quickly by fine sediments. Therefore, gravel dumpings are recommended only for narrow river sections with high flow rates. The water depth should range between 20 and 50 cm. A success monitoring of the treatments could not be conducted so far. The monitoring results will be published in ANLiegen Natur as soon as they are available." **19296.** Rabitsch, W.; Genovesi, P.; Scalera, R.; Biala, K.; Josefsson, M.; Essl, F. (2016): Developing and testing alien species indicators for Europe. Journal for Nature Conservation 29: 89-96. (in English) ["Alien species indicators provide vital information to the biodiversity policy sector on the status-quo and trends of biological invasions and on the efficacy of response measures. Applicable at different geographical scales and organizational levels, alien species indicators struggle with data availability and quality. Based on policy needs and previous work on the global scale, we here present a set of six alien species indicators for Europe, which capture complementary facets of biological invasions in Europe: (a) an combined index of invasion trends, (b) an indicator on pathways of invasions, (c) the Red List Index of Invasive Alien Species (IAS), (d) an indicator of IAS impacts on ecosystem services, (e) trends in incidence of livestock diseases and (f) an indicator on costs for alien species management and research. Each of these indicators has its particular strengths and shortcomings, but combined they allow for a nuanced understanding of the status and trends of biological invasions in Europe. We found that the scale and impact of biological invasions are steadily increasing across all impact indicators, although societal response in recent years has increased. The Red List Index is fit-for-purpose and demonstrates that overall extinction risks (here shown for amphibians in Europe) are increasing. Introduction pathway dynamics have changed, with some pathways decreasing in relevance (e.g., biological control agents) and others increasing (e.g., horticultural trade) providing a leverage for targeted policy and stakeholder response. The IAS indicators presented here for the first time on a continental basis serve as a starting point for future improvements, and as a basis for monitoring the efficacy of the recent EU legislation of IAS. This will need a better work-flow for data collection and management. To achieve this, all main actors must work toward improving the interoperability among existing databases and between data holders." **19299.** Takeuchi, T.; Yabuta, S.; Tsubaki, Y. (2016): The erroneous courtship hypothesis: do insects really engage in aerial wars of attrition? *Biological Journal of the Linnean Society* 118(4): 970-981. (in English) ["Males of various flying insects perform conspicuous aerial interactions around their mating stations. The broadly accepted interpretation of their aerial interaction is a war of attrition, where two contestants perform costly displays, and the one that reaches its cost threshold earlier gives up. The implicit but important requirement in this model is that some forces that match the intensity of display of the two contestants are necessary, and failure to enforce matching allows foul contestants that delay or stop their display to avoid paying contest costs. In addition, wars of attrition require flying insects to distinguish the sex of flying conspecifics because their aerial interactions begin when intruders fly into the territory. We investigated past research on the behaviour of odonates and butterflies aiming to clarify whether the two prerequisites of wars of attrition are fulfilled: (1) contestants can inflict substantial costs on nondisplaying opponents and (2) contestants can discriminate the sex of flying conspecifics. In odonates, we found an abundance of evidence suggesting that contests involve physical attack and that the ability of sexual discrimination is sufficient. Therefore, wars of attrition may occur in territorial odonates. In butterflies, however, we could not find any evidence that the two prerequisites are filled. The aerial interactions of butterflies are better interpreted as courtship between sexually active males (the erroneous courtship hypothesis). Based on these results, we discuss future directions of research on the aerial contests of flying insects." **19300.** Vannier, J.; Schoenemann, B.; Gillot, T.; Charbonnier, S.; Clarkson, E. (2016): Exceptional preservation of eye structure in arthropod visual predators from the Middle Jurassic. *Nature Communications* 7, Article number: 10320 9 pp. (in English) ["Vision has revolutionized the way animals explore their environment and interact with each other and rapidly became a major driving force in animal evolution. However, direct evidence of how ancient animals could perceive their environment is extremely difficult to obtain because internal eye structures are almost never fossilized. Here, we reconstruct with unprecedented resolution the three-dimensional structure of the huge compound eye of a 160-million-year-old thylacocephalan arthropod from the La Voulte exceptional fossil biota in SE France. This arthropod had about 18,000 lenses on each eye, which is a record among extinct and extant arthropods and is surpassed only by modern dragonflies. Combined information about its eyes,

internal organs and gut contents obtained by X-ray microtomography lead to the conclusion that this thylacocephalan arthropod was a visual hunter probably adapted to illuminated environments, thus contradicting the hypothesis that La Voulte was a deep-water environment." **19302.** Yoshino, Y. (2016): Notes on measurement of flight speed or large size dragonfly (Aeshnidae etc.). *Tombo* 58: 53-60. (in Japanese, with English summary) ["In 2014 and 2015, concerning to 16 species of Aeshnidae, Gomphidae, Cordulegastriidae, Corduliidae & Macromiidae, the flight speeds were measured by continuous shooting (1/7 second interval) using digital camera. The highest of flight speeds measured was 7.6 m/s (27 km/h) for *Anaciaeschna martini* S in crepuscular flight. On the other hand, from the calculated top speed 7.2 m/s already reported for *Anax parthenope julius* male, the same for *Anaciaeschna martini* male was estimated as 7.5 ~ 8.2 m/s, by using equations derived from the definition of the drag coefficient in aeronautical engineering. And under windless, uniform motion and horizontal flight condition, it seems that the top flight speed of *Anaciaeschna martini* male, based on the available power to flight muscles, may be less than 10 m/s, although the top flight speed will be achieved for only the very limited and very short opportunity and it will be extremely difficult to be measured. This reported measurement method of the flight speed, using commercial digital cameras, is comparatively easy for the amateurs, because of the low cost of the measurement equipment." **19303.** Bagheri, Z.M.; Wiederman, S.D.; Cazzolato, B.S.; Grainger, S.; O'Carroll, D.C. (2017): Performance of an insect-inspired target tracker in natural conditions. *Bioinspiration & Biomimetics* 12(2):025006. (in English) ["Robust and efficient target-tracking algorithms embedded on moving platforms, are a requirement for many computer vision and robotic applications. However, deployment of a real-time system is challenging, even with the computational power of modern hardware. As inspiration, we look to biological lightweight solutions-lightweight and low-powered flying insects.

For example, dragonflies pursue prey and mates within cluttered, natural environments, deftly selecting their target amidst swarms. In our laboratory, we study the physiology and morphology of dragonfly 'small target motion detector' neurons likely to underlie this pursuit behaviour. Here we describe our insect-inspired tracking model derived from these data and compare its efficacy and efficiency with state-of-the-art engineering models. For model inputs, we use both publicly available video sequences, as well as our own task-specific dataset (small targets embedded within natural scenes). In the context of the tracking problem, we describe differences in object statistics within the video sequences. For the general dataset, our model often locks on to small components of larger objects, tracking these moving features. When input imagery includes small moving targets, for which our highly nonlinear filtering is matched, the robustness outperforms state-of-the-art trackers. In all scenarios, our insect-inspired tracker runs at least twice the speed of the comparison algorithms." **19304.** Buczynski, P.; Buczynska, E.; Kowalak, E.; Matuszak-Krupa, J.; Plaska, W.; Stryjecki, R. (2017): Dragonflies (Odonata) of the Poleski National Park and its buffer zone: data from the years 2004 – 2016. *Parki nar. Rez. Przyr.* 36(1): 59-86. (in Polish, with English summary) ["The paper sums up the data collected in Poleski National Park during different study projects in the years 2004 . 2016. Forty five sites were examined: 34 in the park and 11 in its buffer zone. Fifty five dragonfly species were recorded: 53 in the park and 39 in its buffer zone. There are 15 special care species. High or extremely high densities of territorial males of *Leucorrhinia pectoralis* were recorded in some sites (38, 50, 61, and 105 ♂♂ 100 m<sup>-1</sup>). The occurrence of particular species, habitat spectrum of ecological elements and valuable odonate assemblages, which are especially formed in lakes, fish ponds and fens and Sphagnum bogs, have been discussed. Considering earlier studies, 59 species of dragonflies have been recorded so far in the study area, which is 80% of the national fauna. This confirms the role of the Poleski National Park and its buffer zone in the protection of species richness of dragonflies and maintaining populations of many stenotopic species. In this area, a very large role is played by the traditional methods of land use and secondary, i.e. anthropogenic habitats. The most significant are fish ponds and fen/peat bog excavations. However, according to the authors, the approach of the park services to these water bodies is too passive. Especially peat excavations on Sphagnum bogs require active conservation, i.e. interference in the succession and deforestation of their marginal zones. Digging new excavations should also be considered, especially on peatlands free of natural water bodies. In comparison to earlier data the following species have not been found: *Ischnura pumilio*, *Coenagrion armatum*, *Gomphus vulgatissimus* and *Ophiogomphus cecilia*. Most of them occur ephemerally in the study area due to lack of suitable habitats, but *C. armatum* had been known from the

five sites and at least at two of them the populations were large and stable. Both sites were investigated after 2004 but the species was absent. This may result in the first case from the changes in vegetation, and, in the second case from the drying out of the habitats. However, it is quite difficult to detect the species and hence it is very likely still occurs in the study area. We need a special research focused on the problem of its occurrence. The species new for the study area are as follows: *Crocothemis erythraea*, *Sympetrum meridionale* and *S. pedemontanum*. This shows that the Poleski National Park is being covered by the ranges of growing number of thermophilous species recently. In the following years, we can expect the increase in the number of such species. However, *S. pedemontanum* can create small, probably ephemeral populations in some regulated rivers and canals in the study area." **19306.** Fletcher, D.E.; Lindell, A.H.; Stillings, G.K.; Blas, S.A.; McArthur, J.V. (2017): Trace element accumulation in lotic dragonfly nymphs: Genus matters. *PLoS ONE* 12(2): e0172016: 27 pp. (in English) ["Constituents of coal combustion waste (CCW) expose aquatic organisms to complex mixtures of potentially toxic metals and metalloids. Multi-element trace element analyses were used to distinguish patterns of accumulation among 8 genera of dragonfly nymphs collected from two sites on a CCW contaminated coastal plain stream. Dragonfly nymphs are exceptional for comparing trace element accumulation in syntopic macro-invertebrates that are all predators within the same order (Odonata) and suborder (Anisoptera), but differ vastly in habitat use and body form. Sixteen trace element (Be, V, Cr, Ni, Cu, Zn, As, Se, Sr, Cd, Sb, Cs, Ba, Hg, Tl, and Pb) were analyzed and trophic position and basal carbon sources assessed with stable isotope analyses (C and N). Trophic positions varied within relatively narrow ranges. Size did not appear to influence trophic position. Trophic position rarely influenced trace element accumulation within genera and did not consistently correlate with accumulation among genera. Patterns between  $\delta^{13}C$  and trace element accumulation were generally driven by differences between sites. An increase in trace element accumulation was associated with a divergence of carbon sources between sites in two genera. Higher trace element concentrations tended to accumulate in nymphs from the upstream site, closer to contaminant sources. Influences of factors such as body form

and habitat use appeared more influential on trace element accumulation than phylogeny for several elements (Ni, Ba, Sr, V, Be, Cd, and Cr) as higher concentrations accumulated in sprawler and the climber-sprawler genera, irrespective of family. In contrast, As and Se accumulated variably higher in burrowers, but accumulation in sprawlers differed between sites. Greater variation between genera than within genera suggests genus as an acceptable unit of comparison in dragonfly nymphs. Overall, taxonomic differences in trace element accumulation can be substantial, often exceeding variation between sites. Our results underscore the element and taxa specific nature of trace element accumulation, but we provide evidence of accumulation of some trace elements differing among dragonflies that differ in body form and utilize different sub-habitats within a stream reach." (Authors) Dromogomphus, Stylurus, Gomphus, Progomphus, Hagenius, Macromia, Epithea, Boyeria] Address: Fletcher, D.E., Savannah River Ecology Lab., Univ. of Georgia, Aiken, South Carolina, USA. **19307.** Fukasawa, K.; Mishima, Y.; Sasaki, K.; Kadoya, T. (2017): Ecological dissimilarity among land-use/land-cover types improves a heterogeneity index for predicting biodiversity in agricultural landscapes. *Ambio* 46(8): 894-906. (in English) ["Land-use/land-cover heterogeneity is among the most important factors influencing biodiversity in agricultural landscapes and is the key to the conservation of multi-habitat dwellers that use both terrestrial and aquatic habitats. Heterogeneity indices based on land-use/land-cover maps typically do not integrate ecological dissimilarity between land-use/land-cover types. Here, we applied the concept of functional diversity to an existing land-use/land-cover diversity index (Satoyama index) to incorporate ecological dissimilarity and proposed a new index called the dissimilarity-based Satoyama index (DSI). Using Japan as a case study, we calculated the DSI for three land-use/land-cover maps with different spatial resolutions and derived similarity information from normalized difference vegetation index values. The DSI showed better performance in the prediction of Japanese damselfly species richness than that of the existing index, and a higher correlation between the index and species richness was obtained for higher resolution maps. Thus, our approach to improve the land-use/land-cover diversity index holds promise for future development and can be effective for conservation and monitoring efforts." (Authors)] Address: Fukasawa, K., Fukushima Branch, National Institute for Environmental Studies, Mihamu, Japan

**19308.** Hacet, N. (2017): Updated checklist of Odonata fauna in the Turkish Thrace Region, with additional records of new, rare, and threatened taxa. *Turkish Journal of Zoology* 41: 33-42. ["A new record for the Odonata from Turkish Thrace, *Lindenia tetraphylla*, and its heterofamilial heterosexual tandem with a female of *Orthetrum albistylum* are reported. This finding increases the species number in the region to 56. The current species list of the region based on unpublished records and available literature is presented. Five species are listed at subspecies levels in the region

and the controversial subspecies status of some species is summarized. Additional records of rare species based on specimens collected in the region between 2001 and 2015 are provided and their distributions and threat statuses in the European regional assessment are considered. *Soma-tochlora flavomaculata* is considered as a species whose presence in the region needs to be confirmed. The presence of *Gomphus schneiderii* is unclear in the region." (Author)] Address: Hacet, Nurten, Dept Biol., Fac. Science, Trakya Univ., Edirne, Turkey. E-mail: nhacet@hotmail.com

**19310.** Sivasankaran, P.N.; Ward, T.A.; Salami, E.; Viyapuri, R.; Fearday, C.F.; Johan, M.R. (2017): An experimental study of the elastic properties of dragonfly-like flapping wings for use in Biomimetic Micro Air Vehicles (BMAV). *Chinese Journal of Aeronautics* 30(2): 726-737. (in English) ["This article studies the elastic properties of several Biomimetic Micro Air Vehicle (BMAV) wing structural designs that are based on a dragonfly wing. BMAVs are a new class of unmanned micro-sized air vehicles that mimic the flapping wing motion of flying biological organisms (e.g. insects, birds, or bats). Three structurally identical wings were fabricated using different materials: acrylonitrile butadiene styrene (ABS), polylactic acid (PLA) and acrylic. Simplified wing frame structures were fabricated from these materials and then a nanocomposite film was adhered to them which mimics the membrane of an actual dragonfly. These wings were then attached to an electromagnetic actuator and passively flapped at frequencies of 10–250 Hz. A three dimensional high frame rate imaging system was used to capture the flapping motion of these wings at a resolution of 320 × 240 pixels and 35,000 frames per second. The maximum bending angle, maximum wing tip deflection, maximum wing tip twist angle and wing tip twist speed of each wing were measured and compared to each other and an actual

dragonfly wing. The results show that the ABS wing has considerable flexibility in the chordwise direction, whereas the PLA and acrylic wings show better conformity to an actual dragonfly wing in the spanwise direction. Past studies have shown that the aerodynamic performance of a BMAV flapping wing is enhanced if its chordwise flexibility is increased and its spanwise flexibility is reduced. Therefore, the ABS wing (fabricated using a 3D printer) showed the most promising results for future applications." **19312.** Dolný, A.; Šigutová, H.; Ožana, S.; Choleva, L. (2018): How difficult is it to reintroduce a dragonfly? Fifteen years monitoring *Leucorrhinia dubia* at the receiving site. Biological Conservation 218: 110-117. (in English) ["Highlights: •Population reintroductions are potential effective tools for wildlife conservation. •*L. dubia* larvae were translocated to artificially created bog pools. •The population was monitored for 15 years after larvae release. •Population size increased over the monitoring period with high genetic variability. •Reintroductions are effective measures for dragonfly conservation. Abstract: Conservation translocations (including reintroductions) are potentially powerful tools for wildlife conservation, and their use has increased worldwide. However, most studies have focused on vertebrates, with the long-term impact and ecological progress of translocations being neglected. Moreover, such projects rarely target insects. The present study reports the long-term persistence of a population of *L. dubia* reintroduced to artificially created bog pools in the Czech Republic. Eighty (pen)ultimate instar *L. dubia* larvae were translocated in 2001, and the dragonfly assemblage at the reintroduction site was monitored for 15 years following larvae release. In 2015–2017, the capture-mark-recapture method, the Jolly-Seber model, and exuviae collection were used to evaluate the demography of the translocated population. Microsatellite analysis was performed to assess the genetic variability of source and reintroduced populations. Over the monitored period, population size increased (80 larvae released vs. 108–115 exuviae and 75 adults at the end of the study) and *L. dubia* became a dominant species, whereas the composition and

abundance of the local dragonfly assemblage were not substantially changed. These results indicate that reintroductions are effective measures for dragonfly conservation, as translocating a relatively small number of individuals led to the establishment of a self-sustaining population. Using (pen)ultimate instar larvae was optimal for dragonfly translocation, but the availability of a high-quality habitat and the active collaboration with nature conservation authorities were vital for the successful outcome. Genetic analysis suggested that the translocated population might serve as a source of genetic variation for the original population, if depleted." **19315.** Ren, H.; Cui, N.; Tang, Q.; Tong, Y.; Zhao, X.; Liu, Y. (2018): High-performance, ultrathin, ultraflexible organic thin-film transistor array via solution process. Small 14(33), August 16, 2018, 1801020: (in English) ["Ultrathin organic thin-film transistors (OTFTs) have received extensive attention due to their outstanding advantages, such as extreme flexibility, good conformability, ultralight weight, and compatibility with low-cost and large-area solution-processed techniques. However, compared with the rigid substrates, it still remains a challenge to fabricate high-performance ultrathin OTFTs. In this study, a high-performance ultrathin 2,7-dioctyl[1]benzothieno[3,2-b][1]benzothiophene (C8-BTBT) OTFT array is demonstrated via a simple spin-coating method, with mobility as high as  $11 \text{ cm}^2 \text{ V}^{-1} \text{ s}^{-1}$  (average mobility:  $7.22 \text{ cm}^2 \text{ V}^{-1} \text{ s}^{-1}$ ), on/off current ratio of over  $10^6$ , switching current of  $>1 \text{ mA}$ , and

a good yield ratio as high as 100%. The ultrathin thickness at  $\approx 380$  nm and the ultralight weight at  $\approx 0.89$  g m<sup>-2</sup> enable the free-standing OTFTs to imperceptibly adhere onto human skin, and even a damselfly wing without affecting its flying. More importantly, the OTFTs show good electrical characteristics and mechanical stability when conformed onto the curved surfaces and even folded in a book after 100 folding cycles. These results illustrate the broad application potential of this simply fabricated ultrathin OTFT in next-generation electronics such as foldable displays and wearable devices.. ## 2019

- 19316.** Aziz, M.A.A.A.; Mohamed, M. (2019): Annotated checklist of odonates (Insecta: Odonata) in Sungai Bantang Recreational Forest, Bekok, Johor, Malaysia. IOP Conf. Series: Earth and Environmental Science 269 (2019) 012002: 15 pp. ["A total of 34 species of odonates, including 17 species of dragonflies (Anisoptera) belonging to 2 families, and 15 species of damselflies (Zygoptera) belonging to 8 families were collected and recorded from Hutan Lipur Sungai Bantang in January, May and July 2017. From Anisoptera, Libellulidae is the most dominant family with 15 species and from Zygoptera, the richest family were Chlorocyphidae, Euphaeidae and Platycnemididae, each with three species respectively. A detailed list of odonates recorded from Hutan Lipur Sungai Bantang is presented. The result forms a baseline data of odonate fauna in this forest reserve useful in the monitoring of water quality of rivers found in the forest reserves in the future." - 19317.** Bakker, W.; Ruiters, E.J.; Bunschoek, M.; Bakker, W.; Milder-Mulderij, G.; Achterkamp, B. (2019): Dark Whiteface (*Leucorrhinia albifrons*) discovered in 2016 at Delden. *Brachytron* 20(2): 63-70. (in Dutch, with English summary) ["In 2016 *Leucorrhinia albifrons* was discovered at the Twickel estate near Delden, Overijssel, the Netherlands. During the year 2017, a systematic search in a wider area resulted in observations of at least six males and one female. In 2018 a single male was found. Because the species has been seen at this location during three consecutive years, it is very likely that a population has been present for a longer period of time. Indications of reproduction of *L. albifrons* were however not observed. In the summer of 2018 *L. albifrons* was also observed at other locations in the Netherlands, at several sites multiple individuals were seen." (Authors)] Address: Bakker, W.: spitskip@gmail.com
