**21562.** Hsu, C.-B.; Yang, P.-S. (2005): Examining the relationship between aquatic insect assemblages and water variables by ordination techniques. *Formosan Entomol.* 25: 67-85. (in English, with Chinese summary) ["Aquatic insects were sampled quarterly at five sites along the upper Keelung River, which runs through the Taipei metropolitan area and receives various forms of pollution and anthropogenic disturbances, between August 1996 and April 1997 to examine the distribution patterns of aquatic insects and their relationships with the water variables using univariate and multivariate analyses. Upstream sites 1 to 3 significantly differed from the downstream sites 4 and 5 in the number of taxa, density, Shannon diversity index, and the proportion of dominant taxon in the univariate analyses. *Baetis* spp. was the dominant taxon (14.22%) and Chironomidae was the dominant family (21.78%) in the entire study reach. The results of canonical correspondence analysis (CCA), a eigenanalysis-based ordination, were compared with the results of non-metric multidimensional scaling (MDS), a distance-based ordination. Differences in aquatic insect assemblages at the first three sites were only found by the multivariate approaches, not by the univariate approach. High number of taxa and abundances at the three upstream sites contributing to variances in the aquatic insect assemblages were perceived on the CCA ordination diagrams. However, the common taxa at the three sites also increased the community similarities and formed an upstream group of samples separate from the downstream group in the MDS plots. Differences in the results between the univariate and multivariate analyses at the three upstream sites were mainly caused by the limited distributions of some taxa, such as *Epeorus erratus*, *Amphinemura* sp., *Protonemura* sp., and *Rhyacophila* spp. at site 1. In the CCA, conductivity and biochemical oxygen demand (BOD) on axis 1 and water temperature and pH on axis 2 were the water variables that best explained about 42.9% of the variance in aquatic insect assemblages on the first two axes. In the MDS, chemical oxygen demand (COD) and BOD showed the highest correlation with aquatic insect assemblages in the upper Keelung River." (Authors) *Euphaea formosa*, *Matrona basilaris* subsp. *maba*, *Heliogomphus retroflexus*, *Onychogomphus formosanus*, *Sieboldius deflexus*, *Stylogomphus shirozui*, *Zygonyx takasago*.] Address: Yang, P.-S., Dept of Entomology, National Taiwan University, 1 Roosevelt Rd., Sec. 4, Taipei 106, Taiwan. **21564.** Truchon, G. (2007): Des demoiselles qui pratiquent la plongée. *Nouv'Ailes* 17(1): 13. (in French) [Verbatim/Google translate: Ladies who practice diving: The female of some Zygoptera (*Calopteryx*, *Coenagrion*, *Enallagma* and *Hetaerina*) lays her eggs by submerging herself completely under water. The number of eggs deposited is proportional to the immersion time and the females can dive several times a day in different places. Japanese researchers wanted to check whether these repeated dives were associated with a limited ability to breathe underwater. A series of experiments in the laboratory and in the field allowed them to demonstrate that these small dragonflies use a reserve of oxygen contained in the trachea which gives them an autonomy of about 30 minutes. To this reserve is added the air trapped on the surface of the wings and the body. Indeed, when the damselflies dive under water, a thin film of air covers the wings and the body. This reserve of air provides part of the oxygen required during immersion. Tsubaki et al. (2006) observed under the microscope the surface of the wings of different species of damselflies. They noted the presence of a structure facilitating the retention of air. This structure, which has the appearance of "spiky hairs", is denser in insects that dive regularly, compared to those that dive occasionally or rarely, and is absent in species that do not have the habit of laying their eggs. under water. Oxygen-rich water promotes the passage of this molecule to the air bubbles trapped under the wings and body of dragonflies. This allows the insect to replenish its oxygen reserves even while remaining underwater. Added together, these different mechanisms allow young ladies to dive for periods that can exceed 120 minutes. It therefore does not seem that the numerous dives observed are associated with a limited ability of these insects to remain underwater. Spawning underwater protects the eggs from desiccation and exploits additional substrate sites. But above all, it seems that it is to have peace that these little dragonflies immerse themselves. This habit allows them to avoid being harassed by males during spawning!]) Address: not stated

**21565.** Dumont, S.; Handfield, N. (2008): Émission de timbres sur les insectes utiles. *Nouv'Ailes* 18(1): 13. (in French) [Verbatim/Google translate: On October 11, I was about to mail the paper copies of the fall issue of *Nouv'Ailes* when I noticed that Canada Post was going to issue, the next day, a series of five stamps on the theme of beneficial insects. On these stamps, we find the convergent ladybug (1¢), the golden-eyed lacewing (3¢), the polar bumblebee (5¢), the Canadian aeschne (10¢) and finally the cecropia moth (25¢). As mentioned by one of our members on our discussion forum, the choice of the cecropia lead moth seems questionable as a beneficial insect, although if we go to the site <http://www.postescanada.ca/personal/collecting/default-f.asp?stamp=stpartl&detail=2187> to read the presentation

text of the series, we can see that they define beneficial insects as being those which contribute to pest control, provide pollination, eliminate animal waste and feed the wildlife. Cecropia moth, our largest moth, is there as food for wildlife; an important link in some food chains. It is of course an extended definition of beneficial insects, but it must be admitted, it is a very beautiful species. For collectors, these stamps are available in souvenir sheets of five stamps (we had some drawn at the meeting of the Montreal section on October 12!). This souvenir sheet also appears on the beautiful first day cover. Each stamp can also be purchased in sheets of 50 via <http://www.canadapost.ca/personal/collecting/default.asp?stamp=stpartl&detail=2187> This is not the first time that Canada Post has issued stamps featuring insects. In 1988, we were treated to four stamps on the butterflies of Canada [...] Address: not stated

**21566.** Hutchinson, R. (2008): Examen du tube digestif d'une libellule. *Nouv'Ailes* 18(1): 5. (in French) [Verbatim/Google translate: Recently, I found on my work table, near my binocular magnifying glass, an adult dragonfly, *Tetragoneuria spinigera*, in alcohol. The label indicates that the specimen, damaged (separate thorax and abdomen), comes from Baie-des-Rochers (Charlevoix-Est census division), July 2003. Examining the long stocky abdomen, I noticed that a small part of the digestive tract was visible and that I could extricate it by gently pulling it out of the abdominal cavity, which I did on the spot. I then spread it out on a piece of white cardboard. I was thus able to examine the contents of a good part of the digestive tract. I saw there shreds of wings, legs, thorax of more or less shredded insects. The experience allowed me to observe that there were many Diptera, in particular of the following families: Simuliidae (black flies), Chironomidae, some mosquitoes (Culicidae) and representatives of the family Tipulidae. Determining the genus and species of all these prey is the responsibility of specialists in each group of Diptera. Nevertheless, this experiment confirms the assertions of several odonatologists to the effect that flies are the main constituents of the diet of dragonflies. For an exhaustive treatment of the subject, I invite readers to consult Corbet (1999).] Address: deceased

**21568.** Hutchinson, R.; Ménard, B. (2010): Des araignées (Araneae) dans des exuvies de libellules (Odonata: Anisoptera). *Nouv'Ailes* 20(1): 3. (in French) [Verbatim (Google translate): On October 1, 2005, we were picking dragonfly exuviae from the inside walls of a small bridge that spans a body of water. It is, in fact, only an extension of the Ottawa River, in the heart of the city of Gatineau. In addition, an earthen embankment blocks this water to prevent it from reaching the Casino de Hull. The harvested exuviae were sheltered from the wind and the flow of rainwater. An exuviae is the remains or skin from which an adult dragonfly emerged, thus ending its larval existence. We noticed that some exuviae contained live spiders. We mention below the odonate species found with the spiders that had taken up residence in their exuviae. An exuviae of *Epicordulia princeps* contained the living spider, *Steatoda bipunctata* (L.) female (Theridiidae), with two Diptera (fly) remains, an indeterminate insect larva and a molting flap of a spider. Another *Epicordulia princeps* harbored a *Tetragnatha* sp. alone, who seemed immature to us. On the other hand, in an exuviae of *Neurocordulia yamaskanensis*, we discovered another female *Steatoda bipunctata* with remains of spider molts. Finally, we highlight the presence of a spider in the exuviae of two other dragonfly species, one in the remains of *Libellula luctuosa* and another in that of *Tetragoneuria cynosura*. Unfortunately for us or fortunately for the two coveted spiders, we dropped them on the grassy ground without being able to recover them. When handling these exuviae, it would be wise to place an insect net underneath to avoid losing the spiders hiding there. It is interesting to note that an American odonatologist (Manolis, 2008) reports that a male jumping spider, *Sassacus vitis* (Salticidae), absent from Quebec, was found in the large exuviae of *Macromia magnifica*, a species from western Canada and the United States. In Quebec we find the species *Macromia illinoiensis* Walsh (Macromiidae). We must remember that these exuviae were probably in these places since June or July, since they are odonates that emerge during the first half of the summer flight season of these splendid winged creatures, which are dragonflies. They are sheltered from the natural elements. It is possible that we can even redo this excursion in winter with the possibility of new discoveries. A question arises! Does the large size, in particular the enlargement and the rounded shape of the middle of the abdomen, of the exuviae of *E. princeps* and *Macromia*, and to a lesser extent, the size of *Neurocordulia*, favor their colonization by spiders? looking for shelter? Let us mention in passing that *Steatoda bipunctata* literally invade the exterior of human buildings almost everywhere in Quebec, thousands can be found under the shingles of a house, an experience that the first author once had when replacing old shingles. aluminum by new ones on a friend's house. In conclusion, we believe that a new avenue of research is opening up on the life of spiders and odonates. It is important to know if the size of the exuviae that clears space for a guest is a colonization factor for other organisms such as spiders. We urge naturalists to try such an experiment in order to advance our knowledge on a completely unusual subject.] Address: Menard, B., 16, rue Smith, Gatineau (Québec) J8T 3A1. Email: ménard-ben@vidéotron.ca

**21569.** Kazanci, N.; Ekingen, P.; Türkmen, G.; Ertunç, Ö.; Dügel, M.; Gültutan, Y. (2010): Assessment of ecological quality of Aksu Stream (Giresun, Turkey) in Eastern Black Sea Region by using Water Framework Directive (WFD) methods based on benthic macroinvertebrates. *Review of Hydrobiology* 3,2: 165-184. (in English, with Turkish summary) ["1. This research contains the first assessment of water quality

of Aksu Stream (Giresun, Turkey) by using benthic macroinvertebrates and physicochemical variables. 2. In July 2008 and June 2009, benthic macroinvertebrates were collected by standard D-frame net from each type of habitat of Aksu Stream's sites. Physicochemical variables were also measured for each sites. 3. Some metrics [Biological Monitoring Working Party Score (BMWP), Average Score per Taxon (ASPT), Simpson Diversity Index, Shannon-Wiener Diversity Index, Margalef Diversity Index, Ephemeroptera Plecoptera Trichoptera (EPT), Ephemeroptera Plecoptera (EP)] and functional feeding group ratio which are wanted to implement by European Union Water Framework Directive were applied to Aksu Stream with physicochemical variables for the first time. 4. These metrics were performed in order to evaluate the water quality of the stream by using ASTERICS software and to identify reference sites for Aksu Stream. The benthic macroinvertebrate communities of reference sites of Aksu Stream were also given. These reference sites and their benthic macroinvertebrate communities could be used to determine ecological quality of same types of streams in Eastern Black Sea Region. 5. Habitat quality of the Aksu Stream was high at the upstream region and was lower at the downstream region due to physical habitat degradation, urban waste waters, touristic, seasonal dwelling and agricultural activities." (Authors) The taxa list includes "Aeshnidae" and "Gomphidae".] Address: Kazanci, Nilgün, Hacettepe Üniversitesi, Fen Fakültesi, Biyoloji Bölümü, Hidrobiyoloji Anabilim Dalı, Beytepe, Ankara, Turkey. ## 2012

**21570.** Hutchinson, R. (2012): Une nouvelle mention de l'araignée rarement récoltée au Québec, *Clubiona maritima* (Araneae: Clubionidae) dans une exuvie de *Stylurus notatus* (Odonata: Gomphidae). *Nouv'Ailes* 22(2): 16. (in French) [Verbatim/Google translate: On June 16, 2012, I collected a mature male of the spider *Clubiona maritima* from an exuviae of the dragonfly *Stylurus notatus*, which was in one of my vials containing only the remains of this species of gomphid. The exuviae was picked up in Luskville, on a stone wall that forms a rampart to prevent the water of the Ottawa River from flooding the raised grounds of riverside cottages. This is the second confirmed record of *C. maritima* for Quebec. Bélanger & Hutchinson (1992) report that the species was known only from Brown Lake in Gatineau Park. These mention many habitats. As far as I am concerned, I consider the carpets of dead and yellowed grasses and sedges that litter the damp ground near bodies of water as potential microhabitats leading to the capture of other *C. maritima*. By examining the specimens of the species deposited in the CNC (Canadian National Collection of Insects, Arachnids and Nematodes), I note that there are about ten vials from American states, and especially from Ontario, especially in the Niagara Peninsula. In the distribution map of the species by Dondale and Redner (1982), the reader finds about fifteen squares indicating capture sites, almost all located around the Great Lakes, with two exceptions. Our activity, which consists in collecting odonate exuviae as an integral part of our inventories of this marvelous group of insects, allows us to observe that the presence of spiders in exuviae does not seem to be a rare phenomenon, as evidenced by our mentions in a brief communication published in NOUVAILES (Hutchinson and Ménard, 2010) and also a brief note by Manolis (2008), an American odonatologist. In this regard, I can also add recent data, namely the collection of the female *Steatoda bipunctata* spider from an exuviae of

*Epithea spinigera* stuck to the inside wall of a bridge spanning a busy street in Gatineau, Boulevard Fournier, August 12, 2012. During this excursion, I also observed twice ants taking refuge in exuviae. Perspectives: Our odonatological activities, including exuviae, allow us to advance our knowledge in two important groups of invertebrates, namely dragonflies and spiders. Once again, we note that the collection of odonate remains is of great importance and we intend to pursue this type of initiative, which will bring great discoveries to come.] Address: deceased

## 2013

**21571.** Hutchinson, R. (2013): La recherche nocturne de libellules dans leur dortoir. *Nouv'Ailes* 23(1): 14-15. (in French) [Verbatim/Google translate: When the light of day disappears, the temperature drops, the coolness sets in, where to find the myriads of dragonflies that the odonatologist observed during the day? What are they doing? All must find a substrate to live there in a comatose state, in total immobility. Their customary activity can only resume with daylight, the return of the sun and a favorable temperature. Finding these sites, or roosts, where dragonflies take refuge to spend the night, is an arduous activity that I did many years ago. I searched enthusiastically in the field, flashlight in hand, in the late evening and at dusk, to discover adult dragonflies in their nocturnal lairs. I published my meager findings (Hutchinson, 1976c). In addition, I identified known cases from the odonatological literature (Corbet, 1999; Hutchinson 1976a, b). In this regard, it is fascinating to report five observations of dragonflies of the genus *Boyeria* (Aeshnidae) found in a comatose state on buildings of three nature initiation camps that I attended. The first two were internships of the Cercles de Jeunes naturalistes and the last, the Ère de l'estuaire camp, located in Port-au-Saumon, in Charlevoix-Est, which was the "theatre" of three of these observations. On August 8, 2000, at the Marist camp, in Rawdon, young naturalists drew my attention to a female *Boyeria vinosa* suspended, motionless, from the ceiling inside a building, near the exit door, next to a twinkling light. Two years later, the young naturalists were at another camp in Chertsey, located in the Laurentians. A similar case was reported to me at the end of July 2002. Another female *Boyeria vinosa* was observed with its front legs affixed to the ceiling of an outdoor toilet near a light left on for the convenience of campers. These observations have been the subject of a short note (Hutchinson, 2001). In Port-au-Saumon, we are able to add three other observations of *Boyeria grafiana*, a species of Aeshnidae that frequents the Port-au-Saumon River, located near the Ère de l'estuaire camp. These adult Odonates have adopted parts of buildings to spend the night there. Thus, on July 31, 2009, the camp director, Denis Turcotte, spotted a male of this species hanging from the upright or the post of the Demeurance gallery, the activity leaders' building, just below a light that had remained on at the end of the evening. The next day, trainees showed me another *Boyeria grafiana*, a female, almost in the same place in the gallery, always with lights on to attract insects. Finally, a final noteworthy observation, a female *Boyeria grafiana* was clinging by the forelegs to the ceiling of a building housing showers, next to a flickering lamp, for the comfort and well-being of campers who would otherwise have had to wash in the dark. My experience in the field spanning many years, combined with bibliographic research, allow me to present three situations likely to promote the discovery of Odonata in their dormitories. I mention, in the first place, the search in the aquatic vegetation, emerged and semi-emerged from the edge of the water, to

find Zygoptera and Sympetrum (Odonata: Libellulidae), for example. The naturalist or odonatologist can then carefully examine the shrubs, either on the banks or even others a little further from the banks to discover another host of larger species. Finally, Odonata who adopt trees, including their crowns, most often remain inaccessible to the odonatologist, unless they can scrutinize the smallest recesses of the foliage of large trees.] Address: deceased

**21572.** Hutchinson, R.; Ménard, B. (2013): Nouvelles récoltes de naïades, d'exuvies et d'émergences de *Williamsonia fletcheri* Williamson (Odonata: Anisoptera: Corduliidae), près de Poltimore dans l'Outaouais québécois. *Nouv'Ailes* 23(2): 12. (in French) [Verbatim/Google translate: On May 18, 2009, we were revisiting a site very near Poltimore (45°47'N 75°42'W) in the census division of Papi-neau. It is a minerotrophic environment at one end of a lake (Ménard & Hutchinson, 1999), where the soggy ground is punctuated by small ponds containing very little water. Quite quickly, BM had the pleasure of discovering, observing and picking three emergences (two males, one female, with the exuviae) of this species of odonates rarely found in Quebec (Pilon & Lagacé, 1998) and a little throughout its range. For his part, RH was able to collect an adult male, an exuviae and three larvae. By examining all the material brought home, RH is able to add for both, an emergence, being a female (with the exuviae), another adult, an exuviae and seven larvae, for a grand total of 22 specimens. We returned on May 24, 2009 to the same site. BM brought back two exuviae and RH also two exuviae and three *Williamsonia fletcheri* larvae. Finally, another excursion, on May 21, 2011, allowed us to collect three other immature larvae, including one larva. The wing sheaths reached the end of the fourth abdominal segment in one case and the beginning of the third for the larva. Our harvests before 1999 We refer the reader to the articles by Ménard (1990, 1996) and Ménard & Hutchinson (1999), the last, quite exhaustive, detailing all our harvests before the year 2000. These harvests took place in three sites of Quebec's Outaouais, particularly in the fen, near Poltimore, in the Danford lake sector (45°57'N 76°08'W) and that of Jean-Venne lake (45°41'N 76°04'W), not to mention the great bog of Alfred, in Ontario. We mainly collected larvae, exuviae, and sometimes emergences. The aforementioned articles also mention the times when we observed adult individuals. Distribution and Abundance Pilon & Lagacé (1998) list only seven localities where this diminutive Cordulid has been found, and this only in the cold temperate zone of the province. Savard (2011) summarizes the state of the captures, these being in southwestern Quebec. On the other hand, he recently reported the capture or observations of the Black Emerald in Lac Saint-Jean and in the Quebec region. No doubt these finds will be the subject of mentions in later publications, since it is an extension of the interesting distribution area. The larva of *W. fletcheri* remained unknown until recently (Charlton & Canning 1993). Moreover, we provided, at their request, specimens and information on our harvests from the Alfred peat bog and the environment located near Lake Jean-Venne, a fact cited in their description article. It bore the name of Lac Duncan at the time, although it was mentioned, without our knowledge, under the name of Lac Jean-Venne in the Répertoire toponymique du Québec (1987). The adult of the species was described by Williamson (1923) and the genus established by Davis (1913). No doubt the species will be found elsewhere in Quebec, further north and further east. It is a question of interested odonatologists and naturalists looking for *W. fletcheri* in environments conducive to its development. Happy hunting everyone!] Address: Menard, B.,

16, rue Smith, Gatineau (Québec) J8T 3A1. Email: ménardben@vidéotron.ca

**21573.** Hutchinson, R.; Menard, B. (2013): Les larves d'*Anax junius* (Drury) (Odonata: Aeshnidae) peuvent-elles vivre dans des eaux peuplées de poissons? *Nouv'Ailes* 23(1): 6-7. (in English) [Verbatim/Google translate: On August 16, 2012, during an excursion to Parc national de Plaisance, located about 40 km east of the city of Gatineau, we collected 15 exuviae of *A. junius*, at the edge of the Ottawa River. We were walking on a long wooden plank walkway, which the English call a "boardwalk", which spans the banks of the Ottawa River in the park. We carefully unhooked, on each side of the footbridge or the passage, the exuviae which were on the stems of aquatic plants at different heights from the surface of the water. On August 18, 2012, Benoît Ménard (BM) collected three mature *Anax junius* larvae on the shores of Lac Beauchamp, located in the municipal park with the same name. The lake, fed by underground springs, does not seem to have deteriorated despite the fact that the site was first a quartz mine, which was transported by train to Montreal, then a dump and finally, a park with trails for walking, cycling and nature observation. To his great surprise, BM was happy to find that the three larvae, brought alive to his home, turned into adult *A. junius*, two males and one female. The photos accompanying this article bear witness to this. The two environments mentioned above are populated by an ichthyofauna rich in species and individuals. At Lac Beauchamp, the fishing activity is clearly visible during our visits to study the dragonflies, as we can frequently see fishermen showing off their catches. In addition, the park authorities, whom we consulted, tell us that they recently stocked the lake with 4,000 brown trout. These collections contradict data from the odonatological literature, according to which the larvae of this species of Aeshnidae only thrive or even can live in waters devoid of fish (Corbet, 1999; Dunkle, 2000). Moreover, the first author cites other sources that support this thesis. Unusual fact, it is interesting to note that Paulson (2011) does not retain this particularity of the larvae of *A. junius* which would only live in waters devoid of fish. The reader can, moreover, consult the articles of Trottier (1966) and Young (1965 and 1967) to glean useful knowledge on the life of *A. junius*. As far as we are concerned, in the past we have collected many larvae and exuviae of *A. junius* in waters where the presence or proliferation of fish is rather unlikely, for example, in ponds and ponds of sand and gravel pits. These discoveries should encourage odonatologists and naturalists to increase research to confirm or invalidate the thesis that the larvae of *A. junius* live in waters devoid of fish. [...] As a corollary activity, the odonatologist can quite easily dissect fish from environments rich in Odonata larvae to examine the stomach contents and see if there are dragonfly larvae. It could thus determine which species have been victims of predation. The digestive tract of fish is a long tubular structure that runs through a good part of the body in its length. When preparing the fish, to cut out the edible muscle filets, it is possible to isolate the digestive tract and place it on a white sheet, for example to examine its contents. I did these dissections on speckled trout, with trainees from the Ère de l'estuaire camp, in Port-au-Sauzon (Charlevoix-Est) for several years. The odonatologist, who consults Corbet (1999), discovers that research on Odonata larvae in fish-rich environments or not, can be popular with certain odonatologists and aquatic biologists, few in number, it should be noted. However, this field of research requires knowledge of both the dragonfly larvae and the fish that inhabit the waters of our regions. We encourage Quebec naturalists to continue this research on the fauna of our

vast territory.] Address: Menard, B., 16, rue Smith, Gatineau (Québec) J8T 3A1. Email: ménardben@vidéotron.ca

**21574.** Hutchinson, R.; Menard, B. (2013): Spiders collected in Odonata exuviae in the province of Quebec. *Argia* 25(1): 18. (in English) ["For over thirty years, both authors have been collecting a few odonate larvae and exuviae at each outing. About 6,000 larval and exuvial specimens have been donated to the Canadian National Collection (CNC) of insects, arachnids and nematodes of Agriculture Canada, in Ottawa. About 80 species or more are in the CNC. However, a few need to be identified to species, namely zygopterans, Aeshna specimens and some Somatochlora. Both authors have fairly large holdings of larvae and exuviae in their homes. The first author has furthermore learned to identify many common Quebec spiders to species with the help of Charles Dondale and Jim Redner, CNC arachnologists (now retired), who built the AgricultureCanada Spider Collection (about 500,000 specimens). Recently, we discovered that live spiders could be found in dragonfly exuviae. Although this behavioral trait of spiders does not appear to be very frequent, we are able to report a few cases where we have found spiders in odonate exuviae. On 1 October 2005, under a bridge with much traffic in Gatineau, we discovered exuviae containing live spiders, including a female *Steatoda bipunctata* (Theridiidae; False Widow) spider residing in a larval skin of *Epitheca princeps*. The remains of two flies and some spider silk (probably part of a molt) were observed in the dragonfly exuvia. Another *E. princeps* exuvia contained a *Tetragnatha* sp. (Tetragnathidae; Orbweaver) spider, and an exuvia of *Neurocordulia yamaskanensis* was found to harbour a *Steatoda bipunctata* female and the remains of a spider molt. We also collected exuviae of *Libellula luctuosa* and *Epitheca cynosura* with spiders but lost the spiders because they fell from the exuviae on the grassy soil at our feet. We were unable to recoup the lost spiders (Hutchinson & Menard, 2010). When the presence of a spider is suspected in a skin, it is advisable to keep an insect net underneath so that the specimen will fall into the net, instead of on the ground. On 16 June 2012 at Luskville, on the shore of the wide Ottawa River, one of many larval skins collected of *Stylurus notatus* contained a rarely found spider for the province of Quebec, *Clubiona maritima* (Leafcurling Sac Spider), only the second record for the province (Beianger & Hutchinson, 1992). Details of this capture are given in Hutchinson (2012). Manolis (2008) has also reported a male *Sassacus vitis* (Jumping Spider) in a larval skin of *Macromia pacifica*. When searching for spiders in odonate exuviae, one must isolate each species in an individual vial while observing the possible presence of silk, remains of molt or prey, etc. It remains to be discovered how frequently spiders may adopt odonate larval skins as a refuge or residence to pursue their activities. In Gatineau, the underside of the bridge where our specimens were found is protected from wind and water and many spiders can be observed walking or hiding near the Odonata skins. The same cannot be said of the extensive stone walls on the shore of the Ottawa River in Luskville. Larval skins on the underside of the Gatineau Bridge can remain there for months protected from wind and water and snow, so that spiders can in all likelihood find long-term lodgings. The skins in Luskville are often blown away by wind or washed away by trickling water." (Authors)] Address: Menard, B., 16, rue Smith, Gatineau (Québec) J8T 3A1. Email: ménardben@vidéotron.ca

**21575.** Susanto, M.A.D.; Firdhausi, N.F.; Bahri, S. (2013): Diversity and community structure of dragonflies (Odonata) in various types of habitat at Lakarsantri District, Surabaya,

Indonesia. *Journal of Tropical Biodiversity and Biotechnology* 8(2): 17 pp. (in English) ["Dragonflies are insects that are very dependent on the existence of freshwater ecosystems. However, the population of dragonflies in urban freshwater ecosystems is at risk due to a number of issues. Consequently, it is essential to carry out research and efforts to preserve dragonflies in urban areas. This study aims to provide information about the diversity and structure of dragonfly communities in various habitat types in the Lakarsantri, Surabaya. Data collection in this study was carried out in the habitat types of ponds, reservoir, river, and rice field in July to September 2021. The study results show there are 22 species from 4 families with a total of 827 individuals. Analysis of the Shannon-Wiener diversity index showed that the highest value of dragonfly diversity was found in a pond, with a value of  $H' = 2.40$ , and the location with the lowest value was a river, with a value of  $H' = 1.77$ . At four research locations that have different aquatic ecosystems, the community structure of dragonfly is also different. The composition of the dragonfly community structure at the reservoir location has similarities to a pond, and at a river location, it has similarities to a paddy field. Differences in abiotic factors consisting of light intensity, humidity, and temperature at each study location have a correlation with differences in dragonfly community structure. In addition, the composition of the vegetation at each location is also one of the factors causing differences in the structure of the dragonfly community." ## 2014

**21577.** Hutchinson, R.; Ménard, B.; Piché, C. (2014): *Perithemis tenera* (Say) (Odonata: Libellulidae) Nouveau pour la vallée de l'outaouais québécois. *Nouv'Ailes* 24(1): 15-16. (in French) [Records of *P. tenera* between 2012 and 2013 in Quebec's Outaouais Valley are documented.] Address: Ménard, B., 16, rue Smith, Gatineau (Québec) J8T 3A1, Canada. Email: ménardben@vidéotron.ca

**21578.** Hutchinson, R.; Ménard, B.; Piché, C. (2014): *Pachydiplax longipennis* (Burmeister) (Odonata: Libellulidae) dans la région de l'Outaouais. *Nouv'Ailes* 24(1): 5-7. (in French) [Verbatim/Google translate: During our odonatological excursions in the Ottawa Valley, excursions that date back to the summer season of 1987 for RH and BM, we had never encountered this species of dragonfly (Ménard 1996) which nevertheless had a vast geographical distribution in North America. North (Needham et al. 2000). The literature on our odonates does not mention the presence of this dragonfly either for the Outaouais region of Quebec (see Pilon & Lagacé 1998, Walker & Corbet 1975, Robert, 1963). The first mention

for Quebec is reported by Mochon (2012). During the summer of 2012, we observed and collected adult *Pachydiplax* at various sites in the city of Gatineau. It was in 2013, however, that we began to find larvae and exuviae of this monotypic dragonfly species. Thus, BM captured the first larva identified for Quebec on Monday, June 3, 2013, at the Touraine marsh. Touraine is a sector of the city of Gatineau (figure 1). First, we detail somewhat our harvests of the species during 2012-2013. We then present the general distribution for the North American continent. Finally, some data on the biology of this species of dragonfly will allow the reader to become aware of the interest and the importance of following the evolution of the presence, even the progressive invasion of this odonate, especially in the southwest. of the Quebec territory; more precisely in Gatineau, on the south bank of the Ottawa River facing Ottawa (Ontario). Summary of our observations: At all sites, males were present and showed a lot of aggression towards conspecifics. BM and RH saw few females. However, BM observed egg-laying and attempted egg-laying at the edge of Lac Beauchamp. The individuals observed were almost always at the edge of water bodies with abundant riparian vegetation, either floating or upright. At some sites in Gatineau Park, RH and BM were unable to collect specimens, as they did not hold a collection permit from Gatineau Park, which owns the site. Geographical distribution Literature data: According to Needham et al. (2000), the geographical distribution of *Pachydiplax* encompasses much of North America, as well as Mexico, Bermuda and the Bahamas. Walker & Corbet (1975) report the presence of the species in eastern parts of Ontario, Manitoba and British Columbia. Pilon & Lagacé (1998) and Savard (2011) do not mention the species as a component of the odonofauna of Quebec. On the other hand, Mochon (2012) makes a first mention of Quebec in one of his articles; thus, the species is a new element that enriches our odonatological heritage. In addition (Mochon (2014) observes that at the sites he has visited since 2012, particularly in Estrie and Montérégie, these are populations and not isolated individuals. Our mentions for the Outaouais are firsts for our region. Biological elements: At sites where the species is well established, the frequency of sightings and the omnipresence of individuals make them the odonates of choice for ecological and behavioral studies, as evidenced by the many books and journal articles to their subject. The Quebec naturalist and odonatologist can glean many fascinating facts from general works, such as Dunkle, 1989, 2000 and Paulson, 2011, and also from Walker & Corbet (1975). Among a few traits mentioned by these three authors, it is important to note a certain resemblance between the males of *Erythemis* and *Pachydiplax*. However, the former often land on the ground, while the *Pachydiplax* often adopt perches on the vegetation, at different heights. We can also look for individuals of the latter species, either in wooded areas or often at the edge of the water where emergent vegetation is spreading. Observers have discovered feeding sites or territories far from the shores of bodies of water. Near the water, the males perch on riparian plants, such as shrubs, and claim a portion of the shore that they defend aggressively. Tandems (male-female) are rarely observed. Copulation lasts 10 to 40 seconds, according to Paulson (2011). Males provide hover surveillance around females, which lay 300 to 700 eggs in 35 seconds (Dunkle 1989, Paulson 2011). During our observations in 2012 and 2013, we observed many males who seemed to want to take over parts of the shore with aggressive flights, and whose movements seemed to us to be somewhat erratic. For more specific and detailed research, we refer the reader to the work of Fried & May (1982), feeding and territory of males, Johnson (1962), territorial behavior and reproduction, Robey (1975), reproduction, and

Sherman (1983), post-copulatory behavior. In addition, these articles provide information on other research on *Pachydiplax*, cited in the references. Outlook In Quebec, we are only at the beginning of our observations and our research on *Pachydiplax*. We still have to verify the behavioral traits mentioned above and first follow, if necessary, the invasion of the species to determine its geographical distribution, as it settles in Quebec territory. For the Outaouais, we need to assess the importance or the permanence of the establishment of *Pachydiplax* populations elsewhere than in the city of Gatineau, for example on a perimeter of 50 km around, say up to Kazabazua, for example. As to whether the arrival of the species here in Quebec would be linked to climate change, it would perhaps be wise to wait a few years before deciding.] Address: Menard, B., 16, rue Smith, Gatineau (Québec) J8T 3A1, Canada. **21580.** Ceballos, C.P.; Zapata, D.; Alvarado, C.; Rincón, E. (2016): Morphology, diet, and population structure of the Southern White-lipped Mud Turtle *Kinosternon leucostomum* postinguinale (Testudines: Kinosternidae) in the Nus river drainage, Colombia. *Journal of Herpetology* 50(3): 374-380. (in English, with Spanish summary) ["Most existing studies on *K. leucostomum*, have been based on northern Central American populations, leaving a lack of information on populations from southern Central America and South America. Herein we studied morphology, diet, and population structure of a population of the southern *Kinosternon leucostomum* postinguinale inhabiting four creeks in Colombia. Observed habitats used were highly variable, ranging from relatively clean waters to streams used for sewage disposal of wastewater from a human settlement. Body size was smaller than that of other populations of southern *K. l. postinguinale* and also than that of the northern *K. l. leucostomum*. Sexual dimorphism was evident, with males heavier, longer, and wider than females. Body size was associated with the habitat of origin, with Barrio Nuevo individuals being the largest. The main components of the diet were plant material, insects [Odonata: n=1], snails, and algae. We did not find evidence of sexual differences in the diet, but we found geographic differences in the body size. The population with the largest individuals, from Barrio Nuevo Creek, consumed more snails while those from Totumo Creek, the population with the smallest individuals, consumed more ants and plant material as compared to the other creeks. Additionally, we found a highly male-biased sex ratio, with 2.5 adult males per female, very few juveniles, and no nests, which suggests a dangerous risk of population decline. We suggest continued monitoring of the demography of this population, emphasizing its reproductive biology." **21582.** Entomofaune du Québec (2016): Publication d'un guide sur les naïades et exuvies des libellules du Québec. *Nouv'Ailes* 26(2): 4. (in French) ["A new guide, in French, has just been published: "Naiads and exuviae of dragonflies in Quebec: key to gender determination", published by Entomofaune du Québec. The two authors, Raymond Hutchinson and Benoît Ménard, well known to members of the AEAQ, offer naturalists the labor of thirty years devoted to the observation of the underwater world of dragonflies. This 73-page practical guide opens up a vast field of knowledge. It allows the identification and study of dragonfly naiads, either before they emerge from the water, or as exuviae left by new adults. The proposed identification key makes it possible to confidently separate the 52 genera of Zygoptera and Anisoptera listed in Quebec and near its borders. In addition, the key allows the identification of 32 species. From a scientific name, the naturalist will be able to consult reference works in the natural sciences and navigate effectively on the Internet to enrich himself with the knowledge accumulated before him. In this way, he will be able to communicate his observations and discoveries with passion and accuracy. No less than 116 anatomical drawings and 15 plates of illustrations, including 79 color photos, will help the naturalist finally give a name to his exuviae or dragonfly naiad specimens. The coiled book, in 7" X 9" (18 X 23 cm) format, printed on thick, semi-gloss paper, allows intensive use in the workshop or lab. You can order this magnificent guide, for \$33 (taxes and postage included), by consulting the publisher's website: [www.entomofaune.qc.ca](http://www.entomofaune.qc.ca)" (Publisher)] Address: Entomofaune du Québec inc., 108-637 boulevard Talbot Saguenay (Chicoutimi), Québec G7H 6A4, (418) 545-5011, postes 6542 ou 5076

**21583.** Hutchinson, R.; Ménard, B.; McAllister, L.; Larochelle, M. (2016): Découverte de naïades d'*Epiaeschna heros* (Fabricius) (Odonata: Aeshnidae) à Gatineau en 2016 et émergence d'un individu dans un bac aménagé chez soi. *Nouv'Ailes* 26(2): 12-13. (in French) [Verbatim/Google translate: On August 27, 2016, the four naturalists went to the municipal park of Lac Beauchamp in order to visit a shrubby forest swamp and observe aquatic organisms, for example dragonfly naiads. Among the organisms encountered, they were surprised to catch three naiads or larvae of the largest dragonfly in Canada, *Epiaeschna heros*. Lyne, BM's spouse, caught one and BM, two. To our knowledge, this is only the second historical naiad fishery for this aeshnid in Quebec. Moreover, the species remains little captured at the adult stage in the province, of which the southwest constitutes the northern limit at present. According to Savard & Mochon (2014), the adult has been captured only once in the past 25 years, on June 24, 2013. The biotope of Parc du lac Beauchamp consists of a wooded shrubby swamp whose main plant components are red maple, winterberry, sphagnum

moss and sensitive fern. Although the free and open water column is very shallow, there seems to be enough space for the movements of such a large naiad. The bottom is usually lined with dead leaves with small trunks and branches lying here and there under the water or emerging on the surface. The middle consists of several connected ponds. These naiads play dead when fished or handled. One cannot help but observe the dark coloring of their bodies in harmony with the branches and the dead leaves in the middle. BM brought the three naiads home alive, installed them in breeding tanks to observe them, fed them and hoped to witness emergences, all for the taking of digital photos which will document this crucial aspect of their existence. In fact, on August 29, BM had the privilege of discovering the emergence of a male. Apparently, the emergence would have occurred on the ground in the entrance portico of the accommodation. BM observes that in a breeding tank (aquarium, artificial environment), these naiads of *Epiæschna* present some behavioral traits to remember. They are rather apathetic. They can also float like a twig in the water column or even land on different substrates. This is the second time in eleven years that RH and BM have discovered this species of æshnid in the wild, again at the municipal park of Lac Beauchamp, in Gatineau, but in another wooded swamp located about a kilometer from the first (Hutchinson & Ménard 2007). We had visited the first biotope nine times, from May 29 to November 5, 2005, allowing us to sample four larvae or naiads, two of which had subsequently emerged in the aquarium at BM. In addition, one molt and twenty exuviae were collected at the site. The vegetation composition of the 2005 treed swamp was somewhat different from our 2016 site where black ash dominated tree vegetation. *Hydrocharis morsus-ranae* covered much of the surface of the water. When the environment was completely dry in autumn, the water-hemlock, an umbellifer, almost dominated the swamp. Finally, let's mention *Alisma plantago-aquatica* and a few mosses that popped up here and there. Thus, some females of *Epiæschna heros*, entrusted their eggs to two different types of swamps according to their plant composition and probably their pH, the second being acidic. It is interesting to mention some habitats gleaned from the odonatological literature. Walker (1958) writes that *E. heros* haunts dark ponds and ditches as well as draining marshes. Dunkle (2000) also mentions ponds in wooded areas, but also slow-moving streams, including swamps and temporary ponds or ponds. Paulson (2011) specifies the following biotopes: swamps and slow-moving streams rather in wooded areas, where the water can be very shallow. It even evokes temporary environments where the presence of water remains seasonal. According to Savard and Mochon (2014), the odonatologist can select the following habitats: temporary ponds, shaded river marshes under a forest cover. To better understand the components of the habitat of *E. heros* at Beauchamp Park in Gatineau, we visit and sample the many pools of water to see which ones may prove favorable to the presence of this enormous Aeshnidæ. To date, we manage to distinguish at least two types of ponds or swamps to explore. First, water bodies with forest cover comprising a combination of the following elements: plants that grow in the water, trees, shrubs, herbaceous plants, mosses, with a bottom lined with dead leaves, twigs, logs, present in even a modest and shallow water column. Second, there are habitats made up mostly of dead leaves and decaying plant matter. These environments are often inhabited by recyclers of the Asellidæ and Ostracods type, crustaceans. These latter biotopes, so far, are the least likely to harbor *E. heros*. A final fascinating aspect to raise is the probability, or at least the possibility, that these larvae survive the drying up of these environments (see Arai 1984).] Address: Menard, B., 16, rue Smith, Gatineau (Québec) J8T 3A1. Email: ménardben@vidéotron.ca

Gatineau (Québec) J8T 3A1, Canada. Email: ménardben@vidéotron.ca

**21584.** Hutchinson, R.; Ménard, B. (2016): Émergences de *Neurocordulia michaeli* Brunelle (Odonata: Libellulidae: Corduliinae) dans un bac d'élevage, chez soi, l'hiver. *Nouv'Ailes* 26(1): 11. (in French) [Verbatim (Google translate): In Quebec, *Neurocordulia yamaskanensis* has been known for a long time (Provancher, 1875). This odonate is mentioned many times at different sites in the province (Pilon & Lagacé, 1998). It is one of the two species of dragonflies in the world's odonatofauna described by a Quebecer, Father Léon Provancher, the other being *Somatochlora brevicincta*, discovered and named by Brother Adrien Robert (1954). *Neurocordulia michaeli* was unknown to science until very recently (Brunelle, 2000). This species has recently become part of our entomological heritage (Charest & Savard, 2014). We have not yet found this Cordulid in the Outaouais. To familiarize ourselves with *N. michaeli*, we must therefore go to the edge of the Petawawa River, in Ontario. For example, on June 6, 2015, a trip to the Petawawa River caught a naiad (larva) of *N. michaeli* and two of *N. yamaskanensis* in torrential waters fed by the spring melt. RH and BM, the latter accompanied by his daughter Sophie and his nephew Daniel, waded into this rebellious water without the expected success. At the end of the season, on October 12, 2015, [...] Indeed, they caught 34 naiads of *Neurocordulia*, almost all of them *michaeli*, about ten larvae or mature naiads as well as 24 of medium size and this, in about an hour and a half of intense fishing. The sampling method consisted of lifting the submerged stones to pick the *Neurocordulia* larvae attached to them. These submerged stones were mostly the size of a hand and were found under water with moderate current. At home, BM fed the naiads of *Neurocordulia* mosquito larvae and pupae, small amphipods and other small aquatic organisms. Naiads of *Neurocordulia michaeli* have obviously adapted to the new "artificial" micro-environment since in December 2015, BM had the chance to witness six emergences of *N. michaeli*, i.e. three males and three females, as evidenced by the photos accompanying this article. These attempts are part of a research spread over two or three seasons of research in the field, with partial breeding at home or in the laboratory, therefore outside the natural environment. We need to improve the diet of naiads in an artificial environment and do research on whether or not these larvae diapause are obligatory in the winter period to explain their emergence in the middle of winter. These data will therefore be integrated into one or two subsequent articles to be produced which will report on our next data collected during the 2016 and possibly 2017 seasons on our two species of *Neurocordulia*.] Address: Menard, B., 16, rue Smith, Gatineau (Québec) J8T 3A1. Email: ménardben@vidéotron.ca

**21585.** Hutchinson, R.; Menard, B. (2016): Premières mentions de naïades d'*Hetaerina americana* (Fabricius) (Odonata: Zygoptera: Calopterygidae) au Québec. *Nouv'Ailes* 26(2): 10. (in French) [10 larvae of *H. americana* were caught at July 19, 2015, at the banks of the Châteauguay River, in Saint-Martine, south of Montreal. Habitat: "running water flowing over many flat stones or rocks, often with only a few centimeters of water deep. The water flows into a widening of the river with more stagnant water. It was in this section of the river that the fished naiads were found. To our knowledge, these are the first captures of naiads of this species in Quebec, undoubtedly one of the most boreal sites for this species of Zygoptera." (Authors/Google translate)] Address: Menard, B., 16, rue Smith, Gatineau (Québec) J8T 3A1, Canada. Email: ménardben@vidéotron.ca

**21586.** Hutchinson, R.; Ménard, B. (2016): Plusieurs émergences de l'espèce rarement trouvée au Québec *Stylurus amnicola* (Walsh) (Odonata: Gomphidae) dans des bacs d'élevage. *Nouv'Ailes* 26(2): 15. (in French) [Verbatim/Google translate: On June 19, 2016, BM, [...] traveled to the Petite-Nation River, at a site located approximately 4 km north of the municipality of Plaisance in the province of Quebec. They explored a sandy, muddy and muddy section at the confluence of the Saint-Sixte and Petite-Nation rivers. They caught eight larvae of *Stylurus amnicola*, which they brought back alive to Gatineau. BM installed them in breeding containers. He did not have to feed them, since they emerged without additional feeding. In fact, they are burrowing larvae and we have yet to find out if these naiads will hunt prey by burrowing and moving in the sand, or by walking on the surface of the sand. It therefore remains to be observed. He obtained seven emergences, from June 21 (for the first), to June 29 (for the last). He also caught naiads of the following odonate species: *Stylurus spiniceps* (3), exuviae of *Ophiogomphus anomalus* two larvae of *Neurocordulia yamaskanensis*. It was very difficult to get to the collection site because of the steep banks and the inaccessibility of walking paths to get to the coveted biotopes. On August 12, 2016, a BM expedition to the river Désert, in the municipality of Maniwaki, in Quebec's Outaouais, again allowed him to meet this species of gomphid, very rarely found in Quebec until very recently. [...] to catch a few additional naiads of *Stylurus amnicola*. These naiads are also being farmed in Gatineau, at BM, in the hope of obtaining emergences and use it to make other quality photographic shots, after having meticulously cleaned them with artists' brushes. *S. amnicola* has remained unknown in Quebec, except for the mention of Stöhr in 1918 in the Outaouais, on the banks of the Gatineau River. The mystery surrounding the existence of this species persisted until the early nineties. It began to dissipate thanks to the discoveries of Ménard (1996) who added the following sites: the Petite-Nation river, upstream from the falls, north of Plaisance, and the Désert river, in Maniwaki. Pilon & Lagacé (1998) add Moulin Banal Cove, near Quebec City, a site near the St. Lawrence River. Recently, an odonatologist from Lac Saint-Jean discovered a large number of exuviae on the banks of the Ashuapmushuan River, north of this immense lake (Michel Savard, personal communication). It is important to remember that even today, adult and mature individuals of this dragonfly remain almost impossible to spot in the airspace around bodies of water. The naturalist must, most of the time, rely on the collection of larvae and exuviae to document the existence of this species of odonate in nature. We must also draw attention to the fact that in 1996, larvae fishing in the Rivière Petite-Nation and the Rivière Désert was carried out approximately at the sites already listed. These are therefore not new references. Through these returns to sites already explored, BM hopes to gather additional data, particularly on the diet and behavior of naiads in captivity. He also intends to obtain many photos of living individuals taken at home, in an aquarium, after cleaning the naiads kept alive in the laboratory.] Address: Menard, B., 16, rue Smith, Gatineau (Québec) J8T 3A1, Canada. Email: ménardben@vidéotron.ca

**21587.** Menard, B.; Hutchinson, R. (2016): Pêche de 2 larvules de *Progomphus obscurus* (Odonata: Gomphidae) près de Maniwaki: une première et une deuxième mentions de l'espèce pour la province de Québec. *Nouv'Ailes* 26(2): 6-7. (in French) [Verbatim/Google translate: On August 12, 2016, BM fished an immature dragonfly naiad, a larva, at the Désert River, in Maniwaki (Mont Cerf), [...] Vast sandy beaches

stretched along the shores. At the first cast of the net, he caught a small gomphid larva with very fast movements, which was silting up at lightning speed. The unusual shape and morphological characteristics of this naiad allowed us to quickly come to the conclusion that it was a gomphid, in particular *Progomphus obscurus*. This is the first record for the province of Quebec for both this genus and species of odonate. Subsequently, about thirty additional hauls enabled BM to catch naiads of *Ophiogomphus colubrinus*, *Gomphus adelphus* and *Macromia* larvae. The people of the village define this sector of the shores as the 16th beach from the Maniwaki bridge. There would be up to 104 in the area. On August 20, 2016, BM resolved to return to the capture site of the first *Progomphus* caught on August 12. [...] The naiad was dragged from the sand among heaps of dead wood lying in the water of the river. Lyne also caught several larvae of *Stylurus amnicola* (8). The expedition brought back specimens of the following species: *Stylurus spiniceps* and scudder, as well as *Stylogomphus albistylus*. They also found *Macromia* larvae and *Ophiogomphus* naiads.] Address: Menard, B., 16, rue Smith, Gatineau (Québec) J8T 3A1, Canada. Email: ménardben@vidéotron.ca

**21588.** Sheela, S.; Subramanian, K.A.; Das, D.; Venkataraman, K. (2016): The type specimens in the National Zoological Collection ODONATA. Type Catalogue Series, 3: 1-36. **21589.** Turgeon, R. (2016): Découverte du Gomphe ventru en Beauce une libellule menacée de disparition au Canada. *Nouv'Ailes* 26(1): 5. (in French) [Verbatim/Google translate: At the end of June 2015, on Saint John's Day, I walked through a forest clearing crossed by a small mountain stream in the hope of tracking down a *Somatochlora tenebrosa*. This dragonfly, rarely seen in Quebec, is familiar to me in this habitat. I am then about three kilometers from downtown Saint-Georges-de-Beauce, in the northern part going towards Notre-Dames-Pins. At a good distance, that is to say at least half a kilometer from the Chaudière River, in the low herbaceous vegetation of a maple stand dotted with softwoods, I capture in an entomological net a male clubtail exposing a large club. Without being able to put a name to it immediately, I take a series of point-blank photos of it. Hoping that it stays in place, I then place it on some foliage, but it's a waste of time for other photos because it immediately flies towards the canopy! It is only by examining my photos on the computer, and by consulting the guide to the odonates of Algonquin Park, that I realize that it could be *Gomphus ventricosus*. I send my photos to Michel Savard who confirms my identification. Back in the field, on June 30, at exactly the same place, I captured another male whose coloring turned out to be slightly different from the first due to the extent of the yellow in the eighth abdominal segment. According to the state of our knowledge, this would only be the third mention of this species in Quebec. We have to go back to June 18, 1940, in Farnham, for the discovery of the Skillet Clubtail in Quebec, by Brother Adrien Robert, author of the volume "Les libellules du Québec". Then, we refer to July 4, 2011 for the discovery of a male, on the bank of the Batiscan River in Mauricie, by Pierrette Charest (see the Entomofauna Bulletin of November 2011). At the suggestion of Michel Savard, the coordinator of the Initiative

pour un atlas des dragonflies du Québec (IALQ), I then explored the surroundings of the Chaudière hoping to find exuviae of the species there, but without success. I retain a constant between the observations of Adrien Robert and mine. The various males captured in the forest were far from a large watercourse. For the new season, in June 2016, I will try to document the abundance of the Skillet Clubtail at my observation site. This is quite a challenge for a species that the Committee on the Status of Endangered Wildlife in Canada (COSEWIC, 2010) considers endangered.] Address: not stated

## 2017

**21590.** Hutchinson, R.; Ménard, B. (2017): Pêches de naïades de *Somatochlora brevicincta* (Odonata: Corduliidae) à Senneterre en 2016. *Nouv'Ailes* 27(1): 4-5. (in French) ["On July 20, 2016, BM, accompanied by Majella Larochelle, allowed himself a two or three-day expedition to Lake Mistassini in the hope of collecting naiads of *S. brevicincta* and other species of odonates which mainly inhabit the subarctic regions. Due to the short time devoted to fieldwork and the great distance to travel from Gatineau to finally catch larvae in the field, the results were modest and mixed. No water nymphs were caught, unlike the 1996 expedition (Hutchinson & Ménard, 2000). However, on the way back, a brief stop in a reticulated bog in Senneterre allowed BM to catch two *S. brevicincta* larvae. These were brought back alive to Gatineau and placed in breeding tanks. In the subfamily Corduliinae, the genus *Somatochlora* has the largest number of species in North America (Needham et al., 2000). This statement also applies to the province of Quebec where 14 species are found (Savard, 2011). The description of *S. brevicincta*, as a new species, dates from a relatively recent period compared to all known taxa for Quebec (Robert, 1954). Moreover, the description of the larva or naiad is also recent (Hutchinson & Ménard 2000). [...] *S. brevicincta* was little known at the time of Walker & Corbet (1975). It is currently listed in the following geographic entities: Quebec, Nova Scotia and British Columbia, for Canada and Maine and Minnesota, for the United States (Paulson, 2011). In Quebec, the distribution of *S. brevicincta* currently encompasses the regions of Abitibi, Lac Mistassini, Sept-Îles (Buidin & Rochepault, 2008), Lac-Saint-Jean (Michel Savard, pers. comm.) and Parc National Frontenac (Alain Mochon, pers. comm.). For naturalists and odonatologists wishing to fish for *S. brevicincta* naiads, BM offers the following technique. Once at the edge of the minerotrophic ponds of our peat bogs, the collector must recommend the following fishing procedures: with his net, he executes a circular movement from the bottom of the pond upwards in the direction of the opposite shore; in order to detach or extirpate the naiads clinging to the sphagnum moss or other plant material that lines or borders the pond, it agitates and grazes the bottom and the sphagnum, always directing the net towards the opposite bank. BM used this method at Lake Mistassini in 1996 and at Senneterre in 2016. It is worth remembering that adults of *S. brevicincta* are very discreet in nature and are often difficult to spot in flight or perched low in peat environments. Fishing for larvae therefore becomes an important activity to avoid returning empty-handed from one's odonatological expeditions. By the way, hello and good luck!" (Author/Google translate)] Address: Menard, B., 16, rue Smith, Gatineau (Québec) J8T 3A1. Email: ménardben@vidéotron.ca

**21591.** Johansson, F. (2017): Population structure of *Leucorrhinia dubia* (Vander Linden) the White-faced Darter in Europe with special reference to the population at Chartley Moss. *J. Br. Dragonfly Society* 33(2): 73-78. (in English)

["This article describes the population structure with regard to genetic variation and isolation of *L. dubia* in Western Europe, with a special focus on the British population at Chartley Moss. The British population is genetically closest to those in Switzerland and France but is genetically isolated from all populations in Europe. Information is also provided about Variation in the length of the spines in larvae raised in the absence of fish. This feature is of particular interest because these spines provide protection from fish predators as well as being used for keying out species at the larval stage." (Authors)] Address: Johansson, F., Animal Ecology, Dept of Ecology & Genetics, Uppsala University, Sweden

**21595.** Ménard, B.; Hutchinson, R. (2017): Nouvelles pêches de naïades de *Progomphus obscurus* (Rambur) (Odonata: Gomphidae) au Québec. *Nouv'Ailes* 27(2): 5. (in French) ["On September 16, 2017, BM and his wife Line went again to the edge of the Désert River, near the town of Maniwaki, to the site where they had found two larvae of *P. obscurus* on August 12, 2016, a first and second mention of the species for Quebec (Hutchinson & Ménard, 2016). This time, they caught five naiads of *P. obscurus*, three almost mature specimens and two larvae (immature). These are five other mentions for the Quebec territory, at the same site however. These discoveries seem to confirm that a large population is spreading at least at this site and perhaps elsewhere in Quebec. BM therefore put them in breeding at his home in Gatineau. He feeds them with mosquito larvae (Culicidae). However, these naiads seem reluctant to adopt the proposed diet. Research should be undertaken to better under-

stand the usual prey of organisms of the genus *Progomphus*, which burrow and live in the sand. We hope to have positive news to deliver on the evolution of the larvae kept in captivity at BM at later dates. We also intend to visit the site again in the hope of finding new confirmations of the importance of this population of *P. obscurus* on the banks of the Desert River. As additional information on the richness of the odonatofauna of the Desert River, BM reports that an impressive population of naiads of *Stylurus amnicola* of all sizes inhabit the site of this watercourse surveyed by BM and his wife, Line. This species was very rarely found for a very long time in Quebec." (Authors/Google translate)] Address: Menard, B., 16, rue Smith, Gatineau (Québec) J8T 3A1. Email: ménardben@vidéotron.ca

**21596.** Nagel, P.B. (2017): Diskussionsbeitrag: Populationshaltende Maßnahmen im artenschutzrechtlichen Ausnahmeverfahren. ANL Liegen Natur 39(1): 79-81. (in German) [If, for example, an infrastructure project fulfills the prohibition of species under species protection law, the project can only be approved by way of an exception under Section 45 (7) of the German Federal Nature Conservation Act. Among other things, it must be checked whether the conservation status of the populations of a species is not deteriorating. In practice, it is difficult to make a statement on this. The procedure discussed here offers approaches for a simplified examination of this question. As part of the exception, measures to ensure the conservation status of the affected populations of a species (including FCS measures, favorable conservation status) can be taken. However, these are not mandatory, such as measures to ensure coherence in European area protection. They are required when the conservation status would otherwise deteriorate or, in the case of Annex IV species of the Fauna-Flora-Habitat Directive with an unfavorable conservation status, it would be difficult to improve the status. A corresponding statement at the expense of the project is difficult to provide. In this article, a proposal for a simplified procedure is presented and discussed. The problems arisen, are discussed using the example of *Ophiogomphus cecilia*.] Address: Nagel, P.B., Bayerische Akademie für Naturschutz und Landschaftspflege (ANL), Seethalerstr. 6, 83410 Laufen, Germany. **21598.** Bartolucci, J.C. (2018): Amélioration des connaissances sur la répartition de l'Agrion de Mercure (*Coenagrion mercuriale*) en Lot-et-Garonne. Conservatoire d'espaces naturels d'Aquitaine: 53 pp. + annexes. (in French) ["Conclusion: In 2018, only eight locations of *C. mercuriale* were discovered. 58.1 kilometers were prospected via transects to which are added observations made outside transects. The distribution of the species on the territory is very heterogeneous with a good representation on the Landes plateau and the areas bordering the department. The meshes of the central part of Lot-et-Garonne remain unoccupied by *C. mercuriale* in view of the knowledge resulting from this work and previous work. Seven meshes are added to the atlas of the odonates of Aquitaine for this species which brings to 37 in total, or 47% of the department. Statistical analyzes of the variable analysis type were not possible due to the low number of stations discovered. However, for the sites where the species was observed, aquatic vegetation occupied 10 to 80% of the watercourse. The presence of typical watercress plants will reveal a significant potential for the site to host *C. mercuriale*. The surrounding environments were quite varied with crops, pastures, meadows, lawns in urban areas and roads. In addition to the presence of this vegetation, the management of the watercourse and its banks will strongly influence the potential of the environment for *C. mercuriale*. In general, it will prefer sites with a buffer zone (grass strip), strong sunlight and nearby shrubby areas allowing it to mature after emergence. All the data will be transmitted to the DDT47 in connection with the agreement set up specifically for this study. The elements collected in the field will be able to provide information on watercourses awaiting classification or highlight changes in already classified watercourses (flow that has become temporary, for example). CEN Aquitaine deemed it necessary to revisit certain favorable sites where the species could not be identified. In 2019, a special effort will be made to raise awareness among owners, users and managers of these small waterways. The main objective will be to introduce them to *C. mercuriale* and the importance of the departmental level of ensuring the conservation of the species and its habitat. It is planned to have a document signed in order to formalize, in a non-regulatory manner, the commitment to this cause of the various interlocutors. *C. mercuriale* presents a strong challenge at the level of the department. Despite the possibility of finding imagoes in sites considered unfavorable to the species, the limiting factors for its establishment are induced by the larvae which have much stricter ecological requirements. Also, the intensification of anthropogenic pressures and alteration factors have led to its severe scarcity. If nothing is done quickly to protect this dragonfly, the remaining populations could still experience drastic drops with an increase in disappearances locally, or even eventually in most of the department." (Author/Google translate)] Address: Bartolucci, J.-C., chargé de missions, CEN Aquitaine - Antenne Lot-et-Garonne - Chemin du Rieulet - 47 160 Damazan, France. Email: jc.batolucci@cen-aquitaine.fr

Lac-Saint-Jean, Québec. Fabriques 30: 18. (in French) [18-VI-2007, river Brassard, near Roberval (48°30'11"N, 72°14'56"E).] Address: Chiricota, Lise, 448, rue Léger, Roberval, (Québec) G8H 3G7, Canada.

**21600.** Evans, B.J.E. (2018): Neuronal encoding of natural imagery in dragonfly motion pathways. Dissertation Note: Thesis (Ph.D.) – University of Adelaide, Adelaide Medical School, 2019: 243 pp. (in English) ["Vision is the primary sense of humans and most other animals. While the act of seeing seems easy, the neuronal architectures that underlie this ability are some of the most complex of the brain. Insects represent an excellent model for investigating how vision operates as they often lead rich visual lives while possessing relatively simple brains. Among insects, aerial predators such as the dragonfly face additional survival tasks. Not only must aerial predators successfully navigate three-dimensional visual environments, they must also be able to identify and track their prey. This task is made even more difficult due to the complexity of visual scenes that contain detail on all scales of magnification, making the job of the predator particularly challenging. Here I investigate the physiology of neurons accessible through tracts in the third neuropil of the optic lobe of the dragonfly. It is at this stage of processing that the first evidence of both wide-field motion and object detection emerges. My research extends the current understanding of two main pathways in the dragonfly visual system, the wide-field motion pathway and target-tracking pathway. While wide-field motion pathways have been studied in numerous insects, until now the dragonfly wide-field motion pathway remains unstudied. Investigation of this pathway has revealed properties, novel among insects, specifically the purely optical adaptation to motion at both high and low velocities through motion adaptation. Here I characterise these newly described neurons and investigate their adaptation properties. The dragonfly target-tracking pathway has been studied extensively, but most research has focussed on classical stimuli such as gratings and small black objects moving on white monitors. Here I extend previous research, which characterised the behaviour of target tracking neurons in cluttered environments, developing a paradigm to allow numerous properties of targets to be changed while still measuring tracking performance. I show that dragonfly neurons interact with clutter through the previously discovered selective attention system, treating cluttered scenes as collections of target-like features. I further show that this system uses the direction and speed of the target and background as one of the key parameters for tracking success. I also elucidate some additional properties of selective attention including the capacity to select for inhibitory targets or weakly salient features in preference to strongly excitatory ones. In collaboration with colleagues, I have also performed some limited modelling to demonstrate that a selective attention model, which includes switching best explains experimental data. Finally, I explore a mathematical model called divisive normalisation which may partially explain how neurons with large receptive fields can be used to re-establish target position information (lost in a position invariant system) through relatively simple integrations of multiple large receptive field neurons. In summary, my thesis provides a broad investigation into several questions about how dragonflies can function in natural environments. More broadly, my thesis addresses general questions about vision and how complicated visual tasks can be solved via clever strategies employed in neuronal systems and their modelled equivalents." (Author)] Address: Evans, B.J.E., Univ. of Adelaide, Adelaide, 5005 South Australia, Australia

**21601.** Felix, R.P.W.H.; van Hoof, P.H.; Hoppenbrouwers, P.; de Jong, V.; Krekels, R.F.M. (2018): Insects in selected areas in the province of Limburg. Three years of research into dragonflies, butterflies, grasshoppers and crickets. *Natuurhistorisch maandblad* 107(7): 125-134. (in Dutch, with English summary) ["In the Netherlands, it is the provincial authorities which are responsible for nature conservation. They have set up a subsidy system, to which organisations and civilians managing nature areas can apply for financial support for their management activities. This subsidy system, called 'Subsidiestelsel Natuur en Landschap'(SNL), requires monitoring of the results of the management activities. Hence, a monitoring system has been developed, which is based on a defined set of management types. These management types are studied with regard to a variety of factors relating to the quality of nature areas. One of the factors assessed is the occurrence of selected flora and fauna species. In the 2014–2016 period, Bureau Natuurbalans – Limes Divergens carried out a survey of butterflies, dragonflies, grasshoppers and crickets in the province of Limburg according to the SNL assessment methodology. Roughly 6,100 ha of management types for which insects are used as quality indicators for SNL purposes were surveyed over this three-year period. The areas investigated include nearly 90% of all Natura 2000 areas in Limburg. The survey resulted in a dataset of 44,000 records collected in nearly 7,500 1-hectare grid squares, which comprise 45 butterfly, 55 dragonfly and 34 grasshopper and cricket species. Records mostly concern the more common species, which are often under-represented in databases based on sightings by volunteers. One of the results of this study is a set of comprehensive distribution patterns of fairly common species like Meadow brown (*Maniola jurtina*) and Bog bush-cricket (*Metriopectera brachyptera*). This information is very difficult to gather using only the nonsystematic sightings collected by 'citizen science'. The article also describes aspects of the distribution of some less common or rare species. An example is given of the way the quality of the management types in one particular area, viz. the National Park Maasduinen, can be assessed using our data, following the guidelines described in the SNL methodology. The paper concludes with some notes on the method, based on our experiences in the field." **21605.** Kobayashi, T.; Ralph, T.J.; Lobb, J.; Miller, J.; Theischinger, G.; Hunter, S.J.; Jacobs, S.J. (2018): Dunphy Lake in Warrumbungle National Park, NSW: aquatic animal community after the Wambelong fire in 2013. Australian Zoologist volume 39 (3): 469-479. (in English) ["Fires are a common occurrence in Australian terrestrial ecosystems. A large fire occurred in January 2013 within and adjacent to the Warrumbungle National Park, near Coonabarabran in NSW, burning over 560 km<sup>2</sup> of the park and surrounding region (the Wambelong fire). The Wambelong fire affected Dunphy Lake, the only lake in the park. In this study, we assessed the post-fire aquatic animal community of the lake in March and September 2014. At the times of sampling the lake was largely dry and had only small isolated pools. We found 53 invertebrate taxa including the larvae of the dragonfly *Austrogynacantha heterogena* and one vertebrate species (larvae of the frog *Litoria rubella*) in the pool-water samples. Artificial inundation of the lake sediment samples under laboratory conditions led to the emergence of 31 taxa, totalling 62 taxa in the lake overall. Most taxa found in the lake are opportunistic and characteristic of those in still-water bodies. Dunphy Lake seems to be highly resilient in sustaining diverse aquatic animals. We highlight the importance of complementary pre- and post-fire data for improved assessments and interpretations of fire impacts to guide monitoring of post-fire recovery." (Authors)] Address: Kobayashi, T., Science Division, Office of Environment & Heritage NSW, PO Box A290 Sydney South NSW 1232, Australia. Email: Yoshi.Kobayashi@environment.nsw.gov.au

**21606.** Kobayashi, T.; Ralph, T.J.; Berney, P. (2018): Aquatic animal community at Dunphy Lake after the Wambelong fire indicates the importance of ephemeral pools and lake sediment for recovery process. In: 2018 Linnean Society of New South Wales Natural History Field Symposium: volcanoes of northwest New South Wales: exploring relationships among geology, flora, fauna and fires: 16-["Fires are a natural phenomenon in many terrestrial ecosystems. The ecological effects of fires can be complex, depending on the attributes of fires, landscapes, as well as local climate and weather. A large fire occurred in January 2013 within and adjacent to the Warrumbungle National Park, affecting a large area of the park including Dunphy Lake (the Wambelong fire). We assessed the aquatic animal community of Dunphy Lake in March and September 2014. The lake was largely dry and covered with grasses, with only small isolated pools of water in the lake. We found 53 invertebrate taxa including the larvae of the dragonfly *Austrogynacantha heterogena* and one vertebrate species (larvae of the frog *Litoria rubella*) in the pool-water samples. Artificial inundation of the lake sediment samples under laboratory conditions led to the emergence of 31 taxa, totalling 62 taxa in the lake overall. Our results indicate the importance of ephemeral pools and lake sediment as refugia against drought and fires for aquatic organisms. The conservation of these seemingly marginal habitats across the park would help the

recovery process of aquatic organisms and thus maintain the aquatic species diversity and function after major environmental disturbance." (Authors)] Address: Berney, P. National Parks and Wildlife Service NSW, Narrabri, NSW 2390

**21607.** Kulakov, O.I.; Tatarinov, A.G. (2018): Population of dragonfly larvae (Insecta, Odonata) in "floodless Lake Middle Week", Komi Republic. Biodiagnostics of the state of natural and natural-manmade systems. Materials of the 16th All-Russian Scientific and Practical Conference with international participation. 2018. Publisher: Vyatka State University (Kirov): 169-172. (in Russian) ["The first list of 35 species of dragonflies in the Komi Republic was published in the monograph by K. F. Sedykh [1]. The article by T. G. Stronk [2] provides information on 46 species of dragonflies. Currently, 53 species are included in the regional odonofauna [3, 4]. If the species composition of dragonflies has been revealed in sufficient detail, then there is practically no information on the structure of the population and the distribution of larvae in the water bodies of the republic. Studies of the population of dragonfly larvae were carried out in the Beloyarsky complex reserve, on the territory of which the biostation of the Syktyvkar State University is located (Kortkerosky district of the Komi Republic, 61°47'32" N, 51°48'23" E). The material was collected in the second ten days of June and the third ten days of July 2017 in the lakes Long, Priruslovoe and Krasivoye, which are floodplain closed water bodies formed as a result of separation from the oxbow lakes of the river. Vychehda. The collection of dragonfly larvae was carried out by "mowing" (wiring) with a water net over submerged vegetation in test plots 5 m long, up to 70 cm deep from the surface of the water surface and within 1.5 m from the shore to the center of the lake. In total, 12 plots were processed (four on each lake), on which 48 hydrobiological samples were taken for research, containing 634 specimens. larvae. The species diversity of dragonfly larvae in the surveyed lakes was assessed using the Margalef species richness (DMg), dominance D, Simpson evenness (DSm), and Berger-Parker (DB-P) indices widely used in ecological studies [5]. The abundance of larvae in water bodies was assessed using a five-point logarithmic scale [6]. Dragonfly larvae presented in hydrobiological samples belonged to 18 species from two suborders and five families (table). This is about 50% of the total identified composition of the odonofauna of the reserve [3]. As expected, the samples did not contain rheophilic representatives of the families Calopterygidae and Gomphidae, as well as the species *Platycnemis pennipes*, *Coenagrion lunulatum*, *Libellula depressa*, whose larvae were found in other local water bodies. Oz. Priruslovoe (I). In 2017, 209 specimens were found in hydrobiological samples. larvae of 12 species of dragonflies of different ages. In hydrobiological samples, representatives of the genera *Coenagrion* (*C. johanssoni*, *C. hastulatum*) and *Sympetrum* (*S. flaveolum*, *S. vulgatum*) dominated in terms of abundance; they accounted for more than half of the collected individuals. Three species can be attributed to the category of subdominants, the share of each of which in the samples was about 10%: the black pebble stone (*Sympetrum danae*), the metal headstock (*Somatochlora metallica*), and the rock rush (*Aeschna juncea*). The average density of larvae in the lake during the season was about 8 ind./m<sup>2</sup>. Oz. Beautiful (II). Hydrobiological samples in 2017 contained 243 specimens. larvae of all 18 dragonfly species. The structure of the population turned out to be different than in the lake. Priruslov. Large representatives of the Anisoptera suborder dominated in terms of abundance: *Aeschna juncea*, the large k. The subdominants in terms of abundance were

*Cordulia aenea*, *Sympetrum danae*, and *S. flaveolum*. The average density of larvae in the lake during the season was about 13 ind./m<sup>2</sup>. Oz. Long (III). In 2017, 182 larvae of 14 species of dragonflies were caught in this water body. The most abundant species were *Aeshna grandis*, *Somatochlora metallica*, *Coenagrion johanssoni*, *C. hastulatum*, and *Sympetrum flaveolum*. The composition of the background species included *Cordulia aenea*, *Aeshna juncea*, and *S. vulgatum*. The average density of larvae in the lake did not exceed 10 ind./m<sup>2</sup>. In the odonatofauna of the studied water bodies, five morpho-ecological groups of dragonfly larvae are represented. The largest number of species was found in three groups: broad-gill larvae of stagnant and slow-flowing water bodies, short-bellied crawling larvae of stagnant water bodies, and long-bellied actively swimming larvae of stagnant and slow-flowing water bodies. For the larvae of dragonflies of the three indicated groups, the living conditions in the studied water bodies are the most favorable. The calculation of the indices of species richness and dominance also showed an approximately equal level of species diversity of dragonflies in the studied water bodies. This is explained by the close location of the lakes and the similarity of the structure of aquatic habitats (vegetation, depth, water surface area). How stable the structure of the population of dragonfly larvae in lakes, whether it is possible to speak about the existing structure of the population is a topic for further research." **21609.** Pilon, J.G. (2018): *Argia fumipennis* (Burmeister) et *Boyeria grafiana* Williamson (Odonata), deux nouvelles mentions pour les îles de la Madeleine. Fabriques 30: 14. (in French) [Verbatim (Google translate): During an excursion to the Magdalen Islands from July 11 to 18, 2004, we explored the national wildlife reserve at the eastern tip of Grosse Île and the forest area of the southern dune of Île du Haven to Houses. We collected seven species of odonates there. At this point in the summer season, *Libellula quadrimaculata* Linnaeus was found to be the dominant species in swampy areas, heathlands and shrubby areas. As secondary species, we found *Cordulia shurtleffi* and *Sympetrum danae*, mainly in shrubby areas. *Lestes dryas* and *Enallagma hageni*, mainly restricted to wetlands, were species of tertiary importance. These five species have already been identified for the fauna of the Magdalen Islands (Pilon & Lagacé 1998). During our investigations, we also found two other species of odonates. We first collected a female individual of *Argia fumipennis* at the eastern tip of Grosse Île (zone 11N12 of the National Topographic System of Canada) on July 12 in the marshy area. On July 14, we captured a female individual of *Boyeria grafiana* in a forest

area of the southern dune of Havre aux Maisons Island (area 11N05). The present mentions of these two species constitute additions to the fauna of the Islands.] Address: Pilon, J.G., 576 Terrasse Magnan, Sainte-Thérèse (Québec) J7E 4Z4, Canada

**21610.** Amila Faqhira, Z.; Suhaila, A.H. (2019): Drift pattern of tropical stream insect: Understanding the aquatic insects movement. *Serangga* 24(1): 1-10. (in English, with Malaysian summary) ["An investigation to determine the drift pattern of aquatic insects in an upstream river in Perak, Malaysia was carried out. Drift was sampled by collecting drifting insects using drift sampler at every six hourly intervals within 24-hours period. A total of 3147 individuals of drifting aquatic insects was collected represented by 9 orders, 49 families and 81 genera. There was a significant difference in the temporal drifting pattern in aquatic insects (Kruskal-Wallis test,  $P=0.00$ ). Greatest drift abundance occurred at night time, which approximately 40 % higher than during the daytime samples, signifying diel periodicity of aquatic insect drift. In addition, nights without moonlight exhibited more drift rate as compared to bright, full-moonlit nights and differed significantly ( $P<0.05$ ). Drifting aquatic insects displayed alternant pattern with the greatest abundance at 0200 to 0800 h interval, and the least was at 1400 to 2000 h interval." (Authors) Taxa include Odonata, and a treated at genus level.] Address: Suhaila, A.H., School of Biological Sciences, Universiti Sains Malaysia. 11800 Minden, Penang, Malaysia. **21611.** Bangser, K. (2019): Investigation of even-skipped, a developmentally-regulated gene controlling neural segmentation in dragonflies. Union College - Schenectady, NY. Honors Theses. 2267. <https://digitalworks.union.edu/theses/2267>: II + 22 pp. (in English) ["A comprehensive understanding of the genetic mechanisms underlying pattern formation and neurogenesis is necessary in order to trace the evolutionary history of insect embryogenesis. One of the most important processes of embryogenesis is the organized pattern formation that allows for proper body segmentation and neural development. Proper segmentation, which relies on a series of specific gene expressions, is necessary for the development of an operational nervous system. Even-skipped (*eve*), one such regulatory gene, has been studied extensively in certain model organisms, and theories regarding the evolution of its functional role could be further elucidated by visualizing its expression in adult and larval dragonflies, which has yet to be accomplished. Through a protocol of immunofluorescence using antibodies raised against the even-skipped protein product (*eve*), this study aimed to visualize the localization of *eve* expression in both adult and larval dragonflies and thereby compare its expression throughout development. However, several methodological limitations were encountered, including a lack of published literature detailing a procedure for immunostaining in dragonflies and subsequent inability to properly permeate the target ganglia. Future research should attempt alternative methods of tissue permeation in order to successfully access the target neurons as well as explore alternative primary antibodies for use in targeting *eve* in tissue samples." **21613.** Briggs, A.J.; Pryke, J.S.; Samways, M.J.; Conlong, D.E. (2019): Complementarity among dragonflies across a pondscape in a rural landscape mosaic. *Insect Conservation and Diversity* 12(3): 241-250. (in English) ["1. Networks of ponds (pondscapes) are becoming increasingly significant for resilient landscape planning in rural areas. Farmland and forestry ponds are habitat islands that support heterogeneous communities of aquatic organisms. 2. Species richness, Dragonfly Biotic Index (DBI), Shannon's index, and species composition are used here to assess the complementary conservation value of adult dragonfly assemblages associated with forty ponds across a protected area-sugarcane-forestry mosaic. 3. Despite differences in environmental variables among the various ponds, dragonfly species richness, DBI, Shannon index scores, as well as responses to particular environmental variables, did not differ between ponds in sugarcane, plantation forestry, and protected areas. Dragonfly composition differed in response to vegetation cover. 4. Our results highlight the importance of catchment and regional management for all ponds within the pondscape, and show that ponds in the transformed areas (i.e. sugarcane and forestry areas) are important contributors to regional conservation. As the various ponds were complementary in their dragonfly assemblages, we recommend conservation focus at the level of the pondscape rather than on individual ponds." **21614.** Cerini, F.; Bologna, M.A.; Vignoli, L. (2019): Dragonflies community assembly in artificial habitats: Glimpses from field and manipulative experiments. *PLoS ONE* 14(6): e0214127. <https://doi.org/10.1371/journal.pone.0214127>: 16pp. (in English) ["Several factors act on community structure, so determining species composition and abundance patterns. Core processes operating at local scales, such as species-environment matching and species interactions, shape observed assemblages. Artificial habitats (simplified structure) are useful systems for assessing the main factors affecting community composition and disentangling their assembly rules. Drinking troughs (brickwork tanks for free-ranging cattle watering) are widespread in Italy and represent a suitable aquatic habitat for colonization by various aquatic organisms. Dragonflies larvae are usually found in drinking troughs and often exhibit strong species interactions and striking community assembly patterns. Our primary aim was to search for Odonata communities exhibiting non-random co-occurrence/segregation patterns in drinking troughs. We performed null-model analyses by measuring a co-occurrence index (C-score) on larval Odonata assemblages (13 species

from 28 distinct troughs). Overall, we found a non-random structure for the studied dragonfly assemblages, which, given their fast generation time, must have been generated by short-term ecological processes (i.e. interspecific interactions). We thus analyzed potential competition/predation among and within ecological guilds. From the field data, we speculated that interactions within the sprawlers' guild is likely among the main drivers structuring the studied assemblages, especially the effect of intraguild predation between *C. erythraea* and *Sympetrum* spp larval stages. We then experimentally tested these interactions in laboratory and demonstrated that intraguild predation among larvae at different development stages may result in an effective exclusion/negative impact on density pattern, representing one of the processes to take into consideration when studying dragonfly assemblages." **21621.** Dettner, K. (2019): Chapter 9. Defenses of water insects. K. Del-Claro, R. Guillermo (eds.), *Aquatic Insects*, Springer Nature Switzerland AG 2019. <https://doi.org/10.1007/978-3-030-16327-39>: 191-262. (in English) ["This chapter compiles active and passive defensive mechanisms of aquatic and semiaquatic developmental stages of all insect orders against various predators. Mainly escape reactions, mechanical defense, defensive stridulation, and especially chemical defenses are described, illustrated, and tabulated. Apart from the large aquatic groups of ephemeropteran, Odonata or Trichoptera larvae especially aquatic bugs and water beetles are considered by even including small groups from Collembola up to Mecoptera. Differences between defensive mechanisms and strategies in aquatic and terrestrial insects are described. Aquatic insects especially rely on escape, mechanical defenses, defensive stridulation, and chemical defenses. Exocrine glands are mainly restricted to large taxa with both terrestrial and aquatic representatives (adephagan beetles, Heteroptera) and not invented in aquatic groups. Chemically aquatic insects especially evolved biosynthesis of aromatic and few aliphatic compounds against microorganisms. In contrast mainly steroids are targeted against cold-blooded vertebrates such as fishes and amphibians. As compared with terrestrial insects, aquatic representatives lack many mechanisms of defense such as reflex bleeding, incorporation of toxic compounds from plants, freshwater animals, or microorganisms. Exocrine secretions of water insects are usually externalized by secretion grooming in order to receive a clean body surface, to achieve an optimal breathing, and to modify the wettability of the body surface. Generally there exists a considerable lack of knowledge concerning bionomy and especially defenses of aquatic insects." (Author) Odonata are treated in Chapter 9.2.] Address: Dettner, K., Dept of Animal Ecology II, University of Bayreuth, Bayreuth, Germany. E-mail: k.dettner@uni-bayreuth.de

**21623.** Evans, B.J.E.; O'Carroll, D.C.; Fabian, J.; Wiederman, S.D. (2019): Differential tuning to visual motion allows robust encoding of optic flow in the dragonfly. *Journal of Neuroscience* 39(41): 8051-8063. (in English) ["Visual cues provide an important means for aerial creatures to ascertain their self-motion through the environment. In many insects including flies, moths and bees, wide-field motion-sensitive neurons in the 3rd optic ganglion are thought to underlie such motion encoding, however these neurons can only respond robustly over limited speed ranges. The task is more complicated for some species of dragonflies that switch between extended periods of hovering flight and fast-moving pursuit of prey and conspecifics, requiring motion detection over a broad range of velocities. Since little is known

about motion processing in these insects, we performed intracellular recordings from hawking, emerald dragonflies (*Hemicordulia* spp.) and identified a diverse group of motion sensitive neurons that we named Lobula Tangential Cells (LTCs). Following prolonged visual stimulation with drifting gratings, we observed significant differences in both temporal and spatial tuning of LTCs. Cluster analysis of these changes confirmed several groups of LTCs with distinctive spatiotemporal tuning. These differences were associated with variation in velocity tuning in response to translated, natural scenes. LTCs with differences in velocity tuning ranges and optima may underlie how a broad range of motion velocities are encoded. In the hawking dragonfly, changes in LTCs tuning over time are therefore likely to support their extensive range of behaviours, from hovering to fast speed pursuits. Understanding how animals navigate the world is an inherently difficult and interesting problem. Insects are useful models for understanding neuronal mechanisms underlying these activities, with neurons that encode wide-field motion previously identified in insects such as flies, hawkmoths and butterflies. Like some Dipteran flies, dragonflies exhibit complex aerobic behaviours such as hovering, patrolling and aerial combat. However, dragonflies lack halteres that support such diverse behaviour in flies. To understand how dragonflies might address this problem using only visual cues, we recorded from their wide-field motion sensitive neurons. We found these differ strongly in the ways they respond to sustained motion, allowing them collectively to encode the very broad range of velocities experienced during diverse behaviour." (2019): Predator-induced changes in the chemical defence of a vertebrate. *Journal of Animal Ecology* 88(12): 1925-1935. (in English) ["1. Inducible defences are ubiquitous in the animal kingdom, but little is known about facultative changes in chemical defences in response to predators, especially so in vertebrates. 2. We tested for predator-induced changes in toxin production of larval common toads (*Bufo bufo*), which are known to synthesize bufadienolide compounds. 3. The experiment included larvae originating from three permanent and three temporary ponds reared in the presence or absence of chemical cues of three predators: dragonfly larvae, newts or fish. 4. Tadpoles raised with chemical cues of predation risk produced higher numbers of bufadienolide compounds and larger total bufadienolide quantities than predator-naïve conspecifics. Further, the increase in intensity of chemical defence was greatest in response to fish, weakest to newts, and intermediate to dragonfly larvae. Tadpoles originating from temporary and permanent ponds did not differ in their baseline toxin content or in the magnitude of their induced chemical responses. 5. These results provide the first compelling evidence for predator-induced changes in chemical defence of a vertebrate that may have evolved to enhance survival under predation risk." (Authors)]

**21627.** Lorenzo-Carballa, M.O.; Torres-Cambas, Y.; Heaton, K.; Hurst, G. D. D.; Charlat, S.; Sherratt, T.N.; Van Gossom, H.; Cordero-Rivera, A.; Beatty, C.D. (2019): Widespread *Wolbachia* infection in an insular radiation of damselflies (Odonata, Coenagrionidae). *Scientific Reports* 9, Article number: 11933: 13 pp. (in English) ["*Wolbachia* is one of the most common endosymbionts found infecting arthropods. Theory predicts symbionts like *Wolbachia* will be more common in species radiations, as host shift events occur with greatest frequency between closely related species. Further, the presence of *Wolbachia* itself may engender reproductive isolation, and promote speciation of their hosts. Here we screened 178 individuals belonging to 30 species of the damselfly genera *Nesobasis* and *Melanesobasis* — species radiations endemic to the Fiji archipelago in the South Pacific — for *Wolbachia*, using multilocus sequence typing to characterize bacterial strains. Incidence of *Wolbachia* was 71% in *Nesobasis* and 40% in *Melanesobasis*, and prevalence was also high, with an average of 88% in the *Nesobasis* species screened. We identified a total of 25 *Wolbachia* strains, belonging to supergroups A, B and F, with some epidemic strains present in multiple species. The occurrence of *Wolbachia* in both males and females, and the similar global prevalence found in both sexes rules out any strong effect of *Wolbachia* on the primary sex-ratio, but are compatible with the phenotype of cytoplasmic incompatibility. *Nesobasis* has higher species richness than most endemic island damselfly genera, and we discuss the potential for endosymbiont-mediated speciation within this group." **21628.** Maldonado, M.A.; Manara, E.; Martín, P.R. (2019): Antagonistic effects of a native apple snail on other snails and macroinvertebrates in Southern Pampas waterbodies: a mesocosm approach. *Limnologica* 78, September 2019, 125694: (in English) ["Macroinvertebrates represent an important component of communities and trophic webs of freshwater ecosystems. *Pomacea canaliculata* (family Ampullariidae), an invasive apple snail native to the Pampas ecoregion, acts as a voracious grazer and plays a structuring role on submerged macrophytes that serve as food, habitat or foraging ground for many macroinvertebrates. Laboratory studies show that *P. canaliculata* can also act as a competitor or predator of other macroinvertebrates. Using a

mesocosm approach, we sought to investigate if this species of apple snail affects other freshwater snails (*Chilina parhappii*, *Heleobia parhappii*, *Biomphalaria peregina* and *Melanoides tuberculata*) as well as other macroinvertebrates and if consumption of submerged macrophytes and detritus mediates these effects. After twelve weeks we estimated in mesocosms with and without apple snails the abundance of snails and macroinvertebrates through samples taken separately from sediment and from macrophytes. We also estimated the coverage and biomass of macrophytes and the detritus biomass. Significantly lower abundance occurred in mesocosms with apple snails for all snail species and representative macroinvertebrates (i.e., Hirudinea, Ephemeroptera, Chironomidae and Odonata). Mesocosms with apple snails also resulted in lower total abundance of macroinvertebrates. We speculate that the negative effects of *P. canaliculata* on most other snails and macroinvertebrates living on macrophytes relates to their grazing on detritus and macrophytes. In contrast, the density of snails and macroinvertebrates in the samples from sediments were not affected by *P. canaliculata*. One snail species and Ephemeroptera were negatively affected by mechanisms not related to the reduction in macrophyte biomass and detritus. A decrease in the microhabitats provided by macrophytes probably mediated the negative effects on Odonata nymphs. The reduction in the abundances of snails and macroinvertebrates caused by *P. canaliculata* may have cascading effects on higher trophic levels in waterbodies from Southern Pampas but also in invaded regions." **21629.** Mishra, A.; Rastogi, N. (2019): Unraveling the roles of solitary and social web-making spiders in perennial ecosystems: Influence on pests and beneficials. Proceedings of the National Academy of Sciences, India Section B: Biological Sciences 90: 567-576. (in English) ["The results show that the orb-weaver spiders, *Neoscona theisi* and *Cyrtophora citricola*, occurred in both guava and citrus agroecosystems, and their prey primarily comprised a wide diversity of insect pests. In contrast, the sheet web-constructing social spider, *Stegodyphus sarasinorum*, occurred only in the citrus agroecosystem and preyed mainly on the beneficial insects, particularly the pollinators, including the Asian honeybee, *Apis cerana*, along with the predaceous ladybird beetle, *Coccinella septempunctata*, *Agriocnemis femina*, and the ant, *Camponotus compressus*. Field observations revealed that the beneficial insects caught and captured by the social spiders comprised mainly the flower-visiting insects of ornamental and weed plants growing in the vicinity of the fruit trees. *N. theisi* preyed predominantly on pests of paddy (*Nephotettix nigropictus*, *Oxya nitidula*), wheat (*Rhopalosiphum padi*), citrus (*Papilio demoleus*) and guava (*Bactrocera dorsalis*) and to a lesser extent on damselflies, houseflies, and ants. *C. citricola* with smaller orb webs preyed upon *N. nigropictus*, *R. padi*, *M. domestica*, *C. septempunctata*, and *C. compressus*. Except the guava pest, *B. dorsalis*, the pests of paddy and wheat from the infested crops cultivated in the nearby ~500-m distant located farm were attracted by the streetlights and were preyed upon by the arboreal spiders. The results highlight the significant role of orb web spiders in the suppression of insect pests of crops and also provide direct evidence of the negative role of social spiders as predators of the Asian honeybee, *A. cerana*, and other beneficial insects." **21630.** Monguí Torres, J.P. (2019): Patterns of genetic and morphological diversity in the highly polymorphic Neotropical banner damselflies, *Polythore* (Polythoridae: Odonata). Trabajo presentado como requisito para optar por el título de Biólogo. Facultad de Ciencias Naturales y Matemáticas Pregrado en Biología Universidad del Rosario, Bogotá: 31 pp. (in Spanish, with English summary) ["Genetic divergence across populations can be favored by geographical and/or phenotypic processes. However, phenotype polymorphisms caused by natural and/or sexual selection can obscure patterns of genetic divergence due to disparity across the morphological or behavioral traits with the genetic makeup in the populations. [...] *Polythore*, exhibit a striking wing color polymorphism across all its geographical range, which includes the Andes Cordillera and Amazon Basin. The latter suggests that they are excellent model organisms to test the effects of high phenotypic polymorphisms and geographical processes on the patterns of genetic diversity. Our aim was to explore the genetic and morphological diversity across the phylogenetic tree of these colorful damselflies. Our mtDNA phylogenetic reconstruction shows a strong association with geographical location, resulting on the recovery of four well-supported geographical clades (i.e: Amazon clade; and the West, Southeast and Northeast Andean clades). Overall, the patterns of genetic and morphological diversity are high and concordant across all members tested in the Amazon clade; suggesting that these population may have been experiencing divergence due to vicariant events. While for the Andean clades, the morphospecies showed a pattern of recent diversification that might be promoted by dispersal events. Finally, the wing color pattern seems to be shaped by other selective pressures including, sexual and/or natural selection." **21632.** Perich Prujà, A.; Leahy, K.; Piera, J. (2019): Reporting changes on species distributions using citizen science observations: The example of *Trithemis kirbyi* and *Natusfera*. 1st Meeting of the Iberian Ecological Society (SIBECOL) & XIV AEET Meeting: Abstract book: 134 (2019): 1 p. (in English) [Verbatim: A critic question in biogeography is how species will response in front of current rates of climate change: we may find many examples in the scientific literature reporting changes in species distributions worldwide that could be linked to climatic effects. A particular case is the dragonfly species *Trithemis kirbyi* Selys, 1891, originally distributed in Africa and southern Asia and associated to arid areas, that has been reported in the last years in the Iberian Peninsula. New observations in northern territories are among the most interesting to confirm the expansion rate of this species.

In this sense, the participation of non-academic experts that may contribute with new observations (what it is known as citizen science) could be very helpful, since this type of collaboration allows to cover a much wider monitoring area. The number of potential observations (and the covered area) may increase much more if volunteers do not require previous training nor expertise on identifying the reported observations. As an example, in this contribution we report probably the northernmost observation of *Trithemis kirbyi* in Catalonia (in the population of Albanyà, near the French border-line) using the citizen science platform Natusfera. This platform allows collaborative identification of the reported observations. We believe that this type of collaborative platforms could be used extensively to monitoring changes on species distributions, being a complementary tool for biogeographic studies] Address: <https://digital.csic.es/handle/10261/192298>

**21634.** Rocha-Ortega, M.; Rodríguez, P.; Córdoba-Aguilar, A. (2019): Can dragonfly and damselfly communities be used as bioindicators of land use intensification? *Ecological Indicators* 107, December 2019, 105553: (in English) ["Highlights: • We assessed odonata richness, body size and species' response to land use intensification. • Dragonflies indicated current land use while damselflies indicated time-lagged land use. • Large species allowed evaluating recent reduction of original vegetation. • Small species provided information of historic habitat modification. • Individual species did not reflect ecological integrity. • Some species' combinations indicate environmental degradation. Abstract: There is a growing need to identify efficient biological indicators for assessing accelerated land use intensification, as well for understanding the effects of past environmental changes on species distributions. To address this, we used an extensive opportunistic survey dataset of 254 adult odonate [...] species collected in nine Mexican hydrological regions during two time windows (1980–1993 and 1994–2010). We evaluated species richness, body size and individual species' response to land use intensification over time at a national scale using Phylogenetic Bayesian Regression Mixed Models. We found that dragonfly species serve as good indicators of current land use, whereas damselfly species show time-lagged effects of land use intensification. Large species could thus be used as a proxy of recent reduction of original vegetation, whereas small species provide information on historic habitat modification. Odonate body size seems to be a better variable for measuring the integrity of original vegetation than the more commonly used species richness. Finally, the use of individual species as bioindicators at broad spatial and temporal scales is not encouraged, as it does not reflect the degree of ecological integrity, and only the occurrence of some species combinations can indicate environmental degradation." **21636.** Schilling, E.G.; Lawrenz, R.; Kundel, H. (2019): A review of the reproductive habitat preferences and conservation challenges of a rare, transient, and ecologically restricted damer dragonfly: *Rhionaeschna mutata*. *International Journal of Odonatology* 22: 1-9. (in English) ["*R. mutata* is a rare North American dragonfly that is considered a species of concern or threatened throughout its range. It is most widely distributed in the eastern USA, but recent adult records indicate that its range extends further north and west than previously known. Effective conservation planning for rare species requires understanding their habitat requirements, and no comprehensive characterization of this species' reproductive habitat has previously been conducted. We conducted a review to synthesize information from records throughout this species' range and identified a narrow set of conditions that describe *R. mutata* reproductive habitat: small, heavily vegetated, fish-free ponds with a wooded riparian edge and with sphagnum present. While this habitat type may formerly have been widespread across this species' native range, anthropogenic activities have likely resulted in loss and increased fragmentation of *R. mutata* reproductive habitat. Our review also revealed that this species is transient or ephemeral, collected at a site one year and absent in subsequent years. Effective conservation planning for ecologically restricted odonates, such as *R. mutata*, requires consideration of multiple anthropogenic activities that threaten species' ability to persist." **21637.** Schneider, M.F. (2019): Einfluss des Klimawandels auf Flora, Fauna und Lebensräume in den Landkreisen Ober-, Ost- und Unterallgäu (Bayern, Deutschland). *Naturkundl. Beiträge Allgäu* 54: 3-31. (in German) ["The aim of the present study was to investigate changes in air and water temperatures, the length of stay of migratory birds and the length of the growing season in the districts of Ober-, Ost- und Unterallgäu. The annual average temperatures have increased by 1.4 °C to 2.4 °C since 1850, the water temperatures in the bodies of water examined increased by 1.2 °C to 3.4 °C between 1981 and 2018. The length of the vegetation

period in the examined locations was between 238 and 271 days in 2016 and has increased by up to 35 days compared to 1952. Of 20 migratory bird species examined, 16 species returned from the wintering grounds an average of 13 days earlier in the 30-year period examined in 2017. Finally, biologists, lepidopterists, herpetologists and experts from forestry and water management were asked about their assessment of the impact of climate change on flora, fauna and habitats in the Allgäu (Bavaria), the results were presented and discussed. .... A "Mediterranization" of the Allgäu was caused by the following dragonfly species: *Lestes barbarus* with distribution area in the Mediterranean region, among others, in the Upper Allgäu Finds since 1963; *Aeshna affinis*, distribution area including southern Europe, found in Oberallgäu since 2002; *Anax ephippiger*, distribution area from Africa to India, unique find in Oberallgäu in 2000; *Crocothemis erythraea*, distribution area including the Mediterranean region, on the Upper Rhine since 2000, first found in Oberallgäu in 2002; *Sympetrum fonscolombii*, distribution area including Africa to India, found in Oberallgäu since 1990 (Karle-Fendt & Stadelmann, 2006). "The first record of *Sympetma fusca* was in Oberallgäu in 2008, and the species has since become established on the edge of the Alps. Another beneficiary of climate change, with many new discovery sites throughout Central Europe in recent years and a number of new populations in the Allgäu, is *Leucorrhinia pectoralis*" (pers. comm. Alfred Karle-Fendt)." (Author)] Address: Schneider, M.F., Pfeiffermühle 3, 87497 Wertach, Germany. Email: michaelfschneider@gmx.de

**21638.** Singh, D.; Hermans, J. (2019): Odonata observations in the Bandh Baretha region, Rajasthan, India. *Brachytron* 20(1): 38-48. (in English, with Dutch summary) ["Bandh Baretha dam is a water reservoir, part of Kakund river, situated in the Bharatpur District in the south eastern part of Rajasthan (India). The dragonfly fauna of the water reservoir and adjacent region was examined from 2010-2018. Field surveys were carried out between February and November across seven selected habitats. To date 50 dragonfly species have been recorded: 14 Zygoptera and 36 Anisoptera. Three species are reported for the first time for Rajasthan: *Ictinogomphus angulosus*, *Gomphidia t-nigrum* and *Aethriamanta brevipennis*. The present study describes the existence of characteristic dragonfly assemblages in the investigated habitats. It also emphasizes that long-term field studies are necessary to understand the status, distribution and stability of dragonfly populations in relation to changes in their environment due to increasing human influence" (Authors)] Address: Hermans, J.T., Hertestraat 21, 6067 ER Linne, The Netherlands. Email: jthermans21@gmail.com

**21639.** Slaats, J. (2019): Dragonflies of the Waterbloem area. *Naturhist. maandbl.* 108(6): 153-160. (in Dutch, with English summary) ["Extensive habitat management projects have been carried out in the Waterbloem nature reserve, situated near the village of Heibloem in the province of Limburg. Measures have included restoration of the Roggelse Beek brook and the transformation of coniferous woods into moist grassland and heather. Measures to retain precipitation have led to higher groundwater levels. Since these projects were expected to have favourable effects on the dragonfly fauna of the area, the dragonflies were investigated in 2005, 2012 and 2017. A total of 36 species were observed. Unfortunately, the expected positive effects on the dragonfly fauna were not observed. Common species have become even more common, and rare species became rarer or even disappeared from the area. It is not clear why the management measures had such a meagre impact on the dragonfly

fauna. Perhaps a further raising of the groundwater level and/or deepening of stagnant water bodies could have a positive impact." (Author)] Address: Slaats, J., Astenseweg 6, 5768PD, Meijel, The Netherlands. Email: jan.slaats@hetnet.nl

**21640.** Souilmi, F.; Ghedda, K.; Fahde, A.; EL Fihri, F.Z.; Tahraoui, S.; Elasri, F.; Malki, M. (2019): Taxonomic diversity of benthic macroinvertebrates along the Oum Er Rbia River (Morocco): implications for water quality bio-monitoring using indicator species. *West African Journal of Applied Ecology* 27(1): 137-149. (in English) ["The macroinvertebrates of the Oum Er Rbia River were studied from samples collected seasonally from September 2015 to September 2016 at 10 sampling sites. The macroinvertebrates found during the sampling period were distributed into twelve orders. The most abundant order was Diptera, having 9618 individuals, followed by Ephemeroptera with 2985 individuals. Coleoptera, odonates and crustaceans represent only a small fraction of the total fauna. Hydropsyche, Chironomidae sp. and Simuliidae are numerically more inventoried. The composition and distribution of the species were directly or indirectly affected by the physicochemical variables and the quality of the habitat. Correspondence analysis results showed that habitat quality and quality of water represented species distribution patterns and species can be used as indicators to assess the quality of the Oum Er Rbia River system. Habitat management along the Oum Er Rbia river should be aimed at preserving native species, especially during the summer, when the biotope requirements are optimal. The results obtained in this study showed an alarming situation of the water quality of the Oum Er Rbia River and particularly in downstream segment. To solve this problem, we recommend the development of the wastewater discharge of Khenifra and Kasba Tadla and the purification of wastewater before it is discharged into the river." **21641.** Sukkaphat, P.; Saetang, W.; Poolprasert, P. (2019): Landmark-based geometric morphometric analysis of wing venation between two libellulid species, *Brachythemis contaminata* and *Diplacodes trivialis*. *YRU Journal of Science and Technology* 4(1): 8-13. ["In this current research, a discrimination of two distinguished dragonfly species: *Brachythemis contaminata* and *Diplacodes trivialis* from Phichit-Phitsanulok areas was conducted using geometric morphometric analysis of wing venation. A total of 120 wings obtained from both males and females in each species (30 wings per sex in each species) were analyzed. Afterwards, a set of 15 landmarks in each digitized right forewing was chosen and all data were computed under the computer program. Our results revealed the patterns of forewing venation of dragonfly between sexes in the same species were more closely related to each other than the dragonfly of the same sex in another species. In this regards, it might be said that the landmark-based geometric morphometrics of the wing could be applied to identify libellulid group or species. Besides, the different sexes of dragonfly could be also classified. Thus, morphometric analysis of wing venation could be as a useful tool for systematic biology of dragonfly and other insects or fossil records which are merely known from a wing." **21642.** Van Dievel, M.; Tüzün, N.; Stoks, R. (2019): Latitude-associated evolution and drivers of thermal response

curves in body stoichiometry. *Journal of Animal Ecology* 88(12): 1961-1972. (in English) ["1. Trait-based studies are needed to understand the plastic and genetic responses of organisms to warming. A neglected organismal trait is elemental composition, despite its potential to cascade into effects on the ecosystem level. 2. Warming is predicted to shape elemental composition through shifts in storage molecules associated with responses in growth, body size, and metabolic rate. Our goals were to quantify thermal response patterns in body composition, and to obtain insights in their underlying drivers and their evolution across latitudes. 3. We reconstructed the thermal response curves (TRCs) for body elemental composition [C(carbon), N(nitrogen), and the C:N ratio] of damselfly larvae from high- and low-latitude populations. Additionally, we quantified the TRCs for survival, growth and development rates and body size to assess local thermal adaptation, as well as the TRCs for metabolic rate and key macromolecules (proteins, fat, sugars, and cuticular melanin and chitin) as these may underlie the elemental TRCs. 4. All larvae died at 36°C. Up to 32°C, low-latitude larvae increased growth and development rates and did not suffer increased mortality. Instead, growth and development rates of high-latitude larvae were lower and levelled off at 24°C, and mortality increased at 32°C. This latitude-associated thermal adaptation pattern matched the 'hotter-is-better' hypothesis. With increasing temperatures, low-latitude larvae decreased C:N, while high-latitude larvae increased C:N. These patterns were driven by associated changes in N contents while C contents did not respond to temperature. Consistent with the temperature-size-rule and the thermal melanism hypothesis, body size and melanin levels decreased with warming. While all traits and associated macromolecules (except for metabolic rate that showed thermal compensation) assumed to underlie thermal responses in elemental composition showed thermal plasticity, these were largely independent and none could explain the stoichiometric TRCs. 5. Our results highlight that thermal responses in elemental composition cannot be explained by traditionally assumed drivers, asking for a broader perspective including the thermal dependence of elemental fluxes. Another key implication is that thermal evolution can reverse the plastic stoichiometric thermal responses, hence reverse how warming may shape food web dynamics through changes in body composition at different latitudes." **21643.** Vega-Sánchez, Y.M.; Mendoza-Cuenca, L.F.; González-Rodríguez, A. (2019): Complex evolutionary history of the American Rubyspot damselfly, *Hetaerina americana* (Odonata): Evidence of cryptic speciation. *Molecular Phylogenetics and Evolution* 139, October 2019, 106536: 11pp. (in English) ["Highlights: • Genetic structure in *Hetaerina americana* was analyzed throughout its distribution. • High genetic differentiation was found for both nuclear and mitochondrial markers. • Mitonuclear discordance may be related to purifying selection on the mitogenome. • Morphological variation in caudal appendages is congruent with nuclear genetic structure. • We conclude that that *Hetaerina americana* represent a complex of cryptic species. Abstract: Analyzing the magnitude and distribution of genetic variation within and among populations allows for hypothesis testing about historical demographic size changes, secondary contacts, refugia, and speciation patterns. Species distribution and genetic structure are greatly influenced by the complex life cycle and behavior of odonates. *H. americana* has been widely used as a model system in behavioral

studies, but its population genetic structure has not been analyzed, except for a single study that included only three populations but identified the presence of markedly differentiated genetic groups, suggesting the existence of cryptic species. Here, we tested this hypothesis by assessing throughout the distribution range of *H. americana* the patterns of genetic and morphological variation in the male caudal appendages, due to the great importance of these structures in mate recognition. As molecular markers we used sequences of the mitochondrial cytochrome oxidase I (COI) gene and the nuclear internal transcribed spacer (ITS) region, as well as six nuclear microsatellites. We found very high population genetic differentiation ( $F_{ST} > 0.51$ ) in the three sets of markers but with strong mitonuclear discordance. A neutrality test suggested that the mitochondrial genome might be under purifying selection in association to climatic variables (temperature seasonality). The assignment of individuals to nuclear genetic groups showed little admixture and complete congruence with morphological differentiation in the male caudal appendages. Hence, the results suggest that *H. americana* represents at least two different cryptic species which are isolated reproductively." **21644.** Araújo, M.F.A.; De Marco, P.; Juen, L.; Tôres, N.M. (2020): Vulnerability of *Phyllocycla* species (Odonata: Gomphidae) to current and planned anthropic activities by the Brazilian Government. *Neotropical Entomology* 49: 24-32. (in English) ["Although most species distribution modeling (SDMs) are constructed at the species level, an appreciation of evolutionary processes has led to modeling above this level. In view of the difficulty in estimating the impacts of human actions on rare or deficient data species, we proposed a new approach to vulnerability assessment based on concepts already well established in the literature (ecological niche, niche conservatism, and extinction thresholds). We used distribution modeling to predict where species of the genus *Phyllocycla* (Calvert 1948) are most vulnerable to local extinctions and how the implementation of planned anthropic activities by the Brazilian government may modify the potential distribution of the genus in Brazil. We chose that genus because its conservation status is little known, especially due to the data gap about its geographical distribution. We proposed modeling the whole genus and used the niche conservatism theory to justify our methods. The anthropic activities considered in our analysis were agriculture and livestock, rural settlements, energy production installations, transportation, oil extraction, mining, and urbanization. We found that only 55.3% of the original potential distribution of *Phyllocycla* in Brazil remains available. The area compromised by anthropic activities comprises mainly the Cerrado and Atlantic Forest biomes, with less impact on the Amazon. However, with the implementation of activities planned by the Brazilian government, it is possible that an additional 13.6% of this area will be unavailable to species of *Phyllocycla*, especially in the Amazon, where interest in mining and the implementation of new hydroelectric production have increased." - 21647.** Chance, F.S. (2020): Interception from a dragonfly neural network model. *Proceedings of ACM International Conference on Neuromorphic Systems (ICONS'20)*. ACM, New York, NY, USA, <https://doi.org/10.1145/nnnnnnn.nnnnnn>: 5 pp. (in English) ["While dragonflies are well-known for their high success rates when hunting prey, how the underlying neural circuitry generates the prey-interception trajectories used by dragonflies to hunt remains an open question. I present a model of dragonfly prey interception that uses a neural network to calculate motor commands for prey-interception. The model uses the motor outputs of the neural network to internally generate a forward model of prey-image translation resulting from the dragonfly's own turning that can then serve as a feedback guidance signal, resulting in trajectories with final approaches very similar to proportional navigation. The neural network is biologically-plausible and can therefore be compared against in vivo neural responses in the biological dragonfly, yet parsimonious enough that the algorithm can be implemented without requiring specialized hardware." (in English) ["This insect survey was conducted from 13<sup>th</sup> to 18<sup>th</sup> of January, 2020 in Mount Silam forest, Lahad Datu, Sabah. An average of 108 nocturnal insect species from 148 individuals was recorded from a one-metre-square area of the light-trapping cloth. The mean Shannon Index was 4.17 while Simpson Index was 129.84 and Fisher Alpha Index was 193.60. At least 15 Bornean endemic species were recorded during the brief survey. These pioneer data will serve as baseline information for other research work in future. The data will further strengthen the management of Mount Silam within Sapagaya Forest Reserve as a Class I Forest Reserve (Protection). The information on insect diversity and the aesthetic value of some of the flagship species can be used to promote sustainable nature tourism in Mount Silam since this area is a tourist attraction in Lahad Datu. ... At least 14 taxa of Odonates were recorded (Appendix 4), with two Bornean endemics. Both endemics are *Libellago phaeton* and *Coelicia nigrohamata*. *L. phaeton* is known to be very common but localized on small clear streams and *C. nigrohamata* is also confined to small forest streams (Orr 2003)." - 21650.** Fortunato, M.H.T.; Lopes de Melo, C.; Fonseca Mendes, H. (2020): Piscicultura brasileira e a influência da ordem Odonata, uma revisão. *Arquivos de Ciências Veterinárias e Zootecia da UNIPAR* 23(1): 7 pp. (in Portuguese, with English and Spanish summary) ["Brazilian fish farming is expanding in Brazil, presenting exceptional annual growth. However, during the larviculture phase, where fish is inserted in excavated ponds, due to their vulnerability and size, they become susceptible to diseases and predators. Aquatic insects feature among the predators in fish farming, with the Odonata order being the most prominent. Despite their predatory action during the larvae phase of fish, the Odonata order plays an important role in the aquatic environment and is considered as bioindicators. Despite its importance, to solve these problems, fish farmers end up using agrochemicals or providing intense liming, which can have serious consequences for both fish and water quality. Therefore, in face of this scenario, further studies on fish farming sustainability with management or control of those predators would be important in order to mitigate the environmental impacts. Thus, the objective of this paper was to address the history of Brazilian fish farming, the problems faced in larviculture due to predation by Odonata and to offer sustainable control alternatives." **21651.** Gillespie, C.M.; Mumme, R.L.; Wissinger, S.A. (2020): Pond drying cues promote cannibalism in larval *Anax junius* dragonflies. *Freshwater Science* 39(3): 576-583. (in English) ["Global climate change is expected to shorten hydroperiods and accelerate drying of ephemeral freshwater habitats, a shift that is likely to increase intraspecific competition and cannibalism in the aquatic animals that rely on those habitats. We experimentally examined the effects of simulated pond drying, tank size (initial larval density), and body size on survival and cannibalism in larvae of the dragonfly *Anax junius*, a species known to show frequent size-structured cannibalism. Thirty tanks of 3 different sizes were each stocked with 8 *A. junius* larvae (6 small, 1 medium, and 1 large) along with *Enallagma* damselfly larvae as prey. *Anax junius* survival and cannibalism were documented daily for 16 d. For tanks in the permanent hydroperiod treatment, we maintained water depth at a constant 14 cm for all 16 d, while we gradually reduced depth in the temporary hydroperiod tanks from 14 to 2 cm to simulate pond drying. We found that cannibalism was strongly size-dependent, as 31, 7, and 0% of small, medium, and large larvae, respectively, were cannibalized. Tank size (initial larval density) and hydroperiod treatment both affected larval survival and cannibalism. However, the effects of simulated pond drying were more pronounced than those of tank size. In addition, hydroperiod treatment was a predictor of daily risk of larval cannibalism, but daily volumetric larval density (number of *A. junius* alive divided by water volume present that day) was not. Our results, therefore, indicate that 1) pond drying can substantially increase cannibalism in larval odonates beyond its simple effect of producing high-density populations as water levels recede and 2) the effect of drying cues on the behavior and life-history characteristics of aquatic invertebrates merit increased attention from freshwater ecologists." **21653.** Harabis, F.; Hronkova, J. (2020): European database of the life-history, morphological and habitat characteristics of dragonflies (Odonata). *Eur. J. Entomol.* 117: 302-308. (in English) ["Climate change and an ever-increasing effect of humans on the great majority of freshwater ecosystems have affected not only individual organisms but also the links between them. In order to effectively protect communities or entire freshwater ecosystems, we need to understand how individual organisms react to these changes and the functional interconnections between individual species. This can be achieved by evaluating the functioning of individual species, i.e. their traits. Odonata are increasingly used as indicators of changes in freshwater ecosystems. Although this taxonomic group is the subject of many ecological studies, there is no comprehensive database of the

traits of European species. This is, why we decided to lay the foundations for an European database of dragonfly traits called dragonfly-database.eu, which is mainly based on Web of Science (WOS) publications and several monographs, and currently includes information on 79 European species. The main advantage of our database is that it is open to downloading, uploading, and storing of data. This is extremely important, because a database's applicability increases with the quality of the data it contains. Initially in compiling the database, we encountered several fundamental shortcomings in the knowledge of some often easily measurable traits in, some species. We believe that in combination with new statistical methods dragonfly-database.eu will become a very useful tool for many ecological studies and more effective conservation of threatened species." (2020): Infection under the ion beam: focused ion beams and antibacterial properties of biomaterials. *JYU dissertations* 236, Faculty of Mathematics and Science, University of Jyväskylä: 167 pp. (in English) ["In this thesis, Helium Ion Microscopy (HIM) imaging and milling on organic and antibacterial materials will be discussed. In addition, I will discuss the antibacterial properties of surface-immobilized bacteriophages. HIM is a recently developed imaging method, which is especially suitable for biological samples because they can be imaged without a metal coating. Because of the state-of-the-art ion source, the microscope has also a higher imaging resolution compared to the scanning electron microscope (SEM). The suitability of HIM imaging for the bacteria-phage interactions is discussed in addition to the more delicate nanocellulose samples. High beam damage on the cellulose was found which has not been reported previously with HIM. Indeed an ion beam can have a milling property, which is demonstrated here with bacteria, bacteria-dragonfly interactions and encapsulated bacteriophages to obtain volumetric information. The antibacterial effectivity of immobilized bacteriophages was analyzed quantitatively with HIM-imaging and biological measures. It was found that detaching phages from the material are likely the major contributor to the infectivity of the phage-biomaterial." (Author)] Address: not stated

**21656.** Nelsen, J. (2020): Do mosquito pesticides harm their natural enemies? Ecological impacts and non-target effects of larvicides on mosquito predators. M.Sc. thesis, Biological, Environmental, and Earth Sciences: X + 102 pp. (in English) ["Larvicides are chemicals used to kill juvenile mosquitoes. When applied to an area, other aquatic organisms are exposed to these chemicals. The removal or impairment of top insect predators could be beneficial to mosquito populations

once harmful pesticide levels dissipate. Two common larvicides were examined: growth regulators (IGRs) and surface films (SFs). The goal of this project was to determine if larvicides harm mosquito predators common to southern Mississippi. I surveyed aquatic sites before and after IGR and SF treatments, and then compared changes in insect community structure. Community evenness was lower in SF treated habitats. When analyzing prey taxa only, evenness and diversity changed in control treatments, which suggests that differences measured were due to other environmental factors, not larvicide presence. I examined lethal and behavioral effects of IGRs and SFs on predatory insects. Surface films were lethal to *Laccophilus* adults (Coleoptera: Dytiscidae) at recommended and high concentrations. Dragonfly nymph location preference in aquariums varied between SFs and IGRs. *Laccophilus* larvae in IGRs spent more time moving and eating compared to SFs. Behavioral differences were among combined concentrations in both larvicide treatments, not within their respective concentrations and controls. Experiments were conducted to determine IGR and SF effects on the mosquito-regulating ability of predaceous insects. Treated predators were placed in mesocosms containing mosquito larvae. Mosquito survival was quantified by capturing emerging adults. There were no differences in emergence among all treatments. Implications of the findings from this thesis, similarities to past research, and suggestions for future work are discussed." (Author)] Address: not stated

**21657.** Nitzsche, K.N.; Shin, K.-C.; Kato, Y.; Kamauchi, H.; Takano, S.; Tayasu, I. (2020): Magnesium and zinc stable isotopes as a new tool to understand Mg and Zn sources in stream food webs. *Ecosphere* 11(8), August 2020, e03197: 20 pp. (in English) ["Non-traditional stable isotopes of metals were recently shown as new dietary tracers in terrestrial and marine mammals. Whether these metal stable isotopes can be used to understand feeding habits in stream food webs is not known yet. In this study, we explored the potential of stable isotopes of essential Mg ( $\delta^{26}\text{Mg}$ ) and Zn ( $\delta^{66}\text{Zn}$ ) as a new tool in stream ecology. For this purpose, we determined  $\delta^{26}\text{Mg}$  and  $\delta^{66}\text{Zn}$  values of stream organisms and their potential metal sources in upper and lower reaches of two streams in the Lake Biwa catchment, Central Japan. Our goals were (1) to explore variations in  $\delta^{26}\text{Mg}$  and  $\delta^{66}\text{Zn}$  across organisms of different feeding habits and (2) to understand Mg and Zn sources to stream organisms. Overall,  $\delta^{26}\text{Mg}$  and  $\delta^{66}\text{Zn}$  values of organisms were neither related to each other, nor to  $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$  values, indicating different elemental sources and factors controlling isotopic fractionation depending on element and taxa. Low  $\delta^{26}\text{Mg}$  values in filter-feeding caddisfly larvae and small gobies indicated aqueous Mg uptake. Higher  $\delta^{26}\text{Mg}$  values in leaf-shredding crane fly and grazing mayfly larvae suggested Mg isotopic fractionation during Mg uptake from the diet. While the  $\delta^{26}\text{Mg}$  values of stonefly nymphs reflected those of caddisfly larvae as a potential prey, the highest  $\delta^{26}\text{Mg}$  values found in dobsonfly nymphs can be explained by  $^{26}\text{Mg}$  enrichment during maturing.  $\delta^{66}\text{Zn}$  values of caddisfly and mayfly larvae indicated Zn was a mixture of aqueous and dietary available Zn, while higher  $\delta^{66}\text{Zn}$  values in crane fly larvae pointed to Zn isotopic fractionation during Zn uptake from plant litter.  $\delta^{66}\text{Zn}$  values in stonefly and dobsonfly nymphs were often in the range of those of caddisfly larvae as their prey, while gomphid nymphs and small goby were depleted in  $^{66}\text{Zn}$  relative to their dietary Zn sources. We conclude that  $\delta^{26}\text{Mg}$  is a promising indicator to assess Mg sources in stream ecology depending on taxa, while the use of  $\delta^{66}\text{Zn}$  is limited due to the complexity in Zn sources." **21658.** Rowe, R.; Player, W. (2020): Diet analysis of juvenile dragonflies using group-specific polymerase chain reaction. Poster Number 104, Biology and Biomedical Research, College of Arts and Sciences Department, Department of Biology, Winthrop University. (in English) ["Aquatic food webs are complex, and understanding interactions in these food webs can give an indication of ecosystem health and stability, as well as movement of energy and nutrients through ecosystems. Previous studies have utilized both microscopic gut content analysis and stable isotopes to aid in constructing food webs in these ecosystems. However, gut content analysis is time-consuming, stable isotope analysis can be cost prohibitive, and both methods only identify general categories of food items. The application of newer, molecular-based approaches has the potential to provide previously unavailable taxonomic resolution in aquatic food webs (i.e., who is eating whom?). DNA-based methods have been used in other disciplines for diet analyses, but have not been widely applied in freshwater ecology. We collected juvenile dragonflies (Odonata, Anisoptera) from Winthrop Lake in Rock Hill, South Carolina, dissected gut contents, and extracted DNA from individuals in three genera. We amplified DNA via PCR, using group-specific primers targeting mitochondrial CO1 gene regions for midges (Diptera, Chironomidae) and mosquitoes (Diptera, Culicidae) to identify these potential prey in gut contents; we used gel electrophoresis as a presence/absence test for DNA from these prey groups. Occurrence of prey groups in gut contents varied by individual and by genus of dragonfly examined. With further refinement, these methods have the potential to provide previously unavailable detail on predator-prey interactions in these ecosystems." (2021): Predicting the distributions of regional endemic dragonflies using a combined model approach. *Insect Conservation and Diversity* 14(1): 52-66. (in English) ["1. Climate warming is predicted to have large effects on insects, yet several data shortfalls, including distributional information, impede effective conservation strategies. 2. Knowledge of species distributions is a critical component for assessing conservation need but is often lacking for endemic or rare taxa, especially invertebrates. 3. One approach to better inform this gap is by using species distribution modelling (SDM) to predict suitable habitat and guide field surveys. 4. Here, we combine the predictions of two machine learning algorithms, maximum entropy and Random Forest, to estimate the current and future distributions of two endemic dragonflies of the Ozark-Ouachita Interior Highlands region in the southcentral United States. 5. Current suitable areas predicted by both algorithms largely overlapped for each species, but different environmental variables were most important for predicting their distributions. Field validation of these models resulted in new detections for both species showing their utility in guiding subsequent field surveys. 6. Future projections under two climate change scenarios support maintaining current suitable areas as these are predicted to be strongholds for these species. Our results suggest that combining outputs of multiple species distribution models is a useful tool for better informing the distributions of geographically limited or rare species." **21665.** Clark, C.; Hossie, T.J.; Beresford, D.V. (2021): Density-dependent cannibalism in dragonfly nymphs (Odonata: Anisoptera) overwintering in temperate freshwater ponds. *Environmental Entomology* 50(6): 1483-1489. (in English) ["Density-dependent mortality by predation and cannibalism has been observed in aquatic insects such as dragonflies in response to shrinking habitat caused by summer drought. Winter conditions might also reduce the amount of livable habitat in temperate ponds and could augment rates of cannibalism. We hypothesized that cannibalism in dragonfly nymphs would increase in winter due to a seasonal decrease in available habitat caused by stratified lower oxygen levels leading to increased nymph density around pond edges. To determine whether cannibalism in nymphs is density-dependent and size-dependent (i.e., with smaller nymphs consumed) we experimentally manipulated nymph density in aquaria. To evaluate whether these patterns are observed in nature during the winter, we conducted field surveys for nymphs in two ponds across the fall and winter seasons. When nymphs were housed at different densities for 24 h, cannibalism was density-dependent, and only smaller nymphs were preyed upon. Our field surveys found that fewer nymphs were caught in the late winter sampling period (mixed-effects model,  $P < 0.001$ ), and that these were larger than nymphs caught in the fall, although both patterns were restricted to the deeper pond ( $P < 0.05$ ). Our results were consistent with the process we hypothesized, and the observed reduction in dissolved oxygen at the bottom of the deeper pond. The lack of significant changes to the relative abundance and size of nymphs in the shallower pond reveals that differences in pond characteristics can influence the degree to which winter conditions induce density-dependent cannibalism among dragonfly nymphs." **21667.** García-Pozuelo-Ramos, C. (2021): Primera observación de *Coenagrion mercuriale* (Charpentier, 1840), (Odonata: Coenagrionidae), en la provincia de Toledo (España central). *Boletín de la Sociedad Andaluza de Entomología* 31: 143-147. (in Spanish) ["This note reports the first observation of *C. mercuriale* in the province of Toledo, contributing

to broaden the knowledge of the odonatofauna of this province. The population referred to in this note is located in Illescas, at the source of La Viñuela (UTM 30T 424621/-4441444, datum ETRS89, 607 masl). This spring flows into the La Viñuela stream, which is generally dry, except in the section flooded by the spring. This has a small and fluctuating flow, depending on the rainy season. Even so, in the last 45 years it has never dried up. It is located outside any urban area and is part of a cereal-growing steppe environment with olive groves. The episodes of fire in the surrounding vegetation and the removal of sediment from the small stream, formed by the drainage of the basin, are repeated in it. The channel cleared of vegetation does not usually exceed 15 meters in length, nor 10 centimeters in depth. This little anthropized stream, and the small pool it forms, are populated by the helophytes *Typha* sp. and *Veronica* sp. Riparian vegetation includes a small group of trees, including *Alnus glutinosa* (L.) Gaertn and *Populus nigra* (L.). In the immediate vicinity there is also the rush *Scirpus holoschoenus* (L.) Soják and the abundant blackberry (*Rubus ulmifolius* Schott). Overall, the habitat is typical of the species: a small stream, with sunny parts where the insect develops, with abundant riparian and semi-aquatic vegetation (Torralla-Burrial et al., 2011; Dijkstra et al., 2020). The observations of *C. mercuriale* in the Viñuela spring are the following: On May 14, 2021, at 2:00 p.m., with a light wind, 19°C and an almost clear sky, 11 specimens were observed, 9 males and 2 females. Both were forming a tandem with their own males. The set was located in the sunny areas of the stream. On May 23, 2021, at 1:30 p.m., with a breeze, 25°C and clear skies, 5 males and 3 females were found. Tandems and copulation attempts were produced. Copulation lasted approximately 25 minutes, after which the tandem entered the tangle of vegetation, being observed laying eggs on a submerged stem of *Veronica* sp." **21668.** Glad, A.; Mallard, F.; Gourvil, P.-Y.; Goudiaby, A.; Bailleux, G. (2021): Chapitre 5. Évolution spatiale des leucorrhines et du cortège d'odonates associé des lagunes des Landes de Gascogne. In: Mallard F. (coord.), 2021. Programme les sentinelles du climat – Tome X: Réponses des espèces animales et végétales face au changement climatique et pistes d'actions de conservation de la biodiversité en région Nouvelle-Aquitaine, C. Nature: Le Haillan, Gironde, 724pp: 191-220. (in French)]["In order to help measure the impact of current climate change on biodiversity, odonates have been selected to serve as bio-indicators. Leucorrhines are particularly targeted by this study since these, with Boreo-montane affinities, are expected to be sensitive to climatic variations. In view of these elements, odonatologists agree that leucorrhine populations in the Landes de Gascogne are likely to become rare, or even disappear, if average temperatures increase. STELI transect type monitoring was set up for the imagoes (9 passages per site) as well as for the exuviae (three passages per site). Thus, 16 sites have been monitored since 2018 in the Landes and Gironde. The study of the microclimate shows that the sites are very similar climatically but that the annual variations are important. Variations in the abundance of species are observed on the sites, but the number of species counted each year is stable for each site. However, there are differences in terms of the composition of the processions between the sites studied. Taking into account new years of follow-up and new parameters could make it possible to better understand these differences. *Leucorrhinia albifrons* was observed in 6 lagoons in 2021 with 87 individuals (8 lagoons in 2020

with 180 individuals). *L. pectoralis* was not observed in 2020. The summers of 2018, 2019 and 2020 proved to be very hot, even scorching per period, while the year 2021 was characterized by high rainfall in spring and summer, therefore high water levels in the lagoons during the first passages with lower temperatures. The correlative distribution models created for 53 species of odonates present in the Nouvelle-Aquitaine region show varied responses to climate change. While some species are losing a large part of favorable habitats, others, on the contrary, are seeing their potential distribution extended to a large part of the region. The most important climatic variables for the species are degree-days above 30°C and rainfall, showing that the accumulation of high heat and drought can have a strong impact on these species." **21670.** Hermans, J.T. (2021): The Golden-ringed dragonfly (*Cordulegaster boltonii*) in the Dutch province of Limburg. A species severely endangered by worsening droughts Part 1: Distribution and habitat requirements. Naturhist. maandbl. 110(7): 151-164. (in Dutch, with English summary)]["*C. boltonii* is a distinctive and impressive dragonfly with black-and-yellow patterning. The female has a long, needle-like ovipositor. It is the only *Cordulegaster* species that occurs in a large part of western and northern Europe. It favours woodlands with small streams but also occurs along acidic running waters in open moorland and heath. The species is characteristic of swift clear running waters where sandy, silty or peaty debris on the bottom provides suitable hiding places for the larvae. The main flight period of the adults is from June to late July. *C. boltonii* is very rare in the Netherlands and has suffered a severe decline. One or two small, vulnerable populations remain in the province of Noord-Brabant, while the province of Limburg houses three important populations, at the Maalbeek, Meinweg and Haeselaarsbroek areas. These three populations are mainly situated in nature reserves, where groundwater feeds small streams and rivulets, mostly surrounded by woodland. The largest population of the *C. boltonii* in the Netherlands is found in the Meinweg National Park. This population is divided over four brooks: Bosbeek, Venbeek, Nartheciumbeek and Roode Beek. All habitats and populations of the Golden-ringed dragonfly in Limburg are briefly discussed." (Authors)] Address: Hermans, J.T., Hertestraat 21, 6067 ER Linne, The Netherlands. Email: jthermans21@gmail.com

**21671.** Hermans, J.T. (2021): The Golden-ringed dragonfly (*Cordulegaster boltonii*) in the Dutch province of Limburg. A species severely endangered by worsening droughts. Part 2: Ecology and threats. Naturhist. maandbl. 110(9): 207-

217. (in Dutch, with English summary) ["The ecology, biology and behaviour of larvae and adults of *C. boltonii* are discussed, based on the findings of recent research, which are compared with the available literature. The research particularly concerns the investigation of a population along the Roode Beek brook in the Meinweg National Park, which has been carried out since 2015. The main goal was to get more information about the oviposition sites and the presence of larvae. Oviposition was observed three times at small seepage streams where they flow into the Roode Beek. Most larvae were found in shallow places along the banks of the Roode Beek, where sand, fine mud and detritus had accumulated behind stones or wood, in meanders or where banks have collapsed. The article ends with an overview of threats, and presents advice about necessary measures to reduce habitat damage. One of the main threats to *C. boltonii* is the increasing drought due to climate change. Groundwater supplies to some seepage streams are diminishing, and hence a rivulet like the Bosbeek brook falls dry every year for several weeks to months, which may cause the local population to go extinct. Conversely, seepage streams along the Roode Beek may become inaccessible as ovipositing sites if the water level is raised as a consequence of dam-building by Beavers (*Castor fiber*). Some populations of *C. boltonii* are very small and vulnerable, e.g. those at the Haeselaarsbroek site and along the Venbeek brook (Meinweg), where local threats can easily wipe out these populations. The province of Limburg harbours the largest and therefore most important populations of this species in the Netherlands. Improved protection of their breeding sites is necessary to give this beautiful dragonfly a brighter future." (Author)] Address: Hermans, J.T., Hertestraat 21, 6067 ER Linne, The Netherlands. **21672.** Liu, Y.; Wang, Q.; Wu, Y.; Yang, C.; Luo, X.; Mai, B. (2021): Bioaccumulation of short- and medium-chain chlorinated paraffins in aquatic insects from an e-waste recycling site. *Environmental Chemistry* 40(10): 3037-3045. (in Chinese, with English summary) ["The concentrations of short-chain chlorinated paraffins (SCCPs) and medium-chain chlorinated paraffins (MCCPs) in aquatic insects and water from an electronic waste recycling site in Longtang Town, Qingyuan County of Guangdong Province were determined using gas chromatographic-mass spectrometric (GC/MS). The results showed that  $\Sigma$ SCCPs and  $\Sigma$ MCCPs concentrations in aquatic insects were range from 52 ng·g<sup>-1</sup> to 410 ng·g<sup>-1</sup> and 40 ng·g<sup>-1</sup> to 740 ng·g<sup>-1</sup> wet weight (ww), respectively. Damselfly larvae have the highest level of  $\Sigma$ SCCPs and the highest level of  $\Sigma$ MCCPs was found in waterbeetles. Principal component analysis was conducted, and species-specific different composition patterns of SCCP and MCCP congeners were seen among aquatic insects. This may be due to differences in diet, feeding habits and bioaccumulation ability among different species. Bioaccumulation factor (BAF) values of  $\Sigma$ SCCPs and  $\Sigma$ MCCPs in aquatic insects were range from 3.27 to 3.79 and 2.62 to 3.34, respectively. BAFs of  $\Sigma$ SCCPs and  $\Sigma$ MCCPs in dragonfly larvae were lower than that of  $\Sigma$ PCBs (4.87) and  $\Sigma$ PBDEs (4.65), suggesting the bioaccumulation potential of SCCPs and MCCPs was below that of PCBs and PBDEs in aquatic insects. Significant negatively correlations ( $P < 0.05$ ) were observed between BAF values and octanol-water partition coefficient ( $K_{OW}$ ) and carbon-chain length ( $C_{10-17}$ ) of SCCPs and MCCPs. Those results indicated that the physicochemical properties of compounds affected the bioaccumulation of SCCPs and MCCPs by aquatic insects, and homologues with low  $K_{OW}$  and low carbon chain length were preferred to bioaccumulation." **21674.** Moore, M.P.; Martin, R.A. (2021): Natural selection on adults has trait-dependent consequences for juvenile evolution in dragonflies. *The American Naturalist* 197(6): 677-689. (in English) ["Although natural selection often fluctuates across ontogeny, it remains unclear what conditions enable selection in one life-cycle stage to shape evolution in others. Organisms that undergo metamorphosis are useful for addressing this topic because their highly specialized life-cycle stages cannot always evolve independently despite their dramatic life-history transition. Using a comparative study of dragonflies, we examined three conditions that are hypothesized to allow selection in one stage to affect evolution in others. First, we tested whether lineages with less dramatic metamorphosis (e.g., hemimetabolous insects) lack the capacity for stage-specific evolution. Rejecting this hypothesis, we found that larval body shape evolves independently from selection on adult shape. Next, we evaluated whether stage-specific evolution is limited for homologous and/or coadapted structures. Indeed, we found that selection for larger wings is associated with the evolution of coadapted larval sheaths that store developing wing tissue. Finally, we assessed whether stage-specific evolution is restricted for traits linked to a single biochemical pathway. Supporting this hypothesis, we found that species with more wing melanization in the adult stage have evolved weaker melanin immune defenses in the larval stage. Thus, our results collectively show that natural selection in one stage imposes trait-dependent constraints on evolution in others." **21675.** Sandu, C. (2021): The synthesis, characterization, and antimicrobial analysis of copper nanoparticle doped graphene-matrix material. MSc. thesis, Materials Science and Engineering, University of California, Riverside: IX + 44 pp. (in English) ["Pathogenic microbes pose a serious threat to public health. Specifically, antibiotic abuse is creating new strains of antibiotic resistant bacteria and creating a public health crisis. There are many health risks associated with the overuse of antibiotics. Their broad bactericidal effects can disrupt an individual's symbiotic relationship with beneficial bacteria [1]. Furthermore, antibiotics can be toxic to human and create serious side effects from skin sensitivity to organ failure [2]. In addition to some microbes' inherent antibiotic resistive genes, microbes evolve and mutate quickly thereby quickly producing antibiotic resistance. Antibiotic sensitive bacteria are able to acquire antibiotic resistance genes via horizontal gene transfer, causing the organism to then become resistant to specific classes of antibiotics, further

complicating treatment [3]. It is therefore of great interest in the scientific community to examine other methods of infectious disease prevention and treatment. Since the introduction of the GAIN Act in 2012, there has been new stimulated interest in the battle against bacteria, however no significant strides have been made yet [3]. Growing resistance to antibiotics continues to be a devastating public health problem. Attempts to tackle the problem involve research teams at the Massachusetts Institute of Technology (MIT) who utilize a type of phage therapy to target antibiotic resistance genes directly via the CRISPR (clustered, regularly interspaced short palindromic repeats) Cas9 gene editing technology [3]. The engineered phage (a phage is a virus which infects bacteria) delivers the CRISPR Cas9 RNA tool into resistant bacteria, resulting in genomic expression of the CRISPR Cas9 tool which then programs the bacteria to either become sensitive to drugs or to undergo lysis [4]. The CRISPR Cas9 tool encodes a DNA nuclease (DNA degrading enzyme) that recognizes and cleaves specific genes which code for antibiotic resistance [3]. The phage tool selectively kills bacteria with chromosomally integrated resistance genes, while bacteria with plasmid-integrated resistance genes become sensitive and continue to survive, adding a selective pressure which favors sensitive bacteria to resistant bacteria [4]. The surviving bacteria can then be effectively treated with antibiotics. Ironically, the CRISPR Cas9 system is a part of bacteria's natural immune defense against phage attacks [3]. While this tool seems very promising in research, gene therapy is very difficult to implement and apply. Furthermore, it does not prevent the development of antibiotic resistance; there will always be too great a pressure for bacteria to evolve further resistance and survive. The common solution to prevent pathogenic infections tends to rely on organic disinfectants or drugs, however this solution may lead to drug resistance and can harm the environment. Since about 80% of microbes are transmitted through surface contact, another approach to preventing the spread of harmful microbes is to develop surface technology which not only is bactericidal, but also overcomes the concern of drug resistance and is safe environment [5]. Naturally occurring structures can serve as templates for such bactericidal applications. It has been reported that the nanoscale structure of dragonfly wings may serve as a bactericidal surface [6]. Their natural structure can rupture adjacent microbial cells thereby killing and preventing bacterial growth. These organic templates can be reproduced synthetically and applied to the development of microbicide technologies. It has been observed that the interaction between synthetic nanoparticles and biological cells can be enough to cause cell lysis and death without any other external forces, chemical nor mechanical [7]. This idea is a promising opportunity for the development of novel bactericidal surface technologies which are effective and safe. Nanomaterials have the capacity to enhance the field of science that relies on public health and sterility, from water treatments, medical devices, and food processing [8]. Metal oxide nanoparticles such as zinc oxide and copper oxide exhibit antimicrobial behavior at different degrees in a variety of materials, forms, and morphologies [6]. The functional activity of nanoparticles is affected by material size, shape, and morphology. Analyzing and characterizing the effects of nanoparticles of varying properties is of current interest in research for biomedical and industrial applications. Medical devices may harbor harmful bacteria which can be deadly for an immune compromised or elderly patient [2]. Bacteria can produce highly resistant biofilms which allow them to survive on such surfaces for long lengths of time. *Staphylococcus aureus* and *Escherichia coli* are commonly acquired hospital infections that may cause deadly bloodstream, urinary tract, lung, heart,

and skin infections [9]. These microbes can be very resistant to conventional antibiotics, requiring the need for novel methods of reducing microbial infections. Metallic nanoparticles have been reported to show antimicrobial activity especially towards pathogenic bacteria such as *E. coli* and *S. aureus* [7] [10]. Antimicrobial effects of the nanoparticle depend on the particle size, stability, and concentration; with the right preparation and application, these particles can hold a promising future in safely reducing infection. Furthermore, graphene based nanomaterials show promising development in the antimicrobial community [6]. Graphene materials have been shown to interact with biomolecules such as proteins, nucleic acids and membranes; these material-microbial interfaces are worthy of analysis in order to further understand the beneficial application of such materials [6]. Here, an economical, scalable and facile sol-gel method to synthesize a metallic copper nanoparticle embedded carbon matrix material (CMAT) is described. Furthermore, CMAT's antimicrobial potential is investigated. CMAT possesses hydrophobic properties as well as high flame resistivity and a high absorption ability of oils. These properties generate a spectrum of prospective CMAT applications ranging from environmental decontamination, biomedical antimicrobial coatings, storage solutions, and air filters." **21681.** Calvão, L.B.; Siqueira, T.; Faria, A.P.J.; Paiva, C.K.S.; Juen, L. (2022): Correlates of Odonata species composition in Amazonian streams depend on dissimilarity coefficient and oviposition strategy. *Ecological Entomology* 47(6): 998-1010. (in English) ["Environmental and spatial heterogeneity affects the distribution of aquatic insects, determining or influencing the variation in local species composition. Odonata have different strategies for oviposition site selection that depend on environmental conditions. However, Land Use and Land Cover (LULC) can reduce the availability of suitable sites for Odonata oviposition through environmental homogenization. We investigated the relationship between environmental and spatial heterogeneity and variation in species composition of Odonata with different oviposition strategies (endophytic, epiphytic and exophytic) in Amazonian streams in a gradient of LULC. We used the Jaccard and Bray-Curtis coefficients and the Manhattan distance to estimate a continuum of variation in species composition. Variation in the composition of endophytic and epiphytic species was explained by spatial heterogeneity. Using abundance data and the Manhattan distance, we found a relationship between variation in species

composition and environmental heterogeneity. Endophytic species composition was related to perch heterogeneity, while exophytic species composition was related to perch and canopy cover heterogeneity. Exophytic and endophytic species could be used in biomonitoring as they respond to specific environmental predictors and because exophytic species do not have spatial patterns across the landscape. Different dissimilarity coefficients provide complementary information about the responses of multispecies communities to land use, as some will represent strong effects (presence-absence indexes) while others will represent more subtle effects (abundance-based indexes). Land use can increase the environmental heterogeneity of some predictors (perches and canopy cover). Physical changes in streams such as hydro-morphological alterations can modify specific habitats, affecting oviposition strategies and supporting tolerant species." **21683.** Hermans, J.T. (2022): The Banded darter (*Sympetrum pedemontanum*) in the Dutch province Limburg (Odonata: Libellulidae). Rise and demise of a pioneer species. *natuurhistorisch maandblad* 111(6): 145-155. (in Dutch, with English summary) ["This tiny, but eye-catching, dragonfly with characteristic brown bands near the tip of each wing in both sexes, has a wide distribution area that extends from western Europe to Japan. The Banded darter is rare over large areas. In Europe it is widely distributed, with a continuous range from northern Italy across central Europe to northern Germany and the Netherlands. Since the middle of the 20th century, it has expanded its range to the low-lying parts of Europe, colonising large parts of Germany and becoming regionally common in the Netherlands (provinces of Noord-Brabant and Overijssel). The first individuals in Limburg were seen in 1982. Since then, the numbers of observed Banded darters have increased in Limburg, though most records have concerned wanderers. It is only at two locations, near Weert and Montfort, that populations were established in recent decades. The Banded darter favours habitats with emergent vegetation which is neither too tall nor too dense, such as those present in flood plains of lakes and streams. Presently, many of these natural habitats have been altered by human activities, and their water regime changed. Today the Banded darter occurs mostly in man-made habitats like slow-flowing ditches, canals, quarries or fish pond complexes. In the Netherlands, it is mainly found along man-made ditches, usually surrounded by open agricultural land. Unfortunately, both populations of the Banded darter in Limburg have vanished. The main reason for the decline and local extinction in Weert and Montfort was the management of the water regime practiced by the regional water board. Activities like cleaning up ditches or changing the water level were often carried out during the main flight and reproduction period of the Banded darter. This caused a collapse of the populations from which they were not able to recover." (Author)] Address: Hermans, J.T., Hertestraat

**21685.** Maurice, N. (2022): Les zones de rejet végétalisées de grande taille: observation et modélisation. Génie des procédés. PhD thesis, Sciences et Ingénierie des Molécules, des Produits, des Procédés et de l'Énergie Laboratoire Réactions et Génie des Procédés, Université de Lorraine: 288 pp. (in French, with English summary) ["Despite regulations, the anthropic pollution (nitrogen, phosphorus, trace elements (TE), pharmaceuticals, faecal coliforms, etc.) related to urban wastewater (wastewater treatment plant (WWTP) and urban stormwater runoff (USR)) is not negligible because it weakens aquatic ecosystems and it can be harmful for human health. In order to minimize its impact, the amount of pollutants must be reduced. Wetlands are wonders of nature and are often describe as Earth's kidney due to their capacity to filter pollutants, so they would be interesting candidates. Unfortunately, they have been in decline for several centuries (13 % of 17th century wetlands still remain at the beginning of the 21st century. This is why in 2011 the AZH-UREV project (Aménagement d'une Zone Humide à Reims pour l'Épuration et le Vivant) was born. This project allowed the implementation of a large scale (6 ha) surface-flow constructed wetland (CW) (first water supply in 2017) at the outlet of the Grand Reims WWTP (capacity of 450,000 population equivalents). It is composed of three basins of 2 ha fed in parallel, by part of the effluents of the WWTP (10%), or by the USR (25 %) during rainy events, to improve the quality of these waters before their discharge into the environment. Initially these basins were different because of the quantity and type of emergent vegetation planted (*Phragmites australis*, *Glyceria maxima*, *Scirpus lacustris*). Today, there is no more difference because the proportion of planted plants has drastically decreased, *P. australis* being the only species still present, to the benefit of opportunistic species (submerged or floating). These basins were able to reduce the concentration of many compounds through various processes, oxidation/reduction (nitrogen, TE), precipitation /coprecipitation with carbonates and hydrogen sulphide (TE), biodegradation or photodegradation (pharmaceuticals, faecal coliforms), adsorption to sediments (TE and pharmaceuticals), or uptake by plants (nitrogen and phosphorus). Bacteria and aquatic plants are responsible for most of these mechanisms. Thus, the basins are better able to remove pollutants in summer due to the higher temperatures

and longer days. Bacterial activity has a direct effect on pollutants and the bacterial genera found at the outlet of the CW take part in the nitrogen, sulphur and carbon cycles. Whereas the effect of plants is more indirect by promoting bacterial development (source of carbon and energy, support for the biofilm) and by bringing organic matter (adsorption site for pollutants) into the sediment during senescence. These plants are also a source of food (submerged or floating plants), a habitat and/or nesting area (emergent plants) for many wild animals, whether they are considered "harmful" (muskrat or coypu) or not (swan, coot, duck, grebe, frog, dragonfly, damselfly, gammarid, snail, etc.). Therefore, this CW offers two advantages: it improves the quality of urban water before it is discharged into the receiving environment and it provides food and shelter for many animal species that depend on this type of environment. The interconnection of the multiple variables measured has been transcribed into a conceptual model. These results are encouraging for a possible extension of the CW." (Author) Records of *Coenagrion scitulum*, *Ischnura elegans*, *Crocothemis erythraea*, *Libellula quadrimaculata*, and *Aeshna mixta* are documented.] Address: not stated

**21686.** Petermann, J.S.; Gossner, M.M. (2022): Aquatic islands in the sky: 100 years of research on water-filled tree holes. *Ecology and Evolution* 12(8).e9206: 17 pp. (in English) ["Water-filled tree holes are unique ecosystems that may occur high up in tree crowns and are essentially aquatic islands in the sky. Insect larvae, mesofauna, and other organisms colonize the waterbodies and feed on the accumulating detritus. Water-filled tree holes are not only important habitats for these species but have been used as model systems in ecology. Here, we review more than 100 years of research on treehole inhabiting organisms and show that most studies focus on selected or even single species (most of which are mosquitoes), whereas only few studies examine groups other than insects, especially in the tropics. Using a vote counting of results and a meta-analysis of community studies, we show that the effects of tree-hole size and resources on abundance and richness were investigated most frequently. Both were found to have a positive effect, but effect sizes were modulated by site-specific environmental variables such as temperature or precipitation. We also show that parameters such as the height of the tree holes above ground, tree-hole density, predation, and detritus type can be important drivers of organism abundance or richness but are less often tested. We identify several important research gaps and potential avenues for future research. Specifically, future studies should investigate the structure, functions, and temporal dynamics of tree-hole food webs and their cross-system interactions, for example, with terrestrial predators that act as a connection to their terrestrial surroundings in meta-ecosystems. Global observational or experimental tree-hole studies could contribute pivotal information on spatial variation of community structure and environmental drivers of community assembly. With a better understanding of these unique aquatic habitats in terrestrial ecosystems, natural and artificial tree holes can not only serve as model systems for addressing fundamental ecological questions but also serve as indicator systems of the impacts of environmental change on ecosystems." **21688.** Roy, S.; Singhamahapatra, A.; Nayak, A.K. (2022): Observations of Odonata (Insecta) from heterogeneous patches of Bankura district with first report of *Microgomphus torquatus* (Selys, 1854) from West Bengal state of India. *Journal of Animal Diversity* 4(2): 121-151. (in English) ["The diversity and heterogeneity of Odonata was studied at 10 sites located across almost all parts of the Bankura district (except northwestern and northeastern boundary regions), in the state of West Bengal, India from July 2015 to June 2022. Analysis of variance and rarefaction was performed to study the  $\beta$ -diversity and compare the taxa abundance at the sites to understand the heterogeneity of Odonata observations. The seasonality of the species and their site-wise distribution were also studied. A total of 74 odonate species belonging to eight families, represented by 46 genera were recorded. The study adds 17 species to the known Odonata fauna of Bankura district, including the addition of *M. torquatus* to the fauna of West Bengal. It also confirms the addition of *Ictinogomphus kishori* to the known Odonata fauna of West Bengal, which has been confused with and misidentified as *Ictinogomphus distinctus* for long, the latter being described from the state of West Bengal and is also found in the region adjacent to the study area. Most recorded odonates belonged to the family Libellulidae (29 species), followed by Coenagrionidae (19 sp.), Gomphidae (9 sp.), Platycnecidae (6 sp.), Aeshnidae (5 sp.), Macromiidae (3 sp.), Lestidae (2 sp.), and Chlorocyphidae (1 sp.). Species diversity and abundance assessments are essential for conserving the habitats of the restricted and endemic (to peninsular India) species." **21689.** Sadler, I.G. (2022): Functional feeding groups responses to fertilization and Largemouth Bass in southern Illinois experimental ponds. MSc. thesis, Southern Illinois University Carbondale: VIII + 98 pp. (in English) ["Eutrophication is a pervasive issue in freshwater systems. However, the effects of nutrient and piscivorous fish additions on freshwater invertebrate diversity, functional feeding groups (FFGs), and stoichiometric ratios are difficult to predict. These relationships are important to quantify in small lentic systems where nutrients like nitrogen (N) and phosphorus (P) and piscivorous fish are frequently added to enhance sport fishing. To study this, I administered 2 treatments, fertilization and Largemouth Bass (*Micropterus salmoides*, LMB) additions, to 28 experimental ponds in a fully crossed experimental design and estimated benthic invertebrate biomass and diversity before and after administering the treatments. I also sought to improve my understanding of the relationships between specific FFGs and nutrients by measuring the elemental

composition of coarse (CPOM) and fine particulate organic matter (FPOM) and invertebrates before and after administering the treatments. Because consumer stoichiometric ratios are shaped by their environment and life histories, which can be governed by their functional role and/or evolutionary history, I was interested in determining whether my treatments and invertebrate FFG or taxonomic group better explained variation in invertebrate elemental nutrient content. I verified that fertilization altered nutrient availability in the ponds by measuring the nutrient content and biomass of FPOM and CPOM. FPOM P concentrations ( $\mu\text{gP/L}$ ) were higher in ponds that received fertilizer ( $f= 4.84(1,22)$ ,  $P= 0.03$ ) and LMB ( $f= 5.26(1,22)$ ,  $P= 0.04$ ). Fertilization also increased CPOM biomass ( $f= 8.95(1,21)$ ,  $P=0.007$ ). I found that Shannon diversity was increased or better maintained in ponds that received the fertilizer treatment ( $f= 6.54(1,20)$ ,  $P= 0.02$ ). Predator ( $f= 4.47(1,21)$ ,  $P= 0.047$ ) and GC ( $f= 5.05(1,21)$ ,  $P= 0.04$ ) biomass increased after the addition of LMB to ponds. For scraper biomass, there was a significant interaction between fertilization and LMB additions such that LMB additions increased scraper biomass, but fertilization counteracted this effect ( $f= 4.93(1,17)$ ,  $P= 0.04$ ). Fertilization increased the biomass of FCs ( $f= 6.64(1,9)$ ,  $P= 0.03$ ) but decreased shredder biomass ( $f= 5.71(1,6)$ ,  $P= 0.004$ ). In control ponds, SIMPER analysis revealed that a decrease in the predatory crayfish Cambaridae accounted for the greatest differences between pre and post sampling, followed by Odonates. Odonates and gastropods caused the greatest shifts in both fertilized and LMB ponds. The difference between fertilized and LMB ponds was that Coenagrionidae biomass did not increase and Dytiscidae did in fertilized ponds. Invertebrate elemental stoichiometric ratios were not affected by our treatments, which supports the assumption of homeostasis in ecological stoichiometry models. However, nutrient ratios varied across both FFG and taxonomic group, likely because of varying diets and life history strategies. Model comparison suggests that order best explained most of the variation in elemental ratios across invertebrates; however, FFG and order best explained invertebrate %P content and class and FFG best explained %C content. We found that predators, specifically Odonata and Hirudinea, have higher N content than other FFGs, and gathering-collectors (GCs), specifically Ephemeroptera, have a higher P content. Predators may have a higher N content because they feed on higher dietary N than herbivores. I determined that order was the best predictor of elemental nutrient content; however, FFG is also an acceptable predictor, which is important because identifying species to FFG is more rapid than taxonomic identification. In conclusion, humans are heavily altering the availabilities of N and P in freshwater ecosystems; thus, knowing the stoichiometric contents of individuals (at the order or FFG level) can facilitate predictions about how communities respond to nutrient additions. Furthermore, understanding how invertebrate communities respond in their functional makeup is of importance.] Address: not stated

**21690.** Samarasinghe, L.V. (2022): Observations on underwater oviposition of *Pseudagrion microcephalum* (Odonata: Coenagrionidae). *Sri Lanka Naturalist* 11: 18-20. (in English) ["The oviposition behavior of a pair of *P. microcephalum* was observed in the Bellanvila-Attidiya sanctuary during the months of June and July 2021. This species associated with a medium-size stream, and shrubs as well as grasses are found along its banks (Figure 1). The behaviors were observed for six days by naked eye and the photographs were taken using the Redmi 7 mobile phone camera (dual camera setup of 12MP + 2MP in the rear). A pair was observed flying near the canal and they were in tandem position and occasionally

landed on foliage of the bushes near the banks of the stream (Figure 2). Then they started mating and forming the heart wheel position for several minutes. After that the female laid down on a leaf on the surface of the water and prepared to lay eggs. Then slowly moved into the water, and few minutes later the male floated into the water (Figure 4). They remained in the water for about 15 minutes, during that time the female continued to lay eggs. This was observed for a few days but the heart wheel position was seen only two days. In this observation, the male separates in the tandem position in the water, but the female continues to lay eggs under the water (Figure 3), and when the female returns from the water, the male again caught in the tandem position. During the observed period, they showed an average submergence time of 8.33 minutes, with a minimum of three (3) minutes and a maximum of 27 minutes." **21691.** Savard, M. (2022): Découverte d'une population de l'amphiagrion rougeâtre, *Amphiagrion saucium* (Odonata: Coenagrionidae), au Saguenay–Lac-Saint-Jean, une espèce vulnérable inféodée aux prés sourceux. *Le Naturaliste canadien* 146(1): 17-28. (in French) ["The discovery of a population of *Amphiagrion saucium* in the Parc de la Rivière-du-Moulin, an urban park in the city of Saguenay (Québec, Canada), represents a new addition to the known Odonata fauna of the lowland enclave of the Saguenay–Lac-Saint-Jean region. This population occupies a series of spring-fed marshes along the bed of an old meander exposed following a landslide during the Saguenay flood in 1996. Adults specifically use pools dominated by variegated scouring-rush (*Equisetum variegatum*). Their number declines rapidly from mid-July, which coincides with the start of the breeding season of *Lestes disjunctus* and *Sympetrum obtrusum*. At the northern limit of its range, the presence of beaver activity likely plays an important role in the population dynamics of *A. saucium*. In Québec and other inhabited regions of eastern North America, its specialized habitat, its low dispersal rate and its sensitivity to anthropogenic threats make this species vulnerable. In urban areas, it could benefit from improved stormwater management incorporating holding ponds. The abundance and phenology of all 15 species of Odonata found breeding in the study area in 2020 and 2021 are provided." (Author)] Address: Email: michel.savard@ssss.gouv.qc.ca

**21692.** Vilenica, M.; Katar, M.; Koren, T.; Štih Koren, A. (2022): Dragonfly fauna (Insecta: Odonata) of Papuk Nature Park, Croatia. *Nat. Croat.* 31(2): 351-364. (in English, with Croatian summary) ["Odonata is an amphibious insect order constituting an important link between aquatic and terrestrial habitats. Members of the group are widely used as bioindicators of freshwater habitat health. The Odonata fauna of a total of 44 freshwater habitats in the wider area of Papuk Nature Park was investigated in the spring and summer of 2017 and 2019. Twenty-three lotic and 21 lentic habitats were included in the study. We recorded 39 Odonata species, with a higher species richness (i.e. 35) documented at lentic than at lotic habitats (i.e. 16 species). *Calopteryx virgo* was the most widespread species in the area, while *Aeshna affinis*, *Epitheca bimaculata*, and *Sympetrum meridionale* were the rarest. The most frequently recorded species at lentic sites were *Platycnemis pennipes*, *Coenagrion puella*, and *Ischnura elegans*, while *Calopteryx virgo*, *Onychogomphus forcipatus*, and *Cordulegaster bidentata* were the most common species in lotic habitats. Although we recorded numerous

anthropogenic pressures in freshwater habitats in the Park, 11 recorded species are of conservation concern, which highlights the conservation value of aquatic habitats in the study area. Our results represent the first Odonata checklist of Papuk Nature Park, and as such, they are an important contribution to our knowledge of the Odonata fauna and species distribution in Croatia." **21693.** Zheng, H.; Mofatteh, H.; Habicsek, M.; Abdolhamid, A.; Akbarzadeh, M. (2022): Dragonfly-Inspired Wing Design Enabled by Machine Learning and Maxwell's Reciprocal Diagrams. *Research Square* 2207635: 15 pp. (in English) ["This research relates the morphology of the structural network of a dragonfly wing to the static equilibrium of forces using a geometry-based equilibrium method known as graphic statics. It then develops machine learning algorithms to generate similar structural networks for designing airplane wings using the in-plane equilibrium information of the dragonfly wing. This approach can generate a structural network in equilibrium with no prior information related to the topology or geometry of the network just by receiving the boundary geometry of the wing. This research shows that the internal network of the dragonfly wing can be assumed to be compression or tension-only system on a 2D plane. Consequently, another diagram is constructed to represent the geometric equilibrium of the forces in the initial network. This diagram is called the force diagram in the context of graphic statics. A new wing geometry is reconstructed from the force diagram, with its members sized according to the force magnitude. Both form of the network and its force diagram are used to train machine learning models for the generation of the structural network of the wing. The developed methodology is also capitalized to generate microstructural patterns inspired by other species with networks of convex polygons. We numerically and experimentally examine one application of this method in designing the cellular core, 3D printed by fused deposition modeling, of the airfoil wing, which suggests up to 25% improvement in the out-of-plane stiffness. Our findings suggest this ML-assisted approach enables leveraging million years of evolution in nature to develop the next generation of high-performance, lightweight structures." **21694.** Akamagwuna, F.C.; Odume, O.N.; Richoux, N.S. (2023): Agricultural disturbance affects taxonomic and functional diversity of Afrotropical macroinvertebrate composition in a South African river system. *Environmental and Sustainability Indicators* 18, 100251: 12 pp. (in English) ["Highlights: • We identified indicator taxa and indices of agricultural pollution. • Macroinvertebrate communities responded differentially to agricultural pollution. • *Lymnaea* spp., *L. columella*, *Appasus* spp., *Biomphalaria* spp., *Trithemis* spp. and *Oligochaeta* were tolerant to agriculture. • *Afrotiptilum* spp., *P. piscis*, *B. harrisoni*, *Potamonautes* spp. and *Pseudocloeon* spp. were sensitive to agriculture. Abstract: Developing species-level biomonitoring tools to monitor riverine systems threatened by anthropogenic pollution, including local agricultural activities in the Afrotropical region, remain a critical challenge. Here we explored the utility of taxonomic-based (diversity, richness, and composition) as well as functional-based (functional diversity) indices to examine the effects of

agricultural disturbance on macroinvertebrate communities in the Kat River, Eastern Cape Province of South Africa. We collected physicochemical parameters and macroinvertebrates from eight sites delineated into four land-use categories (highly impacted, HIC; impacted category, IC; moderately impacted, MIC and least impacted, LIC) using agricultural land cover. We recorded 70 macroinvertebrate taxa belonging to 49 families and 48 genera in the Kat River. Redundancy analysis (RDA) and Pearson correlation analysis revealed that species of Lymnaeidae, Belostomatidae, Planorbidae and Libellulidae families and class Oligochaeta were tolerant to agricultural disturbance, as they were dominant in the highly impacted sites and were significantly associated with high salinity, temperature, total dissolved solids (TDS), flow velocity and nutrients. Conversely, species of Baetidae, Caenidae and Potamonautidae were negatively associated with the highly impacted sites and high salinity, temperature, and nutrients. On the other hand, taxonomic indices showed more sensitivity to indicators of agricultural pollution than functional indices, with taxon richness, Shannon index, Simpson's index and Margalef's index declining significantly in the highly disturbed sites ( $p < 0.05$ ). They were negatively associated with high electrical conductivity, large river width, and high nitrite and nitrate concentrations; hence they were identified as indicator metrics sensitive to agricultural pollution. Overall, our study revealed that agricultural disturbance could differentially affect the structure and function of macroinvertebrates, and indicator taxonomic and functional indices were identified for long-term monitoring of rivers that drain agricultural landscapes." **21695.** Akindele, E.O.; Adedapo, A.M.; Fagbohun, I.R.; Akinpelu, O.T.; Aliu, O.O.; Kowobari, E.D. (2023): Macroinvertebrate metric indicators should be juxtaposed with the community conservation index as ecological tools for conservation evaluation of pristine freshwater ecosystems. *Biologia* 78: 1067-1078. (in English) ["The ecological significance of freshwater ecosystems for conservation in the temperate zone has been determined by aquatic biologists using a variety of ecological techniques. One such tool is the Community Conservation Index (CCI), which was primarily developed in Britain but is also recommended for international use. The current study intends to further test the CCI's applicability and its sensitivity in identifying freshwater systems of high conservation importance. The pristine condition of three natural monument (Arinta, Ekor, and Oowu waterfalls) streams was evaluated in this study using the macroinvertebrate metric indicators, and the results were compared with their CCIs. The relative compositions of stress-sensitive species, facultative species, functional feeding guilds (FFGs), and modes of locomotion or microhabitat preference (ML/MP) were selected as the macroinvertebrate metrics. The fauna was dominated by the taxonomic group EPT (Ephemeroptera, Plecoptera, Trichoptera), with the highest EPT-related metrics found at Oowu Waterfalls. Ironically, because a vulnerable species (i.e. *Pentaplebia stahli*) is present there, the Ekor Waterfalls, which had the lowest values for the EPT-related metrics, had the highest CCI. Although both the CCI ( $> 20$ ) and macroinvertebrate metrics suggest that the three sites had high conservation value, the CCI proved to be more goal-oriented in determining the conservation value of pristine freshwater ecosystems. In light of the findings of this study, it is recommended that the CCI be utilized in conjunction with macroinvertebrate metric indicators for studies of a similar nature, particularly in Afrotropics' protected

and pristine sites that are a potential refuge for rare and threatened species." (Authors)] Address: Akindele, E.O., Dept Zoology, Obafemi Awolowo Univ., Ile-Ife, Nigeria

**21697.** Amrulloh, M.F.F.; Arifin, M.; Aini, N.; Shinta, A.; Nihayah J, A.Z. (2023): Keanekaragaman Capung (Odonata) di Kawasan Sungai Gendol, Jambon, Ngemplak, Sleman, Yogyakarta Pasca Banjir Lahar Dingin Gunung Merapi. *Science and educational Journal* 1(1): 37-45. (in Indonesian) ["The research aims to determine the diversity (Odonata) in the Kali Gendol area after the cold lava flood of Mount Merapi. The research was conducted in November 2015 for  $\pm 10$  hours of total observation. The method used is the point count method, namely following the transect line accompanied by making 10 observation points with a distance between points of 50 m, at each point dragonflies are caught with insect nets at a radius of 10 m from the observation point for 15 minutes. Captured dragonflies are further identified using determination books or research journals. The calculation of the Dragonfly Diversity Index was carried out using the Shannon-Wiener ( $H'$ ) formula. The results showed that there were 13 species of dragonflies found, 6 species from 2 families of the order Anisoptera with 25 individuals and 8 species from 4 families of the Zygoptera order with 359 individuals. The highest relative abundance was *Libellago lineata* (32.81%), followed by *Pseudagrion pruinatum* (30.21%), *Copera marginipes* (20.31%). The diversity index of dragonflies obtained in the Kali Gendol area, Jambon, Ngemplak, Sleman, Yogyakarta after the cold lava flood of Mount Merapi was 0.71. This indicates that the diversity of dragonflies in the Kali Gendol area is relatively low due to several factors including biotic and abiotic factors." **21698.** Assefa, W.W.; Eneyew, B.G.; Wondie, A. (2023): Macroinvertebrate assemblages along a gradient of physicochemical characteristics in four riverine wetlands, Upper Blue Nile basin, Northwestern Ethiopia. *Environmental Monitoring and Assessment* 195, Article number: 643: (in English)

["This study aims to examine the physicochemical variables that influence macroinvertebrate assemblages in wetlands of the Fetam River watershed. Macroinvertebrates and water quality samples were collected from 20 sampling stations across four wetlands between February and May 2022. Principal component analysis (PCA) was used to elucidate the physicochemical gradients among datasets and canonical correspondence analysis (CCA) was applied to explore the relationship between taxon assemblages and physicochemical variables. Aquatic insects such as Dytiscidae (Coleoptera), Chironomidae (Diptera), and Coenagrionidae were the most abundant families, and they comprised 20–80% of the macroinvertebrate communities. As demonstrated by cluster analysis, three site groups including slightly disturbed (SD), moderately disturbed (MD), and heavily disturbed (HD) sites were identified. PCA showed a clear separation of slightly disturbed sites from moderately and highly impacted sites. Differences in physicochemical variables, taxon richness and abundance, and Margalef diversity indices were observed along the SD to HD gradient. Phosphate concentration was an important predictor that influenced richness and diversity. The extracted two CCA axes of physicochemical variables accounted for 44% of the variability in macroinvertebrate assemblages. Nutrient concentration (nitrate, phosphate, and total phosphorus), conductivity, and turbidity were the main drivers of this variation. This suggested the need for sustainable wetland management intervention at the watershed level, ultimately benefiting invertebrate biodiversity." (Authors)] Address: Assefa, W.W., School of Fisheries & Wildlife, Dept of Biology & Blue Nile Water Institute, Bahir Dar University, Bahir Dar, Ethiopia

**21699.** Banda, K.; Ngwenya, V.; Mulema, M.; Chomba, I.; Chomba, M.; Nyambe, I. (2023): Influence of water quality on benthic macroinvertebrates in a groundwater-dependent wetland. *Frontiers in Water* 5: 1177724: 11 pp. (in English) [Zambia "Benthic invertebrates communities are frequently used as indicators of aquatic ecosystem health since many species are sensitive to pollution and abrupt changes in their environment. Limited knowledge exists on the interlinkages of hydrological dynamics, water quality and the ecological character of groundwater-dependant ecosystems especially in developing countries. In this study we assessed the sensitivity of benthic macroinvertebrates to water quality dynamics in the Barotse Floodplain, a groundwater-dependant wetland. Benthic invertebrates were sampled in the dry season using the kick-net method at selected points upstream, mid-stream and downstream. The selection of sampled points was based on an initially conducted water quality survey that characterized the wetland into mainly two water types, NaHCO<sub>3</sub> (upstream) and CaMgHCO<sub>3</sub> (downstream). Canonical Correspondence Analysis (CCA) was used to investigate the influence of water quality on macroinvertebrate subclass-taxa level. Furthermore, factor analysis was used to derive the processes propagating the observed water quality variability. It was established that the composition and diversity of macroinvertebrate communities at subclass-taxa level was influenced by effects of the wetland flood pulse, salinity (mineralisation) from groundwater input and biogeochemical processes during the expansion and contraction of the floodplain-river exchange. This study has demonstrated that biomonitoring was effective in capturing the natural processes/regimes of the environmental (such as flooding) and thus has potential to be used for monitoring extreme effects of phenomenon such as climate change. It is recommended that, the families, genus and species taxonomic levels are needed to improve the understanding of responses of the subclass-taxa level and the detection of specific contamination

signatures, to ensure wetland conservation and protection. Integrated water resources management for wetlands thus should incorporate biomonitoring conjunctively with traditional methods to ensure vital ecosystems are not compromised at the expense of maximizing the economic and social welfare of humanity." (Authors) Taxa - including "Odonata" - are treated at the order level.] Address: Kawawa Banda, Integrated Water Resource Management Centre, Dept of Geology, School of Mines, Univ. of Zambia, Lusaka, Zambia

**21700.** Bandara, Y.M.; Samarasinghe, L.V.; De Silva Ranasinghe, A.N.; Peiris, S. (2023): Diversity of dragonflies and damselflies (Order Odonata) in Bellanwila-Attidiya sanctuary at Ramsar City Colombo, Sri Lanka. *Citizen Scientist Symposium on Conservation and Ecology*: 19. (in English) ["Odonata are one of the most popular insect species in the world. About 132 species are recorded in Sri Lanka. They are widespread in ecosystems such as reservoirs, open fields, forests, and agricultural lands. Bellanwila Attidiya Sanctuary is an urban wetland in the lowland wet zone of Sri Lanka. Being located in a highly urbanized area, the level of contamination of the soil and water in this area and its impact on the biological balance is high. Odonata are considered as bio-indicators, so the study was carried out to identify the diversity of Odonata in the area. Observations were carried out in three selected 100m long transects between 0600h to 0900h in the morning, monthly for a period of six months from November 2021 to March 2022. Data acquisition was carried out with the naked eye and binoculars, and photographed where necessary. The data were analysed using Microsoft Excel software and diversity indices. During the study, 13 species of Odonata belonging to three families, including nine species of Anisoptera and four species of Zygoptera were recorded from Bellanwila Attidiya Sanctuary. In Anisoptera, Family Libellulidae was well represented by eight species, followed by Family Gomphidae (1 species). Accordingly, the overall Shannon-Weiner index for all transects is 1.66, and Simpson's index is 0.75. *Brachythemis contaminata*, *Ceragrion coromandelianum*, and *Ischnura elegans* were highest abundant, while *Tholymis tillarga*, *Urothemis signata*, and *Pseudagrion microcephalum* being the lowest. Compared with previous studies, the diversity of Odonata in the study area is low, while a few species dominate the area. The loss of diversity can be due to land and water pollution, the increase of invasive plant and animal species, and changes in natural conditions over time. The prevalence of *Brachythemis contaminata*, used as an environmental indicator, testifies to environmental pollution in the area." **21701.** Beresford, N.A.; Gashchak, S.; Wood, M.D.; Barnett, C.L. (2023): Mammals in the Chernobyl Exclusion Zone's Red Forest: a motion-activated camera trap study. *Earth Syst. Sci. Data* 15: 911-920. (in English) [Also a dragonfly was captured on the motion-activated digital trap cameras. "Since the accident at the Chernobyl Nuclear Power Plant in 1986, there have been few studies published on medium and large mammals inhabiting the area from which the human population was removed (now referred to as the Chernobyl Exclusion Zone, CEZ). The dataset presented in this paper describes a motionactivated camera trap study (n D 21 cameras) conducted from September 2016 to September 2017 in the Red Forest located within the Chernobyl Exclusion Zone. The Red Forest, which is likely the most anthropogenically contaminated radioactive terrestrial

ecosystem on earth, suffered a severe wildfire in July 2016. The motion-activated trap cameras were therefore in place as the Red Forest recovered from the wildfire. A total of 45 859 images were captured, and of these 19 391 contained identifiable species or organism types (e.g. insects). A total of 14 mammal species were positively identified together with 23 species of birds (though birds were not a focus of the study). Weighted absorbed radiation dose rates were estimated for mammals across the different camera trap locations; the number of species observed did not vary with estimated dose rate. We also observed no relationship between estimated weighted absorbed radiation dose rates and the number of triggering events for the four main species observed during the study (brown hare, Eurasian elk, red deer, roe deer). The data presented will be of value to those studying wildlife within the CEZ from the perspectives of the potential effects of radiation on wildlife and also rewilding in this large, abandoned area. They may also have value in any future studies investigating the impacts of the recent Russian military action in the CEZ. The data and supporting documentation are freely available from the Environmental Information Data Centre (EIDC) under the terms and conditions of a Creative Commons Attribution (CC BY) license: <https://doi.org/10.5285/bf82cec2-5f8a-407c-bf74-f8689ca35e83> (Barnett et al., 2022a). **21702.** Boeiro, M.; Antunes, S.; Figueiredo, H.; Soares, A.; Lopes, A.; Monteiro, E.; Garcia-Pereira, P.; Rego, C.; Conde, J.; Borges, P.A.V.; Serrano, A.R.M. (2023): Standardised inventories of lepidopterans and odonates from Serra da Estrela Natural Park (Portugal) - setting the scene for mountain biodiversity monitoring. *Biodiversity Data Journal* 11: e99558: 22 pp. (in English) ["Background: Mountain insect biodiversity is unique, but is menaced by different drivers, particularly climate and land-use changes. In mainland Portugal, the highest mountain - Serra da Estrela - is one of the most important biodiversity hotspots, being classified as Natural Park since 1976. Many lepidopteran and odonate species, including rare and protected species, are known to occur in Serra da Estrela, but basic knowledge on their abundance, distribution and ecology is still lacking. Standardised sampling of these communities is crucial to provide valuable biological information to support short-term decision-making for conservation management, setting simultaneously the standards for mountain biodiversity monitoring aiming to tackle the effects of environmental change in the long-term. New information: This study reports novel information on lepidopteran and odonate species diversity, distribution and abundance from Serra da Estrela Natural Park (Portugal). 72 lepidopteran and 26 odonate species were sampled in this protected area, including the first findings of *Apatura ilia*, *Macromia splendens* and *Vanessa virginiensis*. New populations of *Euphydryas aurinia* and *Oxygastra curtisii*, protected species under the Habitats Directive, were found in this Natural Park and novel distribution and ecological data were collected for most species, including several rare species and subspecies [e.g. *Aeshna juncea*, *Coenonympha glycerion iphioides* Staudinger, 1870, *Cyaniris semiargus* and *Sympetrum flaveolum*. All data were collected using standardised sampling allowing its use as a baseline for biodiversity monitoring in Serra da Estrela." **21703.** Cadena, J.T.; Boudot, J.-P.; Kalkman, V.J.; Marshal, L. (2023): Impacts of climate change on dragonflies and damselflies in West and Central Asia. *Diversity and Distributions* 29: 912-925. (in English) ["Aim: To project the impact of climate change on dragonfly and damselfly diversity in West and Central Asia. Location: West and Central Asia. Time period: 1900–2020 data used to predict distributions in 2070 and 2100. Methods: Based on 149,001 records, distribution models were created for 159 species using MaxEnt. Environmental variables consisted of climate variables taken from BI-OCLIM, river data and soil data. The future climate data were obtained from CHELSA from CMIP6 climate models. The same variables were collected for three scenarios (SSP1-2.6, SSP3-7.0 and SSP5-8.5) of shared socioeconomic pathways for the years 2050–2070 and 2080–2100. For each scenario and period, diversity maps were prepared for six species groups: all species, Lentic, Lotic, Oriental, Afrotropical and Palaearctic species. Results: Strong declines in diversity are expected in western Turkey, the Levant and Azerbaijan, and to a lesser extent in parts of Iran and southern Central Asia. An increase is expected in eastern Turkey and at higher elevations in Central Asia with a limited increase throughout the Arabian Peninsula. In contrast to expectations, a decrease in areas with <15 species was found. Faunal composition is predicted to show strong shifts, with Palaearctic species declining and Oriental and Afrotropical species increasing. No clear difference between the trend of lentic and lotic species is found, although there are clear spatial differences in trend between these groups. Main Conclusions: Climate change will result in strong changes in diversity and distribution of dragonflies and damselflies in West and Central Asia with regional declines and increases. None of the species are predicted to go extinct based on the impact of climate change only, however, the combined impact of climate change and anthropogenic forces is likely to push some of the species to near extinction by 2100." **21707.** Das, B.K.; Kunui, A.; Nandy, S.K.; Sahoo, A.K.; Meena, D.K.; Paul, S.K.; Sarkar, U.K.; Mondal, K. (2023): Altitudinal and seasonal distribution of benthic macroinvertebrates in River Tons — a tributary of Yamuna River, Uttarakhand, India. Environmental Monitoring and Assessment 195, Article number: 902: (in English) ["The main tributary of the Yamuna, the Tons River, exhibits altitudinal changes in its macroinvertebrate community's diversity, abundance, and composition. Between May 2019 and April 2021, the study was conducted in the upper section of the river. A total of 48 numbers of taxa from 34 families and ten orders were recorded during the investigation. At this elevation of 1150 to 1287 m, the two most predominant orders are Ephemeroptera (32.9%) and Trichoptera (29.5%). During the premonsoon season, they had the lowest macroinvertebrate density (250–290 individuals/m<sup>2</sup>), and the post-monsoon season had the highest density (600–640 individuals/m<sup>2</sup>). During the post-monsoon season, the maximum larval forms (60%) of various insect orders were predominant. The findings indicated that lower altitudes (1150–1232 m) have higher macroinvertebrate abundance than higher ones. The diversity of dominance is shallow at site-I (0.0738) and strong at the site-IV during the premonsoon season (0.03837). Taxa richness, as measured by the Margalef index (D), peaked in the spring season (January to March) at 6.9 and reached its lowest point (5.74) in the premonsoon season (April to May). Only 16 taxa were discovered in site-I and site-II, but 39 taxa were discovered at low altitudes (site-IV, 1100 m) (1277–1287 m). The Tons River contains a total of 12 and 13 genera, respectively, that belong to the orders Ephemeroptera and Trichoptera, according to qualitative study of the macroinvertebrates. The current study supports the use of macroinvertebrates as bioindicator species for monitoring biodiversity and assessing the health of ecosystems." (Authors) In site-IV *Ophiogomphus* sp. ... was the most prominent species during premonsoon.] Address: Das, B.K., I-CAR-Central Inland Fisheries Research Institute, Barrackpore, Kolkata, West Bengal, 700120, India

**21708.** Datta, D.; Agarwala, B.K.; Majumder, J. (2023): Addition to the Odonata fauna of Tripura, India. Journal of Threatened Taxa 15(6): 23327-23337. (in English, with Bengali summary) ["The present study was conducted in nine different locations (forested areas and unclassified natural areas) of six administrative districts of Tripura State from March 2012 to May 2019 as part of the biodiversity exploration of the state for further addition of odonate fauna. ... Before this study, quality field data on distribution and habitat preference of odonates was scanty from most of the eastern

Himalayan range, particularly from the southern and eastern parts including the state Tripura of India. Present study is a substantial advancement of the odonate diversity of Tripura over the earlier studies (Srivastava & Sinha 2000; Majumder et al. 2014). After this study with addition of 13 species, the updated odonate fauna of Tripura state is represented by 75 species under 49 genera (28 Anisoptera genera and 21 Zygoptera genera) and nine families (4 Anisoptera and 5 Zygoptera); ... *M. montanus*, *D. walli* and *E. campioni* showed Data Deficient as per IUCN Red List categories of threatened species. Among the 13 species reported here, 12 species are endemic to India except *D. walli* as per Subramanian & Babu (2017). *P. magdalena*, *Macrogomphus montanus*, *Tetrathemis platyptera*, *Tramea limbata*, *Trithemis festiva*, *Z. petiolatum*, *Aciagrion occidentale*, *Argiocnemis rubescens*, *Mortonagrion aborense*, *Elatoneura campioni*, *Prodiasineura verticalis*, *Pseudocoptera ciliata* are endemic to India recorded from this study. Members of *T. festiva* are found commonly near streams and those of *Zygomma petiolatum* are common in shady areas surrounded by big trees and shrubs. Members of *Aciagrion occidentale*, *Argiocnemis rubescens*, *Mortonagrion aborense*, *P. ciliata* are very common in their respective study sites. However, *P. magdalena*, *M. montanus*, *T. platyptera*, *T. limbata*, *Dysphaea walli*, *E. campioni*, *P. verticalis* are found to be comparatively rare in their study sites. The documenting of the regional species pool from this part of India has benefited the inclusion of previously unrecorded odonate species, which will help future researchers in the understanding of species biology, distributional ranges, and prospective habitats." **21709.** Deacon, C.; Govender, S.; Samways, M.J. (2023): Overcoming biases and identifying opportunities for citizen science to contribute more to global macroinvertebrate conservation. Biodiversity and Conservation 32: 1789-1806. (in English) ["Citizen Science (CS) provides valuable data to assist professional scientists in making informed decisions on macroinvertebrate conservation. However, CS is not developed nor implemented uniformly across the globe, and there are biases and challenges in the extent that it can contribute to global macroinvertebrate conservation. Here, a meta-analysis was performed using 107 Citizen Science Projects (CSPs) to identify underlying biases related to taxon representativity, country wealth, and demographic participation. Macroinvertebrate orders with the highest representativity were Lepidoptera and Hymenoptera, accounting for 53% of represented macroinvertebrate groups. The orders Scorpiones, Parasitiformes, and Spirobolida had proportionately the highest IUCN threat statuses, but significantly lower CSP representation, indicating that these orders require more public attention. Hymenoptera, Odonata, Coleoptera, Hemiptera, Diptera and Clitellata had the highest levels of Data Deficient species, suggesting that the primary objective of CSPs targeted at these orders should be collecting distribution and abundance data to improve Red List assessments. Global distribution of CSPs was uneven and the number of CSPs per country was positively correlated with national Gross Domestic Product (GDP) and GDP per capita, suggesting that countries with relatively low GDP face challenges to successfully establish and maintain CSPs. Establishing new CSPs can assist macroinvertebrate conservation in these countries, where biodiversity levels are often high. To accommodate these biases, CSP development should adopt a bottom-up approach, in which CSPs are designed to address data gaps, and to address local

socio-economic limitations and cultural ideologies. Guidelines for such development are presented here, with emphasis on addressing societal variations and inter-disciplinary communication gaps to ensure equitable opportunities for CSP participation." (Authors)] Address: Deacon, C., Dept Conserv. Ecol. & Ento., Stellenbosch Univ., P/Bag X1, Matieland 7602, South Africa. Email: charldeacon@sun.ac.za

**21710.** El Yaagoubi, S.; El Alami, M.; Harrak, R.; Azmizem, A.; Ikssi, M.; Mansour, M.R.A. (2023): Assessment of functional feeding groups (FFG) structure of aquatic insects in North-western Rif - Morocco. *Biodiversity Data Journal* 11: e104218. doi: 10.3897/BDJ.11.e104218: 23 pp. ["The involvement of trait-based approaches is crucial for understanding spatial patterns, energy flow and matter transfer in running water systems, which requires consistent knowledge of the functional structures of aquatic communities, with the advantage of combining physical properties and behavioral mechanisms of food acquisition rather than the taxonomic group. The present study indicated how functional feeding groups may be used as a proxy for classical taxonomic evaluation, as well as the potential interest in incorporating them as indicators of anthropogenic stressors. The composition and abundance of the functional feeding groups of aquatic insects were examined from September 2021 to August 2022 along the Western Rif Region. Benthic samples were collected from nine sampling points in the studied area using a Surber sampler with a mesh size of 500 µm and a diameter of 20\*20 cm. The stations included in this work were chosen for their accessibility as well as their position on the hydrographic systems. The abundance of sampled aquatic organisms in the whole study area revealed 5,342 individuals belonging to 60 families and seven orders of aquatic insects, classified into five feeding functional groups. In terms of abundance, Collectorgatherers (Ephemeroptera and Diptera) were the most abundant trophic group at most of the sites, with a proportion of 38.47%. Predators (Coleoptera, Hemiptera and Odonata) were the second group at all sites, followed by Collector-filters, accounting for 39.53%, 28.14% and 22.37% respectively, while Scarpers and Shredders had the lowest representation across all sites with 4.16%. The high number of registered Collectors could be related to their ability to feed on a diverse range of food items compared to the remaining trophic guilds. According to the Canonical Correspondence Analysis results, physicochemical (i.e. T, pH, BOD, Cl- and NO-) and hydromorphological (i.e. current velocity and depth) variables were amongst the key predictors of shaping the functional structure of aquatic biota during this investigation. It is highly recommended to carry out suitable measures to largely attenuate anthropogenic pressures in order to preserve the integrity of freshwater bodies and their biota." **21713.** Engelhardt, E.K.; Bowler, D.E.; Hof, C. (2023): European Habitats Directive has fostered monitoring but not prevented species declines. *Conservation Letters* 16(3) e12948: 10 pp. (in English) ["Strong biodiversity declines have been reported across the European Union, especially in insects, despite conservation policy such as the Habitats Directive that aims to halt biodiversity loss. Using 50 years of observational data, we examined indicators for the goals of the Directive in terms of improving monitoring efforts and occupancy trends of butterfly and dragonfly annex species in a central European region. We quantified annual monitoring effort and used occupancy-detection models to compare species trends for 18 years before and after legal implementation of the Directive. Monitoring efforts increased after implementation, while occupancy trends both improved and deteriorated. Contrary to its main goal, the European Habitats Directive did not prevent a worsening of all annex species' occupancy trends in the studied region. While the increased monitoring efforts aid biodiversity assessments, more serious broad-scale conservation measures are needed to halt biodiversity loss across Europe." (2023): Honeybee wings hold antibiofouling and antimicrobial clues for improved applications in health care and industries. *AIMS Microbiology* 9(2): 332-345. (in English) ["Natural surfaces with remarkable properties and functionality have become the focus of intense research. Heretofore, the natural antimicrobial properties of insect wings have inspired research into their applications. The wings of cicadas, butterflies, dragonflies, and damselflies have evolved phenomenal anti-biofouling and antimicrobial properties. These wings are covered by periodic topography ranging from highly ordered hexagonal arrays of nanopillars to intricate "Christmas-tree" like structures with the ability to kill microbes by physically rupturing the cell membrane. In contrast, the topography of honeybee wings has received less attention. The role topography plays in antibiofouling, and antimicrobial activity of honeybee wings has never been investigated. Here, through antimicrobial and electron microscopy studies, we showed that pristine honeybee wings displayed no microbes on the wing surface. Also, the wings displayed antimicrobial properties that disrupt microbial cells and inhibit

their growth. The antimicrobial activities of the wings were extremely effective at inhibiting the growth of Gram-negative bacterial cells when compared to Gram-positive bacterial cells. The fore wing was effective at inhibiting the growth of Gram-negative bacteria compared to Gram-positive samples. Electron microscopy revealed that the wings were studded with an array of rough, sharp, and pointed pillars that were distributed on both the dorsal and ventral sides, which enhanced anti-biofouling and antimicrobial effects. Our findings demonstrate the potential benefits of incorporating honeybee wings nanopatterns into the design of antibacterial nanomaterials which can be translated into countless applications in healthcare and industry.] Address: Ewunkem, A.J., Department of Biological Sciences, Winston Salem State University, Winston-Salem, North Carolina, USA

**21715.** Faasen, T. (2023): *Tukanobasis huamantincoae*, a new species of damselfly from Peru (Odonata: Coenagrionidae), with updated generic characterization. *International Journal of Odonatology* 26: 54-62. (in English) ["*Tukanobasis huamantincoae* sp. n. (holotype male: Peru, Loreto Región [MUSM]) is described and illustrated. Males of *T. huamantincoae* can be distinguished from *T. corbeti* by the presence of postocular spots and antehumeral stripes, the absence of apical brown wingspots, smaller number of postnodals, shorter CuA, vein descending from quadrangle not forming straight line to wing margin, pterostigma in HW distally distinctly yellow, S8–10 orange/red, cerci more strongly curved and with apical blunt appendix, genital ligula with triangular lateral lobes and overall smaller body dimensions. With the description of this second species of *Tukanobasis* it becomes clear that some characters previously attributed to the genus are species-specific, requiring an updated generic characterization." **21716.** Farfán-Beltrán, M.E.; Arellano-Aguilar, O.; Córdoba-Aguilar, A. (2023): Understanding the impact of physico-chemical parameters on aquatic invertebrates in Lake Chalco, Mexico City. *Revista Mexicana de Biodiversidad* 94, e944846: 14 pp. (in English, with Spanish summary) ["Many urban environments are places with strong stressors that substantially modify water quality. Although tests evaluating water quality are usually physico-chemical, including biological components can also provide relevant information. Lake Chalco, at the border between Mexico City and Estado de México, interacts with the surrounding human population. We investigated some water quality parameters and the community of macroinvertebrates living in Lake Chalco. From January to October 2017, we sampled water along the shoreline in 4 permanent areas of the lake. We recorded the NH<sub>4</sub><sup>+</sup>, NO<sub>3</sub><sup>-</sup>, NO<sub>2</sub><sup>-</sup>, total P, Zn, Cu<sup>2+</sup>, ORP, DO, TDS, conductivity, and pH. In addition, we characterized the richness, composition, and abundance of the macroinvertebrate community. There was spatial and temporal variation in physico-chemical parameters, perhaps due to the agricultural activity around the lake. Nevertheless, water quality was unable to be placed in a category of the national law. Four out of 20 macroinvertebrate RTU's significantly correlated with environmental variables. Thus, no bioindicators could be proposed. In general, lake water quality is poor, so it is not recommended for anthropic activities. Yet, the lake may be important as a center of dispersion for aquatic invertebrates." (Authors)] Only *Anax junius* is listed in an appendix of recorded taxa.] Address: Farfán-Beltrán, M.E., Univ. Nac. Autónoma de México, Inst. de Ecología, Depto de Ecol. Evol., AP 70-275, Ciudad Universitaria, 04510 Ciudad de México, Mexico

**21717.** Fekete, J.; De Knijf, G.; Dinis, M.; Padisák, J.; Boda, P.; Mizsei, E.; Várbíró, G. (2023): Winners and losers: Cordulegaster species under the pressure of climate change. *Insects* 14, 348. <https://doi.org/10.3390/insects14040348>: 15 pp. (in English) ["Simple Summary: Climate change is already affecting biodiversity and will do so even more in the future. As bioclimatic parameters, such as precipitation and temperature, directly or indirectly determine the occurrence of species, the accelerated changes in these variables could have a huge impact on species distributions. In this study, we aimed to use species distribution modeling to predict the potential distribution of the Balkan Goldenring (*Cordulegaster heros*) and the Two-Toothed Goldenring (*C. bidentata*) under recent and future climatic conditions to obtain a more accurate picture of the most suitable areas over time, thus facilitating the planning of conservation projects. According to our results, these montane species are strongly influenced by climatic variables. The models predict that the two species respond differently to changes in bioclimatic variables in the size of the potential range but similarly in range shift. Abstract: (1) Bioclimatic factors have a proven effect on species distributions in terrestrial, marine, or freshwater ecosystems. Because of anthropogenic effects, the changes in these variables are accelerated; thus, the knowledge of the impact has great importance from a conservation point of view. *C. heros* and *C. bidentata*, confined to the hilly and mountainous regions in Europe, are classified as "Near Threatened" according to the IUCN Red List. (2) Modeling the potential occurrence of both species under present and future climatic conditions provides a more accurate picture of the most suitable areas. The models were used to predict the responses of both species to 6 different climate scenarios for the year 2070. (3) We revealed which climatic and abiotic variables affect them the most and which areas are the most suitable for the species. We calculated how future climatic changes would affect the range of suitable areas for the two species. (4) According to our results, the suitable area for *C. bidentata* and *C. heros* are strongly influenced by bioclimatic variables and showed an upward shift toward high elevations. The models predict a loss of suitable area in the case of *C. bidentata* and a large gain in the case of *C. heros*." (Authors)] Address: Fekete, Judit, Research Group of Limnology, Centre of Natural Science, Univ. of Pannonia, Egyetem St. 10, 8200 Veszprém, Hungary. Email: feket.judit@ecolres.hu

**21718.** Ferreira, V.R.S.; de Resende, B.O.; Bastos, R.C.; da Brito, J.S.; de Carvalho, F.G.; Calvão, L.B.; Oliveira-Junior, J.M.B.; Neiss, U.G.; Ferreira, R.; Juen, L. (2023): Amazonian Odonata Trait Bank. *Ecology and Evolution*. 2023; 13: e10149. 21pp. (in English) ["Discussion regarding the gaps of knowledge on Odonata is common in the literature. Such gaps are even greater when dealing with basic biological data for biodiverse environments like the Amazon Rainforest. Therefore, studies that address, classify, and standardize functional traits allow the elaboration of a wide range of ecological and evolutionary hypotheses. Moreover, such endeavors aid conservation and management planning by providing a better understanding of which functional traits are filtered or favored under environmental changes. Here, our main goal was to produce a database with 68 functional traits of 218 Odonata species that occur in the Brazilian Amazon. We extracted data on behavior, habit/habitat (larvae and adults), thermoregulation, and geographic distribution from 419 literature sources classified into different research areas. Moreover, we measured 22 morphological traits of approximately 2500 adults and categorized species distributions based on approximately 40,000 geographic records for the Americas. As a result, we provided

a functional matrix and identified different functional patterns for the Odonata suborders, as well as a strong relationship between the different trait categories. For this reason, we recommend the selection of key traits that represent a set of functional variables, reducing the sampling effort. In conclusion, we detect and discuss gaps in the literature and suggest research to be developed with the present Amazonian Odonata Trait Bank (AMO-TB)." **21720.** García-Giron, J.; Bini, L.M.; Heino, J. (2023): Shortfalls in our understanding of the causes and consequences of functional and phylogenetic variation of freshwater communities across continents. *Biological Conservation* 282 (2023) 110082: 8 pp. (in English) ["Freshwater ecosystems harbour a disproportionately high biodiversity relative to their area, being also one of the most threatened ecosystem types worldwide. However, our capacity to design evidence-based conservation plans for this realm is restricted by all biodiversity shortfalls that have been recognized so far. In this context, the paucity of comparable field data and information on traits and phylogenies of freshwater organisms should be emphasized. Here, we highlight how increased knowledge could be gained and where we should aim at in research on the functional and phylogenetic features of freshwater communities. First, attempts to combine datasets from different sources should pay careful attention to data harmonization. Second, more effort should be focused on natural history observations on species habitats and life histories, providing the backbone of information for multi-trait databases. Third, fully resolved phylogenies would be required for deciphering the evolutionary relationships of freshwater organisms. Provided that these three hurdles can be overcome, conducting studies of local freshwater communities across continental spatial extents would pave the way for mapping functionally important ecosystems and evolutionarily valuable areas for the conservation of freshwater organisms and their habitats." **21723.** Gazzola, A.; Guadin, B.; Balestrieri, A.; Pellitteri-Rosa, D. (2023): Effects of predation risk on the sensory asymmetries and defensive strategies of *Bufo balearicus* tadpoles. *Animal Cognition* 26: 491-501. (in English) ["Lateralization consists of the differential use of bilateral organs or limbs and is well described in many taxa and in several contexts. Common ecological frameworks where it can be observed are foraging and predatory ones, with benefits related to both visual and auditory lateralization such as faster response or increasing neural processing ability. Anuran amphibians are considered relevant models for investigating lateralization, due to their great ecological variety and the possibility of easily being raised under laboratory conditions. By adopting the "rotational preference test", we used Balearic green toad tadpoles to test the effects of behavioural defensive responses triggered by different predator types (native vs alien, i.e. dragonfly larvae *Aeshna cyanea* and adult red swamp crayfish *Procambarus clarkii*) and diets (fasted vs. tadpole-fed predators) on their lateralization. We recorded tadpoles' responses to five different chemical cues: clean water (control treatment), fasted dragonfly larvae and crayfish, and tadpole-fed dragonfly larvae and crayfish. Green toad tadpoles did not show a bias in a predominant direction, although lateralization occurred at the individual level, as shown by the intensity index (LA). Perceived predation risk was the highest in tadpoles exposed to the combined chemical cues of conspecific prey and native predators, which elicited both changes in the intensity of lateralization and a marked reduction in tadpoles' activity level. Our results suggest that contextual predation threat may induce very rapid changes in the expression of asymmetries at the individual level, and might play a role as part of the complex defensive strategies adopted by prey in the attempt to escape predators." In: Walter Leal Filho, Marina Kovaleva, Fátima Alves, Ismaila Rimi Abubakar (editors) (2023): *Climate change strategies: Handling the challenges of adapting to a changing climate.* <https://doi.org/10.1007/978-3-031-28728-2>. Publisher: Springer Cham: 545-566. (in English) ["Odonata are good indicators of climate change effects due to their fast response to climatic variables such as temperature, humidity and amount of rainfall. This study aims to investigate the effect of three scenario of climate change at a regional scale (New Aquitaine region,

France) on 59 Odonata species distribution using species distribution modeling methods. Those results allow to identify species that will be the most impacted by climate change but also to evaluate changes in Odonata diversity across the study area, through the calculation of diversity indices for each climate scenario. 24–33% of the species are predicted loss between 75 and 100% of suitable habitat by 2100 under two scenarios. Predicted distribution map can be used by managers, and stakeholders to target areas to be protected in priority. Different approaches can be pursued: protections of areas that are suitable or will be suitable in the future for rare species and/or target areas that will be suitable for high number of species leading to a higher diversity. By protecting wetland suitable for diverse Odonata species, other wetland affiliated species such as amphibians, birds, and plants might benefit from those actions." **21725.** Gong, L.; Gu, H.; Chang, Y.; Wang, Z.; Shi, B.; Lin, A.; Wu, H.; Feng, J.; Jiang, T. (2023): Seasonal variation of population and individual dietary niche in the avivorous bat, *la io*. *Oecologia* 201: 733-747. (in English) ["The variation in niche breadth can affect how species respond to environmental and resource changes. However, there is still no clear understanding of how seasonal variability in food resources impacts the variation of individual dietary diversity, thereby affecting the dynamics of a population's dietary niche breadth. Optimal foraging theory (OFT) and the niche variation hypothesis (NVH) predict that when food resources are limited, the population niche breadth will widen or narrow due to increased within-individual dietary diversity and individual specialization or reduced within-individual dietary diversity, respectively. Here, we used DNA metabarcoding to examine the composition and seasonality of diets of the avivorous bat *la io*. Furthermore, we investigated how the dietary niches changed among seasons and how the population niche breadth changed when the availability of insect resources was reduced in autumn. We found that there was differentiation in dietary niches among seasons and a low degree of overlap, and the decrease of insect resource availability and the emergence of ecological opportunities of nocturnal migratory birds might drive dietary niche shifts toward birds in *la io*. However, the population's dietary niche breadth did not broaden by increasing the within-individual dietary diversity or individual specialization, but rather became narrower by reducing dietary diversity via predation on bird resources that served as an ecological opportunity when insect resources were scarce in autumn. Our findings were consistent with the predictions of OFT, because birds as prey for bats provided extremely different resources from those of insects in size and nutritional value. Our work highlights the importance of size and quality of prey resources along with other factors (i.e., physiological, behavioral, and life-history traits) in dietary niche variation." (2023): Assessment of targeted enrichment locus capture across time and museums using odonate specimens. *Insect Systematics and Diversity* 7(3): 1-9. (in English) ["The use of gDNAs isolated from museum specimens for high throughput sequencing, especially targeted sequencing in the context of phylogenetics,

is a common practice. Yet, little understanding has been focused on comparing the quality of DNA and results of sequencing museum DNAs. Dragonflies and damselflies are ubiquitous in freshwater ecosystems and are commonly collected and preserved in museums collections hence their use in this study. However, the history of odonate preservation across time and museums has resulted in wide variability in the success of viable DNA extraction, necessitating an assessment of their usefulness in genetic studies. Using Anchored Hybrid Enrichment probes, we sequenced DNA from samples at 2 museums, 48 from the American Museum of Natural History (AMNH) in NYC, USA and 46 from the Naturalis Biodiversity Center (RMNH) in Leiden, Netherlands ranging from global collection localities and across a 120-year time span. We recovered at least 4 loci out of an >1,000 locus probe set for all samples, with the average capture being ~385 loci (539 loci on average when a clade of ambiguous taxa omitted). Neither specimen age nor size was a good predictor of locus capture, but recapture rates differed significantly between museums. Samples from the AMNH had lower overall locus capture than the RMNH, perhaps due to differences in specimen storage over time." **21727.** Grether, G.F.; Beninde, J.; Beraut, E.; Chumchim, N.; Escalona, M.; MacDonald, Z.G.; Miller, C.; Sahasrabudhe, R.; Shedlock, A.M.; Toffelmier, E.; Shaffer, H.B. (2023): Reference genome for the American rubyspot damselfly, *Hetaerina americana*. *Journal of Heredity* 114(4): 385-394. (in English) ["Odonata play important roles in both aquatic and terrestrial food webs and can serve as sentinels of ecosystem health and predictors of population trends in other taxa. The habitat requirements and limited dispersal of lotic damselflies make them especially sensitive to habitat loss and fragmentation. As such, landscape genomic studies of these taxa can help focus conservation efforts on watersheds with high levels of genetic diversity, local adaptation, and even cryptic endemism. Here, as part of the California Conservation Genomics Project (CCGP), we report the first reference genome for *H. americana*, a species associated with springs, streams and rivers throughout California. Following the CCGP assembly pipeline, we produced two de novo genome assemblies. The primary assembly includes 1,630,044,487 base pairs, with a contig N50 of 5.4 Mb, a scaffold N50 of 86.2 Mb, and a BUSCO completeness score of 97.6%. This is the seventh Odonata genome to be made publicly available and the first for the subfamily Hetaeriniinae. This reference genome fills an important phylogenetic gap in our understanding of Odonata genome evolution, and provides a genomic resource for a host of interesting ecological, evolutionary, and conservation questions for which the rubyspot damselfly genus *Hetaerina* is an important model system." (in French, with English summary) ["Despite its isolation, Anticosti Island has been the subject of several entomological inventories over the last 150 years. William Couper was the first to inventory Anticosti in 1872. In 1904, Joseph Schmitt reported 161 species in *Monographie de l'île d'Anticosti (golfe Saint-Laurent)*. In the 1970s, the work of Luc Jobin on the hemlock looper outbreak facilitated access to the island and naturalists or students inventoried Coleoptera, Odonata and Orthoptera. After the Earth Summit in 1992, the entomofauna of Anticosti Island was inventoried by the Canadian Forest Service, using different types of traps. During the same time period, two other inventories of Odonata were carried out by naturalists. Finally, in a master's thesis, Pierre-Marc Brousseau reported several hundred species of insects of little studied orders. To date, 1541 species are listed. Trapping data provide standardized estimates and reliable time markers for measuring insect response to environmental changes. These data suggest that the decline of insects, reported elsewhere on the planet, is also observed on Anticosti. The island offers an ideal context to study the decline of insects and establish a biodiversity monitoring network." (Author)] Address: Christian Hébert: Email: christian.hebert@nrccan-mcan.gc.ca

**21730.** Hersch, K.; Moore, M.P. (2023): Ormentation diversified faster than eco-morphology across Nearctic dragonflies. *Biological Journal of the Linnean Society* 139(1): 70-78. (in English) ["Eco-morphology and ornamentation are two phenotypic dimensions along which co-existing species often diverge, yet theory makes contrasting predictions about how these phenotypes diversify relative to each other. Some theory predicts that intense reproductive demands cause more pronounced divergence in ornamentation than in eco-morphology. Other theory predicts that preferences for condition-dependent ornamentation in species encountering divergent ecological conditions will facilitate rapid divergence in eco-morphology but not ornamentation. We evaluated these conflicting predictions in Nearctic Libelluloidea dragonflies by testing if the diversification of a condition-dependent ornament, male wing melanization, was slower and less pronounced between species than the diversification of two key eco-morphological traits, body size and relative wing size. We found that male wing melanization evolved much faster than either body size or relative wing size. Furthermore, in contrast to the patterns for either eco-morphological trait, the best-supported models of diversification in male wing melanization indicate that the majority of divergence arose between the most closely related species. These results reveal that the primary axis of divergence between closely related Libelluloidea dragonflies is ornamentation rather than eco-morphology. Our study therefore suggests that evolutionary responses to disparate reproductive demands may be fundamental to the persistence and co-existence of closely related species." *rubilio* Selys, 1876 (Odonata: Coenagrionidae) in Taiwan. *International Journal of Odonatology* 26(8): 63-73. (in English) ["Although *Ischnura aurora* (Brauer, 1865) was traditionally considered to be widely distributed in Asia, the populations west of continental China have recently been identified as equivalent to *Ischnura rubilio* Selys, 1876. While the Taiwanese population has long been regarded as *I. aurora* as well, Taiwan in fact represents the distribution boundary between *I. aurora* and *I. rubilio*. Based on molecular and morphological analyses, we confirm that the "I. aurora-like" damselfly in Taiwan corresponds to *I. rubilio*. It is noteworthy that the abdominal blue spots of males in the Taiwan population have a unique phenotype compared to those found in specimens from India and continental China. According to past references and current surveys, the *I. rubilio* population in Taiwan has critically declined, with only one confirmed locality currently remaining. To maintain the Taiwanese population of *I. rubilio*, we recommend that prompt conservation measures of the habitat be implemented, focusing on the concept of the Satoyama Initiative." **21733.** Jumaat, A.H.; Hamid, S.A.B. (2023): Monitoring heavy metal bioaccumulation in rivers using damselflies (Insecta: Odonata, Zygoptera) as biological indicator. *Sains Malaysiana* 52(2): 321-331. (in English, with Malaysian summary) ["Contamination by pollutants in freshwater ecosystem has been identified extensively in river, sediments, and freshwater biota. Pollutants may have incorporated into the sediments and accumulated in tissue of aquatic organisms which persist as difficult to degrade matter in upper trophic level. Therefore, few selected heavy metals were measured from the river sediment and tissue of Odonata larvae collected from the selected rivers using inductively coupled plasma optical emission spectrometry (ICP-OES). The results showed metals in Odonata tissue were higher than in the sediments. Mn and Zn were found in greatest concentrations both in sediment and Odonata's tissue. Biota-sediment accumulation factors (BSAF) were computed based on these data, and it was discovered that all values of BSAF for Cd, Cu, Mn, and Zn were typically high (BSAF >1). In conclusion, the rivers contamination induced accumulation of heavy metal in the river sediments and Odonata larvae (*P. microcephalum*, *P. fraseri*, and *C. marginipes*). The highest concentration value was calculated as 29.23 for Cd in the *C. marginipes*. The high concentrations of this element in the insect body tissue has shown a trace of bioaccumulation and may pose biomagnification

to organisms in the upper trophic level. The results of this study indicated that damselfly is reliable to become a bioindicator for heavy metals particularly pollution in the river." (Authors)] Address: Jumaat, A.H., School of Biol. Sciences, Univ. Sains Malaysia, 11800 Minden, Penang, Malaysia

**21734.** Keinath, S.; Onandia, G.; Griesbaum, F.; Rödel, M.O. (2023): Effects of urbanization, biotic and abiotic factors on aquatic insect diversity in urban ponds. *Frontiers in Ecology and Evolution* 11:414: 16 pp. (in English) ["Urbanization leads to drastic modifications of the terrestrial and aquatic environment. However, urban ponds may provide valuable habitats for different taxa, including aquatic insects and amphibians. We aim to understand how a set of biotic and abiotic factors influence aquatic insect diversity in 18 urban ponds in the German metropolis Berlin, one of the greenest whilst most densely populated European cities. Greenspace is important for the terrestrial stages of some aquatic insects and amphibians, providing crucial resources. Thus, greenspace was assumed to have positive effects on aquatic insect diversity, whereas built-up area was assumed to affect diversity negatively. Because some aquatic insects prey on tadpoles, their abundance and diversity were assumed to depend on tadpole abundance, which in turn, depends on other food (i.e., phytoplankton) availability in ponds. We visited the ponds twice a year, in spring and summer, and collected data on aquatic insects that are known to prey on tadpoles, tadpole abundance, phytoplankton biomass, the presence or absence of large insect predators, as well as physical-chemical parameters. We assumed higher total aquatic insect abundance, genera richness, alpha-diversity, and evenness, as well as abundance and genera richness of different aquatic insect taxonomic groups to be associated with high tadpole abundance in ponds surrounded by high amount of greenspace and low levels of built-up area. Accordingly, we expected aquatic insects to be modulated by phytoplankton biomass, the presence of newts and fish, and to be affected by ponds' abiotic conditions. Our results showed that biological interactions and abiotic water conditions override urban effects in ponds' terrestrial surroundings on aquatic insect diversity levels, whereas aquatic insects' taxonomic groups responded differently on different land-use types around ponds. We explain our findings due to different dependences and demands towards terrestrial and/or aquatic habitats by different taxonomic groups of aquatic insects, and differences in their colonization behavior." **21737.** King, B.H.; Gunathunga, P.B. (2023): Gustation across the class insecta: Body locations. *Annals of the Entomological Society of America* 116(2): 76-82. (in English) ["This review summarizes which body parts have taste function in which insect taxa. Evidence of taste by mouthparts, antennae, and tarsi is widespread. Mouthparts that commonly have taste function are the labium, including the labella and labial palps, the maxillae, including the galeae and maxillary palps, the inner surface of the labrum or clypeolabrum of chewers, and inside the precibarium/cibarium of hemipterans, which have piercing-sucking mouthparts. Tasting with mandibles has not been found, and tasting with the hypopharynx is seldom reported. Use of the antennae appears uncommon among fly species, but common among species of lepidopterans, hymenopterans, beetles, and bugs. Although tasting with legs, especially tarsi, is reported mostly for fly and lepidopteran species, there is also evidence of it for multiple species of beetles, grasshoppers, and hemipterans, and one species of a roach, an ant, and a bee. Ovipositor taste function has been supported for some species of flies, lepidopterans, hymenopterans, orthopterans, and odonates. Taste by wings has been much less studied, but has been documented in a few fly species. Taste remains unstudied for any species or any body parts of Archaeognatha, Dermaptera, Mantodea, Mecoptera, Phasmatodea, Megaloptera, Neuroptera, Phthiraptera, Psocoptera, Siphonaptera, as well as Raphidioptera, Strepsiptera, Embioptera, Notoptera, and Zoraptera. Across holometabolous insects, larvae have not often

been examined, the exception being some species of lepidoptera, flies, and beetles. Taste studies of antenna and legs are uncommon for even lepidopteran and beetle larvae." **21739.** Kusumorini, A.; Rahmah, N.A.; Kinasih, I. (2023): Identification of insects visitors to oil palm flowers in the community plantation of Kalicinta village, North Kotabumi district, North Lampung regency. *Advances in Engineering Research. Proceedings of the 12th International Conference on Green Technology (ICGT 2022): 239-254.* (in English) ["Palm oil is a plantation commodity with economic value in Indonesia. Insects are one of the crucial factors influencing oil palm fruit productivity. The study aimed to identify the insect visitors on male and female palm flowers based on border habitat types and visitation times. The research was conducted in Kalicinta Village, North Kotabumi District, from August 2020 to September 2020. The study was carried out at three observation stations: SS (palm plantations bordering palm plantations), SK (palm plantations bordering rubber plantations), and (palm plantations bordering cassava plantations). Insects were collected using the swap and yellow sticky trap methods. 25 morphospecies and eight insect orders visited oil palm flowers. The result showed that oil palm flowers were visited by 25 morphospecies and eight insect orders. These orders were Coleoptera, Dermaptera, Diptera, Hymenoptera, Hemiptera, Lepidoptera, Odonata [*Neurothemis*, *Orthemis* (sic!)], and Mantodea. Male palm flowers were visited by 25 morphospecies of insects, while female palm flowers were visited by only 5 morphospecies. *Elaeidobius* sp. (Coleoptera: Curculionidae) was the most common species to visit both male and female flowers, followed by *Apis* sp. (Hymenoptera: Apidae), and *Camponotus* sp. (Hymenoptera: Formicidae) respectively. Most insects visit in the morning and the habitat of palm bordering palm is the most

visited." (Authors)] Address: Kusumorini, Astuti, Department of Biology, Faculty of Science and Technology, The State of Islamic University of Sunan Gunung Djati of Bandung, Bandung, West Java, Indonesia. Email: astuti@uinsgd.ac.id

**21740.** Kutasi, K.; Kolozsvári, I. (2023): Comparative study of the dragonfly habitats around Tisobikeny. 6th International conference of young scientists. *Kharkiv Forum of Natural Sciences, May 18-19, 2023: 332-334.* (in English) [19 odonate species including *Coenagrion scitulum* and *Aeshna viridis* are documented. "The results show that the Batar-Magosliget section is more species-rich than the Ukrainian part, according to the literature. The Batar is a small lowland river with a slow flow, so larvae of dragonfly species with a preference for a slight current and a higher tolerance for stagnant water are found. Stagnant water species are present in the fishpond in the Tisobikeny. In the Tisza, mainly reophilic species with a more specialised tolerance are found in smaller numbers of species and individuals. The dragonfly fauna of all three water types is very different." (Authors)] Address: Kutasi, K., Ferenc Rákóczi II Transcarpathian Hungarian College of Higher Education, Ukraine. **21741.** Landmann, A. (2023): Die Libellenfauna (Odonata) eines Wildflusstales in den Alpen (Tiroler Lechtal) – mit Bemerkungen zum Erstnachweis von *Gomphus pulchellus* in Tirol. *Entomologica Austriaca 30: 67-84.* (in German, with English summary) ["The dragonfly fauna (Odonata) of a wild-river valley in the Alps (Tyrolean Lech) – with remarks on the 'first' record of *G. pulchellus* in Tyrol. The Tyrolean Lech-river valley is widely regarded one of the least impaired river ecosystems of the Alps. In the Lech region some river stretches indeed were preserved where semi-natural braided floodplains predominate and where a high diversity of spring waters, bogs, ponds and running as well as stagnant riverine water bodies can be found offering attractive habitats for Odonata. This paper illustrates the regional diversity and distribution patterns of Odonata in the river valley. So far, 38 species (14 Zygoptera, 24 Anisoptera) were recorded along a 60km long stretch of the Lech at 800–1,200m a.s.l. The species list not only includes *Coenagrion hylas* as a special odonatological gem, whose only larger self-sustaining European populations inhabit the valley, but also a high proportion of lotic or rheophilic species bound to landscapes with a network of undisturbed or near-natural running waters. This e.g. includes *Ischnura pumilio*, *Cordulegaster bidentata* and *Orthetrum coerulescens* which are listed in higher threat categories in several Red Lists of the Alpine countries. In addition, the data at hand indicate that *Gomphus pulchellus* – that recently was reported as new for the Tyrolean Odonata fauna based on a record from 2020 has already been observed 17 years earlier in the upper part of the Lech valley." **21742.** Landmann, T.; Schmitt, M.; Ekim, B.; Villinger, J.; Ashiono, F.; Habel, J.C.; Tonnang, H.E.Z. (2023): Insect diversity is a good indicator of biodiversity status in Africa. *Communications Earth & Environment 4( 234): 11 pp.* (in English) ["Reliable metrics to monitor human impacts on biodiversity are essential for informing conservation policy. As insects are indicators of global change, whose declines profoundly affect ecosystems, insect diversity may predict biodiversity status. Here we present an unbiased and straightforward biodiversity status metric based on insect diversity (richness) and landscape naturalness. Insect diversity was estimated using spatially explicit earth observation data and insect species

assemblages across microhabitats in two agro-ecological zones in Africa. Landscape naturalness was estimated using various human impact factors. Biodiversity status values differed considerably ( $p < 0.05$ ) between protected and non-protected areas, while protected areas, regardless of agro-ecology, shared similar biodiversity status values. The metric is consistent when using richness from different indicator taxa (i.e., stingless bees, butterflies, dragonflies) and independent data for landscape naturalness. Our biodiversity status metric is applicable to data-scarce environments and practical for conservation actions and reporting the status of biodiversity targets." (Authors)] Address: Landmann, T., International Centre of Insect Physiology and Ecology, Nairobi, Kenya. Email: tlandmann@icipe.org

**21743.** Lemmers, P.; Aukema, R.; Crombaghs, B.H.J.M.; Hermans, J.T. (2023): Impact of activities of the beaver (*Castor fiber*) on the sustainable conservation of Brook lamprey (*Lampetra planeri*) and Golden-ringed dragonfly (*Cordulegaster boltonii*) in the Roode Beek brook (Meinweg area). *natuurhistorisch maandblad* 112(3): 93-101. (in Dutch, with English summary) ["The Roode Beek brook in the province of Limburg is known as one of the most natural brooks in the Netherlands. In 2012, the first sightings of Beavers were recorded along this brook. There were concerns that the habitats of Brook lamprey and *C. boltonii*, which in the vulnerable developmental stage largely depend on sand and soil banks in fastflowing streams, would be affected or could even disappear. Between 2018 and 2021, using a specially designed rake, silt and sand accumulations and detritus in nine sections of the brook were surveyed for the presence of Brook lamprey larvae and *C. boltonii* larvae. Larvae of both species were found in similar habitats in shallow sections of the brook (depth < 50 cm). The established larval densities of Brook lamprey in the study area were low despite the presence of abundant habitat. Further analysis of previous observations and the literature revealed that the density in the study area has probably always been low and that the species mainly occurs in more downstream parts of the Roode Beek. In contrast, more larvae of *C. boltonii* were found when more upstream parts of the brook were sampled. The distribution pattern and age structure of these larvae were consistent with the outcomes of a similar survey conducted in 2007, before the arrival of the Beaver. The presence and influence of smaller dams does not seem to hinder *C. boltonii*, as larvae of all length classes were found upstream and downstream of small dams. However, impoundment by the large dam at St. Ludwig does seem to affect larval distribution locally, an effect seen in a stretch of about 50 m of the brook. The effect is caused by increasing water depth, lack of flow and associated increased silt sedimentation, which are direct results of the large dam. Larvae were found again where appreciable water flow returned and silt sedimentation was significantly decreased. Based on the present study, it is estimated that the sustainable conservation of both Brook lamprey and *C. boltonii* in the Roode Beek is not affected by Beaver activities." **21744.** Li, Z.; Cheng, Y.; Chen, J.; Xu, W.; Ma, W.; Li, S.; Du, E. (2023): Widely targeted HPLC-MS/MS metabolomics analysis reveals natural metabolic insights in insects. *Metabolites* 2023, 13(6), 735; <https://doi.org/10.3390/metabo13060735>: 17 pp. (in English) ["Insect metabolites play vital roles in regulating the physiology, behavior, and numerous adaptations of insects, which has contributed to them becoming the largest class of Animalia. However, systematic metabolomics within the insects is still unclear. The present

study performed a widely targeted metabolomics analysis based on the HPLC-MS/MS technology to construct a novel integrated metabolic database presenting comprehensive multimetabolite profiles from nine insect species across three metamorphosis types. A total of 1442 metabolites were identified, including amino acids and their metabolites, organic acids and their derivatives, fatty acids (FAs), glycerophospholipids (GPs), nucleotides and their metabolites, and benzene and its substituted derivatives. Among them, 622 metabolites were used to generate a 0 and 1 matrix based on their presence or absence, and these metabolites were enriched in arachidonic acid metabolism, tyrosine metabolism, phenylalanine metabolism, and insect hormone biosynthesis pathways. Our study revealed that there is a high coincidence between the evolutionary relationships of the species and the hierarchical cluster based on the types of metabolites, while the quantities of the metabolites show a high diversity among species. The metabolome of the nine representative insects provides an important platform for implementing the analysis of insect systemic metabolites and biological events at the metabolic level. ... Nine species representing three metamorphosis types were used in this study, as shown in Figure 1, including one ametabolous species (*Thermobia domestica*), four hemimetabolous species (*Pantala flavecens*, *Calopteryx splendens*, *Locusta migratoria*, *Periplaneta americana*, *Apolygus lucorum*), and four holometabolous species (*Apis mellifera*, *Tenebrio molitor*, *Bombyx mori*, *Drosophila melanogaster*)." **21747.** Lövei, G.L.; Ferrante, M.; Möller, D.; Möller, G.; Vincze, E. (2023): The need for a (non-destructive) method revolution in entomology. *Biological Conservation* 282, 110075: 5 pp. (in English) ["Highlights: • Arthropod decline triggered arthropod conservation efforts. • Traditional entomological methods often result in killing study subjects. • Currently, lethal methods dominate in tropical and multiple-species focus studies. • Dragonflies, grasshoppers and butterflies are often studied by non-lethal methods. • Entomologists should promote non-lethal methods, especially in conservation research. Abstract: There are worrying signs that arthropods are in decline both in density and diversity. This threatens global biodiversity as well as the ecosystem services provided by arthropods. Nonetheless, entomological research, even when studying arthropods with a conservation focus, frequently uses lethal methods. We analysed 1029 articles published in the major biological conservation journals between 2014 and 2020 and found that, while single-species-focused studies used more non-lethal than lethal methods (76.3 % vs. 23.7 %, respectively), the opposite was true for multiple-species ones (24.0 % vs. 76.0 %). In tropical regions, 74.6 % of studies used lethal methods vs. 18.5 % non-lethal ones. Of the major orders, Odonata, Lepidoptera and Orthoptera were generally studied using non-lethal methods (88.1 %, 80.7 %, and 70.8 %, respectively) in non-tropical regions, while in the tropics, only Lepidoptera were frequently (51.9 %) studied by such methods. We argue that even if the evidence for arthropod decline were uncertain, and even if research would not add much to the overall level of mortality, entomologists should be showing an example. If research on invertebrates continues to be ethically blind, entomologists risk losing public support for conserving arthropod diversity." **21748.** Lu, K.; Shen, S.; Miller, L.M.; Huang, X. (2023): Golden ratio in venation patterns of dragonfly wings. *Scientific Reports* 13(7820): 6 pp. (in English) ["The vein pattern in insect wings allows this lightweight structure to carry multiple biological functions. Here, an investigation of the angular distribution of the vein struts in dragonfly wings revealed that the golden angle or golden ratio dominates the venation

patterns. We find that the golden angle dominates the intervein angles in regions where thin veins and membranes demand strength reinforcement. A golden ratio partition method has thus been developed that explains a set of preferred intervein angles in distorted polygon-shaped venation cells throughout the venation pattern in dragonfly wings. These observations provide new evidence that the wing structure is spatially optimized, by the golden rule in nature, for supporting biomechanical functions of dragonfly wings." **21749.** Marcellino, B.J.L. (2023): Behavioural responses as a function of temperature and interactions between behaviour and melanin ornaments in dragonflies. MSc. thesis, Ecology & Evolutionary Biology, University of Toronto, Canada: VII + 50 pp. (in English) ["Sexual selection creates and maintains elaborate phenotypes despite costs imposed by natural selection. This creates a trade-off between natural and sexual selection, whereby organisms can display traits that decrease survivorship if they sufficiently improve reproductive success. In many species of odonates males possess ornaments, formed by melanin, which increase their mating success, but also increase body temperature, potentially imposing novel trade-offs in a warming climate. Using a combination of comparative and experimental methods, I examined the effects of temperature on mating and thermoregulatory behaviour in *Celtis elisa* and *Leucorrhinia intacta*. In *C. elisa*, I found evidence for this trade-off with positive associations between temperature and time spent thermoregulating and a negative association with time spent mating. In *L. intacta*, only thermoregulatory behaviour was positively associated with temperature. My results suggest that some dragonflies will have reduced time windows for mating as climate change continues." (Author) <https://tspace.library.utoronto.ca/handle/1807/128174>] Address: Marcellino, Bianca, Graduate Dept Ecology & Evolutionary Biology Univ. Toronto, Canada

**21750.** Marshall, C. (2023): Damselflies, climate change, and microbiomes. MSc thesis, Biology Education Centre and Department of Animal Ecology, Uppsala University. 18 pp. (in English) ["Climate change is expected to increase temperatures across the world. These changes can have a profound negative impact on biodiversity, threatening endangered species under pressure from anthropogenic sources (e.g., burning fossil fuels, deforestation, etc.). Gut microbiomes have become a focus of research in wildlife due to the role they play in the health and fitness of an organism. Increased temperatures have been shown to disrupt microbial communities, limiting the adaptive potential of species confronted with these changes. In this study damselflies were used to experimentally study the effect different temperature regimes and detritus levels have on the abundance of different microbial communities. A metabarcoding technique using the 16S rRNA gene to extract, amplify, and identify bacterial communities within damselfly guts. Species of bacteria that were once difficult to identify via culturing are now easily classified with modern molecular and bioinformatic methods. The study found that temperature, and to a lesser extent grass, had a significant effect on damselfly larva microbiome. The overall composition of the damselfly microbiome shifted over time. The proportion of the microbiome represented by the taxa Proteobacteria increased due to temperature, aligning with previous research on invertebrates. These findings suggest that damselfly microbiomes have a resident microbiome which is sensitive to environmental conditions and should be considered when assessing threats to biodiversity." (Author)] Address: not stated

**21751.** Masina, F.M.; Wasserman, R.J.; Wu, N.; Mungenge, C.P.; Dondofema, F.; Keates, C.; Shikwambana, P.; Dalu, T. (2023): Macroinvertebrate diversity in relationship to limnochemistry in an Austral semi-arid transboundary aquifer region pan system. *Science of The Total Environment* 878, 163161: (in English) ["Highlights: • All metals and nutrients were significant seasonal with the exception for P and K concentrations. • Toxic risk index values indicated low toxic risk across all seasons. • 41 macroinvertebrates species belonging to 7 orders were identified. • First two CCA axes accounted for 76.1 % of the total explained fitted cumulative variance. • Understanding relationships between macroinvertebrates and their environment is crucial in understanding how ecosystem functions. Abstract: Pan-wetland systems are one of the world's essential and productive ecosystems and are considered important, unique and complex ecosystems. Anthropogenic activities around the temporary pans in the Khakhea Bray Transboundary Aquifer region [Botswana/South Africa] are increasingly becoming a big issue of concern as this may affect pan biodiversity. The study specifically aimed to investigate spatial and temporal distributions of metal and nutrient concentrations within the pans in relation to land use, identify potential pollution sources in this water-scarce region, and assess macroinvertebrate diversity and distribution in relation to pan limnochemistry using a combination of multivariate analyses from 10 pans across three seasons. Environmental and anthropogenic variables influence water quality and the distribution of metals concentration in Khakhea-Bray pan systems. Anthropogenic activities such as animal grazing, infrastructure degradation, water withdrawal and littering have resulted in poor water quality within temporary pans, which may strongly influence macroinvertebrate diversity and distribution. 41 macroinvertebrate species from 5 insect orders (i.e., Coleoptera, Hemiptera, Odonata, Ephemeroptera, Diptera), Crustacea and Mollusca were identified. Significant differences were observed across the seasons for macroinvertebrate taxa, with high and low species richness being observed in autumn and winter, respectively. Water (i.e., temperature, dissolved oxygen, pH, salinity, conductivity), physical (i.e., stone composition) and sediment (i.e., sulphur, sodium) parameters were found to have a significant impact on the macroinvertebrate communities. Therefore, understanding the relationships between macroinvertebrates and their environment is crucial in understanding how the ecosystem taxa are structured and is vital for informing conservation managers on how to properly manage and protect these systems from further degradation." (Authors)] Address: Aquatic Systems Research Group, School of Biology and Environmental Sciences, University of Mpumalanga, Nelspruit 1200, South Africa. Email: dalutatenda@yahoo.co.uk

**21752.** Mejillón Vargas, D.S.; Suárez Vera, K.P. (2023): Estado poblacional de Lepidópteros y Odonatos presentes en un fragmento del bosque húmedo tropical Olón, provincia de Santa Elena, Ecuador. *La Libertad. UPSE, Matriz. Facultad de Ciencias del Mar*: 94 pp. (in Spanish) ["Ecuador is a megadiverse country with characteristics of presenting ideal ecosystems for many species, including insects, this research work was developed during the dry season from August to December 2022, which aimed to determine the diversity of Odonata and Lepidoptera through the identification and population count of species present in three transects placed on the Las Cascades trail, providing information on two bioindicator groups of the tropical humid forest Olón, Santa Elena. Two capture methods were applied: entomological net and V.S.R traps and they were established with 5 traps per transect. With the implemented methodology, a total of

897 individuals of the Order Lepidoptera and 351 individuals of the Order Odonata were registered. The registered lepidopteran community is made up of 6 families consisting of Nymphalidae, Hesperidae, Papilionidae, Lycaenidae, Pieridae and Riodinidae, the first being the most abundant and diverse. The registered Odonata belong to five families made up of Aeshnidae, Libellulidae, Coenagrionidae, Calopterygidae and Heteragrionidae, the third being the most diverse group and showing the most abundant genus *Argia* (121 ind), however, the diversity obtained from the Shannon indices (3.28 bit) and Margalef (6.12 bit) was high in the case of Lepidoptera and for Odonata it was medium (2.00 bit) and low (1.75 bit) respectively. The presence and absence of organisms was taken into account to obtain the Jaccard similarity indices, which were relatively high (0.6), highlighting the similarity of transect 1 and 2 for both orders. This work aims to provide information on Lepidoptera and odonates present in Ecuador for future research." (Authors/Google Translate) the following taxa are listed: *Rhionaeschna psilus*, *Erythrodiplax umbrata*, *E. fusca*, *Brechmorhoga praecox*, *Erythemis vesiculosa*, *Macrothemis* sp., *Orthemis* sp., *Argia inculta*, *A. acridens*, *Leptobasis linda*, *Ischnura* sp., *Acanthagrion* sp., *Telebasis brevis*, *Hetaerina occisa*, *H. cooki*] Address: <https://repositorio.upse.edu.ec/bitstream/46000/9669/4/UPSE-TBI-2023-0035.pdf>

**21753.** Mochon, A.; Savard, M. (2023): Premier inventaire de l'odonatofaune du parc national du Bic et liste annotée des espèces de la région administrative du Bas-Saint-Laurent, Québec (Insecta: Odonata). *Le Naturaliste canadien* 147(2): 3-56. (in French, with English summary) ["The first comprehensive inventory of dragonflies in the Parc national du Bic (Bic National Park, Québec, Canada) was conducted between 2021 and 2022. Fifty species were identified from 6 biotopes: a fast-flowing river, a recent pond in a restored exploited peatland, a shallow kettle lake, a salt marsh, a beaver pond, and a set of 4 small forest ponds. The discovery of an exuviae of *Libellula pulchella* in the park provided the first proof that this species can complete its development at this latitude. The update to the list of odonates occurring in the Bas-Saint-Laurent region added 38 species, bringing the total to 81. Global warming seems to have favoured the northward expansion of *Aeshna constricta*, *Leucorrhinia intacta* and of *Plathemis lydia* in the province of Québec." **21754.** Mogali, S.; Saidapur, S.; Shanbhag, B. (2023): Behavioral responses of tadpoles of *Clinotarsus curtipes* (Anura: Ranidae) to odor cues of dragonfly larvae. *Phyllomedusa: Journal of Herpetology* 22(1): 11-20. (in English, with Portuguese summary) ["In aquatic environments, many prey animals, including anuran larvae, predominantly use chemical cues to assess predation risk. In such systems, a variety of chemical cues (e.g., kairomones, alarm, dietary) affect the behavioral responses of the prey tadpoles. Many anuran tadpoles are able to discriminate different chemical cues and exhibit differential antipredator behavioral responses according to the perceived risk. The behavioral responses of tadpoles of *Clinotarsus curtipes* to predatory larvae of the dragonfly *Pantala flavescens* were studied in the laboratory. The predator's kairomones (water conditioned by a starved predator) or its diet-derived metabolites released in excreta of a predator after consumption of conspecific (*C. curtipes*) or heterogeneric (*Indosylvirana temporalis*) prey tadpoles were used to simulate predation threat. The tadpoles of *C. curtipes* had no behavioral response to predator kairomones. However, the tadpoles showed antipredator behavioral responses i.e., reduced swimming movements and overall time

spent swimming, and had a higher burst speed in response to water-borne cues released from the excreta of predators fed both conspecific and heterogeneric prey. The antipredator behavioral responses of tadpoles were most intense in response to cues of predators fed on conspecific prey. The findings of the present study show that tadpoles of *C. curtipes* are capable of assessing levels of predation threat and modulating the intensity of their defense behavior in accordance with the perceived threat." **21755.** Moi, D.; Barrios, M.; Giancarlo, B.; Tesitore, G.; Burwood, M.; Romero, G.Q.; Mormul, R.P.; Kratina, P.; Juen, L.; Michelan, T.S.; Montag, L.F.A.; Cruz, G.M.; García-Girón, J.; Heino, J.; Hughes, R.M.; Figueiredo, B.R.S.; Teixeira de Mello, F. (2023): Human land-uses homogenize stream assemblages and reduce animal biomass production. *Journal of Animal Ecology* 92(6): 1176-1189. (in English) ["1. Human land-use change is a major threat to natural ecosystems worldwide. Nonetheless, the effects of human land-uses on the structure of plant and animal assemblages and their functional characteristics need to be better understood. Furthermore, the pathways by which human land uses affect ecosystem functions, such as biomass production, still need to be clarified. 2. We compiled a unique dataset of fish, arthropod and macrophyte assemblages from 61 stream ecosystems in two Neotropical biomes: Amazonian rainforest and Uruguayan grasslands. We then tested how the cover of agriculture, pasture, urbanization and afforestation affected the taxonomic richness and functional diversity of those three species assemblages, and the consequences of these effects for animal biomass production. Single trait categories and functional diversity were evaluated, combining recruitment and life-history, resource and habitat-use, and body size. 3. The effects of intensive human land-uses on taxonomic and functional diversities were as strong as other drivers known to affect biodiversity, such as local climate and environmental factors. In both biomes, the taxonomic richness and functional diversity of animal and macrophyte assemblages decreased with increasing cover of agriculture, pasture, and urbanization. Human land-uses were associated with functional homogenization of both animal and macrophyte assemblages. Human land-uses reduced animal biomass through direct and indirect pathways mediated by declines in taxonomic and functional diversities. 4. Our findings indicate that converting natural ecosystems to supply human demands results in species loss and trait homogenization across multiple biotic assemblages, ultimately reducing animal biomass production in streams." **21758.** Moore, M.P. (2023): Ornamented species incur higher male mortality in the larval stage. *Biology Letters* 19(5): 5 pp. (in English) ["Life-cycle stages are not always capable of evolving independently from each other, but it remains unclear if evolving to meet the demands of one stage actually imposes costs on other stages. Male ornamentation is a useful trait in which to test this potential evolutionary constraint because ornaments improve reproduction in the adult stage but can require the expression of risky traits in the juvenile stage. Here, I compared larval mortality between populations of ornamented and non-ornamented dragonfly species. Since males produce more exaggerated melanin wing ornaments than females, I tested if larval mortality of males is higher in populations of species that have evolved adult male wing ornamentation. My analyses uncover male-biased larval mortality in species that have evolved male ornamentation. These findings indicate that evolving to optimize mating for the adult stage imposes a cost to survival in the larval stage. Thus, this study reveals that evolution in one life-cycle stage can impose fitness costs on other stages that persist over macroevolutionary timescales." **21759.** Nakanishi, K.; Usio, N.; Yokomizo, H.; Takashima, T.; Hayashi, T.I. (2023): Chlorantraniliprole application differentially affects adult emergence of *Sympetrum* dragonflies in rice paddy fields. *Paddy and Water Environment* 20: 177-183. (in English) ["Rice paddy fields are important habitat for many dragonfly species. In Japan, populations of dragonflies inhabiting rice paddies, in particular *Sympetrum* (Odonata: Libellulidae), have decreased greatly in the last few

decades. A major cause of the decline has been suggested to be the use of systemic insecticides (e.g., phenylpyrazole and neonicotinoid) in nursery boxes of rice seedlings. In this study, we examined the effects of chlorantraniliprole (CAP), a novel anthranilic diamide insecticide, on adult emergence of *Sympetrum* dragonflies in ten rice paddy fields by counting their exuviae remaining on the rice plants as an abundance index. Our results suggest that CAP is a potential factor that reduced the emergence rate of *S. infuscatum* but not of *S. frequens*. This difference may be due to differential sensitivity to CAP, different lengths of the nymphal stage, or different effects of bottom-up controls via reduction of prey organisms that are highly sensitive to CAP." **21762.** Nienhaus, H.; Fitzpatrick, S.W.; Bloom, D.D.; Schriever, T.A. (2023): Dispersal ability and biogeographic gradients influence gene flow of 3 aquatic insects in Laurentian Great Lakes interdunal wetlands. *Freshwater Science* 42(1): 88-103. (in English) ["Population genetic connectivity is influenced by multiple abiotic and biotic attributes, including geography, dispersal ability, and life history, which may lead to different patterns of population structure of organisms occupying similar habitats. We investigated how differences in dispersal ability and biogeographic gradients correspond with population structuring of 3 aquatic insect species found within naturally fragmented interdunal wetlands along the eastern shoreline of Lake Michigan in midwestern USA. Interdunal wetlands are small, highly fragmented, and patchily distributed along the eastern coast of Lake Michigan, USA. Our focal species, *Anax junius*, *Notonecta undulata* Say, 1832, and *Caenis amica* Hagen, 1861 were chosen as high, intermediate, and low dispersers, respectively. We hypothesized that all insect populations experience isolation by distance with relatively low gene flow among sites, but that the strength of isolation by distance varies with dispersal ability. We used cytochrome c oxidase subunit I sequence data to confirm species identification and restriction enzyme association DNA sequencing for population genomic analyses. Our cytochrome c oxidase subunit I data revealed that *Caenis* populations consisted of multiple species split along a latitudinal gradient. Restriction site-association DNA sequencing data showed that *A. junius* displayed strong isolation by distance, where *N. undulata* did not. Additionally, both *A. junius* and *N. undulata* populations displayed 2 genetic clusters along the coastline, and genetic diversity increased along with latitude. These results indicate that biogeographical

variables, such as latitude and covarying abiotic factors, may be stronger predictors of population structure than dispersal ability and that inference of population structure within aquatic macroinvertebrates should be on a species-specific basis." (2023): Influence of granulometry on the distribution of benthic macro invertebrates in some streams of the Mvilla and Haut-Nyong watersheds in Cameroon. *World Journal of Advanced Research and Reviews* 17(2): 658-677. (in English) ["This study was conducted from November 2018 to October 2019 in 8 forested streams in the Haut-Nyong and Mvilla watersheds to determine the influence of substrates granulometry on benthic macroinvertebrates. The physicochemical analyses showed highly oxygenated, weakly mineralized and slightly acidic waters. The granulometric analyses reveal 9 categories of substrates depending on the scale of sand, sand+gravel or sand+mud. Sampling of benthic macroinvertebrates allowed the collection of 15058 organisms divided into 5 classes, 14 orders and 49 families [including Odonata]. The results showed a taxonomic richness strongly influenced by the nature of the substrate. The combination of coarse sand + silt + dead leaves was more favored the development of benthic macroinvertebrates with 48 families. The taxonomic richness associated to the different index revealed good ecological quality of Sounou, Bengo'o and Lo'o rivers." (Authors)] Address: Nyambe Mbia, D.-I., Lab. Hydrobiol. Environ. (LHE), Fac. Sci., Univ. of Yaounde I, P.O. Box: 812 Yaounde-Cameroon.

**21768.** Oldak, K.A. (2023): Dragonflies (Odonata) of the "Bagno Pogorzal" Nature Reserve (east-central Poland). *Park nar. Rez. Przyr.* 42(1): 23-39. (in Polish, with English summary) ["The aim of the study was to determine the species composition of Odonata of the "Bagno Pogorzal" Nature Reserve (east-central Poland), comprising, i.a., complex of Sphagnum bogs and dystrophic lakes. The study was conducted in 2021-2022 and consisted of the observation of imagines and the collection of exuviae. A total of 31 species of dragonflies were found (41.9% of the Polish odonate fauna), 23 of which were classified as autochthonous or probably autochthonous. The species found were mostly eurytopes, although there was also a significant proportion of tyrophobionts and tyrophobiles. The most abundant species were *Libellula quadrimaculata*, *Coenagrion pulchellum* and *C. puella*. Five species protected

by law in Poland were recorded: *Nehalennia speciosa*, *Sympetma paedisca*, *Aeshna subarctica*, *Leucorrhinia albifrons* and *L. pectoralis*. The endangered *N. speciosa* is the most interesting of the recorded species due to its severely fragmented extent and relict and fairly rare occurrence in Poland. It was observed in the ecotone zone between a *Pinus sylvestris* forest and an open peatland or dystrophic lake. Six species classified as umbrella species for Sphagnum bogs were recorded: *N. speciosa*, *A. subarctica*, *A. juncea*, *L. albifrons*, *L. dubia* and *L. pectoralis*. Value of biocenosis naturalness qualitative index (Wns) for Sphagnum bogs was 3.65. In light of the literature data, this value is at most moderate, suggesting the disturbed naturalness of the boggy complex. The reserve is one of the Poland's important refuges of "special concern" dragonfly species. Threats to the local dragonfly populations have been identified in the reserve: some forms of human impact and drying out of the peatland. There is a need to prepare a conservation plan for the reserve, taking into account the conservation policy towards dragonflies." (Author)] Address: Oldak, K.A., ul. **21769.** O'Neill, D.; Häkkinen, H.; Neumann, J.; Shaffrey, L.; Cheffings, C.; Norris, K.; Pettorelli, N. (2023): Investigating the potential of social media and citizen science data to track changes in species' distributions. *Ecology and Evolution* 13(5), e10063: 13 pp. (in English) ["How to best track species as they rapidly alter their distributions in response to climate change has become a key scientific priority. Information on species distributions is derived from biological records, which tend to be primarily sourced from traditional recording schemes, but increasingly also by citizen science initiatives and social media platforms, with biological recording having become more accessible to the general public. To date, however, our understanding of the respective potential of social media and citizen science to complement the information gathered by traditional recording schemes remains limited, particularly when it comes to tracking species on the move with climate change. To address this gap, we investigated how species occurrence observations vary between different sources and to what extent traditional, citizen science, and social media records are complementary, using *Calopteryx splendens* in Britain as a case study. *C. splendens* occurrences were extracted from citizen science initiatives (iRecord, iNaturalist) and social media platforms (Facebook, Flickr, Twitter), and compared with traditional records primarily sourced from the British Dragonfly Society. Our results showed that species presence maps differ between record types, with 61% of the citizen science, 58% of the traditional, and 49% of the social media observations being unique to that data type. *C. splendens* habitat suitability maps differed most according to traditional and social media projections, with traditional and citizen science being the most consistent. We conclude that (i) social media records provide insights into *C. splendens* distribution and habitat preference that are different from, and complementary to, the insights gathered from traditional recording schemes and citizen science initiatives; (ii) predicted habitat suitability maps that ignore information from social media records can substantially underestimate (by over 3500 km<sup>2</sup> in the case of *C. splendens*) potential suitable habitat availability." und Landschaftsplanung 55(7): 30-36. (in German, with English summary) ["Sensitivity of dragonflies to invasive crustaceans – Risk analysis for the Rhineland-Palatinate part of the Northern Upper Rhine Plains. In Rhineland-Palatinate, six invasive crayfish species (Decapoda) with varying degrees of threat potential for dragonflies and other aquatic organisms and ecosystems have been identified in the Northern Upper Rhine Plain. The signal and calico crayfish in particular have a very negative effect; the no less invasive marbled crayfish and the red swamp crayfish have only spread locally so far. The negative effects on dragonflies have been documented several times; in this article, a risk analysis is carried out by overlapping the distribution data of crayfish and dragonflies in the Rhineland-Palatinate part of the Northern Upper Rhine Plain. It shows that more than 80 % of dragonfly species are affected, with many endangered and/or protected species being affected. In addition, many nature reserves and protected areas under the EU Habitats Directive are also affected in the alluvial zone of the river Rhine. Due to the steady spread of invasive crayfish, this will continue to increase. Finally, some management suggestions are made, although their impact will remain limited." **21772.** Pereira-Moura, L.; Veras, D.S.; de Carvalho, F.G.; Juen, L.; Marques Couceiro, S.R. (2023): Habitat specificity and morphology-main filters for the distribution of Odonata in the Cerrado Maranhense, Brazil. *Aquatic Ecology* 57: 443-458. (in English) ["Our study evaluates the relationship among habitat specificity, morphology and differences in spatial niche breadth of Odonata, in streams with different environmental conditions in the Cerrado Maranhense. We collected in 24 streams between May and November 2016 and March and April 2017. A total of 824 specimens were collected, distributed in 57 species, of which 12 were classified as generalists and five as specialists in integral habitat. Habitat generalists tend to be larger than species that

specialize in intact environments; PERMANOVA showed a significant separation between the generalist and specialist groups in environments with less anthropic impact (Pseudo  $F = 0.173$ ;  $p = 0.001$ ). The length and width of the wings along with the length of the chest were the most important characteristics for this differentiation. *Telebasis griffinii* and *Epipleoneura williamsoni* (OMI – 0.0 and 5.0) presented the lowest spatial niche values. However, specialist species did not always show the lowest values. More than half of the species in our study ( $n = 35$ ) were considered rare by the Multinomial species classification method (CLAM) for having an abundance of less than seven individuals. The number of rare species is a matter of concern given the fragmentation of the region's aquatic environments, which has been shaping Odonata assemblages, making room for generalist species and excluding species that need more complete conditions." (Authors)] Address: Pereira-Moura, L., Programa de Pós-Graduação em Biodiversidade e Biotecnologia - BioNorte, Lab. de Ecologia e Taxonomia de Invertebrados Aquáticos, Univde Federal do Oeste do Pará, Campus Tapajós, Vera Paz, sn, bloco 11, sala 03, Salé, Santarém, PA, Brazil

**21773.** Pinto, T.J.; Smith, W.S. (2023): Impacts of sedimentation and dam failure on the macroinvertebrate community in a tropical stream. *Limnetica* 42(1): 19-36. (in English, with Portuguese summary) ["Impacts of sedimentation and dam failure on the macroinvertebrate community in a tropical stream Changes in land use due to human activities lead to disturbances related to sedimentation in aquatic ecosystems. Furthermore, the construction of dams in streams raises concerns about their safety, and the rupture of these structures implies significant impacts. Thus, this article assessed the effects of sedimentation and dam failure on the aquatic macroinvertebrate community in a tropical stream and verified its influence on the structural and functional composition of this assemblage of organisms. Water physical-chemical parameters and macroinvertebrate fauna data were obtained from monitoring data for both the pre- and post-rupture period. Macroinvertebrates were identified at the family level and classified according to functional feeding groups. Structural and functional biological indexes were applied, and data were analyzed using comparison tests, correlation matrix, correspondence, and cluster analysis. The results showed that sedimentation resulted in the impoverishment of macroinvertebrate fauna, with the loss of important functional feeding groups, indicating a low environmental quality. Dam failure changed the composition of the fauna, leading to the disappearance of important orders, the appearance of organisms belonging to the order Coleoptera, and the loss of feeding groups with consequent loss of ecological functions. The dam failure was not the only stressor for the studied stream, because it already suffered from small and medium scale disturbances related to sedimentation. However, the rupture of the structure resulted in greater environmental losses, and is considered large scale, implying the need to implement recovery measures in the area." **21777.** Putra, I.L.I.; Putri, W.A. (2023): Keanekaragaman Jenis Capung (Hexapoda: Odonata) Di Sekitar Kampus 4 Universitas Ahmad Dahlan, Yogyakarta. Diversity of dragonfly (Hexapoda: Odonata) around Universitas Ahmad Dahlan, Campus. *Metamorfosa: Journal of Biological Sciences* 10(1): 84-95. (in Indonesian, with English summary) ["This study aims to determine the diversity of species, characteristics of species, and species of dragonflies which were abundant around campus 4 Universitas Ahmad Dahlan (UAD). The sampling location was divided into four, namely rice fields, housing, vacant land and campus areas. Each area had 2 plots measuring 35 x 20 m<sup>2</sup>. Each plot had 5

subplot measuring 150 m<sup>2</sup> dispersed in the plot. Sampling was conducted at 08.00 - 11.00 WIB and 15.00 - 17.00 WIB. Sampling was done using a net. The dragonfly that caught was inserted in the papillot paper and the thorax was pressed to death. Dragonflies were identified to the species level by comparing their morphology with an identification reference book. Abiotic factors that measured were air temperature and humidity, wind speed, CO, DO and water pH. The results of this study were there were 4 species of dragonflies that obtained, namely *Pantala flavescens*, *Orthetrum sabina*, *Sympetrum fonscolombii* and *Diplacodes trivialis* with a low diversity level of 0.36. The most abundant dragonfly species, *S. fonscolombii*, was 249 individuals with a dominance index value of 0.74 and the least abundant was *Diplacodes trivialis* with 10 individuals, with a dominance index value of 0.03. The conclusion of this research is that in the area around campus 4 UAD there is a disturbance in the form of land use change which causes a small index of dragonfly species diversity at that location." (Authors) The occurrence of *S. fonscolombii* in Indonesia (Sumatra) is more than questionable.] Address: Putri, W.A., Laboratorium Ekologi dan Sistemika, Program Studi Biologi, Fakultas Sains dan Teknologi Terapan, Universitas Ahmad Dahlan

**21778.** Rahim, A.M.; Hamid, S.A. (2023): A note on diversity of aquatic insects in rivers of Royal Belum State Park, Perak. *J. Trop. Resour. Sustain. Sci.* 10: 64-67. (in English) ["Royal Belum State Park is one of the oldest, protected and pristine land masses that joins hundreds of small tributaries that feed Lake Temenggor. A scientific expedition was conducted, and the diversity of aquatic insects was studied. Five rivers namely Sungai Ta Ng, Sungai Papan, Sungai Gen, Sungai Ruok and Sungai Rambutan were chosen. A kick-sampling technique was deployed to collect the aquatic insect larvae. The study recorded a total of 42 families and 61 genera of aquatic insects which Sungai Papan has the largest number of taxa recorded (18 families, 26 genera). The number of intolerant taxa (Ephemeroptera, Plecoptera, Trichoptera; EPT) in Sungai Papan was substantial (15 genera). Odonata was discovered to be the most diverse order (13 genera), followed by Ephemeroptera (10 genera) and Trichoptera (10 genera). The findings provided a concise richness of aquatic insects, which might serve as a good tool for evaluating the conservation needs of the area." (Authors) Taxa are treated at genus level.] Address: Hamid, S.A., School of Biological Sciences, Universiti Sains Malaysia. 11800 Minden, Penang, Malaysia. Email: ahsuhaila@usm.my

**21781.** Rivas-Torres, A.; Di Pietro, V.; Cordero-Rivera, A. (2023): Sex wars: a female genital spine forces male damselflies to shorten copulation duration. *Evolution*, qpad073, <https://doi.org/10.1093/evolut/qpad073>: 8 pp. (in English) ["In some species males use weapons to harm females, increasing their short-term fitness. Here we show that females can use genital adaptations against males. Females of the damselfly *Enallagma cyathigerum* have a conspicuous vulvar spine on the 8th abdominal segment, which contacts with the male during copulation. We tested three hypotheses for its function: (i) inflicts damage to the male during copulation; (ii) facilitates endophytic oviposition; (iii) stimulates males during copulation to increase their investment. We found that males mated on average for 54 min with control females, but increased copulation to 99 min with females without spine. There was no evidence of physical harm of the spine on the male's seminal vesicle, which shows 8-18 folds, exactly where the spine contacts during copulation. Females with and without spine exhibited the same egg-laying rates and showed similar fecundity and fertility. Longevity was also similar in males mated to control and spineless females. In contrast to many species where females resist male harassment by behavioral responses, the morphological adaptation observed in *E. cyathigerum* appears to act as a sexual weapon, allowing females to control copulation duration. We suggest that the spine has evolved because of sexual conflict over mating duration." **21782.** Romero-Lebrón, E.; Fernández-Monescillo, M.; Matshkina, N.; Delclòs, X.; Gleiser, R. M. (2023): Damselflies (Coenagrionidae) have been avoiding leaf veins during oviposition for at least 52 million years. *iScience* 26(6) 106865: 14 pp. (in English) [Plant-insect interactions can provide extremely valuable information for reconstructing the oviposition behavior. We have studied about 1350 endophytic egg traces of coenagrionid damselflies from the Eocene, identifying triangular or drop-shaped scars associated with them.

This study aims to determine the origin of these scars. Our behavioral study of about 1,800 endophytic eggs from recent coenagrionids indicates that these scars were caused by ovipositor incisions, but without egg insertion. The scar correlates ( $c_2$ -test) with leaf veins in both fossil and extant species. We infer that a female would detect the proximity of a leaf vein and avoid egg-laying, generating a scar that also fossilizes. For the first time, a scar produced by the ovipositor has been identified, indicating the existence of undesirable areas for oviposition. Accordingly, we recognize that Coenagrionidae damselflies (narrow-winged damselflies or pond damselflies) have been avoiding leaf veins for at least 52 million years." **21783.** Sammoudi, R.; Chahlaoui, A.; Khaffou, M.; Elouahli, A.; Fekhaoui, M.; Arahou, M. (2023): Biodiversity assessment and ecotopology of the Taanzoult plain running water (Aguelmam Sidi Ali, Morocco). *Scientific African* 20, July 2023, e01631: 12 pp. (in English) ["Highlights: • Biological diversity is low in the dry season and increases along the flow gradient. • Low representation of bioindicators indicates the degradation of an aquatic biotope. • Imminent health risk due to the presence of anopheles and the abundance of Lymnaeidae. • Poor biological waters quality in dry seasons compared to the wet season. Abstract: The Taanzoult plain is an integral part of the Aguelmam Sidi Ali wetland in the central Moroccan Middle Atlas. Its composition, of several geomorphological facies and terrestrial and aquatic habitats, offers consequent ecosystemic and socioeconomic services. Nevertheless, it is subject to strong anthropic pressure. The objective of this study is to measure the biodiversity and to evaluate the anthropogenic interactions within the aquatic environment. Benthic population dynamics were analyzed at seven monthly stations along the 12-month hydrobiological cycle. The study allowed the inventory of 25432 individuals divided into nine taxonomic classes. The taxonomic wealth is 106 taxa belonging to 92 genera and 64 families of which 70 taxa were recorded at water sources and 77 taxa at the streams. This richness is composed mainly of 64% of insects, 10% of ditellates, 9% of gastropods and 9% of crustaceans. The quantitative and qualitative biological indicators have generally concluded to a poor water quality for both springs and streams. Moreover, the bioindicator species of the good quality of water resources and the surrounding terrestrial ecosystem (Odonata and Plecoptera) are less present despite the absence of their aquatic predators (fish). Thus, the presence of Lymnaeidae and Planorbidae hosts of several pathogens responsible for waterborne diseases and the presence of Anopheles (Culicidae) agent responsible for malaria. In this context, the aquatic biodiversity is significantly influenced by the anthropogenic impact according to a spatiotemporal typology. Indeed, these observations highlight aquatic life degradation and put in suspicion the quality of drinking water and hydropathy. So, it would be judicious to set up a rigorous surveillance system to prevent the imminent health risk and to regulate the pastoral activity in the wetland, in order to foresee adequate development of the water sources in order to perpetuate the offered ecosystem services. ... it was noticed that the Odonata (six taxa with 48 individuals) and the Plecoptera (one taxon with nine individuals) are less represented despite the absence of their aquatic predators (fish)." **21786.** Sarsavan, A.; Wasnik, A.; Soman, S.C. (2023): Climate change effects on tropical odonate community. *Holistic Approach Environ.* 13(3): 92-105. (in English) ["Climate change, such as increased rainfall variability, has affected Yavatmal district in the last decade. Uncertainty of rainfall affects the inter-annual vegetation growth, and thus biodiversity. A baseline study was carried out in 4 habitats in Waghadi basin of Yavatmal district to analyse Odonates species abundance, richness, and diversity as a prerequisite for the protection and management of these habitats. A total of 1263 individuals of 30 species distributed in 6 families were collected. Libellulidae is most dominant family with 13 species. The influence of vegetation on species richness and diversity was analysed (using normalized difference vegetation index values at buffer zones of 1000 m, 500 m, 100 m and 50 m), with further research into the trends of species diversity for each habitat. There was an increase in species richness and diversity with an increase in the dense vegetation, especially around temporary water bodies. This study indicates the contribution of temporary water bodies to ecosystem function and suggests its conservation by monitoring the impacts of increased rainfall variability and anthropogenic influence using odonates." (2023): "A nice old greybeard" - Friedrich Ris' correspondence archived at the Senckenberg Museum Frankfurt/Main, Germany. *International Dragonfly Fund Report* 180: 1-84. (in English) ["The private papers of Friedrich Ris including letters he received were digitized and perused. Altogether 1635 letters written by 118 correspondents are considered, and their content is summarized. In addition 14 letters sent to Ris' relatives after his death are included. The correspondence covers the 53 years from 28-xii-1884 to 28-i-1931. Generally the correspondence involves an exchange of expertise, publications, illustrations, photographs, and to some extent private matters. Also the selling of specimens is mentioned in some letters. During the First World War Ris, a neutral Swiss citizen, corresponded with several entomologists from warring nations on both sides of the conflict. The lack of letters from Förster and Krüger is discussed. The correspondence resulted in the discovery of some Odonata specimens captured by Bartenev. *Calopteryx splendens* was a species of special interest to Ris, he requested specimens from several correspondents at least after 1912. There is evidence for the deposition of the holotype of *Selysiotthemis nigra* in Selys' collection. Furthermore the correspondence provides information e.g. about the exchange of type material, the discovery of new species, the extensive collecting of [E.B.] Williamson, of different points of view regarding the correct spelling of *Aeshna*, and further odonatological topics. Apparently unpublished data found in the correspondence are the first records of *Lestes macrostigma* at the Lake Neusiedl, Austria in 1923 by Zerny, and the quantities of *Somatochlora arctica* captured by Morton during his 1904 trip to Switzerland. Probably the earliest photographs of water mites on the wings of *Sympetrum meridionale* were found in Ris mss responding to a letter of Viets." (Authors)] Address: Seehausen, M., Zool. **21792.** Sharma, A.K.; Kumar, N.; Naveen; Tare, S.; Nayak, S.; Seervi, S. (2023): Phototactic response and taxonomic distribution of predaceous species of paddy ecosystem. *Biological Forum – An International Journal* 15(3): 91-94. (in English) ["The present investigation was carried out at the Research Farm of the College of Agriculture, JNKVV, Jabalpur (M.P.) during Kharif 2020 with a view to collect valuable information on the distribution of predatory species of paddy ecosystem in the Jabalpur region. The majority of nocturnal insect pests with a positive phototropic response are being controlled with light traps. Therefore, gathering data and documentation on natural enemies found in the paddy ecosystem's light traps is equally crucial. During the investigation, light trap collection was represented by a total of 17 predatory species. These species belong to 5 orders and 13 families. Among these orders, Coleoptera was the highest order with 4 families and 6 species. The highest size of trap catch of 3,856 beetles was recorded in *Coccinella* sp. of the family Coccinellidae. Hemiptera was the next order, represented by 3 families and 5 species. Major hemipteroid predatory species were *Canthecona furcellata* (166), *Antiloclus* sp. (122) *Ectomocoris cordiger* (145), *Sirthena* sp. (98) and *Erthesina fullo* (52). Among the other predatory orders, Odonata was represented by *Libellula* sp. (224) and *Coenagrion* sp. (52). Similarly orders Hymenoptera was also represented by two species viz. *Eumenes* sp. (58) and *Dorylus* sp. (21) while order Dictyoptera was represented by only one species each. Thus, these results concluded that the positive benefit far outweighs the negative effect, demonstrating the safety of using light traps in IPM programmes with regard to their influence on natural enemies." (Authors)] Address: Sharma, A.K., Department of Entomology, College of Agriculture, Jawaharlal Nehru Krishi Vishwa Vidyalaya, Jabalpur (Madhya Pradesh), India

**21793.** Sharma, P.; Kangale, M.; Agase, D.M. (2023): Study of odonates diversity near Koradi Lake, Koradi, Nagpur, Maharashtra. *Journal of Entomology and Zoology Studies* 11(1): 126-130. (in English) [Odonata are "prevalent near marshy areas, ponds, lakes, rivers, ditches, and other water bodies. They contribute significantly to the biological foundation of all terrestrial ecosystems as herbivores, pollinators, seed dispersers, predators, detritivores, and vectors. They also serve as effective environmental indicators and biocontrol agents. The objective of the present study was to determine the diversity of odonates in the area around Nagpur's Koradi Lake, which is home to a wide variety of birds and insects. Twenty species of Odonates from 15 genera and three families were discovered during the monitoring in the marked areas near the lake. In total, 1071 individual odonates have been observed in the Koradi region.

Libellulidae had the most species (12), followed by Coenagrionidae (7 species), and Aeshnidae (1 species). It was noted that urbanisation and pollution could have a negative impact on the diversity of odonates in the Koradi region." (Authors)] Address: Agase, D.M., Govt. J.S.T.P.G. College, Balaghat, Madhya Pradesh, India

**21796.** Sittenthaler, M.; Fischer, I.; Chovanec, A.; Koblmüller, S.; Macek, O.; Sattmann, H.; Szucsich, N.; Zangl, L.; Haring, E. (2023): DNA barcoding of exuviae for species identification of Central European damselflies and dragonflies (Insecta: Odonata). *Journal of Insect Conservation* 27: 435-450. (in English) ["Monitoring of odonates has become an important instrument for ecological status assessment of (semi-)aquatic habitats. Besides information on presence and abundance, knowledge about a species' autochthony at the surveyed waterbody is a significant information within the assessment process. Here, the finding of exuviae represents the ultimate proof of successful reproduction. Although feasible for most odonate species, morphological identification of exuviae is often time consuming, as it relies

on small, fragile structures. To facilitate species identification of exuviae, a DNA barcoding approach was developed, including (1) non-destructive extraction of DNA using whole exuviae or their tracheal tubes, and (2) primer systems for long (< 600 bp) and short (< 200 bp) CO1 fragments. A total of 85 exuviae from 33 species were analysed and compared to results of morphological identification. Additionally, factors potentially influencing DNA quality and quantity, as well as PCR and sequencing success were investigated. Eighty-two exuviae matched the morphologically identified genus, and 60 matched at species level. Of the 33 species present in the data set, 82% could be identified to species level via DNA barcoding. The results show how DNA-based approaches can support fast and accurate species identification and therefore enhance monitoring of an ecologically important taxonomic group, with high relevance for conservation and habitat restoration. Moreover, the use of exuviae as DNA resource once more shows that non-invasive sampling offers great potential for molecular species identification, which is essential when studying rare and endangered species. Implications for insect conservation Our results show how molecular tools, here DNA barcoding of odonate exuviae, can support species monitoring without the need of catching individuals, harming, or even killing them. Obtaining DNA from non-invasive sources can thus be a direct advantage to the conservation of insects, especially when dealing with rare and endangered species and/or populations. Using the example of odonates as bioindicator organisms for aquatic and semi-aquatic habitats, we highlight the importance of non-invasive genetic approaches for population studies and monitoring of insect species and/or species communities for ecosystem assessments and conservation management." **21797.** Spoelstra, J.; Post, R. (2023): Groundwater characterization of the eastern Minesing Wetlands in support of the endangered Hine's emerald dragonfly (*Somatochlora hineana*). *Wetlands Ecology and Management* 31: 309-327. (in English) ["The Minesing Wetlands contain Canada's only known population of Hine's emerald dragonfly (HED), a species listed as endangered since 2011. The HED relies on groundwater discharge areas to complete its life cycle and therefore the population is potentially sensitive to changes in groundwater. The goals of this study were to, (1) characterize groundwater discharge to the eastern portion of the Minesing Wetlands, which corresponds to the HED habitat, (2) document any significant changes in groundwater chemistry since a 1998 study, and (3) establish a comprehensive baseline water quality data set to facilitate future comparisons. Consistent with HED habitats in the USA, the chemistry of Minesing Wetlands groundwater was dominated by calcium and bicarbonate. Low groundwater chloride and nitrate concentrations indicated minimal impact from activities such as road salt application and fertilizer use. Nitrate was generally only found at the wetland margin where groundwater springs emerged from the base of the uplands. The dominant form of inorganic nitrogen in wetland groundwater was ammonium (max = 1.5 mg N/L), and soluble reactive phosphorus concentrations were also relatively high (8 to 122 µg/L). The most consistent change in wetland groundwater chemistry between the 1998 study and samples collected in 2015–2017 was that chloride concentrations in 10 of 23 wells increased over time, however the maximum mean well chloride (11.6 mg/L) remained well below the guideline for the protection of aquatic life (120 mg/L). To preserve HED habitat, potential

impacts to groundwater need to be considered during land use planning for the recharge area." (Authors)] Address: Spoelstra, J., Environment & Climate Change Canada, Canada Centre for Inland Waters, 867 Lakeshore Road, P.O. Box 5050, Burlington, ON L7S 1A1, Canada. E-mail: John.Spoelstra@ec.gc.ca

**21798.** Tadhg, C.; Stafford, R.; Gillingham, P.K.; Bullock, J.M.; Brown, D.; Brown, M.; Walls, R.M.; Diaz, A. (2023): Correlated biodiversity change between plant and insect assemblages resurveyed after 80 years across a dynamic habitat mosaic. *Ecology and Evolution* 13:e10168: 13 pp. (in English) ["Historical data on co-occurring taxa are extremely rare. As such, the extent to which distinct co-occurring taxa experience similar long-term patterns in species richness and compositional change (e.g., when exposed to a changing environment) is not clear. Using data from a diverse ecological community surveyed in the 1930s and resurveyed in the 2010s, we investigated whether local plant and insect assemblages displayed cross-taxon congruence — that is, spatiotemporal correlation in species richness and compositional change — across six co-occurring taxa: vascular plants, non-vascular plants, Orthoptera, ants (Hymenoptera: Formicidae), hoverflies (Diptera: Syrphidae), and Odonata. All taxa exhibited high levels of turnover across the ca. 80-year time period. Despite minimal observed changes at the level of the whole study system, species richness displayed widespread cross-taxon congruence (i.e., correlated temporal change) across local assemblages within the study system. Hierarchical logistic regression models suggest a role for shared responses to environmental change underlying cross-taxon correlations and highlight stronger correlations between vascular plants and their direct consumers, suggesting a possible role for biotic interactions between these groups. These results provide an illustration of cross-taxon congruence in biodiversity change using data unique in its combination of temporal and taxonomic scope, and highlight the potential for cascading and comparable effects of environmental change (abiotic and biotic) on co-occurring plant and insect communities. However, analyses of historical resurveys based on currently available data come with inherent uncertainties. As such, this study highlights a need for well-designed experiments, and monitoring programs incorporating co-occurring taxa, to determine the underlying mechanisms and prevalence of congruent biodiversity change as anthropogenic environmental change accelerates apace." (in German) [Hessen, Germany "A female *Cordulegaster bidentata* was observed by the second author on June 12, 2022 in a wet old grass fallow on the edge of the Gundwiesen in the nature reserve "Mönchbruch near Mörfelden and Rüsselsheim" in the northern Upper Rhine plain next to Frankfurt Airport. This first record of an imago of this species in the lowlands is described and discussed in more detail." (Authors)] Address: Opper, E., 65812 Bad Soden, Germany. Email: nachtfalter1@gmx.de

**21800.** Tantipanatip, W. (2023): The relationship between diversity of aquatic insects with water quality in Rama Public Park, Phra Nakhon Si Ayutthaya province. *Pathumwan Academic Journal* 13(36): 67-77. (in Thai, with English summary) ["Diversity of aquatic insects along with the water

quality in Rama Public Park, Phra Nakhon Si Ayutthaya province were examined 10 sites from June 2017 to April 2018. A total of 1,041 individuals in 22 families and 4 orders of aquatic insects were found in this study. The order Hemiptera had the highest number of families (7 families), followed by order Odonata (6 families), Coleoptera (5 families), Diptera (4 families). Physico-chemical water quality parameter at each site, such as total dissolved solids, biochemical oxygen demand and conductivity were significantly different ( $P < 0.05$ ). Most of physico-chemical water quality parameters in Rama Public Park were in class 3 and 4 of the Classification and Standards of Water of Thailand for agriculture. The correlation between physicochemical water quality parameters and aquatic insects were analyzed. The physico-chemical parameters, such as, water and air temperature, turbidity, BOD, pH and conductivity were significantly correlated with Coenagrionidae, Notonectidae, Dytiscidae, Corduliidae, Protoneuridae and Naucoridae ( $P < 0.05$ ). Assessment of water quality could lead to an administrative planning and management of water resources in the Rama Public Park. Promoting conservation of water resources should be emphasized." **21804.** Tshimwandi, F.S. (2023): Feeding ecology of the African tigerfish *Hydrocynus vittatus* castelneau, 1861 in the floodplains of the Kavango river, Namibia. M.Sc. thesis, Biodiversity Management, Faculty of Agriculture, Engineering and Natural Sciences, University of Namibia: IX + 41 pp. (in English) ["The feeding ecology of the African tigerfish *Hydrocynus vittatus* was investigated in the floodplains of the Kavango River, Namibia. A total of 275 samples of tigerfish were caught, using a seine and an experimental multifilament gillnet, during the annual flooding period between February and May 2020. The result of the study shows a significant ontogenetic dietary shift ( $P < 0.05$ ) between size classes of tigerfish. The study also find a significant different ( $P < 0.05$ ) in the diet composition of different size classes of tigerfish, where small size class tigerfish (20 mm -149 mm) fed predominately on aquatic macro invertebrates, which contributed by percentage number 94.5 % (N%), feeding mainly prey on the group of Corixidae 42.5%, Notonectidae 25.5% and Letophlebiidae 18.2%. Medium size class tigerfish (150 mm – 190 mm) fed on both portions of fish (*Entomomus* spp) and aquatic macro invertebrates (*Trichoptera* and *Libellulidae*) and the large size class tigerfish (200 mm - 585 mm) were predominately piscivorous (68.2 % N), feeding mainly on *Cichlidae* 34.9% and *M. altisambesi* 15.9 %. Overall, the results of the study show that tigerfish did not consume prey larger than 150 mm in total length (TL), and the predator - prey length ratio was approximately 23%. The study findings show that tigerfish on the Kamutjonga floodplains feed predominately on aquatic macro invertebrates when in the early stages of life and are piscivorous in the adult stage life. The study results provide important information in understanding the dietary requirement of tigerfish in the Kamutjonga floodplains. Such information is important in conservation measure of tigerfish. Henceforth, the study recommended multi-species modeling studies based on predator-prey interactions, in order to better understand, resource use and partitioning among species on the Kamutjonga floodplain." **21805.** Tuhin, M.I.A.; Nasiruddin, M.; Nayem, Z. (2023): Diversity and relative abundance of entomofauna of four ecologically different areas of Chittagong University Campus, Bangladesh. *American Journal of Life Science and Innovation*, 2(2), 1–11.: 1-11. (in English) ["The present study was conducted to find the relative abundance and diversity of insects in the four areas of the Chittagong University (CU) campus from January 2018 to December 2018. The entire study found six orders - Odonata, Orthoptera, Coleoptera, Lepidoptera, Diptera, and Hymenoptera. Three families under Odonata, two under Orthoptera, four under Coleoptera, five under Lepidoptera, five under Diptera, and three under Hymenoptera were collected from the four study spots. Among them, fifteen species of Odonata, seven species of Orthoptera, seven species of Coleoptera, thirty-five species of Lepidoptera, five species of Diptera, and four species of Hymenoptera were identified. The highest number of insects (478) were collected in January 2018, whereas the lowest number of insects (404) were collected in August 2018. The highest abundance (1598) of insects was found in spot 1 (ground area) and the lowest (990) in spot 2 (hilly area). Lepidoptera (2688) was the most dominant order in the four studied spots, followed by Odonata (1453), Orthoptera (505), Coleoptera (223), Diptera (202), and Hymenoptera (186). During the study period, the highest species richness was observed in Spot 3 ( $2.61 \pm 0.01$ ) and lowest in Spot 2 ( $2.03 \pm 0.008$ ); the highest species diversity was observed in Spot 1 ( $1.36 \pm 0.02$ ) and lowest in Spot 2 ( $1.09 \pm 0.01$ ); and the highest species evenness was observed in

Spot 1 ( $0.53 \pm 0.006$ ) and lowest in Spot 2 ( $0.47 \pm 0.006$ ). Compared with the previous study, it can be concluded that the species diversity and abundance of Odonata, Orthoptera, and Lepidoptera were increased, whereas the diversity and abundance of Coleoptera and Hymenoptera were decreased. The abundance and diversity of insects depended on seasonal fluctuation and ecological and environmental conditions." **21806.** Udayanga, L.; Perera, S.J.; Ranathunge, T. (2023): Chapter 24: Natural enemies against dengue. In: Meththika Vithanage, Majeti Narasimha Vara Prasad (eds.): One health: Human, animal, and environment triad. <https://doi.org/10.1002/9781119867333.ch24>: 351-362. (in English) ["Dengue is recognized as one of the most common and rapidly spreading mosquito-borne viral disease, causing approximately 100 million infections annually around the world, also making a major challenge to the health sectors of Sri Lanka, due to the absence of a specific treatment or a vaccine. Hence health entities around the world rely upon vector control as the primary management strategy for dengue prevention. Regardless of the availability of diverse vector control strategies, unintentional ill effects on the environment and the fast development of insecticide resistance have hindered their success. Biological control of larval and adult stages of *Aedes* vector mosquitoes using locally available natural predators provides a cost-effective, sustainable, and environmentally friendly strategy for dengue vector control. The remarkable ecosystem diversity in Sri Lanka harbors a wide range of natural predators of *Aedes*, which range from microscopic copepods (*Mesocyclops leuckarti* and *Mesocyclops scirassus*) to macroscopic dragonflies (*Pantala flavescens* and *Anax indicus*) and fish (*Aplocheilus dayi*, *Aplocheilus parvus*, and *Puntius bimaculatus*). Ongoing research recommends aforementioned native species as excellent biological control agents of *Aedes* over some exotic species introduced for the same purpose, as a major contributing aspect in integrated vector management for dengue." **21807.** Verheyen, J.; Cuyppers, K.; Stoks, R. (2023): Adverse effects of the pesticide chlorpyrifos on the physiology of a damselfly only occur at the cold and hot extremes of a temperature gradient? *Environmental Pollution* 326, 121438. (in English) ["Ecotoxicological studies considerably improved realism by assessing the toxicity of pollutants at different temperatures. Nevertheless, they may miss key interaction patterns between pollutants and temperature by typically considering only part of the natural thermal gradient experienced by species and ignoring daily temperature fluctuations (DTF). We therefore tested in a common garden laboratory experiment the effects of the pesticide chlorpyrifos across a range of mean temperatures and DTF on physiological traits (related to oxidative stress and bioenergetics) in low- and high-latitude populations of *Ischnura elegans* damselfly larvae. As expected, the impact of chlorpyrifos varied along the wide range of mean temperatures ( $12\text{--}34^\circ\text{C}$ ). None of the physiological traits (except the superoxide anion levels) were affected by chlorpyrifos at the intermediate mean temperatures ( $20\text{--}24^\circ\text{C}$ ). Instead, most of them were negatively affected by chlorpyrifos (reduced activity levels of the antioxidant defense enzymes superoxide dismutase [SOD], catalase [CAT] and peroxidase [PER], and a reduced energy budget) at the very high ( $=28^\circ\text{C}$ ) or extreme high temperatures ( $=32^\circ\text{C}$ ), and to lesser extent at the lower

mean temperatures ( $=16^\circ\text{C}$ ). Notably, at the lower mean temperatures the negative impact of chlorpyrifos was often only present or stronger under DTF. Although the chlorpyrifos effects on the physiological traits greatly depended on the experimentally imposed thermal gradient, patterns were mainly consistent across the natural latitude-associated thermal gradient, indicating the generality of our results. The thermal patterns in chlorpyrifos-induced physiological responses contributed to the observed toxicity patterns in life history (reduced survival and growth at low and high mean temperatures). Taken together, our results underscore the importance of evaluating pesticide toxicity along a temperature gradient and of taking a mechanistic approach with a focus on physiology, to improve our understanding of the combined effects of pollutants and temperature in natural populations." **21808.** Walia, G.K.; Chahal, S.S.; Singh, N. (2023): Chromosomal characterisation of three dragonflies' species (Odonata: Anisoptera: Gomphidae). *Proceedings of the Zoological Society* 76: 55-58. (in English) ["Dragonflies of the family Gomphidae (order Odonata) possess characteristic club-like structure in the last segment of abdomen. Male germ cell chromosomes of *Lamelligomphus biforceps*, *Nepogomphus walli* and *Onychogomphus grammicus* of family Gomphidae were investigated, using carbolfuchsin staining, C-banding, silver nitrate staining and sequence specific staining. All the three possess chromosome complement  $2n = 23$ , which is the type number of the family Gomphidae with XO/XX sex determining mechanism. Terminal C-bands are present on the autosomal bivalents, while bivalents show variation in distribution of NORs (Nuclear Organiser Regions). X chromosome is C- positive and NOR rich in all the species. All the autosomes show CMA3 (Chromomycin A3) bright signals in *Lamelligomphus biforceps*, whereas bright DAPI (4',6-diamidino-2-phenylindole) signals in *Onychogomphus grammicus*, and both DAPI and CMA3 bright signals in *Nepogomphus walli*. The X chromosome of *L. biforceps* possesses DAPI bright signals, while it reveals both DAPI and CMA3 bright signals in *N. walli* and *O. grammicus*. Cytogenetic analyses of all the species have been done for the first time." **21809.** Wang, C.; Wang, X.; Yu, J.; Ding, B. (2023): Highly transparent carbon nanofibrous membranes inspired by dragonfly wings. *ACS Nano* 17(11): 10888-10897. (in English) ["Carbon nanofibrous membrane (CNFM) materials are commonly black and opaque, and their poor optical performance severely limits their application in emerging fields, such as electronic skin, wearable devices, and environmental technologies. However, it is extremely difficult for carbon nanofibrous membranes to achieve high light transmittance owing to their complex fibrous structures and high light absorption. Few researchers have studied transparent carbon nanofibrous membrane (TCNFM) materials. In the current study, a biomimetic TCNFM inspired by dragonfly wings is fabricated using electrospinning technologies and a self-designed patterned substrate, with the aim to construct a differential electric field. Compared with the disordered CNFM, the resultant TCNFM yields an approximately 18-fold higher light transmittance. The freestanding TCNFMs also exhibit high porosities ( $>90\%$ ), good flexibility, and good mechanical properties. The mechanism by which the TCNFMs achieve

high transparency and reduce light absorption is also elucidated. In addition, the TCNFMs display a high PM<sub>0.3</sub> removal efficiency (>90%), low air resistance (<100 Pa), and good conductive properties, including a low resistivity (<0.37 Ω cm)." (Authors)] Address: unknown

(in Dutch, with English summary) ["On 26 March 2022, Bastiaan Kiauta (1937 – 2022) passed away at the age of 85. A short outline is given of his contribution to the study of dragonflies in the Netherlands. In the first place he contributed to the knowledge of dragonfly distribution, especially in the sixties. Secondly, he was the key initiator of the Dutch Dragonfly Researchers (the NLO), which was the predecessor of the NVL (Dutch Dragonfly Society) founded in 1997. In the third place, for more than 40 years he was editor-in-chief of the world dragonfly journal *Odonatologica* of the SIO. This journal is on the one hand a platform for publications, on the other hand Kiauta provided a summary of all publications which appeared in the period 1971-2013. His death marks the end of a special era in Dutch dragonfly study." (Authors)] Address: Wasscher, M., Minstraat 15bis, NL-3582 CA Utrecht, The Netherlands, E-mail: marcel.hilair@12move.nl

**21811.** Wildermuth, H. (2023): Libellen der Pfäffikersee-Gegend. *Ornithologischer Beobachter* 120(2): 131. (in German) [Verbatim (translation, Google translate): Lecture «Dragonflies of the Pfäffikersee area» Then Hansruedi Wildermuth, who knows dragonflies better than anyone else in Switzerland, presents the most important dragonfly species in Lake Pfäffikon and their habitats with magnificent pictures. Of the approximately 80 species occurring in Switzerland, almost 50 species have been identified in the Pfäffikersee area. Dragonflies spend most of their lives as larvae in water. They have very different ways of life and colonize different habitats such as the lake shore, ponds, fens, raised bogs, watercourses and ditches. A special feature of the Pfäffikersee is the dwarf dragonfly, which has its last location here in the canton of Zurich. In addition, it is only represented in Switzerland on Lake Neuchâtel. In order to promote the demanding species of large and small moss damsels, heavily forested raised bogs were cleared and peat cuts were renatured. Locations for observing dragonflies on the Pfäffikersee are the nature center in Pfäffikon, the Aa bridge and the boat harbor and the fishing piers at the southern end as well as the Messikommerweg through the Robenhuserried. At the end of his presentation, Hansruedi Wildermuth would like to thank everyone who works to preserve and enhance the landscape jewel of the Pfäffikersee. The audience thanked the speaker with long-lasting and hearty applause.] Address: Wildermuth, H., Haltbergstr. 43, CH-8630 Rüti, Switzerland. E-mail: hansruedi@wildermuth.ch

**21812.** Wondmagegn, T.; Mengistou, S. (2023): Development of macroinvertebrate based multimetric index for ecological health monitoring in Lake Hawassa, Ethiopia. *Environmental and Sustainability Indicators* 18, June 2023, 100242. in English ["Highlights: • A macroinvertebrate multimetric index (MMIH) was developed to assess the ecological condition of Lake Hawassa. • Habitat disturbance score against notable human activities was conducted to set reference conditions. • The newly developed MMIH index discriminates very well between the reference and non-reference sites of the lake. • It was validated and performed well in discriminating the reference and non-reference sites the independent data sets. Abstract: Little information is available on the use and applicability of biotic indices in

aquatic resource conservation and management in Eastern Africa, especially in lentic ecosystems. The aim of this study was to develop a macroinvertebrate multimetric index (MMIH) to assess the ecological condition of Lake Hawassa. Sampling sites were clustered based on percentage disturbance score (PDS) and categorized into minimally (three sites), moderately (three sites) and highly disturbed (three sites). Physicochemical and invertebrate sampling was done at these clustered sites along the lakeshore area from February to November 2015 and 2016. Out of a total of 35 macroinvertebrate candidate metrics, ten core metrics were selected based on redundancy analysis, metrics response to environmental parameters, percent discriminatory efficiency (%DE) and box and whisker plots, and incorporated in the development of MMIH. The developed MMIH index performed well and showed a clear demarcation between the reference and non-reference sites and between the three-disturbance levels. The validation of the MMIH index performed well in discriminating the independent data sets taken from Lake Hawassa and L. Ziway. Besides, it also showed a strong but inverse relation with PDS ( $R^2 = 0.91$ ,  $P = 0.0003$ ). Hence, in a lentic ecosystem, this index should be considered as a starting point in terms of lake bio-assessment in Ethiopia, but additional data in all ecoregions of the country are necessary to determine the long-term reliability and usefulness of the MMIH. In the short-term, this index will provide resource managers and aquatic environmentalists with a tool to assess the ecological condition of freshwater lakes." (Authors)] Address: Wondmagegn, T., Department of Animal Science, Debre Markos University, Debre Markos, Ethiopia. Email: wondmagegn@gmail.com

**21813.** Woods, T.; McGarvey, D.J. (2023): Drivers of Odonata flight timing revealed by natural history collection data. *Journal of Animal Ecology* 92(1): 310-323. (in English) ["(1) Global change may cause widespread phenological shifts. But knowledge of the extent and generality of these shifts is limited by the availability of phenological records with sufficiently large spatiotemporal extents. Using North American odonates as a model system, we show how a combination of natural history museum and community science collections, beginning in 1901 and extending through 2020, can be leveraged to better understand phenology. (2) We begin with an analysis of odonate functional traits. Principal coordinate analysis is used to place odonate genera within a three-dimensional trait ordination. From this, we identify seven distinct functional groups and select a single odonate genus to represent each group. Next, we pair the odonate records with a list of environmental covariates, including air temperature and degree days, photoperiod, precipitation, latitude and elevation. An iterative subsampling process is then used to mitigate spatiotemporal sampling bias within the odonate dataset. Finally, we use path analysis to quantify the direct effects of degree days, photoperiod and precipitation on odonate emergence timing, while accounting for indirect effects of latitude, elevation and year. (3) Path models showed that degree days, photoperiod and precipitation each have a significant influence on odonate emergence timing, but degree days have the largest overall effect. Notably, the effect that each covariate has on emergence timing varied among functional groups, with positive relationships observed for some group representatives and negative relationships observed for others. For instance, *Calopteryx* sp. emerged earlier as degree days increased, while *Sympetrum* sp. emerged later. (4) Previous studies have linked odonate emergence timing to temperature, photoperiod or precipitation. By using natural history museum and community science data to simultaneously examine all three influences, we show that

systems-level understanding of odonate phenology may now be possible." (Authors)] Address: Woods, T., Department of Ecology and Evolutionary Biology, The University of Tennessee, Knoxville, Tennessee, USA. Email: woodstaylorlizab@purdue.edu

**21814.** Wos, G.; Palomar, G.; Marszałek, M.; Babik, W.; Snięgula, S. (2023): The effect of temperature and invasive alien predator on genetic and phenotypic variation in the damselfly *Ischnura elegans*: cross-latitude comparison. *Frontiers in Zoology*, 10 Apr 2023, 20(1):13. DOI: 10.1186/s12983-023-00494-z PMID: 37032330 PMCID: PMC10084621: 14 pp. (in English) ["Background: Understanding and predicting how organisms respond to human-caused environmental changes has become a major concern in conservation biology. Here, we linked gene expression and phenotypic data to identify candidate genes underlying existing phenotypic trait differentiation under individual and combined environmental variables. For this purpose, we used *Ischnura elegans*. Egg clutches from replicated high- (southern Sweden) and central-latitude (southern Poland) populations facing different degrees of seasonal time constraints were collected. Damselfly larvae were exposed to experimental treatments: current and mild warming temperatures crossed with the presence or absence of an invasive alien predator cue released by the spiny-cheek crayfish, *Faxonius limosus*, which is only present in Poland to date. We measured the following traits: larval development time, body size, mass and growth rate, and used the larvae for gene expression analysis by RNA-seq. Data were analysed using a multivariate approach. Results: We showed latitudinal differences in coping with mild warming and predator cues. When exposed to an increased temperature and a predator cue, central-latitude individuals had the shortest development and the fastest growth compared to high-latitude individuals. There was a general effect of predator cues regarding mass and growth rate reduction independent of latitude. Transcriptome analysis revealed that metabolic pathways related to larval anatomy and development tended to be upregulated in response to mild warming but only in fast-growing central-latitude individuals. Metabolic pathways linked to oxidative stress tended to be downregulated in response to a predator cue, especially in central-latitude individuals. Conclusion: Different phenotypic and transcriptomic responses to environmental factors might be attributed to the variability in *I. elegans* life history strategies between the two latitudes caused by seasonal time constraints and to its coexistence with the invasive alien predator in nature. By providing insights into how organisms may respond to future anthropogenic changes, our results may be of particular interest in conservation biology." (Authors)] Address: Wos, G., Institute of Nature Conservation Polish Acad. of Sciences, al. Adama Mickiewicza 33, 31-120 Kraków, Poland. Email: wos@iop.krakow.pl

**21815.** Xu, J.; Liu, W.; Shang, W.; Chen, J.; Lian, J. (2023): Drop impact dynamic and directional transport on dragonfly wing surface. *Friction* 11(5): 737-747. (in English) ["The ability of dragonflies to fly in the rain without being wetted by raindrops has motivated researchers to investigate the impact behavior of a drop on the superhydrophobic wings of dragonflies. This superhydrophobic surface is used as a reference for the design of directional surfaces and has attracted extensive attention owing to its wide applicability in microfluidics, self-cleaning, and other fields. In this study, the static contact angle and rebound process of a drop impacting a dragonfly wing surface are investigated experimentally, whereas the wetting pressure, Gibbs free energy,

and Stokes number vs. coefficient of restitution are theoretically calculated to examine the dynamic and unidirectional transport behaviors of the drop. Results show that the initial inclination angle of the dragonfly wing is similar to the sliding angles along with the drop sliding. The water drop bounces from the bottom of the dragonfly wing to the distal position, demonstrating directional migration. The drop impacts the dragonfly wing surface, and the drop exhibits compression, recovery, and separation phases; in these three phases, the drop morphology evolves. As the Gibbs free energy and cross-sectional area evolve, the coefficient of restitution decreases as the drop continues to bounce, and the Stokes number increases." (Authors)] Address: Chen, J., School of Mechanical Engineering, Purdue University, West Lafayette, Indiana 47907, USA. E-mail: junchen@purdue.edu

**21816.** Yoshioka, A.; Mitamura, T.; Matsuki, N.; Shimizu, A.; Ouchi, H.; Oguma, H.; Jo, J.; Fukasawa, K.; Kumada, N.; Jingu, S.; Tabuchi, K. (2023): Camera-trapping estimates of the relative population density of *Sympetrum* dragonflies: application to multihabitat users in agricultural landscapes. *PeerJ* 11:e14881: 22 pp. (in English) ["Although camera trapping has been effectively used for wildlife monitoring, its application to multihabitat insects (i.e., insects requiring terrestrial and aquatic ecosystems) is limited. Among such insects, perching *Sympetrum* are agroenvironmental indicators that substantially contribute to agricultural biodiversity. To examine whether custom-developed camera traps for perching dragonflies can be used to assess the relative population density of darter dragonflies, camera trapping, a line-transect survey of mature adult dragonflies, and a line-transect survey of exuviae were conducted for three years in rice paddy fields in Japan. The detection frequency of camera traps in autumn was significantly correlated with the density index of mature adults recorded during the transect surveys in the same season for both *Sympetrum infuscatum* and other darter species. In analyses of camera-detection frequency in autumn and exuviae in early summer, a significant correlation was observed between the camera-detection frequency of mature adults and the exuviae-density index in the following year for *S. infuscatum*; however, a similar correlation was not observed for other darter species. These results suggest that terrestrial camera trapping has the potential to be effective for monitoring the relative density of multihabitat users such as *S. infuscatum*, which shows frequent perching behavior and relatively short-distance dispersal." **21823.** Bönsel, A. (2006): First results of mapping and monitoring four dragonfly species of the FFH Directive (Annex II and IV) in Mecklenburg-Vorpommern (Insecta: Odonata). *Schriftenreihe des Landesmuseums Natur und Mensch Oldenburg* 43: 38-45. (in English, with German summary) ["*Leucorrhinia pectoralis*, *L. albifrons*, *L. caudalis* and *Aeshna viridis* are present in Mecklenburg-Western Pomerania, *Stylurus flavipes* is only found on the Elbe. In the period 2001-2003, ten colonies of *A. viridis*, six of *Leucorrhinia albifrons* and three of *L. caudalis* became known through evidence of exuviae. *L. pectoralis* was observed at 51 sites, and exuviae finds at 18 bodies of water proved that it was native. It is assumed that this species has adapted to changing habitat conditions in eutrophic and thus relatively quickly silted up waters through a metapopulation structure. In order to be able to interpret the results of mapping on species distribution and monitoring, such facts and habitat claims must be

clearly clarified in the future. Habitat maintenance measures for such FFH species should also be discussed further, since it has been shown that habitat focuses vary in different geographical landscape units. Protective measures should then not be formulated uniformly in Europe." (Author/Google translate)] Address: Bönsel, A., Vasenbusch 15, 18337 Gresenhorst, Germany. E-mail: andre.boensel@gmx.de

**21824.** Bogdanovic, T. (2006): Ekološka, morfološka i citogenetička obilježja roda *Lindenia* (Insecta, Odonata, Gomphidae) u Hrvatskoj. PhD thesis, Univ. Zagreb; Doktorska disertacija, Prirodoslovno – matematički fakultet, Sveučilište u Zagrebu: VIII + 192 pp. (in Croatian) ["Ecology, morphology and cytogenetics of genus *Lindenia* (Insecta, Odonata, Gomphidae) in Croatia. - Based on the investigated ecological and morphological differences, two different populations of dragonflies of the genus *Lindenia* were established in Croatia. One is a species of *Lindenia tetraphylla*, while the other has different characteristics. In order to determine whether they are two different species or the same, a series of experiments were carried out in different areas. Ecological, morphological and cytogenetic characteristics of these populations were investigated. The results of research into the qualitative and quantitative composition of dragonfly fauna in coastal Croatia revealed a total of 52 species. Maps of the distribution of individual species in the researched area were created using the latest methods using GIS technology. Results of application of S&oslashash ; Rensen's methods in researching populations in this paper showed that in the researched area there are three types of population communities that are related to specific ecological conditions in the habitats. Seasonal and daily dynamics were investigated and it was determined that dragonflies are most active during the day in the late morning hours, and during the season from the end of June to the beginning of August. Some forms of behavior in dragonflies were investigated and it was determined that they can be classified into two groups. The first, behavior during the preservation of territories and the second, behavior during mating. Differences between the studied populations in the way of eating, choice of prey and manipulation of prey during feeding were also determined. The most important morphological features by which we can distinguish them have been investigated. They refer to the following external morphological characteristics: total body length, wingspan, body color, basic tan markings on the face, shape and structure of the male and female reproductive and receptive organs, and the shape, structure and size of additional sexual organs in males. The results of the research using statistical tests showed that there are significant morphological differences between the investigated populations and that based on morphological characteristics they can be considered different species. Cytogenetic studies of kinship at the chromosome level were made by comparing the number of chromosomes and their basic characteristics. For both populations, the X0/XX type of sex determination was determined, where the male is the heterogametic sex. In the samples of male species *Lindenia tetraphylla* as well as *Lindenia* sp. processed in this work in spermatogonial metaphases, the diploid number of chromosomes  $2n = 23$  and the corresponding chromosomal formula  $2n = 22a+X$  was determined." **21829.** Outomuro, D.; Ocharan, F.J. (2006): De Monstruos & Prodigios: Depigmentación alar en *Calopteryx xanthostoma* (Charpentier, 1825) (Odonata: Calopterygidae). Boletín de la S.E.A. 39: 360. (in Spanish) ["Description of the teratological specimen: Mature male captured in the Narcea river as it passes through the town of Cornellana, (Asturias, N Spain; UTM 29TQJ306104), on 07.VI.2006. At this point the species coexists with *C. virgo meridionalis*. Despite having a completely normal morphology, the right forewing is virtually colorless, although a slight shade of pigmentation can be perceived. In addition, there are other quite marked depigmentation spots on the rest of the wings (moreover, they are frequent in *Calopteryx* populations). In this family, the definitive wing coloration is acquired during a period of maturation after the emergence of the adult individual. A greater proportion of the wing spot reveals a greater ability of the male to defend the territory, obtain more copulations and have fewer intestinal parasites, which feed on the food ingested by the host (Córdoba-Aguilar, 2002). These depigmentations would therefore be indicators of low biological efficacy for the individuals that present them, and could be the object of sexual selection (Siva-Jothy, 1999; Córdoba-Aguilar, 2002). The specimens are deposited in the Dept Biol. of Organisms and Systems of the Univ. of Oviedo." **21832.** Wilson, K. (2006): Commercial odonate fishery at

Cao Hai, Guizhou Province, southwest China. Echo January 2006: 11-12. (in English) ["In August 2005 I travelled from Guangzhou to Weining in west Guizhou, Province, southwest China and visited a large montane lake known as Cao Hai. To my surprise I found the local Hui and Yee people actively engaged in commercial fishing for odonate larvae destined for human consumption" (2,215 m.a.s.l, 26° 51.442'N, 104° 167.194'E). "I examined the catch of one fyke net, which contained many bitterlings, small crucian carp and rice eels in addition to *Anax parthenope* larvae. Given the extremely high density of fyke nets the high numbers of small fishes and absence of large fishes was not unexpected. The commercial odonate fishery is based entirely on the capture of *Anax parthenope* larvae. The larvae are dried and sold at retail prices by merchants for ca 100 yuan per kg (US\$ 13/kg). Each kg contains several thousand *Anax* larvae. In Weining we encountered several dried food merchants supplying odonates with each trader holding stock of millions of dried larvae. The commercial fishery appeared to have no significant impact on the local population of *Anax parthenope*. During my short visit from 15th August 2005 to 19th August 2005 I observed many thousands of *Anax partheope* exuviae, which had successfully avoided entrapment in fyke nets and used clumps of emergent vegetation or the outside of fyke nets for support during emergence. In a local restaurant in Weining my group ordered a dish of odonates and were promptly served with a dish of freshly fried and seasoned larvae. Surprisingly they were quite tasty; a bit like oily crisps with no strong or unpleasant flavours." (Author)] Address: Wilson, K.D.P., 18 Chatsworth Rd, Brighton, E Sussex, BN1 5DB, UK. ## 2007

**21833.** Cremona, F. (2007): Transfert de méthylmercure et structure des réseaux trophiques chez les macroinvertébrés littoraux. Dissertation, Sciences de l'environnement, Université du Québec, Montreal: XIV, 159 pp. (in French and English) ["Within the framework of the case study of the St Lawrence River of the COMERN network, the general objective of the thesis was to determine the role of coastal macroinvertebrates in the transfer of methylmercury (MeHg) in the ecosystem of Lake St Pierre. The first chapter was devoted to the quantitative contribution of non-edible invertebrates ("trophic dead ends") to the transfer of MeHg to fish. For this, the concentrations of total mercury (THg) and MeHg in four functional groups of coastal macroinvertebrates (grazers, detritivores, edible predators, non-edible predators) were measured. The results showed that non-edible predators had the highest concentrations of THg, MeHg and the highest proportion of MeHg/THg of all functional groups. The MeHg load (concentration\*biomass) of non-edible predators accounted for 10–36% of the MeHg pool of phytophilic invertebrates. This high proportion of MeHg sequestered in trophic impasses could help explain the low Hg concentrations measured in fish from Lake St Pierre. Our results show that non-consumable organisms must be taken into account in predictive models of Hg contamination of ecosystems in order to avoid overestimating the quantities of MeHg bioavailable to fish. In the second chapter, the objective was to determine the links between the source of organic matter (OM) and MeHg contamination in primary consuming littoral macroinvertebrates. An isotopic approach was applied to meet this objective. Autochthonous sources (epiphytes and macrophytes) predominated in the OM assimilated by primary consumers, with a lower proportion of allochthonous OM (particularly suspended particulate matter). MeHg/THg in macroinvertebrates was positively correlated with epiphyte

proportions, whereas the latter were negatively correlated with inorganic Hg fraction. This finding suggests that the main entry route for MeHg into littoral food webs is in the epiphytes. Primary consumers could then modulate the transfer of MeHg to higher trophic levels depending on whether they feed on OM sources with high or low MeHg concentration. The third chapter dealt with the influence of the functional group (grazer, collector, fragmenter, omnivore, predator, predator-hematophagous, biting-sucker) and spatiotemporal variables (year, month, sampling station) on the signature of  $\delta^{15}\text{N}$  of coastal macro invertebrates of Lake St Pierre. Station was the most important factor in explaining variations in  $\delta^{15}\text{N}$ , followed by sampling month and functional group. higher than those of the north shore which receives contributions from the Canadian Shield. The  $\delta^{15}\text{N}$  signature of the organisms increased by about 3‰ during the sampling period, from May to September, equivalent to one trophic level. The enrichment of  $\delta^{15}\text{N}$  from herbivores to predators averaged 1.6‰, which is lower than the 3.4‰ generally considered in organisms in the pelagic zone. Since isotopic fractionation is not homogeneous throughout the food web, we recommend using fractionation values specific to the considered trophic levels, in order to better reconstruct littoral food webs. In the last chapter, the roles of macrophyte habitat and architecture on the biomass and abundance of phytophilic invertebrates were investigated. We also calculated a lake-wide estimate of macroinvertebrate biomass associated with different macrophytic habitat types to estimate the quantitative effects of vegetation change on macroinvertebrate communities. Invertebrate community biomass, abundance, and richness were higher in submerged macrophyte habitats than in floating and emergent macrophyte habitats. Macrophytes with complex architecture did not host significantly more macroinvertebrate biomass than those with simpler architecture. In the case of a drop in the water level of Lake St Pierre, we predicted that the total biomass of phytophilic invertebrates would decrease by 16% at the lake level. In littoral food webs, it appears that energy and MeHg fluxes are not perfectly superimposed. First, the low trophic levels constituted by primary consuming macroinvertebrates are able to modulate MeHg fluxes depending on the nature of their OM sources. Secondly, among secondary consumers a significant proportion of the MeHg pool will be little or not available for transfer to fish. The small difference of  $\delta^{15}\text{N}$  between primary and secondary consumers allows us to express doubts about the usefulness of this tool as a tracer of the trophic level of an organism in the littoral zone compared to  $\delta^{13}\text{C}$ . " (Author) The list of taxa includes *Coenagrion* sp., *Libellula* sp. and *Aeshnidae* (Tab. 1.1)] Address: not stated

**21834.** Emiliyamma, K.G.; Radhakrishnan, C. (2007): Fauna of Kudremukh National Park (Karnataka): Insecta: Odonata. Zoological Survey of India. Conservation Area series 32: 27-48. (in English) ["The present study based on a representative faunal collection from KNP comprises of 32 species of Odonata from 21 genera under 7 families, a systematic account of which is presented below. This account forms the first authentic report on the odonate fauna of the Kudremukh National park. **21835.** Harabis, F.; Dolny, A.; Plasek, V. (2007): Could the fen rise in a place of a strip mine lake? In: Kocárek P., Plášek V. & Malachová K. (eds.), Environmental changes

and biological assessment III. Scripta Facultatis Rerum Naturalium Universitatis Ostraviensis Nr. 163, Ostrava: 212-214. (in English) ["Since 2001 intensive survey of chosen bioindicative taxa (especially of dragonflies) has been carried out in the localities of anthropogenic origin in Karviná region (NE Silesia, Czech Republic). We have found several fen-living species (including endangered ones) on irrigated mine subsidence. Thanks to this discovery we could presume that irrigated mine subsidence could offer similar conditions such as fens. It is evident that observed species do not require strictly fen biotopes. ... The result of the survey was surprising. We have found 45 species of dragonflies in a relatively small area (see Tab 1 in Appendix). An occurrence of rare and endangered dragonflies in industrially devastated environment is anything unknown. Several rare dragonfly species which occurred in anthropogenic biotopes, with intensive mining activities have been described in the Czech Republic, e.g. *Sympetma paedisca* (Hájek & Mocek, 2000) or *Libellula fulva* (Dolný & Matijka, 2006). We have found some typical fen-living dragonfly species there, such as *Lestes virens*, *Somatochlora flavomaculata*, *Leucorrhinia pectoralis*, *L.rubicunda*. Observed species with similar biotope preference also has been: *Lestes sponsa*, *Aeshna juncea*, *Somatochlora metallica* and *Sympetrum danae*. Most of them are species with high bioindication value (Zachorowski & Buczyński, 1999). We supposed, that some species e.g. *Nehalennia speciosa*, *Leucorrhinia albifrons* didn't exist in Moravia and Silesia regions. This could be caused by geographical reasons." **21838.** Schiel, F.-J. (2007): Starker Einflug von *Sympetrum fonscolombii* im Jahr 2007. *Mercuriale* 7: 17-28. (in German) ["A strong flight of *S. fonscolombii* in 2007 is documented based on our own random observations, evaluations of the GdO mailing lists and reports from several SGL employees. As can be concluded from the nationally highly synchronized reports of finds, the flight to Germany took place mainly during the last decade of May and reached its peak until mid-June. The first observations date to 18./19. May. The earliest observation of still uncured 2nd generation animals is from July 15th, the last one from October 15th. Nationwide, there are 91 records from 53 localities, including 64 records of the first generation at 44 sites and 23 records of reproduction of the second generation from 16 bodies of water. There was also evidence of development of the first generation in only two bodies of water. In addition, a further 49 reports of finds from Germany and Switzerland are documented. The frequency of the evidence and the high level of representation in the GdO mailing lists suggest an even larger flight event than in the years 1987 and 1996. An evaluation of the evidence in the SGL database from the last 31 years shows that reports of finds in Baden-Württemberg have increased significantly." (Author)] Address: Schiel, F.-J., Inst. Naturschutz & Landschaftsanalyse, Turenweg 9, 77880 Sasbach, Germany. E-mail: Franz-Josef.Schiel@INULA.de

**21839.** Ternois, V.; Lambret, J.-L.; Fradin, E. (2007): La Cordulie à corps fin *Oxygastra curtisii* (Dale, 1834): état des connaissances pour le Parc naturel régional de la Forêt d'Orient (Odonata, Anisoptera, Cordulidae). *Courrier Scientifique du Parc Naturel Régional de la Forêt d'Orient* 31: 77-87. (in French) ["Currently, *O. curtisii* is only known from the Aube and Seine valleys, their tributaries (the Voire) and their outlets (gravel pits, valleys, dead branches). However, considering the biotopes mentioned in the literature, it is not impossible that the species reproduces on certain fish ponds, or even on the lakes of the Orient Forest. For the latter, it is especially on the tails of wooded reservoirs that the species has the best chance of establishing itself. Elsewhere, the dynamics of these large reservoir lakes (increase in water levels until the end of June then a rapid drop in water levels at the beginning of July) does not seem favorable to the reproduction of this odonate. If the observations on the rivers (Aube, Seine and Voire) are not very important, the species is obviously very well established on the gravel pit systems of the Plaine de Brienne and the Seine. *O. curtisii* is relatively abundant in these areas, in particular on old gravel pits that are around 30 years old, with little or no maintenance. Some gravel pits are not sufficiently advanced today to allow reproduction, but they will be soon. Considering the future evolution of these spaces, there is no doubt that *O. curtisii* still has a bright future in Champagne-Ardenne, even if the transformation of many gravel pits into leisure areas may harm its establishment. Moreover, the reproduction now proven within alluvial gravel pits must be a major element to be taken into account in the rehabilitation and ecological enhancement of these artificial environments after the cessation of industrial activity. This favorable situation should not hide the fragility of the species in its original habitats. On watercourses, the conservation of riparian forests and hydraulic annexes remains essential to ensure the maintenance of populations." **21846.** Jakob, C. (2008): Résultats du suivi odonates pour la période de mai à octobre 2008 dans le cadre du suivi écologique en parallèle à des opérations de démolition au Bti sur le périmètre du Parc Naturel Régional de Camargue. Parc Naturel Régional de Camargue, Station Biol. Tour de Valat, Le Sambuc, Aries, France: 18 pp. (in French) ["Evaluation of Methods: The results of the monitoring of odonate adults in 2008 showed the effectiveness of the simplified method with regard to the census of frequent to dominant species. On the other hand, the rarest species in the Camargue, due to their erratic behavior (*Oxygastra curtisii*), or having a biological cycle with a very synchronized emergence (*L. macrostigma*), are generally not represented. The relative abundances obtained therefore fairly well reflect the structure of a population, made up of species hunting their

prey in the marshes and species that reproduce there. The adult monitoring method, decided in 2007, is therefore appropriate, however it would be wise to add one or two samplings at favorable times for certain rare species (eg May-June for *L. macrostigma*, *Oxygastra curtisii*). Especially since the latter is the only species present in the Camargue listed in Appendix II and IV of the "Habitat Directive" (Directive 92/43/EEC). Sampling of larvae and exuviae are generally means of proving the reproduction of the species on the site, of knowing the success of hatching and of calculating the abundance of the breeding species. However, with regard to the sampling of larvae in 2008, extended to the spring and using the surber technique, the results here are limited to providing proof of reproduction for 2 species in the habitat sampled. Identifying whether the very low number of specimens sampled is due to a technical or sampling frequency problem or to a very low number of clutches in these temporary habitats in 2008 is not clearly feasible. But the comparison with the core sampling the previous year shows a strong difference, which would rather indicate an effect of the year (hydrology, temperatures in spring). The same questions arise for the collection of exuviae, but it should also be noted that grazing on the sampled sites can greatly reduce the number of exuviae attached to the vegetation following the passage of cattle. The larval development of certain species takes place rather in the irrigation canals near the monitored temporary marshes which are very attractive for the imagoes which come to feed or shelter there. Followed This second year of study was able to provide the first quantitative results essential for the monitoring of Odonates. These results on specific richness by site and season show a non-significant difference between the control sites and the Bellugue site. This trend of a lower number of species at this station remains to be confirmed over an additional year. A conclusion on a possible effect of BTI treatment on species richness is currently impossible. The relative abundance of adult odonates observed, all seasons combined, highlights the dominance of four species (73%) on all sites, first *Ischnura elegans* and *I. pumilio*, then *Crocothemis erythraea* and *Orthetrum cancellatum*. A low number of species with high numbers corresponds to frequent functioning in rather extreme habitats (salinity, temporality) and not very heterogeneous (Begon et al., 1996), such as the Camargue. On the other hand, the difference between control sites and site treated with BTI remains to be further investigated. The relative abundance of adults by season and site show results related to their annual development cycle in temporary habitat. Thus, small species with a shorter larval development cycle appear earlier in the season, most Anisoptera species are observed later. The numbers observed at La Fangouse and Rousty tend to be larger but this needs to be confirmed by an additional monitoring season. The large variation in abundance between sites may be due to mass or "synchronized" hatching, which may have taken place on the day of the observation ("spring species", Corbet). This is frequently observed in odonates, which reproduce in temporary environments with strong temperature variations (Corbet, 1957; Suhling, 1994). Among the Libellulidae, mass spawning in temporary Camargue habitats is known and their interspecific larval behavior adapted to competition (Suhling, Lepkojus, 2001). Nevertheless, neither at La Bellugue nor at La Boutardière this phenomenon of mass hatching could be observed at this time. But these marshes dried up more quickly than the first two and the adults observed could come from neighboring permanent habitats. The variation in relative abundances between seasons for a given species seems to correspond to the known phenology for the species mentioned and does not show any particularities between sites. Shannon's diversity

index, commonly used for comparisons between sites (Pinkney et al, 2000), does not show any significant difference in central Camargue (including Bellugue). On the other hand, the index of the Boutardière station (MDV) is higher. This could be linked to the supply of fresh water and the proximity of running water sites which have an influence on the range of species. The Odonata group represents an important link in the Camargue ecosystems. With a complex life cycle, both aquatic and aerial predators, they are therefore twice exposed to possible changes in the abundance of prey and consequently their predators as well. Hafner (1971) was able to show that odonates made up about 12% of the prey species (by dry weight) of four species of herons. For this first year of extended study, the quantitative results on the populations of Odonates detect certain trends between control sites and sites treated with BTI. However, only longer-term monitoring can confirm these trends." (Author/Google translate)] Address: Jakob, Christiane, Tour du Valat, Le Sambuc, 13200 Arles, France. Email: christianeiakob@oranae.fr

**21847.** Karle-Fendt, A. (2008): Bestandserfassung der Libellen des Strausbergmooses mit besonderer Berücksichtigung der Alpenmosaikjungfer (*Aeshna caerulea*). Mitteilungen des Naturwissenschaftlichen Arbeitskreises Kempten 43: 3-8. (in German) ["In the 2006 season, the Strausbergmoos (1180 m above sea level, district of Oberallgäu, Bavaria, Germany; top map 8528/1) was systematically examined for dragonflies. The aim was to use quantitative exuvia collections at one of the two lowest localities in Bavaria to find out whether the population of *A. caerulea* is collapsing or even disappearing due to climate change. 61 exuviae were found in 19 inspections. This leads to the conclusion that the Strausbergmoos is still home to one of the largest occurrences of *A. caerulea* in Germany. In addition, the entire dragonfly fauna of the moor was examined except for *Cordulegaster boltonii* and *C. bidentata* that are bound to running water." **21848.** Kistermann, K.; Brux, H. (2008): Pflege- und Entwicklungskonzept für das FFH-Teilgebiet Heumoor (Lkr. Oldenburg) unter besonderer Berücksichtigung von Libellen (Odonata) und Bodenverhältnissen. Natur- und Umweltschutz (Zeitschrift Mellumrat) 7(1): 21-28. (in German, with English summary) [Niedersachsen, Germany; "The investigation area Heumoor, a former raised bog, has an expansion of about 90 ha. It is part of a larger nature reserve of high diversity (including heathland, two lakes and a part of the river Lette). The existing habitats are the results of dewatering and soil degradation leading to a vegetation which mainly consists of purple moor-grass, wetland, shrubs and trees. Soil, habitat types and dragonflies were investigated and other available information was evaluated. 17 dragonfly species (including 6 endangered) were recorded. Even though the critically endangered *Ceriagrion tenellum* was found to be indigenous for 10 years, emphasis is laid on certain species protection measures. The main objective is to obtain the good state of preservation for all habitat types according to the FFH-Directive as well as the protection of endangered species. The recommended main tool is raising the ground-water level in order to restore wetland habitat conditions. A set of accompanying measures including cutting of shrubs and trees in the bog and mowing of wet greenland is part of the management program." **21851.** Ngai, J. (2008): Trophic effects on nutrient cycling. PhD thesis, Fac. Grad. Studies (Zoology), Univ. of British Columbia, Vancouver: 83 pp. (in English) [Field work was conducted in the Area de Conservacion Guanacaste, in northwestern Costa Rica (10°59' N, 85°26' W). The dominant predator in this system is a damselfly larva (*Mecistogaster modesta* Selys, Pseudostigmatidae, Odonata), which is most common in bromeliads greater than 100 ml in capacity. "The top-down effects of consumers and bottom-up effects of resource availability are important in determining community structure and ecological processes. I experimentally examined the roles of consumers — both detritivores and predators — and habitat context in affecting nutrient cycling using the detritus-based insect community in bromeliad leaf wells. I also investigated the role of multiple resources in limiting plant productivity using metaanalyses. The insect community in bromeliads only increased nitrogen release from leaf detritus in the presence of a predator trophic level. When only detritivores were present, the flow of stable isotope-labeled nitrogen from detritus to bromeliads was statistically indistinguishable from that in bromeliads lacking insects. I suggest that emergence of adult detritivores constitutes a loss of nitrogen from bromeliad ecosystems, and

that predation reduces the rate of this nutrient loss. Hence, insects facilitate nutrient uptake by the plant, but only if both predators and detritivores are present. Moreover, predators can affect nutrient cycling by influencing the spatial scale of prey turnover. This mechanism results in a pattern opposite to that predicted by classic trophic cascade theory. Increasing habitat complexity can have implications for nutrient cycling by decreasing the foraging efficiency of both predators and their prey, and by affecting the vulnerability of predators to intraguild predation. Along a natural gradient in bromeliad size, I found that, depending on the relationship between community composition and habitat size, habitat complexity interacts with the changing biotic community to either complement or counteract the impact of predators on nutrient uptake by bromeliads. In contrast to the existing emphasis on single-resource limitation of primary productivity, meta-analyses of a database of 653 studies revealed widespread limitation by multiple resources, and frequent interaction between these resources in restricting plant growth. A framework for analyzing fertilization studies is outlined, with explicit consideration of the possible role of multiple resources. I also review a range of mechanisms responsible for the various forms of resource limitation that are observed in fertilization experiments. These studies emphasize that a wider range of predator and nutrient impacts should be considered, beyond the paradigm of single resource limitation or classic trophic cascades." **21852.** Schmidl, J. (2008): Libellen- und Wasserkäferfauna schwäbischer Niedermoor-Gewässermeulanlagen. Evaluierung artenschutzfachlicher Relevanz und Besiedlungs-Sukzession der Libellen und Wasserkäfer in Niedermoor-Gewässermeulanlagen unterschiedlichen Alters und Ausprägung. Ökologisches Fachgutachten. bufos büro für faunistisch-ökologische studien, Nürnberg., im Auftrag des Bund Naturschutz Bayern e.V.: 117 pp. (in German) ["A total of 30 ponds from 12 fen areas were examined as part of a study on the colonization and biomass of new small water bodies in Swabian fens. The animal groups water beetles ... and dragonflies (larvae) were recorded semi-quantitatively and their relative biomass was determined. The water properties are determined and documented in the form of 19 physical-chemical parameters and other physiographic data. 62 species of water beetles and 22 species of dragonflies were detected and documented faunistically, including 15 species from the Red List of Bavaria (2003), 12 species of water beetles (1x RL1, 4 x RL 2, 7 x RL 3) and 3 species of dragonflies (2 x RL 2, 1x RL 3). Remarkably, more than half of the endangered species can be found in the higher endangerment categories "Critically Endangered" or "Critically Endangered", a clear indication of the species protection importance of the examined water bodies. The percentage of RL species in the total spectrum of species (84 species) is 17%, a high value. ... The occurrence of *Brachytron pratense* is remarkable. (RL 2, in the NSG Gundelfinger Moos and NSG Leipheimer Moos), *Somatochlora flavomaculata* (RL 3, in the NSG Meringer Hölle) and *Sympetrum flaveolum* (RL 2, in the Oberen Ried Oberndorf a. Lech). An evaluation of the examined waters and fen areas under faunistic-ecological aspects is carried out; For this purpose, a spectrum of fen character species is defined for the water beetle. In an in-depth analysis, the present work evaluates the species communities of water beetles and dragonfly larvae using multivariate methods and correlates them with the recorded environmental parameters. The data are analyzed using canonical correspondence analysis and other statistical applications. Detailed relationships between the recorded environmental parameters

and the species spectra of dragonflies and beetles in the individual bodies of water are shown, and mechanisms of action between individual nutrient components and the relative biomass supply in fen ponds are presented. Based on the results of the multivariate analyses, information on the creation and maintenance of new small water bodies is derived. It is shown that the construction of the ponds has a significant influence on the development of species communities typical of fens (with high proportions of stenök species, character species and Red List species). New plants showing the mineral soil cut below the peat cover and thus begin their succession on mineral substrate, build up higher biomass of insects due to the better supply of nutrients, however, the faunistic development begins with pioneer and communal pond settlers and only leads to the species communities typical of fens with increasing substrate coverage by detritus and peat. In contrast, new plants that remain in the peat body begin their biocenotic development with species communities typical of fens and higher species protection values. This control option is also pointed out in connection with the creation of feeding waters for ornithological objectives. In this study, the quantitative differences in the biomass of water beetles and dragonfly larvae in syntopically populated waters are described for the first time. Apparently, biological-bionomic, possibly also antagonistic properties of these two dominant predator groups among the insects of the fenland water community lead to the two groups having their maxima in terms of occurrence (number of species) and abundance (biomass) in different types of water bodies and in different trophic and structural configurations." ## 2009

**21854.** Bayer, N. (2009): Biodiversität von Libellen an künstlichen Stillgewässern unter Einbeziehung ökomorphologischer Gewässerbewertungen. Staatsexamensarbeit Technische Universität Kaiserslautern, Fachbereich Biologie: 106 pp. (in German) ["The aim of the present work was to record and evaluate the dragonfly fauna in a representative selection of still water bodies in the Palatinate Forest. For this purpose, in the period from mid-July to the end of September 2008, 17 wooges were examined for their dragonfly occurrences. The registration of the dragonflies focused primarily on the visual observation of reproductively active adults. In addition, freshly hatched animals and exuviae were searched for as evidence of the indigenous nature of a species. In addition, important structural and physical-chemical parameters of the water bodies were recorded. A total of 22

dragonfly species were identified, 18 of which were considered likely to be native, although it should be noted that only still waters were examined. Overall, the dragonfly fauna was dominated by euryemic species such as *A. cyanea*, *C. puella*, *I. elegans*, *P. nymphula* and *P. pennipes*, while specialized species were almost completely absent from the ponds studied. The typical running water species *C. boltonii*, *C. splendens* and *C. virgo* are only to be regarded as guests at the still waters. The latter in particular occurred with striking frequency but mostly in low abundance in the study waters. Particularly noteworthy are the finds of *C. hastulatum* and *L. dryas*, which are classified nationwide as highly endangered, each on one of the bodies of water. Furthermore, dragonfly species such as *L. sponsa* and *S. sanguineum* that prefer reed and reed areas could be detected, whereas dragonfly species that prefer floating leaf zones such as *A. imperator* and *E. najas* were rather rare and species such as *O. cancellatum* and *L. depressa*, which prefer to colonize water bodies free of vegetation, were almost completely absent. The detected species were described in terms of their habitat requirements and possible reasons for their distribution in the study waters were discussed. In addition, the results obtained during the inventory were statistically evaluated in order to be able to make statements about the connection between the number of species or the occurrence of endangered species on the one hand and certain biotope parameters such as Woog size, degree of shading and silting up on the other. The bodies of water differ considerably in terms of the number of species occurring there. It was shown that both the size of the water body and the degree of shading play an important role in biodiversity. Diversity is greatest in larger bodies of water with little shading. The degree of silting up, on the other hand, did not prove to be decisive for colonization of a water body by dragonflies. This is probably rather favored by the presence of certain vegetation structures. It was also determined that the occurrence of bog species is limited to dystrophic water bodies with intermediate bog silting up areas, since their occurrence depends, among other things, on the presence of peat moss (*Sphagnum spec.*). In order to be able to make concrete statements, however, a larger number of water bodies would have to be examined over a longer period of time." (Author)] Address: not stated; Bayer, Nadine

**21855.** Burk, G.; Ott, J.; Schröder, K. (2009): Entwicklung der Libellen im Eglinger Filz (Teil des FFH-Gebietes Nr. 8135-371) 2004 – 2008. Landesbund für Vogelschutz (LBV) Kreisgruppe Bad Tölz-Wolfratshausen (Hrsg.): 81 pp. (in German) ["Despite the well-known typical population fluctuations in dragonflies, the 5-year monitoring in the Eglinger Filz (Bavaria, Germany) resulted in very meaningful data. Odonata colonized the new moor water areas immediately after the rewetting – further good evidence that the renaturation made sense. Immediately after it began in 2004, the total number of individuals sighted per year doubled to over 1,000 specimens. The number of dragonfly species sighted increased by 71% to 48. The endangered species in particular benefited from the LBV measure. Their number even doubled. In 2008 alone, 5 new species were found, *Aeshna affinis*, *A. subarctica*, *Anax parthenope*, *Cordulegaster bidentata*, and *Sympetrum meridionale*. The rare new discoveries also include the eastern mermaid (2004) and the northern mermaid (2007 and 2008). A special thank you for financial support goes to Mr. Johannes Voith from the State Office for the Environment in Augsburg. The dragonfly investigations in the Eglinger Filz are to be continued.] Address: [https://bad-toelz.lbv.de/app/download/15313372124/Libellenbericht\\_-2004-2008.pdf?t=1674814562](https://bad-toelz.lbv.de/app/download/15313372124/Libellenbericht_-2004-2008.pdf?t=1674814562)

**21856.** Dommanget, J.-L.; Prioul, B.; Gajdos, A.; Boudot, J.-P. (2009): Document préparatoire à une Liste Rouge des Odonates de France métropolitaine complétée par la liste des espèces à suivi prioritaire. Décembre 2007 – réactualisation: décembre/février 2009. Société française d'odonatologie (Sfonat). Rapport non publié: 47 pp. (in French) ["A preparatory document for a new Red List of Odonates in metropolitan France is presented. The methodology used is inspired by the national application methods of the IUCN protocol. The approach adopted is the evaluation of the status of each of the species of the fauna of France to obtain a classification according to the categories proposed by the IUCN. The assessment was carried out on the basis of the eligibility conditions (reference period, native status, etc.), then using the "species" and "habitats" criteria (table III page 123). The "species" criteria include 1) the analysis of data from the Invod program, 2) a synthesis of the literature from which ten regional Red Lists were taken into account (table IV), 3) other criteria such as the fragmentation of populations, endemism, the different national and Western European protection statuses, etc. The "habitats" criteria have been added and take into account euryoeces species, which use varied environments, globally little or not threatened, and the stenoecious species, which develop in a smaller range of habitats, more threatened. The difficulties encountered show that the sole use of an inventory database is not sufficient for such an evaluation and that it is important to complete the analysis by using criteria based on expert opinion. The preparatory Red List brings together 27.5% of the fauna species of France, of which two are considered extinct, two others are in critical danger of extinction, eleven are in danger and ten are vulnerable. Species on the Red List and those classified in the "Near Threatened" category are included in the Sfonat priority species monitoring programme." **21860.** Montpeyó i Garcia-Moreno, D. (2009): Els Odonats d'Osona. *Col·legi Sant Miquel dels Sants: 74 pp.* (in Catalan, with English summary) ["The work "Odonats d'Osona 1988-2008" consists of a study of odonates in the region of Osona. Just over 20 years ago, the Meganeura group for the study of odonates began work with similar characteristics. "The Odonats of Osona 1988-2008", apart from studying the current situation of the odonates of Osona, it also aims to make a comparative study of both works, studying how the population has evolved in these 20 years and what they could have been the factors that have participated in this change. One of these factors, water quality, has been studied in detail using water quality analytics in 6 aquatic habitats in the county, to compare whether the quality has changed since the work of Meganeura, who also studied these same habitats. Finally, the aim is to determine which species in the region are threatened and which are protected by current legislation and which would serve to be used as bioindicators of water quality. It has been tried that the methodology of the work strictly follows the scientific method. We can divide the practical part of the work into two: Field work: it consists of trips of approximately two hours in 18 different habitats throughout the region with the aim of identifying the different species of odonates found there, in addition to noting the environmental conditions in which the departure was made. The aim is to obtain updated information on odonate populations. Based on the data obtained, a table has been drawn up, organized by registered appointments and by trips made, to work more comfortably and not make mistakes. Lab. work: with the water samples collected in the 6 habitats where Meganeura did its analyzes and at the same time of the year, analyzes were carried out to check how the quality of the water has varied and how this has affected the odonate population. The analyzes could be done by direct measurement (with probes), with chemical tests on site or in a Lab., depending on each parameter. The results that have been obtained point to an increase in the diversity of odonate species in the various habitats studied in the Osona region based on the results obtained by the Meganeura group in their work. From the parallel studies to

determine the water quality of the 6 habitats studied, it has been possible to verify that the waters of the region have, in general, experienced a remarkable improvement. With all the data and results obtained, the conclusion has been reached that the diversity of the odonate populations in the region has increased considerably over the last 20 years and this is most likely due to the improvement in the quality of the water experienced by Osona's watercourses and ponds, due to a tightening of regulations and the installation of treatment plants. It is necessary, however, to continue to ensure that its quality does not deteriorate again by combating the activities that still today continue to pollute the oceanic aquatic environment. ver, is to release information about dragonflies, which are unknown and not studied in detail." **21861.** Muscatello, J.R. (2009): Selenium accumulation and effects in aquatic organisms downstream of uranium mining and milling operations in northern Saskatchewan. PhD thesis, Toxicology Graduate Program, Univ. of Saskatchewan, Saskatoon: xxi, 232 pp. (in English) ["The overall objective of this thesis was to determine selenium (Se) levels in the major compartments of aquatic ecosystems and correlate these data with potential Se effects on early life stages of two native fish species. This work was conducted at two uranium (U) mines located in northern Saskatchewan, Key Lake mine and McClean Lake mine. In addition, a site fidelity study was conducted at Key Lake mine to evaluate movement patterns of northern pike inhabiting lakes receiving effluent discharges. At Key Lake mine, Se was accumulated and biomagnified several orders of magnitude higher than its concentration in water (0.7-2.7 µg/L) in lakes receiving discharges, with Se in prey organisms reaching levels above the proposed 3-11 µg/g dry weight (DW) dietary toxicity threshold for fish. Increased concentrations of Se in aquatic biota led to an increase in the Se concentrations in eggs and tissues of northern pike that rely on these organisms as food sources. Furthermore, increases in the incidence of Se-induced deformities above 30% were recorded in fry originating from adults exposed to high levels of dietary Se (> 3µg/g, DW). The increased frequency of deformities found in northern pike fry was associated with a significant increase in the level of Se in northern pike eggs from exposure sites (31.28 - 48.23 µg/g DW) compared to reference (3.19 ± 0.29 µg/g DW). At McClean Lake mine, Se was accumulated and biomagnified through the aquatic food chain with concentrations in some biota groups (e.g., forage fish) exceeding the lower limit (> 3µg/g DW) of the 3-11µg/g (DW) threshold for dietary Se toxicity in fish. Although both northern pike and white sucker females collected from the exposure site showed greater levels of Se in egg and tissues compared to fish collected from a reference site (likely caused by exposure to elevated levels of Se in prey organisms), no increases in Se-induced deformities were found in the developing fish larvae. The lack of a toxic response in fish larvae is in agreement with Se thresholds for early life stage deformities, with egg Se concentrations in northern pike and white sucker collected at the exposure site below the proposed 10 µg/g (DW) threshold associated with the presence of developmental abnormalities. The applicability of the proposed 7.91 µg/g (whole body, DW) Se toxicity threshold to cold water fish is controversial given that most of the research has focused on warm water fish. Therefore, there is an urgent need to conduct studies that allow us to better understand the environmental fate and effects of Se in north temperate (cold water) aquatic systems. The results of my research will contribute valuable information for the establishment of

a realistic and environmentally relevant Se threshold for the protection of fish populations in Canadian waters. During the site fidelity study, fish locations were seasonally and daily recorded using a Lotek SRX\_400 receiver with hand-held Yagi antenna. The results suggest that tagged pike did not migrate out of the study area throughout the study period, with the mean distance traveled ranging from 50 to 400 m. Differences in movement (distance traveled) and home range were found between reference and exposure sites. Overall data suggest that radio-telemetry is a useful tool in environmental studies. This information on northern pike behavior will be valuable towards developing non-lethal sampling methods that could be applied for assessing the effects of industrial discharges in north temperate aquatic ecosystems." (Author) The study includes many references to "Odonata".] Address: Email: [jrm202@mail.usask.ca](mailto:jrm202@mail.usask.ca); <https://harvest.usask.ca/handle/10388/etd-02122009-130012>

**21862.** Sherwin, S. (2009): Welchen Einfluss haben Sukzession und Klimawandel auf die Libellenzönosen von Stillgewässern? / Die Libellenzönosen von Stillgewässern in Münster (Westfalen). Diplomarbeit. Westfälische Wilhelms-Universität Münster: 33 pp. (in German, with English summary) ["The Odonata communities of 31 waterbodies were examined in 2008 and were compared with older surveys from 1997 and 2001. The waterbodies could be divided into an early or late succession stage by means of structural and hydrological parameters. Thirteen waterbodies could directly be compared with each other. To examine how the population of the species developed, all of the waterbodies from the current survey and the data from 1997 and 2001 were included in the analysis. The comparison of the thirteen waterbodies showed no differences with regard to species richness (26 vs. 24 species) or endangered species (each with 5 species). But the comparison of all waterbodies indicated that the southern species increased. For the first time the Mediterranean species *Crocothemis erythraea* was detected in Muenster at three young waterbodies with successful reproduction. The results show that the richness in species and the endangered species are higher in the early succession stage of the waterbodies than in later stages of succession. Except for *Erythromma viridulum* the southern species also prefer the early succession stage. The Odonata communities of 31 pools and ponds in Muenster were investigated in 2008. The waterbodies could be divided into seven different structural types by means of environmental parameters such as water-level fluctuations, submerged vegetation and marsh plants. The structural types were characterized by specific dragonfly communities. Character and differential species were described at the habitat and structural level. As regional character species for pools and ponds *Aeshna affinis*, *Ischnura pumilio*, *Lestes barbarus*, *L. dryas*, *L. sponsa*, *Libellula depressa* and *Sympetrum vulgatum* were specified. *Aeshna cyanea*, *A. mixta*, *Anax imperator*, *Erythromma najas*, *E. viridulum*, *Lestes viridis*, *Libellula quadrimaculata*, *Platycnemis pennipes* and *Sympetrum sanguineum* act as differential species for particular structural types in this habitat. Waterbodies in an early or middle succession stage have a higher species richness and more endangered species. On the basis of the required results the consequences for conservation are pointed out." **21863.** Tessier, M.; Sfreddo, G.; Ouin, A. (2009): Étude des peuplements d'odonates dans une plaine agricole du sud de la France. *Revue d'écologie - Terre et vie* 64(1): 41-50. (in French, with English summary) ["Odonata communities in an agricultural lowland in the South of France. — Odonata

communities were studied in an agricultural landscape where semi-natural habitat patches (pastures and woods, with a dense network of deep ditches) are embedded in a crop mosaic (cereals, irrigated maize). We compared species richness and diversity of aquatic plants and Odonata in ditches surrounded by pastures or by crops. Ours results showed that this surrounding (pastures vs crops) has no effect on aquatic plant and Odonata species richness and diversity. However, in cultivated areas water supply through irrigation and deep ditches with plant-covered borders could promote Odonata species. High level of vegetation cover (particularly with *Typha* sp.) limited Odonata richness and diversity. A rare species in Europe, protected and sensible to pollution, *Coenagrion mercuriale*, occurred in many ditches including those surrounded by crops, particularly those with an intermediate semi-aquatic vegetation cover. The regular maintenance of ditches, by limiting shrubs and trees height, keep them open and facilitate the dispersal of this little mobile species. Although irrigated crops seem to support a high level of Odonata diversity, a new intensification of agricultural practices in this area by increasing the pollutant input and/or by converting pastures to crops could be detrimental to Odonata communities and particularly to some species like *C. mercuriale*." **21865.** Vermeersch, G.; Beckers, K.; Maes, D.; Adriaens, T.; De Beer, D.; De Knijf, G.; Hendrickx, F.; Jooris, R.; Maelfait, J.P.; Van Den Berghe, K.; Van Keer, K.; Van Landuyt, W.; Van Thuyne, G.; Verbeylen, G. (2009): Een gericht natuurbeleid voor de prioritaire soorten in de provincie Antwerpen. *Antenne* 3(3): 14-20. (in Dutch) ["A targeted nature policy for the priority species in the province of Antwerp: In 2001, following the preparation of the Provincial Nature Development Plan (PNOP), the Institute for Nature and Forest Research (INBO) made an initial study to introduce the concept of 'typical', 'priority' and provincial 'attention' species on this basis (Bauwens D. et al, 2001) (figure 1). At the end of 2008, the Institute for Nature and Forest Research (INBO) and the province of Antwerp joined forces and INBO was asked to update that study. Based on the most up-to-date possible distribution data of various groups of species (higher plants, locusts, dragonflies, butterflies, spiders, fish, mammals, amphibians, reptiles and breeding birds), the province wants to scientific criteria lead to priority species for the provincial nature policy. This was done in collaboration with Natuurpunt Studie, Arabel, Saltabel and the Flemish dragonfly working group. The same methodology was followed for all taxonomic groups (Bauwens et. al, 2001). The group of mushrooms was examined by Natuurpunt Studie itself and a separate criterion was used for this on the basis of data from the database 'FUNBEL' (see the following article, page 21). Analyses were carried out by the various database managers in order to draw up a list of priority species per species group. If at least 33% of the current, known distribution area of a species in Flanders is located within the province of Antwerp

and if this percentage is also significant or if the species concerned appears on a Flemish Red List, it is initially included in the analysis. The province wanted to further refine the group of species into species of interest. An expert assessment was therefore formulated by all species specialists, on the basis of which the lists were further narrowed down and it could be clearly stated per species why it should be able to count on the necessary attention within Antwerp's nature and environmental policy. Species that only occur in European protected areas or areas where they can already benefit from efficient protection in another way, were therefore still excluded. In the end, 148 species were retained. A very high number of priority species are tied to stream and river valleys. This will give an extra boost to the efforts that the province is already making there." (Authors/Google translate) The list includes 13 odonate species: *Aeshna isoceles*, *A. juncea*, *Brachytron pratense*, *Calopteryx virgo*, *Coenagrion lunulatum*, *C. pulchellum*, *Gomphus vulgatissimus*, *Leucorrhinia pectoralis*, *L. rubicunda*, *Libellula fulva*, *Orthetrum coerulescens*, *Sympetrum depressiusculum*, and *Lestes dryas*.] Address: Knijf, G. de, Research Institute for Nature and Forest (INBO), Havenlaan 88 bus 73, 1000 Brussels, Belgium. **21866.** Ewald, N.; Nicolet, P.; Oertli, B.; Della Bella, V.; Rhazi, L.; Raymond, A.-S.; Minssieux, E.; Saber, E.; Rhazi, M.; Biggs, J.; Bressi, N.; Cereghino, R.; Grillas, P.; Kalettka, T.; Hull, A.; Scher, O.; Serrano, L. (2010): A preliminary assessment of Important Areas for Ponds (IAPs) in the Mediterranean and Alpine Arc. European Pond Conservation Network (EPCN), c/o Hepia, Univ. of Applied Sciences Western Switzerland, 1254 Jussy/Geneva, Switzerland: V + 41 pp. (in English) ["The Important Areas for Ponds (IAPs) concept was developed to raise awareness of geographic regions that support ponds of national or international biodiversity importance, and help focus strategies for pond monitoring, protection and appropriate management and creation. Ponds are vitally important for freshwater biodiversity and particularly recognised as stepping stone habitats. They also provide a range of ecosystem services and have been used for centuries by local communities. Ponds and pond networks are abundant across Europe and Northern Africa, in spite of significant losses, but are not adequately protected by current legislation even within the European legislative framework for nature conservation and water management. The information gathered during the identification of IAPs will be used to encourage better protection measures for ponds at the regional, national and international level, and their inclusion in biodiversity and water protection strategies (e.g. Water Framework Directive, River Basin Management Plans). In order to achieve greater protection for ponds in Europe there needs to be coordination between countries. The European Pond Conservation Network (EPCN), as part of the ProPond Project (Promoting Pond Conservation in Europe and the Mediterranean Region, a project supported by the MAVA foundation), has begun this work by concentrating on two biogeographical regions – the Mediterranean Basin and the Alpine Arc. Selection of IAPs was based on a set of criteria including the presence of species or habitats of conservation importance, pond density, and their socio-economic importance (providing this did not undermine their biodiversity value) and other factors such as important assemblages of species e.g. dragonflies and macrocrustaceans. IAPs were identified using both GIS techniques and expert knowledge from a wide range of pond workers including both researchers and practitioners. For this first analysis, 140 proposed IAPs

(pIAPs) have been identified in the Alpine Arc (30 pIAPs) and in the Mediterranean region (110 pIAPs), the latter including sites both from Northern Africa and the Middle East (28 pIAPs) and from Europe (82 pIAPs). A profile of each IAP has been produced with information on its (i) location, (ii) biodiversity, historical and social value, and (iii) threats. In the Mediterranean basin, pIAPs have been identified in 17 countries in Southern Europe, North Africa and the Eastern Mediterranean. The selected pIAPs reflect the heterogeneity of pond sites, and range from individual ponds in Spain supporting 18 species of European conservation importance to pond networks in Italy known to contain over 60 species of European conservation importance. Many areas qualified as IAPs because of high pond density (e.g. over 15 ponds per km<sup>2</sup> in Greece) whereas others qualified because they contained many ponds scattered over large areas (e.g. 1613 ponds over 200000 ha in Morocco), representing a dispersed but highly significant freshwater biodiversity resource in the region. The socio-economic value of ponds was also recognised in their identification as pIAPs: some such as in Israel show evidence of continuous use since the Roman occupation. Many IAPs, particularly in Northern Africa and the Eastern Mediterranean have no current protection, in spite of the habitats and species of conservation concern they support, and all are under significant threat from the increasing pressures of agriculture and development. Raising the profile of these sites through designation as IAPs will help to secure their protection and future sustainable management. In the Alpine Arc, a total of 30 pIAPs were proposed in the four main countries which made up the region. Some had exceptionally high pond densities (e.g. pIAPs with over 30 ponds per km<sup>2</sup> in the French Alps), whereas others in the same region comprise a single pond with important assemblages of species. Pond networks were also identified: some extended over large areas, exceeding 2000 ha in Italy, whilst others (e.g. in Austria) were concentrated within an area of less than 20ha. The majority of pIAPs in the Alpine Arc contained species of European conservation importance but also high altitude stenothermal species. However, these alpine ponds are not well represented in the list of pond types given under the Habitats Directive leading to a lack of designation within the European legislative framework of protected sites. The identification of networks of ponds in the Alpine region as IAPs will provide greater recognition of their importance to biodiversity at an international level. This is particularly relevant to high altitude sites, as they are under significant threat from climate change, an issue which requires cooperation and implementation of conservation initiatives at an international level. IAPs in the Alpine Arc also demonstrate the cultural importance of ponds. Many have a long history of use particularly within the traditional pastoral economy of the region. More recently pond networks are providing a valuable research and educational tool for both the scientific community and the wider public. This report is a preliminary assessment of IAPs in the Mediterranean and Alpine Arc region. Proposed IAPs (pIAPs) will be reviewed through a public consultation process and either accepted as a full IAP, modified or declined. The pIAPs identified as part of the ProPond Project will be published on the EPCN website. This should ensure that the information is rapidly disseminated to pond conservation practitioners and turned into positive action to protect and enhance the pond biodiversity resource. The pIAPs presented in this report incorporate the high quality ponds so far known: we anticipate that, as the profile and knowledge of ponds grows, aided by the IAP process itself, considerably more high quality pond will be found in these regions than have currently identified. The EPCN will now continue to coordinate and facilitate this work, building on the momentum of

the ProPond project. A key role of the network and its members is now to disseminate the information presented here as widely as possible as part of a consultation process, but also to inform international and national policymakers." Biol., Entomology, Univ. Sao Paulo: X + 60 pp. (in Portuguese, with English summary) ["Sexual size dimorphism (SSD) can in some species result from the selection acting through different mating systems. Behavioural studies of neotropical species are rare, and few is known about the Brazilian species. In this study, we described the behaviour of three neotropical species that occur in the Brazilian neotropical savannah: *Acanthagrion truncatum*, *Argia reclusa* and *Hetaerina rosea*. We demonstrate the SSD in these species and investigates through behavioural observations, how SSD develops in species with different mating tactics. With our results, we can see that in territorial species the males are larger than females, while in non-territorial species the females are larger than males. We suggest that, unlike other studies, in Zygoptera the kind of mating system adopted by males may determinate the SSD in a species." **21868.** Jakob, C. (2010): Résultats du suivi écologique en parallèle à des opérations de démoustication au BTI sur le périmètre du Parc Naturel Régional de Camargue - Partie Odonates. Rapport final 2010. Parc naturel regional de Camargue. Rapport Odonates-BTI 2010: 14 pp. (in French) ["Conclusion and outlook for 2011: The results of the 2010 study on the sites in the Camargue confirm the significant difference observed in 2009 with a lower species richness observed on the sites treated with BTI compared to the untreated sites. The relative abundances vary between treated and untreated sites, distributed over a smaller number of species on the untreated sites, generally more common species. This result is similar to that of 2009. The integration of environmental variables important for the life cycle of Odonates via a statistical analysis made it possible to test their respective impact on Odonates compared with the BTI treatment. Thus, the hierarchical ANOVA analysis made it possible to identify the significant impact of BTI on species richness compared to two other factors (site and year), in which other factors are interwoven (conductivity, hydroperiod). This result is all the more important since currently, few studies are available on the long-term monitoring of the effects of BTI on non-target organisms in their natural habitat (e.g. Boisvert et al, 2004; Niemi et al, 1998, and recently Poulin et al, 2010). For 2011, the continuation of monitoring identical to that carried out in 2010, is proposed on the 7 sampling sites in 6 zones and during the 3 seasons of Odonate activity. The sampling campaign in 2011 will make it possible to use the same hierarchical analysis approaches for abundance and to extend the model to other factors such as conductivity." **21870.** Schnauder, I.; Rudnick, S.; Garcia, X.-F.; Aberle, J. (2010): Incipient motion and drift of benthic invertebrates in boundary shear layers. River Flow 2010 - Dittrich, Koll, Aberle & Geisenhainer (eds) - © 2010 Bundesanstalt für Wasserbau ISBN 978-3-939230-00-7: 1453-1461. (in English) ["The present study aimed to identify threshold shear stresses to cause benthic invertebrates to drift in boundary shear layers. Lab. experiments were carried out in a small tilting flume, 10 cm wide and 3 m long with a closed recirculation system and a fixed sand bottom of uniform grain size. Benthic invertebrates from different orders (Achaeta, Gastropoda, Crustacea, Ephemeroptera, Odonata, Megaloptera, Trichoptera) were collected from a lowland river (Spree, Germany) and kept in aquariums to adapt to the Lab. conditions. Individuals were placed in the flume at low flow conditions, before gradually increasing the discharge until drift occurred. Photos were taken from the side through the flume walls to capture the behaviour and strategies of the organisms to cope with the flow. Photos against millimeter grid graph paper in the background were taken for each individual in order to quantify the body height and length exposed to flow. Subsequently, velocity and shear stress profiles were measured above the drift location with an Acoustic Doppler Velocimeter (ADV, Nortek Vectrino). Bed shear stresses were determined by extrapolation of the Reynolds shear stress profiles in subcritical flow conditions. For supercritical flow conditions, a simple particle tracking velocimetry was applied to determine velocity profiles. Bed shear stress was then estimated from fitting of a log-law. Results are presented in tabular form, containing the average drift shear stress and drift velocity for 15 taxa commonly found in lowland rivers. Drift shear stresses, which can be interpreted as abiotic 'absence' criteria of the species, were in most cases exceeding the conditions of preferential habitats and incipient motion threshold of the sediments. However, it was observed that sudden changes in the angle of flow attack (e.g. by burst events or surface waves) or direct interaction with sediment motion (animals hit by moving grains or erosion of the grains serving as anchorage) were key factors triggering invertebrate drift. ... 5.2.3 *Calopteryx splendens*, *Coenagrionida* sp. (damselflies): These damselfly species abundant in River Spree, are typically found in macrophyte stands where they are well camouflaged due to their slender morphology (Figure 4). We collected larvae shortly before emergence, thus having a body length of about 30 mm. Both taxa resisted the highest stresses and velocities reached, and in 85% of all tests they were not drifted at all. In the few drift incidents, the individual was moving towards the flume corners or lifted off the bed by a strong ejection event *C. splendens* applied rheotaxis by keeping the head low, while the abdomen was detached from the bed and legs absorbed near-bed turbulent fluctuations. Swimming movements by sweeping the tail back and forth were only observed for low velocities but not during drift. 5.2.4 *Gomphus vulgatissimus*, *Cordulia aenea* (dragonflies): These dragonfly taxa (Figure 5) live in loose fine sediments close to the banks and are active predators during night. They are not very agile and the physiognomy is adapted to dig into the substrate, where they hide during resting periods. Their claws were not suited well to attach to the grains and drift occurred quickly for all tests in subcritical conditions, often while moving towards the flume corners. For *G. vulgatissimus*, the drift stress is approximately in the range of the incipient motion of the sand used in the tests (*u*

. = 1.76 cm/s) and indicates the adaptation to life in lentic environment. When drifted, *G. vulgatissimus* propelled itself forward by sucking water into the body and expelling it through its anal pore. *C. aenea* has longer legs and a shorter body which allow it to sustain higher stresses than the shortlegged *G. vulgatissimus*." However, no rare species was observed in the vicinity of rare species was observed. At the higher altitudes, on the summit plateau of the Schlern, only one single species was found: *Aeshna juncea*. Only *Cordulegaster bidentatus*, a wood dragonfly living along small along small watercourses, is an interesting find: *Aeshna juncea*. interesting find: It is considered rare in South Tyrol South Tyrol and has been included in the Red List. list.] Address: Abteilung Natur und Landschaft, Amt für Naturparke, Rittner Straße 4, 39100 Bozen, Italy

**21872.** Winter, P. (2010): Views and reviews: Britain's Dragonflies (second edition) by Dave Smallshire & Andy Swash. WILDGuides, 2010. 208pp., 428 photos, 290 illustrations and 66 maps. Sbk with plastic sleeve. ISBN 978-1-903657-29-4. £17.95. Atropos 41: 46-47. (in English) ["Most people with an interest in British dragonflies will be familiar with the original 2004 edition of this book, which received favourable reviews. Personally I felt that certain sections were crammed and, as skilfully created as the some species to be too small and sometimes difficult to distinguish from the background. Would the second edition improve these and other areas? On opening the book the answer was a definite 'yes'. There are 40 additional pages which have been used to expand several sections, a different font has been used, the layout of the text has been improved making it more readable, and the images have greater clarity. The Biology section, in addition to containing larger images to support the revised text, now has a page showing the stages of aging in a dragonfly, which I hope that newcomers to the subject Will read before diving straight into the species pages. The Habitats section also benefits from a modified layout making it easier to see the species found in different types of habitat. There is also a new page detailing some locations for rare, scarce and localised dragonflies. The summary identification charts, possibly the best innovation in the first edition with the key separating features in red text, are now spaced out over 12 pages rather than the original eight. Southern Emerald Damselfly *Lestes barbarus* and Willow Emerald Damselfly *L. viridis* have been added to the charts, the font is larger and more readable, there are fewer families per page, and the darters page now includes excellent drawings of the heads. There is also a two-page spread on identifying male emeralds, hawkers and emperors in flight. I was pleased to read that for Common Hawker *Aeshna juncea* the yellow costa 'may' be visible as it usually fails to be visible to me unless seen at very close range! The

species accounts benefit from a revised layout. As in the first edition the text and distribution map are on the left hand page with the photographs opposite. Set in a pale blue background and with the relief layer removed, each map is clearer in addition to being brought up-to-date. The paragraphs on Adult Identification, Eggs and Larva, Behaviour, and Breeding Habitat are, not surprisingly, largely unchanged. Confusion species now have their own paragraph captioned 'Look-Alikes' with references to the appropriate species pages. The Population and Conservation entries are revised to include recent changes. The main improvement in the species accounts is in the photographic plates. The images for damselflies are all now twice life-size, hawkers remain at life-size, and all other dragonflies are at x1.5. Many of the images are new and they stand out much better from the background than in the first edition. There are now 44 breeding species with the addition of the two emeralds and the removal of Highland Darter, which is now considered to be a form of Common Darter *Sympetrum striolatum*. These are followed by 19 former breeding, vagrant and potential vagrant species, each with the same two-page layout as the breeding species, making information fuller and easier to find. *Sympetma fusca* has moved from potential to actual vagrant, *Aeshna viridis* and *Epiptera bimaculata* are no longer thought potential visitors but *Lestes virens* now is. Although the book concentrates on adult identification the section on larvae and exuviae has doubled, now covering 20 pages. There are now 10 pages of larval identification charts in tabular format with the key identification features highlighted in red text. This section is now extremely clear and easy to use. I tried hard to find faults with the book. I would have preferred the use throughout of pterostigma rather than 'wing-spot' and some images are a little tight to the inner margin of the page, but these are just minor quibbles. At less than £18 you have an excellent, well laid out, well illustrated, bang up-to-date field guide that I would gladly recommend as the one dragonfly guide to take out into the field." **21874.** Blanco, T.; Gavira, O.; Herrera, F. (2011): Estudios sobre el estado ecológico del río Genal (Málaga): Compatibilizando los trabajos científicos con la información directa a la población. VII Congreso Ibérico sobre Gestión y Planificación del Agua "Ríos Ibéricos +10. Mirando al futuro tras 10 años de DMA" 16/19 de febrero de 2011, Talavera de la Reina: 1-8. (in Spanish) ["The results of a project carried out by the Fundación Nueva Cultura del Agua on the characterization of the ecological state of the Genal River (Málaga) are presented. Said project constitutes a pilot and original experience because it is based on two differentiated but, at the same time, interrelated phases. On the one hand, a technical-scientific study of the ecological state of the river (water quality, aquatic macroinvertebrates, fish and riverbank

vegetation) was carried out. On the other hand, an intense effort was made to inform the population, especially the local one, about the results of the study. This experience, which has made scientific work compatible with direct and continuous information to the population, has proven to be a useful tool for the conservation of the river. In this sense, the local population itself, now informed and sensitized, is the one that is demanding the protection of this fluvial jewel in the south of the Iberian Peninsula. ... The community of aquatic macro-invertebrates in the Genal basin is extraordinarily diverse. In total, 91 different taxa belonging to 16 orders were identified. Of all of them, the Diptera and Trichoptera stand out with 18 and 13 families respectively. Other diverse orders are the Odonata (9 families), ... Among the macroinvertebrates, it is worth highlighting the order of the odonata (dragonflies and damselflies), which was made up of at least 18 species. *Oxygastra curtisii* and *Macromia splendens* were two of the most outstanding species of this faunal group. Both are considered "Endangered" and appear in the Andalusian Catalog of Threatened Species." (Authors/Google translate) Address: Blanco, F., MEDIODES, Consultoría Ambiental y Paisajismo S. L. Bulevar Louis Pasteur nº1 blq 2-1º-1 29010 Málaga, Spain. Email: paco.blanco@mediodes.com

**21875.** David, S. (2011): The importance of anthropogenic water biotopes on the example of dragonflies (Odonata) of Slovakia. *Životné prostredie* 45(4): 217-221. (in Slovakian, with English summary) ["We have assessed ecological significance of 5 anthropogenic water biotopes (Košské mokrade – wetlands) after the brown coal mining, water reservoirs, gravel pits, sand pits and lowland channels. We have used the data from 252 localities in which we found 22 270 specimens. The highest species richness has the gravel pits – 50 species, lowland channels – 48 species and water reservoirs – 45 species respectively. The first of them has the highest Shannon diversity ( $H' = 2.83$ ) as well. *Ischnura elegans*, *Platycnemis pennipes*, *Enallagma cyathigerum*, *Coenagrion puella* as well as eurytopic and stagnicolous spp. are the dominant ones. We confirmed 25 endangered and protected species for example *Coenagrion ornatum*, *Cordulegaster heros*, *Epitheca bimaculata*, *Libellula fulva*, *Orthetrum coerulescens*. The biotopes differ one from another and each of them also vary on the microhabitat level. Basically the evaluated biotopes are the dynamic ecosystems vulnerable to disturbance, the change of water conditions, the increasing eutrophication and the spread of both alien and invasive plants. Thus usages of older data have the limited period of validity." Sborník abstrakt z konferencie 17.-18. února 2011: 50. (in Czech) [Verbatim(Google translate): A new discovery of *Coenagrion ornatum* (Selys. 1850) in Slovakia. In 2010, we carried out field research with the aim of supplementing the data on the European-important species - the ornamental stilt *Coenagrion ornatum*. At 18 localities in Hronská pahorkatin, Ipe ské pahorkatin and Ipe ské kotlin, we obtained 494 specimens, from which we identified 23 species of dragonflies. The research was carried out in localities with the potential occurrence of *C. ornatum*. 8 larvae of *C. ornatum* were detected at the locality Balog nad Ipom, code DFS

7980B2, 129 m a.s.l. The habitat of the species is a channel overgrown with vegetation with gap-like stands of willows, beech and inundated areas 50-60 m wide is mowed. In addition, the species *Calopteryx splendens*, *Ischnura elegans* and *Platycnemis pennipes* were found at the site. The location represents a typical habitat of the ornamental needlehorn. If the high water levels, typical of 2010, are not repeated, the confirmation of other locations of *C. ornatum* is highly likely.] Address: David, S., Dept of Ecology & Environmental Sciences, Faculty of Natural Sciences, Constantine the Philosopher Univ. in Nitra, Slovakia

**21877.** David, S. (2011): Bionomie vážky ervené *Crocothemis erythraea* (Brullé, 1832) (Odonata: Libellulidae) na Slovensku. Bryja, J., Eh´ak, Z. & Zúkal, J. (Eds.): *Zoologické dny Brno 2011*. Sborník abstrakt z konferencie 17.-18. února 2011: 50-51. (in Czech) [Verbatim (Google translate): Bionomics of *Crocothemis erythraea* (Brullé, 1832) (Odonata: Libellulidae) in Slovakia. Of the 10 species of the genus *Crocothemis* Brauer, 1868, *C. erythraea* occurs in Central Europe. The species is classified as an Ethiopian (Afrotropical) faunistic element with a tendency to spread from the Mediterranean in a northerly direction, occurrence is recorded from northern Poland. Currently (31.12.2010) I have 109 records of the species ( $n = 324$ , of which 7 exuvium and 34 larvae) from 76 localities in Slovakia. The locations are located in 47 squares of network mapping (out of 432 that extend into the territory of Slovakia). The most common type of habitat where larvae are found and found are dead river branches (21 records), ponds (15 records), small water reservoirs (10 records) and gravel pits (15 records). Hypsometrically, *C. erythraea* belongs to lowland species. The average altitude of occurrence is 195 m with a minimum occurrence at 98 m a.s.l. and a maximum at 683 m a.s.l. (1 entry). The highest frequency of occurrence is found at an altitude of 100 to 150 m above sea level (60 records = 55%), 19 records (17%) are from the height interval 150-200 m above sea level. *C. erythraea* is found in the most species-rich odonate coenoses of stagnant, eutrophic and vegetated waters. *Ischnura elegant*, *Coenagrion puella*, *Platycnemis pennipes* and *Enallagma cyathigerum* are eudominant in odonatocenoses with the occurrence of *C. erythraea*. *C. erythraea* currently shows no signs of invasive spread.] Address: David, S., Dept of Ecology & Environmental Sciences, Fac. of Natural Sciences, Constantine the Philosopher Univ. in Nitra, Slovakia

**21881.** Hutchinson, R.; Ménard, B (2011): *Stylurus notatus* Rambur (Odonata: Gomphidae): mise à jour de nos récoltes dans l'Outaouais, répartition géographique et quelques notes biologiques. *Nouv'Ailes* 21(2): 9-10. (in French) [Verbatim/Google translate: Until the mid-1990s, we did not suspect the existence of a large population of *S. notatus* on the banks of the Outaouais, in the locality of Luskville (N45°29.51' W76°0.438, alt. 32 m) (Menard 1996). Hence the absence of mention of this magnificent odonate for this locality in the work of Pilon and Lagacé (1998). We have since recovered, since visiting a first site a few times, from 1996 to 2011, on the banks of the Outaouais, allowed us to collect many exuviae. These were often found on stone walls, sometimes on blades of grass, aquatic plants, rarely on sand, mud or piles of dead vegetation (Hutchinson 2001). In 2011, we discovered a second environment, along the Outaouais, located about one hundred meters from the first. The rocky, muddy shoreline was littered with exuviae of *S. notatus*. Finally, our participation in the annual meeting of the Society of Odonatology of the Americas, which took place in Arnprior, Ontario, enabled us to collect other exuviae from this magnificent *Stylurus* for the Outaouais (Catling et al. 2005). First, we present the summary of our collections of *S. notatus*, to date, as well as some data gleaned from the literature concerning this gomphid. It is important to remember that our excursions generally lasted one or two hours at most. We left the place even if there were probably other exuviae not picked, lying on the ground or clinging to the stones. Summary of our collections of *Stylurus notatus* Luskville (Qc), first site 1996-2001, June 30 to August 5, 130 exuviae, plus 15 exuviae (Hutchinson 2001). June 11, 2005, no exuviae found, water too high. June 13, 2009, no exuviae found, however harvest of exuviae of a dozen other species of odonates. June 26, 2011, collection of about thirty exuviae and seven larvae which came out of the water and were preparing to emerge (see drawing of a larva and an exuviae). Luskville (Qc), second site August 13, 2011, collection

of 51 exuviae, often lying on the ground, sometimes buried in mud or among plant debris, for example in the leashes formed by the accumulation of the waves: three exuviae were suspended from spider threads. Westmeath (On), third site July 10-11, 2005, about twenty exuviae collected by the authors, plus those of other participants in the odonatological meeting (Catling et al. 2005). As Perron & Ruel (2002) demonstrated by collecting, for three years, on a daily basis, 2342 exuviae of *S. notatus* in the intertidal zone of the St. Lawrence River, at Saint-Augustin-de-Desmaures, near de Québec, the species still seems to be well established in the river and its tributaries. Our collection of exuviae along the Ottawa River is proof of this. Our brief harvests represent evidence that the species is surviving the harmful effects of pollution, including discharges, effluents from nearby towns and villages, not to mention changes and diversions of currents due to the erection of dams. It is interesting to read from the pens of Daigle & Vogt (1988) that *Stylurus notatus* has been rarely observed in the United States since the early 1940s. Hutchinson & Ménard (1999) presented known data on the species at that time. Needham et al. (2000) specify that this clubtail is known from three Canadian provinces, namely Quebec, Ontario and Manitoba, and from 21 American states. Still according to them, its flight period extends from May 30 to October 4 for the entire territory identified. Pilon & Lagacé (1998) mention sixteen localities for south-western Quebec, all in the cold temperate zone of the province. Mead (2003) writes that detectable exuviae are very numerous, but adults are rarely observed, which Walker (1958) had already mentioned. As far as we are concerned, we only have adults obtained by exuviation, therefore teneral individuals, after having collected larvae whose emergence was imminent. We hope, despite everything, to have the chance to capture adult, mature and reproductive individuals one day. The two aforementioned authors specify that the adults perform their long spectacular flight in a dive, in open water, in the middle of large expanses of water, to then take refuge in the crown of riparian trees, which is confirmed by Dunkle (2000). According to the latter, the male patrol is between noon and 3 p.m. Perspectives: Among the initiatives to be set in motion to better understand this elusive species, the following should be mentioned: 1) observing the flight of adults from a boat in the middle of large rivers on the banks of which are strewn the exuviae often in large number; 2) find ways to capture them in this wide open habitat; 3) establish patrol times for males; 4) look for larvae in the sandy bed of large rivers (Needham & Heywood 1929).] Address: Ménard, B., 16, rue Smith, Gatineau (Québec) J8T 3A1. Email: ménardben@vidéotron.ca

**21882.** Koch, K. (2011): Die Libellenfauna der Stillgewässer des FFH-Gebietes Kottenforst bei Bonn (Insecta: Odonata). Diplomarbeit. Rheinische Friedrich-Wilhelms-Universität Bonn: IV + 142 pp. (in German) ["In the present work, investigations were carried out on the dragonfly fauna of the still waters of the fauna-flora-habitat area Kottenforst near Bonn (North Rhine-Westphalia). For this purpose, from April to October 2010, 30 bodies of water of different sizes and locations were examined, which were distributed over the approximately 40 km<sup>2</sup> area. The adults were recorded by visual observation and catching nets, the exuviae and larvae by random searches. One focus was on the comparison of bodies of water that had existed for a long time with those that were created by the Bonn Biological Station in the years 2006-2008 as part of species protection projects. The investigation of the still waters of the Kottenforst, consisting of five inspections per water body, yielded 2482 observations of imagines, 847 exuvia and 975 larvae. The total

spectrum of species consisted of 23 species, one of which is a running water species. The main species found in the Kottenforst were *Coenagrion puella*, *Pyrrhosoma nymphula*, *Aeshna cyanea*, *Sympetrum sanguineum* and *S. striolatum*, as well as *Lestes viridis*. The remaining 18 species appeared as companion species with less abundance and less continuity. 15 native species, one potential native species and seven guests were recorded. Taking into account the current Red List and thus the latest knowledge at state level, the species spectrum consists of 18 endangered species, two species on the early warning list, two endangered species (*Aeshna juncea*, *Ischnura pumilio*) and one highly endangered species (*Lestes dryas*). The historical comparison of the data showed that many earlier species could no longer be confirmed for the Kottenforst, probably because their habitats were destroyed. In addition, there was a low number of climate change beneficiaries compared to other areas, since the area has a (still) cool climate due to its abundance of trees and the elevated position. There was no significant difference in the number of imagines or species between the biostation and the backwaters. A clear concentration of endangered species of the current Red List of North Rhine-Westphalia on the biostation waters was recognizable. Eight parameters were examined to examine possible influencing factors for the detection probability of dragonflies. It could be determined that the factors time of day, wind, cloud cover, predators and disturbing factors have no significant influence on the presence of dragonflies. On the other hand, the time of inspection, the air temperature and the current level of sunshine in a body of water at the time of mapping proved to be significant. To determine habitat preferences, seven different parameters were examined. Of these, the factors of water temperature, electrical conductivity and pH had no significant impact on the number of imagines found or the number of species. An influence on the number of species could be determined in relation to the size of the water body (area/circumference) and the type of soil substrate. The design of the banks turned out to be a significant factor with regard to the number of imagines. The investigations into the species spectrum of the vegetation yielded relatively homogeneous results for the 30 investigation water bodies. The degree of coverage of different vegetation categories turned out to be the decisive parameter. The investigation of the populations in the Kottenforst revealed a balanced sex ratio in the exuviae and a clear excess of males in the imagines. In summary, it can be said that the Kottenforst is interesting for dragonflies due to its mosaic of water bodies of different stages of succession and has an average dragonfly fauna for a deciduous forest area. The maintenance of the existing habitats and the creation of new habitats should take place in order to maintain the current status or to improve it." **21885.** Steinke, T. (2011): Fühlinger See und Escher See – Zwei Sport- und Naherholungsgebiete im Spannungsfeld zwischen naturverträglicher Gestaltung und intensiver Nutzung – Untersucht am Beispiel von Libellen als Modellorganismen. Hausarbeit zur Ersten Staatsprüfung. Universität zu Köln: 53 pp. (in German) ["The aim of this thesis was to investigate a possible conflict of interest between nature-friendly design and intensive use of the sports and recreation areas of Lake Fühlingen and Lake Escher using dragonflies as a model organism. For this purpose, the dragonfly species spectra of the two water bodies were first recorded. Due to the scarcity of species found, it seemed more meaningful to take the absence rather than the presence of the species as the starting point of the analysis. With the help of a reference study (Olthoff, Menke, Rodenkirchen 2011), a dragonfly species spectrum was then compiled that would have been characteristic for secondary biotopes - such as the two water bodies studied. Due to the absence of many species that were actually to be expected, assumptions could now be made regarding the reasons for this. One result is that the preservation of the Fühlinger and Escher lakes as local recreation areas on the one hand, and the protection of dragonflies at these water bodies on the other hand, are closely connected. For this reason, the two complexes should not be considered separately, but together. This applies in particular to possible design measures at the lakes: these can contribute both to improving the habitats for dragonflies, but at the same time also to safeguarding the water quality and thus the continued usability of the local recreation areas. These include preventive measures such as the reduction of direct (bathing, litter, fish feeding) or indirect (increasing waterfowl populations through feeding) nutrient inputs into the water bodies. Increased education and more strictly controlled bans can contribute significantly to this. Rotational models for watercourse and shoreline management are one way of conserving waterbodies in a way that does not restrict lake visitors, yet is likely to have positive effects on dragonfly and other fauna in the lakes and their surroundings. Also helpful for the protection of both dragonflies and the waters themselves would be the reduction of fish stocking and the occurrence of *Myocastor coypus* (nutria) and *Ondatra zibethicus* (muskrat), as well as the promotion of structural diversity in general. In addition, this work has also discussed those measures for more nature-oriented design that provide for restrictions in watercourse use in certain areas. However, in addition to dragonfly protection, these also have the long-term usability of the water bodies as sports and recreation areas in mind. Examples of such design interventions would be making further lake areas inaccessible and creating new shallow water zones. In conclusion, it can be said that the preservation of the two study waters as local recreation areas and the protection of dragonflies are not fundamentally mutually exclusive. In this respect, it is to be hoped that the future development and maintenance of the Fühlinger See and the Escher See will also take dragonfly protection measures into account, representing sustainable and nature-compatible landscape development for the protection of flora and fauna." **21886.** Thorp, J.H.; Rogers, D.C. (2011): Chapter 21 – Dragonflies and Damselflies: Insect Order Odonata. Field Guide to Freshwater Invertebrates of North America. Elsevier: 191-197. (in English) ["Another ancient insect order is Odonata, which

consists of about 318 species of Anisoptera and 132 species of Zygoptera in North America. This aquatic group has a close evolutionary link to the order Ephemeroptera but differs greatly from mayflies in body form, life history, and ecology. These predaceous insects are relatively long-lived in both the nymphal (or larval) and adult stages, but especially in the former. Odonates are relatively well known to the average person because the adults are colorful, relatively large, and easily visible as they flit about all freshwater ecosystems and nearby lands in pursuit of insect prey, including pesky mosquitoes, blackflies, and deer flies. However, they are harmless to humans—except for an occasional finger nipping if you hold them carelessly! Their bright colors and distinctive patterns are not only useful in some species identifications but also make odonates attractive to nature lovers and many artists. In fact “dragonfly watching” has become very popular, and many guides are available for identifying adults. The nymphal stages also consume many invertebrates, and even small fish in rare cases. These larvae are much more diverse in body form than the adults, especially among the dragonflies.] Address: not stated

**21887.** Toth, S. (2011): Data on the dragonfly (Odonata) fauna of Hungary according to my scatter-collections by December 31, 1987. *Studia odonotol. hung.* 12: 33-46. (in Hungarian, with English summary) ["This is the 16th paper of a series directed at communicating faunistic data of Hungary which had been unpublished until December 31, 1987 (cf. Dévai, G. et al. 1993). The author presents 578 faunistic data, results of a survey based on his own scatter-collections and other specimens captured by Malaise-traps and collected by 22 colleagues. The adult dragonfly series is from 125 localities throughout the country, but mostly from the sampling sites of Transdanubia. The localities are situated in 66 cells according to the 10×10 km UTM grid map. Collections were made on 201 days in 24 years between 1959 and 1988. In all cases it was possible to provide the number of individuals as well, thus the paper is based on the study of 2449 presented specimens (1150 male, 961 female and 338 specimens with undecided sex). In conclusion, 49 species (20 Zygoptera and 29 Anisoptera) were recorded throughout the country, out of which 1 belongs to the very frequent, 19 to the frequent, 14 to the less frequent, 6 to the rare and 9 to the sporadic class of country-wide occurrence frequency." ## 2012

**21888.** Eriksson, L. (2012): Habitat impact on Odonata species occurrence and detectability. MSc. thesis, Biology and environmental science, Dept of Ecology, Swedish Univ. of Agricultural Sciences, Uppsala: (in Swedish) ["This study aims to investigate how the habitat affects the dragonfly species' occurrence patterns and the detectability of larvae of different species, as well as the effectiveness of the inventory method. Detectability means the probability that the species has been detected given that it is present on the premises. Both larvae and adult dragonflies were inventoried in 14 ponds in Frihult, Sjöbo municipality in Skåne during June-August 2009. The larvae were surveyed by moulting and for each moult the dominant vegetation was noted. Occurrence data for dragonfly larvae and pond characteristics were analysed species by species using the software Presence4.2. I tested whether the ponds' pH, surface area, depth and degree of shading affected the probability of a species occurring, and whether vegetation and the time of the inventory affected the probability of discovering a certain species. For each pond, observations of

larvae were compared with observations of adults of the same species. 28 species were found during the inventory, a total of 22 species of larvae and 25 species of fully formed dragonflies. The 13 most common species were analyzed. Shading was the characteristic that affected the most species. Most of these species preferred more sun-exposed ponds. The three species affected by the pond surface all tolerated larger ponds. According to the statistical analyses, on average, a species was found in 16% more ponds than it was discovered in. Thus, one can expect to miss relatively many occurrences of larvae even during an intensive inventory like this. If the purpose of an inventory is to find many species within a larger area, an inventory of adults is most effective, but if you want to investigate which habitats are important for reproduction, the larvae must be inventoried. When raking larvae, it is important to be outside both at the beginning and end of summer as there is no time when larvae of all species are present in the pond. If there are several types of vegetation, you should rake in all of these as the probability of discovering a certain species varies depending on the type of vegetation." **21889.** Klink, A. (2012): Paleo-ecologisch onderzoek van de Overijsselse Vecht. Onderbouwing van maatregelen ten behoeve van ecologisch herstel. Hydrobiologisch Adviesburo Klink Rapporten en Mededelingen nr. 121 Project 341, Juni 2012. In opdracht van Waterschap Velt en Vecht: 62 pp. (in Dutch) [In the Overijsselse Vecht, a paleo-ecological study was carried out to learn more about the biotic community in the past. To this end, boreholes have been drilled in abandoned residual channels at a number of locations between the German border and Ommen. Based on old (reliable) maps, these deposits have been dated to the period 1670 – 1950. A number of deposits in existing waters (old meanders) do not appear to contain stream-loving fauna, but most deposits drilled from surface level contain usable material. Based on the traits database of the Ecological Water Management Working Group, environmental variables were determined on the basis of the macrofauna encountered. Most of the calculated changes are marginal, do not look realistic and the limitations of this method are great because: • Environmental factors are determined on the basis of all waters in which a species is found. The Vecht is certainly not an “average” water • Validation of the database for the Vecht is missing The most striking change has taken place in the current, which was much higher in 1670 to 1850 than in the subsequent period. Furthermore, the reduced trophic and saprobia appear to have changed little over the past 340 years. Additional analysis of higher plants and diatoms from relevant deposits may nuance this picture. In order to contribute more to the character of the Vecht, a proprietary traits database was subsequently drawn up based on the macrofauna data collected in the Vecht in 2005 – 2010 (Klink, 2011a). This lacks chemical data, but the allocation of the individual species to habitat looks more realistic. The calculations indicate that the Vecht was a river in previous centuries, where the sandy bottom was by far the most important habitat. Wood and riparian vegetation played a minor role and submerged vegetation in 70 2010 flow varied widely

between the deposits, but also within the individual sites. As a result, the share of this habitat seems to say something about the geomorphological processes in the Vecht. A number of species have been found, particularly in the stretch upstream of Hardenberg, which indicate a much more natural character of the Vecht than was known until now. The stonefly *Isoperla grammar*, the beetles *Macronychus quadrimaculatus* and *Stenelmis canaliculatus* and the caddis fly *Itthytrichia lamellaris* no longer occur in the Netherlands and have never been collected in the Vecht in the past. These species are still common in the undammed lowland rivers of northern France with good water quality and great biotope diversity. Despite the (scarce) occurrence of these special species, the density and diversity of critical macrofauna, even in the oldest deposits, is deplorable. A comparison with the Aisne, a corresponding river in northern France, shows that mayflies, caddis flies and beetles (Elmidae) are strongly underrepresented in the deposits and Chironomidae and Simuliidae together dominate the fauna with a share of 97%. This observation is a clear signal that the macrofauna community was also under great stress in the past. Two possible causes come to mind: • Physical limitations for the macrofauna exist in the form of a treeless drifting landscape, which was aptly mapped in 1722 by Peter de la Rive (in Neeffes et al., 2011). The macrofauna present in the deposits indicates a dominant role for sand and a varying proportion of aquatic and riparian plants. The small proportion of the fauna that can be attributed to wood dwellers indicates that wood was hardly present in the Vecht. In comparable rivers with forest on the banks, wood dwellers are the dominant group ((Behning, 1932; Benke et al., 1985; Klink, 1992 and 2011b). The barren landscape and the busy Vecht (Emst & Scharlo, 2006) are in accordance with this • Chemical limitations are seen in the calculated oxygen content that amounts to a maximum of 6 mg/l over the period under investigation This finding will have no consequences for the current ecological recovery of the Vecht This may be different for the dissolved levels of heavy metals (period 2004-2010) According to the literature, the strongly increased content of iron and aluminum in particular, probably the result of natural leaching of iron ore, appears to pose a serious threat to the occurrence of mayflies, stoneflies and caddis flies (Beasley & Kneale, 2003; Clements et al., 2000; Deutsch, 1981; Hickey & Clements, 1998; Malmquist and Hoffsten 1998; Winner et al., 1975; Winner et al., 1980) These groups are the prime target species for the WFD yardstick for the Vecht. For a better understanding of the ecological functioning of the Vecht in the past, it is of great importance to also determine the remains of the higher plants and the diatoms and to integrate the results in the current understanding. This research makes an essential contribution to estimating the potential of paleo-ecological research in running water. An earlier publication already provided insights into the enormous ecological significance of trees in rivers (Klink, 1992). In this study, the macrofauna community of the Vecht has been dug up since 1650. The fact that the natural conditions, including the occurrence of iron in the Vechtdal, may limit the ecological objectives is an aspect that had not previously come to light." (Author/Google translate) The following odonate taxa are listed: *Brachytron pratense*, *Calopteryx splendens*, *Coenagrion pulchellum*, *Erythromma najas*, *Ischnura elegans*, *Libellulidae*, *Orthetrum cancellatum*, and *Platycnemis pennipes*.] Address: Klink, A., Boterstraat 28, 6701 CW Wageningen, The Netherlands. **21890.** Marchi, M.; Jørgensen, S.E.; Bécares, E.; Fernández-Aláez, C.; Rodríguez, C.; Fernández-Aláez, M.;

Pulselli, F.M.; Marchettini, N.; Bastianoni, S. (2012): Effects of eutrophication and exotic crayfish on health status of two Spanish lakes: a joint application of ecological indicators. *Ecological Indicators* 20: 92-100. (in English) ["Lake Sentiz and Lake Chozas are two small water bodies in the Province of León (NW Spain). The former is mesotrophic and the latter went from oligotrophic to turbid in 1997, due to introduction of an invasive allochthonous crayfish *Procambarus clarkii* ([0275], [0280], [0210] and [0215]). We set out to study health status of the two ecosystems by the joint use of different but correlated ecological indicators, supplementing the values obtained by monitoring campaigns. We examine three scenarios: (1) Lake Sentiz, (2) Lake Chozas before and (3) Lake Chozas after the biological invasion. We evaluate eco-exergy, energy and eco-exergy-empower ratio, three holistic ecological indicators based on the thermodynamics of far-from-equilibrium systems. When structural changes take place in ecosystems it is recommended to apply holistic thermodynamic indicators as presented in [0190] and [0195]. We propose their joint application for a complete overview of the monetary value of natural capital, because they provide information added to statistical analysis and direct measurement. The aim is to determine which of these indicators best represents the effects of eutrophication and perturbations caused by alien species in the two freshwater systems. The eco-exergy-empower ratio gives the best results, since it clearly indicates lake efficiency in transforming direct and indirect solar energy inputs into organization. The eco-exergy (work capacity) results are used to estimate ecosystem services and quantify the economic value of lake natural capital. Calculation of ecosystem services on an eco-exergy basis provides good indications of monetary gains or losses possible in perturbed systems, including eutrophic or invaded ecosystems. This is not surprising, because work capacities include all possible services offered by ecosystems, not only the services actually used by humans. Eco-exergy and the eco-exergy-empower ratio can be guidelines for the calculation of ecosystem services, although they give only a partial indication of the environmental costs and benefits of a given level of information. The present results suggest political and economic considerations and solutions, and are a useful example for organisations involved in environmental management of pollution and biological invasions by exotic species. Highlights: \* We set out to study health status of lakes Sentiz and Chozas (León, NW Spain). \* Eco-exergy, energy and eco-exergy-empower ratio quantify ecosystem health status. \* Eco-exergy-empower ratio reflects the perturbations better than the other indicators. \* We determine ecosystem services and sustainability from eco-exergy or work capacity. \* It is useful to apply thermodynamic holistic indicators for bio-invasion management." **21891.** Radulovic, S.; Boon, P.J.; Laketic, Dušanka, Simonic P., Puzovic S., Živkovic Milica, Jurca Tamara, Ovuka M., Malaguti S., Teodorovic Ivana (2012): Preliminary checklists for applying SERCON (System for Evaluating Rivers for Conservation) to rivers in Serbia. *Archives of Biological Sciences* 64(3): 1037-1056. (in English) ["This paper describes the first steps in gathering biological data to assess the conservation value of rivers in Serbia, using SERCON (System for Evaluating Rivers for Conservation). SERCON was developed in the UK to improve consistency in assessments of river 'quality' by using a scoring system to evaluate habitat features and species groups, catchment

characteristics, and the potential impacts to which river systems may be subjected. This paper provides checklists for aquatic, semiaquatic and marginal plants, macroinvertebrates, fish and birds associated with rivers in Serbia, collated from a wide range of published and unpublished sources. These lists should be regarded as provisional because few wide-ranging biological surveys have been carried out specifically on Serbian rivers; further revisions are likely as more information becomes available in future. Ultimately, the work will benefit regulators and decision-makers with responsibility for river management under the new Water Law, and contribute to river protection and conservation in Serbia." (Authors) Odonata are treated at family level.] Address: Radulovic, Snezana, Univ. of Novi Sad, Faculty of Sciences, Dept Biol. and Ecology, 21000 Novi Sad, Serbia

**21892.** Salewski, V (2012): Eine Neuansiedlung der Feuerlibelle *Crocothemis erythraea* (Brulle, 1832) in Regensburg. *Acta Albertina Ratisbonensia* 59: 52-53. (in German) [Verbatim/Google translate: In the summer of 2013, *C. erythraea* was found in the area of the abandoned clearing ponds of the former sugar factory near Irl in the south-east of Regensburg. From the end of July the area was regularly visited by the author about once a week. The first fire dragonfly, which was a fully colored male, was observed on July 27 (Fig. 1). It was identified by the bright red body and eyes, the dorso-ventrally flattened abdomen (Fig. 2), its size, and the orange spot at the base of the hind wings (Dijkstra & Lewington 2006). These characteristics distinguished it from males of various darter species *Sympetrum* sp., which are also found in the area. Up to the end of August, up to six fire dragonflies could be observed regularly, most of which were males. There were no indications that they were native. The fire dragonfly originally had an African-Mediterranean distribution, but has been steadily expanding northwards for several decades as a "winner" of global warming. After it was first recorded in Germany in 1918, it now occurs in almost all federal states, and the number and size of the populations continue to increase, especially in southern Germany (Ott 2007). In Bavaria, the fire dragonfly is regarded as a breeding guest, with the number of records and individual indications of indigeneness also steadily increasing since 1993 (Kuhn & Burbach 1998). According to Kuhn & Burbach (1998), the fire dragonfly was not yet known from the Regensburg area; the closest evidence is from Bogen and the Naab valley near Schwarzenfeld. A fire dragonfly was never observed on regular visits to the area during the summer of 2012, nor on more infrequent visits in previous years. It can therefore be assumed that 2013 was at least a temporary resettlement that fits into the usual pattern of the spread of the species. Further observations over the next few years will have to show whether the species can establish itself permanently.] Address: Salewski, V., Prinz-Rupprecht-Str. 24, 93053 Regensburg, Germany

**21894.** Wiemers, M.; Denner, M.; Schweiger, O.; Winter, M. (2012): Biodiversitätsindikatoren für Klimaveränderungen am Beispiel der Tagfalter und Libellen Sachsens. In: Horst Korn, Ute Feit und Rainer Schliep (Red.): *Biodiversität und Klima – Vernetzung der Akteure in Deutschland VIII – Ergebnisse und Dokumentation des 8. Workshops*. BfN – Skripten 307: 54-57. (in German) ["Biodiversity indicators for climate change using the example of butterflies and dragonflies in Saxony: The Community Temperature Indices (CTI) according to DEVICTOR et al. (2008) calculated. The basis for this are Species Temperature Indices (STI), which represent the mean annual temperatures in the entire European range of a species. STI values were first reported for birds of France and by VAN SWAAY et al. (2008) also calculated for European butterflies. In both works, individual numbers from monitoring programs were used for the weighting. In the analyzes the CTI showed a clearly positive trend analogous to the general temperature development in almost all cases, which means that populations of warmth-loving species are increasing in relation to cold-loving species; however, the correlation between the annual values of the CTI and the mean area temperature was not examined in the work mentioned. Our analyzes with the Saxon data also revealed a positive trend for butterflies and dragonflies, which, however, as in the aforementioned studies, is lower than the temperature increase observed in the area over the same period. According to DEVICTOR et al. (2008) conclude that the temperature increase exceeds the adaptability of the species community. The shape of the curve was only slightly affected by a change in species selection, which indicates the robustness of this index. However, strong immigration events of non-established species can lead to biases. Instead of individual numbers, dataset numbers per species can also be used for weighting, but this reduces the sensitivity of the indicator. While the CTI values for butterflies (Figure 1) correlate strongly with the annual mean temperatures, there was no correlation for dragonflies. This can probably be explained by the different generation length of up to five years in dragonflies compared to a maximum of one year in butterflies. Accordingly, the highest correlations of the CTI values were found with the 2-year moving mean temperature of the current and previous year (for butterflies) or the 5-year moving mean temperature of previous years (for dragonflies). These highly significant correlations with short-term climate variability support the reliability of the measured long-term trends. The CTI therefore appears to be a particularly well-suited biodiversity indicator for climate change, especially for monitoring data such as that obtained in Citizen Science projects such as Germany's butterfly monitoring (TMD; <http://www.tagfalter-monitoring.de/>). Climate changes can not only lead to shifts in abundance within species communities, but also to shifts in range, as is well known. However, the detection of area changes is more complicated than is often assumed. This is due to the fact that the population densities along the area boundaries are often very low. On small-scale scales such

as individual federal states, there are hardly any zonal distribution limits and the accuracy of most of the data is insufficient for recording the vertical distribution. Saxony also has a topography that is unfavorable for zonal distribution limits (mountains on the southern border). Therefore, the Area Index (AI) was developed to record range shifts, which reflects the ratio of the areas of warmth-loving to cold-loving species. An objective assignment to one of the two groups can be guaranteed by an STI-based weighting. The difference between the STI value of the individual species and the CTI (as a total mean of all species of the respective taxon) is used for weighting. The analysis of the Saxon data shows a positive trend and a high correlation with the CTI for both the butterflies (Figure 2) and the dragonflies, especially when using the STI-based weighting. The lower slope of the Area Index shows that it reacts less sensitively to climate changes than the CTI. Nevertheless, the area index seems particularly suitable for faunistic data sets with good spatial coverage for recording the climate reaction, and can also be used for species groups for which no STI values can be calculated due to the lack of total distribution maps." ## 2013

**21895.** Bouton, F.M. (2013): Recherche de *Sympetrum danae* (Sulzer, 1776), et identification du cortège odonologique de zones humides du boisement de Marchevert (Conflans-sur-Anille, 72). Ligue pour la Protection des Oiseaux de la Sarthe, Maison de l'Eau - 43 rue de l'Estérel - 72 100 Le Mans: 58 pp. (in French) ["Within the framework of the National Action Plan in favor of Odonata, a list of species considered as priorities has been defined for the Pays de la Loire, broken down regionally. These species were chosen based on their degree of threat and rarity. Among these is the Black *Sympetrum* (*Sympetrum danae*). As this species has never been the subject of specific research on a regional scale, no recent data on an attested breeding site exists (for the Dept of Sarthe, the most recent dating from 2004). Its current autochthony therefore remains to be proven, especially since it is a species with a high potential for erratism (Dijkstra K.-D.B. & Lewington R., 2007; Grand D. & Boudot J.-P. 2006). This report gives an account of the study carried out by the LPO Sarthe, with the support of the Loire Bretagne Water Agency, the Regional Group for the Study of Armorican Invertebrates (GRETIA), the association leading the regional implementation of the Action Plan and the Regional Center for Forest Property (CRPF) of the Pays de la Loire, which aims to rule on the presence and, where appropriate, on the reproductive status of the species on the Bois de Marchevert site (part of the Vibraye forest massif) in the communes of Conflans-sur-Anillé, Montaillé and Semur-en-Vallon in the Sarthe Dept. In addition, a second objective of this study was to identify the odonatological procession existing on the site (classified as ZNIEFF type 1) as well as on the neighboring wetlands (namely the Anille river and the Fief pond within the Marchevert forest), all located within the watershed of the valley of the Brayé." (Author/Google translate) <https://side.developpement-durable.gouv.fr/cent/digitalCollection/DigitalCollectionAttachmentDownloadHandler.as?parentDocumentId=335495&documentId=632382&skipWatermark=true&skipCopyright=true>] Address: Bouton, F.M., 18, rue Saint Pavin de la Cité, 72000 Le Mans, France. E-mail: fmb72@yahoo.fr

**21896.** Faton, J.-M. (2013): Le *Sympetrum danae* (Sulzer, 1776) reproducteur dans les habitats fluviaux duranciens. *Sympetrum* 17: 5-7. (in French) ["Like most *sympetrum*s, *S. danae* is a pioneer and opportunistic species. The discovery of a large population of this species in the Hautes-Alpes, breeding in the river annexes of the Durance, is however a surprise. Here, *Sympetrum danae* is an abundant and very adaptable species, as can be *Sympetrum striolatum* in many regions." (Author/Google translate)] Address: Faton, J.-M., Gare des Ramières, Route de Grane - 26400 Alex, France

**21897.** Harms, T.M.; Rasmussen, R.D.; Kinkead, K.E.; Frese, P.W.; Dinsmore, S.J. (2013): Springtime Darner (*Baiaeschna janata*) new to Iowa. *Argia* 25(3): 25. (in English) ["An individual *B. janata* was first observed by Ryan Rasmussen on 5 May 2012 at Lacey-Keosauqua State Park in Van Buren County. No other individuals were observed in 2012. Rasmussen returned to the area on 13 May 2013 and observed a small group of six individuals near Lake Lacey, which is located within the park (OdonataCentral record #400091)." (Author)] Address: Harms, T.M., Center for Survey Statistics and Methodology, Iowa State Univ., 208 Office and Lab. Building, Ames, IA 50011, USA. E-mail: harmsy@iastate.edu

**21898.** Hatfield, J.K. (2013): A possible hybridized *Platthemis lydia* (Common Whitetail) x *Platthemis subornata* (Desert Whitetail) specimen? *Argia* 25(4): 16. (in English) [7-IX-2013, Bottomless Lakes State Park, Roswell, New Mexico, USA] Address: Jerry K. Hatfield: Email: jerry.hatfield@um-healthsystem.com

**21899.** King, S. (2013): A mass movement of Autumn Meadowhawks (*Sympetrum vicinum*). *Argia* 25(4): 17. (in English) ["On 8-X-2013, a swarm of *S. vicinum* coalesced in our backyard in Northfield, Minnesota, USA. This concentration of dragonflies stayed put throughout the afternoon, busily feeding, and was gone the next day. Dozens of mature meadowhawks, both male and female, perched on garden fences, tree trunks, and grapevines, until all the good spots were taken. Dan Tallman, another Northfield resident, reported seeing them at his home on the opposite side of town on this day as well, so the swarm stretched at least several miles. Whether it was a county-wide cloud or a thin red line fallen by chance across the town like a dropped ribbon, there's really no way to know." (Author)] Address: Scott King. Email: ldng@meadowhawks.info

**21900.** Lyons, R. (2013): An observation of *Octogomphus specularis* (Grappletail) oviposition. *Argia* 25(3): 27. (in English) [27-VI-2013, Golden and Silver Falls State Natural Area in Coos County, Oregon (north-east of Coos Bay), USA] Address: Ron Lyons, Bandon, Oregon. Email: pondhawk@uci.net

**21901.** McHugh, M.; Hummel, S. (2013): First record of *Epi-theca semiaquea* (Mantled Baskettail) for Missouri. *Argia* 25(3): 24. (in English) [The record had been vetted on 24 April 2011 as *Epi-theca cynosura*. A subsequent re-evaluation, showed this record to actually be *E. semiaquea*.] Address: McHugh, M., Kansas City, USA. E-mail: Emchugh2@kc.rr.com

**21902.** Mguni, S. (2013): Enigmatic rock paintings of insectifroms in the Cederberg, western cape, South Africa. *South African Archaeological Bulletin* 68(198): 160-172. (in English) ["In this paper I describe an unusual triad of images from

the northern Cederberg, Western Cape. The probable origin of their subject matter is implied by the depicted morphological features. While their heads are distinctly anthropomorphic, nothing else invokes the humanoid form. Their identification is sought elsewhere, outside the mammalian kingdom. Even though a few traits suggest insectiforms, these are too few to be useful in identifying exact species. Nevertheless, the most likely generic candidate [Odonata] is identified, which offers the potential for interpreting these images by assembling multifarious and nuanced readings of possible San ethnographic correlations." (Author)] Address: Mguni, S., Rock Art Research Institute, Private Bag 3, WITS, 2050 South Africa. E-mail: Siyakha@rockart.wits.ac.za

**21903.** Moser, I. (2013): Monitoring gefährdeter Tierarten im Raum Bannriet-Spitzmäder Bericht 2012 – 2013. Verein Pro Riet Rheintal, Schwalbenweg 16, 9450 Altstätten, Switzerland: 41 pp. (in German) [Results of the monitoring of *Lestes virens* are documented. Conservation measures are outlined. Records of *Aeshna isoceles*, *Crocothemis erythraea*, *Aeshna affinis*, *Lestes barbarus* and *Sympetrum meridionale* are briefly documented. For more details see: [https://pro-riet.ch/wp-content/uploads/2020/08/Bericht\\_Monitoring\\_2013.pdf](https://pro-riet.ch/wp-content/uploads/2020/08/Bericht_Monitoring_2013.pdf)] Address: Verein Pro Riet Rheintal, Schwalbenweg 16, 9450 Altstätten, Switzerland

**21904.** Nirschl, R. (2013): First record for *Libellula auripennis* (Golden-winged Skimmer) in Michigan. *Argia* 25(3): 18. (in English) [On 14-VI-2013, Nan Weston Preserve in Washtenaw County, Michigan, USA.] Address: Rick Nirschl: Email: ricknir@hotmail.com

**21905.** Patten, M.A.; Smith-Patten, B. (2013): First record of the Marsh Bluet (*Enallagma ebrium*) for Colorado. *Argia* 25(3): 26. (in English) [6-VII-2013, Alamosa National Wildlife Refuge, San Luis Valley, Alamosa County, Colorado, USA.] Address: Patten, M.A., Oklahoma Biological Survey, Univ. of Oklahoma, Norman, OK 73019, USA. E-mail: mpat-ten@ou.edu

**21906.** Paulson, D. (2013): An apparently introduced population of California Spreadwings (*Archilestes californicus*). *Argia* 25(3): 14. (in English) [The author describes a "range extension" of *A. californicus* to Magnuson Park, Seattle, King County, Washington, USA, probably caused by landscaping with native vegetation, including many willows.] Address: Paulson, D.R., Slater Museum, Univ. of Puget Sound, Tacoma, WA 98416, USA. E-mail: dennispaulson@comcast.net

**21907.** Roble, S.M.; Chazal, A.C.; Pendleton, W.T. (2013): *Enallagma carunculatum* (Tule Bluet), an addition to the Virginia damselfly fauna. *Argia* 25(4): 14. (in English) ["This species has not been previously recorded from Virginia, but it was listed as a potential member of the state's fauna by Roble (1994). During a visit to the Carnegie Museum of Natural History (Pittsburgh, Pennsylvania) in February 2013, Roble and Chazal learned that their holdings included a small collection of pinned Odonata (n=37) from Virginia, most of which were collected by H. C. Will at Dayton, Rockingham County during 1930-1931. Will's name only appears on the 1931 collection labels (and on several without dates), but the 1930 labels are similar except for the lack of a collector's name. All but a few of these specimens were previously unidentified, including all of the damselflies. Closer examination revealed that two males collected on 14 June 1930 are referable to *E. carunculatum*, the first known

specimens from Virginia, thus becoming the 19th *Enallagma* and 56th damselfly species recorded from the state, and extending the species' range in the East slightly to the south." (Authors)] Address: Chazal, Anne, Virginia Dept of Conservation and Recreation, Division of Natural Heritage, 600 E. Main Street, 24th Floor, Richmond, Virginia 23219, USA

**21908.** Ruffoni, A. (2013): La cordulie à corps fin (*Oxygastra curtisii*) en Bourgogne: espèce discrète de plus en plus observée. La feuille de *Neomys*. La lettre de l'Observatoire de la FAune de Bourgogne 9: 6. (in French) [Verbatim (Google translate): This large green and yellow anisoptera is one of the 6 species of Corduliidae present in Burgundy. It is protected in France and listed in appendix 2 and 4 of the Habitat Directive. Knowledge of the distribution of the species is very incomplete in Burgundy. Before the launch of the Atlas inventory, 23 stations were known, since, thanks to targeted searches, at the beginning of 2013, 25 more stations have been discovered. In the south-east of the Yonne Dept, the species was quite easily detected during "atlas" surveys on various rivers: the Serein, the Armançon, the Cure, the Yonne and marginally on the Cousin. On the Serein, the species is at least regularly present on 25 kilometers of river. It was also discovered on many gravel pits in Auxerrois, environments that seem to be good substitute biotopes for the development of larvae. Most of the time the species was detected thanks to the collection of exuviae, out of a total of 101 data of the species present in the BBF, 36 data correspond to exuviae (36%). A survey carried out at the right time and targeted on the larval remains is therefore imperative if we want to advance knowledge of the distribution of the species in Burgundy. It is sought on various rivers: the Nièvre, the Aron, the Saône, the Yonne, the Seille, the Arroux, the Grosne, the Alène, the Seine (downstream part), the Tille, the Loire, the Allier, ... as well as on gravel and sand pits. Reminders on the species Preferred habitats: calm areas of rivers and streams, to be sought upstream of the reaches (e.g. upstream of the mill), ponds, gravel pits and sand pits. Note: gravel pits/sand pits seem to be good substitute sites. Supposed distribution: scattered presence on the territory, to be sought on the main rivers. Detection: exuviae to look for on the trunks of trees (alder, willow and ash) whose roots plunge into the water of sectors with a calm current and fairly deep, imagoes. Flight period: from mid-May to mid-August with a greater presence from June to mid-July.] Address: Ruffoni, A., Société d'histoire naturelle d'Autun/Groupe Odonates Bourgogne et Société française d'Odonatologie - shna.ruffoni@orange.fr

## 2014

**21909.** Adu, B.W.; Ogbogu, S.S.; Ogunjobi, J.A. (2014): Odonata biodiversity: An indicator of anthropogenic activity in Aponmu forest, Akure, southwestern Nigeria. *FUTA Journal of Research in Sciences* 10(1): 35-42. (in English) ["Diversity assessment of Odonata in Aponmu forest was carried out to determine its composition, abundance, and distribution. Biodiversity of the taxon was also used as a measure of human activities in the forest. Three study sites were identified at the forest which were: "Ago-Store" Pond (AGO), "Alatori" stream (ALA) and River "Aponmu" (APO). Both adults and larvae specimens of Odonata were collected. Only advanced penultimate and ultimate larvae were collected and were reared to adults. Some physico-chemical parameters that influenced the existence of Odonata within the forest were also investigated. Diversity indices and inferential statistic were applied to the data collected at the

forest. Water samples collected were analyzed so as to determine quality of water which houses the immature stages of the fauna. 1385 individuals were collected from the forest. Most of the species collected were ubiquitous. "Alatori" stream was the richest study site, while river "Aponmu" was the least. Generally, the study indicates that the dominance of ubiquitous species of Odonata with broad niches in the forest may be a result of anthropogenic activity going on in the forest." (Authors)] Address: Adu, B.W., Biological Science Dept, Ondo State Univ. of Science and Technology, Okitipupa, Nigeria. E-mail: williamsadubabs@yahoo.com

**21910.** Almeida, D.; Grossman, G.D. (2014): Regulated small rivers as 'nursery' areas for invasive largemouth bass *Micropterus salmoides* in Iberian waters. *Aquatic Conservation: Marine and Freshwater Ecosystems* 24(6): 805-817. (in English) ["Few studies have assessed the ecological role of regulated small rivers in the environmental biology of invasive largemouth bass *Micropterus salmoides* in Iberian waters. Size structure, diet, physical condition, and developmental stress of largemouth bass populations were compared between two contrasting habitats in the Iberian Peninsula, the Encinarejo Reservoir and the small River Jándula below the dam (Guadalquivir River Basin, southern Spain). Size structure differed between river and reservoir populations of small (<180 mm FL) largemouth bass, with a higher proportion of individuals between 30 and 60 mm in the river and a higher proportion of 20–40 mm individuals in the reservoir. In the river, the most important prey for small largemouth bass were Ephemeroptera, Plecoptera and Odonata nymphs. In the reservoir, Gerridae insects and pumpkinseed *Lepomis gibbosus* were the most important prey in terms of ingested biomass for small largemouth bass, whereas large individuals consumed high percentages of common carp *Cyprinus carpio* and pumpkinseed. Prey richness, trophic niche breadth, and trophic diversity were significantly higher in small largemouth bass from the river, as well as eviscerated mass and glucose level. Fluctuating asymmetry was lower in the river for branched rays of pectoral fins, eye diameter, and length of pectoral fins. Overall results indicate that largemouth bass are taking advantage of both habitat differentiation and flow regulation in Mediterranean streams. Therefore, regulated small rivers may play an ecological role as 'nursery' areas, where developmental stress is low and thus, juvenile fish can display better body condition and nutritional status than their reservoir counterparts. The present study provides information relevant to the management of largemouth bass and subsequent conservation of the valuable and endemic Iberian fish fauna. For example, size-specific culls in the reservoirs and below the dams are suggested strategies to control the reinforcement of downstream populations." (Authors)] Address: Almeida, D., Dept of Zoology and Physical Anthropology, Complutense Univ. of Madrid, E-28040 Madrid, Spain. E-mail: dalmeidareal@yahoo.es

**21911.** Ananian, V. (2014): On the need of protection of goldenring *Cordulegaster vanbrinckae* in Armenia. *Biological journal of Armenia* 66(4): 27-30. (in Russian, with Armenian and English summaries) ["*C. vanbrinckae* is a rare relict species in Armenia, which requires study of its biology and implementation of urgent complex conservation measures. Establishment of microreserves in its habitats would prevent their destruction and would contribute to preservation of the species in the country." **21914.** Furness, A.N. (2014): Why shouldn't the dragonfly cross the road? The influence of roadway construction and vehicle speed on the behavior, mortality, and conservation of adult dragonflies (Odonata: Anisoptera). M.Sc. thesis, Univ. of South Dakota: 94 pp. (in English) ["Roads are a ubiquitous part of landscapes across the globe. Unfortunately their ecological effects are numerous and widespread as well. Impacts include disturbance of the physical environment, modification of the chemical environment, shifts in human use of land and water, spread of exotic species, alterations of animal behaviour, and wildlife mortality due to road construction and collisions with vehicles. A growing body of literature has focused on the effects of roads on wildlife, especially vertebrates; however, only select studies have examined the impacts of roads on invertebrates, with very few looking at insects in particular. This thesis attempts to understand how roads, including a bridge, affect dragonflies, especially the federally endangered Hine's emerald dragonfly (*Somatochlora hineana*). It also investigates potential ways to lessen their effects. To determine whether the I-355 bridge interrupts movement of adult dragonflies, flight behaviour was recorded in the I-355 corridor prior to, during, and after construction. I compared the proportion of individuals initiating crossing behaviour between the pre-bridge, bridge, and open bridge stages as well as the proportions attempting to cross above and below the bridge deck after completion. In order to better understand which factors make dragonflies vulnerable to collisions with vehicles, I recorded the result of dragonfly-vehicle encounters at select speeds. By analyzing flight heights and flight types in combination with vehicle speeds, I was able to esti-

mate the probabilities of being hit for different kinds of dragonflies at varying speeds. Measures to moderate and/or reduce vehicle speed in high- risk areas during peak flight times could decrease dragonfly roadkill rates. The use of diversion structures was also assessed by conducting observations of *S. hineana* flights at a simulated roadway location with and without nets up. Diversion netting has the potential to deter *S. hineana* from crossing roadways as well as cause them to fly over roadways at heights above that of most vehicles, depending on the spacing of nets." (Authors)] Address: Furness, Amber Nichole

**21915.** Groupe Odonates Bourgogne ; Ruffoni, A. (coord.) (2014): Atlas préliminaire des odonates de Bourgogne (Odonata), version 2014. Société d'histoire naturelle d'Autun, Société française d'Odonatologie: 43 pp. + annexes. (in French) [[https://www.researchgate.net/publication/336956799\\_Atlas\\_preliminaire\\_des\\_odonates\\_de\\_Bourgogne\\_Odonata\\_version\\_2014](https://www.researchgate.net/publication/336956799_Atlas_preliminaire_des_odonates_de_Bourgogne_Odonata_version_2014)] Address: Ruffoni, A., Maison du Parc, F-58230 Saint-Brisson, France. **21916.** Houard, X.; Merlet, F.; (coord.) (2014): Liste rouge régionale des libellules d'Île-de-France. Natureparif – Office pour les insectes et leur environnement – Société française d'Odonatologie. Paris: 80 pp. (in French) ["A quarter of the dragonflies in Île-de-France threatened or disappeared. By examining the dragonflies listed in the region, this is the first time that the process of drawing up the Ile-de-France Red Lists has focused on the vast world of insects and particularly those that thrive in aquatic environments. This synthesis work was carried out by applying the official methodology established by the IUCN and constitutes a new standardized reference recognized internationally. This Red List was jointly piloted by the Office for Insects and their Environment and the French Society of Odonatology as part of the regional implementation of the National Action Plan for Odonata. A group of a dozen regional experts volunteered for this evaluation exercise. Thus, more than 28,800 observation data from the naturalist testimonies of 303 contributors, compiled since the beginning of the 1980s in a computerized database, were analyzed. In total, of the 59 species observed in Île-de-France over the period 1992-2012, one is already considered "Regionally extinct" (2%), thirteen are considered threatened (19%) and eight have been assessed as "Near Threatened" (14%). The destruction and degradation of wetlands induced by urbanization and the intensification of agricultural practices are the main causes of the disappearance of dragonflies. The disappearance and rarefaction of dragonflies in the Ile-de-France region is characteristic of the damage caused to the region's aquatic ecosystems. Despite these ever-increasing pressures, Île-de-France has significant assets in terms of wetland conservation and must therefore be able to mobilize to preserve its threatened dragonfly populations. Thus, by way of examples, thanks to this Red List, *Leucorrhinia caudalis* is classified as "Vulnerable" and *Coenagrion pulchellum* is classified as "Endangered" and can now be considered as ambassadors of wetlands that should be pampered and protected. taken into account in the implementation of sustainable regional development policies." (Authors/Google translate)] Address: Merlet, Florence, 78 rue de Cornouailles, F-78180 Montigny-le-Bretonneux, France. Email: [florence.merlet@gmail.com](mailto:florence.merlet@gmail.com)

**21917.** Hutchison, L. (2014): Male aggression in the banded demoiselle damselfly *Calopteryx splendens*. MSc.

thesis, Dept Biol., Lund Univ.. <http://lup.lub.lu.se/student-papers/record/4360319>: (in English) [*Calopteryx splendens* is a sexually dimorphic insect that is currently moving north, into new geographic areas of Fennoscandia. In doing so, this damselfly species is coming into contact with naïve populations of a closely related conspecific: the beautiful demoiselle damselfly, *Calopteryx virgo*. This study revealed that male *C. splendens*' aggression appears to be influenced by both age and experience; however, there was no evidence of learned species recognition in outdoor cage experiments. Teneral (immature) and mature males responded at significantly different strengths to intruding males, indicating that the age at which they were caught affected the development of territorial responses. Whether *C. splendens* came from allopatric or sympatric populations did not statistically significantly influence their response to intruding males. Average male aggression levels were positively correlated with male survival rate, although the causal factor behind this correlation is unknown. Moreover, *C. splendens* survived longer in the cages than *C. virgo* revealing interspecific differences in longevity, and *C. splendens* individuals from an allopatric population survived significantly longer compared to *C. splendens* individuals from a sympatric population. This result might indicate that *C. splendens* suffer from shorter life span in the presence of the heterospecific competitor *C. virgo*. Male *C. splendens* responded differently to female con- and heterospecific individuals depending on the male's origin, suggesting that field experience with the opposite sex and species was important in determining male mate preferences towards females. Finally, cage density had no significant impact on male *C. splendens*' aggression towards conspecifics. Popular science summary: As the climate warms and species move northwards, some species encounter populations of a similar species. In this case, the banded demoiselle damselfly *Calopteryx splendens* is moving north, further into Fennoscandia than it has been known to go before, and is meeting populations of the beautiful demoiselle damselfly *Calopteryx virgo*. Males of both species set up and defend territories along the banks of freshwater streams. If these two species are to co-exist, one or both should theoretically be able to discriminate between individuals of their own and of the other species to avoid hybridising. This project aimed to understand whether learning or genetics determine how a male *C. splendens* responds to intruding males of his own species and of the other species, *C. virgo*. The response to females of both species was also tested. The work was carried out in 27m<sup>3</sup> mesh cages at Stensoffa field station, in southern Sweden and 2 nearby sites were used to capture the insects. At one site, only *C. splendens* was present, at the other both *C. splendens* and *C. virgo* were present. One male and one female of each species were tethered to a stick of roughly 1.5 m in length and were then presented to free-flying, but caged, males. A four-point scale was used to record the reaction from the free-flying male. A threat response is illustrated in the figure opposite. The effect of cage density on aggression in *C. splendens* was tested by keeping males and females in cages with a ratio of 2 males to 1 female. Low density cages had a maximum of six individuals; high density cages had a maximum of twelve. In this study, mature individuals of neither species were more or less aggressive towards males of their own of the other species. This finding contrasts with previous field studies which found that *C. virgo* males show stronger species recognition than *C. splendens* males (Svensson, et al. 2007). *C. splendens* males caught as sexually mature individuals responded more aggressively towards intruders than did those caught as sexually immature. This is not sur-

prising as sexually immature individuals are not yet competing for territories. Interestingly, this species appears to go against the classic trade-off hypothesis of "live fast, die young" as the longer an individual lived, the more aggressive it appeared to become. Sexually immature male *C. splendens* responded less aggressively towards females of either species than did sexually mature male *C. splendens*. Males from populations where both species are present responded more strongly to females of their own species than to females of the other species. This supports the hypothesis that age or experience is important in determining the response to intruders. Cage density did not affect the average aggression levels displayed by male *C. splendens*. Origin also had no significant impact on the aggression level therefore hinting at a possible genetic component in the response to intruders. Individuals showed repeatability in their response to different intruders indicating a possible genetic component, but further study would be needed to confirm this. In conclusion, it is likely that both genetics and experience play a role in determining the reaction of male *C. splendens* to intruders and that experience is necessary in fixing the genetic response." (Author)] Address: not stated

**21918.** Izzat-Husna, M.; Ahmad, A.B. (2014): Odonata (Class: Insecta) of Sungkai Wildlife Reserve, Perak, Malaysia. *Journal of Wildlife and Parks* 29: 23-30. (in English) ["Protected areas need to be continuously monitored for their flora and fauna for the ecosystem management and conservation purposes. Odonata is a good bio-indicator for habitat monitoring; they are ecologically conspicuous and sensitive to environmental changes. A two-day survey was done at Sungkai Wildlife Reserve (SWR), Perak in June 2014 to record the odonate diversity of the areas. Twenty-one species from seven families were collected, namely Libellulidae with seven species, Protoneuridae and Chlorocyphidae (four species each), Calopterygidae and Euphaeidae (two species each), and Platynemididae and Coenagrionidae with a single species respectively. Despite the short collection period, this area showed a rich odonate fauna but further survey is needed to obtain a complete picture. The results formed the first checklist of odonate fauna here and may serve as baseline information for future research towards habitat monitoring, conservation and management of SWR." **21919.** Jurkiewicz-Karnkowska, E.; Zontek, M.A. (2014): Occurrence and domination relations of benthos organisms accompanying mollusc species in the Nature Reserve Stawy Siedleckie. In: *Sposób cytowania: Górski P.* 2014. *Kleszcze rezerwatu Stawy Siedleckie*. [W:] M. Falkowski, K. Nowicka-Falkowska, M. Omelaniuk (red.). *Bogactwo przyrodnicze rezerwatu Stawy Siedleckie*. Monografia Przyrodnicza. s. 57, Siedlce: 145-150. (in Polish, with English summary) ["In the collected samples, representatives of 12 higher taxonomical units of invertebrates were noted. They were: Annelida, Hirudinea, Oligochaeta, Arachnida, Odonata, Coleoptera, Crustacea, Diptera, Ephemeroptera, Hemiptera, Lepidoptera, Megaloptera and Nematoda. In the scale of the whole nature reserve the dominant group of macrofauna accompanying mollusk species were representatives of the order Hemiptera. The highest benthos biodiversity was observed in fishponds "Stary" and the lowest – in fishpond "Wyrostkowy". Fishpond "Stary" was distinguishable by the largest vegetation cover (61%), that was

the result of its ageing due to fish farming cessation, whereas fishpond "Wyrostowy" was intensively used (intensive fish farming, periodic rising and lowering of water level)." **21920.** Kiszewski, A.E.; Teffera, Z.; Wondafrash, M.; Ravesi, M.; Pollack, R.J. (2014): Ecological succession and its impact on malaria vectors and their predators in borrow pits in western Ethiopia. *Journal of Vector Ecology* 39(2): 414-423. (in English) ["Soil pits excavated for home construction are important larval habitats for malaria vectors in certain parts of Africa. Borrow pits in diverse stages of ecological succession in a maize-farming region of Western Ethiopia were surveyed to assess the relationships between stage of succession and the structure and composition of invertebrate and plant communities, with particular attention to *Anopheles gambiae* s.l. and *An. coustani*, the primary local malaria vectors. An array of 82 borrow pits was identified in a multi-lobed drainage basin in the community of Woktola. Each pit was evaluated on its physical features and by faunal and floral surveys during August, 2011, at the height of the longer rainy season (kiremt). *Anopheles gambiae* s.l. and *An. coustani* were the sole immature anophelines collected, often coexisting with *Culex* spp. Sedges were the most common plants within these pits, and included *Cyperus elegantulus*, *C. flavescens*, *C. erectus* and *C. assimilis*. The legume *Smithia abyssinica*, Nile grass (*Acroceras macrum*), cutgrass (*Leersia hexandra*), clover (*Trifolium* spp.), and the edible herb *Centella asiatica*, were also common in these habitats. No plant species in particular was strongly and consistently predictive of the presence or absence of mosquito immatures, particularly with regard to *An. coustani*. The presence of *An. gambiae* s.l. immatures in borrow pit habitats was negatively correlated with the presence of backswimmers (Notonectidae) ( $Z = -2.34$ ,  $P = 0.019$ ). Young (freshly excavated) borrow pits more likely contained immature *An. gambiae* s.l. ( $Z = -2.86$ ,  $P = 0.004$ ). Ecological succession was apparent in older pits, and as they aged, they became less likely to serve as habitats for *An. gambiae* s.l. ( $Z = 0.26$ ,  $P = 0.796$ ), and more likely to support *An. coustani* ( $Z = 0.728$ ,  $P = 0.007$ ). As borrow pits age they become less suitable for *An. gambiae* s.l. breeding and more likely to harbor *An. coustani*. The abundance of notonectids in habitats was a negative indicator for *An. gambiae* s.l. abundance. Plant species are not reliable indicators for the presence or absence of malaria vectors in borrow pits. ... Odonata were also highly represented with dragonflies from the family Lestidae in over 51% of sites, and 33% of sites bearing specimens from the family Aeshnidae ... Backswimmers (Notonectidae) and dragonfly naiads (odonates) were found to be the most efficient arthropod predators of immature *An. ...* While dragonfly nymphs have previously been found to be effective predators of anopheline immatures ... ] (Authors) Address: Kiszewski, A.E., Dept of Natural and Applied Sciences, Bentley Univ., Waltham, MA 02452, USA. **21921.** Klecka, J.; Boukal, D.S. (2014): The effect of habitat structure on prey mortality depends on predator and prey microhabitat use. *Oecologia* 176(1): 183-191. (in English) ["Structurally complex habitats provide cover and may hinder the movement of animals. In predator-prey relationships, habitat structure can decrease predation risk when it provides refuges for prey or hinders foraging activity of predators. However, it may also provide shelter, supporting

structures and perches for sit-and-wait predators and hence increase their predation rates. We tested the effect of habitat structure on prey mortality in aquatic invertebrates in short-term Lab. predation trials that differed in the presence or absence of artificial vegetation. The effect of habitat structure on prey mortality was context dependent as it changed with predator and prey microhabitat use. Specifically, we observed an 'anti-refuge' effect of added vegetation: phytophilous predators that perched on the plants imposed higher predation pressure on planktonic prey, while mortality of benthic prey decreased. Predation by benthic [Libellula depressa, Platycnemis pennipes, Sympetrum sanguineum, Coenagrion sp.] and planktonic predators on either type of prey remained unaffected by the presence of vegetation. Our results show that the effects of habitat structure on predator-prey interactions are more complex than simply providing prey refuges or cover for predators. Such context-specific effects of habitat complexity may alter the coupling of different parts of the ecosystem, such as pelagic and benthic habitats, and ultimately affect food web stability through cascading effects on individual life histories and trophic link strengths." **21922.** Orwa, P.O.; Omondi, R.; Okuku, E.; Ojwang, W.; Njuguna, S.M. (2014): Composition, abundance and feeding guilds of macroinvertebrates in lake Kenyatta, Kenya. *International Journal of Environmental Monitoring and Analysis* 2(5): 239-243. (in English) ["In an attempt to describe the benthic macroinvertebrate assemblage of Lake Kenyatta and recommend possible interventions for sustainable management, sampling was done at different stations using an Eckman grab and a scoop net. At each station, six samples were taken (three grabs and three scoops). The samples were washed using a 300µm sieve, sorted live and identified to genus level and where possible to species level using appropriate keys. The specimens were further categorized into functional feeding guilds. The data were then analyzed for diversity, evenness, abundance and dominance. Forty two species in 25 families and 13 orders were recorded [including 13 odonate taxa]. The organisms were further grouped into 4 functional feeding groups. The order Pulmonata dominated the macroinvertebrates sampled with 34.3% relative abundance while the lowest were Rhynchobdellida and Lepidoptera with 0.3% each. The high abundance of mollusks in the lake is probably an indication of absence of a predator. It is thus recommended that a fish species be introduced to convert these mollusks into fish biomass. This will enhance the economic gains and reduce the risk of bilhazia infestation since the host snail exists within the lake." **21926.** Walsh, C.J.; Bloink, C.; Hehir, G. (2014): Preliminary report on macroinvertebrate assemblages of Pyrites and Goodmans Creek in relation to the management of Merrimu Reservoir: patterns in 2013 in early stages of flow manipulation. Melbourne Waterway Research-Practice Partnership Technical Report 14.8. Waterway Ecosystem Research Group, The Univ. of Melbourne: 17 pp. (in English) ["Environmental flow management requires understanding of the degree to which the natural flow regime must be replicated to protect ecological structure and function of streams. A basic requirement, particularly in the application of environmental flow management to intermittent streams, is a robust understanding of ecological responses to different aspects of the flow regime. This report presents an analysis of macroinvertebrate assemblage composition in two intermittent streams, Pyrites and Goodmans creeks, in the early stages of an environmental flow program in the lower reaches of Pyrites Creek. Both creeks have segments with augmented flows that are used as water supply conduits, and Pyrites Creek has a large water supply reservoir, which greatly reduces the variability and volume of flow downstream, while producing a small permanent flow through leakage for several kilometres downstream. We assess the nature of variation in assemblage composition, between the two creeks, along each creek, and among the segments with differing flow regimes. Specifically, we aimed to assess the likely effects on assemblage composition of a) the use of the streams as water supply conduits and b) Merrimu reservoir (Pyrites Creek only) in its pre-2014 flow management. Finally, we considered appropriate analytical approaches for assessing changes resulting from environmental flow releases from Merrimu reservoir now and in the future. Pyrites Creek macroinvertebrate assemblage composition downstream of the reservoir was distinct from all other sites. The permanently flowing sites downstream of the reservoir were in substantially worse condition than most other sites, with a much greater dominance of scrapers (algal grazers) than other sites. This suggests a shift in trophic functioning of the stream from a riparian-organic-matter-dominated foodweb to an algal-dominated one. The higher abundance of scrapers (primarily several snail families and notonemourid stoneflies) and other disturbance-tolerant families was accompanied by an absence or low abundance of a range of sensitive families. In the Pyrites Creek segment further downstream, in which the small permanent flow transitioned into intermittency with reduced flows, the macroinvertebrate assemblage showed greater similarity to upstream, intermittent sites. Intermittent sites with augmented flows differed in assemblage condition from other intermittent sites and had higher family richness. The most upstream intermittent sites were more similar to the Pyrites Creek sites downstream of the reservoir, than to other upstream sites, which we hypothesize is a result of those sites having shorter and less reliable wet periods or being at a later stage of the annual drying cycle than others. The dominance of scrapers downstream of the reservoir suggests that a strong, detectable change in assemblage composition to an assemblage more dominated by riparian inputs of organic matter is possible, if environmental flow releases adequately mimic the magnitude and frequency of

high-flow events capable of scouring biofilms. However, transfer rates limit capacity to use flows to scour the stream bed and remove the stands of Typha that have colonized the channel downstream of the reservoir. Thus changes to assemblage composition are likely to be limited. The large seasonal variability in intermittent streams such as these, present challenges for robust monitoring of changes resulting from management actions. As much temporal replication of sampling as possible is recommended. Spatial autocorrelation among sites points to the need to use Bayesian statistical methods for future analyses, comparing 2013 assemblage patterns with those in future years following longer periods of ongoing environmental flow management." (2015): Aquatic macroinvertebrates of the Sava River. The Sava River. The Handbook of Environmental Chemistry 31: 335-359. (in English) ["The objective of this chapter is to present the data on aquatic macroinvertebrate communities along the Sava River, based on investigation performed during 2011 and 2012 at 12 sampling sites within the sector between Vrhovo (Slovenia) and Belgrade (confluence to the Danube). During our study 227 macroinvertebrate taxa were recorded in the Sava River. Having in mind that upper stretch of the Sava River was not covered by this work (alpine and subalpine stretch), as well as based on the review of previous works on the macroinvertebrate fauna of the Sava River, more than 300 species will be confirmed for the Sava River. The data on the distribution of aquatic macroinvertebrates revealed five different stretches — alpine, subalpine, Upper Sava plain, Middle Sava and Lower Sava. Physical habitat degradation, pollution and pressure caused by biological invasions were found to be the main factors of endangerment of aquatic macroinvertebrate fauna diversity. There is an obvious need for further investigation of the Sava River in order to complete the data on aquatic macroinvertebrates and to provide the basis for accurate assessment of environmental status of the river." (Authors) The occurrence of *Coenagrion mercuriale* is questionable.] Address: Paunovic, M., Institute for Biological Research "Sinisa Stankovic", Univ. of Belgrade, 142 Bulevar Despota Stefana, Belgrade, Serbia. **21929.** Buchsbaum, R.; Leahy, C.W.; Allison, T. (2016): Distribution and abundance of Odonata species across Massachusetts: Results of a long-term monitoring program. *Northeastern Naturalist* 23(4): 501-524. (in English) ["Surveys of Odonata were carried out at Mass Audubon wildlife sanctuaries in all regions of the state and in multiple habitats. Our goals were to provide a comprehensive look at patterns of species distribution and relative species richness across Massachusetts and compare surveys where effort was and was not controlled. Observers encountered a total of 146 species, 11 of which were very widespread, having been recorded at more than 40 of the 54 properties examined. Thirty-five species were relatively rare, occurring at only 1 or 2 sanctuaries. A few sanctuaries were particularly notable for supporting somewhat uncommon species. These sites were not located in any particular ecoregion, but reflected local conditions. In surveys where effort was not controlled, a regression analysis indicated that about two thirds of the variation in species richness among sanctuaries could be explained by the amount of observer effort, the size of the sanctuary, and the extent of wetland habitat. Quantitative surveys that used transects or point counts to control for sampling effort resulted in observation of fewer species, including state-listed taxa, compared to the non-quantitative surveys. Despite producing fewer species, data from these quantitative surveys can be used to make statistical comparisons with data from future studies and detect changes over time in species richness, abundance, and frequency of occurrence." **21930.** Docile, T.N.; Figueiró, R.; Portela, C.; Nessimian, J.L. (2016): Macroinvertebrate diversity loss in urban streams from tropical forests. *Environmental Monitoring and Assessment* 188(4):237: (in English) ["The increase of human activities in recent years has significantly interfered and affected aquatic ecosystems. In this present study, we investigate the effects of urbanization in the community structure of aquatic macroinvertebrates from Atlantic Forest streams. The sampling was conducted in the mountainous region of the State of Rio de Janeiro, Brazil in 10 urban and 10 preserved streams during the dry season (August–September) of 2012. The streams were characterized by its environmental integrity conditions and physico-chemical properties of water. The macroinvertebrates were sampled on rocky substrates with a kicknet. A total of 5370 individuals were collected from all streams and were distributed among Ephemeroptera, Odonata, Plecoptera, Hemiptera, Megaloptera, Coleoptera, Trichoptera, Lepidoptera, and Diptera. In urban sites, all those orders were found, except Megaloptera, while only Mollusca was not found in preserved streams. We performed a non-metric multidimensional scaling (NMDS) analysis that separated two groups distributed among sites in urban communities and another group outside this area. The dominance was significantly higher at urban sites, while the a diversity

and equitability were greater in preserved sites. A canonical correspondence analysis (CCA) was also performed, indicating that most taxa associated with high values of the Habitat Integrity Index (HII) and a few genus of the order Diptera with the high values of ammonia, total nitrogen, associated to streams in urban sites. Urban and preserved streams differ by physical-chemical variables and aquatic macroinvertebrates. In urban streams, there is most dominance, while a diversity and equitability are higher in preserved streams." (Authors)] Address: Docile, Tatiana, Lab. ## 2017

**21934.** Finotello, S.; Feckler, A.; Bundschuh, M.; Johansson, F. (2017): Repeated pulse exposures to lambda-cyhalothrin affect the behavior, physiology, and survival of the damselfly larvae *Ischnura graellsii* (Insecta; Odonata). *Ecotoxicology and Environmental Safety* 144: 107-114. (in English) ["Highlights: •Pyrethroids can have negative impact on behaviour, physiology, and survival on non-target organisms. •We simulated natural frequent runoff events of the pyrethroid lambda-cyhalothrin in a Lab. study on damselfly larvae. •Prey capture success on prey decreased significantly following lambda-cyhalothrin exposures compared to the control. •We found a lower growth rate (up to ~20%) and lipid content (up to ~30%) of damselflies at 50 and 250 ng lambda-cyhalothrin L<sup>-1</sup>. •Long-term exposure towards lambda-cyhalothrin pulses at concentration found in nature can affect damselfly behaviour, physiology and survival. Abstract: Damselflies form an essential part of the aquatic and terrestrial food web. Pesticides may, however, negatively affect their behaviour, physiology, and survival. To assess this, a 42-day-lasting bioassay was conducted, during which damselfly larvae (*Ischnura graellsii*; n = 20) were repeatedly exposed to lambda-cyhalothrin (3 days at; 0, 10, 50, 250, 1250, and 6250 ng LCH L<sup>-1</sup>), followed by recovery phases (4 days) in pesticide-free medium for six weeks. This exposure design was used to simulate frequent runoff events in the field. Variables related to the behaviour (strikes against prey and capture success), growth, physiology (lipid content and fatty acid composition), as well as mortality were assessed throughout the experiment. The two highest LCH concentrations induced 100% mortality within the first 48 h, whereas 85% of the test organisms survived 28 days under control conditions. The number of strikes against prey was not affected by LCH. In contrast, prey capture success decreased significantly (up to ~50% at 250 ng LCH L<sup>-1</sup>, for instance, after the third pulse exposure) following LCH-exposures compared to the control. This difference was not observed after recovery phases, however, which did not counteract the enhanced energy demand for detoxification and defense mechanisms indicated by a lower growth rate (up

to ~20%) and lipid content (up to ~30%) of damselfies at 50 and 250 ng LCH L<sup>-1</sup>. In addition, two essential fatty acids (eicosapentaenoic acid and arachidonic acid) and two precursors (linolenic acid and a-linolenic acid) decreased in their concentrations upon exposure towards 250 ng LCH L<sup>-1</sup>. Thus the results of this study indicate that long-term exposure towards LCH pulses can affect damselfly behaviour, physiology and survival. Given the essential role of damselflies in food web dynamics, these effects may potentially translate into local population impairments with subsequent bottom-up directed effects within and across ecosystem boundaries." **21935.** Gassmann, D. (2017): Unerschöpfliche Vielfalt: neue Libellenarten (Odonata) aus Papua-Neuguinea. *Jahresbericht 2015/16, Zoologisches Forschungsmuseum Alexander Koenig*: 10-12. (in German) [Verbatim: "The insect and arthropod fauna of the Papuan biogeographical region, which stretches south of the equator from the Moluccas in the west to the vast island of New Guinea and the Solomon Islands in the east, remains largely unexplored. In principle, this could also apply to the Papuan dragonflies, especially since only a handful of systematists (including the author) are working on this group today. However, it is mainly thanks to the Dutch entomologist Maurits A. Liefstinck (1904-1985), who described more than half of the species known today, that we know the dragonfly fauna of New Guinea and the surrounding islands comparatively better than other insect groups in the region. According to current knowledge, the Papuan dragonflies with about 600 species make up about 12% of the global odonate fauna. Dragonflies are semi-aquatic insects whose larvae (or better: nymphs) live predatory in the water before they leave it to hatch and conquer the airspace as adults. As a guest researcher in the Arachnida Dept, which curates the ZFMK dragonfly collection, I have been able to contribute to research on the biodiversity of this group for more than two years, building on my previous work at the Naturalis Biodiversity Center in Leiden/Netherlands. The publication of a complete annotated and illustrated list of species from one of my previous trips to northern New Guinea and the Bismarck Archipelago fell during this period. In addition to the new species already described in previous years, the final evaluation of this expedition yielded some remarkable new distribution data and first records for islands in the Bismarck Archipelago. Subsequently, a number of new species from Papua New Guinea were described in collaboration with Australian and American colleagues. This work was based in large part on the recent collections of Dr. Stephen J. Richards associated with the South Australian Museum in Adelaide as a herpetologist and odontologist. Reference specimens in the form of paratypes of two of these species could be retained for the ZFMK collection. Surely the most spectacular first description that comes from this cooperation is that of *Macrocnemis gracilis*, for which a new genus had to be set up, since the examination of the morphological characteristics initially did not allow a clear family relationship. In addition, *M. gracilis*, with a wing length of around three centimeters and an abdomen length of almost five centimetres, is the largest feathered dragonfly from the subfamily Idiocnemidinae and thus one of the largest dragonfly damselflies in the Papuan region. The species and genus is only known from the montane rainforest of the Hindenburg Mountains, a remote region in western Papua New Guinea. An interesting redescription in 2016 was that of *Pseudagrion woodlarkensis* from Woodlark Island, far east of New Guinea. The genus *Pseudagrion* (Elf Maidens),

restricted to the Old World, represents the largest genus of slender dragonflies (Coenagrionidae) and also occurs in the Papuan region with around a dozen species. The new species is characterized by the very complex abdominal appendages of the males. Similar structures are only found in two other Pseudagrion species from mainland New Guinea. The pretty, bright yellow forehead dragonfly can be considered endemic to Woodlark, possibly including some outlying islands, and has been found on medium-sized streams with rich riparian vegetation, even in moderately disturbed habitats. In addition to *P. woodlarkensis*, only one other potentially endemic woodlark dragonfly species is known. However, expeditions to the archipelagos off New Guinea repeatedly lead to the discovery of new dragonfly species. Only in 2011 did I describe another new Pseudagrion species from the largest Bismarck Island, New Britain. Like Woodlark's Pseudagrion, it was by no means rare on the island; only there are comparatively few entomologists who venture into this remote part of the world and recognize new species as such. The series of new Papuan dragonfly species was supplemented in 2016 by the first description of *Idiocnemis schorri*. From the species-rich genus *Idiocnemis*, which I had already subjected to a taxonomic revision several years ago, potentially new species from southern Papua New Guinea have repeatedly appeared in recent years. Of the new, handsomely marked species, specimens were available from the foothills of the Müller Mountains, the aforementioned Hindenburg Mountains, and the Kikori Basin, all regions of southern Papua New Guinea. Once again the new species showed the strong radiation of endemic genera in the New Guinea region and at the same time demonstrated how incomplete our knowledge of the dragonfly diversity of southern New Guinea is, from where I am currently working on one or two other new *Idiocnemis* species. Obtaining such data on biodiversity is of crucial importance for the protection of nature and species in the region. Many of the new species have been and are being discovered as part of Rapid Biodiversity Assessments organized by NGOs (Non-Governmental Organizations) such as Conservation International and the Wildlife Conservation Society. The rapid inventory of the species spectrum and the analysis of endemism patterns in the often completely unexplored rainforest areas is the basis for initiating protective measures and provides the biological facts to give them more weight. In the Koenigiana and in two public evening lectures at the ZFMK and the Natural History Museum in Braunschweig, I reported on my work to a wider audience. The ongoing processing of New Guinean and especially Philippine dragonfly collections in the ZFMK collection will be reported elsewhere. My taxonomic work was financially supported by the International Dragonfly Fund (IDF) in 2016." **21937.** Adande, R.; Liady, M.N.L.; Bokossa, H.K.J.; Djidohokpin, G.; Zouhir, F.; Mensah, G.A.; Fiogbe, E.D. (2018): Utilisation rationnelle de fertilisants organiques pour la production de macroinvertébrés benthiques d'eau douce en pisciculture. Biotechnol. Agron. Soc. Environ. 2018 22(4): 12 pp. (in French, with English summary) [Benin; "Rational utilization of organic fertilizers for freshwater benthic macroinvertebrate production in fish farming. Description of the subject: This study aims to determine optimal conditions of rabbit manure utilization in freshwater benthic macroinvertebrate production in order to produce fish at low cost. Objectives: To determine the optimal dose of rabbit manure to be used for freshwater macroinvertebrate production. Method: Six treatments, including one control, received respectively 0%, 10%, 25%, 50%, 75% and 100% of rabbit manure compared to the substrate total volume. Cultures were carried out in buckets, which received 10 dm<sup>3</sup> of substrate, 16 dm<sup>3</sup> of groundwater and 4 dm<sup>3</sup> of fishpond water. The initial seeding density was 6 ind·dm<sup>-2</sup> of odonates, 6 ind·dm<sup>-2</sup> of annelids or (3 ind·dm<sup>-3</sup>, for 0.5 m depth), 8 ind·dm<sup>-2</sup> of chironomids or (4 ind·dm<sup>-3</sup>) and 10 ind·dm<sup>-2</sup> of mollusks or (5 ind·dm<sup>-3</sup>). Physicochemical and biological parameters were measured during the 63 days of the experiment. Results: The highest densities of benthic macroinvertebrates were obtained within treatment T2, with 192 ± 1.20 ind·dm<sup>-2</sup> of chironomids, 52 ± 0.8 ind·dm<sup>-2</sup> of mollusks, 6 ± 0.33 ind·dm<sup>-2</sup> of odonates and 6 ± 0.33 ind·dm<sup>-2</sup> of annelids. Considering the depth of our experimental buckets (0.5 m), these highest densities also corresponded to respectively: 96 ± 1.20 ind·dm<sup>-3</sup> of chironomids, 26 ± 0.8 ind·dm<sup>-3</sup> of mollusks, 3 ± 0.33 ind·dm<sup>-3</sup> of odonates [Libellulidae] and 2 ± 0.33 ind·dm<sup>-3</sup> of annelids). The highest biomass of chironomids and mollusks was obtained within treatment T2, with respectively 728.1 ± 2.23 mg dry matter·dm<sup>-2</sup> and 699.98 ± 22.49 mg dry matter·dm<sup>-2</sup> (i.e. respectively 364.05 ± 2.23 mg dry matter·dm<sup>-3</sup> and 349.99 ± 22.49 mg dry matter·dm<sup>-3</sup>). Conclusions: Considering these results, treatment T2 with 140 g dry matter of rabbit manure·dm<sup>-2</sup> of substrate (i.e. 75 g dry matter of rabbit manure·dm<sup>-3</sup> of substrate) could constitute the optimal dose that could be recommended for the optimal production of freshwater benthic macroinvertebrates." **21944.** Kietzka, G.J.; Pryke, J.S.; Gaigher, R.; Samways,

M.J. (2019): Applying the umbrella index across aquatic insect taxon sets for freshwater assessment. *Ecological Indicators* 107, December 2019, 105655: (in English) ["Highlights: • The umbrella index successfully identified sensitive freshwater taxa as indicators. • It performed well in a biodiverse region with many rivers and varying disturbances. • Eight Ephemeroptera/Plecoptera/Trichoptera and seven Odonata were selected. • Both groups co-occurred with high percentages of own taxa and for the other group. • These groups have great potential and interchangeable for biodiversity conservation. Abstract: Biological surrogates in conservation biology are valuable for rapid biodiversity and environmental surveys, and as an early warning of potential threats. However, these surrogates need to be simple and inexpensive to apply. The umbrella index was applied here to quantify the selection of surrogate species for biodiversity assessments, but requires interrogation for application in areas rich in threatened endemic species. Aquatic larvae of Ephemeroptera, Plecoptera and Trichoptera (EPT), as well as the adult Odonata, are all highly responsive to changes in freshwater condition. Using the umbrella index, we evaluated the performance of the surrogate species approach for aquatic insect conservation in a region (Greater Cape Floristic Region) with an exceptional level of rare and endemic species, across multiple rivers with different disturbance levels. Due to a lack of species level information, EPT taxa were calculated using morphospecies within families, and Odonata were identified to species level. The umbrella index identified eight EPT species and seven Odonata species as potential surrogates. Both these groups co-occurred with high percentages of their own overall groups (EPT surrogates for overall EPT, and Odonata surrogates for overall Odonata), as well as for the other group (EPT surrogates for overall Odonata, and Odonata surrogates for overall EPT). The index was surprisingly flexible, and performed well in an area with so many species of conservation concern, as well as across spatial scales greater than a single river, with varying degrees of disturbance. Both EPT and Odonata showed promise as potential biodiversity surrogates, and for future conservation planning. Ideally, conservationists should aim to use taxa that are easy to identify to species level, with known sensitivities to human disturbance. However, when this is not a possibility, the umbrella index is still applicable and accurate for morphospecies (family level sensitivities)."] (Authors)] Address: Kietzka, Gabriela, Dept of Conservation Ecology & Entomology, Stellenbosch Univ., Matieland, South Africa. **21947.** Tran, T.T.; Janssens, L.; Dinh, K.V.; Stoks, R. (2019): An adaptive transgenerational effect of warming but not of pesticide exposure determines how a pesticide and warming interact for antipredator behaviour. *Environmental Pollution* 245: 307-315. (in English) ["Highlights: •We studied transgenerational effects of pesticide and warming on mosquito behaviour. •Exposure to chlorpyrifos (CPF) and warming reduced antipredator behaviour. •The effect of CPF on antipredator behaviour was smaller under warming. •Parental exposure to warming shaped combined effect of CPF and warming in offspring. Abstract: The impact of pesticides on organisms may strongly depend on temperature. While many species will be exposed to pesticides and warming both in the parental and offspring generations, transgenerational effects of pesticides under warming are still poorly studied, particularly for behaviour. We therefore studied the single and combined effects of exposure to the pesticide chlorpyrifos (CPF) and warming both within and across generations on antipredator behaviour of larvae of the vector mosquito *Culex pipiens*. Within each generation pesticide exposure and warming reduced the escape diving time, making the larvae more susceptible to predation. Pesticide exposure of the parents did not affect offspring antipredator behaviour. Yet, parental exposure to warming determined how warming and the pesticide interacted in the offspring generation. When parents were reared at 24°C, warming no longer reduced offspring diving times in the solvent control, suggesting an adaptive transgenerational effect to prepare the offspring to better deal with a higher predation risk under warming. Related to this, the CPF-induced reduction in diving time was stronger at 20°C than at 24°C, except in the offspring whose parents had been exposed to 24°C. This dependency of the widespread interaction between warming and pesticide exposure on an adaptive transgenerational effect of warming is an important finding at the interface of global change ecology and ecotoxicology." ## 2021

**21952.** Ertas, A.; Boz, T.; Kizilkaya, I.T. (2021): Comparative analysis of benthic macroinvertebrate-based biotic and diversity indices used to evaluate the water quality of Kozluoluk Stream (West Anatolia of Turkey). *Community Ecology* 22: 381-390. (in English) ["Freshwater ecosystems are vitally important which supports biological diversity. With this aim, a total of eight biotic and three species diversity indices were used to determine water quality of Kozluoluk Stream in West Anatolia of Turkey. The biotic indices were: Saprobii (SI), Biological Monitoring Working Party (BMWP-O, BMWP-S and BMWP-G), Average Score per Taxon (ASPT), Family Biotic Index (FBI), Belgian Biotic Index (BBI), EPT-Taxa [%], and species diversity indices consisted of: Shannon-Weaver (SWDI), Simpsons (SDI) and Margalef (MDI). Principal component analysis (PCA) was applied to the physicochemical and biotic dataset. Similarities between the sampling stations were clustered by using cluster analysis (CLUS). Pearson-based correlations were used to determine which index is more suitable in determining water quality of the stream. The nine taxonomic groups were found in Kozluoluk Stream

consisting of Amphipoda, Oligochaeta, Gastropoda, Ephemeroptera, Plecoptera, Trichoptera, Odonata, Coleoptera and Diptera. The 1st and 2nd stations (90%) were the most similar stations in terms of benthic macroinvertebrate species distribution. The results indicate that the ASPT, BBI, BMWP-O, BMWP-S, BMWP-G and EPT-Taxa [%] are more proper than FBI and SI indices to determine the water quality of Kozluoluk Stream. The water quality along the stream varied from good class in upstream stations, to moderate in downstream stations. This study clearly showed that the specific biotic index according to the ecological characteristics of Turkey should be developed." (2022): Distribution, ecology and conservation of *Aeshna caerulea* (Ström, 1793) and *Aeshna subarctica elisabethae* Djakonov, 1922 (Insecta: Odonata) at the southernmost limits of their range. *Aquatic Insects* 44(2): 136-150. (in English) ["We provide an overview of the distribution, habitat preference, phenology, and conservation of *A. caerulea* and *A. subarctica elisabethae* in Italy. Both species are found exclusively in the Central Eastern Alps. By 2021, *A. caerulea* has been reported for 31 sites, whereas *A. s. elisabethae* for 15. The new southernmost global range limit for *A. caerulea* was found in the Adamello massif and the new southernmost Western Palearctic limit for *A. s. elisabethae* in the Tesino plateau (Trentino-Alto Adige). *A. caerulea* reproduces at high-altitude ponds or small lakes, inundated fens or fen meadows, and occasionally in the depressions within raised bogs. *A. s. elisabethae* is found at lower altitudes, only at raised bogs and, to a lesser extent, in acidic transitional mires rich in *Sphagnum* mosses. 46% of the reproduction sites of *A. caerulea* and 93% of those of *A. s. elisabethae* are included within a national/local protected area or the Natura 2000 network." (Authors)] Address: Assandri, G., Area Per L'Avifauna Migratrice, Istituto Superiore per la Protezione e la Ricerca Ambientale (ISPRA), Ozzano dell'Emilia, Italy. Email: giacomo.assandri@gmail.com

**21957.** Burch, S.F. (2022): The Dragonflies and Damselflies of Oxfordshire. *Fritillary* 10: 9-108. (in English) ["This paper provides a timely update of current knowledge of the dragonflies of Oxfordshire. All 37 species that have been recorded are described and distribution maps for all species, derived from all records within the National Biodiversity Network (NBN) Atlas database are given. An analysis to show how the relative recording frequencies of individual species have changed over time has been carried out and highlights increases and decreases relative to the numbers of records received for all dragonflies. This includes species recently arrived in Oxfordshire having expanded their range from continental Europe to England. For three highly localised species, the results from the recording frequency analysis are supplemented by summary plots of quantitative data from BBOWT transect surveys that have taken place over almost the last twenty years at two reserves at Cothill. In addition, phenology data were obtained from the NBN Atlas for first and last sighting dates and are compared with the corresponding information from 1996." (Author)] Address: Stephen Burch: Email: stephen\_burchemail@yahoo.co.uk

**21958.** Bylak, A.; Kukula, K. (2022): Impact of fine-grained sediment on mountain stream macroinvertebrate communities: Forestry activities and beaver-induced sediment management. *Science of the Total Environment* 832 155079:

16 pp. (in English) ["Highlights: • In mountain areas, fine sediment influx is mostly generated by forestry activities. • Fine sediments disturb benthic habitats and lead to decreased invertebrate density. • Fine sediments clogging spaces between stones limit the presence of rheophilic taxa. • Fewer scrapers and shredders may affect the food-web structure in stream ecosystems. • Fine sediments trapped in beaver ponds may accelerate recovery of stream sections. Abstract: Fine-grained sediments are a natural component of river systems. Human activities generate additional sources of fine sediment. In mountainous areas, the anthropogenic inputs of fine sediments are associated with forestry. The aim of this study was to analyse the differences in the macroinvertebrate communities between the reference and caused by forest harvesting activities increased influx of fine-sediment to mountain streams. The tested hypothesis was that the macroinvertebrate communities will differ depending on the intensity of forest harvesting practices in the stream catchment that causes excessive influx of fine sediment into the stream. The reintroduction of beavers in the study area, and the formation of in-stream beaver dams, contribute the accumulation of sediments in stream sections with slower water. Thus, it was also assumed that by capturing and storing fine sediments, may contribute to the restoration of the natural structure of the benthic communities downstream of the ponds. The study was carried out in a mountain stream catchment area (Carpathians, Poland), in which inflow of fine sediments in the stream sections varied in intensity. The study was conducted over three years (2018–2020). The extensive use of forest roads, timber skidding trails, and timber storage areas produced fine sediments that clogged the interstitial spaces between the stones in the riffles, limiting the presence of rheophilic taxa associated with coarse-grained substrates. The reduction of the number of scrapers and shredders (i.e. primary consumers) associated with the influx of fine sediments may significantly affect the entire food-web structure in stream ecosystems. The capture and deposition of fine sediments in beaver ponds may accelerate the revitalisation of the flowing sections of the stream. Beaver-induced sediment management is strongly recommended as a beneficial practice that could contribute to ecological preservation and the potential of streams, particularly in mountain areas." **21959.** Costa, R.M.G.; Ferro, J.L.S.; Farjalla, V.F. (2022): Disentangling the mechanisms related to the reduction of aquatic habitat size on predator–prey interactions. *Hydrobiologia* 849: 1207-1219. (in English) ["Reductions in aquatic habitat size facilitate encounters between predators and prey by reducing the height of the water column and the water volume. Here, we proposed to disentangle the effects of these mechanisms on predation rates and parameters of functional response curves of predators. We paired active-search predators (*Buenoa*, Hemiptera) or ambush predators (*Pantala*, *Lestes*) with prey of different mobility types (*Argyrodiaptomus*, Copepoda; *Culex*, Diptera). Three treatments were established: high water column height and high water volume (H + V +), low water column height and high water volume (H - V +), and low water column height and low water volume (H - V-). We used contrast analysis to separate the effects of water column height (H +, H-) and water volume (V +, V-). Predation rates were higher in V- than in V + for *Pantala* and *Buenoa* consuming *Argyrodiaptomus*. In addition, we observed an increase in attack rates and a decrease in handling time in V- in relation to V + for *Pantala* and *Lestes* consuming *Argyrodiaptomus*. We concluded that reduction in the water volume was main responsible factor for

the changes in predator–prey interactions. These changes depended on the prey behavior and predator foraging modes: ambush predators were the most benefited, and highly mobile prey were the most consumed." **21960.** Ertas, A.; Yorulmaz, B. (2022): Comparative performance of the indices used for bioassessment of water quality of Sangi stream (West Anatolia, Turkey). *Russian Journal of Ecology* 53: 318-327. (in English) ["This study has been carried out to determine water quality of Sangi Stream (West Anatolia, Turkey) and to compare the performance of indices used. Five biotic and three diversity indices have been used for determination of water quality of Sangi Stream. The assessment of water quality has been done based on benthic macroinvertebrate and physicochemical parameters. The following biotic indices have been used: Saprobii Index (SI), Biological Monitoring Working Party (BMWP), Average Score per Taxon (ASPT), Family Biotic Index (FBI), Belgian Biotic Index (BBI), as well as the following diversity indices: Shannon–Weaver index (SWDI), Simpsons index (SDI), Margalef index (MDI) and Evenness (E1). Principal component analysis (PCA) has been applied to the physicochemical variables. The similarities between the sampling stations have been clustered by using Cluster analysis (CLUS). Our results have shown the presence of 9 taxonomic groups in Sangi Stream: Crustacea, Oligochaeta, Gastropoda, Ephemeroptera, Plecoptera, Trichoptera, Odonata, Coleoptera, and Diptera. The water quality along the Sangi Stream has varied from high class quality in station 1, 2, 3 and 4, to good and moderate quality in station 5 and 6. The results indicate that the SI, BMWP, FBI and ASPT were sufficient in the estimation of water quality in the examined watercourse. This study has clearly shown that a specific biotic index according to the ecological characteristics of Turkey should be developed." (Authors)] Address: Ertas, A., Ege Univ., Faculty of Science, Dept Biol., Bornova, Izmir, 35100, Turkey

**21961.** Feng, Z.; Wan, S.; Sui, Q.; Labandeira, C.; Guo, Y.; Chen, J. (2022): A Triassic tritrophic triad documents an early food-web cascade. *Current Biology* 32(5): 5165-5171. (in English) ["Highlights: • Body-fossil evidence is described from egg chorions for insect-endophytic oviposition. • Late Triassic evidence of egg predation is documented based on insect-feeding damage. • An ecological cascade of a plant host-ovipositing insect-egg predator link is shown. Summary: Endophytic oviposition behavior, the insertion of eggs into plant tissues, represents a sophisticated reproductive strategy of insects. This process is accomplished by employing a specialized egg-laying device, the ovipositor, that effectively protects eggs through plant tissue concealment. Endophytic oviposition behavior is currently common in many lineages of several major, extant insect orders, principally Odonata, Orthoptera (katydid and grasshoppers), Hemiptera (cicadas, aphids, scale insects, whiteflies, leafhoppers, and bugs), Coleoptera, Lepidoptera (moths), and Hymenoptera (sawflies). Based on the occurrences of egg insertion damage and associated scar tissue expressed in fossil plant stems and leaves, endophytic ovipositional behavior is presumed to have emerged as early as the Early Pennsylvanian Period. However, for impression fossils, egg morphology and surrounding scar tissue can be difficult to discern on plants, often resulting in ovipositional damage that may be assigned to exophytic (eggs laid on plant surfaces) or to endophytic behavior. This ambiguity is due to the spatial relationships and histological mingling of ovipositional damage and enveloping

scars with adjoining plant-host tissues. Here, we describe body fossils of insect eggs within ginkgophyte leaves from the Upper Triassic of China. Feeding damage from an egg-predatory insect commonly occurs on these eggs, as some eggs bear up to several feeding punctures. We provide exceptional body-fossil evidence for resource use of a host plant by an ovipositing insect and unravel the earliest-known tritrophic cascade of a host plant, an ovipositing insect, and an egg-predatory insect." This is the first record of this species from Ibaraki Prefecture and the northernmost record for Japan." (Author)] Address: Email: gea01624@nifty.com

**21965.** Futahashi, R.; Koshikawa, S.; Okude, G.; Osanai-Futahashi, M. (2022): Diversity of melanin synthesis genes in insects. *Advances in Insect Physiology* 62: 339-376. (in English) ["Melanins are tyrosine-derived pigments that are ubiquitous in animals, plants, and fungi. Melanins are often associated with black and brown pigmentation, which provide a variety of biological functions, such as mimicry, camouflage, thermoregulation, and UV protection. The synthetic pathway of melanin pigments has been extensively studied in vertebrates, but interestingly, it has become clear

that the kinds of melanin pigments and genes involved in melanin biosynthesis differ significantly between insects and vertebrates. Dopamine melanin is the major melanin pigment in various insects. In insects, most of the melanin synthesis genes are highly conserved, but the yellow family genes and aaNAT family genes exhibit diversity in gene repertoire among diverse insect taxa. In this review, we introduce eight melanin synthesis genes involved in insect epidermal pigmentation: tyrosine hydroxylase (TH), dopa decarboxylase (DDC), aspartate 1-decarboxylase (ADC, black), N- $\beta$ -alanyldopamine synthase (NBADS, ebony), N- $\beta$ -alanyldopamine hydroxylase (NBADH, tan), arylalkylamine N-acetyltransferase (aaNAT), multicopper oxidase 2 (MCO2, laccase2), and yellow. For each gene, we show the molecular phylogenetic tree based on the amino acid sequences of six representative insects, the fruit fly *Drosophila melanogaster* (Diptera), the silkworm *Bombyx mori* (Lepidoptera), the swallowtail butterfly *Papilio xuthus* (Lepidoptera), the red flour beetle *Tribolium castaneum* (Coleoptera), the honeybee *Apis mellifera* (Hymenoptera), and *Ischnura senegalensis*, which highlights the diversity of melanin synthesis genes among insects. We also introduce the current knowledge of the melanin synthesis gene that contribute to colour pattern formation in various insects." (Authors)] Address: Futahashi, R., Nat. Inst. Advanced Indust. **21967.** Hisamatsu, S. (2022): Life history of *Sympetrum uniforme* (Selys, 1883) and future actions to preserve its habitat. Tombo 65: 1-7. (in Japanese, with English summary) ["*S. uniforme* is ranked as "endangered" by the Ministry of the environment, Japan; its current habitats have been identified in only seven prefectures. In this paper, I report on the current condition of the existing habitats and about the seasonal prevalence of this species, which were investigated by the author in Ehime Prefecture in 2016-2019. From the results of the investigation, it is inferred that water-edge vegetation, such as *Phragmites australis* and *Paspalum distichum*, is needed for the emergence of the species; traditional management methods of the ponds in the study area, such as mowing the grass in fixed months and water management, are associated with the life history of the species. There are some ponds in which no adults emerge if the mature adults have territorial and oviposition behavior in the ponds. Additionally, the results also revealed that immature adults spend time in high-altitude areas and mature adults spend time in vegetation and/or fruit gardens near the habitat ponds at night. The results of the investigation suggest that preserving a wide range of areas is needed, not only for preserving the particular habitat ponds but also pond groups and areas at the foot of mountains." (Author)] Address: Email: s-hisamatsu@uhe.ac.jp

**21968.** Iida, M.; Tamada, A. (2022): First record of *Macromia daimoji* Okumura, 1949 from Miyagi Prefecture, Japan. Tombo 65: 54-55. **21970.** Kita, H. (2022): Overwintering process of *Aciagrion migratum* (Selys, 1876) in a Cypress forest in Tokyo. Tombo 65: 8-20. (in Japanese, with English summary) ["The overwintering conditions or adult *A. migratum* were observed through winter from December, 2021 to February, 2022 in a Cypress forest in western Tokyo. The longest observed continuation or overwintering conditions was 57 days among the 4 male and 5 female individuals continually observed (it was 61 days in Chigasaki City, Kanagawa Prefecture). 'Overwintering conditions' are defined as the state in which an individual stays in the same place all day without flying during the winter. On December 21st, the flight of an individual was observed, while no flight for three resting individuals was confirmed on January 13th. The beginning of overwintering conditions was therefore estimated to be early January. The height of resting position utilized by the overwintering individuals was in the range of 1.2 m to 3.5 m above the ground. Even individuals in overwintering conditions can perform slight locomotion by walking, self-cleaning and hiding behaviors. The final confirmation date (the date just before the end of the overwintering conditions) of 1 ♂ and 2 ♀, whose overwintering conditions were continuously monitored, was March 13th. From this, it was estimated that the overwintering conditions ended around mid-March at this location. Since the temperature in the forest during mid-March exceeded 15°C, the repetition of similar warm weather within several days was considered to be one of the factors that terminated the overwintering conditions. In addition, the end of the overwintering conditions was earlier in the sunny coniferous and broad-leaved mixed forest facing east in Chigasaki City than in the shaded forest. From the above results, it is pointed out that the start and end of overwintering conditions for this species were considerably affected by not

only temperature, but also sunlight." (Author)] Address: kita-1114-age@u01.gate01.com

**21971.** Magliochetti, C. (2022): High trophic niche overlap within the aquatic carnivore guild in vernal ponds. MSc. thesis, Rutgers, The State Univ. of New Jersey: 39 pp. (in English) ["the underlying mechanisms shaping niche size and overlap within and between species are crucial for understanding species coexistence and community assembly. The hunting strategy of and the competition between predators shape their diets, but many species can adjust their niches via trophic or microhabitat differentiation to minimize foraging competition with co-occurring species. Niches can also change in response to environmental factors such as nutrient enrichment, which can affect the diversity and abundance of prey resources to consumers. Here we tested for trophic niche partitioning and niche specialization within an invertebrate carnivore guild. To do this, we sampled populations of arachnids and odonates, dominant riparian carnivores, in vernal ponds across a nutrient gradient in the New Jersey Pine Barrens. We used stable isotope analysis of carbon ( $\delta^{13}\text{C}$ ) and nitrogen ( $\delta^{15}\text{N}$ ) to obtain time- and space-integrated information on trophic niches of these populations. Our results showed variation in the trophic niche size of arachnids and odonates, however, our findings revealed a lack of niche differentiation between populations of arachnids and odonates within and across ponds. Additionally, neither nutrient enrichment, nor prey abundance or diversity were good predictors of niche width of these predators. Our results suggest that these co-occurring predators can coexist with minimal trophic niche overlap. As changes in climate shift species distributions and alter community assemblages, it is important to be able to predict how species will respond to overlaps in their distributions." **21972.** Mavromati, E.; Kemitzoglou, D.; Tsiaoussi, V.; Lazaridou, M. (2022): A new WFD—compliant littoral macroinvertebrate index for monitoring and assessment of Mediterranean lakes (HeLLBI). *Environmental Monitoring and Assessment* volume 193, Article number: 745: 16 pp. (in English) ["A new multimetric index (HeLLBI) based on littoral benthic macroinvertebrates is presented in this paper for classification of Greek natural lakes, in compliance with the requirements of Water Framework Directive (WFD). The method was developed based on the collection of littoral benthic invertebrate fauna and environmental data from 109 sampling sites in 21 natural lakes of the Greek National Water Monitoring Network. We focused the analysis on the effects of shore morphological alterations and eutrophication to the littoral invertebrate fauna, identified to family level, except oligochaetes, which were identified as a class, and more particularly to taxonomic composition and abundance, to taxa sensitivity, and to richness/diversity. Three metrics were included in the multimetric index: the relative abundance of Odonata classes, the Average Score per Taxon, and the Simpson's diversity index. The metrics were converted to ecological quality ratios and ecological class boundaries were defined. The final multimetric index HeLLBI is expressed as an arithmetic average of normalized ecological quality ratios of the above metrics and a final score was assigned to each lake. Pressure-response relationships of HeLLBI scores were statistically tested for morphological alterations, expressed as percentage of artificial shoreline, and eutrophication, expressed as total phosphorus. The HeLLBI scores correspond to ecological classes, according to WFD, and sampling sites with different ecological

status contained distinct biological communities; those at high status where more diverse and with sensitive taxa and as the water quality deteriorated, macroinvertebrate assemblages consisted of fewer and more tolerant to degradation taxa. The HeLLBI method gave a reliable assessment of littoral benthic invertebrate fauna of Greek natural lakes and could be a useful tool for the classification of ecological status of other Mediterranean lakes.] Address: Mavromati, Efraxia, The Goulandris Natural History Museum, Greek Biotope/Wetland Centre, 14th km Thessaloniki. **21973.** Morita, R.; Watanabe, T.; Futahashi, R. (2022): The second record from Japan of an interspecific hybrid between *Paracercion sieboldii* and *P. melanotum* from Ishioka City, Ibaraki Prefecture, Honshu, Japan). *Tombo* 65: 44-46. (in Japanese, with English summary) ["We report a male interspecific hybrid between *Paracercion sieboldii* (Selys, 1876) and *P. melanotum* (Selys, 1876) collected in Ishioka City, Ibaraki Prefecture. This is the second record of the hybrid or this combination in Japan. The markings on the antefrons and postocular spots, and the shape of the appendages are intermediate between the two species. Nuclear DNA analysis indicated an interspecific hybrid between *P. sieboldii* and *P. melanotum*, and mitochondrial DNA analysis confirmed that the mother species is *P. sieboldii*." (Authors)] Address: Futahashi, R., National Inst. Advanced Industrial Science and Technology (AIST), Central 6, Tsukuba, Ibaraki 305-8566 Japan. E-mail: ryo-futahashi@aist.go.jp

**21974.** Nakada, T.; Futahashi, R.; Hori, S. (2022): A record or the pale-winged male of *Sympetrum croceolum* (Selys, 1883) from Hokkaido, Japan. *Tombo* 65: 47-48. (in Japanese, with English summary) ["An abnormal pale-winged male of *S. croceolum* was collected in Eoetsu-shi, Hokkaido, Japan. Nuclear DNA analysis confirmed that this individual is a pure *S. croceolum*, not a hybrid with other species." (Authors)] Address: Futahashi, R., National Inst. Advanced Industrial Science and Technology (AIST), Central 6, Tsukuba, Ibaraki 305-8566 Japan. E-mail: ryo-futahashi@aist.go.jp

**21975.** Nicolai, B.; Grimm, H. (2022): Zur Nahrung des Turmfalken *Falco tinnunculus dacotiae* Hartert, 1913 (Aves: Falconidae) auf Fuerteventura (Kanarische Inseln, Spanien). *Vernate* 41: 81-90. (in German, with English summary) ["From 2019 to 2021, the diet of kestrels on Fuerteventura (Canary Islands, Spain) was studied. For this purpose, pellets were collected at resting/sleeping sites of adult birds. In total 5756 prey items were identified, mainly invertebrates (insects and spiders). In terms of biomass, lizards make up the largest proportion of the diet. Although other vertebrates (small mammals, birds) also provide a share of the biomass, these prey items are not regularly consumed or sufficiently accessible for the kestrels. The calculation of prey value (BW) results in only the following significant food items: Lizards (Squamata) (BW 54-78 %), Grasshoppers (Orthoptera) (BW 8-21 %), Spiders (Arachnida) (6-9 %) and Beetles (Coleoptera) (5-9 %). The results confirm the previously known composition of the diet of kestrels on the Canary Islands. In addition, there are indications, especially due to the drought of recent years, that under the (increasingly?) arid conditions of the island - besides a general reduction in the supply of potentially suitable prey - the proportion and thus the importance of lizards in particular, and also of invertebrates, in the diet are increasing." (Authors) The diet includes "Odonata".] Address: Bernd Nicolai, B., Herbingstr. 20, 38820 Halberstadt, Germany. Email: nicolai-bea@gmx.de

**21976.** Ocampo, M.; Chuirazzi, C.; Takahashi, M.K. (2022): The effects of road salt (NaCl), predation, and competition on the growth and community interactions of Spotted Salamanders (*Ambystoma maculatum*) and Wood Frogs (*Lithobates sylvaticus*). *Environmental Pollution* 315, 120349: (in English) ["Road deicing salts are frequently used in northern regions of the world during the winter and early spring months. As a result, a significant portion of road runoff into surrounding aquatic habitats contains road deicing salts. Previous studies found road salt contaminations in vernal pools that pond-breeding amphibians commonly use, including *A. maculatum* and *L. sylvaticus*. Studies have examined the impact of road salt on both amphibian species, but to our knowledge no previous studies have examined how road salt impacts the interspecific competition between both amphibians. We hypothesized that road salt would negatively impact growth and survivorship of both amphibian species. During the spring and summer of 2017, we conducted an outdoor mesocosm experiment in which we created eight experimental conditions with three main factors: presence/absence of NaCl (1000 mg/L Cl<sup>-</sup>), presence/absence of interspecific competition between the two amphibian species (*A. maculatum* and *L. sylvaticus*), and presence/absence of predatory dragonfly larvae (*Libellulidae*). Our experiment revealed that salt delayed hatching and increased deformity in spotted salamander hatchlings. Additionally, salt significantly decreased both salamander and frog survivorship. Wood frog tadpoles and road salt interacted to further diminish salamander survivorship, likely through an increase in interspecific competition. Road salt increased the larval period of salamanders and decreased the proportion metamorphosed by the end of the experiment. Dragonfly larvae caused a reduction in survivorship of salamander larvae, whereas they increased wood frog tadpole development rates. Dragonfly larvae and salt interacted to alter tadpole denticle size, with salt negating the impact of dragonfly larvae. This may signify that salt interferes with aquatic predatory chemical cues. Overall, our data suggest that the application of road de-icing salt has many far-reaching impacts on amphibians and their aquatic communities." **21977.** Ott, J. (2022): Interessante Arten an den LIBELLULA-Teichen bei Trippstadt – mit einem aktuellen Brutnachweis der Krickente (*Anas crecca*). *Fauna Flora Rheinland-Pfalz* 14(4): 1459-1470. (in German, with English summary) ["The author reports on the faunistic species found between 2013 and 2022 at the ponds of the LIBELLULA environmental education center in the Karlstal near Trippstadt. A particularly outstanding feature this year was the successful breeding of an Eurasian teal (*Anas crecca*) with nine chicks. Overall, a large number of protected and endangered animal species from a wide variety of taxonomic groups was found in the approximately one-hectare wetland area – a former fish pond system now left to free succession –, which underlines the high nature conservation value of the area." (Author) The author compiles records of 27 species.] Address: Ott, J., Friedhofstr. 28, 67705 Trippstadt, Germany. E-mail: ott@lupogmbh.de

**21978.** Péricat, A.; Maury, L.; Theaud, R.; Chalais, B. (2022): Étude hydrologique du lac Achard et des zones humides connexes: diagnostic et définition de scénarios de restauration pour une gestion environnementale du lac – phase 1: Diagnostic. Commune de Chamrousse, S.T.E. Sciences et Techniques de l'Environnement - Rapport 21-8570: 120 pp. (in French) [Isère, France; "This study aims to establish a

synthesis of the quality of Lake Achard and its related environments, through the analysis of previous data, supplemented by field investigations carried out in 2021-2022 to determine the hydromorphological parameters of the lake and its quality. physico-chemical and hydrobiological. Flora and fauna inventories were carried out in parallel to define the heritage issues of the site, in particular on the related wetlands, and their alterations. This diagnosis made it possible to characterize the body of water and to understand the origin of the turbidity of the water: it is about algal developments (phytoplankton). Nutrient inputs to the lake are low, but the water body has high primary production. This natural phenomenon does not indicate any deterioration in the quality of the environment apart from a visual impact. At the heritage level, the flora and fauna inventories (amphibians and odonates) have highlighted a certain diversity of wetland habitats (low marshes) with heritage stations of Lai-che des Bourbiers. Lac Achard displays a lack of aquatic grass beds and shows a degradation of riparian habitats. This "diagnosis" report constitutes the 1st volume of this study. The second volume aims to define restoration scenarios for the environmental management of the lake. It is therefore a question of defining the issues and the proposals for action with the ultimate objective of achieving the good status of this body of water and the good quality of the expected uses." (Authors/Google translate) The following taxa are treated: *Aeshna* sp.; *Aeshna cyanea*, *A. juncea*, *Coenagrion hastulatum*, *C. puella*, *Lestes dryas*, *Lestes* sp., *L. sponsa*, *Leucorrhinia dubia*, *Libellula depressa*, *L. quadrimaculata*, *Pyrhosoma nymphula*, *Somatochlora alpestris*, *S. metallica*, *Sympetrum flaveolum*.] Address: Sciences et Techniques de l'Environnement – B.P. 90374, 17, Allée du Lac d'Aiguebelle - Savoie Technolac, 73372 Le Bourget du Lac cedex, France; [http://www.mairiechamrousse.com/images/pdf/zones\\_naturelles/Etude\\_hydro\\_Lac\\_Achard\\_phase1diagnostic\\_E\\_NS\\_2022\\_compressed.pdf](http://www.mairiechamrousse.com/images/pdf/zones_naturelles/Etude_hydro_Lac_Achard_phase1diagnostic_E_NS_2022_compressed.pdf)

(holotype male from Kon Ka Kinh National Park, 14.3672° N, 108.5368° E, alt. 1000 m) and *C. vani* sp. nov. (holotype male from Chu Yang Sin National Park, 12.4780° N, 108.4617° E, alt. 749 m). Furthermore, *C. gracilis* Wilson & Reels, 2001 is recorded from Vietnam for the first time, with notes on its morphology and detailed illustrations of male and female structures." (Authors)]

**21980.** Pinilla-Rosa, M.; García-Saúco, G.; Santiago, A.; Ferrandis, P.; Méndez, M. (2022): Can botanic gardens serve as refuges for taxonomic and functional diversity of Odonata? The case of the botanic garden of Castilla-La Mancha (Spain). *Limnology* 24(1): 37-50. (in English) ["In a scenario with declining biodiversity and habitat loss, botanic gardens could serve as refuges for invertebrates, but the opportunities they offer for animal conservation are still poorly understood. Odonata is a good model group for conservation studies, because it includes threatened species and responses to habitat disturbance are well documented. In this study, we assessed the role of the botanic garden of Castilla-La Mancha in Spain as a refuge for members of Odonata by analysing their taxonomic and functional diversity. We explored if the small size of the botanic garden might constrain

the taxonomic diversity of Odonata and if low habitat diversity might limit their functional diversity. We sampled adult Odonata from five water bodies along a gradient of human impact and characterized the Odonata communities based on 12 functional traits in Odonata. We used a species-area relationship to control for differences in the size of water bodies. Compared with natural lakes, the Odonata communities contained less species and their functional diversity was lower in the botanic garden ponds, where generalist species were basically hosted. Despite these limitations, the botanic garden ponds hosted the number of species expected for natural water bodies with the moderate surface area and functional diversity, thereby demonstrating that they are a valuable habitat for Odonata in an urban environment. Appropriate management involving the removal of exotic fish and habitat diversification, including creating lotic environments, would increase the taxonomic and functional diversity of Odonata in this urban system." **21983.** Sáenz Oviedo, M.A.; Kuhn, W.R.; Sepulveda, M.A.R.; Abbott, J.; Ware, J.L.; Sanchez-Herrera, M. (2022): Are wing contours good classifiers for automatic identification in Odonata? A view from the Targeted Odonata Wing Digitization (TOWD) project. *International Journal of Odonatology* 25: 96-106. (in English) ["In recent decades, a lack of available knowledge about the magnitude, identity and distribution of biodiversity has given way to a taxonomic impediment where species are not being described as fast as the rate of extinction. Using Machine Learning methods based on seven different algorithms (LR, CART, KNN, GNB, LDA, SVM and RFC) we have created an automatic identification approach for odonate genera, through images of wing contours. The training population is composed of the collected specimens that have been digitized in the framework of the NSF funded Odomatic and TOWD projects. Each contour was pre-processed, and 80 coefficients were extracted for each specimen. These form a database with 4656 rows and 80 columns,

which was divided into 70% for training and 30% for testing the classifiers. The classifier with the best performance was a Linear Discriminant Analysis (LDA), which discriminated the highest number of classes (100) with an accuracy value of 0.7337, precision of 0.75, recall of 0.73 and a F1 score of 0.73. Additionally, two main confusion groups are reported, among genera within the suborders of Anisoptera and Zygoptera. These confusion groups suggest a need to include other morphological characters that complement the wing information used for the classification of these groups thereby improving accuracy of classification. Likewise, the findings of this work open the door to the application of machine learning methods for the identification of species in Odonata and in insects more broadly which would potentially reduce the impact of the taxonomic impediment." **21986.** Scheibler, E.E.; Montemayor, S.I.; Melo, M.C. (2022): Macroinvertebrate communities in high mountain desert wetlands: Building biological indexes to address the vulnerability of species and communities. *Insect Conservation and Diversity* 15(6): 714-724. (in English) ["1. Andean wetlands in arid climates are isolated ecosystems surrounded by steep terrain and have crucial relevance as a water resource. The species inhabiting them are adapted to these

habitats and vulnerable to environmental changes. 2. The aim of this study is to evaluate the vulnerability of invertebrate aquatic species to climate change and organic pollution through an index adapted from the species distribution models (SDM) score [vulnerability of aquatic invertebrate species index (Vais)], and the vulnerability of the invertebrate communities through an index developed herein [wetland community vulnerability index (Wcv)]. 3. The Vais index ranges from 1 (highly vulnerable) to 0 (non-vulnerable species). It was calculated for 22 species of the orders Coleoptera, Ephemeroptera, Hemiptera, and Odonata. According to our results, the most vulnerable species belong to the orders Ephemeroptera (2) and Odonata (8) (scores 0.63–0.76); species with medium vulnerability belong to the orders Coleoptera (1) Ephemeroptera (1), Hemiptera (4) and Odonata (1) (scores 0.43–0.54); and the most tolerant species belong to the orders Coleoptera (2) and Hemiptera (3) (0.31–0.29). 4. The Wcv index was calculated for 31 communities in Andean wetlands. Lower Wcv values correspond to less vulnerable communities and higher values to more vulnerable communities. According to our results, communities can be divided into three groups: the most vulnerable (scores 0.61–0.71), the ones with medium vulnerability (scores 0.49–0.59), and the least vulnerable (scores 0.33–0.48). 5. The Vais and Wcv indexes are useful tools for evaluating the vulnerability of aquatic species and wetland communities, providing valuable information for defining conservation strategies." (Authors) The following species are used of assessment: *Ischnura fluviatis*, *Erythrodiplax corallina*, *Progomphus joergenseni*, *Cyanallagma interruptum*, *Erythrodiplax connata*, *Rhionaeschna absoluta*, *Ischnura ultima*, and *Andinagrion peterseii*.] Address: Montemayor, Sara Itzel, División Entomología, Facultad de Ciencias Naturales y Museo, Univ. **21987.** Seok, Y.; Kim, D.G.; Son, J.; Park, J.; Lee, J. (2022): The importance of the Mujechineup wetland for biodiversity: an evaluation of habitat quality and ecosystem service value. *Landscape and Ecological Engineering* 18(4): 477-491. (in English) ["Wetlands are important multifunctional systems that provide various ecological services for animal populations, particularly with regard to regulation and support. The biodiversity of wetlands is threatened by human activities that cause habitat fragmentation and destruction. The international community needs to make efforts to measure habitat quality and recognize the value of biodiversity. This study aimed to evaluate the value of *Nannophya koreana* habitat restoration in the Mujechineup wetland. First, through a literature review, this study estimated the expected ecosystem service value of the Mujechineup wetland compared to existing wetlands. The Mujechineup wetland's ecosystem service value ranged from a minimum of \$109,296.00 (SD \$32,752.00) to a maximum of \$679,457.14 (SD \$4,611,730.90). Second, we quantified the habitat quality of the Mujechineup wetland in Ulsan for biodiversity measurements using the integrated valuation of ecosystem services and tradeoffs (INVEST). The analysis showed that there was a difference in the quality of the habitat depending on the spatial unit. Samsong-myeon was processed for 2 min with a mean value of 0.094. Ulju-gun was processed for 1 h 14 min with a mean value of 0.146. In addition, as a result of the field survey, the ratio of Hemiptera, Odonata and Coleoptera (HOC) groups in the Mujechineup wetland where *Nannophya koreana* lives was more than 50%, but the ratio of predators was approximately 10% on average. Third, this study investigated the willingness to pay to restore the habitat of *Nannophya koreana*, which lives in the Mujechineup wetland. The

average amount that people would be willing to pay annually for the restoration of the Mujechineup wetland was \$33,652. The study found that awareness of the importance of *Nannophya koreana* and the need for restoration of its habitat environment was high. These findings can be used to recognize the value of the Mujechineup wetland as a habitat for *Nannophya koreana* and to communicate its importance." **21990.** Silas Veras, D.; Silva Pinto, N.; Calvão, L.; Santana Lustosa, G.; Silva de Azevêdo, C.A.; Juen, L. (2022): Environmental thresholds of dragonflies and damselflies from a Cerrado-Caatinga ecotone. *Environmental Monitoring and Assessment* volume 194(9), Article number: 614: (in English) ["Aquatic ecosystems are affected by different land uses that modify gradients of environmental conditions. These impacts act directly on the community structure, especially the most sensitive ones, such as aquatic insects. Thus, dragonflies have been used as good models to assess these changes, since their suborders Anisoptera and Zygoptera have different ecophysiological and behavioral requirements. This study aimed to evaluate the following hypotheses: (1) dragonfly species composition differs along the environmental gradients of streams; therefore, we expect a higher proportion of species of the suborder Anisoptera in environments with a higher degree of disturbance, since these environmental conditions select heliothermic species with exophytic oviposition; (2) the reduction of habitat integrity and canopy cover will lead to a lower richness of the Zygoptera, due to the restrictions of its thermoregulation and oviposition behavior in relation to Anisoptera, since the higher light input

would favor heliothermic and exophytic species; (3) alterations in habitat integrity create ecological thresholds and points of change in the abundance and frequency of Odonata species, generating gradients in the environmental integrity conditions. Specimens were collected from 24 streams (first to third order), in a gradient of land uses. Canopy cover and stream width were predictors of taxonomic richness and abundance of the suborders Anisoptera and Zygoptera, with greater coverage and smaller width, positively affecting Zygoptera and negatively Anisoptera. The turning points were determined by a habitat integrity index, where below 0.38 there is an increase in generalist taxa and a decline in sensitive taxa. On the other hand, above 0.79, there was a sensitive taxa increase in detriment of generalists. Four individual taxa indicators were selected, two of which associated with a negative response (*Perithemis tenera* and *Acanthagrion aepiolum*) and two with positive responses (*Epipleoneura metallica* and *Zenithoptera lanei*) for habitat integrity. Our results are important to guide management strategies, recovery, and protection policies for areas of permanent protection, aiming to conserving biodiversity and natural resources essential to life quality maintenance." (in Japanese, with English summary) ["The shape of a lobe between the cerci at the anal appendages of final instar larvae between *Calopteryx japonica* and *Atrocalopteryx atrata* is compared. It is revealed to be clearly different, i.e. the apex of the lobe in *C. japonica* protrudes in a mountain shape, whereas that

of *A. atrata* is rounded." (Author)] Address: Email: takashi.umed@jcom.home.ne.jp

**21994.** Van Eupen, C.; Maes, D.; Herremans, M.; Swinnen, K.R.R.; Somers, B.; Luca, S. (2022): Species profiles support recommendations for quality filtering of opportunistic citizen science data. *Ecological Modelling* 467, May 2022, 109910: (in English) ["Highlights: • Taxonomy and relative species traits support data quality filtering recommendations. • Species profiles reveal relative importance of species traits. • Clearest recommendations for filters based on observer activity/validation status. • Improving species knowledge and record validation protocols increase data quality. • Filtering is not recommended when sample size decreases over 75 percent. Abstract: Opportunistic citizen science data are commonly filtered in an attempt to improve their applicability for relating species occurrences with environmental variables. Recommendations on when and how to filter, however, have remained relatively general and associations between species traits and filtering recommendations are sparse. We collected six traits (body size, detectability, classification error rate, familiarity, reporting probability and range size) of 52 birds, 25 butterflies and 14 dragonflies. Both absolute (values not rescaled) and relative traits (values rescaled per taxonomic group) were linked to filter effects, i.e. the impact on three different measures of species distribution model performance caused by applying three different quality filters, for different degrees of sample size reduction. First, we applied multiple regressions that predicted the filter effects by either absolute (including taxonomic group) or relative traits. Second, a principal component and clustering analysis were performed to define five species profiles based on species traits that were retained after a multiple regression model selection. The analysis of the profiles indicated the relative importance of species traits and revealed new insights into the association of species traits with changes in model performance after data quality filtering. Both taxonomic group (more than absolute traits) and relative species traits (mainly classification error rate, range size and familiarity) defined the impact of data quality filtering on model performance and we discourage the selection of a quality filtering strategy based on one single species trait. Results further confirmed the importance of considering the goal of the study (i.e. increasing model discrimination capacity, sensitivity or specificity) as well as the change in sample size caused by stringent filtering. The general species knowledge amongst citizen scientists (importance of observer experience), together with the mechanism of record verification in an opportunistic data platform (importance of verifiable metadata) have the largest potential for enhancing the quality of opportunistic records." **21995.** Wang, Y.-J.; Tüzün, N.; Sentis, A.; Stoks, R. (2022): Thermal plasticity and evolution shape predator-prey interactions differently in clear and turbid water. *Journal of Animal Ecology* 91(84): 883-894. (in English) ["1. Warming and eutrophication negatively affect freshwater ecosystems by modifying trophic interactions and increasing water turbidity. We need to consider their joint effects on predator-prey interactions, and how these depend on the thermal evolution of both predator and prey. 2. We quantified how 4°C warming and algae-induced turbidity (that integrates turbidity per se and increased food for zooplankton prey) affect functional response parameters and prey population parameters in a common-garden experiment. We did so for all combinations of high- and low-latitude predator (damselfly larvae)

and prey (water fleas) populations to assess the potential impact of thermal evolution of predators and/or prey at a high latitude under warming using a space-for-time substitution. We then modelled effects on the system stability (i.e. tendency to oscillate) under different warming, turbidity and evolutionary scenarios. 3. Warming and turbidity had little effect on the functional response parameters of high-latitude predators. In contrast, warming and turbidity reduced the handling times of low-latitude predators. Moreover, warming increased the search rates of low-latitude predators in clear water but instead decreased these in turbid water. 4. Warming increased stability (i.e. prevented oscillations) in turbid water (except for the "high-latitude predator & high-latitude prey" system), mainly by decreasing the prey's carrying capacity and partly also by decreasing search rates, while it did not affect stability in clear water. Algae-induced turbidity generally decreased stability, mainly by increasing the prey's carrying capacity and partly also by increasing search rates. This resembles findings that nutrient enrichment can reduce the stability of trophic systems. The expected stability of the high-latitude trophic system under warming was dependent on the turbidity level: our results suggest that thermal plasticity tends to destabilize the high-latitude trophic system under warming in clear water but not in turbid water, and that thermal evolution of the predator will stabilize the high-latitude system under warming in turbid water but less so in clear water. 5. The extent to which thermal plasticity and evolution shape trophic system stability under warming may strongly differ between clear and turbid water bodies, with their contributions having a more stabilizing role in turbid water." **21996.** Wolz, M.; Schrader, A.; Whitelaw, E.; Müller, C. (2022): Gregarines modulate insect responses to sublethal insecticide residues. *Oecologia* 198: 255-265. (in English) ["Throughout their lifetime, insects face multiple environmental challenges that influence their performance. Gregarines are prevalent endoparasites in most invertebrates that affect the fitness of their hosts, but are often overlooked in ecological studies. Next to such biotic factors, a current common challenge is anthropogenic pollution with pesticides, which causes a major threat to non-target organisms that are readily exposed to lethal or sublethal concentrations. In a Laboratory study, we investigated whether the presence of gregarines modulates the food consumption and life history traits of a (non-target) leaf beetle species, *Phaedon cochleariae*, in response to sublethal insecticide exposure. We show that the larval food consumption of the herbivore was neither affected by gregarine infection nor sublethal insecticide exposure. Nevertheless, infection with gregarines led to a delayed development, while insecticide exposure resulted in a lower body mass of adult males and a reduced reproduction of females. Individuals exposed to both challenges suffered most, as they had the lowest survival probability. This indicates detrimental effects on the population dynamics of non-target insects infected with naturally occurring gregarines that face additional stress from agrochemical pollution. Moreover, we found that the infection load with gregarines was higher in individuals exposed to sublethal insecticide concentrations compared to unexposed individuals. To counteract the global decline of insects, the potential of natural parasite infections in modulating insect responses to anthropogenic and non-anthropogenic environmental factors should be considered in ecological risk assessment." (2022): Biomagnification of persistent organic pollutants from terrestrial and aquatic Invertebrates to songbirds: Associations with physiochemical and ecological indicators. *Environmental Science & Technology* 56: 12200-12209. (in English) ["Biomagnification of persistent organic pollutants (POPs) is affected by physiochemical properties of POPs and ecological factors of wildlife. In this study, influences on species-specific biomagnification of POPs from aquatic and terrestrial invertebrates to eight songbird species were investigated. The median concentrations of polychlorinated biphenyls (PCBs) and polybrominated diphenyl ethers (PBDEs) in birds were 175 to 13 200 ng/g lipid weight (lw) and 62.7 to 3710 ng/g lw, respectively. Diet compositions of different invertebrate taxa for songbird species were quantified by quantitative fatty acid signature analysis. Aquatic insects had more contributions of more hydrophobic POPs, while terrestrial invertebrates had more contributions of less hydrophobic PCBs in songbirds. Biomagnification factors (BMFs) and trophic magnification factors had parabolic relationships with log KOW and log KOA. The partition ratios of POPs between bird muscle and air were significantly and positively correlated with log KOA of POPs, indicating respiratory elimination as an important determinant in biomagnification of POPs in songbirds. In this study, the species-specific biomagnification of POPs in songbird species cannot be explained by stable isotopes of carbon and nitrogen and body parameters of bird species. BMFs of most studied POPs were significantly correlated with proportions of polyunsaturated fatty acids in different species of songbirds." **22004.** Borkenstein, A.; Jödicke, R. (2023): Langjährige Entwicklung der Libellenfauna zweier Moore in Nordwestdeutschland und Einfluss der Dürreperiode 2018–2020 (Odonata). *Libellula* 41(3/4): 115-153. (in German, with English summary) ["Long-term development of the dragonfly fauna of two bogs in north-west Germany and influence of the drought period 2018–2020 (Odonata) – The population development of dragonflies in two lowland bogs in Lower Saxony was surveyed for 18 and 12 years, respectively. In all, 41 species were identified. The most significant changes in the dragonfly fauna happened when both study areas dried up in 2018–2020 due to summer rain deficits and hot spells. In the years before this drought, there were fairly stable populations of regularly reproducing species, but also those with occasional reproductive success as well as visitors. During the study period, there were no colonisations by southern species expanding their range to Lower Saxony as a result of global warming. However, even before the dry years, some species, such as *Lestes sponsa*, *Aeshna juncea* or *Sympetrum flaveolum*, showed significant to extreme population declines. This negative development was in line with the regional trend. In the dried-up bogs during the drought summers only a few individuals of a few species could be observed. According to our observations, no larva survives dry and hot peat soil. As an exception, a few teneral individuals of *Libellula quadrimaculata* and *Leucorrhinia rubicunda* had apparently been able to survive as larva in the few still humid dipo. Some univoltine species, such as *L. sponsa*, *Coenagrion puella* or *S. danae*, survived the drought as imago, and their offspring emerged before the bogs dried out again in the following season. *Lestes dryas*, which colonised the areas during the drought period, proved to be the beneficiary of

the drought. Also, *L. virens* only reproduced in the dry years and became the most abundant damselfly species. During the comparatively wet following year of 2021 we observed a resettlement by most species. Apparently, the arrival of dispersing mature individuals from surrounding waters without desiccation problems played a decisive role. The population of *C. lunulatum* did not recover until the end of our study. In addition to the disappearance of this species, which has become rare in Germany, the rapid expansion of the common rush in the dry phases poses a significant problem, because the shallow waters and bights overgrown by it irreversibly lost their bog character. As climate change continues, the drought years described here will recur and eventually become the norm. Losses among the odonate species, especially those of the bog dwellers, will steadily increase. The protection program of bogs in Lower Saxony is in danger of failing due to the lack of summer rain in connection with extreme heat waves." **22009.** Chang, S.-C.; Li, Y.; Zheng, D. (2023): Dating amber: Review and perspective. *Minerals* 2023, 13, 948. <https://doi.org/10.3390/min13070948>: 15 pp. (in English) ["Amber is a fossilized tree resin that ranges in age from the Carboniferous to the Cenozoic. It occurs globally from the Arctic to Antarctica. As the resin petrifies and turns into amber, it can enclose and preserve other materials. Amber with inclusions can help reconstruct past biodiversity and ecosystems. Some amber contains fossils representing the oldest and most detailed records of critical evolutionary traits or markers. Inclusions can even capture behavioral indicators previously only observed in extant organisms. Evidence of insect pollination of flowering plants and dragonfly mating behavior appears in amber, as does the morphological specialization of insects, indicating sociality and social parasitism. Dating amber deposits can help calibrate evolutionary events and inform reconstructions of past ecosystems. While the direct dating of amber remains impossible, age constraints on most amber deposits are based on correlations or relative dating, methods that come with significant uncertainties. This study discusses two cases using <sup>40</sup>Ar/<sup>39</sup>Ar and U-Pb geochronologic methods to constrain the ages of amber deposits in China and the paleo-ecosystems they record. This paper also summarizes how radio-isotopic dating and other techniques combined with the analysis of inclusions in amber can help elucidate biogeography and the dynamic relationship between life and the physical environment." **22010.** Cranston, J.; Isaac, N.J.B.; Early, R. (2023): Associ-

ations between a range-shifting damselfly (*Erythromma viridulum*) and the UK's resident Odonata suggests habitat sharing is more important than antagonism. *Conservation and Diversity* 16(3): 416-426. (in English) ["1. Species shifting their ranges under climate change are a conservation dilemma. Range-shifters may be threatened by climate change in their historic range. However range-shifters are likely to be generalist opportunists, which could mean they could harm aspects of biodiversity in their new ecosystems. Therefore, we need approaches to rapidly assess how range-shifters may integrate into the community of historically resident species. 2. *E. viridulum* has shifted into the UK since 1999, and may affect resident Odonata via intraguild predation. We asked whether the damselfly's arrival is associated with a decline in resident Odonata. 3. We harnessed the British Dragonfly Society's dataset, using records from 49,788 site visits between 2000-2015 to construct dynamic species occupancy models for 17 resident UK Odonata. We estimated the potential effect of *E. viridulum* presence on the probability that each species would persist at a given site, while controlling for potential effects of climate and recording effort. 4. On average, Anisoptera persisted more frequently at sites where *E. viridulum* had established, whilst Zygoptera showed no change in persistence. Nevertheless, two resident damselflies, including *E. viridulum*'s congener, disappeared more frequently when the range-shifter established. 5. We suggest *E. viridulum* poses minimal risk to most UK resident Odonata. Rather, *E. viridulum* may be differentially establishing in areas with good habitat quality, where many species of historically resident Odonata are also found. Therefore, high quality, bio-diverse sites may become home to increasing numbers of range-shifters in future. Our approach permits rapid-detection of how range-shifters are integrating into resident biota." (Authors)] Address: Early, R., Centre for Ecology & Conservation, Univ. Exeter, Penryn Campus, Penryn, TR10 9FE, UK. Email: r.early@exeter.ac.uk

Gmelin, 1788) (Aves: Strigiformes: Strigidae) from two localities in the foothills of the Western Ghats of Goa, India. *Journal of Threatened Taxa* 15(7): 23514-23520. ["The Brown Fish-Owl is a large nocturnal bird of prey that has a vast distribution range. However, there is a significant literature gap on the ecology of this species in the Western Ghats ecoregion, particularly in regard to its food spectrum. In the present study, we assessed the diet composition of this species in the foothills of the Western Ghats of Goa, India. The diet was evaluated by analysing the undigested prey remains in regurgitated pellets obtained from the banks of forest streams and roosting sites. A total of 104 pellets were collected from two localities that exhibited similar landscape characteristics. Our analysis indicated that crabs contributed to a significant proportion of the diet of the species (75.47%), followed by amphibians (frogs, 8.02%), fishes (7.08%), reptiles (snakes, 2.83%), birds (2.36%), scorpions (1.89%), and insects (Odonata, 0.47%). Additionally, 1.89% (n = 4) of the prey items could not be identified due to their disintegrated nature. Furthermore, an assessment of Food Niche Breadth (FNB) indicated that *K. zeylonensis* exhibited a high degree of specialization in terms of its diet in the study areas." **22016.** Ferzoco, I.M.C.; McCauley, S.J. (2023): Breaking down the components of the competition-colonization trade-off: New insights into its role in diverse systems. *Journal of Animal Ecology* 92(2): 352-366. (in English) ["(1) Performance trade-offs between competition and colonization

can be an important mechanism facilitating regional coexistence of competitors. However, empirical evidence for this trade-off is mixed, raising questions about the extent to which it shapes diverse ecological communities. Here, we outline a framework that can be used to improve empirical tests of the competition-colonization trade-off. (2) We argue that tests of the competition-colonization trade-off have been diverted into unproductive paths when dispersal mode and/or competition type have been inadequately defined. To generate comparative predictions of associations between dispersal and competitive performance, we develop a conceptual trait-based framework that clarifies how dispersal mode and type of competitor shape this trade-off at the stage of dispersal and establishment in a variety of systems. Our framework suggests that competition-colonization trade-offs may be less common for passively dispersing organisms when competitive dominants are those best able to withstand resource depletion (competitive response), and for active dispersers when traits for dispersal performance are positively associated with resource pre-emption (competitive effect). (3) The framework presented here is designed to provide common ground for researchers working in different systems in order to prompt more effective assessment of this performance trade-off and its role in shaping community structure. By delineating key system properties that mediate the trade-off between competitive and colonization performance and their relationship to individual-level traits, researchers in disparate systems can structure their predictions about this trade-off more effectively and compare across systems more clearly." **22017.** Fischer, I.; Chovanec, A.; Kargl, V.; Sittenthaler, M.; Sattmann, H.; Haring, E. (2023): The dragonfly fauna of the Vienna Lobau – a survey from 2017–2020. *Acta ZooBot Austria* 159: 119-136. (in German, with English summary) ["In this study, the ecological status of the water bodies in the Viennese part of the Danube Floodplain National Park, the Viennese Lobau, was assessed from a dragon fly ecology perspective. The surveys for this were conducted in 2017, 2018 and 2020. The assessment was based on the comparison of the status quo with the water body type-specific reference coenosis, based on a classification of the Lobau waters using the Lorenzo map (surveyed 1816–1817). The reference coenosis was dominated by rheophilous species and dragonfly species that depend on dynamic waters with fluctuating water levels. Due to the low abundance of stillwater habitats, limnophilic species played only a minor role in the reference situation. The dragonfly fauna recorded during the study – 43 dragonfly species, with 39 of them autochthonous – consists for the most part (74%) of species with a distribution focus in the limnophilic range. Rheophilic species and species adapted to strongly fluctuating water levels made up only a small part of the species spectrum and also occurred (especially in the Upper Lobau) only to a very limited extent. Due to this, the dragonfly ecological status of the waters in the Lobau was assessed as "poor". **22018.** Fortunato, M.H.T.; Mendes, H.F.; Hayashi, C.; Faria, L.R. de; Melo, C.L. de; & Ananias, I. de M.C. (2023): Predation rate of dragonfly (Odonata: Libellulidae) on tilapia (*Oreochromis niloticus* Linnaeus 1758) and the availability of alternative preys (Insecta: Diptera: Chironomidae) to increase fish survival. *Acta Scientiarum. Biological Sciences*

45(1), e65291: 12 pp. (in English) ["The objective of this work was to evaluate the predation rates of two genera of Odonata *Miathyria* Kirby, 1889 and *Erythemis* Hagen, 1861 in post-larviculture of tilapia (*Cichlidae*) with and without availability of Chironomidae. For that, 3 experiments were carried out, the first to analyze which size scale of these two genera would be more efficient in the predation of tilapia and the other 2 experiments with the selected size scales, to analyze the predation rates on tilapia with different Odonata densities, with and without availability of the aquatic insect Chironomidae. For statistical analysis of the data, an analysis of variance (ANOVA) was applied with the Duncan test searching for the means in all experiments. In experiments 2 and 3 a linear regression model was also applied. In experiment 1, there were significant differences between treatments, and in the phase with *Miathyria* the predation of tilapia post-larvae was higher among odonates that corresponded to the size scale from 7.1 to 9.9 mm and therefore the scale was also selected for the next experiments. For *Erythemis*, the consumption of tilapia was higher in the size scale between 12.1 to 14,2 mm. In the following experiments, there were significant differences between treatments. With the increase in Odonata densities the predation of the fish was greater. With the availability of Chironomidae, the consumption of tilapia post-larvae decreased. The consumption of Chironomidae was higher than the consumption of fish in experiment 3. *Miathyria* proved to be more efficient than *Erythemis* in predation and the use of Chironomidae can be a sustainable alternative for post-larvae predation control on fish farms." **22026.** Ge, Y. García-Girón, J.; Heino, J.; Liu, Z.; Zhang, C.; Yan, Y.; Xie, Z.; Li, Z. (2023): Dispersal syndromes mediate phylogenetic distance decay relationships in a dendritic stream network. *Journal of Biogeography* 50(3): 897-908. (in English) ["Aim: Understanding the mechanisms underlying the structure and connectivity of ecological communities is a central issue in biogeography. Dispersal syndromes are tightly woven into organisms' life history seen across populations and communities, but measuring dispersal is still complicated in practice. We investigated the role of dispersal syndromes (here, associated with body size, adult flying ability and voltinism) to predict phylogenetic distance

decay relationships (DDRs) of aquatic insect assemblages in dendritic stream networks. Location: Du River Basin, China. Taxon: Aquatic insects (Coleoptera, Diptera, Ephemeroptera, Hemiptera, Lepidoptera, Megaloptera, Odonata, Plecoptera and Trichoptera). Methods: We applied multiple methods (i.e. deconstruction approach, null models, Mantel tests and partial Mantel tests) to enhance our basic understanding of phylogenetic distance decay patterns. To provide additional insights into correlates of phylogenetic dissimilarity between stream sites, we modelled potential dispersal routes based on overland, watercourse and cost distances. Results: Overland distances were among the main correlates of phylogenetic distance decay in the stream networks studied, suggesting that aquatic insects disperse overland seeking for habitats suitable for survival and reproduction. However, local environmental filtering was generally more important for phylogenetic DDRs than geographical distances alone. The interaction between environmental vs. dispersal processes in driving spatial patterns of phylogenetic dissimilarity was contingent on different dispersal syndromes. More specifically, significant phylogenetic DDRs were detected only for subsets of large-bodied, univoltine taxa with strong adult flying abilities, such as dragonflies. Main Conclusions: Overall, historical constraints affect the phylogenetic DDRs in aquatic insects. Dispersal syndromes associated with body size, adult flying ability and voltinism are key features underlying distance decay in phylogenetic assemblage similarity and the evolutionary legacies of aquatic insects in dendritic stream networks." **22027.** Gómez-Llano, M.; McPeck, M.A.; Siepielski, A.M. (2023): Environmental variation shapes and links parasitism to sexual selection. *Evolutionary Ecology* 37: 585-600. (in English) ["Parasite-driven population divergence in hosts can be exacerbated by environmental factors affecting host parasitism, as well as by increasing sexual selection against parasitized hosts. Environmental factors can influence parasitism directly by affecting parasite survival, and indirectly by affecting host condition, which can in turn shape host sexual selection. To disentangle these potential alternative paths, we used a damselfly (host) - water mite (parasite) system to examine how environmental factors directly and indirectly drive heterogeneity in parasitism across populations and influence the strength of sexual selection acting against parasitized males. We found substantial heterogeneity in parasitism across populations, driven mainly by lake pH, and damselfly density. Although this heterogeneity in parasitism did not translate directly into variation in sexual selection, the density of predatory fish increased sexual selection strength, likely through the effects on damselfly condition. These results imply that parasitism alone may not cause differences in sexual selection across populations, but when linked with underlying environmental conditions, parasitism can increase the strength of selection. More broadly, these results suggest that elucidating how parasitism may drive sexual selection requires consideration of the intertwined effects of ecological processes. ... Damselflies were collected from 10 populations of *E. ebrium* and eight population of *E. geminatum* in Vermont and New Hampshire, USA." **22028.** Greenhalgh, J.A.; Genner, M.J.; Jones, G. (2023): Diel variation in insect-dominated temperate pond soundscapes and guidelines for survey design. *Freshwater Biology*

68(7): 1148-1160. (in English) [1. Passive acoustic monitoring has been used for decades as a non-invasive tool for quantifying biodiversity in terrestrial and marine ecosystems. Recently, there has been increased interest in the potential for the method to survey freshwater biodiversity. Fundamental aspects of freshwater soundscape phenology, however, often remain poorly understood, despite their importance for suitable survey design. 2. To gain a greater understanding of daily acoustic variation in aquatic insect-dominated temperate pond soundscapes, 840 hr of underwater sound recordings were collected from five ponds in the southwest of the U.K. We calculated six commonly used acoustic indices to investigate diel trends and evaluated the suitability of each acoustic index to identify biologically complex pond soundscapes. In addition, macroinvertebrates were collected from each pond to investigate potential drivers of diel soundscape variation. 3. The ponds studied possessed clear patterns of daily acoustic variation, with acoustic activity typically peaking between 02:00 and 04:00 and around the solar noon. Acoustic Entropy showed the greatest variation between day and night soundscapes and was best suited for detecting overall daily acoustic variation in the study ponds. However, the Normalised Difference Soundscape Index and the Bioacoustic Index captured strong diel variation in aquatic insect-dominated soundscapes. Furthermore, we calculated that a minimum hydrophone deployment time of 24 hr is required to ensure that soundscape variation is adequately captured. 4. This study provides an increased understanding of daily acoustic variation in insect-dominated temperate pond soundscapes, enabling us to provide guide-lines for the design and implementation of future passive acoustic monitoring surveys. We suggest that a minimum of 24 hr is required to adequately capture pond soundscape variation. This will increase the chance of detecting key soniferous species in the soundscape and enable more accurate assessments of temperate pond soundscapes." (Authors) Figure 1 includes "Coenagrionidae"; no further discussion of Odonata is made.] Address: Greenhalgh, J.A., School of Biological Sciences, Univ. of Bristol, Life Sciences Building, 24 Tyndall Avenue, Bristol, BS8 1TQ, U.K. Email: jackhalgh95@gmail.com

(2023): The global EPTO database: Worldwide occurrences of aquatic insects. *Global Ecology and Biogeography* 32(5): 642-655. (in English) [1 Motivation: Aquatic

insects comprise 64% of freshwater animal diversity and are widely used as bioindicators to assess water quality impairment and freshwater ecosystem health, as well as to test ecological hypotheses. Despite their importance, a comprehensive, global database of aquatic insect occurrences for mapping freshwater biodiversity in macroecological studies and applied freshwater research is missing. We aim to fill this gap and present the Global EPTO Database, which includes worldwide geo-referenced aquatic insect occurrence records for four major taxa groups: Ephemeroptera, Plecoptera, Trichoptera and Odonata (EPTO). Main type of variables contained: A total of 8,368,467 occurrence records globally, of which 8,319,689 (99%) are publicly available. The records are attributed to the corresponding drainage basin and sub-catchment based on the Hydrography90m dataset and are accompanied by the elevation value, the freshwater ecoregion and the protection status of their location. Spatial location and grain: The database covers the global extent, with 86% of the observation records having coordinates with at least four decimal digits (11.1 m precision at the equator) in the World Geodetic System 1984 (WGS84) coordinate reference system. Time period and grain: Sampling years span from 1951 to 2021. Ninety-nine percent of the records have information on the year of the observation, 95% on the year and month, while 94% have a complete date. In the case of seven sub-datasets, exact dates can be retrieved upon communication with the data contributors. Major taxa and level of measurement: Ephemeroptera, Plecoptera, Trichoptera and Odonata, standardized at the genus taxonomic level. We provide species names for 7,727,980 (93%) records without further taxonomic verification. Software format: The entire tab-separated value (.csv) database can be downloaded and visualized at [https://glowabio.org/project/epto\\_database/](https://glowabio.org/project/epto_database/). Fifty individual datasets are also available at <https://fred.igb-berlin.de>, while six datasets have restricted access. For the latter, we share metadata and the contact details of the authors.] Address: Grigoropoulou, A., Dept of Community & Ecosystem Ecology, Leibniz Inst. **22031.** Higashikawa, W.; Sueyoshi, M.; Mori, T.; Yonekura, R.; Nakamura, K. (2023): The Satogawa Index: A landscape-based indicator for freshwater biodiversity in Japan. *Ecological Indicators* Volume 152, August 2023, 110350: 8 pp. (in English) [1 Highlights: • The 'Satogawa' Index (SGI) is based on the heterogeneity of freshwater landscape. • Diversity and shape complexity of freshwater land covers were considered in the SGI. • The SGI correlated well with species richness of Odonata and freshwater fish. • The SGI may assess the effects of the changes in land use on freshwater biodiversity. Abstract: Nationwide biodiversity indicators based on landscape heterogeneity have been developed primarily for terrestrial ecosystems, but not well for freshwater ecosystems worldwide. A plausible reason for this limitation is the difficulty in the fine discrimination of freshwater environments by remote sensing. However, in recent years, Geographic Information System (GIS) vector data of freshwater land cover are classified in detail (i.e. rice paddy

fields, other marshy wetlands, rivers, ponds and lakes) in Japan. Using these GIS data, we developed an index for freshwater landscape heterogeneity with 1 km square as the spatial unit, which was named the 'Satogawa' Index (SGI). The SGI formula consisted of two-component terms, one reflecting the diversity of freshwater land covers, and the other representing their spatial shapes. We calculated the SGI at a central region in Japan and found significant relationships with the species richness of Odonata (dragonflies and damselflies) and freshwater fish. The amounts and spatial patterns of freshwater landscape elements by which the SGI was estimated were different among regions in Japan; however, the SGI may be adapted to other regions as a surrogate of aquatic species richness, a typical measure of freshwater biodiversity. Although several modifications are underway that may have negative consequences for freshwater biodiversity, land use has been changed to prevent flood damage and improve the freshwater environment. The SGI may reveal the influences of the changes in land use on freshwater biodiversity and may identify the type and amount of lotic and lentic environment that should be supplemented to improve freshwater biodiversity at a certain location." (2023): Estudio del orden Odonata en el caserío Nuevo Perú del Centro Poblado Huambocancha Baja - Cajamarca - Peru. *Revista Peruana de Entomología* 56(1): 1-15. (in Spanish, with English summary) ["Study of the Odonata order in the Nuevo Perú hamlet of the Huambocancha Baja Population Center - Cajamarca. *Rev. peru. entomol.* 56 (1): 1-15. In the Nuevo Perú hamlet, Centro Poblado Huambocancha Baja, district, province and Dept of Cajamarca - Peru, the investigation was carried out with the objectives of determining the diversity of the order Odonata and taxonomically identifying the specimens collected at the genus level. During eight months and on a weekly basis, the collection of immature and adult stages was carried out during the time of day in which they showed their greatest activity (between 10:00 a.m. and 2:00 p.m.). To collect adults, the aerial entomological net was used and in the case of immature stages (eggs and naiads), the aquatic net was used. Each insect collected was assigned a field code and the corresponding observations (code, date, altitude (masi), latitude, longitude, and collector) were noted on a form. Three water sources were evaluated and the Margalef, Simpson and Shannon indices were determined to assess diversity. The eggs, naiads and adults collected were placed in 70% alcohol and in entomological envelopes to be later transferred to the Entomology Lab. of the Faculty of Agrarian Sciences of the National Univ. of Cajamarca. For the identification of the collected species, the taxonomic keys of Borror (1942), Von Ellenrieder (2003), Trapero & Naranjo (2004), Bermúdez (2005), Heckman (2006), Trapero & Naranjo (2009) and Ramírez were used. (2010). Likewise, they were identified by Dr. Cornelio Bota Sierra and Dr. Natalia Von Ellenrieder. The best conformed and in good condition insects were mounted dry and wet, and labeled with the basic field data, to be considered within the collection of Odonata of the Entomological Museum of the Faculty of Agrarian Sciences of the National Univ. of Cajamarca. In conclusion, the order Odonata is represented by at least four species in Caserío Nuevo Perú, Huambocancha Baja, Cajamarca." (Authors) Morphology of the following species is treated in great detail: *Rhionaeschna marchali* (Rambur, 1842), *Sympetrum gilvum* (Selys, 1884), *Erythrodiplax fusca* (Rambur 1842),

and *Oxyallagma dissidens* (Selys 1876).] Address: Huamán-Tucumango, J.K.D., Tesista de la Universidad Nacional de Cajamarca, Peru. Email: jhuamant13@unc.edu.pe

**22034.** Iezekiel, S.; Dimitriou, K.; Bakaloudis, D.E.; Kotsonas, E.G.; Aristophanous, M.; Yosef, R. (2023): First confirmed breeding records of Grey Wagtail *Motacilla cinerea* Tunstall, 1771 (Passeriformes: Motacillidae) in Cyprus. *Ornithological Science* 22(2): 151-159. (in English) ["In this paper we describe first breeding of *M. cinerea* in Cyprus. 23 nests were found during the 2020 and 2021 breeding seasons in riparian habitats adjacent to major river systems in the Paphos State Forest. Most nests were located on roadside banks at a height of 2.38 m above the ground and at a distance of about 0–10 m from the river. Nests consisted of grassy cups with a mean diameter of 13.39 cm, while the nest cup itself had a mean diameter of 7.07 cm and a depth of 3.41 cm. 20 nesting attempts were monitored with females laying eggs between early April and early July. A total of 54 eggs were laid and 44 nestlings were successfully raised from the 12 nests. The mean clutch size was 4.5 eggs per nest, the mean number of hatched eggs was 3.92 and the mean number of fledglings was 3.67. Parents fed their young mostly on invertebrates and in particular on insects. Diptera and Odonata were the most common insect Orders comprising the majority of prey items. Average insect prey size was 10.79 mm (range 2–60 mm), with little difference in prey size between that delivered by males and females. This study confirms the first breeding of the species in Cyprus, where it follows a breeding pattern similar to that in other parts of Western Palearctic range. The affinity of the Grey Wagtail to human structures and the low predation rate highlight the successful breeding potential and the future range expansion of the species across the island of Cyprus." **22035.** Indriani, G.R.; Singkam, A.R. (2023): Population dynamics of dragonflies at the paddy field ecosystem, Sidorejo, Central Bengkulu. *Jurnal Ilmiah Biologi Eksperimen Dan Keanekaragaman Hayati (J-BEKH)* 10(1): 69-74. (in English) ["The rice fields of Sidorejo Village have the potential for dragonfly diversity. This study aims to analyze fluctuations in the diversity and abundance of dragonflies in three ecosystem conditions of rice fields in Sidorejo Village, Bengkulu Tengah. Sampling using purposive sampling with the cruising method. Data analysis was carried out descriptively through the identification of characteristics to obtain the name of the species. After the species name was obtained, the relative abundance, Shannon Wiener diversity index, and species evenness index were calculated. The results of the study found that the harvest ecosystem had the highest diversity and abundance of dragonflies (13 species and 45

individuals). The species that were consistently found in three types of ecosystems were *Orthetrum sabina*, *O. testaceum*, and *Pantala flavescens*. The species with the highest relative abundance was *O. sabina* with 32%. The diversity index ranged from 1.32 (post-harvest) to 2.25 (harvest). The highest evenness index was in the post-harvest ecosystem at 0.95, and the lowest was in the harvest ecosystem at 0.87. The results of this study are expected to show that the diversity and abundance of dragonflies fluctuate depending on seasonal ecosystem conditions in the rice fields." **22040.** Karube, H., Kameda, Y., Kaga, R., & Fujita, E. (2023): Contamination status or neonicotinoid insecticides for the habitat of endangered Odonata in Japan. Tombo 66: 13-24. (in Japanese, with English summary) ["We studied the contamination status of neonicotinoid insecticides in the habitats or endangered Odonata from Hokkaido (northern Japan) to the Ryukyu Archipelago (southern Japan), as well as the population status. This survey shows that neonicotinoid insecticides were detected in almost all of the studied areas, although contamination concentration was not so high as that of preceding studies on the habitats of *Sympetrum maculatum* and *Libellula angelina*. The result also found that multiple pollutions by neonicotinoid insecticides were often detectable and that the pollution extends to good habitat and to areas not adjacent to agricultural land. The detection of these insecticides in habitats where surface soil inflow and underground water contamination are improbable suggests these pollutions occurred via evapotranspiration and snowfall from the foothills. These findings represent only a part of the pollution. Considering the risk of exposure to lethal contamination concentrations even once during the larval period, it is strongly desired from the perspective of conservation, that plural surveys in each season, research on the effects or insecticides and herbicides other than neonicotinoid, and the effects of these pesticides on larvae of the endangered species, be undertaken." (Authors)] Address: Karube, H., Kanagawa Prefect. Mus. Nat. Hist., 499 Iryuda, Odawara, Kanagawa, 250, Japan. E-mail: paruki@nh-kanagawa-museum.jp

**22041.** Kašák, J.; Holuša, O.; Mazalová, M. (2023): Artificial habitat – a chance for survival of a rare montane dragonfly (Odonata): case study on an alpine emerald (*Soma-tochlora alpestris*). Journal of Insect Conservation 27: 315-321. (in English) ["The mountain ecosystems of Central Europe are an important natural phenomenon. The character of small isolated islands also predetermines their vulnerability. Typical inhabitant of subalpine and alpine peat bogs, tiny montane habitats, is the endangered dragonfly *S. alpestris* a glacial relict surviving in restricted area of several mountain ranges within Central Europe. Species is threatened mainly by habitat loss and its transformation due to climate change, the expansion of tourist activities and plant succession. In our study from three mountain ranges in the Czech Republic, we bring the first ever evidence of successful development of *S. alpestris* in artificial habitats. Successful development of the species was recorded in peat pools created by the movement of heavy machinery on now almost abandoned forest roads. Some of the pools have been colonized in great numbers - up to tens of larvae of different instars, exuviae and imagoes have been found. Successful colonisation of the species was mainly due to: (i) proximity to source sites, (ii) suitable environmental parameters of the secondary habitat and (iii) the gradual abandonment of the paths' use, leading to a reduction in the frequency of disturbance." **22042.** Kirkpatrick Baird, F.; Spray, D.; Hall, J.; Stubbs Partridge, J. (2023): Projected increases in extreme drought frequency and duration by 2040 affect specialist habitats and species in Scotland. *Ecological Solutions and Evidence* 4(3) e12256: 12 pp. (in English) ["Climate-driven increases in drought occurrence are an overlooked risk in temperate climates, which may be less resilient to water scarcity than arid habitats. Scotland provides an example of a temperate oceanic climate in which drought risk is understudied, but could have substantial ecological impacts, particularly in combination with additional stressors. We modelled changes to risk of extreme drought occurrence in Scotland, and considered potential impacts of these changes on two key habitats, ombrotrophic (precipitation fed) wetlands and temperate rainforest. Using temperature and precipitation data from the UK Climate Projections 2018 and the drought index Standardized Precipitation-Evapotranspiration Index, we calculated and mapped likely changes in extreme drought for the near future (2021–2040) in comparison to a baseline (1981–2001). We found likelihood of extreme drought events increased from an average of one event every 20 years in the baseline period, to one event every 3 years by 2040. Typical events were projected to be up to 2–3 months longer, with an average of 11 extra drought months per decade. Increases were projected throughout the country, but the effect was most severe in the east, and during autumn. Ombrotrophic wetlands have some level of adaptive resilience to drought, but are considered at high risk as several key sites are in drought hotspot areas. In contrast, Scotland's temperate rainforest is located in lower risk areas, but is typically less drought resilient. Potential impacts on these habitats include reductions in ecosystem services including carbon capture, reduced breeding success for multiple taxa and increased competition among plant communities, which threatens drought-sensitive species. These projections suggest that climate-driven drought risk is a significant and imminent threat, even in wet climates. In Scotland, the results can direct mitigation and management actions to areas likely to be at greatest risk, as well as informing conservation interventions that can cope with drought. Additionally, other areas with a temperate oceanic climate may be at risk of extreme drought and could experience similar consequences. Therefore, these results have implications both for facilitating improved resilience to extreme drought in Scotland and for potentially overlooked impacts of drought in oceanic climates elsewhere." (Authors) "These impacts affect wetland-adapted animal species, for which substantial or prolonged changes in water availability could have serious implications for long-term population health. For example, the breeding success of waders ... can be reduced when surface water pools where chicks forage dry up (Burstons, 2006), and frequent drought periods have been linked to population declines or losses in great crested newts *Triturus cristatus* (Miró et al., 2017). Similarly, nationally scarce invertebrates, including Odonata such as *Aeshna caerulea* and *Leucorrhinia dubia*, rely on waterbodies for all life stages. Scottish Odonata larvae spend two or more years in water, so could suffer population crashes if pools dry for even one season (Hogreve & Suhling, 2022). Less-mobile and short-lived species especially can recover or recolonize from short-term losses, but may decline under frequent and severe drought episodes."] Address: Fairlie Kirkpatrick Baird: Email: fairlie.kirkpatrickbaird@gmail.com

**22045.** Lambret, P.; Jeanmougin, M.; Stoks, R. (2023): Factors driving larval abundance and adult size of the threatened *Lestes macrostigma* (Odonata): keys for water management and habitat restoration. *Journal of Insect Conservation* 27: 389-402. (in English) ["*L. macrostigma* is a damselfly of temporary brackish ponds, and is threatened in Europe. Better understanding its larval ecological requirements is imperative to inform conservation management measures and habitat restoration programs. We studied in a set of 33 temporary ponds the effect of 14 biotic and abiotic variables (including hydroperiod, pond surface area, water salinity, oviposition plant availability and predator relative abundance) on *L. macrostigma* larval abundance and adult size at emergence. Contrarily to our expectations, salinity level and oviposition plant availability did not drive the species larval abundance. Instead, the later the flooding date of the pond in autumn/winter the higher the larval abundance in the next spring. This effect seemed mediated by the aeshnid dragonfly larvae, as the size and relative abundance of these predators were lower in later flooded ponds. Larval abundance of *L. macrostigma* also increased with decreasing pond surface area. *Lestes macrostigma* adults tended to be bigger when they emerged from ponds with higher water levels, likely because deeper waters have lower water temperatures; this larger size may positively affect adult lifespan and fecundity. Our results contribute to explaining the species strong inter-annual variation in population abundance and further illustrate the threat of artificial early flooding of ponds for Mediterranean species. Implications for insect conservation: To improve *L. macrostigma* conservation actions, our results advocate to avoid temporary pond flooding before late autumn and to maintain high water levels until adults emerge in the next spring. Further, to increase habitat availability, our data indicate the importance of creating a network of small and deep temporary ponds." **22046.** Lee, S.H.; Park, J.S.; Pyo, J.-Y.; Kim, S.-S.; Kim, I. (2023): The complete mitochondrial genome of the blue-tailed damselfly *Ischnura elegans* (Odonata: Coenagrionidae) — a climate-sensitive indicator species in South Korea. *International Journal of Industrial Entomology* 46(2): 41-54. ["*I. elegans* is a climate-sensitive indicator species in South Korea. In this study, we sequenced the complete mitochondrial genome (mitogenome) of *I. elegans* collected from South Korea for subsequent population genetic analysis, particularly to trace population movements in response to climate change. The 15,963 base pair (bp)-long complete mitogenome of *I. elegans* has typical sets of genes including a major non-coding region (the A+T-rich region), and an arrangement identical to that observed in ancestral insect species.

The ATP6, ND3 and ND1 genes have the TTG start codon, which, although rare, is the canonical start codon for animal mitochondrial tRNA. The A/T content was 71.4% in protein-coding genes, 72.1% in tRNAs, 72.9% in the whole genome, 74.7% in srRNA, 75.3% in lrRNA, and 83.8% in the A+T-rich region. The A+T-rich region is unusually long (1,196 bp) and contains two subunits (192 bp and 176–165 bp), each of which is tandemly triplicated and surrounded by non-repeat sequences. Comparison of the sequence divergence among available mitogenomes of *I. elegans*, including the one from the current study, revealed ND2 as the most variable gene, followed by COII and COI, suggesting that ND2 should be targeted first in subsequent population-level studies. Phylogenetic reconstruction based on all available mitogenome sequences of Coenagrionidae showed a strong sister relationship between *I. elegans* and *I. senegalensis*.] Address: Kim, I., Dept of Applied Biology, College of Agriculture & Life Sciences, Chonnam National Univ., Gwangju 61186, Republic of Korea. **22047.** Lieckweg, A.; Hesse, V.; Mau-Hansen, C.; Lüers, E. (2023): Recherche der historischen Verbreitung von *Coenagrion scitulum* in Nordwestdeutschland (Odonata: Coenagrionidae). *Libellula* 41(3/4): 179-202. (in German, with English summary) ["Research of the historical distribution of *Coenagrion scitulum* in northwestern Germany (Odonata: Coenagrionidae) – Historical reports of *C. scitulum* for northwestern Germany have been reviewed several times over the last few decades. Some of these could be discarded due to the respective research or at least assessed as implausible. In some cases, no intensive research had been done or the whereabouts of the collection specimens were unknown, e.g. in the case of a finding of "*Agrion scitulum*" near Hanover (Schumann Specimen) that was corrected again shortly after its publication, and supposed specimens of "*Agrion scitulum*" from Lower Saxony (Genz Specimen) and northern North Rhine-Westphalia (Kiebitz Specimen). These collection specimens were searched for in various museums in Lower Saxony, Bremen, Hamburg, and North Rhine-Westphalia. The Schumann Specimen is located in the Zoological Museum Hamburg. It was indeed not a male of *C. scitulum*, but of *Coenagrion hastulatum*. The Genz Collection is located in the Übersee-Museum Bremen. Three specimens to be examined were females of *C. pulchellum* and not of *C. scitulum*. Regarding the report of the finding for northern North Rhine-Westphalia (Kiebitz Specimen), no specimen could be found despite extensive research. Therefore, a comparative photo analysis was carried out here. This showed that the Kiebitz Specimen was most likely not a male of *C. scitulum*, but a male of *C. pulchellum*. No historical finds of the species for northwestern Germany could be confirmed or newly detected. Based on the knowledge gained, a reassessment of the historical area extents of *C. scitulum* is carried out." (Authors)] Address: Lieckweg, Ariane, Artillerieweg 9, 26129 Oldenburg, Germany. **22048.** Lishawa, S.C.; Schrank, A.J.; Lawrence, B.A.; Monks, A.M.; Albert, D.A. (2023): Aquatic connectivity treatments increase fish and macroinvertebrate use of *Typha*-invaded Great Lakes coastal wetlands. *Freshwater Biology* 68(8): 1462-1477. (in English) ["1. Coastal wetlands provide critical habitat for aquatic organisms and important ecosystem services for the terrestrial and aquatic landscapes that they bridge, but increasingly common invasive macrophytes disrupt plant communities, food webs, habitat structure and littoral–pelagic linkages. In Laurentian Great Lakes coastal wetlands, invasive cattails (*Typha × glauca* and *T. angustifolia*, hereafter *Typha*) homogenise ecosystem structure and

reduce nearshore dissolved oxygen, and plant, fish and macroinvertebrate diversity. We hypothesised that management treatments which reduce *Typha* and its abundant litter promote structural heterogeneity and mitigate physicochemical and biodiversity impacts. 2. To test this hypothesis, we implemented a large-scale (2,048 m<sup>2</sup> treatment units), multi-site (four coastal wetlands) experiment in northern Michigan (USA.) to examine how invasive *Typha* mechanical harvesting treatments (biomass harvest, aquatic connectivity channels, *Typha*-dominated control) altered fish, macroinvertebrate, plant, larval amphibian abundance and diversity, and water quality for 2-year post-treatment. 3. Both harvest and channel treatments reduced *Typha* biomass, cover and dominance; harvest increased multi-taxa species richness, fish diversity and abundance; and channels altered plant, fish, and macroinvertebrate community structures. Dissolved oxygen was greater and litter was reduced by both treatments, indicating likely mechanisms for shifts in fish and macroinvertebrate use. 4. Our results suggest that harvesting invasive macrophytes can ameliorate biodiversity impacts and improve habitat quality, and that adding aquatic connectivity channels can increase community complexity. 5. *Typha* management that incorporates both harvesting and aquatic connectivity channels appears to provide the greatest benefit to several taxonomic groups, likely by reducing *Typha* and its litter, increasing dissolved oxygen availability, and increasing the connection between open water and wetland interiors. Increasing habitat complexity and aquatic connectivity of invaded wetlands can promote biodiversity and provides a more realistic management goal than the complete elimination of invasive macrophytes." (Authors) Lestidae were similar in abundance in control and harvest treatments, but never found in channels.] Address: Lishawa, Shane C., School of Environmental Sustainability, Loyola Univ. **22053.** Mataba, G.R. (2023): Exploring integrated strategies to control oviposition and larval development in mosquitoes in northern Tanzania. PhD thesis, Faculty of: Sciences and Bioengineering, Vrije Universiteit Brussel: VIII + 216 pp. (in English) ["Besides services, ecosystems can also provide disservices. A significant disservice is the

emergence of mosquitoes from freshwater habitats. These mosquitoes transmit diseases which claim millions of lives every year worldwide. The problem is exacerbated by the absence of vaccines or effective cures for many mosquito borne diseases, making effective control of mosquito populations the only reliable method to control these diseases. The widespread development of mosquito resistance against widely used insecticides hinders successful control of mosquito borne diseases using chemicals. This resistance in combination with the environmental hazards of pesticides point out the need for alternative, more effective and ecologically friendly means of mosquito control. Biological control of mosquitoes could therefore become an appropriate complementary method. In this thesis, we investigated different strategies of biological control of mosquito populations by means of reducing oviposition and larvae development. Using field surveys, we investigated which factors limit population of mosquito larvae in aquatic habitats including temporary ponds, artificial habitats (e.g., discarded tires, flowerpots) and small ground pools (e.g., hoofprints, puddles, and small pools). In a next step, we used field mesocosms to investigate whether aquatic predators could control mosquito populations by deterring oviposition. Lastly, we investigated whether pesticides (e.g., *Bacillus thuringiensis* var *israelensis* - Bti) could control mosquito populations by mechanisms other than lethal effects, such as deterring or attracting oviposition. We found that in our study region (Lake Manyara Basin, Tanzania), populations of larval mosquitoes in aquatic habitats are controlled by different factors. In temporary ponds, populations of mosquito larvae are controlled by aquatic predators, while in small ground habitats their abundance is determined by the level of turbidity and proximity of habitat to houses. In artificial habitats, populations of mosquitoes (i.e., larvae) are mainly determined by covering, emptying, and refilling of water storage vessels by residents. In addition, we found evidence that presence of predators in a breeding habitat deters mosquito oviposition. Lastly, we found that the pesticide Bti was effective in controlling larvae abundance by killing them but not by altering mosquito oviposition and there was no change in the pond invertebrate community structure. We conclude that in our study region, it is important to have an integrated mosquito control approach which prioritizes controlling mosquito larvae of small ground habitats with environmentally friendly larvicides and conservation of mosquito predators in temporary ponds. Also, proper management of water storage containers and discarded artefacts is emphasized in this region. ... The thesis includes the following chapter: Interactive effects of dragonfly larvae and the biocide *Bacillus thuringiensis* var. *israelensis* on mosquito oviposition and survival in temporary pond communities: a field test in the Afrotropics. Worldwide, a variety of larvicides are used to control reproduction of mosquitoes in freshwater habitats. However, their broader impact on the ecosystem including non-target species is often unclear. In addition, it is unknown how larvicides may interact with local mosquito predators to shape oviposition site selection of mosquitoes. We used an outdoor mesocosm experiment to investigate the effects of realistic concentrations of the bio-larvicide *Bacillus thuringiensis* var *israelensis* (Bti) on *Culex* oviposition, larval density, survivorship and on densities of non-target species. We also manipulated the complexity of the community by manipulating the presence of dragonfly larvae as a predator. *Culex* oviposition was unaffected by Bti but the larvicide effectively reduced larval density and survivorship in all treatments. Bti did not affect non-target insects but stimulated phytoplankton density. The presence of dragonfly larvae in mesocosms did not reduce *Culex* oviposition or larval sensitivity to Bti. We conclude that Bti may effectively reduce the density and survivorship of *Culex*

quinquefasciatus mosquitoes in this part of East Africa, but possibly at the cost of higher phytoplankton densities. Bti treated mesocosms were not more or less attractive for mosquitoes suggesting that its application would not alter their oviposition behaviour in the field." **22056.** Miralles Núñez, A.; Zaldívar, C.; Prunier, F.; Cabana, M.; Torralba Burrial, A.; Luque, P.; de Vega, L.; Cordero Rivera, A. (2023): An updated and agreed-upon proposal for the common names of dragonflies and damselflies in Spanish. *Asociación española de Entomología, Sociedade Portuguesa de Entomologia, Congreso Ibérico de Entomología* (20<sup>o</sup>. 2023. Alicante): 144. (in English) ["Odonata (dragonflies) is one of the most attractive Order of insects for nature enthusiasts, photographers, and wildlife observers. It is worth noting that unlike all other European countries, there is not yet a widely accepted list of common names in Spanish for dragonfly species present in Spain. Among international organizations, IUCN has asked for such names in Spanish. In recent years, some citizen science publications and web portals have incorporated the use of common names for dragonflies, albeit with a lack of standardization. In 2015, a reasoned proposal was presented at the Iberian Symposium of Odonatology held in Córdoba, but it did not include species found exclusively in the Canary Islands. Although this first proposal generated an enriching debate, it also had some reservations. In 2021, at the III Iberian Symposium of Odonatology held in Irún, another proposal was presented in order to stimulate the need for agreement on Spanish dragonflies common names. In the following weeks, the Grupo Ibérico de Odonatología called for participation and created a working group with the goal of creating such a consensus list. This working group is currently reviewing the 2015 and 2021 proposals, considering the existing names in Catalan (2016) and Galician (2012). As a result, a consensus list has been elaborated for the 82 Ibero-balear

species, plus 4 species exclusive to the Canaries within Spain." (Authors)] Address: Miralles Núñez, Adrià, Grup d'Estudi deis Odonats de Catalunya (Oxygastra-GEOC), Institució Catalana d'Història Natural, Barcelona, Spain

**22057.** Mobasher, A.; Bayrami, A.; Asadi-Sharif, E.; Pouran, S.R. (2023): Ecological indicators for qualitative assessment of Ojarud River: A case study. *Ecology and Evolution* 13(7), e10310: 13 pp. (in English) ["Today, the application of ecological indicators based on organisms has replaced traditional saprobic approaches for assessment of the quality of rivers impaired due to organic pollution and some other environmental disturbances. This study aimed to weigh the quality of the Ojarud River in Ardabil, Iran, applying biological and physiological indices of macro-invertebrates. A total of 12,524 samplings were fulfilled at four stations (S1, S2, S3, S4) from the headstream to downstream by a Surber sampler (30 × 30 cm<sup>2</sup>) from June/2020 to April/2021. All year round, the highest frequent families were Chironomidae (2658), Simuliidae (1025) from Diptera and Caenidae (1855), and Baetidae (724) from Ephemeroptera. The diversity pattern was analyzed by PAST software, and Primer 7 (BIO-ENV analysis) was utilized to understand what factor has the most impact on the distribution of macro-invertebrates. The least similarity of S4 to other stations was recognized by Cluster analysis. As per the ANOSIM (analysis of similarities), a statistically significant difference in the macro-invertebrates' frequency was established between S3 and other stations ( $p = .0001$ ,  $r = .63$ ). Moreover, the relationship between heavy metals and macro-invertebrate showed that the three families of Simuliidae, Gomphidae, and Caenidae had a positive correlation with the concentrations of heavy metals in the sediment. As per the Ephemeroptera, Plecoptera and Trichoptera index, the water quality was placed in the "excellent" class, but the Biological Monitoring Working Party and Hilsenhoff Family Biotic Index indices scored the water quality "good" class at S1 and the "poor" class at S3. Based on the results of this study, the use of physicochemical and hydro-morphological indicators can support the biological indicators but cannot replace them. In addition, careful evaluation of biological indicators is required to develop conservation strategies." **22058.** Mulhair, P.O.; Holland, P.W.H. (2023): Evolution of the insect Hox gene cluster: Comparative analysis across 243 species. *Seminars in Cell & Developmental Biology*: 12 pp. (in English) ["The Hox gene cluster is an iconic example of evolutionary conservation between divergent animal lineages, providing evidence for ancient similarities in the genetic control of embryonic development. However, there are differences between taxa in gene order, gene number and genomic organisation implying conservation is not absolute. There are also examples of radical functional change of Hox genes; for example, the *ftz*, *zen* and *bcd* genes in insects play roles in segmentation, extraembryonic membrane formation and body polarity, rather than specification of anteroposterior position. There have been detailed descriptions of Hox genes and Hox gene clusters in several insect species, including important model systems, but a large-scale overview has been lacking. Here we extend these studies using the publicly-available complete genome sequences of 243 insect species from 13 orders. We show that the insect Hox cluster is characterised by large intergenic distances, consistently extreme in Odonata, Orthoptera, Hemiptera and Trichoptera, and always larger between the 'posterior' Hox genes. We find duplications of *ftz* and *zen* in

many species and multiple independent cluster breaks, although certain modules of neighbouring genes are rarely broken apart suggesting some organisational constraints. As more high-quality genomes are obtained, a challenge will be to relate structural genomic changes to phenotypic change across insect phylogeny." (Authors) *Ischnura elegans*, *Platycnemis pennipes*, *Pantala flavescens*] Address: Mulhair, P.O., Dept Biol., Univ. Oxford, 11a Mansfield Road, Oxford OX1 3SZ, UK. **22060.** Naraoka, H. (2023): Opening angle of the right and left wings while at rest in nine damselfly species (Odonata: Zygoptera). Tombo 66: 34-40. (in Japanese, with English summary) ["The opening angle of the right and left wings at rest for nine Zygopteran species was investigated in Hokkaido and Aomori-pref. in 2019-2022. Four species of the genus *Coenagrion* rested with almost an open-winged posture (> 4°) i.e., more than 93 % in *C. lanceolatum*, 83 % in *C. terue*, 67 % in *C. ecomutum*, and 87 % in *C. hylas*. The wing angle of these four species was larger in the morning and evening, and was smaller during the day. A statistically significant negative correlation was recognized between the wing open angle and air temperature in the former three species. On the other hand, *Paracercion calamorum*, *P. plagiosum*, *Enallagma circulatum* and *Pseudocopteryx annulata* folded their wings together above the body from 70 to 97 % throughout the day. Conversely, almost 90 % of *Lestes sponsa* was opening more than 100° throughout the day." (Author)] Address: Naraoka, H., 36-71, Aza-Motoizumi, Fukunoda, Itayanagi-cho, Kita-gun, Aomori Prefecture, 038-3661, Japan. Email: naraoka62@outlook.jp

**22061.** Nel, A.; Jouault, C.; Ribeiro, G.C. (2023): The third aeschniid dragonfly genus and species from the Lower Cretaceous Crato Formation (Odonata, Anisoptera). *Historical Biology* 35(6): 865-869. (in English) ["*Cratoaeschnidium martinsnetoi* gen. et sp. nov., third genus and species of the family Aeschniidae from the Crato Formation (Brazil), is described and illustrated based on one well-preserved forewing. It can be differentiated from the other genera in the family, inter alia, because its discoidal triangle is very narrow with only one row of cells; three rows of cells between M<sub>sp</sub> and MA<sub>a</sub>, and between R<sub>sp</sub> and IR<sub>2</sub>; one row of cells between CuA<sub>a</sub> and MP in basal part; three rows of cells between RP<sub>3/4</sub> and MA<sub>a</sub>. This new genus and species confirms that much can be expected in regard to discovering the Odonata in the Crato Formation." (Authors)] Address: Nel, A., Lab. Ent. Mus. Natn. Hist. **22064.** Okude, G.; Futahashi, R. (2023): Morphological changes during the final nymphal instar and the genes essential for metamorphosis in dragonflies and damselflies. Tombo 66: 1-12. (in Japanese, with English summary) ["Odonata insects, which belong to the most-ancestral group of winged insects, are key organisms for understanding the evolution of insect metamorphosis. However, the morphological changes that occur via metamorphosis during the final nymphal instar have not been well described, and the molecular mechanisms underlying nymph-to-adult metamorphosis of Odonata have been totally unknown until recently. In this review, we summarize the visually recognizable morphogenetic events in the final nymphal instar and the genes essential for metamorphosis in Odonata based on our recent reports." (Authors)] Address: Futahashi, R., National Inst. Advanced Industrial Science and Technology (AIST), Central 6, Tsukuba, Ibaraki 305-8566 Japan. E-mail: ryo-futahashi@aist.go.jp

**22065.** Okuyama, H.; Kivoshi, T.; Isubaki, Y.; Takahashi, J. (2023): The complete mitochondrial genome and ITS region or nuclear genome sequences of *Libellula angelina* Selys, 1883 from Kirarahama Prefectural Nature Observation Park in Yamaguchi Prefecture, Japan. Tombo 66: 48-55. (in Japanese, with English summary) ["*L. angelina* is classified as Critically Endangered in the Japanese Red List and designated as Endangered Species of Wild Fauna and Flora by Act on Conservation of Endangered Species of Wild Fauna and Flora. In this study, we analyzed the complete mitochondrial genome and ITS regions of the nuclear genome of *L. angelina* from Kirarahama Prefectural Nature Observation Park in Yamaguchi Prefecture, Japan using next generation sequencing. The mitochondrial genome of *L. angelina* consists of a circular molecule of 15,232 bp that includes 37 genes. The ITS1 region is 228 bp and ITS2 region is 312 bp. From a comparison between the complete mitochondrial genome sequence of *L. angelina* from Yamaguchi, Japan and South Korea (MG 189907), 72 gene mutation sites were confirmed. We performed phylogenetic analyses for COI partial gene region, 1-rRNA partial gene region, COI - tRNA-Leu2 - COII region and ITS region. As a result of the phylogenetic analyses, COI partial gene region, 1-rRNA partial gene region and COI - tRNA-Leu2 - COII region of *L. angelina* were found to have some genetic diversities among individuals, but *L. angelina* from Japan did not divide regional clades. On the other hand, the ITS region of *L. angelina* had no genetic mutation among 10 individuals

in 5 regions used in the analysis. And the genetic diversity of *L. angelina* in Yamaguchi Prefecture could be at a low level." (Authors)] Address: Okuyama, H., Faculty of Life Sciences, Kyoto Sangyo Univ., Kamigamo, Motoyama, Kita-ku, Kyoto, Japan. E-mail: k5533@cc.kyoto-su.ac.jp

**22066.** Payra, A.; Tiple, A.D.; Koparde, P. (2023): First descriptions of the females of *Cyclogomphus heterostylus* Selys, 1854 and *Ictinogomphus distinctus* Ram, 1985 from India, with comments on the status of *Cyclogomphus wilkinsi* Fraser, 1926 (Odonata: Gomphidae). *Zootaxa* 5319(3): 421-428. (in English) ["The present paper deals with the first descriptions of the females of two endemic Gomphid dragonflies of India, namely *Cyclogomphus heterostylus* Selys, 1854 and *Ictinogomphus distinctus* Ram, 1985, based on the specimens collected from Maharashtra, India. Additionally present status of *Cyclogomphus wilkinsi* Fraser, 1926 in India is also discussed." **22068.** Pétremand, G.; Cosandey, V.; Freitag, A.; Reymond, A.; Walter, F.; Breitenmoser, S. (2023): L'entomofaune de la réserve naturelle Pro Natura «Au Chevry» (Trélex, Vaud). *Entomo Helvetica* 16: 145-172. (in French, with English and German summaries) ["The entomofauna in the nature reserve Pro Natura «Au Chevry». - The Pro Natura nature reserve «Au Chevry» (Trélex, VD) includes a large part of a rich fen of regional importance. In 2022, several days were organised by the «Société vaudoise d'entomologie» to inventory the insect fauna present in this reserve. Most of the surveys were carried out by active search and focused mainly on saproxylic and aquatic beetles, hoverflies, ants, dragonflies, damselflies, crickets and grasshoppers. A total of 318 species belonging to 71 families and 9 orders (insects and spiders) were identified. Many species are endangered or of regional, national or even European interest. Their occurrence testifies to the exceptional natural values of the rich fen and its associated areas (ash woodland, oak woodland, seepages, dry meadows). These surveys lead to a series of recommendations for the future management of the protected area, including a proposal to extend its perimeter." (Authors) "13 species of Odonata have been identified in the reserve or on its border. Among them, only *Ceragion tenellum* appears on the Swiss red list and is considered endangered there (Monnerat et al. 2021, Tab. 1). This species is very localized in Switzerland and is generally closely associated with low marshes. Only one individual having been observed, it would however be necessary to confirm the presence of a true population of this species on the site. Other species include *Orthetrum coerulescens*, an uncommon species of

regional interest in the canton of Vaud, observed together with *Orthetrum brunneum* in the reserve. *O. coerulescens* is particularly fond of seeps in acid low marshes and peat rivulets poor in vegetation. The latter and *Cordulegaster boltonii* were observed along the seep bordering the northeast area of the reserve, suggesting that these species may be colonizing this flow area. The rest of the faunal procession is made up of ubiquitous species or species with low ecological requirements (stagnant water, ditches, ponds) but fond of sunny sites." (Authors/Google translate)] Address: Pétremand, Gaël, Corcelettes 15, 1422 Grandson, Switzerland. Email: gael.petremand@arvensis-naturalistes.ch

**22071.** Rakotomalala, A.A.N.A. (2023): Review: Klaas-Douwe B. Dijkstra and Callan Cohen: Dragonflies and damselflies of Madagascar and the Western Indian Ocean Islands, Univ. of Chicago Press, Chicago, IL, USA, 2021, 194 pp, US\$ 45.00 (Hardcover), ISBN: 9782957099726. *Community Ecology* 24: 301. (in English) [Verbatim: After almost two decades of research, odonatologist Klaas-Douwe B. Dijkstra and biologist Callan Cohen finally published the first Odonata guidebook of the Malagasy archipelago. This region hosts 227 Odonata species, of which 80% are endemic. Structured in two parts, this book is an excellent primer for this insect group. The first part (circa 41 pp.) covers the biology and ecology of Odonata, provides a guideline for the collection, handling, and preservation of specimens, and introduces their morphology, which is essential for their identification. The second part (137 pp.) consists of an illustrated description of each species, followed by an updated checklist and information about their geographical distribution and conservation status. I particularly liked the identification part; I tried to identify Odonata from photos I took in Madagascar, and I can confirm that it is possible. The species photographs in the book are good enough and clear. However, I noticed that most of them wasted some space on the sides. Filling this space with a distribution map could have been more informative and practical. In addition, color coding according to the family names on the page header would have allowed navigating quickly through the book. Despite these few inconveniences, this book is suitable for amateur entomologists who are patient enough to get familiar with the scientific terms illustrated and well-defined in a glossary. In particular, I would recommend it to anyone who lives in the Malagasy

region or will visit this biodiversity hotspot for entomological research or tourism and to whoever has a particular interest in Odonata.] Address: Rakotomalala, A.A.N.A., Functional Agrobiodiversity, Georg-August-Univ. Göttingen, Grisebachstr. 6, 37077 Göttingen, Germany. Email: andrynyaina001@gmail.com

**22072.** Rani, A.A.; Mishra, A.; Jayashankar, M. (2023): Documenting Odonata along the Sri Krishna Lake, Bengaluru, Karnataka. *Insect Environment* 26(2): 142-145. (in English) ["A total of eleven species of Anisoptera belonging to three different families viz., Libellulidae, Aeshnidae and Gomphidae were observed in which 81.81% observed species belonged to Libellulidae, *Brachythemis contaminata* and *Crocothemis servilia* were found to be abundant and maximum activities were observed during the midday. Simpson's Index (D) (0.2), Simpson's index of diversity (1-D) (0.7), Shannon-H (1.8) and Evenness Index (0.6) indicated good diversity and necessity to continue seasonal observations." **22073.** Ranjan, K.S.; Pawar, A.A.; Roy, A.; Saha, S. (2023): Transoceanic migration network of dragonfly *Pantala flavescens*: origin, dispersal and timing. *Frontiers in Ecology and Evolution* 11:1152384. doi: 10.3389/fevo.2023.1152384: 12 pp. (in English) ["The awe-inspiring multi-generational, transoceanic migration circuit of *P. flavescens* stretches from India to Africa. Understanding the collective role of wind, precipitation, fuel, breeding, and life cycle driving the migration remains elusive. We identify the transoceanic migration route from years 2002 to 2007 by imposing an energetics-based time-constraint on a modified Dijkstra's path-planning algorithm incorporating active wind compensation. The prevailing winds play a pivotal role; the Somali Jet enables migration across the Indian Ocean from Africa to India, whereas the return requires stopovers at the disappearing islands of Maldives and Seychelles. The migration timing, identified using monthly-successful trajectories, life cycle, and precipitation data, corroborates sightings. A branched-network hypothesis connects our sighting in Cherrapunji (North-East India), the likely origin, to the known migration circuit." (Authors)] Address: Saha, S., Indian Inst. Technology Kharagpur, Kharagpur, 721302, West Bengal, India

**22074.** Sadasivan, K.; Nair, V.P.; Samuel, K.A. (2023): A review of *Macromia Rambur*, 1842 (Odonata, Macromiidae) of Western Ghats, with taxonomic notes on *Macromia minuta* Fraser, 1924 and *M. irata* Fraser, 1924. *Entomonia* 48(2): 253-286. (in English) ["A review of the genus *Macromia* Rambur, 1842 (Odonata, Macromiidae) of Western Ghats of Peninsular India is presented with its updated distribution. An attempt is made to collate the scattered data in peer-reviewed literature published to date and is supplemented with field data gathered by the authors over two decades. Although *Macromia* is represented by nine species including six endemics in the Western Ghats, not much has been published on them from the region. *Macromia irata* Fraser, 1924 was described from Coorg but was rarely reported in peer-reviewed literature since its very brief original description by Fraser in 1924. The detailed morphology including that of the genitalia of *M. irata* is discussed. A revised classification based on the species groups and a key to the species of *Macromia* of the Western Ghats of Peninsular India is provided. To quantify the ratios of the number of the prenodal and postnodal veins in Odonata, a new nodal range expression called Standardised Species Nodal Range (SSNR)

and a new index termed Standardised Species Nodal Index (SSNI) is also proposed." (Authors) The study includes the following species: *Macromia annaimallaiensis* Fraser, 1931, *Macromia bellicosa* Fraser, 1924, *Macromia cingulata* Rambur, 1842, *Macromia ellisoni* Fraser, 1924, *Macromia flavicincta* Selys, 1874, *Macromia flavocolorata* Fraser, 1922, *Macromia ida* Fraser, 1924, *Macromia indica* Fraser, 1924, *Macromia irata* Fraser, 1924] Address: Sadasivan, K., Greeshmam, BN 439, Bapuji Nagar, Thiruvananthapuram 695011, Kerala, India. **22076.** Sasamoto, A. (2023): [Annual Meeting of the Dragonfly Society of Japan 2022]. *Tombo* 65: 86. (in Japanese) [The 2022 Annual Meeting of the Dragonfly Society of Japan was held on November 26th and 27th of the same year at the Okazaki Campus of the Univ. of Human Environment in Okazaki City, Aichi Prefecture, under the direction of Executive Committee Chairman Takano Matsuzawa. It was held with the efforts of people. It was the first time since 2019 that it was held locally, and I was able to meet the members for the first time in a long time. In addition, for those who are unable to attend onsite, the general meeting, research presentations, and public symposium will be delivered remotely, making it the first hybrid format. Unfortunately, the social gathering was canceled as the new coronavirus was not over yet, but we were able to have a good time interacting with each other as thorough measures were taken at the venue. The program was the same as before, with board meetings and general meetings on the first day, and research presentations (8 oral presentations and 4 poster presentations) on the second day. In the afternoon of the second day, a public symposium titled "Deep digging for dragonflies in Aichi!" Interesting presentations were made on natural history, etc., and in addition, many excellent images of dragonfly filmed mainly in the Tokai region were held in a format that could be listened to by non-members. Finally, a bouquet of flowers was presented to Mr. Yasuro Takasaki in hopes of his many years of achievement and future success. I would like to express my deep gratitude to all the members of the executive committee for their efforts in making this first local event a success. **22079.** Sharma, N.; Singh, D.; Sharma, S.; Ansari, A. (2023): A preliminary assessment of Odonata (dragonflies & damselflies) across an elevation gradient – insights from Shiwaliks to Alpines, northwestern Himalaya, India. *Journal of Threatened Taxa* 15(7): 23545-23556. (in English, with Dogri summary) ["Understanding the species distribution and richness along an environmental gradient helps identify hotspots and prioritize conservation efforts at landscape scale. This is more effective for the species that are indicators of environmental change, such as odonates. As the information about the distribution of this group of insects is scarce in Jammu & Kashmir, their documentation assumes a greater significance. Here, we present a checklist of odonate species from 23 sites across diverse landscapes in subtropical, temperate, and alpine ecosystems over an elevational gradient of 3,700 m in Jammu division. We recorded 63 species from 39 genera and 11 families, four Anisoptera and seven Zygoptera. The most represented families were Libellulidae (15 genera & 29 species) and Coenagrionidae (five genera & 10 species). The preliminary surveys resulted in addition of 24 new species to the Odonata fauna of Jammu & Kashmir, including three new to the northwestern Himalaya. The study underlines that even opportunistic records are useful in understanding the distribution range and delineating the potential habitats of odonates. The study calls for intensive odonate surveys to better understand their distribution and ecology in hitherto less explored region in the northwestern Himalaya." (Authors)] Address: Sharma, N., Inst. Mountain Environment, Univ. Jammu, Bhaderwah Campus, Bhaderwah, UT of Jammu & Kashmir 182222, India. Email: nirazsharma@gmail.com

**22080.** Shin, I.-C.; Lee, S.-H.; Lee, Y.-M.; Yoon, J.-Y.; Hong, S.-J.; Yoon, H.-J.; Park, S.-G.; Han, E.-J. (2023): Distribution characteristics of macroinvertebrates in an agricultural paddy field and irrigation pond ecosystems in a farmer's practice manual on the village of the Agricultural Environment Conservation Program. *Korean J. Environ. Biol.* 40(2): 148-156. (in Korean, with English summary) ["Ecological occupation in irrigation ponds is a well-acknowledged fact that is essential for biodiversity conservation in agricultural ecosystems. However, there are few studies on the ecological functions and relationship between a paddy field and irrigation using macroinvertebrates in an environmentally friendly paddy field. The objective of this study is to identify the community and distribution characteristics of macroinvertebrates in an agricultural paddy field and irrigation pond ecosystems, and to provide basic data on the ecological function of an environmentally friendly paddy field. Macroinvertebrate sampling was conducted from May to September in an agricultural paddy field and irrigation pond in an environment-friendly paddy field in Boryeong city. We conducted a study to identify the

distribution characteristics using macroinvertebrate species analysis, such as Functional Feeding Groups (FFGs), Habitat Oriented Groups (HOGs), rarefaction curve, and a two-way dendrogram. A total of 37 species of macroinvertebrates in 28 families, 13 orders were collected study during the period of the investigation. Dominant taxa of macroinvertebrates included Coleoptera, Hemiptera, and Odonata [*Ichnura asiatica*, *Anax parthenope*, *Crocothemis servilia*, *Orthetrum albistylum*]. In terms of FFGs, predators and gathering collectors accounted for approximately 70%, in relation to HOGs, and climbers and swimmers occupied more than 50% from both the paddy field and irrigation pond. With respect to the rarefaction curve, the irrigation pond (July) was high as E (S, 141) = 18 species, while the paddy field (May) was comparatively low as E (S, 141) = 9 species. In conclusion, our results revealed that macroinvertebrates, such as *Notonecta triguttata*, *Peltodytes intermedius*, *Appasus major*, *Laccotrepes japonensis*, *Appasus japonicus*, *Sigara substriata*, *Enochrus simulans*, and *Stemolophus rufipes*, were used as a habitat and spawning ground in both paddy field and irrigation pond. The irrigation pond appears to be a very important spawning ground for macroinvertebrates." (Authors)] Address: Han, E.-J., National Acad. Agricultural Science, RDA, Wanju 55365, Republic of Korea. **22082.** Shrestha, P.; Rai, A.; Wagle, P.C.; Ghimire, S. (2023): Evaluation of disturbance zonation of Bagmati River system using benthic macroinvertebrates in the Kathmandu Valley, Nepal. *Journal of Institute of Science and Technology* 28(1): 79-89. (in English) ["The existence of Nepal's holy river, Bagmati, which flows through the core of Kathmandu Valley has been menaced by many anthropogenic threats. It is necessary to identify how vulnerable it has been. This research focuses on the evaluation of disturbance zonation to analyze the Bagmati River System's spatial biological health. Benthic macroinvertebrates (BMIs) were used as biological indicators and were sampled from upstream to downstream using a multi-habitat sampling approach during the post-monsoon period in 2021. The Ganga River System Biotic Score/Average Score per Taxa (GRSBIOS/ASPT) was used to assess river water quality. From the sampling of 21 sites, a total of 5839 individual BMIs from 51 Families and 11 Orders were recorded. Upstream accounted for more than 30% of all the families, making upstream rich in taxonomic preferences, which steadily decreased from midstream to downstream. Facultative taxa were widely distributed in both upstream and midstream, but sensitive taxa were limited to upstream only. There are no signs that facultative and sensitive taxa existed downstream and were fully dominated by pollution-tolerant

species. According to classification, the upstream river within Shivapuri Nagarjun National Park of the Bagmati River System was clean and was categorized as Class I, whereas rivers from the boundaries of the protected area to downstream were categorized as Class IV-V with few sites as Class II and Class III, indicating that this stretch of the river was extremely polluted. Water resource managers should utilize the study's findings to assess and restore the water's quality using biological indicators." (Authors) The paper includes references to "Odonata". **22084.** Simonsen, T.J.; Djernæs, M.; Nielsen, O.F.; Olsen, K. (2023): COI diversity supports subspecific division in Western European *Lestes virens* (Charpentier, 1825) (Zygoptera: Lestidae), but hints at further Mediterranean complexity. International Journal of Odonatology 26: 18-26. (in English) ["We analyse COI sequences of 48 specimens of European *L. virens* to explore patterns in genetic diversity including subspecific boundaries and potential glacial refugia. Our haplotype network and phylogenetic analyses reveal three distinct groups in Western and Northern Europe. One group corresponding to the nominate subspecies *L. virens virens* is confined to the Iberian Peninsula and southwestern France, and one group corresponding to the subspecies *L. virens vestalis* is found in the rest of western Europe including southern Scandinavia, mainland Italy and the Mediterranean island Sardinia. Surprisingly three specimens from the Mediterranean island Sicily form a highly distinct group in all our analyses. An analysis of molecular variance (AMOVA) confirms that almost all observed genetic variance is explained by variation between these three groups rather than by variation between sample areas or between individuals. We conclude that the subspecific division into *L. virens virens* and *L. virens vestalis* is justified, but further studies are needed to determine the status of the populations in Sicily, southeastern Europe, and North Africa. The genetic pattern we find may reflect different glacial refugia: an Iberian/North African refugium for *L. virens virens*; a potential Italian refugium for *L. virens vestalis*; and a Sicilian/North African refugium for the Sicilian populations." **22085.** Somal, D.S.; Walia, G.K. (2023): Cytological study of family Aeshnidae (Odonata: Anisoptera) from India: A review. Biosciences Biotechnology Research Asia 19(4): 843-855. (in English) ["Cytological review of 59 aeshnid species and cytogenetic investigations on *Anax ephippiger*, *Anax immaculifrons*, *Anax indicus*, *Anax nigrofasciatus nigrolineatus*, *Anax parthenope*, *Gynacantha subinterrupta* of the family Aeshnidae by carbol fuchsin staining and C - banding have been undertaken. All the species possess  $2n = 27m$  with X0 - XX sex determination except *Anax ephippiger* with

$2n = 14 + \text{neo XY}$ , resulted by the 13 simultaneous fusions among the autosomes and between autosome and sex chromosome. The structure and behaviour of chromosomes, variation in size of m chromosomes and X chromosome and distribution of C - heterochromatin have been studied and compared among the species. C - bands are mostly present at the terminal regions of autosomal bivalents, while *Anax ephippiger* and *A. parthenope* also possess C - bands at the interstitial and sub-terminal regions of the bivalents. Moreover, sex chromosome and m bivalent show variation in distribution of C-heterochromatin in the species. Out of these, chromosome complement of *A. indicus* Lieftinck, 1942 and C - banding on *A. ephippiger* and *A. indicus* have been investigated for the first time. List of cytologically studied species of family Aeshnidae has been updated to 60 species." **22088.** Tarris-Samaniego, S.; Muzón, J.; Iglesias, M.S. (2023): When size and shape matter: morphometric characterization of two sympatric dragonflies of the genus *Perithemis* Hagen 1861 (Odonata: Libellulidae). Anais da Academia Brasileira de Ciências 95 (suppl 1): 10 pp. (in English) ["*Perithemis mooma*, Kirby, 1889 and *Perithemis icteroptera* (Selys in Sagra, 1857) live in sympatry from southern Brazil to central Argentina. The taxonomy of the genus *Perithemis* Hagen, 1861 has been hampered by the use of characters that are highly variable or show slight differences among species. Our objective was to assess the efficiency of traditional morphometrics (TM) and geometric morphometrics (GM) to discriminate between these species using wing size and shape and vulvar lamina contour, and to analyze the presence of sexual dimorphism in wing size and shape in both species. The TM and landmark-GM methods were applied on the fore and hind wings, while the outline-based GM method was applied on the vulvar lamina. GM allowed species delimitation using shape variables of either wing. The wing and vulvar lamina shapes were confirmed to be good diagnostic characters to separate these species and appear to be promising tools for distinguishing among other species of this genus. Centroid size failed to achieve species separation. Both species exhibited sexual size dimorphism (SSD). In contrast to what would be expected for *Perithemis* whose males are strongly territorial, *P. icteroptera* and *P. mooma* showed female-biased SSD suggesting a common pattern

in Perithemis." **22089.** Tavakol, M.R.; Tooski, M.Y.; Jabbari, M.; Javadi, M. (2023): The effect of graphene nanoparticles on the strength of inspired sandwich panel structure under quasi-static loading. *Amirkabir Journal of Mechanical Engineering* 54(12): 2821-2842. (in Persian, with English summary) ["Dragonfly wings have an interesting biological composite structure and are very specialized flight organs that are well adapted for the flight behavior of each dragonfly. This paper aims to investigate the effect of graphene nanoparticles on the strength of a sandwich structure inspired by the dragonfly wing configuration under quasi-static loading. The streak structures are made of glass/epoxy layers with different percentages of graphene nanoparticles. Also, polyurethane foam was used in the central core of the vein. The crashworthiness characteristics of these structures were discussed. On the other hand, the effect of polyurethane foam on the damage rate of sandwich veins due to quasi-static loading was investigated. In order to investigate the damage in sandwich structures, pictures of the damaged surface and the cut view of the damage were taken, and the results were reported. Finally, FE-SEM analysis was used to evaluate the distribution of graphene nanoparticles in the polymer structure. The results of this study show that the presence of graphene nanoparticles in the sandwich structure resin with foam core will not have much effect on the strength of the structure if it is less than one value. On the other hand, if the amount of graphene nanoparticles in the resin of this type of structure exceeds a certain amount, it shows relatively good resistance." **22091.** Verheyen, J.; Stoks, R. (2023): Thermal performance curves in a polluted World: Too cold and too hot temperatures synergistically increase pesticide toxicity. *Environmental Science & Technology* 57(8): 3270-3279. (in English) ["Ecotoxicological studies typically cover only a limited part of the natural thermal range of populations and ignore daily temperature fluctuations (DTFs). Therefore, we may miss important stressor interaction patterns and have poor knowledge on how pollutants affect thermal performance curves (TPCs), which is needed to improve insights into the fate of populations to warming in a polluted world. We tested the single and combined effects of pesticide exposure and DTFs on the TPCs of low- and high-latitude populations of *Ischnura elegans* damselfly larvae. While chlorpyrifos did not have any effect at the intermediate mean temperatures (20–24 °C), it became toxic (reflecting synergisms) at lower (=16 °C, reduced growth) and especially at higher (=28 °C, reduced survival and growth) mean temperatures, resulting in more concave-shaped TPCs. Remarkably, these toxicity patterns were largely consistent at both latitudes and hence across a natural thermal gradient. Moreover, DTFs magnified the pesticide-induced survival reductions at 34 °C. The TPC perspective allowed us to identify different toxicity patterns and interaction types (mainly additive vs synergistic) across the thermal gradient. This highlights the importance of using thermal gradients to make more realistic predictions about the impact of pesticides in a warming world and of warming in a polluted world." **22093.** Yokoi, N. (2023): Territorial behaviors of *Tanypteryx pryeri* (Selys, 1889) (Odonata: Petaluridae). *Tombo* 66: 25-33. (in Japanese, with English summary) ["The territorial behavior of *Tanypteryx pryeri* (Selys, 1889) was observed in a habitat in Fukushima Prefecture during the 2021 and 2022 flight season. The species showed strong intraspecific struggle and occupancy, and the territory was maintained by the priority male. The struggle for territory has always favored priority male over new intruders. However, the occupancy time was short, about 15 minutes or less. Because of this, many new intruders could become territorial occupants. Territories were graded based on the number of ovipositing individuals and the number of successful matings. The strongest male occupied the highest grade territory. Losers, driven out by occupiers, were relegated to lower grade territory. However, the losers were also able to mate there, albeit with a lesser chance. Occupants staved around the territory for several days and repeatedly flew into the territory to become new occupants each day. The territorial behavior of this dragonfly is simply to occupy the best territorial grounds and mate with females. The breeding system of this dragonfly is thought to be that many males can become occupants one after another through the territory and mate with females." Assen: 123 pp. (in Dutch) ["This atlas has been compiled to represent the libarian fauna in Drenthe from 1995 to 2005. Data from the national dragonfly database was used for this. A year after the first edition of the ZC atlas, this is already the third edition. The Drenthe Dragonfly Working Group was founded in the summer of 2003. One of the objectives of the working group is to compile a distribution atlas of dragonflies in Drenthe. In preparation for this atlas we created this work atlas. The atlas is intended, among other things, for people who want to inventory dragonflies in the province of Drenthe. We therefore hope that this atlas will be an incentive for the members of the working group and volunteers in the Netherlands to map the dragonfly fauna of Drenthe in more detail. In any case, the dragonfly inventory can be carried out even better in the coming years with this new atlas. Thanks to EIS-Nederland, the Butterfly Foundation and the Dutch Association for Dragonfly Study (NVL) who made the data from the national database available and provided financial support for the first atlas. We would like to thank Vincent Kalkman (EIS-Netherlands) for creating the distribution maps and commenting on the original text. In addition, our thanks go to all observers of the Dragonfly Working Group Drenthe for reporting their observations and to Rob van der Es, Willem-Jan Hoeffna-gel, Robert Ketelaar, Renske Postuma and Ben Prins for making their photos available. Furthermore, thanks go to all observers in the Netherlands who made dragonfly observations in Drenthe." **22101.** Tiple, A.M.; Khurad, M., Andrew, R.J. (2008): Species Diversity of Odonata in and around Nagpur City, Central India. *Fraseria* (N.S.) 7: 45-49. (in English) ["A survey of dams, ponds, streams, and garden, fields and forests areas in and around Nagpur City, Central India was conducted from the year 2006 to 2008 to collect and record the Odonate faunal diversity and their Status. A total of 62 species belonging to 35 genera and 9 families viz., Gomphidae, Aeshnidae, Corduliidae, Libellulidae, Coenagrionidae, Platycenemididae, Protoneuridae and Lestidae were recorded. Among them, previously unrecorded 18 species were included in the check list of Nagpur. Of the total 62 species, 13 were abundant, 27 common, 17 rare and 5 very rare in occurrence. These observations indicate that in spite of ecological disturbances in and around the Nagpur city due to industrial and human activities, the odonate fauna is still much richer than previously recorded by earlier workers and the city and its surrounding forms a unique resource of odonate diversity." (Authors) New additions to the regional fauna are: *Cratilla lineata*, *Lathrecista asiatica*, *Orthetrum triangulare*, *Rhyothemis variegata*, *Rhodothemis rufa*, *Tetrathemis platyptera*, *Neurothemis intermedia*, *Aciagrion pallidum*, *Agriocnemis femina*, *Ceriagrion cerinorubellum*, *Pseudagrion microcephalum*, *Gynacantha dravida*, *Anax parthenope*, *Macrogomphus annulatus*, *Copera vittata*, *Libellago lineata*, *Lestes elatus* and *Lestes umbrinus*.] Address: Tiple, A.D., Department of Zoology, RTM Nagpur University, Nagpur-440033, India. **22103.** Dumont, H.J. (2009): A description of the Nile basin, and a synopsis of its history, ecology, biogeography, hydrology, and natural resources. *Monographiae Biologicae* 89: 1-21. (in English) ["Following a description of the Nile, the longest river of the world (ca 6,800 km) and its basin (2.9 × 10<sup>6</sup> km<sup>2</sup>), including its various "source" lakes, some brief notes on its main neighbours (Congo and Logone-Chari) and their history are given. The biota of the basin are moderately diverse, and endemism tends to be low, except in some of the "old" source lakes. The situation is complicated by the fact that at least two of these lakes (Victoria and

Tana) dried out around or slightly before the beginning of the Holocene, and thereafter, speciation (especially of cichlid fish) may have happened at an unusually great speed. In general, the Nile offers a pathway for African species to extend from the tropics to a Mediterranean climate and spill over into the Levant and Arabia. Such incursions may have happened many times across history, with some of the older "waves" using the Red Sea (before its opening to the Indian Ocean) rather than the Nile. Currently, as elsewhere in the world, invasive species in the Nile are becoming more and more common, although the oldest cases (some Ponto-Caspian cnidarians) may date back to the end of the nineteenth century. The water hyacinth *Eichhornia* has invaded the Nile basin in at least three different zones. Since early pharaonic times, man has interfered with the river and its flow regime, in an effort to control the yearly "flood of a hundred days", but large-scale damming only started in the nineteenth century, and culminated with the construction of the Aswan High Dam in the 1960s, reducing the river to a giant irrigation canal. More recent developments include the construction of the Toshka lakes diverticle to Lake Nasser, a project with an uncertain future. The river and its lakes are important fisheries resources; the various dams are generating large amounts of power, and fossil hydrocarbon deposits are under development in at least three zones of the basin. This may contribute to river pollution, which is still a local phenomenon, except in Lake Victoria, which suffers from eutrophication, and in Egypt, that combines a population explosion (almost four doublings in the last century) with a substantial industrial development." (Author) The study includes references to Odonata. For the full paper on Odonata see: [https://www.researchgate.net/publication/2511-31494\\_Aquatic\\_Insects\\_of\\_the\\_Nile\\_Basin\\_with\\_Emphasis\\_on\\_the\\_Odonata](https://www.researchgate.net/publication/2511-31494_Aquatic_Insects_of_the_Nile_Basin_with_Emphasis_on_the_Odonata)] Address: Dumont, H.J., Univ. **22104.** van Calmthout, M. (2010): Libellenvangen langs de Congo. *Volkskrant* of 29 June, 2010: 18-19. (in Dutch) [Verbatim: "In the run-up to the Congo expedition in which he was the only Dutchman to participate this spring, the internationally renowned Leiden dragonfly expert Klaas-Douwe Dijkstra randomly opened drawers in the depots of the Africa Museum in Tervuren. He went from one surprise to another. 'In colonial times, the Belgians literally brought everything that was loose or alive to Belgium and just piled it up in the institute. Canoes, insects, hides, plants. I'm sure after all this time I looked at some of the collections first. It was almost improbable.' Dijkstra, half-shaven, cap, wire glasses, 'KD' for friends and colleagues, is in the former Pesthuis in Leiden, which is now the entrance to the natural history museum Naturalis. There he is an unpaid guest employee. More than a week after returning home, he enjoys two months in the interior of the former Belgian colony. From the end of April, he set out on two ships up the Congo River with dozens of scientists from the Netherlands and abroad. Floating is a better word, he thinks. With a simple idea in itself: the first scientific exploration of the country in Africa, long torn by war and conflict. Biologists went along, linguists, archaeologists, anthropologists. Dijkstra: 'The river Congo, with its almost black water, is in many ways the highway through the area and also the only way to get around. In colonial times, the ends of the wet central part of the country in particular were somewhat looked at. But everything in between was still pure discovery.' The expedition was emphatically part of half a century of independence

from the Belgian colony, which dates from 29 June 1960. In this context, the Belgian government is donating the country, in addition to a new research vessel, also a new center for biodiversity. That comes to the University of Kisangani. This center receives equipment from the expedition, the ships, a few motorcycles, analytical equipment. In addition, personnel were also trained during the trip. Belgian television followed the Grand Gesture almost day by day, from a special media raft. The Flemish photographer Kris Pannecoucke traveled with the group for the entire 350-kilometre round trip, spent the night in the same tents, and watched the fieldwork and the analyzes on the research vessel. He takes hundreds of photos, some of which can be seen on [www.con.go2010.be](http://www.con.go2010.be) and at exhibitions in Tervuren. On some of them, the Dutch dragonfly man Dijkstra, standing in shallow water, swings his butterfly net like a real Prickly Leg, sometimes watched by a whole circle of curious villagers. Motorcycle In other cases, Dijkstra hired a guide with whom he went into the forest on the motorcycle he brought with him. 'I pointed: 'according to my aerial photos, there is a stream where water flows from the hinterland'. And off we went. We came to fantastic places. That's the advantage of looking for insects: you travel light and can work anywhere. In the case of dragonflies, you mainly look for water.' The local population, says Dijkstra, was invaluable, especially for the biologists on the Congo 2010 expedition. "They contribute basically anything they can find for a small fee. Plants and animals that you would otherwise never be able to collect in such a short time.' Of course, the trip did not go entirely according to plan, because it is still Africa. But it wasn't really a moment of fear, says Dijkstra. "You know: this is an area without much authority, so anyone with an opinion and a gun can do what they want." With a smile, he explains how an alleged hijacking of the media raft made the Belgian news. It soon became clear that it was a group of Congolese soldiers and their families, who saw the passing raft as an opportunity to get home faster. 162 species of dragonflies Dijkstra himself scored very well. He found no less than 162 species of dragonflies in just over a month and a half in the forest, which is intersected by the river, creeks and streams. He does not yet know how many of these are new species that are still unknown to science. About six or seven, he reckons. But numbers don't matter that much either. His real treasure, hundreds of dragonflies dried in acetone, is kept in the vault at Naturalis for meticulous scientific research. Years of work. That's what it's really about." (Google translate)]

## 2012

**22106.** Meugrey, F. (2012): A new case of westward dispersal of an Afrotropical species to the West Indies: Keyhole Glider *Tramea basilaris* (Palisot, 1805) in Cuba (Greater Antilles). *Argia* 24(4): 26-27. (in English) ["Working on a small

Collection of specimens from Cuba housed in the Nantes Museum of Natural History, I was surprised to find a male *Tramea basilaris* between several *T. abdominalis* and other species including: *Ischnura ramburii*, *Telebasis dominicanum*, *Dythemis rufinervis*, *Erythrodiplax umbrata*, *Orthemis* sp. cf. *ferruginea*, and *Scapania frontalis*, collected in only two localities (Camargüey and Baracoa). The specimen is a male with both right wings damaged at the tips and labeled as follows: Cuba, Baracoa, 12.X.1984, E. Simon leg. This constitutes, to my knowledge, the first record for the Greater Antilles, the fourth from the New World, and precedes the first documented observation of this species from the New World in Suriname by Belle (1988). I've already reported the observation of *T. basilaris* from the West Indies (Meurgey, 2008; Meurgey & Picard, 2011). This afrotropical species was recorded for the first time in the West Indies from Martinique (2006) and Guadeloupe (2008) in the Lesser Antilles. In Martinique, a single male was caught near Trois-Ilets south of the Island, and additional specimens were seen egg-laying in October 2008 (four of them were caught as voucher specimens). In Guadeloupe a single male was observed near the shoreline at Pointe-dcs-Chateaux, located at the extreme east of the island in October 2009. Since that time and despite intensive searches during the wet season, no additional specimens were seen on both islands. *T. basilaris* is a highly vagrant species in Africa and swarms of hundreds of individuals can be seen during the monsoon time along the Atlantic coasts. It is not surprising that some individuals can reach the Antilles or the South American continent following the trade winds that blow from east to west in winter. This is particularly evident considering the hundreds of *Stifocerca gregaria* (Desert Locust) observed almost every year in the Lesser Antilles. As for the Lesser Antilles, the Cuban specimen was caught during the rainy season (which is between October and December in the Lesser Antilles). This new record suggests that this species may be observed in the Southern States of the USA, especially Florida." (Author)] Address: Meurgey, F., Muséum d'Histoire naturelle de Nantes, 12, rue Voltaire, F-44000 Nantes, France. E-mail: [Francois.Meurgey@mairie-nantes.fr](mailto:Francois.Meurgey@mairie-nantes.fr)

**22107.** Nunner, A.; Bioplan Tübingen (2012): Artenhilfsprogramm Alpen-Mosaikjungfer (*Aeshna caerulea*) im Regierungsbezirk Schwaben. Gutachten im Auftrag der Regierung von Schwaben, Fronhof 10, 86152 Augsburg: 71 pp. ["Local populations and their population sizes: With regard to their location in relation to each other, the finds in the Oberallgäu can be summarized into a total of ten local populations (see Map 1 and Table 2), seven of which are currently populated. Two discovery reports contained in the ASK concern no longer confirmed individual evidence of adults in suboptimal habitats, so that no native occurrence can be derived for these areas (moor pools in Scheuenwald and Guggensee). Core habitats with probably regular reproduction can be found in the following seven areas: Strausberg moss (2 sub-habitats) Engenkopfmoore (1 sub-habitat) Lower Gottesackermauern (5 sub-habitats, of which 3 are core habitats) Piesenkopf-Ziebelmoos (4 sub-habitats, of which only 1 regularly occupied) \* Wannenkopf (4 sub-habitats, of which 2 are regularly occupied) \* Large Ochsenkopf (1 sub-habitat) \* Wilhelminenmoos (1 sub-habitat) In these moors, there was also evidence of imagines and exuvia in the 2012 survey, with the exception of Piesenkopf-Ziebelmoos (imagines only). Subsidiary habitats that are not regularly occupied are probably the following three areas (without evidence in 2012, despite multiple visits) \* Duftmoos/Schnippenalpe (2 sub-habitats) \* Moor near Aibealpe (1 sub-area) \* Moor at Toniskopf (1 sub-area) With regard to their

population size The Strausbergmoos, the Lower Gottesackermauern and the Wannenkopf are among the most important occurrences in Germany, each with an estimated 50-100 adults in favorable years. The Engenkopf moors and the Großer Ochsenkopf are also probably home to larger populations (max. 25-50 adults each per year). Smaller populations can be found in the Piesenkopf-Ziebelmoos and in the Wilhelminenmoos (each max. 10-25 adults/year). Habitat configuration The habitat configuration of all individual-rich occurrences is characterized by a diverse range of permanently water-bearing Schlenken waters (>20 Schlenken), in particular by the presence of larger bog Schlenken (>50m<sup>2</sup>) with free water surface. The regularly occupied deposits are unused and lie outside pasture areas; at the Großer Ochsenkopf the larger Schlenken waters are fenced off. Species assistance program *Aeshna caerulea* in Swabia 8 Impairments and need for action For the majority of the moors examined, the need for action with regard to the habitats of *A. caerulea* is low. Significant impairments due to cattle treading occur in the unfenced Schlenken on the Großer Ochsenkopf and the Toniskopf. Fencing off a large part of the moor area would be strongly recommended for both areas. The wallowing activity of red deer only affects individual loins in most moors, but should continue to be monitored regularly in the future so that measures can be taken if necessary. As a precautionary measure, no salt licks or feeding areas should be set up in or in the immediate vicinity of the habitat to avoid attracting deer. A greater impairment due to use as a deer wallow was found in Duftmoos (Retterschwanger Tal). The aim here was to test whether red deer can be scared away from the moor and whether, for example, they will accept alternative wallows outside the moor. Assessment of the current population situation In 2012, *A. caerulea* was confirmed at all seven larger and well-equipped habitats. Unsuccessful controls have always affected smaller deposits or non-soil deposits. The inventory development can currently be assessed as "stable". The current habitat potential in high-altitude moors in the Oberallgäu has been largely exhausted. The population situation with seven regularly occupied core habitats (three of which have large individual populations) can be assessed as good overall." ### 2013

**22109.** Teder, T. (2013): Sexual size dimorphism requires a corresponding sex difference in development time: a meta-analysis in insects. *Functional Ecology* 28(2): 479-486. (in English) ["The degree and direction of sexual size dimorphism (SSD) vary greatly among animal species. At the ontogenetic level, SSD may result from sex differences in birth size, growth rate and/or development time. Nevertheless, evidence concerning proximate causation of SSD is scattered, and the data used to infer ontogenetic determinants of SSD have not always been appropriate for this purpose. I use a comprehensive literature-derived database of relevant sex-specific traits on 169 species to address the significance of sex differences in larval development time (SDTD) as a proximate source of SSD in insects. In a clear

majority of species (79%), SSD and SDTD were qualitatively congruent, i.e. the larger sex had also a longer larval development. In strongly size-dimorphic species, the qualitative correspondence between SSD and SDTD was nearly universal. Consistently, in a phylogenetically diverse array of insect clades, SDTD increased with increasing SSD across species. The results indicate that the evolution and maintenance of high SSD values are rarely possible without a prolonged development of the larger sex. The role of sex differences in growth rate as the ontogenetic determinant of SSD in insects requires further studies which should ideally be based on detailed monitoring of larval growth schedules. The increase in SDTD with increasing SSD is consistent with the idea that the widespread phenomenon of protandry (the emergence of male adults before females) may primarily be an incidental by-product of other selection pressures." Ross, H.; Roth, N.; Schaubel, K.; Sheid, C.; Schindler, H.; Schirmel, J.; Schleich, S.; Schmidt, C.; Schmidt, T.; Schmolz, M.; Schneider, M.; Schwab, G.; Spieler, P.; Stark, C.; Strubel, J.; Walter, J.; Weber, C.; Weber, D.; Erno, A. (2014): Eine Momentaufnahme aus der Flora und Fauna im grenzüberschreitenden Biosphärenreservat Pfälzerwald. Nordvogesen. Ergebnisse des 14. GEO-Tags der Artenvielfalt am 16. Juni 2012. Ann. Sci. Rés. Bios. Trans. Vosges du Nord-Pfälzerwald — 17 (2013-2014): 29-69. (in German, with French and English summaries) ["As part of the GEO Biodiversity Day, on 16 June 2012 an assessment of the flora and fauna in the cross-border Palatinate Forest-Northern Vosges Biosphere Reserve was conducted. The Rhineland-Palatinate Nature and Environment Foundation directed the event, together with GEO magazine and the two sponsoring associations of the cross-border UNESCO Palatinate Forest-Northern Vosges Biosphere Reserve and numerous other partners. Enjoying suitable weather for field work, the nearly 100 experts invited from Germany and France ranged, according to their individual specialities, through the selected survey areas around Fischbach/Dahn (D), Eppenbrunn (D), Hirschthal (D & F) and Wingen (F). In total, they succeeded in finding evidence of 2081 species from 147 orders and 470 families. The survey revealed many vulnerable or severely endangered species, some of which are extremely rare in Germany or are subject to protection under Annexes II and IV of the European Habitats Directive. The assessment provided the first recordings of some species in the area under investigation. In total of ten new species of cicada were recorded for the state of Rhineland-Palatinate; however, in view of the low level of research so far undertaken on this group here, this was not entirely unexpected. Particularly noteworthy was the first recording in Rhineland-Palatinate of the very rare European hoverfly *Myolepta potens* (RL D: 2). For the first time, clear evidence was found for the carabid beetle *Amara infima* in Rhineland-Palatinate. In addition, the existence of the pygmy locust (*Tetrix bipunctata*) was clearly proven for the first time in the Palatinate Forest. In the French section of the biosphere reserve, the soprano pipistrelle (*Pipistrellus pygmaeus*) had not previously been documented. However, this was achieved several times on the GEO biodiversity day ... Verbatim: (Google translát): 4.8.1 Odonata – dragonflies (Jürgen Ott, Mathias Kitt, Uwe Lingenfelder and Michael Post) Dragonflies are extremely sun worshipers, and so the GEO day was rather "suboptimal" for this group of species; Because it was mostly overcast and the temperatures weren't particularly summery either. Nevertheless, a total of 28 species. eleven damselflies and 17 dragonfly species. were identified in the study areas, which corresponds to more than 40% of the entire range of dragonfly species in Rhineland-Palatinate. In addition to the typical flowing water species that occur throughout the area, such as *Calopteryx splendens* and *C. virgo*, it was also possible to find *Gomphus vulgatissimus* and *Ophiogomphus cecilia*, the latter an FFH appendix II/IV way to prove. The most remarkable, however, are the finds of three moss damsel species: not only *Leucorrhinia dubia*, which is known for the area, but also *Leucorrhinia pectoralis* and *Leucorrhinia rubicunda* flew here. The latter two species. *Leucorrhinia pectoralis* is also an FFH appendix II/IV species. appeared increasingly in Rhineland-Palatinate in 2012, although so far there has been very little evidence of the Nordic moss damsel from Rhineland -Palatinate even exists (OTT, 2012). The finds once again underline the importance of the diverse bodies of water in the area between Eppenbrunn and Fischbach for dragonfly species protection, with the swamps, intermediate moor sites and streams being particularly noteworthy as habitats. These can also be seen in connection

with similar biotopes on the French side, with which they form a composite complex.] Address: Ott, J., Friedhofstr. 28, 67705 Trippstadt, Germany. E-mail: L.U.P.O.GmbH@t-online.de

**22115.** Márquez Rodríguez, J. (2014): Contribución al conocimiento de la odonatofauna costera en la isla de Menorca. Nova Acta Científica Compostelana 21: 7-10. (in Spanish) [<https://dialnet.unirioja.es/servlet/articulo?codigo=4972310>: "This research provides faunal data of the order Odonata in a little-studied biotope on the island: the calcareous cliff and the coastline in the southwest of the island. It is questioned which community of odonates adapts the island cliff as a resource during the driest months of the year, and whether there are species that have been replaced by others in recent years. The possible alteration of the habitat could be influencing the population dynamics compared to the last three decades. *Sympetrum striolatum* is the most common species. *Orthetrum coerulescens* is abundant and very localized in permanent channels with reeds. *Aeshna isosceles* is now very rare and *Anax parthenope* appears to have replaced *Anax imperator*. An analysis of the quality of surface waters with aquatic macroinvertebrates is recommended to know their current status." (Author)] Address:

**22116.** Nixon, M. (2014): Photonic structures in nature: through order, quasi-order and disorder. Diss. University of Exeter: 202 pp. (in English) ["The majority of colours in the natural world are produced via the wavelength selective absorption of light by pigmentation. Some species of both flora and fauna, however, are particularly eye-catching and visually remarkable as a result of the sub-micron, light-manipulating architecture of their outer integument material. This thesis describes detailed investigations of a range of previously unstudied photonic structures that underpin the creation of the interesting visual appearances of several such species of flora and fauna. These structures were examined using a variety of methods, including optical microscopy, scanning and transmission electron microscopy, focused ion-beam milling and atomic force microscopy. This enabled detailed characterisation of the species' photonic systems. The degree of order discerned in the species' photonic structures ranged from: 'ordered' systems, where multiple layers of two materials produces metallic and often mirror-like reflections; to 'quasi-ordered' systems, where an average periodicity of the structure in all directions gives rise to diffuse, coloured scatter; to disordered systems, where no discernible order is observed, which results in a diffuse, broadband, white appearance. In addition to this, the range of systems also encompassed: periodicities in one-dimension in the form of multilayering; 'quasi-two-dimensional' structures in the form of aligned fibres; and three-dimensional structures formed from arrangements of spherical particles. Alongside this experimental characterisation, an in-depth series of supporting theoretical analyses were undertaken. For the one-dimensional systems studied here, the models' theoretical reflectance was calculated using analytical methods. For other systems, with more complex structural-geometries, theoretical simulations of their electromagnetic response to incident radiation were carried out using finite-difference-time-domain and finite-element method numerical modelling approaches. Theoretical modelling results were compared to experimental measurements of each samples optical properties. These were primarily reflectance measurements, which were taken using a range of techniques appropriate for each specific investigation. In addition to this, a synthetic sample, mimicking the white-appearance and remarkable polarisation-dependant reflectance of one insect's photonic structure, was created using polymer electrospinning. Using these experimental measurements and theoretical simulation predictions, the structural colour production mechanisms adopted by several species of flora and fauna were elucidated." (Author) In Chapter 5, the ordered photonic structures in three species of Odonata (*Matronoides cyaneipennis*, *Aristocypha iridea* and *Rhyothemis resplendens*) have been presented and discussed in detail. Address: Nixon, M.R., School of Physics, Univ. of Exeter, Exeter EX4 4QL, UK, E-mail: m.r.nixon@exeter.ac.uk

## 2015

**22117.** Brandon, A. (2015): North Wales North Wales, Dragonfly Newsletter No 82. 2nd Nov 2015. Odonata news and events from across the vice counties of Anglesey, Merionethshire, Caernarvonshire, Denbighshire and Flintshire. North Wales Dragonfly Newsletter 63: 1-3. ["Vagrant Emperor (*Anax ephippiger*) seen on Bardsey. Steve Stansfield photographed a lovely male Vagrant Emperor on Bardsey Island on the 1st November. The recent sighting has been

reported on the Bardsey tweet (<https://twitter.com/bardseyjobs>): Male *Anax ephippiger* on Bardsey, 1st November 2015. Photo Steve Stansfield. This is only the second sighting of the species for North Wales, the first also on Bardsey reported by Steve and Marion Holmes at Nant Pond on the 21st April 2011. They didn't manage to get conclusive evidence in the form of a photo but from their descriptions, and it fitting in with a pattern of mass migration into NW Europe at the time, it was accepted by the Rarities Committee. This relatively small dark emperor species does now seem to be a pretty regular migrant when conditions are right and, given the recent run of southerly winds, Adrian Parr, the BDS Migrants Officer, was half expecting one or more to turn up in the UK from southern Europe. Adrian reports that at least one individual has also been seen in Belgium in recent days. In the UK it is being seen in the cooler months with more frequency in recent years, when few or no other dragonflies are around, so it is worth looking out for, particularly around the coast. If you are planning a walk during this gorgeous weather we're having it might be best to head for the coast. The bright blue band around the top of the abdomen contrasts sharply with the remaining dark brown abdomen and the thorax. Note also its brown eyes – those of the similar Lesser Emperor (*Anax parthenope*), which breeds in the south of Britain, are green. Malcolm Watling's melanistic bluet: Malcolm Watling photographed this somewhat melanistic form of the male Common Bluet (*Enallagma cyathigerum*) at Llyn-yr-Adar [SH656479], near Blennau Ffestiniog, at an altitude of 570m OD, on the 15th July 2015. Note the particularly large pair of black spots on the 8th abdominal segment, an extra pair on the 9th, and an extra large black dorsal spot in the centre of the 4th segment. The individual is reminiscent of quite a few individuals that turned up across the UK during the summer of 2012, the most noteworthy photographed by Ian Standen in the Gwydyr Forest (see North Wales Dragonfly Newsletter No. 63; also Dragonfly News No. 62, Autumn 2012, p.24). Such forms are more common in western Ireland and Scotland and a possible cause proposed at the time was that a particularly cold spring in an upland habitat had affected larval growth in some way." (Author)]

**22118.** Heneberg, P.; Sitko, J.; Bizos, J. (2015): Integrative taxonomy of central European parasitic flatworms of the family Prosthogonimidae Lühe, 1909 (Trematoda: Plagiorchiida). *Parasitology International* 64: 264-273. (in English) ["Species of the family Prosthogonimidae are considered the most pathogenic poultry trematodes worldwide, affecting particularly low intensity farming in rural areas. Adults of *Prosthogonimus* occur mainly in the bursa of Fabricius, oviduct and cloaca of ducks, geese, fowl and other birds feeding at least occasionally on Odonata. We analyzed the central European species of the Prosthogonimidae, namely *Prosthogonimus cuneatus*, *P. ovatus*, *P. pellucidus* and *P. rarus*. We sequenced three nuclear (ITS2) and mitochondrial (CO1, ND1) DNA loci of four species isolated from *Anas clypeata*, *Anas strepera*, *Anas platyrhynchos*, *Aythya ferina*, *Passer domesticus* and *Turdus merula*. Intra- and interspecific sequence variability revealed that all four species represent distinct well-defined entities. Our data, combined with previously published studies, suggest the return of the name *Prosthogonimus rarus* Braun, 1901 for *Schistogonimus rarus* (Braun, 1901). The genus name *Schistogonimus* Lühe, 1909 is considered a junior synonym of *Prosthogonimus* Lühe, 1899. We identified the existence of two clades, one represented by *P. cuneatus* and *P. pellucidus*, and another one formed by *P. ovatus* and *P. rarus*. We also provide comparative measurements of these four central European

prosthognimids, and address their tissue specificity, host-specific prevalence (based on the extensive bird cohort examined in years 1962–2014), and for some bird hosts we address also differences in the prevalence of Prosthognimus spp. in natural and near-natural wetlands in comparison with fishponds utilized for intense carp production. We provide an updated key to European Prosthognimus spp. based on their morphological characters." **22120.** Joest, R.; Wrede, J.; Beckers, B. (2015): Auswirkungen der Entnahme von Fichten und der Renaturierung von Waldbächen auf die Blauflügel-Prachtlibelle und andere Libellenarten. ABU info 36-38: 36-43. (in German) ["Discussion: The results of the monitoring provide clear indications that the forest conversion and water restoration measures carried out as part of the project have had a positive impact on the dragonfly fauna. In the case of the blue-winged damselfly, a clear increase in the density of individuals was evident in the measured sections, which was compared to a constant to slight increase in the control sections of the Große Schmalenau. However, an increase in the density of individuals was also evident in the previously very isolated control sections at the source areas of the Reißmecke. This is probably due to the fact that these previously isolated areas were easier to reach for migrating individuals after the opening of the lower reaches or that individuals flew in from the now more densely populated lower sections. Due to the relatively short period of time between the implementation of the measures and the monitoring, the rapid reaction of the blue-winged damselfly to the measures is probably primarily due to the immigration of adults from the surrounding area. Apparently the exposed areas now corresponded to the habitat search pattern of the species (Stemberg & Buchwald 1999). The trend towards a balanced sex ratio after the implementation of the measures is an indication that an increasing number of females from the surrounding area came to mate and lay eggs in the more open, renatured sections. It is to be expected that egg laying and successful development of the larvae will actually occur in the newly populated, renatured sections. Observations of egg laying are also carried out here as part of monitoring. For spring damselflies, the density of individuals in the measure sections before the implementation of the measures was significantly lower than in the more natural control sections. After implementation, they achieved roughly comparable values in both sections. It can be assumed that the measures carried out as part of the LIFE project had a beneficial effect on the spring damselflies. The measures carried out on the water bodies promote the formation of areas with calm currents,

which serve as egg-laying substrates, while the promotion of deciduous forests has a positive effect on the availability of decomposer organisms as food for larvae (Heitz 2006). In detail, it is not always possible to clearly distinguish whether the effects identified are due to the removal of spruce trees and the associated opening of the areas or to the renaturation of water bodies. It is likely that both factors work together and lead to an improvement in habitat structures. The negative relationship between shading and colonization by dragonflies, which was documented for the blue-winged damselfly regardless of water measures, supports the effect of opening up the waters through the removal of spruce trees. Species-specifically, a two-stage process can probably be assumed: while clearing the waters of spruce trees initially enables individuals to spread and colonize the waters, the water engineering measures promote successful reproduction by promoting calmed sections, fine sediment deposits and aquatic plants as egg-laying substrates and larval habitats. The richly structured, open trees in the vicinity of the reproductive waters initiated by the silvicultural measures also have a function as a ripening and feeding habitat for the striped spring damselfly, for example (Tamm 2012). Orthetrum coerulescens and other dragonflies in still waters in the open country are also likely to have benefited from the measures by creating new habitats, but also by facilitating dispersion along the waters." **22122.** Simic, V.; Petrovic, A.; Erg, B.; Dimovic, D.; Makovinska, J.; Karadzic, B.; Paunovic, M. (2015): Indicative Status Assessment, Biodiversity Conservation, and Protected Areas Within the Sava River Basin. The Sava River. The Handbook of Environmental Chemistry 31: 453-500. ["The aim of this chapter is to provide the overview of the water status, state of the biological diversity, and protected areas along the Sava River as well as to underline the necessity of identification and implementation of effective conservation measures. The chapter is based on historical data on environment and recent investigation on macroinvertebrate communities (2011–2012). Ecological status of water bodies within the Sava River basin ranges from high to poor, while the ecological status of the majority of water bodies is assessed as moderate, which indicates the necessity of design and implementation of relevant mitigation measures. The assessment of water quality and ecological status of the river Sava based on the macroinvertebrates community, alongside with the use of several standard biological methods and regional biotic index BNBI indicates a high correlation of the obtained results. BNBI has proven to be a method reliable enough for both the assessment of water quality and the assessment of ecological status of large rivers. Based on the results of water status assessment, the Sava

River could be divided into three zones. The best water quality was recorded within the Slovenian stretch of the river, being within the limits of betamesosaprobic zone, while the ecological status was assessed as a good one. The middle part of the Sava River, stretching mainly through Croatia and Bosnia and Herzegovina, has a somewhat worse water quality, approaching the limit of betamesosaprobic zone, while the ecological status in this part of the flow was also determined as a "good" one. The lower parts of the Sava River flow through Serbia are by all indicators more heavily polluted; the water quality is on the border between beta. and alfamesosaprobic zones, while the ecological status is between "good" and "moderate." The biodiversity of the Sava River may be considered significant, when compared to similar water-courses of Central Europe and Balkan Peninsula. The work contains a more detailed analysis of the biodiversity of aquatic macroinvertebrates and fish of the main flow of the Sava River. Based on the condition of biodiversity of these groups, the river's ecosystem is divided into three "macrohabitats." The first macrohabitat includes the upper rhithron parts of the river through Slovenia, with a significant diversity of stenovalent groups of macroinvertebrates (larvae EPT) and salmonid species of fish (brown trout, grayling, and hucho trout). The second macrohabitat includes the parts of the flow through Croatia and Bosnia and Herzegovina with significant diversity of invertebrates from the groups Odonata, Mollusca, Hirudinea, and Chironomidae and fish from the families of Cyprinidae, Percidae, and Gobiidae. The highest number of protected species of fish has been registered in this section. The third "macrohabitat" includes the lower part of the potamon of the Sava River and mostly flows through Serbia wherein this part of the flow represents the most important habitat of the globally endangered and fishing-wise important sturgeon species of sterlet (*Acipenser ruthenus*) in this river. It is characterized by a decreased biodiversity of macroinvertebrates in the main flow of the river and a significant diversity in the flood zones. In the biodiversity of fish, the highest number of allochthonous species appears. In this section, the diversity of fish in flood zones especially as the habitat of endangered species such as *Umbra krameri*, *Misgurnus fossilis*, and *Carassius carassius* is also important. Research has shown that in order to perform a successful conservation of large river biodiversity, the ecosystem must be observed as a complex consisting of the main flow of the river, flood zone, and its tributaries." Publisher: Stichting Libellenwerkgroep Drenthe: 205 pp. (in Dutch) ["This book is the result of ten years of research conducted by volunteers into the dragonfly fauna of the Dutch province of Drenthe. The result is this richly illustrated book containing a large amount of data on the province of Drenthe. The book is not only intended as a resource for local councils and managers, but also as a source of information for dragonfly aficionados. The introductory chapters deal with dragonfly ecology and research in Drenthe. The next, in-depth chapter discusses the different biotopes and landscapes found here, and the typical dragonfly species occurring here. Specific attention is paid to the likelihoods of finding dragonflies in natural reserves and agricultural areas. The largest part of the book is dedicated to the species chapter, describing the 54 species found in Drenthe. For each species habitat, lifestyle, current distribution and expectations for the future are given. The authors per species also discuss potential threats, and any measures that could be taken to protect species and their habitats. Distribution maps are included, with nature reserves overlaid on the maps, and a table with the status of each species in both the Netherlands as a whole and Drenthe in particular, the rarity, population trend and Red List status is given. Graphics show the flight times and dates of earliest and latest observation dates. For each species, multiple colour photos have been included, often showing dragonflies in flight, as well as showing their habitat. The 2016 reprint contains an extra eight pages, contains new distribution maps including data up to 2016, new photos, and revised texts." **22128.** COSEWIC (2018): COSEWIC assessment and status report on the Pygmy Snaketail *Ophiogomphus howei* in Canada. Committee on the Status of Endangered Wildlife in Canada. Ottawa. (<http://www.registrelep-sararegistry.gc.ca/default.asp?lang=en&n=24F7211B-1>). : xi + 46 pp. (in English) ["Executive Summary: Wildlife Species Description and Significance: The Pygmy Snaketail (*Ophiogomphus howei*) is a small (total length of 31–34 mm; wing length of 19–21 mm) dragonfly in the family Gomphidae, commonly referred to as the clubtails. This species is associated with clean fast-moving water. Adults are black in colour, with vivid yellow markings on the abdomen and wings, and with bright green markings on the thorax. The larvae are aquatic, small and cryptic. Distribution: *O. howei* ranges in eastern North America. It is known from two geographic areas: the Appalachian Mountains from northern New Brunswick to northeastern Georgia, and the Midwest from Minnesota, Wisconsin, Michigan, and northwestern Ontario. In Canada it is known from seven large river systems: the Saint John, St. Croix, Magaguadavic, Southwest Miramichi, Cains, and Salmon Rivers in New Brunswick, and the Namakan River in northwestern Ontario. Some snaketails are quite rare, and exuviae (castoff larval skins left behind after emergence) are the most often found evidence supporting the presence of a species. Habitat: *O. howei* larvae occur in larger, swiftly flowing, and moderate gradient rivers with unpolluted water and significant areas of fine sand or pea gravel substrate. Adults are believed to primarily reside in forest canopies near natal rivers. Searches for exuviae at many seemingly appropriate waters, and at the appropriate time of the year, have generally yielded no results for the species; suggesting that suitable habitat, including factors influencing larval success, is more narrowly defined than we currently realize. Biology: The length of time required for larvae to develop and emerge from their aquatic habitats is believed to take at least two years. In Canada, emergence occurs from late May or early June to late June and is largely associated with the synchronous emergence of other members of its genus. After emerging, adults survive for four to six weeks and are rarely encountered at water, but likely spend much of their time in the forest canopy. Population Sizes and Trends: Population estimates of abundance or trends for *O. howei* in Canada are unknown, but the US population is considered stable. Threats and Limiting Factors: Overall impact of threats to *O. howei* are considered low. Potential dam construction is a threat to the Ontario subpopulation. Invasive species can also alter the biota to the detriment of *O. howei*; however, the impact of this threat is unknown. Water pollution due to excessive nutrient input from sewage, or sedimentation due to agricultural or forestry run-off are believed to have a negligible impact on the species. Protection, Status and Ranks: *O. howei* was assessed as Special Concern by the Committee on the Status of Endangered Wildlife in

Canada (COSEWIC) in 2008, and is listed Special Concern under Schedule 1 of Species at Risk Act. It is listed as Special Concern under the New Brunswick Species at Risk Act and Endangered under the Ontario Endangered Species Act. It is ranked N2 in Canada, S1 in Ontario, and S2 in New Brunswick." (Authors)] Address: COSEWIC Secretariat, c/o Canadian Wildlife Service, Environment and Climate Change Canada, Ottawa, ON, K1A 0H3

**22129.** Fabbri, R.; Costa, M.; Cassani, G. (2018): Azioni coordinate per la conservazione di *Coenagrion mercuriale castellanii* (Roberts, 1948) in Emilia-Romagna. In: Azioni coordinate per la conservazione in Emilia-Romagna di *Osmoderma eremita* (Scopoli, 1763), *Rosalia alpina* (Linnaeus, 1758), *Coenagrion mercuriale castellanii* (Roberts, 1948), *Graphoderus bilineatus* (De Geer, 1774): 69-72. (in Italian) ["The translocation program: During the ex ante monitoring of the LIFE EREMITA project the highest number of individuals counted (n. 1513 adults in 2016; n. 1639 adults in 2017) was registered in the Natura 2000 site IT4090002. Torriana, Montebello, Fiume Marecchia in three streams in the municipality of San Leo (RN), while in the site IT4070011. Vena del Gesso Romagnola the species was found in two streams with a few dozen individuals (24 adults in 2016; 56 adults in 2017). Also during the monitoring, it emerged that within the same two sites IT4070011 and IT4090002 are the only watercourses in the region that currently present the ecological characteristics suitable for hosting the species. The Rimini population present in the IT4090002 site is fundamentally isolated from the other Romagna population present in the canals of the IT4070011 site, being at a distance of between 50 and 65 km. On the other hand, it is known that *C. mercuriale castellanii* has a low dispersal capacity and is typically a sedentary species, generally with 75% of adults not making movements greater than 100 m and 95% greater than 300 m (Watts et al., 2004; Watts et al., 2007b). Some studies demonstrate how the species can also make significant movements, over 2 km, in the open agricultural landscape (Keller et al., 2010; Keller et al., 2012; Lorenzo-Carballea et al., 2015); however, when obstacles arise, such as woods and substantial changes in altitude, its dispersion capacity decreases. In light of the historical and current distribution described, extremely reduced compared to the past, and the low dispersal capacity of the species (Watts et al., 2007a, 2007b; Keller et al., 2012), to strengthen the population present in site IT4070011 it is a translocation plan has been prepared with the aim of expanding the distribution area of the species and strengthening its population. The plan involves the movement of some adult specimens from the source site in the Rimini area (IT4090002) towards n. 6 streams present in the IT4070011 Vena del Gesso Romagnola site, following the implementation of habitat improvement and restoration interventions. The movements that will take place within the translocation plan with distances ranging from 50 to 65 km are considered transfers within the same metapopulation. It is believed that it is possible to exclude any risks of genetic pollution between different phyletic lines, as, from recent genetic analyzes (study of the mitochondrial genes COI and 16S rRNA and the nuclear genes PRMT, MLC and AgT) conducted across the entire northern European range African distribution of the species, with materials also coming from various Italian locations from Piedmont to Basilicata, including specimens collected in Romagna in the Vena del Gesso Romagnola, it is possible to state that the Italian populations belong to a single phyletic lineage (Ferreira, 2016). Even the territorial area in which we operate is ecologically similar for both sites (source and repopulation), located on low hills with withdrawal

and release heights between 110-250 m, therefore with altitudinal variations and consequently negligible phenological factors. The translocation plan involves the collection from the source site of approximately n. 170 specimens per year (with sex ratio 1:1) for a period of three years to be divided, during the release phase, among the various eligible channels on the IT4070011 site. The quantity of specimens to be released in individual sites is assessed on a case-by-case basis based on the environmental characteristics, the size of the stream, the result of ex ante monitoring activities on the size of the population and the suitability of the habitat. The translocation operations will begin in spring 2019, at the beginning of the species' activity period, and will be repeated (2 -3 times) until June of the same year. Although the species is bivoltine in Romagna, the operations will take place between April and June, when the majority of adult individuals emerge. The operations will involve the capture of adults in the stations of the IT4090002 site, which will be marked on the wings as described in the monitoring protocol of the species of the LIFE EREMITA project (Fabbri, 2017); for each specimen the size, state of health and vitality will be checked. Subsequently, the captured individuals will be placed inside a fauna box container with some plant stems and food inside (e.g. *Drosophila* sp.). The transport and release operations will take place within an estimated time frame of within two hours. Approximately 10 adults will be placed inside each fauna box and temperature checks will be carried out during the journey. The specimens will be released at the edges of the streams, in partially shaded areas not exposed to the wind. The data of the release operations will be noted on a paper sheet (date, time, environmental conditions of the release watercourse, number of specimens, etc.) and all phases of the translocation activity will be documented with photos and videos. The program developed to date must first be subjected to checks by the Ministry of the Environment and ISPRA provided for by Presidential Decree 357/97. Overall, it is expected that once the conservation plan for the species is fully implemented, in the two Natura 2000 sites in Romagna, it will occupy, at a linear estimate level, approximately 4 km of watercourses compared to the current 1.7 km." **22130.** Fabbri, R.; Barbieri, C.; De Curtis, O.; Poloni, R.; Giangregorio, P.; Malavasi, D.; Monterastelli, E.; Norbiato, M.; Stefanelli, S.; Carchini, G. (2018): Aggiornamento della distribuzione di *Coenagrion mercuriale castellanii* (Roberts, 1948) in Emilia-Romagna. In: Azioni coordinate per la conservazione in Emilia-Romagna di *Osmoderma eremita* (Scopoli, 1763), *Rosalia alpina* (Linnaeus, 1758), *Coenagrion mercuriale castellanii* (Roberts, 1948), *Graphoderus bilineatus* (De Geer, 1774): 63-67. (in Italian) ["Conclusions: The presence of *C. mercuriale castellanii* in Emilia-Romagna is limited to the foothills and localized in only three stations, in separate areas of the Romagna territory. All the known populations fall within sites of the Natura 2000 network, two particularly small ones within the SCI-ZPS IT4070011 Vena del Gesso Romagnola and one, more stable and abundant, within the SCI IT4090002 Torriana, Montebello, Fiume Marecchia. The populations of site IT4070011 are separate from that of site IT4090002 as they are more than 50 km apart. The results confirm the declining trend of the species in Emilia-Romagna, also due to the fact that several reports between the 40s and 70s of the last century have no longer been confirmed recently, due to the progressive disappearance of the small sunny streams with clear and permanent waters suitable for hosting the species. The monitoring made

it possible to plan habitat improvement interventions and translocation actions aimed at strengthening the present populations. The monitoring of *C. mercuriale castellanii* represented the first application in Italy of the methods adopted by ISPRA and the Ministry of the Environment for the monitoring of species of community interest (Stoch & Genovesi, 2016). Using this method also in the ex post monitoring foreseen by the LIFE EREMITA project, for the first time there will be a time series of abundance values from which to obtain quantitative information on the population trend in Emilia-Romagna. Results: The following table shows in chronological order the previous reports (from 1877 to 2010) of *C. mercuriale* in Emilia-Romagna, extracted from the database of reports of the species, available in the archives of the Emilia-Romagna Region. In the ex ante monitoring campaigns of the LIFE EREMITA project in the two-year period 2016 and 2017, *C. mercuriale castellanii* was found to be present in the SIC-ZPS IT4070011 "Vena del Gesso Romagnola", in the province of Ravenna, and in the SIC IT4090002 "Torriana, Montebello, Fiume Marecchia", in the province of Rimini. Furthermore, a male specimen was identified, probably a wandering individual outside the Natura 2000 site, near the SCI IT4070011, in the same stream inside the site where the population is well established. site IT4090002. Torriana, Montebello, Marecchia River in three streams in the municipality of San Leo (RN). With the VES method, no. 1513 adults and in 2017 no. 1639 adults; with the CMR method, applied only in 2016, no. 375 male individuals with n. 8 recaptures (Fabbri et al., 2017). In the IT4070011 Vena del Gesso Romagnola site, n. 24 adults and in 2017 no. 56 adults. Discussion: During the ex ante monitoring, the presence of *C. mercuriale castellanii* was ascertained only in the easternmost territory of the region, despite the effort to extend the study area also to the Natura 2000 sites in the central and western Emilian sector. The species has only been found in the foothills; in particular, in two Natura 2000 sites (IT4070011 and IT4090002), located respectively in the province of Ravenna and in that of Rimini. In the IT4070011 Vena del Gesso Romagnola site the species was contacted with a few specimens only in two transects corresponding to two streams (IT4070011\_MAR\_Coe\_L8, IT4070011\_MAR\_Coe\_L5-3) in the municipality of Casola Val Senio (RA). While awaiting quantitative analyzes of the populations surveyed, the few individuals observed suggest the presence of numerically very small populations, probably due to the widespread coverage of watercourses by trees and bushes which reduce the extension of the habitat suitable for species. These two transects constitute new stations of presence of the species in Emilia-Romagna. In the same Natura 2000 site, in three other monitored transects, corresponding to three different streams, the species was not found. However, these streams present suitability characteristics that can be improved in favor of the species with appropriate and timely interventions on the habitat (thinning out and elimination of tree-shrub vegetation). The IT4070011\_MAR\_Coe\_L4 station in the municipality of Brisighella, however, is no longer suitable for the species, as for most Odonata species, following strong interference from the manager of the adjacent land, who started breeding domestic animals (poultry and other) close to the river; therefore, it was not possible to reconfirm the presence of the species in this station. In the site IT4090002 Torriana, Montebello, Fiume Marecchia the population appears to be large and stable, despite being located near the northern margins of distribution of the subspecies' range in Italy. The population is distributed in three parallel channels, ecologically connected, with discontinuous distribution, located in the Municipality of San Leo (RN). The first stream, corresponding to the IT4090002\_MAR\_Coe\_L1 transect, has the

longest low-shaded stretch and has a resurgence on the south-east side which generates a small marshy area frequented by adults of *C. mercuriale* and other species of Odonata. The third stream, corresponding to the IT4090002\_MAR\_Coe\_L3 transept, appears to be very shaded by tall trees and bushes and is also characterized, together with the second stream (IT4090002\_MAR\_Coe\_L2), by banks with numerous hedges of shrubs and brambles. However, the three streams appear to be particularly suitable for the species because they still have large stretches of their course that are not completely covered by tree-shrub vegetation. It can be assumed that, following interventions to improve the habitat for the species in the shaded stretches of streams, the population could be rapidly distributed in the new suitable stretches (Poloni, 2017). From the comparison of the results of the monitoring carried out as part of the LIFE EREMITA project with previous reports of the species in Emilia-Romagna (Table 2), it is possible to outline a fairly continuous distribution in the past in the foothills, at least between Imola and Rimini, no longer confirmed by the results of the 2016-2017 monitoring. The stations in Bologna and Modena, to which the reports of the last century refer, are no longer suitable to host the species. Other previous reports from the Romagna area were also verified in the field with negative results. The reasons for this result can be traced back to the scarcity of waterways in Emilia-Romagna with morphometric characteristics, water quality and aquatic and riparian vegetation, suitable for hosting the species. In various streams and streams there are pressure factors that reduce their suitability, such as, in order of importance: the presence of spring catchments with a reduction in flow or drying up of the stream, the abandonment of vegetation to free evolution with consequent excessive shading of the stream by shrubs and trees, the presence of civil, agricultural and industrial discharges which reduce the quality of the water, the presence of domestic animals in or close to the watercourses, the management of riparian vegetation with clear cuttings.] Address: Fabbri, R., Museo Civico di Storia Naturale, via De' Pisis, 24. 44100 Ferrara, Italy. **22131.** Fabbri, R. (2018): Aspetti della biologia, ecologia e stato di conservazione di *Coenagrion mercuriale castellanii* (Roberts, 1948) e *Graphoderus bilineatus* (De Geer, 1774). In: Azioni coordinate per la conservazione in Emilia-Romagna di *Osmoderma eremita* (Scopoli, 1763), *Rosalia alpina* (Linnaeus, 1758), *Coenagrion mercuriale castellanii* (Roberts, 1948), *Graphoderus bilineatus* (De Geer, 1774): 56-62. (in Italian) [Verbatim] (Google translate): *C. mercuriale castellanii* (Roberts, 1948): The Mercury damselfly is a small dragonfly with a length between 2.7 and 3.1 cm and a wingspan between 2.5 and 4.0 cm. The body is slender and bright blue with black markings. The specific term mercurial derives from the helmet shape of Mercury, god of Greco-Roman mythology, from the black design on the second abdominal segment. *C. mercuriale* is a species with a predominantly West-Mediterranean geography, present from the United Kingdom and Germany to Spain and North Africa. The species is considered to be divided into three subspecies: *C. mercuriale mercuriale* present in Central Europe, *C. mercuriale hermeticum* present in North Africa and *C. mercuriale castellanii* present in peninsular Italy and Sicily (Ferreira, 2016). In light of the knowledge known so far on its distribution, the taxon *C. mercuriale castellanii* present in Italy is considered by various authors to be an endemic subspecies, while others elevate it to the rank of good species (*C. castellanii*) (Roberts, 1948; Dijkstra & Lewington, 2006; Riservato et al., 2014b; Ferreira 2016). In Italy it is reported in

all peninsular regions from Emilia-Romagna to Calabria, with the exception of Abruzzo and Molise; in the continental sector, populations located in Piedmont and Liguria are known; it is also present in Sicily, while it is not reported in Sardinia (Riservato et al., 2014b). From the historical and recent data on the presence of the species in Emilia-Romagna it is possible to outline a fairly continuous original distribution of the species in the foothills, at least between Imola and the Rimini area. Currently the species is present only in three stations included in two sites: IT4070011 "Vena del Gesso Romagnola" and IT4090002 "Torriana, Montebello, Fiume Marecchia". The species is extremely selective in the choice of breeding habitat and is ecologically demanding. *C. mercuriale* is associated with running, slow, even cold waters, in particular streams, springs and resurgences, often of a karst nature, up to 750 m above sea level. The environmental characteristics that most influence the presence and density of populations are direct exposure to sunlight from the watercourse, the constant presence of water, the presence of perennial aquatic plants for spawning, foraging and shelter, the width and depth of the stream bank and the presence of a predominantly silty substrate (Harris, 2000; Strange, 1999; Purse, 2001; Purse, 2002; Rouquette & Thompson, 2006; Rouquette & Thompson, 2007; Purse & Thompson, 2009). The adult, rather sedentary, flies from April to August and September. During the breeding season the male does not show territorial behavior; he hooks up to the female in flight, then the pair lands on the vegetation. At the end of mating, the female looks for a suitable place for oviposition, often in the company of the male and releases the eggs in the floating or partially emerged vegetation, sometimes completely immersing herself in the water; eggs take two to six weeks to hatch and development is completed in about a year (Thompson et al., 2003). Generally the species occurs monovoltine, semivoltine in Great Britain (Purse & Thompson 2003), but sometimes in the southern part of its range, such as in Southern Italy and Algeria, it behaves as a bivoltine, with two annual generations and adult activity also in September (Conci & Nielsen 1956; Dijkstra & Lewington 2006; Mahdjoub et al., 2015). This behavior was confirmed during the field activities of the LIFE EREMITA project in the Rimini site IT4090002 "Torriana, Montebello, Fiume Marecchia", where the species is present. From the first week of September to the first week of October the species had a second generation, however with a reduced number of adult individuals, around 10% compared to the number of active specimens in spring-summer, therefore with a late summer release only partial. A possible explanation could be attributable to the extension of the summer season into the first part of autumn, with mild temperatures lasting until late October (Mahdjoub et al., 2015). This has also been observed in other easily identifiable species such as *Gryllus campestris*, which in recent years has exhibited autumnal activity (Fabbri, 2015). In the northernmost Romagna site IT4070011 "Vena del Gesso Romagnola", where the species is present but with small populations, a second generation has not been ascertained. The species is included in Annex II of the Habitats Directive 92/43/EEC. In Europe, according to the IUCN, *C. mercuriale* is close to threatened (NT) and has decreasing populations (Kalkman et al., 2010; Lorenzo-Carballeda et al., 2015). The species is also considered near threatened (NT) in the Italian IUCN Red List of Odonata (Riservato et al., 2014c). The conservation status of the species, in fact, at a national level is considered favorable (Riservato et al., 2014a), while in the northern sector of Northern Italy it is considered overall inadequate due to the population trend, worsening for numerous parameters, such as range, population, habitat and future prospects (Riservato et al., 2014a, 2014b, 2014c). Even in Emilia-Romagna the conservation

status of the taxon is inadequate and has been assessed as critically endangered (CR) in the regional Red List (Ag-nelli et al., 2010). There is a real risk at a regional level that the species could disappear within a few years. In fact, there are numerous threats affecting the regional metapopulation; among the main ones we can list: collection and excessive extraction of water from springs for various purposes, evolution of the vegetation succession with a dense tree-shrub cover which causes the closure and shading of water courses, intensive agriculture practices from which it derives water pollution due to the percolation of pesticides and agricultural fertilizers, reorganization of small watercourses, decrease in rainfall due to climate change (Hassall & Thompson, 2008), presence of exotic animals which profoundly alter hydrophytic vegetation (e.g. *Myocastor coypus* and *Procambarus clarkii*), disturbance by domestic animals in the riverbed (ducks, geese, poultry, etc.) and, last but not least, in general the isolation of the subpopulations present, often characterized by a low number of individuals, together with the limited dispersal capacity of the species (Riservato et al., 2014a)." **22135.** Theis, O. (2018): Etat des lieux du patrimoine naturel des marais communaux de Camon (Vallée de la Somme). *College Sciences et Technologies de l'Energie et de l'Environnement de la Cote Basque, Université de Pau et des Pays de l'Adour. Licence Professionnelle Métiers de la Protection et de la Gestion de l'Environnement. Option Biologie Appliquée aux Ecosystèmes Exploités: 54 pp.* (in French) ["The alkaline peat marshes located in the commune of Camon are marked by ancient and current uses. Today, many users share the communal marshes of Camon (hunting, fishing, recreation, grazing, poplar groves). The Conservatory of Natural Spaces is interested in this as part of its management of sites along the Somme Valley. In agreement with the town hall, an inventory was carried out in 2018 through naturalist surveys. Amphibians, birds, odonates [*Aeshna grandis*; *Anax imperator*; *Anax parthenope*; *Calopteryx splendens*; *Ceragrion tenellum*; *Coenagrion puella*; *Coenagrion pulchellum*; *Crocothemis erythraea*; *Enallagma cyathigerum*; *Erythromma najas*; *E. viridulum*; *Gomphus pulchellus*; *Ischnura elegans*; *Libellula fulva*; *L. quadrimaculata*; *Orthetrum cancellatum*; *Platycnemis pennipes*; *Pyrrhosoma nymphula*; *Sympetrum striolatum*], flora and vegetation were the subject of inventories. The data collected could then be processed in order to understand how this site works. Despite numerous ponds, the Camon marshes are home to a limited number of heritage animal species. Few waterbirds nest and the flocks of amphibians and odonates are depleted. The inhospitable banks as well as the lack of small bodies of water without fish could explain this phenomenon. Regarding the flora, numerous heritage species have been inventoried. However, the reduced size of the stations, sometimes limited to a single individual, show that these species risk disappearing if nothing is done, particularly against brush and invasive species whose stations are sometimes very large. The vegetation is quite diverse. However, dynamics of siltation, megaphorbia and brush as well as colonization by invasive species reflect a certain degree of environmental degradation. Successive human interventions such as the digging of ponds, the construction of roads or the connection of the ponds with the Somme have profoundly modified the appearance of the marsh. However, despite these pessimistic observations, the presence of numerous species and vegetation with heritage value shows the potential of this site. With a strengthening of current grazing and mowing practices as well as hydrological developments, the communal marshes of Camon could become a privileged site for the sustainable reception of a diverse heritage fauna and flora." **22140.** Crucitti, P.; Brocchieri, D.; Bubbico, F.; Castelluccio, P.; Cervoni, F.; Di Russo, E.; Emiliani, F.; Giardini, M.; Pulvirenti, E. (2019): Checklist di alcuni gruppi selezionati dell'entomofauna del Parco Naturale Archeologico dell'Inviolata (Guidonia Montecelio, Roma). *XLI contributo alio studio della biodiversità della Campagna Romana a nord-este di Roma. Boll. Soc. Entomol. Ital.* 151(2): 65-92. (in Italian, with English summary) ["Checklist of selected groups of Insects from the Inviolata Natural Archaeological Park (Guidonia Montecelio, Rome). The results of a systematic survey carried out during the years 2016-2019 on selected groups of Insects belonging to Odonata, Orthopteroidae, Dermaptera, Coleoptera, Lepidoptera, Isoptera and Mecoptera, inside the Inviolata Archaeological Natural Park (Rome, Latium), are presented and discussed. The main geomorphological, climatological and vegetational features of the studied area, are described. Sampling was carried out using different methods; manual pick up, traps, light sheets, monitoring of faeces, dead animals and aquatic vegetation. The inventory

is represented by 533 taxa belonging to 101 families, all of which characterized from phenological point of view.... 28 species out of 42 mentioned were recorded in the city of Rome delimited by the GRa (Utzeri & Dell'anna, 1997), 58 in Lazio and 93 in Italy (Riservato et al., 2014) (66.6%, 48.2 % and 30.1%, respectively) included in 18 genera of 7 families. thirteen species (11 genera of 4 families) are zygoptera, 15 species (8 genera of 3 families) are anisoptera. The Odonates of Inviolata were the subject of a specific contribution (Brocchieri et al., 2018), to which *Sympecma fusca* was added, observed in April 2019 at the 1st lake of Tor Mastorta (Fig. 7). Therefore, the total number of species recorded in the Roman countryside north-east of Rome amounts to 35, equal to 37.6% of the national total and 60.3% of the species known for Lazio (Brocchieri et al., 2014; Crucitti et al., 2016; Brocchieri et al., 2018). the analysis of the chorotypes allows us to note the clear dominance of elements with a wide distribution in the Holarctic region (20 species, 71.4%). The contingents of European origin (3 species, 10.7%), of Mediterranean origin (2 species, 7.2%) and of Afrotropical origin (3 species, 10.7%) are significantly lower." **22142.** Feng, Y.; Zhao, M.; Ding, W.F.; Chen, X.M.; (2019): Overview of edible insect resources and common species utilisation in China. *Journal of Insects as Food and Feed* 6(1): 13-25. ["The custom and culture of entomophagy in China has been preserved since ancient times, with a history going back at least 3,000 years. Presently, more than 300 species of insects with edible value have been taxonomically classified in China. These insect species belong to the orders Lepidoptera, Coleoptera, Hymenoptera, Orthoptera, Hemiptera, Isoptera, Odonata, Megaloptera, Ephemeroptera, Diptera and Blattaria, with a majority of these species belonging to Lepidoptera, Coleoptera and Hymenoptera. The most common include silkworm, tussah, Italian honeybee, oriental honeybee, mealworm, wasps, bamboo worm, locust, cicada, diving beetle and black ant. Since 2010, the number of patent applications for these edible insects has increased rapidly, indicating that the development and utilisation of edible insects in China is ongoing. The use of common edible insects primarily involves direct consumption of the insect body. In addition to fresh insects, frozen, canned and dried insects are also sold on the market. Derived extract products, such as protein, oil, chitin and insect health foods remain in the early research and experiment stages,

and the current production scale is small. Bees, silkworm, mealworm and oriental migratory locust come from artificial farming, as farming techniques for these insects are well-developed. Although wasps, sand-crawling insects, bean hawkmoths and bamboo worms have been artificially cultured, the necessary technologies are underdeveloped. The majority of edible insects generally accepted by the public are still primarily collected from nature. In view of the current situation of utilisation, some suggestions have been put forward to strengthen the investigation and evaluation of edible insect resources, and research to focus on utilisation methods and artificial rearing technology in China." **22143.** French, S.K.; McCauley, S.J. (2019): The movement responses of three libellulid dragonfly species to open and closed landscape cover. *Insect Conservation and Diversity* 12: 437-447. (in English) ["1. The land cover between habitats (i.e. matrix environment) can affect connectivity by impacting organismal movement. Many animals, however, have preferences for specific matrix environments, which can affect their movement through the landscape. 2. We examined how different terrestrial matrix environments impacted the fine-scale movement of adult dragonflies. Based on previous studies of adult dragonfly dispersal and larval distributions, we hypothesised that dragonflies would prefer to enter fields rather than forests and that forests would be a barrier to dragonfly movement, due to forests' structural complexity, low understory light availability, and lower air temperatures. 3. To test how adult dragonflies responded to various terrestrial environments, we released 108 *Leucorhinia intacta*, a mixture of 108 *Sympetrum rubicundulum* and *obtrusum/rubicundulum* hybrids, and 108 *Sympetrum vicinum*, at field-forest ecotones and assessed their preferences for fields or forests. Individual behavioural responses were recorded, including their probability of taking flight, their direction of movement with respect to the two matrix types, and flight time. 4. The likelihood of adult dragonflies taking flight was species-specific in response to release location. Adults moved more frequently towards fields than forests when released at a forest edge. Individuals released within forests had shorter flight times, but again this response was species-specific. 5. The presence of an open matrix (field or meadow) is likely important for facilitating movement in dragonflies; however, forests are not movement barriers for all dragonfly species. Integrating assays of matrix and habitat preferences can provide insight into how landscape connectivity can be maintained for actively dispersing species." **22144.** Helebrandová, J.; Pyszko, P.; Dolný, A. (2019): Behavioural phenotypic plasticity of submerged oviposition in damselflies (Insecta: Odonata). *Insects* 2019, 10(5), 124; <https://doi.org/10.3390/insects10050124>: 12 pp. (in English) ["*Lestes sponsa* is a common species within the temperate zone, with no special need for protection. The tactic of submerged oviposition is well known from other Odonata species, but has rarely been noticed or described in *Lestes sponsa*. Our study investigated the tactics of oviposition in this species, and shows that submerged oviposition indeed occurs frequently in *Lestes sponsa*. We experimentally tested the difference in the roles of males and females during the

submerged ovipositional behaviour by combining males/females from submerging populations with males/females from non-submerging populations. We discovered that, whereas submerging males coupling with non-submerging females did not lead to submersion, the opposite combination of pairs submerged. Other patterns of submersions are discussed further in this paper. Our research led to the conclusion that damselflies have the ability to learn and react to different situations in keeping with the learning potential of insects in general." **22145.** Henze, M.J.; Lind, O.; Wilts, B.D.; Kelber, A. (2019): Pterin-pigmented nanospheres create the colours of the polymorphic damselfly *Ischnura elegans*. *Journal of the Royal Society of Interface* 16: 20180785. <http://dx.doi.org/10.1098/rsif.2018.0785>: 11 pp. (in English) ["Animal colours commonly act as signals for mates or predators. In many damselfly species, both sexes go through a developmental colour change as adults, and females often show colour polymorphism, which may have a function in mate choice, avoidance of mating harassment and camouflage. In the blue-tailed damselfly, *Ischnura elegans*, young males are bright green and turn blue as they reach maturity. Females are red (rufescens) or violet (violacea) as immatures and, when mature, either mimic the blue colour of the males (androchrome), or acquire an inconspicuous olive-green (infuscans) or olive-brown (obsoleta). The genetic basis of these differences is still unknown. Here, we quantify the colour development of all morphs of *I. elegans* and investigate colour formation by combining anatomical data and reflectance spectra with optical finite-difference time-domain simulations. While the coloration primarily arises from a disordered assembly of nanospheres in the epidermis, morph-dependent changes result from adjustments in the composition of pterin pigments within the nanospheres, and from associated shifts in optical density. Other pigments fine-tune hue and brilliance by absorbing stray light. These mechanisms produce an impressive palette of colours and offer guidance for genetic studies on the evolution of colour polymorphism and visual communication." **22146.** Ilhamdi, M.L.; Idrus, A.A.; Santoso, D. (2019): Kekayaan jenis capung di Taman Wisata Alam (TWA) Suranadi Sebagai Bahan penyusunan buku suplemen ipa [The richness of dragonfly species in the Suranadi Nature Tourism Park (TWA) as material for preparing science supplement books]. *Prosiding Seminar Nasional SIMBIOSIS IV, Madiun, 15 Agustus 2019*. p-ISSN: 9772599121008 e-ISSN: 9772613950003: 8-14. (in Indonesian) ["The aim of this research is to determine the richness of dragonfly species in TWA Suranadi as material for preparing science supplement books. The research method uses a roaming method following an observation transect route which consists of 4 routes, namely the left edge of the forest, the middle route, the right edge of the forest and the river water route. Dragonflies were observed using binoculars and dragonflies that had not been identified were captured using insect nets and identified in the FKIP Unram biology laboratory. The research results showed that the number of dragonfly species found was 19 species. The species most commonly found is *Pantala flavescens*, the least common is the species *Gynacantha manderica*. The species found were used as material for a science supplement book with a 10-step preparation procedure ... Conclusion: Based on

the research results, it can be concluded that (1) the Odonata found in the Suranadi Natural Tourism Park area consist of 19 species belonging to 5 families with a total of 530 individuals. (2) The highest relative abundance was found in *Orthetrum sabina* (40.25%), followed respectively by *Pseudagrion pilidorsum* (23.50%), *Diplacodes trivialis* (17.75%), *Orthetrum chrysis* (13.25%), *P. pruinatum* (8.75%), *Agriocnemis femina* (8%), *Neurothemis ramburii* (6.75%), *Pantala flavescens* (4.25%), *Aethriamanta brevipennis* (3.50%), *Copera marginipes* (2.25%), *Euphaea ochracea* (1.50%), *Lathrecista asiatica* (1.25%), *Libellago rufescens* (1.25%), *Neurothemis terminata* (1%), *Tholymis tillarga* (1%), *Trithemis furva* (0.50%), *Libellago lineata* (0.50%), *Potamarcha congener* (0.50%) and *Onychothemis culminicola* (0.25%). 3) The richness of species found in TWA Suranadi can be used as material for preparing a contextual science supplement book through 10 steps in its preparation." **22148.** Kosterin, O.E. (2019): New synonyms and a new subspecies of *Macrogomphus Selys, 1858* (Odonata: Gomphidae) from continental south-east Asia. *Zootaxa* 4615(1): 57-90. (in English) ["The taxa of the genus *Macrogomphus Selys, 1858* occurring in continental south-east Asia are reconsidered. *Macrogomphus rivularis* Förster, 1914 (described from Vietnam), *M. borikhanensis* Fraser, 1933 (described from Laos), and *M. guilinensis* Chao, 1983 (described from China), are synonymised with *M. albardae* Selys, 1878. The relationship and conspecificity of the latter with *M. parallelogramma* Burmeister, 1839 are doubtful, perhaps they are bona species. Males of *M. albardae* (and seemingly of *parallelogramma* as well) are approximately trimorphic for the pale pattern of the abdominal S3–S6, being of either a 'dashed morph' (with small isolated anteriolateral spots and conspicuous middorsal streaks), or a 'ringed morph' (with broad anterior rings and less conspicuous middorsal streaks), or an 'intermediate morph'. Validity of the species *M. matsukii* Asahina, 1986 is doubted; its holotype could be an aberrant male of *M. albardae*. The main diagnostic character of *M. albardae*, *M. phalantus* Lieftinck, 1935 and probably *M. parallelogramma*, is clarified to be the structure of the cercus inner branch. *M. phalantus jayavarman* subsp. nov. is described from temporarily inundated forest at the northern bank of the great Lake Tonlé Sap of Cambodia (Siem Reap Province, 1.5 km SSW of Kampong Pluk village, 13.1956° N, 103.9725° E, 3 m a.s.l.), which is ca 1,300 km north and overseas from the presumed range of *M. phalantus phalantus*." O. (2019): Acute toxicity of four metals to three tropical aquatic invertebrates: The dragonfly *Tramea cophysa* and the ostracode *Chlamydotheca* sp. and *Strandesia trispinosa*. *Ecotoxicology and Environmental Safety* 180: 535-541. (in English) ["Highlights: •Acute toxicity data of metals for three species from Neotropical regions are presented. •*Chlamydotheca* sp. was more sensitive to  $\text{CuSO}_4$  than *T. cophysa* and *S. trispinosa*. •Ostracoda species were more sensitive to  $\text{CdCl}_2$  than species from temperate regions. •*S. trispinosa* was the most sensitive Neotropical native ostracod species to  $\text{HgCl}_2$ . Abstract: The relatively low availability of toxicity data for indigenous tropical species has often been discussed. In addition, several taxonomic groups of invertebrates are understudied, such as dragonflies and ostracods. The aim of the present study was therefore to evaluate the acute toxicity of four metals (cadmium, Cd, copper, Cu, manganese, Mn, and mercury, Hg) to the tropical dragonfly nymphs of *T. cophysa* and two tropical ostracod species (*Chlamydotheca* sp. and *Strandesia trispinosa*). Toxicity data for other invertebrates were also mined to allow comparing the sensitivity of the three test species with that of other (temperate and tropical) invertebrates. The order of metal sensitivity was different for the three test species: *T. cophysa*:  $\text{Cu} > \text{Cd} > \text{Hg} > \text{Mn}$ , *Chlamydotheca* sp.:  $\text{Cd} > \text{Cu} > \text{Hg} > \text{Mn}$ , and *S. trispinosa*:  $\text{Cd} > \text{Hg} > \text{Cu} > \text{Mn}$ . However, manganese was the least toxic metal tested for all three species, which is hypothesized to be due to a possible metal transfer to the cuticle of the moulting test species. The sensitivity ranking of the three test species to the metals was *S. trispinosa* > *Chlamydotheca* sp. > *T. cophysa* (except for Cu for which the ranking was *Chlamydotheca* sp. > *T. cophysa* > *S. trispinosa*). Overall, the test species are concluded to be suitable test organisms for tropical toxicity evaluations. Future studies should also evaluate the chronic toxicity and include other important metal exposure routes such as sediment and food." **22150.** Liu, H.; He, G.; Wang, Q. (2019): Numerical study on the aerodynamic performance of the flexible and corrugated forewing of dragonfly in gliding flight. *Chinese Journal of Theoretical and Applied Mechanics* 51(1): 94-102. (in Chinese, with English summary) ["Dragonflies are capable of carrying out dramatic flight manoeuvres, gliding flight is a common mode of flight for dragonfly, and dragonfly wings are the source of dragonflies dramatic flight manoeuvres. Unlike typical engineered airfoil, dragonfly wings are not smooth, wing cross-section are highly corrugated. It has been shown that corrugations could enhance the spanwise stiffness in the wings and influence aerodynamic performance of the dragonfly wings. Flexibility is another characteristic of the dragonfly's wings, which is mainly manifested as the flexible deformation of the wings during the flight. To explore corrugations and flexibility effect on aerodynamic performance of the dragonfly forewings in gliding flight, a computational fluid dynamics (CFD) model and a computational structural mechanics (CSD) model of the corrugated dragonfly forewing are established based on current research, and the modal analysis verified that the model has sufficient accuracy. The corrugated rigid and flexible dragonfly forewing are acquired by using CFD method and CFD/CSD coupling method respectively. The simulation indicated that flexible and corrugated forewings is subjected to aerodynamic load, which only produces bending deformation without torsion deformation in gliding flight, and the aerodynamic response

time is short. Compared with the aerodynamic performance of the rigid and corrugated forewings, the result showed that veins and cuticular membrane of flexible forewing are deformed which caused the lift coefficient and drag coefficient decrease, the leading edge vortex of flexible forewing is much higher than rigid forewings at large angle of attack because of deformed vein. The aerodynamic performance of rigid forewings is better below 10 degree angle of attack, and the aerodynamic performance of flexible forewings is better at large angle of attack as result." **22152.** Mendes, T.P.; Benone, N.L.; Juen, L. (2019): To what extent can oil palm plantations in the Amazon support assemblages of Odonata larvae? *Insect Conservation and Diversity* 12: 448-458. (in English) ["1. The aims of the study were to identify differences in alpha and beta diversity of Odonata larvae of the suborders Zygoptera and Anisoptera found between continuous forest sites (forest) and oil palm sites with forested buffers (oil palm), and to evaluate the extent of turnover and nestedness of communities within each habitat type. 2. 29 streams were sampled, 11 in forests and 18 in oil palm sites in the eastern Amazon. Alpha diversity of Zygoptera and Anisoptera was higher in streams at oil palm sites. Variation in species composition measured by beta diversity is primarily structured by turnover. Biotic heterogeneity of Zygoptera was higher in oil palm sites, while no difference was found in Anisoptera. 3. Forested streams had more wood in the streambed, whereas oil palm sites had finer sediment, higher non-agricultural human impact, water temperature, and road proximity index. Anisoptera turnover was positively correlated with water temperature and amount of wood in the streambed; Zygoptera turnover was positively correlated with non-agricultural human impact. 4. The patterns observed in Zygoptera can be attributed to the presence of forested buffers, which may have influenced the selection of foraging sites by adults and determined larval distribution. 5. We conclude that oil palm plantations can change the environmental structure of streams and influence genus richness and turnover in Amazon streams. These results might help explain changes caused by oil palm plantations on Anisoptera and Zygoptera assemblages." **22153.** Minoti, M.; Le Gall, M.; Husté, A. (2019): Biometry of the large dragonfly *Anax imperator* (Odonata: Aeshnidae): A study of traits from larval development to adults. *Eur. J. Entomol.* 116: 269-280. (in English) ["Insect larval development affects adult traits but the biometric relationships are usually poorly understood, including large odonates. In this study, measurements of morphological traits of larvae, exuviae and adults of *Anax imperator* were recorded. They were used to investigate the effects of early development on adult morphology. Results showed an increase in larval length during the final instar and the length of its exuviae significantly exceeded that of the larva. Length and body mass of teneral adults were strongly related to the length of their exuviae. Adult males were significantly longer than adult females, while both had the same body mass at emergence. Length of teneral adults was negatively related to the date of emergence in both sexes. During maturation, body mass of males only increased slightly whereas that of females increased greatly. Mature specimens were also significantly longer than teneral individuals. Body mass of mature males and length of mature females were both associated with the date of capture. Wing length did not differ between sexes or from data available from Great Britain. This study underscores the importance of taking into account larval growth in order to better understand the adult traits of odonates." (Authors)] Address: Minoti, M., Université de Rouen. ECO-DIV, Bat Blondel, Place Emile Blondel, Mont-Saint-Aignan 76821, France. E-mail: marceau.minot1@univ-rouen.fr,

**22154.** Mokaria, K.; Jethva, B. (2019): Evaluation of community composition of dragonflies and damselflies (Order: Odonata) in Nalsarovar Bird Sanctuary, Gujarat, India. *International Journal of Research and Analytical Reviews* 6(2): 474-479. (in English) ["A study was carried out in Nalsarovar Bird Sanctuary to evaluate community composition of odonates in Nalsarovar Bird Sanctuary (Ramsar Site), Gujarat. Transects survey was carried out at Nalsarovar Bird Sanctuary covering all habitats. Each transect was repeatedly surveyed in all seasons. A total of 30 species of Odonata were encountered belonging to Libellulidae, Gomphidae, Aeshnidae, Coenagrionidae, and Lestidae during the entire study. During the study, percentage frequency of occurrence, abundance and density of odonates were calculated based on data collected to evaluate community composition of Odonata in Nalsarovar Bird Sanctuary. During the entire survey, the percentage frequency of occurrence of *Brachythemis contaminata*, *Pantala flavescens* and *Trithemis pallidinervis* were recorded highest. The most abundant species encountered were *Pantala flavescens* followed by *Trithemis pallidinervis*, *Brachythemis contaminata*, *Ischnura aurora* and *I. senegalensis* respectively among all species encountered during the survey. However, the density of *Trithemis pallidinervis* were highest which was further followed by *Pantala flavescens* and *Brachythemis contaminata*, *Ischnura senegalensis* and *Ischnura aurora* respectively during the entire survey. This study can be used as a benchmark for future conservation and monitoring of Odonates in state and similar wetland worldwide." (Authors)] Address: Mokaria, K., Dept of Science, The Mahatma Jyoti Rao Phoole Univ., Jaipur, Rajasthan

**22155.** Moore, M.P. (2019): Eco-physiological causes and consequences of sexually selected color variation in dragonflies. Doctor of Philosophy, Case Western Reserve University, Biology: 246 pp. (in English) ["Many animals use elaborate adult traits to attract mates and intimidate rivals. However, the development of these sexually selected traits, and the reproductive interactions that confer their benefits,

occur against a complex backdrop of environmental factors. When such features of the habitat modify the costs and benefits of displaying and developing these traits, environmental variation across space and time can shape their diversification. Likewise, sexual selection on these characters may have consequences for how organisms interact with and adapt to different ecological contexts. Here, I explore these themes by investigating the interplay between sexually selected coloration, the external environment, and physiology in dragonflies. I begin by examining the adaptive function of wing pigmentation in *Pachydiplax longipennis*, finding that this trait is intrasexually selected. Using this dragonfly system, I then document how interactions between the environment and an organism's physiological state can drive the divergence in its sexually selected wing coloration. I first show that thermal physiology causes the performance benefits of wing coloration to depend on ambient temperature, and, as a result, males in the warmest parts of North America nearly lack this trait all together. I next illustrate how improving an individual's physiological condition to develop better sexually selected coloration can harm its juvenile survival in the presence of predators. I then consider how sexual selection could feed back to influence ecological adaptation by examining links between wing coloration and immune defense. I find that, in addition to several important ecological costs of deploying immune defenses during the larval stage (e.g. predation vulnerability, delayed emergence), producing a strong immune response directly inhibits wing color development. Moreover, when comparing across species, I show that those species with more wing coloration tend to have weaker immune responses. Thus, due to proximate trade-offs with immune defense, sexual selection on wing coloration can slow ecological adaptation, or even potentially drive maladaptation, to parasites and pathogens. Overall, this work demonstrates how eco-physiology may be an important nexus for the ecological causes and consequences of sexually selected trait variation." **22156.** Paulson, D. (2019): *Dragonflies & Damselflies*. A natural history. Princeton University Press. Princeton and Oxford: 224 pp. (in English) ["Dragonflies and damselflies are large, colorful, active, and visible in daylight hours, so along with butterflies they have always been among the most popular insects. They are a diverse group, the order Odonata, with 6,308 described species at present, occurring on all continents but Antarctica and all islands large enough to contain fresh water. This book is about them. There are two major groups of Odonata: dragonflies and damselflies. There is potential for confusion, as "dragonfly" in some English-speaking countries is used for both groups but in others for just one group (the "true dragonflies," suborder Anisoptera). Therefore, in this book "dragonflies" will be used when referring to the Anisoptera, "damselflies" to the other suborder, Zygoptera, and odonates when referring to all of them. It should also be noted that odonate larvae are also commonly called "nymphs" and less commonly "naiads." Almost all odonates are tied to freshwater habitats, where their larvae live, although the adults roam far and wide. Along with butterflies, they are the largest insects seen by most of us. There are no microscopic species and many that are impressively large. They are typical insects, with six legs and two pairs of wings. They lay eggs, which hatch into larvae, which grow and molt and eventually make a final molt from the larval stage to the adult stage. Odonates are carnivores throughout their lives. Although they are active predators, they are thought to eat no more than about 15 percent of their body weight in

a day; they are certainly slim and trim. Both adults and larvae fit into the food web between the smaller insects and other arthropods that are their primary prey and the birds, many of which eat odonates. They are eaten by some species in all the other vertebrate groups (fishes, amphibians, reptiles, and mammals) as well. The web is complex, though; large larvae eat fish and tadpoles and an adult may take a hummingbird. They are also eaten by other insect predators and, of course, each other. Other than the mosquitoes and other biting flies that they eat, Odonata have been of little economic significance to people. They are of great aesthetic significance, however, with their dazzling colors and aerial acrobatics enthralling anyone who stops for a moment at a wetland. This same charisma has made them favorite, almost iconic, animals of artists and designers of all sorts. Their characteristic outline can be seen on an impressive variety of jewelry, pottery, metalware, and clothing. Dragonfly is a popular brand name, with Dragonfly businesses in many large cities in English-speaking countries—everything from pubs to travel agencies, book stores to beauty parlors. There are novels with Dragonfly and Odonata in their titles. There is a musical group named Dragonfly, and more than 30 other musical groups have produced albums with the title Dragonfly. Damselfly clearly does not have the same cachet; that name is used only rarely. Because odonates are such large and prominent and easily studied insects, they have also long piqued the interest of biologists, and they are of great significance to science. Their adaptations for vision, flight, display, mating, and larval life are unique and lend themselves to speculation, theorization, observation, and experimentation. The resulting research has given us invaluable insights into nature, from freshwater ecology, competition, and predation to mating strategies, metamorphosis, and migration. One of the most interesting aspects of the Odonata, revealed again and again with close study, is the diversity of their adaptations. They very often have more than one morphological or behavioral way to accomplish a particular goal, and learning of these variations has given us an ever-growing appreciation of the special nature of these insects. But beyond this, odonates have caught the attention of amateur naturalists everywhere. Acting as citizen scientists, these dedicated amateurs are in the field day after day documenting populations of these animals by collection, observation, and photography, and often entering their data into ever-growing online databases of greater and greater value as the record of the current status of the group. This book embarks on a journey through the Odonata, peering into every aspect of the lives of these complex animals. In the first chapter, we learn about the evolutionary background of one of the oldest insect groups. When did they first appear? How much have they changed? What do they look like now? Where do they live? To understand their lives, we must know something about their variation in size, structure, and coloration. But it is their behavior that is especially interesting, and the second chapter elaborates on their predatory behavior: what they eat and how they capture prey, what eats them, and how they avoid their predators. Their superb vision and unsurpassed flight abilities are what makes them both great predators and challenging prey, and those aspects of being an odonate will be emphasized throughout the book. The third chapter delves into odonate reproductive biology. The complexity of their sex lives is notoriously interesting to biologists, as odonate reproduction contains behaviors found nowhere else in the animal kingdom. There are many dichotomies in odonate sexual behavior: elegant courtship or quick sex, copulating in flight or at rest, mating very briefly or taking inordinate time, laying eggs in or out of plants, ovipositing in flight or at rest,

and other ways in which they vary a surprising amount. Odonates are above all adaptable, their facultative behavior having allowed them to survive so well into the present. In the fourth chapter we see what goes on underwater during their extended larval life, as they are as much aquatic as they are aerial. Species breed in still or running waters, from large lakes and rivers to tiny seeps and puddles, and even containers of water well above the ground. The larvae are streamlined for fast swimming or flattened to hide among bottom detritus. They detect their prey by sight or by touch. Their emergence from the water and from their larval skin is one of the miniature spectacles of nature. What do people have to do with odonates? That is the subject of the fifth chapter. Dragonflies have sinister reputations in some cultures and are greatly admired in others. They are wonderful organisms for research and education, and they are common in representational art, both two- and three-dimensional. Although they may be more resilient to extirpation than many other freshwater organisms, their populations are still being threatened worldwide, and strong efforts are being made and must continue to be made to preserve the wetlands that they need for life. Finally, we would be surprised if there was not a great amount of diversity in a group with more than 6,000 species, and indeed there is. The sixth chapter explains a bit about how this diversity has come about and in addition presents the broad diversity of the group by featuring an introduction to the 39 families that make up the order Odonata. But it is the species themselves, the endpoints of evolution, that are really the representatives of the Odonata that we all encounter. The book features profiles of 55 of them, appending the first five chapters. For each species, the family name, average total length of males, distribution, and habitat are indicated. The species accounts are often used to make points about odonate biology not covered elsewhere in the text. After the main text, there is an extensive glossary that explains the unfamiliar terms presented about these insects, followed by lists of books and further resources, especially websites, to learn still more about them." **22157.** Peterson, T. (2019): Trollsländor på Lidingö. Resultat av 20 års inventering. Contracting authority: Lidingö City, Environment and City Planning Office: 80 pp. (in Swedish, with English summary) [Dragonflies on Lidingö. Results of 20 years of inventory: "During 20 years of study terminated in and including 2018, 33 species of dragonflies [Insecta: Odonata] are reported from the island of Lidingö, including the archipelagos of Björkskär and Lilla Nassa, of the 52 species known from the province of Uppland. This information is collected in a data base comprising 2489 observations including imagos, aquatic larvae and exuviae. In the general part the natural history, biology, ecology, systematics and interaction with humans, nature protection, possible future species on Lidingö as well as recent observations of species is briefly presented. In the specific part the species are presented with scientific names and popular names in nordic languages and in English and German together with distribution maps covering Lidingö, Sweden and Europe. Size, key characters, similar species and frequency as well as observed flying period on Lidingö is briefly presented. The general part and the species part is illustrated with photos showing different aspects of dragonfly behaviour and different species characters. 3 species of the 33 reported are not approved in this study for reasons justified in the species headings in page 72. In three appendices a synopsis of known species of dragonflies from Lidingö is compared with the

neighbouring municipalities of Stockholm, Danderyd, Vaxholm and Nacka; a list of dragonfly species from European countries and the red list criteria of IUCN widely used in a national and international level. 10 of the species of dragonflies extant on Lidingö are nominated by Linnaeus 1758." **22158.** Roberts, D.; Al-Alawi, N.; Al-Gharibi, M. (2019): Effect of alarm chemicals and predator kairomones on the behaviour of two species of mosquito larvae. *Sultan Qaboos University Journal for Science* 24(1): 18-22. ["Mosquito larvae have developed a variety of responses to reduce the risk of predation, but this requires them to be able to identify the different species of predators and respond accordingly. We investigated the behavioural response of two mosquito species to three chemical signals: kairomones from two predators, and also to alarm semiochemicals from killed mosquito larvae. *Culex perexiguus* mosquito larvae are primarily surface filter-feeders. In response to all three chemical signals, they significantly reduced feeding by the high-risk active bottom scraping of biofilms in favour of the less active (and so lower predator-detection risk) surface filter feeding. Active escape swimming (instead of feeding) also increased for all three signals, but was much less for dragonfly nymph kairomones. Dragonflies are almost entirely bottom feeders and so are a much lower danger to surface feeding mosquitoes compared with damselfly nymphs, which feed at all depths. *Culiseta longiareolata* mosquito larvae normally have a high level of bottom-feeding. This was significantly reduced to all three chemical signals, but escape swimming only occurred for dragonfly kairomones (which are natural predators for the bottom-feeding larvae)." **22160.** Schultz, B.; Koprivnikar, J. (2019): Free-living parasite infectious stages promote zooplankton abundance under the risk of predation. *Oecologia* 191(4): 411-420. (in English) ["Free-living parasite infectious stages, such as the cercariae of trematodes (flatworms), can represent substantial biomass in aquatic ecosystems, yet their interactions with other planktonic fauna are poorly understood. Given that cercariae are consumed by various aquatic predators, sometimes even preferentially over zooplankton, their presence may decrease predation pressure on free-living organisms within similar trophic niches by serving as alternate prey. Here, we experimentally examined how the presence of cercariae (*Plagiorchis* sp.) affected the population dynamics of common freshwater zooplankton (*Daphnia* sp.) in the

presence of a predator (the larval dragonfly, *Leucorrhinia intacta*) known to consume both. After seeding 48 mesocosms with starting populations of *Daphnia*, we used four treatments (12 replicates each) representing a factorial combination of the absence/presence of both cercariae and dragonfly larvae and tracked *Daphnia* populations over 4 weeks. We found a significant interaction between the presence of cercariae and predators on *Daphnia* population size. When faced with predation pressure, *Daphnia* reached ~50% higher numbers when accompanied by cercariae than without, suggesting a "protective" effect of the latter by acting as substitute prey. Within aquatic ecosystems, an abundance of trematodes may prove advantageous for zooplankton communities that share common predators, but further studies will be needed to determine how this varies depending on the predator, trematode, and zooplankton taxa involved." **22161.** Shanmugam, A.R.; Sohn, C.H. (2019): Numerical investigation of the aerodynamic benefits of wing-wing interactions in a dragonfly-like flapping wing. *Journal of Mechanical Science and Technology* 33(6): 2725-2735. ["Numerical simulations are performed to investigate the aerodynamic benefits of wing-wing interactions on a dragonfly-like flapping wing while hovering, at a value of Reynolds number  $Re$  set to 630. The local phase shift  $\psi$  and wing spacing  $L^*$  ( $L/c$ ) are varied to observe their influence on aerodynamic performance. The results show that the aerodynamic benefits due to interactions are strongly dependent on both  $\psi$  and  $L^*$ . The wing-wing interactions are beneficial for the in-phase stroking pattern at  $\psi = 0^\circ$  when  $1.2 \leq L^* \leq 2.3$ , while it is extremely detrimental for the counter stroking pattern at  $\psi = 180^\circ$  when  $1.2 \leq L^* \leq 2.3$ ; these benefits and drawbacks are dependent on the timing of the interactions. The best case, when  $\psi = 0^\circ$  and  $L^* = 2.1$ , can increase the time-averaged vertical force coefficient  $C_v$  up to ~10 % in comparison to the without-interaction case. Two unsteady flow features namely the "enhanced dipole structure" and the "in-sync of wake capture and wing-wing interactions" are observed that increase the vertical force generation in hovering dragonflies. The overall downward momentum imparted by the wing is larger for  $\psi = 0^\circ$  in comparison to  $\psi = 180^\circ$  as the wake has high vertical velocities due to the constructive role played by wing-wing interactions." (Authors)] Address: Shanmugam, A.R., School of Mechanical Engineering, Kyungpook National Univ., Daegu, Korea

**22162.** Soldati Lacerda, D.S.; Machado, A.B.M. (2019): The damselfly genus *Mecistogaster* (Odonata: Pseudostigmatidae) from the Brazilian Atlantic Forest with a description of three new species and a neotype designation for *M. amalia* (Burmeister, 1839). *Zootaxa* 4668(2): 207-228. (in English) ["*Mecistogaster* Rambur, 1842 is a genus of Pseudostigmatidae with five species distributed from Mexico to Argentina. Four of these occur in Brazil, two of which were recorded on the Atlantic Forest, *M. amalia* (Burmeister, 1839) and *M. linearis* (Fabricius, 1776). After examining 140 specimens of *Mecistogaster amalia* it was possible to conclude that it is a complex of species and three new species are described, *M. kesselringi* sp. nov., *M. mielkei* sp. nov. and *M. nordestina* sp. nov. The males differ from each other mainly by the presence or absence of alula, the area occupied by the reddish-brown color of the mesepimeron and penis structure. The females differ mainly by the region occupied for the pale apical area of wing and epiproct shape. The problem of Burmeister's type of *M. amalia* is discussed and a

neotype is erected for it. Distribution and phenology data are provided. A key for males recorded from Brazilian Atlantic Forest is presented." **22163.** Strobl, K. (2019): Evaluating restoration success of rewetted peatlands: Recovery potential, temporal dynamics and comparison of monitoring approaches. PhD thesis, Fakultät Wissenschaftszentrum Weihenstephan für Ernährung, Landnutzung und Umwelt der Technischen Universität München: 79 pp. (in English, with Germany summary) [Bavaria, Germany "Ecological restoration has great potential for counteracting global losses in biodiversity and ecosystem functioning caused by unsustainable human land use. It aims at assisting the recovery of degraded ecosystems. Many restoration projects focus on peatlands, because of the significance of these ecosystems for adaptation and mitigation of climate change. Intact peatlands provide important ecosystem services like storage of water and carbon, and offer habitats for rare and endangered species, while they are highly threatened by drainage, peat extraction and afforestation. Peatland restoration supports biodiversity and ecosystem functions by creating near-natural habitat conditions, mostly through rewetting. While most meta-analyses report an incomplete short-term recovery of restored ecosystems, their longterm dynamics remain largely unknown. Peatland recovery is commonly monitored shortly after restoration, but peatlands develop slowly and initial trends may not continue. Moreover, restored peatlands are expected to provide multiple ecosystem services. This makes their assessment and evaluation of success challenging and requires novel monitoring approaches. Thus, the goals of this thesis are (1) to contribute to the scientific understanding of peatland recovery and its temporal dynamics, and (2) to improve monitoring indicators and analytical methods. For this purpose, I established a chronosequence of 18 years after rewetting in 14 peatlands in a mountainous region in Central Germany comparing three drained, 19 restored and one near-natural peatland transect. Peatlands in the study region had been previously drained and afforested, and from 1998 onwards were rewetted by damming, filling of drainage ditches and removing of trees. For monitoring several ecosystem properties (i.e. water table, peat decomposition, water holding capacity, nutrient level) and characteristic peatland biodiversity (plants, dragonflies and butterflies) were assessed. I also set up a field experiment on phytometer plants in seven restored peatlands and an associated greenhouse experiment. In the first article of the PhD thesis, temporal trends of plant, dragonfly and butterfly diversity were analysed and related to restored habitat conditions. It showed that, rewetting improved habitat conditions, vegetation structure and species diversity. Plants and dragonflies benefitted most from rewetting, while no specialized butterfly species were found within two decades after rewetting, and also generalists increased only temporarily. This is most likely due to poor regional connectivity of the (restored) peatlands. Dragonflies colonized immediately, once suitable bog pools were present in restored sites. Plants more slowly developed towards reference conditions, and mostly depended on undegraded peat with a high water holding capacity. These findings suggest, that recovery is not complete after 18 years and that the three species groups are complementary indicators for restored peatlands. The second article studied the responses of three characteristic

peatland plants (*Drosera rotundifolia*, *Eriophorum vaginatum*, *Vaccinium oxycoccos*) to restored environmental conditions by measuring various fitness traits in two phytometer experiments. While all three species are indicators for intact peatlands, their responses to rewetting were species-specific. *E. vaginatum* performed best, since all individuals survived under field conditions. The development of *D. rotundifolia* and *V. oxycoccos* was less successful, but also those species locally found suitable habitat conditions. These results highlight that local site limitation occurs, but also point at dispersal limitation. Among all measured fitness traits, many growth traits were partly redundant, and survival provided the most conclusive results for species adapted to stressful habitats. Generally, the most suitable fitness trait depends on the growth form of the respective species. The third article analyses the simultaneous recovery of multiple peatland properties with time since restoration using different multifunctionality approaches. As a reference, an optimum level was defined as the mean of the eleven highest values, while the intact peatland was excluded from the analysis. Nine out of 13 studied properties as well as the combined index significantly improved with time since restoration. Most important changes were observed within the first five years, inside the rewetted ditches, and at low or intermediate levels of functioning. A simultaneous recovery of multiple properties at high levels of functioning was not observed. These results highlight, that heavily degraded peatlands show considerable improvements in the first years after restoration, while they cannot fully recover within two decades. The general discussion compares the main findings in order to derive overall conclusions and recommendations for future monitoring and peatland management. New approaches like the use of phytometers or multifunctionality approaches are promising, but differ in their degree of comprehensiveness and explanatory power and therefore need to be carefully selected according to project goals. Indicators (ecosystem properties, taxonomic groups, species traits) differ in their response to the same treatment and therefore have to be thoroughly chosen. Restored peatlands need to be surveyed even longer than two decades in order to understand if full recovery is possible. Finally, additional management measures (dam reinforcement, repeated tree removal, improved connectivity, species introduction) should be further explored in order to advance peatland restoration to its best.] Address: <https://mediatum.ub.tum.de/doc/1484-578/1484578.pdf>

**22169.** Buczyński P.; Bojar, P.; Buczyńska, E.; Góral, N.; Tańczuk, A.; Tarkowski, A. (2020): Dragonflies (Odonata) of the Nowiny Nature Reserve (Roztocze Upland, south-eastern Poland). *Rocznik Muzeum Górnosląkiego w Bytomiu Przyroda* 26(online 012): 1-14. (in Polish, with English summary) ["In 2020 the fauna of dragonflies was studied in the Nowiny Nature Reserve comprising of 5 midforest land depressions with strongly hydrated transitional and raised bogs, some with water bodies. 33 species were recorded (46% of the national fauna), 29 of which were autochthonous or probably autochthonous. In these depressions, 14 to 24 species were recorded. The fauna was dominated by stenotopic species of peat bogs and eurytopic species. Moreover, individual species indicating the drying process of some of the sites (*Lestes dryas*) as well as instability of assemblages (*Libellula depressa*) were recorded. A limnophilous species *Anax parthenope* was recorded on the site with the largest water body (0.27 ha). In the summer, the high number and high breeding activity of thermophilous *Aeshna affinis* were observed. In general, the Nowiny Nature Reserve is an important area for the protection of peat bog fauna because of the odonate assemblages and the occurrence of such species as *Aeshna subarctica* and *Somatochlora arctica*. However, the absence of some expected species (e.g. *Aeshna juncea* and *Leucorrhinia dubia*), low number of some specialists (e.g. *Leucorrhinia rubicunda*) as well as intensive colonization of the researched area by *Aeshna affinis* may suggest the change of its fauna. It is not resulted from the degradation of habitats, but rather from the climate warming which is unfavourable for Siberian dragonflies *sensu* St. Quentin (1960) and favourable for thermophilic ones. Probably in the southern part of Poland, stronger decline of species from the first group is in progress with the simultaneous expansion of species from the second one. These two processes involve not only geographical ranges, but also extending the habitat base. It may intensify the problem with protection of typhobionts and typhophiles, a part of which is already endangered." **22171.** Grill, M. (2020): Vorkommen und Lebensräume der Quelljungfern (*Cordulegaster* spp.) im Inneren Salzkammergut. Diplomarbeit, Karl-Franzens-Universität Graz: 81 pp. (in German, with English summary) ["Occurrence and habitats of the dragonfly genus *Cordulegaster* spp. (Insecta: Odonata) in the Inner Salzkammergut. The occurrence and habitats of the dragonfly genus *Cordulegaster* spp. (Insecta: Odonata) was recorded in the inner Salzkammergut, in the areas of Bad Ischl, Bad Goisern, Hallstatt, Obertraun and Gosau. First, potential habitats were identified by remote reconnaissance using the "Austrian Map" of the BEV. Subsequently, mostly in the period from September to October, field work was carried out, looking for the presence of larvae in 64 potential habitats. In addition, habitat parameters such as altitude, flow speed, water temperature, width of the water and the pH value were noted. Specimens of the *Cordulegaster* spp. could be found at eleven locations. Larvae of *C. bidentata* and *C. boltonii* were found at a total of nine sampling sites. Adults were only found in two of the study areas. *C. heros* could not be found. The habitats of *Cordulegaster* spp. were then evaluated according to the categories "population", "habitat quality" and "impairments". The studies of the habitat parameters showed that *C. boltonii* and *C. bidentata* larvae in the Salzkammergut prefer to develop in slow-flowing, one to two meter wide streams at an altitude of 500 to 600 meters. However, there were also finds at around 800 meters above sea level. Both *Cordulegaster* species require an at least partially wooded bank and a fine gravel / sandy to muddy brook bed." **22172.** Hobson, K.A.; Jinguji, H.; Ichikawa, Y.; Kusack, J.W.; Anderson, R.C. (2020): Long-distance migration of the Globe Skimmer Dragonfly to Japan revealed using stable hydrogen ( $\delta^2\text{H}$ ) isotopes. *Environmental Entomology*, nva417, <https://doi.org/10.1093/ee/nva417>: 9 pp. (in English) ["*P. flavescens* is a long-distance migrant, well adapted to exploiting ephemeral waterbodies. This species occurs in Japan every summer, but overwintering has only been recorded on subtropical Ishigaki Island. It is not known from where the summer immigrants originate, nor what proportion of the globe skimmers seen in Japan are of local origin. We analyzed stable hydrogen isotope ( $\delta^2\text{H}$ ) composition of wings of 189 *P. flavescens* captured at six sites in Japan from August to September in 2016 (n = 57) and from April to November in 2017 (n = 132). We determined that the majority of individuals were immigrants. Individuals of probable Japanese origin occurred only later in the year and were of lower mass on average than immigrants. Immigrants potentially originated from a broad area as far west as northern India and the Tibetan Plateau and, especially late in the season, as near as northcentral China and the Korean peninsula. However, for April samples, the most parsimonious interpretation suggested southern origins, in northern Myanmar to southern China, or possibly Borneo-Sulawesi. Our

investigation underlines the power of combining stable isotope data with other information such as wind speed and direction, arrival dates, and body mass to estimate origins and to understand the life history of this and other insects." (Author)] Address: Hobson, K., Department of Biology, University of Western Ontario, 1151 Richmond Street, London, ON N6A 5B7, Canada. Email: khobson6@uwo.ca

**22173.** Meza-Salazar, A.M.; Guevara, G.; Gomes-Dias, L.; Cultid-Medina, C.A. (2020): Density and diversity of macroinvertebrates in Colombian Andean streams impacted by mining, agriculture and cattle production. *PeerJ* 8: e9619 <http://doi.org/10.7717/peerj.9619>: 26 pp. (in English) ["Background. Mining, agriculture and cattle production are activities that threaten the quality and quantity of water resources in the Colombian Andes. However, many drainage basins in this region have not been subjected to simultaneous evaluation of the impact these activities have on the density, diversity and composition of aquatic macroinvertebrates (AMI). The first two of these ecological variables are expected to decrease drastically from zones with no apparent impact towards areas with anthropogenic activity, which areas with mining will present the most impoverished AMI community. Methods. We evaluated the density, diversity and composition dissimilarity of AMI in streams impacted by gold mining, agriculture and cattle production. Two reference streams were also studied. Six benthic samplings were conducted bimonthly (Feb 2014–Feb 2015) using a Surber net. Water samples were taken in order to make environmental evaluation among the aforementioned streams, including hydrological, physicochemical and bacteriological parameters (HPCB). Diversity was evaluated as the effective number of RTUs—recognizable taxonomic units—by comparing the richness, typical diversity, and effective number of the most abundant RTUs. Compositional dissimilarity was examined with nMDS and CCA analysis. Results. A total of 7,483 organisms were collected: 14 orders, 42 families and 71 RTUs. Our prediction regarding the density and diversity of AMI (Reference > Cattle production > Agriculture > Mining) was partially fulfilled, since the agriculture-dominated stream presented a more impoverished AMI community than that of the gold mining stream. However, these streams presented lower diversity than the cattle production and reference streams, and the AMI density only differed significantly between one reference stream and the agriculture stream. The AMI composition in the agriculture-dominated stream clearly differed from that of the other streams. How to cite this article Meza-Salazar AM, Guevara G, Gomes-Dias L, Cultid-Medina CA. 2020. Density and diversity of macroinvertebrates in Colombian Andean streams impacted by mining, agriculture and cattle production. Discussion. The observation of a more impoverished AMI community in agricultural production areas compared to those with mining or cattle production may reflect the importance of the remaining riparian vegetation, which was scarce at the stream with agricultural activity. Moreover, the low diversity, and mainly the reduced AMI richness, in the agriculture stream coincided with the absence of insect genera are intolerant to deterioration of the biological and physicochemical conditions of the water (e.g. Anacroneria). Conclusions. The results suggest that the local impact of agricultural activities may be of equal or greater magnitude than that of mining in terms of AMI density, diversity and composition, in the Colombian Andean riverscape. Future studies should systematically evaluate, throughout the annual cycle, the relative effects of the productive land use, the remaining native vegetation cover and the consequent changes in the HPCB parameters of the water on AMI communities in Colombian

Andean basins." (Authors) Calopterygidae, Libellulidae] Address: Meza-Salazar, Ana M., Facultad de Ciencias Exactas y Naturales, Grupo de Investigación BIONAT, Universidad de Caldas, Manizales, Caldas, Colombia

**22174.** Román-Heracleo, J. (2020): Diversidad de libélulas (Insecta: Odonata) en ambientes lénticos con diferente grado de alteración antropogénica. Tesis de maestría, Ciudad Universitaria "Rodrigo Facio", Costa Rica: 105 pp. (in Spanish or English) ["Costa Rica is the Central American country where the dragonfly fauna is best known. However, studies have been focused mainly on lotic environments, generating an information gap in lentic environments. The increase in urbanization impacts freshwater ecosystems, generating changes in the landscape and is one of the most significant anthropogenic impacts that threatens biodiversity. This research was carried out for a year in six lagoons: two urban (La Sabana and La Paz), two semi-urban (Lankester and Doña Ana), and two rural (CATIE and El Rodeo). The objective was to evaluate the dragonfly assemblages and relate them to the environmental parameters of each site, as well as to raise larvae in order to associate the larva-adult stages for the species found. The capture of adults was carried out using an entomological net, with a total sampling effort of 5 hours (9:00-14:00pm). For data analysis, a Principal Component Analysis (PCA) was performed to identify the patterns in the lakes using the environmental variables and a similarity test (ANOSIM) was performed to determine the significance of the groups. formed. Finally, a Canonical Correspondence Analysis (CCA) was performed to determine the relationship between the taxa collected in each of the lagoons and the data on the environmental variables. In total, 644 adult specimens from 6 families, 29 genera and 51 species were collected. The families with the greatest richness were Libellulidae with 53% (29 spp.), followed by Coenagrionidae with 25% (15 spp.). The families with the least richness were Lestidae and Gomphidae with one species each. The most diverse genera were Micrathyrina (Libellulidae) with 10% (5 spp.), followed by Argia, Erythemis, Erythrodiplax with 8% of the total species richness (4 spp. each). The ANOSIM confirmed that the assembly of groups is statistically different ( $R=0.68$ ,  $p=0.001$ ). The CCA showed the effect of four physicochemical variables on the assembly of the Odonata ( $\chi^2 = 0.54$ ,  $F=2.58$ ,  $p=0.001$ ). The first two dimensions of the CCA have a significant effect: CCA1 ( $\chi^2 = 0.23$ ,  $F=4.44$ ,  $p=0.001$ ), CCA2 ( $\chi^2 = 0.15$ ,  $F=2.82$ ,  $p=0.008$ ) and we observe the formation of four groups. From the larvae raised in the laboratory, species from the families Aeshnidae, Libellulidae and Coenagrionidae were associated. Of which three species: Acanthagrion speculum, A. trilobatum, Anisagrion allopterum were associated and described for the first time and the redescription of Neoerythromma cultellatum was carried out, these species belong to the family Coenagrionidae. Our results show a high importance of urban aquatic environments for the conservation of species. A good design in the arrangement of lakes with good water quality can serve as a corridor connecting species between the urban and rural landscape, and in this way help not restrict their distribution. Furthermore, this study demonstrated that the protection and management of urban lagoons is essential to maintain the diversity of organisms." perceptions of insects as the determinants of insect conservation through entomological ecotourism. *Journal of Tropical Biology and Conservation* 17: 79-95. (in English) [oas 72: "Insects are commonly featured in recreation and tourism around the world, despite the generally negative public perception surrounding them. Many people enjoy watching butterflies in insectarium gardens, observing and collecting dragonflies, and admiring the light displays of fireflies. In many cases, activities like these are becoming increasingly popular and these positive interactions with insects encourage public appreciation of insects, but vary acutely in their forms and approaches. Thus, understanding the pattern of insect appearances in recreation and tourism activities in a variety of discernments can provide important insights into effective ways of promoting insect conservation through ecotourism, which is often overlooked in biodiversity conservation strategies. However, these types of interdisciplinary studies are relatively new and remain limited in both entomology and tourism sciences. A field survey was carried out at Kangkawat Research Station, Imbak Canyon Conservation Area, where a 1 kilometre entomological ecotourism trail was designed and developed to incorporate insects in enhancing ecotourism at the reserve. Insects that can be found along the 1 kilometre trail were recorded and the collection was conducted using baited traps and sweep netting. Based on the insects survey, the Shannon Diversity Index (H') of Kangkawat is 4.60 while Simpson Index is 176.72 with Fisher Alpha Index at 313.3 that concludes Kangkawat Research Station insect richness to be the second highest after the Crocker Range. In addressing the knowledge gaps between insect conservation and ecotourism, a survey on attitudes towards insects was designed and then completed by 384 tourists around Kota Kinabalu City. The standardized questionnaire known as the Personal Meaning of Insects Map (PMIM) was administered to tourists and their responses were elicited prior to and after observing insect photos. The results shows that "spider" had the 100% connectivity in response to the most detested insect based on their previous encounters with insects. This result shows that there is an existing entomology knowledge gap among the respondents, indicating the need for further interventions in terms of nature interpretation. Therefore a quality guided nature interpretation as an educational tool should take into account how the general public understands (or misunderstands) insects further and where interpretive information could be better applied if we are to develop management and educational tools that address human-insect encounters." (in English, with German summary) ["In this paper we report the first overview of dragonfly fauna of Lastovo Island, southern Croatia, based on published literature data and recent surveys conducted in 2014 and 2018. So far 16 species have been recorded on the island. The following five species were detected for the first time for the island within this survey: *Ischnura elegans*, *Aeshna isocetes*, *Anax parthenope*, *Sympetrum sanguineum*, and *Selysiotthemis nigra*. Of the recorded species the most important is the record of *S. nigra*, an endangered species according to the Red book of Odonata of Croatia, known only from a handful of localities across the coastal parts of the country. On the island, small ponds represent the only source of freshwater habitats suitable for dragonfly development. Most of the visited ponds are in favourable condition and some were also recently cleared of the surrounding vegetation and partially restored." **22178.** Brady, P.C. (2021): Three-dimensional measurements of animal paths using handheld unconstrained GoPro cameras and VSLAM software. *Bioinspiration & Biomimetics* 16 026022: (in English) ["I present the system PATMOS (Paths And Tessellated Meshes from ORB\_SLAM2) for measuring three-dimensional paths of animals in situ using two handheld GoPro cameras and a small spatial reference object. Animal paths were triangulated from mobile camera positions obtained from a modified version of ORB\_SLAM2, an open-source visual simultaneous localization and mapping software package. In addition to path calculation, this process provided a virtual three-dimensional surface approximation to the environment from which path to environment distances can be quantified. PATMOS can also fit a tranquil water's surface to an analytic plane if there are a sufficient number of visible objects intersecting the water's surface and can track objects over the water's surfaces with a single camera by measuring the object with its reflection. This technology was highly portable, could follow moving animals, and gave comparable spatial and temporal resolutions to fixed camera systems that use commercial cameras. An investigation of falling objects yielded a gravitational constant measurement of  $978 \pm 40$  cm/s<sup>2</sup>. I demonstrated PATMOS's utility in terrestrial and aquatic environments by quantifying dragonfly flight characteristics and the inter-spatial distances between substrate and damselfish." **22179.** Cham, S. (2021): Ovipositing behaviour, egg positioning and egg set size of *Chalcolestes viridis* (Vander Linden) (Willow Emerald Damselfly) at a new site in Britain. *J. Br. Dragonfly Society* 37(1): 14-39. (in English) ["Females of *C. viridis* oviposit into the branches of woody plant species

above water or wet ground, a behaviour that is different to any other British odonate species with endophytic oviposition. At some new sites, populations of *C. viridis* can quickly build up to reach high densities. During 2020 high numbers of tandem pairs were observed at a site in Bedfordshire, England, where the availability of suitable oviposition substrates was at a premium, resulting in branches being covered by oviposition scars. These oviposition scars are in lines and each one is the result of a single oviposition event in which a set of eggs is laid. The terminology is discussed. The structure of the ovipositor and the process of oviposition are described." (Author)] Address: Cham, S., 2 Hillside Road, Lower Stondon, Bedfordshire SG16 6LQ, UK. Email: stevecham1@aol.com

**22180.** Cham, S. (2021): Egg hatching, prolarvae and larval development time of *Chalcolestes viridis* (Vander Linden) (Willow Emerald Damselfly) in Britain. *J. Br. Dragonfly Society* 37(1): 40-59. (in English) ["*C. viridis* was first recorded in Britain in 2007. The female behaviour of ovipositing into the branches of willows and other woody plant species is different to any other British species with endophytic oviposition. Egg hatching and larval development times have so far not been studied in UK populations and are the subject of this paper. The results of the study indicate that the hatching period for eggs of *Chalcolestes viridis* is between seven and nine days. Eggs predominantly hatched at night or by 06.00 BST. The viable prolarval stage, when out of water, could last for at least 1 hour 30 minutes. The distance prolarvae propel themselves could be at least 50 mm, confirming the observations of other researchers. The second stadia larvae, which are 3 mm long at transition, need to be on a horizontal water surface to extricate themselves from the prolarval sheath. Observations show the sheath to be composed of hydrophobic droplets, which assist this process." (Author)] Address: Cham, S., 2 Hillside Road, Lower Stondon, Bedfordshire SG16 6LQ, UK. (2021): The wing venation of the Protomyrmeleontidae (Insecta: Odonoptera) reconsidered thanks to a new specimen from Molteno (Triassic; South Africa). *Historical Biology* 33(3): 306-312. (in English) ["Wing venation homologies of the Protomyrmeleontidae, a widespread group of damselfly-like stem-Odonata during the Triassic, are debated. The two main interpretations essentially disagree on the identification of RP branches. Indeed, Protomyrmeleontidae display a very complex wing venation necessarily involving, in a way or another, fusions of the concave RP branches with the convex intercalary veins. As a consequence, vein elevations in the radial area are challenging to interpret. Here, we present a new Triassic specimen from the Molteno Formation (Karoo Basin, South Africa), *Moltenagrion koningskroonensis* gen. et sp. nov. It displays a unique venation pattern supporting a new, alternative interpretation involving

a pair of supplementary intercalaries. The systematic implications of this wing venation interpretation are then discussed. The new species is assigned to the new family Moltenagrionidae fam. nov., itself considered sister-group of the family Protomyrmeleontidae, as previously delimited, both composing the super-family Protomyrmeleontoidea. Diagnoses of these taxa are revised according to our new interpretation." **22186.** Guo, M.; Zheng, G. (2021): Stigma as two degrees of freedom energy sink for flutter suppression. *Journal of Sound and Vibration* 515, 22 December 2021, 116441: (in English) ["Highlights: • A novel explanation on the aerodynamic function of dragonfly stigma is proposed. • Microstructures show that the stigma can be simplified as a two degrees of freedom-energy sink. • The stigma can increase flutter speed and suppress limit cycle oscillations of the dragonfly wing. • The energy sink structure of the stigma has advantages on flutter suppression over conventional sinks. Abstract: This paper presents a novel explanation on the aerodynamic function of the dragonfly stigma, which is a pigmented spot with heavier masses near the tip of a dragonfly's wing. Dynamic modeling based on the micro-structures shows that the stigma can be simplified as two lumped masses connected by a massless beam, and installed on the primary structure by two tow springs. This model works as a two degrees of freedom (2DoF) energy sink. Theoretical modeling and numerical simulations prove that the stigma is capable to suppress flutter – a self-excited vibration. The flutter velocity of a system with the stigma is increased by 15.8% comparing to the case without the stigma, while this increase is only 3.7% if the stigma is merely considered as

a counterweight. The limit cycle oscillations (LCOs) of wing's pitch motion are also significantly reduced. A comparison in the discussion further reveals that this energy sink structure of the stigma has advantages over conventional energy sinks, which is worthy of follow-up bionic research." **22187.** Horváth, G.; Egri, A.; Meyer-Rochow, V.B.; Kriska, G. (2021): How did amber get its aquatic insects? Water-seeking polarotactic insects trapped by tree resin. *Historical Biology* 33(6): 846-856. (in English) ["Amber contains numerous well-preserved adult aquatic insects (e.g., aquatic beetles, water bugs, dragonflies, caddisflies, mayflies, stone flies). Since amber is fossilised resin of terrestrial conifer trees, it is an enigma how aquatic insects have ended up in the resin. Based on field studies in a Hungarian forest along a freshwater creek we suggest that tree resin traps water-seeking flying polarotactic aquatic insects because of its property to polarise reflected light. The sticky tree resin was modelled by a water-proof, transparent, colourless insect-monitoring glue laid on vertical and horizontal fallen tree trunks next to the creek. Adults of various polarotactic aquatic insect species were trapped only by the horizontal sticky trunk. In earlier field experiments we showed that these insects find water by means of the horizontal polarisation of water-reflected light, and therefore are attracted to and land on all surfaces which reflect horizontally polarised light. Using imaging polarimetry, we revealed the criterion of polarisation-based trapping by resinous tree trunks. According to our observations, flying aquatic insects can be trapped by sticky (resinous) regions of fallen tree trunks that reflect horizontally polarised light and thus attract polarotactic species. The resin continues to flow out of the trees even when fallen over or fractured in a storm. Our findings support and complement an earlier hypothesis, according to which amber-preserved adult aquatic insects have been trapped by resinous bark when they dispersed over land.... The sticky vertical barks reflected light with directions of polarisation far from the horizontal, thus these surfaces were not attractive to water-seeking aquatic insects. After emergence, mayfly subimagos usually search any kind of nearby object to land on and moult into an imago. Consequently, their trapping on the vertical sticky trunks could happen incidentally without any motivation related to polarotaxis or seeking water surfaces. This case could be similar for *Alopteryx virgo* nymphs that crawled out from the creek directly onto the sticky surface and then become trapped in the middle of the act of emergence (Figures 6(b), 7(b), 9(a)) just like it has been found in real amber (Bechly & Wichard 2008; Wichard et al. 2009)." **22188.** Kosterin, O.E.; Onishko, V. (2021): *Dragonflies of Russia: Illustrated Photo Guide*. Phytos XXI. ISBN: 97859068-11912: 479 pp. (in Russian, with scientific nomenclature) ["The book offers the first detailed description of the appearance, life history, distribution and diagnostic characteristics of all 156 species of dragonflies and damselflies (Odonata) known to date from the territory of the Russian Federation, based on the authors' extensive experience and scientific literature. Each species is illustrated with original natural photographs of both sexes as well as examples of intra-species variation. Additionally, for each species there are short descriptions of the imago of both sexes, and its change with age are given. Many recently revealed facts are published here for the first time. There are no distribution maps as the

actual range of Odonata borders in Russia remain unknown to a large extent. As is usual in guides based on illustrations, there are no identification keys but diagnostic differences between similar species are provided instead. The introduction leads a reader through the structure, life cycle, habits and classification of dragonflies. The combination of thorough descriptions of differences between similar species, rich illustrations and a detailed introduction allows readers to identify dragonfly species without keys or any specialized knowledge. This book unites the features of a popular atlas with an academic work and fills the gap existing in Russian literature concerning such a conspicuous and attractive group of flying insects as the dragonflies. The book is aimed at a broad range of nature lovers but, as a compilation of all existing knowledge of dragonflies of the country, it will be useful for entomologists as well." (Publisher)]

**22190.** Medina-Espinoza, E. (2021): Análisis del ensamblaje adulto de Odonata (Insecta) en cuerpos de agua de la estación biológica Los Amigos, Madre de Dios. Tesis para Optar el Título Profesional de Bióloga, Facultad de Ciencias, Universidad Nacional Agraria La Molina: 80 pp. (in Spanish, with English summary) ["Freshwater ecosystems are one of the most polluted environments worldwide. Madre de Dios is one of the Peruvian departments that harbors a great diversity of species and one of the main threats it faces is the loss of forests due to gold mining, which has negative effects on its water bodies. Little ecological information is known about Peruvian Odonata, which are freshwater insects. The present study analysed the adult odonate assemblage diversity in three aquatic environments within the Los Amigos biological station (a blackwater pond, an oxbow lake and a stream) in May and October of 2018. A total of 46 species were recorded, belonging to 25 genera and six families. The most represented families were Libellulidae and Coenagrionidae. The assessment sites showed similar diversity values using Hill numbers. However, differences were found in the species composition in the three water bodies assessed, including between lakes. This was because, although they shared a considerable number of

species, the relative abundances of each species varied depending on the assessment site. Therefore, dragonfly assemblages in the Los Amigos biological station change according to the body of water where they are found. This highlights the importance of knowing the taxa that are part of the assemblages of the different types of freshwater environments in order to better understand the changes that might occur in these types of ecosystems." **22192.** Shackleton, M.E.; Dafforn, K.A.; Murphy, N.P.; Greenfield, P.; Cassidy, M.; Besley, C.H. (2021): How does molecular taxonomy for deriving river health indices correlate with traditional morphological taxonomy? Ecological Indicators 125, 107537: 15 pp. (in English) ["Macroinvertebrate surveys are commonly used for assessing the health of freshwater systems around the world. Traditionally, surveying involves morphologically identifying the families, and sometimes genera, present in samples. Biological indices, derived from taxonomic lists, provide convenient ways to summarise community data and may be fairly insensitive to species-level changes in community compositions. In recent years, molecular techniques for identifying taxa have become increasingly popular and metabarcoding approaches that offer the ability to identify species from mixtures of whole animals (bulk-samples) or from environmental samples have gained much attention. However, generating accurate species lists from metabarcode data is challenging and can be impacted by sample type, choice of primers, community composition within samples, and the availability of reference sequences. This study compares the performance of molecular data extracted from bulk-samples against morphological data in calculating two biological indices (the Stream Invertebrate Grade Number Average Level 2 (SIGNAL2), which is calculated from family-level data, and a genus-level equivalent of this index, SIGNAL\_SG) and one biological metric (taxon richness). Further, molecular indices and metrics derived from global, local or mixed reference DNA libraries and with varying degrees of filtering processes applied to them, are compared with respect to the strength of their relationships with morphological indices and metrics. Molecularly derived SIGNAL2 and SIGNAL\_SG scores correlated strongly with morphologically derived scores, and were strongest when using a reference library containing a mix of local and global data. Molecularly derived richness metrics were moderately correlated with morphological taxa richness; however, the strongest correlations were observed when taxa that could not be assigned SIGNAL grades were omitted from analyses. This study highlights the utility of using molecular data as an objective and sensitive alternative to traditional freshwater biological assessment using macroinvertebrates.... The Odonata were the most family diverse taxa and performed relatively well in terms of F1 cores, with scores ranging from 0.67 to 0.92. The notable exception in the Odonata was the family Synthemistidae,

which returned a null F1 score despite being as prevalent as Gomphidae." (Authors)] Address: Shackleton, M.E., Centre for Freshwater Ecosystems, La Trobe University, Australia. Email: m.shackleton@latrobe.edu.au

**22195.** Acquah-Lampitey, D. (2022): Large scale patterns of African and European Odonata; The importance of functional traits. Dissertation, Fachbereich Biologie der Philipps-Universität Marburg: 199 pp. (in English) ["Biodiversity patterns, community composition, and ecological dynamics are linked to species' responses to climatic conditions, biotic interactions, and dispersal limitations. Climate change has led to shifts in species ranges to higher altitudes and latitudes, changes in species population trends, and changes in species phenology. That makes climate change a fundamental concern for biodiversity conservation and makes understanding the effect of climate change on biodiversity a central theme in ecology. A promising approach to understanding the mechanisms shaping species distribution and community composition is linking physiological processes, functional traits, and the climatic environment. Two ubiquitous features of animals of great functional importance are body size and body colour. For instance, both traits influence the temperature excess of species and thereby have significant consequences on species distributions, abundances, activities, and development. However, thus far, support for the importance of body size and body colour is sparse for insects, particularly at larger spatial and taxonomic scales. In addition, the effects of both traits on community composition and species' responses to environmental changes remain poorly understood. Whereas it is difficult to monitor species populations across entire ranges, the IUCN established criteria that allow taxon experts to broadly categorize the threat status of species. However, only 1 % of the insects described so far have been assessed, with 26 % of these

categorised as data deficient. Especially in tropical regions and for tropical taxa, we lack an understanding of the drivers associated with threatened insect species. The overall objective of this PhD thesis was to investigate the importance of interactions between environmental factors and species' functional traits across Europe and Africa. My work focused on damselfly and dragonflies (Odonata) because of their ecological importance and exceptional natural history record among insects. With this, I aim to improve our understanding of the mechanistic processes underlying biogeographical patterns and species extinction risk and ultimately improve forecast of the ecological consequences of climate change. In one chapter of this thesis, I quantified the colour lightness and body volume of European Odonates and combined these traits with survey data for local assemblages across Europe. Based on this continent-wide yet spatially explicit dataset, I tested for effects of temperature and precipitation on the colour lightness and body volume of local assemblages and assessed differences in their relative importance and strength between lentic and lotic assemblages. I show that the colour lightness of assemblages of Odonates increased, and body size decreased with increasing temperature. My results demonstrate that the mechanisms underlying colour lightness and body size variations scale to local assemblages. Together with previous studies on larger spatial scales, these results underline the general importance of colour- and size-based thermoregulation in insects. Both size- and colour-based thermoregulation were of similar importance for species preferring lentic and lotic habitats (standing vs. running water), but the higher dispersal ability of lentic species seems to allow them to better track their thermal optimum. In another chapter, I integrated trait-based models with environmental factors to investigate the mechanistic underpinnings of species' extinction risk for 489 African and European Odonates. Using body size, wing load, and habitat preference, I incorporate current theoretical and empirical support for single effects of environmental variables on species traits into structural ecological models. Specifically, I tested whether species are generally larger in colder environments; whether species adapted to less stable habitats and with lower wing loads have smaller ranges; and finally, the extent to which these trait-environment relationships translate into a higher extinction risk of species. The results of this chapter demonstrate that species adapted to lotic habitats as well as smaller species and species with high wing loads have smaller range sizes. In addition, larger species and those with lower wing loads had more northern distributions and inhabited colder climates. Species with smaller ranges and those occurring in colder and more northern regions had a higher extinction risk. I thereby demonstrate that strong links between intrinsic traits (body size, wing load, and habitat preference) and extrinsic traits (range size, thermal preference, and latitudinal position) can explain a substantial part of the variation in species' extinction risk. However, in contrast to models of extrinsic traits alone, I emphasize that the mechanisms underpinning species' extinction risk are important to consider for understanding which species are particularly threatened and why. Thereby, trait-based models have a high potential to forecast and mitigate the negative impacts of environmental changes and other threats to species. In another chapter, I investigated the potential of Odonates as biological control predators of mosquito larvae under almost natural conditions. I found that the widespread dragonfly *Brachytrichia strachani* is capable of breeding in and naturally colonising water storage containers used in typical rural homes, which are breeding grounds for mosquitoes. My mesocosm experiments show that the presence of *B. strachani* resulted in a drastic reduction of mosquito larvae density, especially in sunlit containers. My

results confirm that dragonfly larvae are effective biological control agents of the disease-causing vector, with great benefits to the livelihood of people. In summary, I demonstrate the importance of the mechanistic links between colour lightness and body size with the temperature regime which shapes the biogeographical patterns of European Odonates using spatially explicit survey data. The consistency of this reiterates the general importance of thermal melanism and Bergmann's rule for ectotherms at the local assemblage scale. However, besides highlighting the essential role of traits involved in thermoregulation in shaping the distribution of Odonates, the greater dispersal ability of lentic species in combination with the climatic history seems to have allowed them to better cope with the historical climatic changes. Furthermore, my results highlight the importance of functional traits in species extinction risk assessments. Body size, habitat preference, and wing load explain why some species are particularly threatened and may thus serve as a red flag for threat assessment in conservation, even for species that lack distribution data. These integrative trait-based analyses are particularly relevant for providing links between ecology and conservation, which are important for completing and predicting species threats. These results underline the ecological importance of Odonates and highlight a great potential for integrating interactions of morphological traits with species phylogenetic data and proxies of dispersal ability, into trait-based models to improve our understanding of biological responses to environmental changes and other potential threats. The importance of the functional traits of species and the generality of their impact on ecological dynamics stress that mobilization of trait data provides an important future avenue to improve baseline predictions and the information basis for large scale conservation of insect diversity." **22196.** Al-Shamry, A.S.H.H.; Mizhir, A.H. (2022): Diversity of aquatic insects in the euphrates River/Najaf province-Iraq. *International Journal of Health Sciences* 6(S7): 3464-3476. (in English) ["Five locations were sampled with three duplicates from each throughout the course of a six-month period, from November 2021 to April 2022, in order to assess the biodiversity of crustaceans. Water was also included in the samples. Certain chemical and physical characteristics of water are measured. the overall density of aquatic insects varied from (1–257) individuals/L, the month of April had the greatest density. According to the findings of the isolation and identification of water insects, Chironomidae larvae were the most numerous throughout the research period, followed by Chironomide pupa, Zygoptera nymph, Odonata larvae, and *Belostoma corodofanum*. According to the relative abundance index for aquatic insects, the Zygoptera nymph species was most prevalent in the first location, whereas Chironomidae larvae were more prevalent in the other sites. The constancy species index (S) of aquatic insects, Chironomidae larvae and Chironomide pupa, were the most constancy across all research locations and throughout the course of the study period. The values of the species richness index ( $D^*$ ) ranged from 0-3.84. While the Shannon-Weiner index ranged between 0-1.361 bit/ind. While the values of the species uniformity index (E) ranged between 0-0.845." (Authors)] Address: Al-Shamry, A., Dept of Ecology and Pollution College of Science, University of Kufa, Najaf, Iraq. área pampeana con diferentes usos del suelo. PhD thesis, Facultad de Ciencias Naturales y Museo Universidad Nacional de La Plata: 175 pp. (in Spanish, with English summary) [Argentina; the thesis includes references on Odonata at the genus level.] Address: [http://sedici.unlp.edu.ar/bitstream/handle/10915/147152/Documento\\_completo.pdf-PDFA.pdf?sequence=1&isAll owed=y](http://sedici.unlp.edu.ar/bitstream/handle/10915/147152/Documento_completo.pdf-PDFA.pdf?sequence=1&isAll owed=y)

**22198.** Association Bourgogne-Franche-Comté Nature (2022): Atlas des odonates de Bourgogne-Franche-Comté. Revue scientifique Bourgogne-Franche-Comté Nature, Hors-série n°17: 446 pp. (in French) [France "A long-term project initiated in 2010 by the Natural History Society of Autun – Burgundy Wildlife Observatory, the National Botanical Conservatory of Franche-Comté – Regional Invertebrate Observatory and OPIE Franche-Comté, and carried out thanks to with the support and involvement of numerous volunteers, allows us to deliver this atlas which, we hope, will amaze you and interest you even more in dragonflies. The work This work aims to present to you the diversity of dragonflies in our region and to share the knowledge acquired throughout these years. Through its 446 pages, the atlas illustrates in detail the 75 species present in the region, their distribution, their biology, and the threats weighing on them. Around twenty chapters complement the monographs, all of which are richly illustrated. This atlas aims to present to you the diversity of dragonflies in our region in a pleasant way and to share the knowledge acquired throughout these years. Finally, let us not forget that nature is constantly in motion and that a work of this type presents an image frozen over a window of time. It will evolve with the populations of odonates, influenced by modifications of natural environments and climate changes, but also by the knowledge we have of them. Authors: Natural History Society of Autun – Burgundy Wildlife Observatory, the National Botanical Conservatory of Franche-Comté – Regional Invertebrate Observatory and OPIE Franche-Comté." **22199.** Ayayee, P.A.; Wesner, J.S.; Ouellette, S.P. (2022): Geography, taxonomy, and ecological guild: Factors impacting freshwater macroinvertebrate gut microbiomes. *Ecology and Evolution*. 2022;12: e9663.: 15 pp. (in English) ["Despite their diversity, global distribution, and apparent effects on host biology, the rules of life that govern variation in microbiomes among host species remain unclear, particularly in freshwater organisms. In this study, we sought to assess whether geographic location, taxonomy (order, family, and genus), or functional feeding group (FFG) designations would best explain differences in the gut microbiome composition among macroinvertebrates sampled across 10 National Ecological Observatory Network's (NEON) freshwater stream sites in the United States. Subsequently, we compared the beta diversity of microbiomes among locations, taxonomy (order, family, and genus), and FFGs in a single statistical model to account for variation within the source microbial community and the types of macroinvertebrates sampled across locations. We determined significant differences in community composition among macroinvertebrate orders, families, genera, and FFGs. Differences in microbiome compositions were underscored by different bacterial ASVs that were differentially abundant among variables (four bacterial ASVs across the 10 NEON sites, 43 ASVs among the macroinvertebrate orders, and 18 bacterial ASVs differing among the five FFGs). Analyses of variations in microbiome composition using the Bray–Curtis distance matrix revealed FFGs as the dominant source of variation (mean standard

deviation of 0.8), followed by stream site (mean standard deviation of 0.5), and finally family and genus (mean standard deviation of 0.3 each). Our findings revealed a principal role for FFG classification in insect gut microbiome beta diversity with additional roles for geographic distribution and taxonomy.... Wollbachia was most abundant in aquatic Coleoptera (70.28%), followed by Odonata (20.08%) [Cordulegaster, Gomphidae], Trichoptera (17.28%), Plecoptera (8.20%), and Ephemeroptera (0.15%)."] (Authors)] Address: Ayayee, P.A., Dept of Biology, Univ. of Nebraska at Omaha, Omaha, Nebraska, USA. **22202.** Grabowski, N.T.; Abdulmawjood, A.; Acheuk, F.; Barragán Fonseca, K.; Chhay, T.; Costa Neto, E.M.; Ferri, M.; Franco Olivas, J.; González Aguilar, DG., Keo, S., Lertpatarakomol, R., Miech, P.; Piofczyk, T.; Proscia, F.; Mitchathai, J.; Guerfali, M.M.; Sayed, W.; Tchibozo, S.; Plötz, M. (2022): Review: Insects — A source of safe and sustainable food? — "Jein" (yes and no). *Front. Sustain. Food Syst.* 5:701797. doi: 10.3389/fsufs.2021.701797: 17 pp. (in English) ["For almost a decade, edible insects have become promoted on a wider basis as one way to combat world hunger and malnourishment, although attempts to do so have a longer history. Contemporary researchers and consumers, particularly those without an entomophagous background, have been rising safety and sustainability concerns. The present contribution seeks a substantiated answer to the question posed above. The possible answer consists of different factors that have been taken into consideration. First, the species and its life cycle. It is mandatory to realize that what is labeled as "edible insects" stands for more than 2,140 animal species, not counting other edible, non-crustacean arthropods. Their life cycles are as diverse as the ecological niches these animals can fill and last between some days to several years and many of them may — or may not—be reproduced in the different farming systems. Second, the level of knowledge concerning the food use of a given species is important, be it traditional, newly created by research, or a combination of both. Third, the existence of a traditional method of making the use of the insect safe and sustainable, ideally from both the traditional and themodern points of view. Fourth, the degree of effectiveness of these measures despite globalization changes in the food-supplying network. Fifth, farming conditions, particularly housing, feeding (type, composition, and contaminants), animal health

and animal welfare. Sixth, processing, transport, and storage conditions of both traditional and novel insect-based foodstuffs, and seventh, consumer awareness and acceptance of these products. These main variables create a complex web of possibilities, just as with other foodstuffs that are either harvested from the wild or farmed. In this way, food safety may be reached when proper hygiene protocols are observed (which usually include heating steps) and the animals do not contain chemical residues or environment contaminants. A varying degree of sustainability can be achieved if the aforementioned variables are heeded. Hence, the question if insects can be safe and sustainable can be answered with "jein," a German portmanteau word joining "yes" ("ja") and "no" ("nein")." Ecological Monographs e1553. <https://doi.org/10.1002/ecm.1553>: 37 pp. (in English) ["Climate warming is considered to be among the most serious of anthropogenic stresses to the environment, because it not only has direct effects on biodiversity, but it also exacerbates the harmful effects of other human-mediated threats. The associated consequences are potentially severe, particularly in terms of threats to species preservation, as well as in the preservation of an array of ecosystem services provided by biodiversity. Among the most affected groups of animals are insects — central components of many ecosystems — for which climate change has pervasive effects from individuals to communities. In this contribution to the scientists' warning series, we summarize the effect of the gradual global surface temperature increase on insects, in terms of physiology, behavior, phenology, distribution, and species interactions, as well as the effect of increased frequency and duration of extreme events such as hot and cold spells, fires, droughts, and floods on these parameters. We warn that, if no action is taken to better understand and reduce the action of climate change on insects, we will drastically reduce our ability to build a sustainable future based on healthy, functional ecosystems. We discuss perspectives on relevant ways to conserve insects in the face of climate change, and we offer several key recommendations on management approaches that can be adopted, on policies that should be pursued, and on the involvement of the general public in the protection effort." **22207.** Kohl, S.; Wildermuth, H. (2022): "Der Greifensee": Libellen und Heuschrecken. Neujahrsblatt 2022 der Naturforschenden Gesellschaft in Zürich: 157-168. (in German) ["Of the approximately 80 dragonfly species identified in Switzerland, 58 are known from the Greifensee area. The relatively high number of species is due to the fact that different, sometimes rare types of standing and flowing water occur in the area. In addition to the largely undeveloped lake shore, these include ponds of various sizes and depths inside and outside the reed areas, former peat ditches and fen ditches, ponds and ponds in gravel pits, spring outflows and spring outflows, as well as the Glatt, the Aabach, the Mönchaltorfer Aa and some smaller streams as tributaries to the lake. These waters must be at least partially sunny for dragonflies. All dragonflies regularly observed in the Greifensee area are summarized here in an overview. Table 1 lists 45 species. We know little about the remaining 13 species. Two of them are extinct: *Nehalennia speciosa*, which was only discovered in 1974 in the Rällikon lake meadows and was last recorded in 1983, and *Leucorrhinia pectoralis*, which develops in peat waters and has not been observed at Greifensee since 1990. In the nearby Pfäffikersee area, she was able to hold on to peat cuttings thanks to care measures. Since dragonflies can fly very far, they sometimes appear as solitary animals in places where they almost certainly did not evolve. These rare guests include *Lestes barbarus* and *L. virens*, *Ophiogomphus cecilia*, *Leucorrhinia dubia*, *Symptetrum pedemontanum*, *S. flaveolum* and *S. meridionale*. The rare *S. depressiusculum* is shown on the cover photo. Recently, in special weather conditions, *Anax ephippiger* and *Aeshna affinis* also occasionally appear in our region. *Coenagrion scitulum* has only been seen once so far, but will probably become established in the future. On the other hand, *Aeshna juncea* and *S. danae* have virtually disappeared as losers from climate change. (Authors/Google Translate)] Address: Wildermuth, H., Haltbergstr. 43, 8630 Rütli, Switzerland. E-mail: hansruedi@wildermuth.ch

**22208.** Mauersberger, R. (2022): Zur Haltbarkeitsdauer der Exuvien von *Aeshna mixta* (Odonata: Aeshnidae) am Schlupfsubstrat. *Libellula* 41(1/2): 69-76. (in German, with English summary) ["Stability duration of exuviae of *Aeshna mixta* at the emergence site – The study site was a reed belt of a small shallow lake in the north of Brandenburg (Germany) consisting of *Phragmites australis* and *Typha angustifolia* with a very high emerging abundance of *A. mixta* in the year 2021 where exuviae of this species were counted recurrently from the main emergence period onwards to the disappearance of all specimens. The number of traceable exuviae was decreasing exponentially. After two weeks less than one third of the exuviae could be observed again, 19% were still detected after 30 days, the last one was found after 136 days. The average duration was 16,3 days." (2022): Revealing natural fluorescence in transparent insect wings by linear and nonlinear optical techniques. *Journal of Luminescence* 254(Part B), 119490; doi: 10.1016/j.jlumin.2022.119490: 16 pp. (in English) ["For most natural organisms, the physical, chemical and biological aspects of fluorescence emission are poorly understood. For example, to the best of our knowledge, fluorescence from the transparent wings of any of the 3000 known species of cicadas has never been reported in the literature. These wings are known to exhibit anti-reflective properties arising from quasi-periodic arrays of nipples. Our study, using linear and nonlinear optical techniques, including spectrofluorimetry, two-photon fluorescence spectroscopy and Second Harmonic Generation (SHG), reveals the fluorescence properties in the wings the grey and the common cicadas (*Cicada orni* and *Lyristes (Tibicen) plebejus*, respectively), as well as the broad-bordered bee hawkmoth (*Hemaris fuciformis*). The study suggests that fluorescence would be more widespread in transparent insect wings than what was previously believed. Comparing this result to the fluorescence emission from the wings of the Bornean damselfly (*Vestalis amabilis*), we inferred that this emission probably arises from resilin, a protein reported to enhance wing flexibility. Moreover, the nonlinear optical investigation of the insects' wings provided further insight into wing structure, indicating that multiphoton techniques add valuable information for the analysis of insect integuments. The strong SHG signal detected from the wing veins implies that these veins are materially organised in a non-centrosymmetric and hence non-random fashion.] Address: Mouchet, S.R., School of Physics, Univ. **22211.** Pan, Y. Zhang, Z.; Dong, H. (2022): Computational study on the gliding flight of a damselfly. *AIAA Science and Technology Forum and Exposition, AIAA SciTech Forum 2022-0728*: (in English) [Verbatim: Gliding flight is commonly accepted to be a valuable energy-saving mechanism used by natural flyers. In this work, the gliding flight of a damselfly undergoing was filmed in a large flight enclosure by using three orthogonally arranged and synchronized high-speed cameras. Using a 3D subdivision surface reconstruction methodology, the damselfly's wing deformation and kinematics were modeled and reconstructed from the high-speed videos. An immersed-boundary-method-based Navier-Stokes equation solver is then employed to compute the aerodynamic performance of damselfly in gliding flight. A comparison between the aerodynamics of solitary wings and the fore-hind wing system suggests that wing-wing interactions can reduce the drag of the forewing and improve its gliding performance. Three Euler angles are employed to define the orientation of the wings in gliding. Parametric studies on these angles are implemented to obtain the optimal orientation of the wings in gliding flight. It is found that the wings with the orientation directly obtained from the experiments achieve the optimal gliding performance among all cases. In addition, vortex structures and surface pressure are also compared and analyzed to better understand the gliding aerodynamics, which can be used for the flight control of flapping-wing micro air vehicles.] Address: not stated

**22212.** Parr, A.J. (2022): Migrant and dispersive dragonflies in Britain during 2022. *J. Br. Dragonfly Society* 39(2): 1-13. (in English) ["In Britain, the year 2022 started dramatically, with the country's second-ever record of *Sympetma fusca* being made near Hedge End, Hampshire, on 5 May; despite the species' current rarity, it may be a potential future colonist. Later highlights included the continuing rapid internal spread of *Aeshna isocetes*, with an apparent new breeding colony being found at Slapton Ley in Devon and with wandering individuals being noted in Somerset, Wiltshire, north Hampshire and, remarkably, near Wigan in south Lancashire. The discovery of a male *Crocothemis erythraea* at Minsmere, Suffolk, on 28 July, and the sighting of a male *Sympetrum flaveolum* at Kilnsea Wetlands near Spurn, East Yorkshire, on 5 September, were also of considerable interest. The record of *S. flaveolum* is the first in Britain for nearly a decade. Meteorologically, summer 2022 was notable for periods of high temperatures and drought over large parts of western Europe. This clearly had an impact on events in the dragonfly world, with seemingly both positive and negative consequences for migration. All of our commoner recent 'traditional' migrants such as *Aeshna affinis*, *Anax parthenope*, *Anax ephippiger* and *Sympetrum fonscolombii* apparently showed influxes during the year, though the growing strength of resident populations of the former two species here made detailed analysis difficult. The numbers of individuals seen were, however, generally unspectacular with the exception of *A. parthenope*, which had a record-breaking season. Much of this good showing by *A. parthenope* seemingly reflected good local breeding, though there were several unexpected records, particularly from northern England and Scotland, that imply that some

long-distance movement also took place." (Author)] Address: Parr, A.J., 10 Orchard Way, Barrow, Bury St Edmunds, Suffolk, IP29 5BX, UK

Insecta) in different habitats of Pune district, Northern Western Ghats, Maharashtra, India. *International Journal of Entomology Research* 7(3): 145-158. (in English) ["68 localities from Pune district, Maharashtra, India were surveyed for diversity, assemblage and seasonal distribution of Odonata along three different habitats viz. agricultural land, forest and wetlands, and urban. The present investigation is based on extensive survey of all three habitats during three major seasons (pre-monsoon, post-monsoon and winter). A total of 4,268 individuals belonging to 68 species in 39 genera under 9 families were recorded during the study period (December 2011-December 2015). Family Libellulidae (44%) was the most dominant and widely distributed in different sampling sites in all the three habitats. The most dominant species was *Pantala flavescens* (18.35 %). Across the three land-use types, there was a difference between the species composition with forest being the most diverse followed by urban habitat and agricultural land, though, the abundance of species were much more in urban habitat. Clustering analysis showed that urban and agricultural lands are more similar forming the same clusters whereas forest forms a different one. Species richness and abundance varied with seasons, post-monsoon being highest in richness as well as abundance. Variation in rainfall patterns has been reported to be one of the important factors. During the present investigation, a total of 52 species were reported from Bhimashankar Wildlife Sanctuary (WLS), and out of which 40 species were new records from the area. A total of 37 species was documented from Ujani Wetland, out of which 21 species have been recorded first time. Thus the present work aims to document the Odonate diversity of the Pune district along with their habitat selection and seasonal variations which provides baseline data that can be used for their conservation strategies." (in German, with English summary) ["European Odonata in the collection of the Zoological Museum of the University of Greifswald – The European Odonata of the collection in the Zoological Museum of the University Greifswald were registered and determined. Altogether 389 European specimens were evaluated. The largest part is from the 19th century and attributed to the former director C.E.A. Gerstaecker. Localities in Germany are in Mecklenburg-Western Pomerania, Brandenburg, Bavaria and Thuringia. Further specimens were collected in Poland, Italy, Austria, and Switzerland. Current specimens were collected during a study in 1996 and 1997 in Greifswald. Concerning Mecklenburg-Western Pomerania,

Bavaria, Berlin, Brandenburg, and Thuringia some blank Plane survey sheets of distribution were completed. Of seven species the earliest known collected specimens from Brandenburg are held in the collection. The historical collection of Emil von Bernuth is mentioned but the specimens lack locality data, thus they are not evaluable." **22219.** Tesar, D.E. (2022): Digging for information: Investigating the efficacy of tracking and augmenting *Lacunicambarus nebrascensis* for endangered dragonfly conservation. MSc. thesis, Department of Biology, Conservation and Biodiversity Specialization Program In the Graduate School The University of South Dakota: 109 pp. (in English) ["Restoration and preservation of habitat for threatened and endangered species can proceed in many ways. Augmentation strategies can be used to supplement threatened and endangered populations or the species and resources on which those imperiled species depend. Comprehensive knowledge of species movement and home range is necessary to formulate effective augmentation plans. For freshwater burrowing crayfish, this type of information is generally lacking. The studies reported here were designed to acquire detailed information that is essential for augmentation of the plains devil crayfish, *Lacunicambarus nebrascensis* (formerly, *Cambarus diogenes*). Although *L. nebrascensis* populations are not considered threatened, this crayfish provides vital refuge for the endangered (*Somatochlora hineana*). Because

the burrows created by *L. nebrascensis* are used by *S. hineana* to survive seasonal drying and overwintering periods; there is potential to enhance *S. hineana* habitat through *L. nebrascensis* augmentation. We tested the use of mobile and stationary PIT telemetry technology to track the movements of *L. nebrascensis* within *S. hineana* habitat (Chapter 1). This work demonstrated that *L. nebrascensis* could be tracked above and below ground and that the use of both stationary and mobile tracking equipment was necessary to recapture *L. nebrascensis* within different microhabitats. We investigated methods for the introduction of *L. nebrascensis*. In the laboratory, providing *L. nebrascensis* with a starter hole significantly decreased burrow initiation time (Chapter 2). This informed our field release trials where pit-tagged *L. nebrascensis* were released with a starter hole and a 24-hour acclimation period. Introduction treatment did not significantly impact the number of crayfish that relocated from their introduction point, and 64% of released *L. nebrascensis* burrowed within 3m of their introduction point. This indicated that a successful release into *S. hineana* habitat was possible. Our work establishes the functionality of PIT telemetry technology for tracking a primary burrowing crayfish species. We present a methodology that can be applied to introducing and tracking of other elusive fossorial species, which can aid in their own conservation or allow them to be used to improve available refuge space for other species that use their burrows." **22220.** Trájer, A.; Trájer, J. (2022): Effect of weather fronts on mosquito (Diptera: Culicidae) number based on a 90-days-long trapping and weather observation. *Acta entomologica slovenica* 30(1): 32-52. (in English, with Slovene summary) ["Mosquitoes are the cause of summer nuisance and vectors of several pathogens. Their activity and abundance are determined by meteorological factors. We performed a 90-days-long mosquito trapping and parallel measuring of temperature, air pressure, and precipitation values in Felsőörs, Hungary. The aim of the study was to find a correlation between the changing weather conditions and the trapped mosquito numbers and the four most abundant mosquito species. A total of 1716 mosquito individuals was trapped, and 19 mosquito species were identified. *Aedes cinereus*, *Aedes vexans*, *Anopheles maculipennis*, *Culex pipiens* formed the 87% of the mosquito material. The regionally rare species, *Ochlerotatus excretians* was also collected. The theoretical threshold of mosquito activity in the study was 11°C. Based on the multiple regression analyses, mean, maximum and minimum temperatures had a moderately strong positive effect, precipitation had a very weak positive effect and air pressure had a very weak negative effect on the number of caught mosquitoes. In the case of the four most abundant mosquito species, similar correlations were found. The statistical analysis of meteorological variables and mosquito numbers showed that higher mean daily temperatures 1 day prior to trapping had the most significant positive effect on mosquito numbers. Lower than average mosquito catches occurred mainly during or 1-2 days after the front passages, and the average mosquito catches generally were associated with front-free periods. It was concluded that weather fronts have a negative effect on mosquito activity ... For example, large dragonflies prefer to quest for prey after the passage of cold fronts (Russell et al. 1998). Swarming, starting immediately before the arrival of cold fronts, could be beneficial for breeding mosquitoes. The predation of dragonflies during swarming could cause notable losses for mosquito populations. This influence is so strong that it affects the timing of swarm

initiation and swarm site selection (Yuval & Bouskila 1993)."] (Authors)] Address: Trájer, A., Univ. of Pannonia, Sustainability Solutions research Lab, H-8200 egyetem utca 10, Veszprém, Hungary. Email address: [attilatrajer@gmail.com](mailto:attilatrajer@gmail.com)

**22221.** Tyrrell, M. (2022): On the success of *Chalcolestes viridis* (Vander Linden) (Willow Emerald Damselfly) and the decline of *Lestes sponsa* (Hansemann) (Emerald Damselfly) at Finedon Pocket Park, Northamptonshire. *J. Br. Dragonfly Society* 39(2): 14-24. (in English) ["The small pond at Finedon Pocket Park, Northamptonshire was the first in the County to be recorded with a colony of *C. viridis*. The species was discovered by the author in 2017, and has been the subject of several papers (Tyrrell, 2019a, Tyrrell, 2020). The pond hosts a strong colony of *Lestes sponsa* which the author has monitored, along with all other species recorded for the past 15 years. Since 2017, the colony of *C. viridis* has increased, with maximum counts in 2022 close to 100 adults while, over the same period, the colony of *L. sponsa* has declined from a maximum of approximately 75 to 5 adults, and adults have now become very hard to find even in their traditional areas. During the same period, the pond has seen several floods (that killed some willow trees) and has had droughts. This review considers the factors that could contribute to the decline in *L. sponsa*, and how the behaviour of *C. viridis* might contribute to its success and the decline in *L. sponsa*, including inter-species competition, egg mortality during winter floods and natural extinction events." **22224.** Abdel-Galil, F.A.; Morsy, S.M.; Farghal, A.I.A.; Abdel-Naser, M.A.; Moharram, A.M.M.; Mousa, S.E. (2023): Highlights on Insects and Fungi Associated with Mosquitoes Inhabiting Agricultural Drain Water in Different Areas of Assiut Governorate, Egypt. *Assiut Journal of Agricultural Sciences* 54(4): 196-211. (in English) ["The objective of the study was to determine the species composition of mosquitoes and their associated insects and fungi inhabiting drain water in different agricultural areas of Assiut governorate, Egypt. During 72 inspection visits and 164 examinations of drain water pools in seven areas of Assiut governorate, results indicated the presence of six identified mosquito species. *Culex pipiens* is considered the most frequent mosquito species with the highest Incidence Area Weight value IAW21. All six identified mosquito species were encountered in El-Badary area with an Incidence Species Weight ISW value of 14. Nine insect species belonging to five orders were recorded. *Pantala flavescens* is considered the most frequently associated insect species in all areas. Incidence Area Weight IAW for each identified species indicated that *P. flavescens* had the maximum value of IAW 14. Also, the maximum value of Incidence Species Weight was ISW 22 in El-Badary area. Twenty-four fungi species were identified from agricultural drain water pools. Aquatic fungi were twenty-two species inhabiting agricultural drain water and Nine fungi species were isolated from the associated insects. Some of these species recorded as entomopathogenic fungi for mosquitoes including *Fusarium oxysporum*, *F. solani*, and *F. incarnatum*. The incidence values of all fungi species isolated reached the maximum of 17 in Spring. So, the associated insect species and fungi with mosquitoes in the present study can play an active role as biological control agents in Integrated Pest Management (IPM) approach. This contributes to achieving the Sustainable Development Goals (SDGs)."] (Authors) Additional odonate species included into the analysis are *Anax ephippiger*, *Ischnura senegalensis* and *Trithemis aurora*.] Address: Abdel-Galil, F.A., Plant Protection Dept, Faculty of Agriculture, Assiut University, Assiut, Egypt. **22226.** Appel, E.; Michels, J.; Gorb, S.N. (2023): Resilin in insect flight systems. *Advanced Functional Materials* 2023, 2215162: 30 pp. (in English) ["Compared to wingless insects, pterygote insects profit from numerous wing-related benefits including a wider distribution range, the exploitation of various food resources and the escape from water. or land-confined predators. In order to maintain the wings' functionality, the wing design and resistance to material fatigue are of key importance. This is even more essential for survival when considering that wings are used for millions of wing beat cycles but cannot be repaired and do not contain inner muscles so that their aerodynamic performance is mainly based on passive, structure-based wing deformations. One of the components serving this purpose is the endowment of certain wing components with the elastomeric protein resilin building stable and complex material composites with the tanned cuticle. Resilin endows the respective structures with, e.g., higher flexibility and compliance and enables elastic energy storage. In this study, the occurrence of resilin in the insect flight system is reviewed based on previous studies of several insect orders including Odonata [*Sympetrum vulgatum*], Orthoptera, Hymenoptera, Coleoptera, Dermaptera, and Diptera, and the function of resilin is discussed with reference to the respective structures."] (Authors)] Address: Appel, Ester, Functional Morphology and Biomechanics, Zoological Institute, Kiel University, Am Botanischen Garten 1-9, D-24118 Kiel, Germany. **22227.** Aristizábal-Botero, A.; Snoeks, J.; Realpe, E.; Vanschoenwinkel, B. (2023): Conductivity and water level modulate developmental plasticity and explain distribution patterns in a diverse neotropical Odonata assemblage. *Freshwater Biology* 68: 1558-1571. (in English) ["The rock pools are located on the summit of two inselbergs inside Bojonawi Nature Reserve (Vichada, Colombia.... Developmental plasticity can help organisms to survive in temporally variable environments. However, it is not well understood how variation in life history plasticity helps species coexist in heterogeneous environments. Here, we investigate the extent to which life-history plasticity explains species distributions in a diverse assemblage of odonates in a tropical freshwater rock pool system characterized by substantial variation in pond permanence. Some Odonata can accelerate their development to leave the water before their habitat dries. However, how they sense habitat drying is poorly understood. Here, we experimentally tested the extent to which elevated concentrations of salts in water or reductions in water level can be used as cues for developmental acceleration in a neotropical Odonata assemblage from granite rock pools. Libellulidae were found along the permanence gradient and

accelerated their growth in response to elevated dissolved salts (measured as conductivity). *Anax amazili* was also found in all environments and did the same in response to lower water levels. In turn, larvae of *Telebasis simulata* were restricted to deeper long-lived pools and did not respond to the tested cues. Differentiation in life-history strategies can contribute to niche differentiation in this diverse predator assemblage. Developmental plasticity triggered by different cues helps odonates avoid mortality and exploit short-lived habitats. The global acceleration of freshwater salinisation due to human activities might disrupt the delicate links between low levels of dissolved salts and life-history responses and represent a significant threat to these ecosystems and their biodiversity." (Authors)] Address: Aristizábal-Botero, Ángela, Dept Biol., Univ.de Los Andes, Bogotá, 111711, Colombia. Email: [angela.aristizabal.botero@vub.be](mailto:angela.aristizabal.botero@vub.be)

**22228.** Arya, M. K.; Chandra, H.; Verma, A. (2023): Spatial insect diversity paradigms and related ecosystem services in the protected Nandhour Landscape of India. *Journal of Insect Biodiversity and Systematics* 9(1): 115-138. (in English, with Arabian summary) ["The Nandhour Landscape located in an eco-fragile biodiversity rich Terai Arc Landscape of India is protected in the form of a wildlife sanctuary and is least explored in terms of insect diversity and functions. Therefore, this study aimed to provide baseline information on the biodiversity of insects and their ecological functions in tropical to sub-tropical forest ecosystems which is important for the successful long-term provisioning of ecosystem functions and services in the protected landscape. Using standardized sampling techniques, the present study examined the structure and composition of insect assemblages in terms of their comparative diversity and richness across a range of habitat types in the Nandhour Landscape. Besides, the present study also evaluated the ecological significance of insect fauna. A total of 230 insect species belonging to 47 families and nine orders were recorded from various habitats and Lepidoptera was the most dominant insect order in terms of both richness and abundance, followed by Coleoptera, Hymenoptera, Odonata [*Acisoma panorpoides*, *Aethriamanta brevipennis*, *Brachythemis contaminata*, *Crocothemis servilia*, *Orthetrum glaucum*, *O. prunosum*, *O. sabina*, *O. taeniolatum*, *O. triangulare*, *Palpopleura sexmaculata*, *Pantala flavescens*, *Rhodothemis rufa*, *Trithemis festiva*, *T. pallidinervis*, *Ceriagrion coromandelianum*, *Ischnura rubilio*, *Pseudagrion australasiae*, *P. rubriceps*, *Neurobasis chinensis*, *Aristocypha fenestrella*, *A. quadrimaculata*, *Paracypha unimaculata*] and others. Species diversity and richness were the highest in dense moist and open dry riverine forests, while the least in plantation forest and agricultural land. The heterogeneous structure and composition substantiated the importance of overall spatial heterogeneity and natural forests in sustaining and maintaining the rich insect diversity. Conservation of insect diversity is highly important as several species provide crucial ecosystem services and aid in the functioning of various ecologically fragile habitats of the landscape." **22231.** Bártová, K. (2023): Vliv kvality prostředí na kondici larev vážek. Effect of habitat quality on the body condition of dragonfly larvae. BSc. thesis, Faculty of Environment, Czech Agrary University in Prague: 45 pp. (in Czech, with English summary) ["Individual species choose their habitats according to certain criteria. If they meet these criteria, the habitat becomes attractive to them. This bachelor's thesis focuses on the topic of ecological traps. Habitats may become such a trap if they are attractive to individuals and yet represent a poor-quality place for them to live. These traps are mostly created by human activities. The aim of this study was to investigate the effect of environmental quality on the fitness of *Sympetrum vulgatum* larvae, which inherit their habitat from their terrestrial mother during oviposition. The evaluation was based on the number of immune cells in their haemolymph. The theoretical section of this work summarizes that the main factors affecting the fitness of larvae are predation, lack of food, pollution and stress, which is both a consequence of these factors and a cause of reduced immune function. The invertebrate immune system is based on both humoral and cellular mechanisms, which are based on cells called hemocytes. Hemocytes are investigated in the experimental section of this thesis, specifically their con-

centration in the haemolymph of larvae coming from different environments. Ten sites in the Sokolov region were selected for the research, 5 of which were natural and 5 were reclaimed sites after lignite mining. The amount of hemocytes and granulocytes in the haemolymph of larvae from both types of habitats collected on two dates was identified in the laboratory. The results of my work confirmed the assumption that larvae from natural sites possess a greater number of immune cells, especially granulocytes, than larvae from reclaimed habitats. In addition, larvae from reclaimed habitats were of smaller size. These differences were particularly evident in the second measurement. From this study, I conclude that environmental quality has a significant effect on the fitness of dragonfly larvae, and this effect increases with the prolonged duration of exposure to a given environment. Understanding similar mechanisms in nature is critical for the conservation of animals and their environment. Building on this knowledge, it is possible to mitigate the impact of human activities through appropriate measures and habitat management. In addition, data concerning invertebrate immunity can contribute to the development of medicine and pest control." (Author)] Address: Bártová, Katerina: <https://theses.cz/id/fnt9i6/23687107>

**22232.** Bastian, H.-V.; Bastian, A. (2023): Specialist or opportunist — the diet of the European bee-eater (*Merops apiaster*). *Journal of Ornithology* 164(4): 729-747. (in English, with German summary) ["*M. apiaster* is considered a foraging specialist for large flying insects, 80% or more of which are Hymenoptera, mainly bumblebees and other bees, including honeybees. Observations of bee-eaters foraging give rise to doubts about an almost one-sided Hymenoptera diet, as Lepidoptera, Odonata, large Diptera or Heteroptera are also regularly and frequently preyed upon and fed to nestlings and brood mates. In a meta-analysis of 56 studies on the bee-eater's diet, a total of 130,624 prey items from 115 food samples were evaluated. Total of 85 samples (74%) with 83,953 items (72%) came from Southern, Eastern and Central Europe; however, studies from North Africa, Central Russia, Ukraine, Turkmenistan, Uzbekistan, Saudi Arabia and South Africa were also included in the analyses. The collection methods significantly influence the results of the dietary composition. In studies of pellet and stomach contents, the diet was less diverse. It consisted of about 90% Hymenoptera and Coleoptera overall, whilst other arthropods were rarely detected. Studies based on direct observation or photo documentation showed that the diet was more diverse, and Hymenoptera were not always the most abundant, but could also include Odonata, Lepidoptera, Tabanidae, Syrphidae, Saltatoria, Heteroptera or Hemiptera in significant amounts. The proportion of Hymenoptera in these studies was 49%, about a third (20%pts – 30%pts) lower than in the pellet and stomach content studies, and the proportion of Coleoptera (13%) about a quarter lower. We assume that bee-eaters completely digest weakly sclerotised prey and that these are, therefore, not detected in pellets and stomachs, or only in low numbers. This means that 81% of published studies on the bee-eater's diet are based on methods that lead to quantitatively and qualitatively unrepresentative results and thus do not provide precise results of diet compositions. Observational and photographic methods have only been used to study the nestling diet. Therefore, a reliable statement about what adult bee-eaters eat themselves and how the diet is composed quantitatively is currently not possible. The diet of adult and juvenile birds could only be compared based on the poorly representative pellet and stomach content analyses. This analysis is limited to the abundance of Hymenoptera and Coleoptera, which

are well detectable in pellets and stomachs. Hymenoptera were significantly more abundant in the nestling diet, whilst coleopterans were more abundant in the adult diet. The diet also varied regionally. Bumblebees, because of their sluggish flight and because they are already active at relatively low ambient temperatures, are important food animals in climatically less optimal and oceanic areas at the northern edge of the range. In other regions, Hymenoptera occur less frequently and less regularly, whilst Coleoptera, Odonata, Lepidoptera, large Diptera, Saltatoria, Isoptera or Hemiptera may occur locally in significant numbers as prey. The extent to which diet varies seasonally could not be clearly proven. Only one of five studies shows weakly significant changes in diet composition over the breeding season. This study is based on direct observation of prey fed to nestlings, whilst the other studies examined prey remains in pellets. Although the pellet studies also showed different food compositions over the course of the brood, trends between studies were inconsistent and not significant overall. We hypothesise that local influences (weather, habitats) affected diet composition. Further analysis is needed to determine whether food supply or demand changes during the breeding season. In addition to analysing the food composition, also the food supply must be surveyed, which has rarely been done so far. The opportunistic use of food resources can support the successful colonisation of breeding areas and is probably an important factor in the current successful expansion of the European bee-eater." **22233.** Bazzi, G.; Galimberti, A.; Fogliani, C.; Bani, L.; Bazzi, L.; Bonvicini, P.; Brembilla, R.; Brigo, M.; Cavenaghi, A.; Colombo, G.; Della Pietà, C.; Galliani, C.; Guarnaroli, E.; Larroux, N.; Monti, A.; Orioli, V.; Ornaghi, F.; Pilon, N.; Pirota, G.; Radaelli, G.; Tessa, G.; Assandri, G. (2023): Odonate diversity of a highly urbanised region: An annotated checklist of the damselflies and dragonflies (Insecta, Odonata) of Lario and Brianza (Lombardy, N Italy). *Biodiversity Data Journal* 11: e111358: 34 pp. (in English) ["Given their sensitivity to environmental alterations, odonates act as reliable bioindicators to assess the effects of changes in freshwater ecosystems and associated terrestrial habitats. The region comprised between Lario and Brianza (Provinces of Como, Lecco and Monza and Brianza, Lombardy, N Italy) is one of the most urbanised of the Italian peninsula and large parts of its territory have been heavily altered, especially at low elevation. Despite this pervasive anthropogenisation, the area is still characterised by a considerable variety of freshwater habitats, possibly harbouring rich odonate communities, which, however, have been never thoroughly investigated. This study aimed to produce the first commented checklist of the Odonata of this region, accompanied by distribution maps. The work is based on 12,093 records spanning from 1981 and 2022, derived from literature (289), revision of collections (42), citizen-science projects (1249) and unpublished data from the authors and their collaborators (10,513). Overall, fifty-five species occur or occurred in the past in the study area (20 Zygoptera and 35 Anisoptera). One species, *Erythromma najas*, was confirmed exclusively before 1978, while seven species (*Lestes barbarus*, *Coenagrion scitulum*, *Aeshna affinis*, *Anax ephippiger*, *Somatochlora arctica*, *Sympetrum meridionale* and *Trithemis anulata*) have been recorded only after 2000. Records referring to *Chalcolestes parvidens* and *Sympetrum flaveolum* were considered questionable and excluded from the checklist. A list of species for each protected site is additionally provided. This work highlighted the importance for odonates of Lario and Brianza Regions from a national perspective,

in particular for species of conservation priority/interest, such as *Symplocma paedisca*, *Oxygastra curtisii* and *Sympetrum depressiusculum*." (Authors)] Address: Galimberti, A. **22234.** Berta, J.L.; Mott, C.L. (2023): Leaves of an invasive shrub induce mass mortality of an amphibian apex predator and its macroinvertebrate prey. *Biological Invasions* 25: 3277-3291. (in English) ["Studies of plant invasions have primarily focused on effects within shared habitats of native and invasive species. However, secondary compounds produced by terrestrial invasive plants can cross terrestrial-aquatic boundaries via senesced leaves, leading to altered patterns of aquatic biodiversity and ecosystem functioning. Impacts of phenolic compounds from senesced leaves have been characterized among relatively lower trophic groups, but effects on keystone species, such as apex predators, should have disproportionately larger effects on aquatic food webs. Using a widespread invasive species (Amur Honeysuckle, *Lonicera maackii*), we employed experimental mesocosms to examine effects of honeysuckle leaf litter addition on survival of apex predators (larval spotted salamanders, *Ambystoma maculatum*), their zooplankton and macroinvertebrate prey, indicators of primary productivity and decomposition, and abiotic variables influenced by phenolic compounds. Despite previous laboratory observations suggesting *A. maculatum* might exhibit resistance to *L. maackii* leachates, we observed near complete loss of both *A. maculatum* and benthic macroinvertebrates in experimental mesocosms, while zooplankton abundance was unaffected. Mortality was likely associated with precipitous declines in dissolved oxygen following rapid decomposition of *L. maackii* leaves, and these conditions facilitated nearly 15-fold increases in larval mosquito abundance. Our results highlight how experimental venue and methodology may alter outcomes of investigations involving senesced leaves of invasive plants. Losses of amphibian predators under quasi-natural invasion conditions indicate important influences on terrestrial-aquatic nutrient exchange, and we highlight phenological patterns of leaf senescence and breeding by aquatic organisms as important avenues for further investigation in characterizing the consequences of plant invasions.... Many invertebrate taxa colonized mesocosms independently; however, three snails and three larval Coenagrionidae were added to each mesocosm prior to introduction of amphibian larvae, since it appeared unlikely these groups." **22235.** Bethoux, O.; Anderson, M (2023): New light shed on Triadophlebiomorpha wing morphology and systematics (Insecta: Odonata). *Geodiversitas* 45(17): 479-496. (in English, with French summary) ["The systematics of the Triadophlebiomorpha, a group of often large-sized stem-Odonata, essentially Triassic, is reconsidered based on new data on some of the known species and on new material from the Molteno Formation (South Africa). New data on *Reisia gelasii* (Reis, 1909) (Anisian; Muschelkalk basin, Germany) and 'Triadotypus' *guillaumei* Grauvogel & Laurentiaux, 1952 (Anisian; Grès à Volt zia, France) allowed reconsidering the delimitation of the corresponding genera, *Reisia* Handlirsch, 1912 and *Triadotypus* Grauvogel & Laurentiaux, 1952, the latter regarded as a junior synonym of the former. Thanks to its pristine preservation of the wing three-dimensional structure, the material of *Piroutetia liasina* Meunier, 1907, re-illustrated, provides further insights on wing venation homologies in the

group. These new data, coupled with new ones on known and new material from Molteno (Carnian; Karoo Basin, South Africa), led us to corroborate the placement of *Triassologus biserialatus* Riek, 1976 to the Triadophlebiomorpha, and to recognize '*Reisia*' *rieki* Deregnacourt, Wappler, Anderson & Béthoux, 2017 as its junior synonym. In turn, it is argued that the sub-contemporaneous species *Iverya aveyri* Béthoux & Beattie, 2010, from Australia, is to be assigned to *Triassologus* Riek, 1976 (and the genus *Iverya* Béthoux & Beattie, 2010 considered its junior synonym), further emphasizing similarities between South African and Australian Triassic insect faunas. A subset of the Triadophlebiomorpha possesses a CuP+AA stem splitting into CuA and CuP+AA (as opposed to Cu and AA). This trait is present in *Nototriadophlebia pritykinae* n. gen., n. sp., an addition to the Triadophlebiomorpha from Molteno." (Authors)] Address: Béthoux, O., CR2P (CNRS, MNHN, Sorbonne Université), Muséum national d'Histoire naturelle, case postale 48, 57 rue Cuvier, 75231 Paris cedex 05, France. Email: obethoux@mnhn.fr

**22236.** Betsi, W.C.N.; Menbohan, S.F.; Lactio, N.L.; Tchouapi, Y.L.; Temgoua, M.A.Z.; Mbia, D.L.N.; Nhiomock, S.R.G.; Nwaha, M.; Ngon, E.B.B.A.; Dzavi, J.; Mboyé, B.R.; Nola, M. (2023): Comparative approach of the fauna diversity of benthic macroinvertebrates in a stream on ferrallitic soil and equatorial climate at 2 seasons in Cameroon (Central Africa). *World Journal of Advanced Research and Reviews* 19(1): 254-264. (in English) ["In order to determine the structure of benthic macroinvertebrates fauna in relation with some environmental factors, a study was carried out in the Esoa river at Nkongsamba in the Littoral region of Cameroon from January 2021 to January 2022. Physico-chemical parameters were measured according to APHA and Rodier recommendations, while benthic macroinvertebrates sampling was done out according to the multihabitat approach at a monthly frequency. The physico-chemical analyses revealed very good oxygenation of the water, a tendency of neutrality for the pH (7.79±0.8 UC) and a low and constant temperature (22.61±1.83 °C). The BMI count showed 3732 individuals, including 4 phyla, 6 classes, 14 orders and 69 families and over 80 species. Besides, the class of insects, and in particular the order of Odonata, supplanted the benthic fauna. The Esoa 2 and Esoa 3 stations recorded the highest relative abundance of BMI (37.43% and 36.99% respectively) with a predominance of pollutant taxa, notably the families of Chironomidae, Physidae, Tubificidae and Lumbricidae. On the other hand, the Esoa 1 station, with low relative abundance (25.56%), was more diversified and dominated by polluosensitive taxa, including Ephemeroptera, Plecoptera and Trichoptera. The high values of the Sørensen similarity index (65.62%) showed a high faunal similarity of the Esoa 2 and Esoa 3 stations. The high values of the Shannon and Weaver diversity index (4.6 bits/ind) indicated a high diversity of benthic macroinvertebrates reflecting the good ecological status of the waters of the Esoa stream ... The abundance of Odonata (of 28.65% relative abundance) is linked to the strong riparian vegetation that borders the watercourse and the bridges present downstream of certain stations that considerably reduce the speed of the current and favour their settlement." (Authors)] Address: Betsi, Wilfreid Christiane Noel, Lab. of Hydrobiology and Environment, Fac. Science, University of Yaoundé I, P.O. BOX 812, Yaoundé, Cameroon.

**22237.** Bezmaternykh, D.M.; Vdovina, O.N. (2023): Composition, structure and formation factors of macroinvertebrate communities in low-mountain lakes of the Russian Altai. *Acta Biologica Sibirica* 9: 433-449. (in English) ["Recent

data suggests a significant difference in physical and biological properties between low-mountain lakes and high-mountain or lowland water bodies. However, the taxonomic composition and structure of bottom invertebrates in low-mountain lakes of Altai remain unknown. Due to climate change and growing anthropogenic impact, studying the composition and structure of macrozoobenthos in these lakes is becoming increasingly urgent. In 2022, a study was conducted on macrozoobenthos from foothill lakes of the Russian Altai, specifically Kireevo in the Krasnogorsk region, Aya (Aiskoye) in the Altai region, Koksha and Svetloye in the Soviet region, Kolyvanskoye in the Zmeinogorsk region, and Belye in the Kuryinsky region of Altai Krai. The study identified 152 species from 9 classes, including Turbellaria (1), Nematoda (1), Oligochaeta (17), Hirudinea (5), Bivalvia (2), Gastropoda (8), Arachnida (10), Crustacea (2), and Insecta (106). Of the insects, the order Diptera (69 species, including 59 chironomids) had the greatest species diversity. Additionally, the orders Trichoptera (16), Coleoptera (7), Ephemeroptera (5), Odonata (4), Heteroptera (4), and Megaloptera (1) were identified. Most of the studied lakes in the Russian Altai (Aya, Belye, Kireevo, and Kolyvanskoye) had a taxonomic composition of macrozoobenthos similar to lowland lakes. Two lakes (Koksha and Svetloye) had a combination of features from both lowland and high-mountain lakes. The content of organic substances and their decomposition products in water, as well as substrate type, were the most significant factors determining the development of macroinvertebrate communities in the studied lakes." (Authors) No species details are given.] Address: Bezmaternykh, D.M., Institute for Water & Environmental Problems, Siberian Branch Russian Acad. Sciences (IWEP SB RAS), 1 Molodezhnaya st. Barnaul, 656038, Russia. Email: bezmater@mail.ru

Middle European Scientific Bulletin 42: 78-83.[Uzbekistan. Records of Calopteryx samarcandica, Sympetrum pedomontanum, Anax imperator, Orthetrum brunneum and Ophiogomphus reductus are figured. The record of Calopteryx virgo is questionable. Additional species are listed in a table: Orthetrum albistylum, O. cancellatum, Sympetrum vulgatum, S. meridionale, Sympecma fusca] Address: Norkobilova Zarina Boyqobil kizi, Senior Lecturer, Department of Zoology Karshi State University Karshi, Uzbekistan.

**22242.** Burwell, C.J.; Power, N.R.; White, D. (2023): Is Agriocnemis rubricauda Tillyard, 1913 (Coenagrionidae) another parthenogenetic species of Odonata? Australian Entomologist 50(3): 206-220. (in English) ["Parthenogenesis, reproduction by females via unfertilised gametes, is widespread in insects but there is only one documented example among the Odonata. Ischnura hastata (Say) (Coenagrionidae) reproduces sexually across its wide range in the Americas from southern Canada to Brazil but has parthenogenetic populations comprising only females in the Azores islands in the eastern Atlantic Ocean. Recent circumstantial evidence suggests that the Australian damselfly Agriocnemis rubricauda Tillyard may also have sexual and parthenogenetic populations. The distribution of A. rubricauda was mapped and the monthly occurrence of males and females of A. rubricauda collated based on specimens in collections, our own photographic records and collections from extensive searches in south-eastern Queensland and north-eastern New South Wales and other photographic records submitted to iNaturalist. There appears to be a substantial gap in the range of A. rubricauda in coastal Queensland, with northern records from the Top End of the Northern Territory

and Queensland wet tropics, and southern records from southern Queensland and north eastern New South Wales. Male *A. rubricauda* are known only from the northern part of the range where there are similar numbers of records of males and females. Only females are known from the southern range where there are records of more than 320 individuals including 41 specimens in museum collections. Despite an estimated 96 person-hours of search effort across eleven locations in south-eastern Queensland and north-eastern New South Wales we encountered only females. In the northern and southern parts of the range, *A. rubricauda* adults have been recorded across most and all months of the year, respectively. We explore several explanations for the lack of males in the southern range and suggest that the most plausible explanation is that southern females are able to reproduce via parthenogenesis." **22243.** Carreira, B.; Kolár, V.; Chmelová, E.; Jan, J.; Adasevic, J.; Landeira-Dabarca, A.; Vebrová, L.; Poláková, M.; Horká, P.; Otáhalová, S.; Musilová, Z.; Borovec, J.; Tropek, R.; Boukal, D.S. (2023): Bioaccumulation of chemical elements at post-industrial freshwater sites varies predictably between habitats, elements and taxa: A power law approach. *Science of the Total Environment* 901 (2023) 165794: 14 pp. (in English) ["Elevated environmental levels of elements originating from anthropogenic activities threaten natural communities and public health, as these elements can persist and bioaccumulate in the environment. However, their environmental risks and bioaccumulation patterns are often habitat-, species- and element-specific. We studied the bioaccumulation patterns of 11 elements in seven freshwater taxa in post-mining habitats in the Czech Republic, ranging from less polluted mining ponds to highly polluted fly ash lagoons. We found nonlinear, powerlaw relationships between the environmental and tissue concentrations of the elements, which may explain differences in bioaccumulation factors (BAF) reported in the literature. Tissue concentrations were driven by the environmental concentrations in non-essential elements (Al, As, Co, Cr, Ni, Pb and V), but this dependence was limited in essential elements (Cu, Mn, Se and Zn). Tissue concentrations of most elements were also more closely related to substrate than to water concentrations. Bioaccumulation was habitat specific in eight elements: stronger in mining ponds for Al and Pb, and stronger in fly ash lagoons for As, Cu, Mn, Pb, Se, V and Zn, although the differences were often minor. Bioaccumulation of some elements further increased in mineral-rich localities. Proximity to substrate, rather than trophic level, drove increased bioaccumulation levels across taxa. This highlights the importance of substrate as a pollutant reservoir in standing freshwaters and suggests that benthic taxa, such as molluscs (e.g., *Physella*) and other macroinvertebrates (e.g., *Nepa*), constitute good bioindicators. Despite the higher environmental risks in fly ash lagoons than in mining ponds, the observed ability of freshwater biota to sustain pollution supports the conservation potential of post-industrial sites. The power law approach used here to quantify and disentangle the effects of various bioaccumulation drivers may be helpful in additional contexts, increasing our ability to predict the effects of other contaminants and environmental hazards on biota." **22244.** Castellano, S.; Falbo, F.; Seglie, D.; Friard, O. (2023): Anti-predator behavior in two brown frogs: differences in the mean behaviors and in the structure of animal personality variation. *Behavioral Ecology and Sociobiology* 77, Article number: 98 (2023): 15 pp. (in English) ["Predation is a major source of selection and prey are known to modify their behavior depending on their past experiences and the current perceived risk. Within a species, variation in experience and in the response to perceived risk combine to explain variation in personality and individual plasticity. Between species, variation in personality and plasticity might also be the evolutionary consequence of different selective regimes. In this study, we describe the anti-predator behavior of two closely related brown frogs, *Rana dalmatina* and *Rana latastei*, and compare their structures of personality variation. We raised tadpoles in a common garden experiment with either fish, dragonfly larvae [*Aeshna* sp.], or no predators. Tadpoles were then repeatedly tested in the presence of the three acute stimuli and their behavioral variation was described in terms of quantity and quality of movements and of path sinuosity. In these tests, tadpoles of both species and ontogenetic treatments responded flexibly to predators by moving less, faster, and with more tortuous movements, and tadpoles raised with predators tended to move even faster. Independent of the acute treatment, *R. dalmatina* moved more and faster than *R. latastei* and the differences were larger without than with predators, demonstrating its higher plasticity. At the individual level, the two species showed qualitatively similar but quantitatively different structures of personality variation. *R. dalmatina*, more active, faster, and more plastic than *R. latastei*, showed also higher repeatability and a larger behavioral variation both among and within individuals. Significance statement: Predators are a major source of selection and preys have evolved the ability to flexibly respond to them. These responses often vary among species, because of their different evolutionary histories, and among individuals, because of their different experiences. We analyzed both these sources of behavioral variation in two closely related brown frogs, *Rana dalmatina* and *R. latastei*. We raised tadpoles either with or without predators and tested them in open field trials both with and without predators. The effects of the raising environment were similar in the two species, whereas the effects of the testing arena differed. Both species decreased activity and increased speed and sinuosity with predators, but *R. dalmatina* moved always more and faster than *R. latastei* and it showed higher plasticity, larger variation among and within individuals, and relatively higher values in repeatability." **22245.** Chalmers, P.; Melchers, G.; Tikka, K.; Richardson, J.S. (2023): Distribution of the grappletail dragonfly (*Octogomphus specularis*), a lake outlet stream specialist at its northern range limit. *Fundamental and Applied Limnology* 197(1): 1-8. (in English) ["*O. specularis* reaches the northern end of its range in Canada and has only seven known occurrences within British Columbia, where its larvae are known only from lake outlet streams. Lake outlet streams provide a unique lotic environment with water from lakes providing high quality seston to filter feeders, favourably warmer water in summer, buffering from variation in discharge, and more stable substrates, in comparison to streams uninfluenced by lakes. We investigated factors that might explain why the distribution of larval grappletails appears to be restricted to lake outlet streams. We sampled the larvae from two outflow streams over one summer to determine

their number of age classes and estimate their abundances relative to distance from the lake outlets. We characterized the thermal regime of each lake outlet stream, and quantified the temperature differences between lake outlets and inflow streams. The two lake outlet streams were on average 37 % warmer (4.4 °C and 7.2 °C) higher than the inflow streams. We found three groupings of larval sizes, indicating a life cycle of three years. In one stream, larval abundance decreased with increasing distance from the lake, but in the other stream there was no pattern of decrease. Our results are consistent with the theory that warmer thermal conditions throughout summer at lake outflow streams provide sufficient degree-days to support development of this species' larvae at the northern end of their global range." (2023): Die Libellenfauna eines Stillgewässers in Niederösterreich unter besonderer Berücksichtigung seiner Salinität. *Libellula* 42(1/2): 1-26. (in German, with English summary) ["Odonata at a stagnant water body in Lower Austria with special reference to its salinity – A standing water body with a size of about 1,500 m<sup>2</sup> was subject of an odonatological survey from 2021 to 2022. Due to heterogenic habitat conditions, 36 odonate species were found with 15 of them autochthonous (e.g., *Coenagrion scitulum* and *Sympetrum meridionale*, both "threatened with extinction" according to the Austrian Red List). In the case of 13 spp. successful development was proven by records of teneralis and exuviae and two spp. were classified as autochthonous because of high abundances in both years. The identification of exuviae was performed using DNA barcoding technique. The results of the study confirm the tolerance of many Central European dragonfly and damselfly species towards salinity. A maximum of 1.8 PSU (Practical Salinity Units) was calculated for the investigated water body due to increased chloride and sodium concentrations. Based on the results obtained in this study, the published tolerance limits of some species have to be raised. Only verbally described plasticity towards salinity in other species is now confirmed by precise values of chloride and sodium. Desiccating parts of the water body in 2022, due to low precipitation and groundwater levels, probably had an important impact on the Odonate community." **22248.** Darkin, J. (2023): The first record of a viviparous lizard *Zootoca vivipara* predated a blue-tailed damselfly *Ischnura elegans*. *The Herpetological Bulletin* 163: 41. (in English) ["On 13 July 2022, I visited Foulshaw Moss Nature Reserve, Cumbria, England (54° 14'39" N, 2° 50'03" W). This reserve is a raised peat bog habitat, situated on the southern tip of the English Lake District covering an area of 3.5 km<sup>2</sup>. It is an ideal habitat for *Z. vivipara* and the northern viper *Vipera berus*. At 12:07 h, when the weather was partly cloudy with an approximate air temperature of 17 °C, a male *Z. vivipara* was observed basking on the edge of the Foulshaw Moss boardwalk close to the peat moss and near a peat pool. It was here the damselfly alighted only to be grasped by the lizard (Fig. 1). I recorded the lizard taking approximately one minute to ingest the damselfly, during which time the lizard shook the damselfly from side to side, dragging it backwards across a portion of the boardwalk to force it into its mouth, eventually swallowing the entire damselfly (BHS video, 2023). Following ingestion, the lizard resumed basking with its mouth agape. The Foulshaw Moss Nature Reserve has an abundance of both damselflies and dragonflies, including the endangered white-faced darter *Leucorrhinia dubia*, as well as a diverse array of other invertebrate prey for *Z. vivipara*." ISBN 978-2-36833-452-2: 324 pp. (in French) ["The product of a collective work of 29 authors, it compiles, in a beautiful 324-page book, (1.4 kg) all of the current knowledge on dragonflies from the six departments of the study. From 2000 to 2020, nearly 2,000 observers mobilized to collect more than 165,000 data, to which were added 25,000 historical observations. Each of the 68 species present in the territory is presented in a monograph which includes its general distribution, its history and its biology in the study area, its status and abundance, the results of the survey and the perspectives concerning it. Distribution maps covering the two periods, phenology graphs and around 250 photos enrich the monographs, as well as a history of Latin and French names. A documented review of the evolution of habitats over the centuries, an analysis of the distribution by watershed and the conservation status of dragonfly populations complete this important work. The book also looks at other original themes such as the history of the study of dragonflies and that of their presence in popular traditions. The recently created Breton names are published for the first time. Finally, a photographic key to the 68 species will allow beginners or experienced naturalists to have a synthetic document to identify them in situ or a posteriori." **22251.** Deacon, C.; Samways, M.J.; Pryke, J.S. (2023): Interplay between pond size and matrix extent drives odonate diversity patterns in a fragmented landscape. *Biodiversity and Conservation* 32: 4767-4785. (in English) ["Landscape fragmentation impacts freshwater habitats and their quality, affecting aquatic insect assemblages. Adjacent terrestrial areas are important secondary habitats where amphibiotic insects mature, feed, find mates, and move to locate aquatic breeding habitats. Using a factorial design with 27 small and large ponds within small and large natural patches in an exotic tree plantation-fragmented landscape of South Africa, and odonates as model organisms, we investigated (1) how pond size/natural terrestrial patch size interaction affects odonate diversity patterns versus habitat quality variables, and (2) determined whether anisopterans and zygopterans respond differently to landscape fragmentation. Species richness was similar among ponds. However, odonate abundance was highest in large ponds regardless of natural terrestrial patch size. Zygopteran functional richness and diversity was driven by pond and natural patch size, suggesting that zygopterans are sensitive to landscape fragmentation. In contrast, anisopterans were more resilient to fragmentation and more likely to select suitable habitats following water chemistry and vegetation characteristics. Overall, large ponds were occupied by different odonate assemblages compared to small ponds, and occupancy was strongly associated with mobility traits. These findings emphasize that ponds in both small and large natural terrestrial patches have conservation value. A pondscape that represents various pond sizes is important for maintaining regional odonate diversity. Pond conservation needs to be considered in the wider terrestrial context, which host a range of important secondary habitats. Adjacent natural terrestrial habitats also connect nearby aquatic habitats, which enable insects to move across the landscape in response to natural and artificial drivers." **22253.** Dharan, D.T.; Greeshma (2023): Preliminary studies on the diversity and abundance of odonates in the selected sites of southern Kerala. *Asian Journal of Conservation Biology* 12(1): 82-89. (in English) ["Biodiversity forms the foundation of the vast array of ecosystem that critically contributes to human well-being. Odonates are considered to be indicator of ecological balance and are commonly seen in and around water bodies. The present study was carried out to assess the Diversity and Abundance of Odonates in the selected sites of Kollam and Trivandrum districts, Kerala, India in 2020-2021. A total of 25 species belonging to 16 genera and 6 families were recorded during the entire study. Suborder Anisoptera was represented by the families Libellulidae, comprising 10 species and Gomphidae, with 1 species; and the suborder Zygoptera was represented by the families Calopterygidae, with 2 species; Platycnemididae, with 3 species; Coenagrionidae, with 8 species; and Chlorocyphidae, with 1 species. Libellulidae was the dominating family with 40% of the total observations, followed by Coenagrionidae family. The only way to save the Odonata fauna and its habitats is creating awareness among the people. In this context, knowledge of Odonata fauna of a region is the first step towards conservation." **22255.** Edegbene, A.O.; Elakhame, L.A.; Arimoro, F.O.; Osimen, E.C.; Edegbene Ovie, T.T.; Akumabor, E.C.; Ubanatu, N.C.; Njuguna, C.W.; Sankoh, A.A.; Akamagwuna, F.C. (2023): How do the traits of macroinvertebrates in the River Chanchaga respond to illegal gold mining activities in North Central Nigeria. *Frontiers in Ecology and Evolution* 11: 15 pp. (in English) ["Africa harbours about a third of the world's largest natural resource reserves of mineral such as gold and diamonds. These vast mineral reserves in Africa are essential to the continent's development and modern industrial society. However, these minerals, including gold, are often illegally mined by locals which leads to biodiversity loss and groundwater and surface water contamination. In the present study, we assess the impact of illegal gold mining (i.e., panning) and other anthropogenic activities on the distribution patterns of macroinvertebrate traits in the River Chanchaga, North central Nigeria. Anthropogenic activities including urban development, agricultural activities, household activities and gold mining are impacting the Chanchaga stream sites samples in Nigeria. We selected four sampling stations (i.e., reaches), denoting increasing disturbance order; Station 1 < Station 2 < Station 4 < Station 3. Four macroinvertebrate traits, body size, mode of respiration, mode of locomotion, and body shape, were selected and categorized into 19 attributes. The trait attributes were assigned to taxa using the fuzzy coding method. The relative abundance of traits in the study river showed that very

large body size (>40–80 mm) macroinvertebrates dominated Stations 1 and 2 while large body size (>20–40mm) dominated Station 3. The relative abundance of macroinvertebrates possessing an integument for oxygen diffusion dominated Station 4. The RLQ model showed that traits such as medium body size (>10–20 mm), gills as mode of respiration, and streamlined and spherical body shapes were positively associated with Stations 1 and 2. Conversely, small (>5–10 mm) and very large (>40–80 mm) body sizes, spiracle: vegetative respiration using plant stems, climbing mode of locomotion, and sprawling mode of locomotion were positively associated with Stations 3 and 4. The fourth-corner test revealed that macroinvertebrates with very small (<5mm) and medium body sizes (>10–20 mm), spiracles mode of respiration and climbing mode of locomotion were positively associated with at least one of the following physico-chemical variables: 1) electrical conductivity [EC ( $\mu\text{S cm}^{-1}$ )], 2) biological oxygen demand [BOD 5 ( $\text{mg l}^{-1}$ )], 3) sulphate ( $\text{mg l}^{-1}$ ), 4) nitrate ( $\text{mg l}^{-1}$ ) and 5) phosphate ( $\text{mg l}^{-1}$ ). These traits were classified as resilient traits to pollution in our study. On the other hand, macroinvertebrates that possess gills and can swim actively were positively associated with dissolved oxygen and were deemed vulnerable to pollution. Based on our findings, we concluded that anthropogenic activities, especially illegal gold mining, alter the distribution patterns of macroinvertebrates traits and, in turn, the ecological balance of the ecosystem. To forestall further damage to the ecological health of the River Chanchaga, the government should regulate the activities of gold miners." (Authors) Taxa. including Odonata. are treated at family level; from the Gomphidae a figure is published, claimed to be an *Ictinogomphus*.] Address: Edegbene, Augustine, Dept of Biological Sciences, Federal Univ. of Health Sciences, Otuokpo, Nigeria. **22256.** Ehling, J.; Zitzmann, F.; Diekmann, L.; Reich, M. (2023): Eine Paludikultur mit Schilf und Rohrkolben in der Etablierungsphase als Lebensraum für Libellen. *Libellula* 42(1/2): 27-47. (in German, with English summary) ["A paludiculture with reed and cattail in the establishment phase as habitat for dragonflies – In order to reduce greenhouse gas emissions from drained peatlands, extensive rewetting activities are required. In this context, paludiculture could play a key role, as it combines climate protection and agricultural production. The establishment of these crops creates novel habitats for fauna and flora. The aim of this work was to assess the habitat potential of a recently established paludiculture with reed and cattail for dragonflies (Odonata). For this purpose, surveys were carried out on a paludiculture pilot site and in different reference habitat types in the district of Oldenburg (NW-Germany). The results show that the investigated paludiculture was of great importance for the dragonfly fauna of the study area in the second year after its establishment. In comparison to the comparatively species-poor reference habitats, the highest total species numbers were recorded (including the endangered pioneer species *Ischnura pumilio*), the detected species had comparatively high abundances, and the highest number of species with reproductive behaviour was found. The high attractiveness of the site probably resulted from the combination of shallow water levels, full-area sun exposure, and a high structural diversity, which simultaneously provided suitable conditions for species with different demands. However, these habitat characteristics are limited to the establishment phase of the crops. Further growth of reed and cattail towards dense stands is expected to rapidly reduce the habitat quality for dragonflies. Since paludicultures with reed and cattail are novel land-use systems and our investigation covered only

a short period of time, there is a considerable need for research on the further succession of the dragonfly fauna as the cultures age, on the effects of harvesting on different dragonfly species, and on potential measures to promote dragonflies and other species groups in paludicultures." (2023): Basal complex: a smart wing component for automatic shape morphing. *Communication Biology* 6:853 | <https://doi.org/10.1038/s42003-023-05206-1>: 9 pp. (in English) ["Insect wings are adaptive structures that automatically respond to flight forces, surpassing even cutting-edge engineering shape-morphing systems. A widely accepted but not yet explicitly tested hypothesis is that a 3D component in the wing's proximal region, known as basal complex, determines the quality of wing shape changes in flight. Through our study, we validate this hypothesis, demonstrating [by using *Sympetrum vulgatum*, *Calopteryx splendens*, *Ischnura elegans*] that the basal complex plays a crucial role in both the quality and quantity of wing deformations. Systematic variations of geometric parameters of the basal complex in a set of numerical models suggest that the wings have undergone adaptations to reach maximum camber under loading. Inspired by the design of the basal complex, we develop a shape-morphing mechanism that can facilitate the shape change of morphing blades for wind turbines. This research enhances our understanding of insect wing biomechanics and provides insights for the development of simplified engineering shape-morphing systems." S1 thesis, biologi, Jurusan Matematika dan Ilmu Pengetahuan Alam, Fakultas Sains dan Teknologi, Universitas Jambi: XIV, 69 pp. (in Indonesian) ["Predatory insects are natural enemies that often visit honey and nectar producing plants as an alternative source of feed. Refugia is a plant of several types of plants that provide shelter, provide a source of food or a source of nutrition, tend to have bright petal colors or flowers with striking colors that aim to attract natural enemy insects. This research is a quantitative descriptive research with the sampling point applied, namely the planting pattern on the edge of the land plot. Sampling was carried out by sweep net technique, direct observation and branch beating. Sampling of predatory insect species in the morning at 06.00–08.00 WIB and in the afternoon carried out 15.30–17.30 WIB. Predatory insects associated with refugia plants number 24 species from 5 orders, namely Coleoptera, Hymenoptera, Diptera, Mantodea, and Odonata [*Orthetrum sabina*, *Rhyothemis fenestrina*, *R. phyllis*]. The association of predatory insects with *Tagetes* sp plants has a low category association index value. Predatory insects associate with plants *Celosia* sp. *Eumenes coronatus* species with an association scale value of 0.95, *Delta campaniforme* species with an association scale value of 0.76 are species with a very high association index value. The diversity of predatory insects found in refugia plants in Solok village, Kumpeh Ulu district, is in the medium category. The evenness value is included in the high category,

while the dominance value is no dominant species." (Authors)] Address: <https://repository.unja.ac.id/57339/3/Skripsi%20mira%20erlita%20nim%20F1C417010%20full.pdf>

**22259.** Fadel, A.; Guerrieri, F.; Pincebourde, S. (2023): The functional relationship between aquatic insects and cyanobacteria: A systematic literature review reveals major knowledge gaps. *Total Environment Research Themes* 8, December 2023, 100078: 18 pp. (in English) ["Cyanobacteria and aquatic insects are major components of food webs in freshwater ecosystems. However, the functional relationship between cyanobacteria and aquatic insects has been poorly studied. The blooms of cyanobacteria are more likely to intensify with rising temperatures, such that climate warming may influence this relationship. To improve our understanding of this relationship, we performed a systematic literature review (SLR) and analyzed 104 peer-reviewed research articles published between 1985 and 2020. The articles were categorized into three themes: the role of cyanobacteria as food source and habitat for aquatic insects, the impact of cyanotoxins on aquatic insects, and the use of *Bacillus thuringiensis* (Bt) expressing transgenic cyanobacteria to control Diptera, mainly mosquitoes. Major findings on each of these themes were summarized and research gaps and opportunities were highlighted. Major gaps include the lack of ecological modelling studies that describe or model this relation, the absence of studies of cyanotoxins' impact on key aquatic insects like dragonflies, the impact of Bt larvicidal engineered cyanobacteria on biological indicators like Chironomidae, the lack of studies on climate change impacts on the functional links between cyanobacteria, aquatic insects and other organisms. These gaps and research opportunities should be addressed in future research to increase the understanding of the relationship between cyanobacteria and aquatic insects and therefore the biology of freshwater ecosystems." **22260.** Fernandez-Nicolas, A.; Machaj, G.; Ventos-Alfonso, A.; Pagone, V.; Ohde, T.; Daimon, T.; Ylla, G.; Belles, X. (2023): Reduction of embryonic E93 expression as a hypothetical driver of the evolution of insect metamorphosis. *Proceedings of the National Academy of Sciences* 120 (7) e2216640120: 7 pp. (in English) ["Significance: Insect metamorphosis is classified into hemimetaboly and holometaboly, which derives from the former. Hemimetabolans nymphs are similar to the adult, whereas in holometabolans embryogenesis produces a larva that differs from the adult, being vermiform in extreme cases. The embryo of the hemimetabolans *Blattella germanica* expresses the gene E93 at high levels. In all insects, E93 triggers adult morphogenesis in the last juvenile stage, but in *B. germanica*, E93 is also crucial for embryogenesis. Intriguingly, E93 expression is high in the embryo of hemimetabolans, but very low in holometabolans. We hypothesize that E93 determines the nymphal genetic program, and that the reduction of embryonic E93 expression has been instrumental for the formation of the larva and the evolution of holometabolans metamorphosis. Abstract: The early embryo of the cockroach *Blattella germanica* exhibits high E93 expression. In general, E93 triggers adult morphogenesis during postembryonic development. Here we show that E93 is also crucial in early embryogenesis in the cockroach, as a significant number of E93-depleted embryos are unable to develop the germ band under maternal RNAi treatment targeting E93. Moreover, transcriptomic analysis indicates that E93 depletion results in important gene expression changes in the early embryo,

and many of the differentially expressed genes are involved in development. Then, using public databases, we gathered E93 expression data in embryo and preadult stages, finding that embryonic expression of E93 is high in hemimetabolans species (whose juveniles, or nymphs, are similar to the adult) and low in holometabolans (whose juveniles, or larvae, are different from the adult). E93 expression is also low in Thysanoptera and in Hemiptera Sternorrhyncha, hemimetabolans with postembryonic quiescent stages, as well as in Odonata, the nymph of which is very different from the adult. In ametabolans, such as the *Zygentoma domestica*, E93 transcript levels are very high in the early embryo, whereas during postembryonic development they are medium and relatively constant. We propose the hypothesis that during evolution, a reduction of E93 expression in the embryo of hemimetabolans facilitated the larval development and the emergence of holometaboly. Independent decreases of E93 transcripts in the embryo of Odonata [*Ischnura senegalensis*], Thysanoptera, and different groups of Hemiptera Sternorrhyncha would have allowed the development of modified juvenile stages adapted to specific eco-physiological conditions." (2023): Wing size, shape, and asymmetry analysis of the wandering glider, *Pantala flavescens* (Odonata: Libellulidae) revealed that hindwings are more asymmetric than the forewings. *Biologia* 78: 2749-2762. (in English) ["The present study aimed to determine the wing asymmetry and sexual asymmetry of *P. flavescens* collected from a paddy field. *P. flavescens* is known as the longest migratory insect species and the morphological architecture of their hindwing aids in long-distance gliding. In our study, we collected F1 generation of male and female *P. flavescens* and used for geometric morphometric study to investigate wing asymmetry. We observed no difference in wing size between sexes from the study, but there are significant ( $p < 0.05$ ) shape differences. The female population was more asymmetric than male population, with a high shape-related fluctuation asymmetry (FA). Discriminant function analysis was used to validate wing asymmetry (right-left) and sexual asymmetry of *P. flavescens*. Canonical variant analysis discriminated the forewings and hindwings of *P. flavescens* both sexes in a distinct morphospace. The PC's warp shape analysis proved that, when compared to forewings, the highest amount of shape variations was observed in hindwings, especially in anal lobe regions. Based on the results, pesticide and fertilizer used in the paddy fields are the primary reason for the high level of FA, and the morphological variations observed in the hindwings may influence the migratory behaviour of *P. flavescens*." **22266.** Golovatyuk, L.V.; Nazarova, L.B.; Kalioujnaia, I.J.; Grekov, I.M. (2023): Taxonomic composition and salinity tolerance of macrozoobenthos in small rivers of the southern arid zone of the East European Plain. *Biology* 2023, 12, 1271. <https://doi.org/10.3390/biology12091271>: 20 pp. (in English) ["Simple Summary: Climate-related salinization of inland waters is observed in many regions of the world as a major environmental problem affecting natural processes in aquatic ecosystems. In order to better predict and control these changes, it is important to study the responses of aquatic fauna to increasing salinity. Macrozoobenthic fauna, which includes mollusks, small crustaceans, and insect larvae, constitutes the main food base for fish and water birds. Due to their relatively short life cycles, large species diversity, and high abundance, macrozoobenthos are the best indicators

of changing water salinity. To determine the species richness, distribution, and salinity tolerance of macrozoobenthos, we investigated 17 small rivers with different water salinity in the southern arid region of the East European Plain. The study shows that the species richness gradually decreases with an increase in water salinity in the rivers. In freshwater rivers, the macrozoobenthos fauna includes more than 100 species, whereas, in hypersaline rivers with salinity comparable to seawater, only 10 species were found. A total of 5 of the 156 invertebrate species can be used as indicators of water salinization in rivers of the arid regions of Europe. Abstract: This study investigated the species composition, distribution, and salinity tolerance of macrozoobenthos in 17 small rivers in the southern arid region of the East European Plain, which are characterized by a small channel gradient, slow-flowing or stagnant water bodies, and a wide range of water salinity, varying between 0.18 and 30 g L<sup>-1</sup>. In total, 156 taxa were found, among which 66 were Diptera species. The study revealed that the formation of benthic communities in the rivers is influenced by natural factors of the catchment basins, including the flat landscape with sparsely developed relief differentiation, climate aridity, and the widespread occurrence of saline soils and groundwater, largely related to the sedimentation of the ancient Caspian Sea and modern climate changes. These conditions are favorable for the occurrence of lacustrine macrozoobenthic species in freshwater, euryhaline, and halophilic ecological groups. The investigation revealed a decrease in species richness in response to an increase in water salinity. The five identified halophilic species *Tanytarsus kharaensis*, *Glyptotendipes salinus*, *Cricotopus salinophilus*, *Chironomus salinarius*, and *Palpomyia schmidti* can be used as indicators of river ecosystem salinization.... Dragonfly larvae showed high diversity and were mainly found in the overgrown areas of the rivers. Among dragonflies, the species *Sympetma fusca* and *Enallagma cyathigerum* were the most common (7% and 5%, respectively)." (Authors) Species composition of macrozoobenthos in the investigated small rivers: *Anax imperator*, *Enallagma cyathigerum*, *Erythromma najas*, *Ischnura elegans*, *Lestes sponsa*, *Orthetrum cancellatum*, *Sympetma fusca*, and *Sympetrum depressiusculum*] Address: Golovatyuk, Larisa, Papanin Institute for Biology of Inland Waters, Russian Academy of Sciences, Borok, Nekouzsky District, 152742 Yaroslavl Oblast, Russia. **22267.** Gómez-Anaya, J.A.; Brug-Aguilar, B.; Vázquez-Hurtado, G.; Novelo-Gutiérrez, R. (2023): Diversity and distribution of Odonata (Insecta) larvae in a subtropical lagoon with different land uses in Veracruz, Mexico. *Revista Mexicana de Biodiversidad* 94: e945158: 17 pp. (in English, with Spanish summary) ["Impacts caused to freshwater reservoirs by human activities have increased in tropical and subtropical regions in the last decades. We studied the effects of land use on the physicochemical properties of water and their effects on larval Odonata diversity in a subtropical lagoon. During 1 year, physicochemical variables were measured, and Odonata larvae were collected in 8 sites (4 in the urbane zone and 4 in the more conserved rural zone) with different land uses that cover the entire periphery of the lagoon. Physicochemically, no clustering of samples from urban and rural zones or by site was observed, rather clustering reflected temporal patterns. A total of 28 species were found and some of them showed a differential distribution between both zones, and between the 8 sites and collectings. The highest diversity was recorded in the rural zone. The site with domestic waste discharges had the lowest diversity and it showed high concentrations of nitrates and

ammonium. We conclude that the effect of land use in this lagoon is still incipient on Odonata diversity. The diversion and treatment of urban waters and proper land management are recommended to ensure the maintenance of Odonata diversity." (Authors)] Address: Novelo-Gutiérrez, R., Instituto de Ecología, A. C., Red de Biodiversidad y Sistemática, Carretera Antigua a Coatepec 351, Col. El Haya, 91073 Xalapa, Veracruz, Mexico. **22268.** Góral, N.; Daraz, B.; Makhkamov, T.; Dabert, M.; Bernard, R. (2023): Taxonomic status of the Central Asian damselfly *Calopteryx samarcandica* Bartenev, 1912 (Odonata: Calopterygidae). *International Journal of Odonatology* 26: 180-189. (in English) ["The taxonomic status of the Central Asian damselfly *C. samarcandica* was determined on the basis of molecular and phenotypic data from the Kugitang Mountains, SE Uzbekistan. Molecular analyses (COI and 18S rDNA, ITS1-5.8S rDNA-ITS2) revealed that *C. samarcandica* forms part of a clade that includes taxa treated in the literature as subspecies of *Calopteryx splendens* and/or related species. However, both mitochondrial and nuclear DNA confirmed that *C. samarcandica* deserves separate species status. The COI distance to *C. splendens* (including *C. xanthostoma*) is moderate (3.47%, K<sub>2</sub>P), but much greater than the internal distances between the sequences qualified in *C. splendens* (0.4%); this difference is supported by the low values of the barcoding gap in this genus. The rather distant separation of *C. samarcandica* from both *C. splendens* (*ancilla*, *taurica*, *intermedia*) and *C. orientalis* and the length of the *samarcandica*-branch recognisable in nuclear rDNA strengthen the independent position of the first species. The phylogenetic position of *C. samarcandica* in the genus *Calopteryx* remains unclear due to the low variability of nuclear rDNA markers and insufficient and partly incomparable data for other taxa. The molecular data support the phenotypic and ecological specificity of *C. samarcandica*, defined by a diagnostic combination of its traits (male and female wing colours and large size and basal diffusion of the wing spot in males) and the conservative association with groundwater-fed natural watercourses in the mountains and foothills fringing the vast Central Asian mountain block." **22269.** Gouvêa, T.P.; Almeida, J.A.M.; Shimamoto, C.Y.; Barbado, N.; Souza, M.M. (2023): Registro de libélulas (Odonata) predadas por aranhas (Araneae) na Mata Atlântica, no Sul do Brasil. *Entomological Communications*, 5, ec05025. <https://doi.org/10.37486/2675-1305.ec05025>: 4 pp. (in Portuguese, with English summary) ["Dragonflies are insects that act as predators and prey, both in freshwater and associated terrestrial ecosystems, which makes the understanding of trophic relationships established by these insects important. In this sense, the present study aimed to report the predation of Odonata by Araneae in areas of seasonal semi-deciduous forest, phytogeography of the Atlantic Forest at the Iguazu National Park (PARNA Iguazu), and in the Bela Vista Biological Refuge (RBBV). The records occurred at random in 2021 from December 13 to 21, and in 2022 from January 4 to April 22. Five individuals of three species and two morphospecies of Odonata preyed upon by three morphospecies of spiders were recorded. Predation of Odonata by spiders seems to be frequent in different ecosystems, but further studies are required to understand the impact of this predation on the size of dragonfly communities in the Brazilian Atlantic Forest biome." (Authors)] *Argia mollis*, *A. reclusa* and *Oxyagrion terminale* were found trapped in suspended

webs of *Tetragnatha* sp., located approximately 2 meters above the ground and 50 cm from the bank of a stream within the dense forest. A predation of *Anax* sp. by an undetermined species of Trechaleidae (immature specimen) that was active and recorded on the soil inside the forest, during twilight. Low light can trigger conditions favorable to the predator, as Trechaleidae spiders are active ambush hunters on the ground and common in environments close to water. *Argia mollis*, *A. reclusa* and *Oxyagrion terminale* are species that explore different ecosystems and occur in different locations in Brazil (Souza et al. 2013; Calvão et al. 2018). These three species of Odonata were found trapped in suspended webs of *Tetragnatha* sp., located approximately 2 meters above the ground and 50 cm from the bank of a stream within the dense forest. Spiders of this taxon commonly inhabit the banks of water bodies, such as rivers and lakes, which may favor the passive capture of adult dragonflies, as they are also considered the most widespread and abundant orb-web spiders in the world (Levi 1981), being found in tropical and temperate climates, and even on oceanic islands (Aiken & Coyle 2000; World Spider Catalog 2023). Predation of *Anax* sp. by an undetermined species of Trechaleidae (immature specimen) was active and recorded on the soil inside the forest, during twilight (Fig. 2), close to the source of the Manoel Gomes River, municipality of Céu Azul (25°09'13.5" S 53°50'43.7"W), Paraná, Brazil. This condition can be explained by the fact that dragonflies are diurnal insects (Corbet 1999), therefore, low light can trigger conditions favorable to the predator, as Trechaleidae spiders are active ambush hunters on the ground (Dias et al. 2009), common in environments close to water (Carico 1993), where Odonata are frequent, because they spend their initial life in freshwater aquatic ecosystems (Costa et al. 2012).] Address: Shimamoto, Carolina, Instituto Federal de Educação, Ciência e Tecnologia, do Sul de Minas Gerais, Campus Inconfidentes, Inconfidentes, MG, Brasil. (2023): Short-term responses of aquatic ecosystem and macroinvertebrate assemblages to rehabilitation actions in Martil River (North-Western Morocco). *Hydrobiology* 2023, 2, <https://doi.org/10.3390/hydrobiology2030029>: 446-462. (in English) ["This study aimed to evaluate the effects of the Martil River rehabilitation project and recently constructed dam infrastructures to reduce flood risks and to promote local socio-economic development on the ecological integrity of the river. The assessment focused on changes in fluvial landforms over time and the evaluation of aquatic ecosystems based on six physicochemical parameters (temperature, pH, electrical conductivity, dissolved oxygen, biochemical oxygen demand, and chemical oxygen demand), morpho-hydrological variables (stream width, water depth, and current speed), habitat indices (QBR, IHF, and MQI), and macroinvertebrate assemblages of EPT, OCH, and Chironomidae (Diptera) at five stations from autumn 2015 to spring 2018 (prior to and during the rehabilitation actions). The results showed that the river rehabilitation project led to profound changes in Martil River's ecosystem and water quality over time. Physicochemical and habitat measurements at the rehabilitated sites revealed a major change in macroinvertebrate communities due to changes in fluvial landforms in relation to flow-sediment regimes. As a result, some typical species of lentic habitats disappeared, while alien, opportunistic, and lotic species appeared." (Authors)] The following odonate taxa are listed: *Lestes barbarus*, *L. viridis*, *Calopteryx* sp., *C. exul*, *Erythromma lindenii*, *Ischnura graellsii*, *Aeshna mixta*, *Anax parthenope*, *Anax* sp., *Onychogomphus forcipatus*

**22272.** Habel, J.C.; Ulrich, W.; Segerer, A.H.; Greifenstein, T.; Knubben, J.; Morinière, J.; Bozicevic, V.; Günter, A. (2023): Insect diversity in heterogeneous agro-environments of Central Europe. *Biodiversity and Conservation* 32: 4665-4678. (in English) [Pfaffenhofen, Bayxern, Germany. "Insect diversity has been decreasing significantly during the past decades. A main driver causing this negative trend is agricultural intensification, which causes habitat destruction and a deterioration of habitat quality. We caught flying arthropods with 28 Malaise traps and two light traps across a heterogeneous Central European agro-environment in southern Germany over a period of four years. The arthropods captured with Malaise traps were assigned to barcode index numbers (BINs) based on metabarcoding. Lepidoptera caught with light traps and light towers were identified based on morphological characters. Within the four years study, a total of 11,984 insect operational taxonomic units (OTUs) related to unique BINs on BOLD (>95% similarity) were recorded across this agro-environment. 7835 of them could be assigned to insect order and the vast majority of them represent different species. Different estimates of the total species richness ranged between 8188 and 11,512 OTUs (a proxy for species). This number corresponds to about 26–36% of the total German insect fauna. Light trapping also yielded a high species diversity and returned 502 Lepidoptera species (compared to 784 species captured with Malaise traps). The overlap between light and Malaise traps was less than 45%. The Malaise trap catches showed that insects are more diverse along forest edges than in the centre of meadows. Our findings underline the high value of heterogeneous agro-environments for biodiversity, and the high value when combining data collected with different sampling techniques.... Only orders such as Trichoptera, Thysanoptera, Ephemeroptera, Odonata, and Psocoptera were less species rich than expected. Trichoptera, and Ephemeroptera, and to a lesser extent Odonata, are hygrophilous and were not expected to occur in high numbers in the Malaise traps set in meadows." (2023): Using bacteria and benthic macroinvertebrates as water quality parameters in Mat River, Albania. *AQUA — Water Infrastructure, Ecosystems and Society* Vol 00 No 0, 1 doi: 10.2166/aqua.2023.081: 15 pp. (in English) ["Highlights: • Assessment of the water quality of Mat River in Albania, using bacteria and benthic invertebrates as biological quality indicators. • The results of our study highlight a deterioration of the water quality of Mat River from the upper reaches to the lower reaches, mainly due to anthropogenic pressure. • The number of benthic macroinvertebrates reflects water quality and organic pollution. Abstract: This research examines the quality of Mat River water to control and reduce the level of environmental pollution in accordance with national rules and regulations. The focus of this study was the assessment of river water quality by using bacteria and benthic macroinvertebrates, as biological markers of stream water quality. The research was conducted from June 2018 to June 2019 at five sampling sites along the Mat River, with monthly sampling for chemical-physical and microbiological parameters and seasonal sampling for benthic macroinvertebrates. The investigated data for the studied parameters were statistically analysed using MINITAB 19 software. The variation in spatial and temporal trends of the investigated parameters showed differences in water quality among different sampling sites. As expected, the bacterial load was found to be higher near urban areas, and the pollution increased with the course of the river. The same tendency in water quality showed up even in the benthic macroinvertebrates population. Pearson correlation coefficients (p. 0.05) between the water quality data revealed the similarity and the associations between parameters. Cluster analysis of the investigated parameters revealed the classification of Mat River water quality and the possibility of using microbiological parameters and/or benthic macroinvertebrates for the assessment of water quality." **22275.** Happle, R.; Eyerich, k. (2023): Autosomal dominant inheritance with sex-limited manifestation: An unusual mode of transmission in humans and animals. *Am J Med Genet.* 191(3): 684-689. (in English) ["Autosomal dominant, sex-limited inheritance is a distinct mode of transmission that should not be conflated with X-linked inheritance. From animal studies, we know that sex-limited inheritance implies the chance to "turn off" some genes in either males or females, in order to meliorate the phenotype, for example, by improving the fecundity. In this way, sex-limited genes play an important role in the evolution of diverse species of animals. In human genetics, however, the biological significance of sexlimited genes is unknown until today. When screening the literature, we found, thus far, three human examples of

sex-limited transmission. Autosomal dominant, malelimited inheritance has meticulously been studied in a particular form of precocious puberty. Limitation to females was described in autosomal dominant lymphedema of the CESLR1 type, being underpinned by convincing molecular findings. Another example is white lentiginosis of Grosshans that shows clinical evidence of such mode of transmission although molecular findings are lacking as yet. In the animal kingdom, autosomal dominant sex-limited inheritance is a well-established phenomenon that has extensively been studied in various species such as butterflies, damselflies [*Ischnura senegalensis*], fish (cichlids), and birds. Hence, at this point in time, it seems likely that other human examples of this mode of inheritance have previously been reported or will be published in the future." **22276.** Harabiš, F. (2023): Post-mining areas as the last area for the expansion of the declining Siberian Winter damselfly (Odonata: Lestidae). *Journal of Insect Conservation* 27: 707-715. (in English) ["The regionally threatened *Sympecma paedisca* is one of the few Central European dragonfly species included is considered as Near Threatened in the European Red list. The major threats to this species remain unclear. This species has a unique life history and several adaptations to enabling survival even in semidesert areas, such as overwintering in the adult stage. However, the closely related, more thermophilic species *Sympecma fusca* has undergone a major range expansion in Europe. Based on data from 129 sites and combining several analytical approaches, I found the following: 1. According to local freshwater conditions, *S. paedisca* is a typical habitat generalist occupying a wide range of habitats. 2. It requires a wide range of terrestrial habitats to complete its life cycle. 3. An analysis of the land used by both species clearly indicates that both species avoid intensive agricultural areas; however, *S. fusca* can also occur in suburban areas, where *S. paedisca* is absent. 4. Projections of the Least Cost Path analysis indicate that the only localities where the species is currently spreading are habitats arising as a consequence of mining activities. The example of *S. paedisca* is clear evidence of a freshwater species that responds very negatively to the homogenization of the terrestrial environment, even when its natal habitat is not significantly affected. The frequent occurrence of species in postmining areas suggests that species with complex habitat requirements can find suitable secondary habitats where they can prosper in the long term. Implications for insect conservation: Even semi-aquatic groups like damselflies can be very sensitive to gradual changes in surrounding land use. Species with very complex habitat requirements also require comprehensive conservation strategies affecting all habitats utilized by the species. However, the return of some landscape features requires a reduction in the area of production areas in favor of hedgerows and ruderals. Such restoration management requires long-term planning and close cooperation with farmers." **22278.** Hermans, J.T. (2023): The White-faced darter (*Leucorrhinia dubia*) in the Dutch Province of Limburg (Odonata: Libellulidae): Severe decline of a characteristic species of bog pools. Part 1: Phenology and distribution. *Natuurhistorisch Maandblad* 112(10): 256-266. (in Dutch, with English summary) ["This rather tiny dragonfly is a specialist of bog pools and is seen in spring and early summer. Both sexes have creamywhite fronts and small black wing-bases; the male is black with red markings, the female is patterned like the male, but in yellow. *L. dubia* is found in Europe and eastwards to Japan and Kamchatka. The species is common in central and northern Europe. In the Netherlands, the White-faced darter is largely restricted to acidic, oligotrophic habitats on Pleistocene soils. It occurs more rarely in raised peat-bog remnants. Since 2007, the species has declined in the Netherlands (and in neighbouring Belgium and Germany), due to eutrophication and acidification caused by high emissions of nitrogen compounds, and desiccation of its habitat (the latter worsened by climate change). This decline has happened more rapidly in the province of Limburg than in other Dutch regions. *L. dubia* formerly had around seven temporary and six stable populations in Limburg. All temporary populations have vanished, and only three of the six stable populations have so far survived, in the Griendtsveen/Mariapeel, Groote Peel and Ravenvenen areas. It is likely that even long-standing populations (known since the 1970s and 1980s) have now become extinct at the Beegderheide and Meinweg areas, the main causes being changes in the vegetation and frequent drying up of the reproduction sites." **22280.** Hogreve, J.; Suhling, F. (2023): Development of *Sympetrum striolatum* and *S. vulgatum* (Odonata: Libellulidae) in brackish water. *International Journal of Odonatology* 26: 190-196. (in English) ["*S. striolatum* and *S. vulgatum* are two closely related Libellulidae that are widespread and common in Central Europe. The idea for this research originates from normally using saltwater shrimps for rearing young larvae, the observations of *Sympetrum* species laying eggs in seawater and the suggested ability of *S. striolatum* to colonize brackish water habitats. This topic will also be of rising relevance for dragonfly populations as in the future due to climatic changes or anthropogenic activity the salinization of freshwaters will likely increase. The experiments presented in this study served to find out whether eggs and larvae of both species can develop in brackish water. For this purpose, eggs of both species were kept at four different salinities from 0.5-1.5% and the development duration, hatching curves and growth rates as well as mortality were recorded and compared to respective data from an earlier experiment conducted in tap water. It was possible to investigate whether embryonic development, the hatching behaviour and larval growth are disturbed by different salinity levels compared to rearing in freshwater. We found for both species that the eggs can develop at different salt concentrations up to 1.5% and the larvae survive and grow in the brackish water. Especially for *S. striolatum* a slightly increased salinity even seems to be advantageous compared to rearing in tap water shown by high hatching and survival rates. The results of this study add some knowledge about the influencing effects of salt on both species. It seems that low salt concentrations seem to be well tolerated by both species or become even beneficial for *S. striolatum*. Furthermore, the results provide methodological aspects about the rearing of young dragonfly larvae." (Authors)] Address: Suhling F., Inst. **22281.** Homberg, U.; Kirchner, M.; Kowalewski, K.; Pitz, V.; Kinoshita, M.; Kern, M.; Seyfarth, J. (2023): Comparative morphology of serotonin-immunoreactive neurons innervating the central complex in the brain of dicondylid insects. *J Comp. Neurol.* 531(14): 1482-1508. (in English) ["Serotonin (5-hydroxytryptamine) acts as a widespread neuromodulator in the nervous system of vertebrates and invertebrates. In insects, it promotes feeding, enhances olfactory sensitivity, modulates aggressive behavior, and, in the central complex of *Drosophila*, serves a role in sleep homeostasis. In addition to a role in sleep-wake regulation, the central complex has a prominent role in spatial orientation, goal-directed locomotion, and navigation vector memory. To further understand the role of serotonergic signaling in this brain area, we analyzed the distribution and identity of serotonin-immunoreactive neurons across a wide range of insect species [including *Leucorrhinia pectoralis*, *Aeshna cyanea*]. While one bilateral pair of tangential neurons innervating the central body was present in all species studied, a second type was labeled in all neopterans but not in dragonflies and firebrats. Both cell types show conserved major fiber trajectories but taxon-specific differences in dendritic targets outside the central body and axonal terminals in the central body, noduli, and lateral accessory lobes. In addition, numerous tangential neurons of the protocerebral bridge were labeled in all studied polyneopteran species except for Phasmatodea, but not in Holometabola. Lepidoptera and Diptera showed additional labeling of two bilateral pairs of neurons of a third type. The presence of serotonin in systems of columnar neurons apparently evolved independently in dragonflies and desert locusts. The data suggest distinct evolutionary changes

in the composition of serotonin-immunolabeled neurons of the central complex and provides a promising basis for a phylogenetic study in a wider range of arthropod species." (in German, with English summary) ["Report on the eighth Insect Camp of the Austrian Entomological Society: hidden treasures of the Weinviertler cliff zone (Lower Austria, Austria). The eighth Insect Camp of the Austrian Entomological Society took place in the Nature Park Leiser Berge from 23 to 26 June 2022. A large number of taxonomic specialists and entomological and arachnological students attended the camp and/or supported the post-processing of samples. During the camp, the participants had the opportunity to experience field research, different trapping, identification and preparation methods. A network of specialist and people of nature conservation and biodiversity is important for biological work. The camp offers the chance to enter this network and gather knowledge on how to conduct scientific work. The study area included 28 different localities in the Nature Park Leiser Berge with different habitats, from water bodies to dry grassland. In total, 1,497 species of 23 orders were recorded: ... 7 of Odonata [*Aeshna cyanea*, *Calopteryx splendens*, *Coenagrion ornatum*, *C. puella*, *Ischnura elegans*, *Sympecma fusca*, *Platycnemis pennipes*], ... **22284.** Ilhamdi, M.L.; Ivansyah, A.R.; Syazali, M. (2023): Exploration of the species richness of butterfly [sic] (Hexapoda: Odonata) in the rice field ecosystem of Perian village, Montong Gading, East Lombok. *Jurnal Biologi Tropis* 23(4): 744-751. (in English) ["Several Odonata studies on Lombok Island still focus on forest and river habitat types. This causes the diversity of this insect group to be unknown in other habitats such as rice fields. This research aims to explore the richness of dragonfly species in the rice field ecosystem of Perian village, Montong Gading subdistrict, East Lombok district. Sample collection was carried out in May – June 2022. Dragonfly searches were carried out in the morning

from 08.00 – 12.00, and in the afternoon from 14.00 – 18.00 on two transects determined purposively. The odonata found were documented using a digital camera, and captured using insect nets. Samples that were successfully collected were identified to the species taxon. The total Odonata we found were 2 suborders, 5 families and 11 species. [...] Of the 11 species that we found, 1 species is endemic, namely *Euphaea lara lumbokensis*. Compared with the results of previous research conducted in Suranadi and Batu Bolong River, there are 5 species which are new records. The five species are *Copera ciliata*, *Rhinocypha bisignata*, *Ischnura senegalensis*, *I. heterosticta*, and *Brachythemis contaminata*. The results of this study indicate that there are more species from the Odonata order on Lombok Island compared to previous reports." **22285.** Isworo, S.; Oetari, P.S. (2023): Diversity of vegetation, birds, dragonflies and butterflies at coal mining reclamation sites in South Kalimantan, Indonesia. *Biodiversitas* 24(10): 5376-5390. (in English) ["Coal mining can help the country's economy, but it can also be detrimental to the environment, especially due to the reduced biodiversity in mining areas. Recovery efforts are therefore needed to reclaim post-coal mining land. The aim of the research is to identify the biodiversity of plants, birds, dragonflies, and butterflies in the coal mining reclamation area in Banjar and Tapin regencies, South Kalimantan Province, Indonesia. A biodiversity survey was conducted on eight sites representing various reclamation conditions and histories. Based on vegetation studies in the reclamation area, 136 species belonging to 101 families were found. Zone TAJ1-4 had the highest diversity index (H') at the tree, stake and sapling strata with the index of 0.96, 1.06 and 1.71, respectively. The highest diversity index at the pole stratum was recorded in the TAJ1-3 zone with 0.6. Zone TAJ5-8 had the highest diversity index at the herbaceous vegetation, with 2.33. The Fabaceae family dominates all observation sites. The species with the highest importance index for the tree stratum was *Acacia mangium*, the pole stratum was *Albizia chinensis*, *Hevea brasiliensis* and *Vitex pinnata*, the stake stratum was *A. chinensis*, the sapling stratum was *A. mangium*, and the herbaceous stratum was *Ottochloa nodosa*. The Sorensen Similarity Index fell into the low category (10.00% to 57.78%), showing varying directions of vegetation succession. There were 21 birds, 10 dragonflies [*Anotogaster sieboldii*, *Diplacodes trivialis*, *Neurothemis ramburii*, *Neurothemis terminata*, *Orthetrum chrysis*, *O. glaucum*, *O. sabina*, *Pantala flavescens*, *Potamarcha congener*, *Rhyothemis phyllis*], and 15 butterflies recorded across the observation sites. According to the IUCN Red List of Threatened Species, no recorded species is listed as protected. The results of this study might be used for the management of post-mining reclamation areas, especially in South Kalimantan.] Address: Isworo, S., Dept of Environmental Health, Universitas Dian Nuswantoro. **22286.** Jaballah, S.; Fernandez Garcia, G.; Martignac, F.; Parisey, N.; Jumel, S.; Roussel, J.-M.; Dézerald, O. (2023): A deep learning approach to detect and identify live freshwater macroinvertebrates. *Aquatic Ecology* 57: 933-949. (in English) ["The study of macroinvertebrates using computer vision is in its infancy and still faces multiple challenges including destructive sampling, low signal-to-noise ratios, and the complexity to choose a model algorithm among multiple

existing ones. In order to deal with those challenges, we propose here a new framework, dubbed 'MacroNet,' for the monitoring, i.e., detection and identification at the morphospecies level, of live aquatic macroinvertebrates. This framework is based on an enhanced RetinaNet model. Pre-processing steps are suggested to enhance the characterization propriety of the original algorithm. The images are split into fixed-size tiles to better detect and identify small macroinvertebrates. The tiles are then fed as an input to the model, and the resulting bounding box is assembled. We have optimized the anchor boxes generation process for high detection performance using the k-medoid algorithm. In order to enhance the localization accuracy of the original RetinaNet model, the complete intersection over union loss has been integrated as a regression loss to replace the standard loss (a smooth l1 norm). Experimental results show that MacroNet outperforms the original RetinaNet model on our database and can achieve on average 74.93% average precision (AP), depending on the taxon identity. In our database, taxa were identified at various taxonomic levels, from species to order. Overall, the proposed framework offers promising results for the non-lethal and cost-efficient monitoring of live freshwater macroinvertebrates." **22287.** Janssen, S.E.; Kotalik, C.J.; Eagles-Smith, C.A.; Beaubien, G.B.; Hoffman, J.C.; Peterson, G.; Mills, M.A.; Walters, D.M. (2023): Mercury isotope values in shoreline spiders reveal the transfer of aquatic mercury sources to terrestrial food webs. *Environmental Science & Technology Letters* 10(1): 891-896. (in English) ["The transfer of aquatic contaminants, including mercury (Hg), to terrestrial food webs is an often-overlooked exposure pathway to terrestrial animals. While research has implemented the use of shoreline spiders to assess aquatic to terrestrial Hg transfer, it is unclear whether Hg sources, estimated from isotope ratios, can be successfully resolved to inform site assessments and remedy effectiveness. To examine aquatic to terrestrial Hg transfer, we collected shoreline spiders (*Tetragnatha* spp.) and aquatic insect larvae (suborder Anisoptera) across a mosaic of aquatic and shoreline habitats in the St. Louis River and Bad River, tributaries to Lake Superior. The fraction of industrial Hg in sediments was reflected in the d202Hg values of aquatic dragonfly larvae and predatory fish, connecting benthic Hg sources to the aquatic food web. Shoreline spiders mirrored these aquatic Hg source signatures with highly positive correlations in  $\delta^{202}\text{Hg}$  between tetragnathids and dragonfly larvae ( $r^2 = 0.90$ ). Further assessment of different spider taxa (i.e., araneids and pisaurids) revealed that differences in prey consumption and foraging strategies resulted in isotope differences, highlighting the importance of spider taxa selection for Hg monitoring efforts." **22288.** Jiang, B.; Yao, Y.; Mauersberger, R.; Mikolajewski, D.J. (2023): Allometry of defense: Predator shift alters ontogenetic growth patterns in an antipredator trait. *Insects* 2023, 14(8), 712; <https://doi.org/10.3390/insects14080712>: 10 pp. (in English) ["Predators drive prey trait diversification and promote ecological speciation. The impacts of predation are not only on the final state of antipredation traits, but also on the development of antipredation traits. Species of the dragonfly genus *Leucorrhinia* are distributed in both habitats

dominated by predatory fish (fish lakes) and habitats dominated by predatory invertebrates (invertebrate lakes). In larval dragonflies, the spine is one of the most efficient traits deterring gape-limited fish predators. However, the spine is not useful in invertebrate lakes. In this study, we compared the developmental patterns of spines in both habitats. We constructed the scaling relationship between spine length and body size and compared the inflexion point on those curves in five species of *Leucorrhinia* dragonfly larvae. Here, we found that fish-lake *Leucorrhinia* species kept a higher spine growth rate than species from invertebrate lakes, and *Leucorrhinia* species from fish lakes displayed accelerated spine growth rate at larger body size compared to invertebrate-lake species. Our results highlight that development patterns, as well as the final states of antipredator traits, are essential to understanding predator–prey interactions. Abstract: Predation is a major factor driving prey trait diversification and promoting ecological speciation. Consequently, antipredator traits are widely studied among prey species. However, comparative studies that examine how different predators shape the ontogenetic growth of antipredator traits are scarce. In larval dragonflies, abdominal spines are effective traits against predatory fish in fish lakes, which prefer larger prey. However, defensive spines increase mortality in habitats dominated by invertebrate predators (invertebrate lakes), which prefer smaller prey. Thus, species from fish lakes may accelerate spine growth at a later body size compared to species from invertebrate lakes when growing into the preferred prey size range of predatory fish. In this study, we constructed the allometric relationship between spine length and body size and compared the inflexion point of those growth curves in five species of *Leucorrhinia* dragonfly larvae. We found that fish-lake *Leucorrhinia* species accelerated spine growth at a larger body size than congeners from invertebrate lakes. Further, rather than extending spine length constantly through development, fish-lake species rapidly accelerated spine growth at a larger body size. This is likely to be adaptive for avoiding invertebrate predation at an early life stage, which are also present in fish lakes, though in smaller numbers. Our results highlight that comparative studies of ontogenetic patterns in antipredator traits might be essential to develop an integrated understanding of predator–prey interactions." **22289.** Khandelwal, P.C.; Zakaria, M.A.; Socha, J.J. (2023): A year at the forefront of gliding locomotion. *Biology Open* (2023) 12, bio059973. doi:10.1242/bio.059973: 6 pp. (in English) ["This review highlights the largely understudied behavior of gliding locomotion, which is exhibited by a diverse range of animals spanning vertebrates and invertebrates, in air and in water. The insights in the literature gained from January 2022 to December 2022 continue to challenge the previously held notion of gliding as a relatively simple form of locomotion. Using advances in field/lab data collection and computation, the highlighted studies cover gliding in animals including seabirds, flying lizards, flying snakes, geckos, dragonflies, damselflies, and dolphins. Altogether, these studies present gliding as a sophisticated behavior resulting from the interdependent aspects of morphology, sensing, environment, and likely selective pressures. This review uses these insights as inspiration to encourage researchers to revisit gliding locomotion, both in the animal's natural habitat and in the laboratory, and to investigate questions spanning gliding biomechanics, ecology, sensing, and the evolution of animal flight." **22290.** Khedre, A.M.; Ramadan, S.A.; Ashry, A.; Alaraby, M. (2023): Ingestion and egestion of microplastic by aquatic insects in Egypt wastewater. *Environmental Quality Management* 33(1): 135-145. (in English) ["Microplastics (MPs) are frequently regarded as environmental and biota contaminants. Yet, research on the accumulation of MPs in living entities, particularly aquatic insects that serve as food resources in the aquatic food chain, is limited. This study to investigate the accumulation of MPs in aquatic insects from water and sediment in an Egyptian wastewater basin. Four typical freshwater insect groups were used. The highest MP load per gram wet weight was reported by collector-gatherers (*Chironomus* sp. and *Hydrophilus* sp.), followed by collector-filterers (*Culex* sp.) with the second highest MP load. However, Predators (*Aeshna* sp.) had the lowest values. Also, the present results showed a reduction in the number of MPs in all insect taxa tested after a 24 h depuration time, with differences in the observed egestion ability. The mean number of MPs per individual significantly reduced after 24 h in both *Chironomus* sp. and *Culex* sp. larvae, where 53% and 40% of MPs particles were ejected from them, respectively. However, the ability of MP egestion decreases in *Aeshna* sp. nymph (25%), and the lowest proportion of ejection was observed in *Hydrophilus* sp. adults (9%). Polyethylene terephthalate fibers were the most abundant type of MP in both sediment and water, followed by fragments (polyethylene and polypropylene). Yet, only polyester fibers were detected in the various insect species. The average length of fibers in the various insects was somewhat shorter than in the surrounding environment. The current study reveals that MP ingestion by aquatic insects is not always related to levels of pollution in the environment, since other factors such as feeding strategies may play a role in MP ingestion. Based on these observations, further studies should be carried out on studies on toxicological impacts of MPs on freshwater/aquatic biota." **22291.** Koene, E. (2023): Langzeitstudie 2016–2022 mit Populationsschätzungen von *Cordulegaster bidentata* und *C. boltonii* an sechs kleinen Bächen bei Bern (Schweiz) (Odonata: Cordulegasteridae). *Libellula* 41(3/4) (2022): 155-177. (in German, with English summary) ["Long-term study 2016–2022 with population estimates of *Cordulegaster bidentata* and *C. boltonii* in six small streams near Bern (Switzerland) (Odonata: Cordulegasteridae) – In the municipality of Wohlten near Bern, situated on a southern slope, many small, unobstructed streams flow into the River Aare or the dammed Lake Wohlensee. They start in old mixed forests and flow through extensive grassland in the lower part. In an area of about 5 km<sup>2</sup>, 445 *Cordulegaster bidentata* males and 2,062 *C. boltonii* males were marked during 820 hours in sunny weather from 2016 to 2022. Daily catches were recorded and visualised in diagrams. The annual number of males per species varied greatly, both in each stream from year to year and between individual streams in the same year. The ratio of the two syntopic species to each other also changed. Both species are widespread in the area. Using the MARK programme, male population sizes were estimated from the catch-recapture data and plotted in annual graphs for each stream. At high flight frequencies, the estimate was two to three times the number marked. For 2022, a very high total of 360 *C. bidentata* and 1,200 of *C. boltonii* males was estimated." **22294.** Let, M.; Grabicová, K.; Ložek, F.; Bláha, M. (2023): Bioconcentrations, depuration, shift in metabolome and a behavioural response in the nymphs of the dragonfly *Aeshna cyanea* (Müller, 1764) to environmentally relevant concentrations of Methamphetamine. *Aquatic Toxicology* 259, June 2023, 106479: 11pp. (in English) ["Methamphetamine (MEA) is commonly detected in municipal wastewater. It causes imbalances in the system of neurotransmitters as well as several other adverse effects on human health. The aim of this study was to investigate bioconcentration and depuration rates at an environmentally relevant concentration of  $1 \mu\text{g}\cdot\text{L}^{-1}$  in *A. cyanea* nymphs exposed to MEA for six days followed by three days of Depuration. The metabolomes from nymphs sampled during Exposure and Depuration were compared using non-targeted screening. Concurrently, a behavioural experiment was run to evaluate the effect of MEA on movement. Since most samples were below the limits of quantification (LOQs) – MEA was quantified in only four out of the 87 samples and only during the first 24 hours of Exposure at concentrations at LOQs level – we estimated the maximal possible bioconcentration factor (BCF) on 0.63 using the LOQs. An MEA metabolite – amphetamine – was not detected in any sample at levels above their LOQs. Numbers

of significant down. and/or up-regulated signals ( $p = 0.05$ ) in metabolomes calculated for particular sampling times possibly correlated to the resulted size of the effect on movement recorded at the same times. In the MEA treatment, movement was not significantly greater during Exposure ( $p > 0.05$ ) but was significantly lower during Depuration ( $p < 0.05$ ). This study shows how MEA acts on dragonfly nymphs, an ecologically important group of aquatic insects with a high trophic level." **22295.** Lin, P.; Wang, C.; Liu, Y.; Ren, L.; Zhang, Z. (2023): Study of a bioinspired rigid-flexible coupling structure based on dragonfly wing by optical/electron microscopy and finite element analysis. *Micron* 174:103534: (in English) ["In this work, mechanical properties of veins and membrane of dragonfly [*Pantala flavescens*] wing were studied by means of optical/electron microscopy, tensile test and nano-indentation. It indicates that veins exhibit significantly higher strength and elastic modulus, as compared with membrane. Furthermore, finite element analysis (FEA) demonstrates that the fluctuation of Von Mises stress and displacement between varying models is undermined, due to presence of the membrane, indicating higher stability. Consequently, according to FEA of varying models involving presence of membrane, the membrane in dragonfly wing not only provides the capability to fly, but also improves obviously the strength and stability of wing structure, despite of its significantly low strength and elastic modulus. It is found that based on proper biomimetic design, bioinspired rigid-flexible coupling structure exhibits superior strength and stability, as compared with conventional rigid structure, which will provide great potential to make novel, smart, and functional structures." **22297.** Mahdjoub, H.; Zebza, R.; Amari, H.; Bensouilah, S.; Zouaimia, A.; Youcefi, A.; Khelifa, R. (2023): Potential fitness consequences of roosting spatiotemporal selection in an endangered endemic damselfly: conservation implications. *Frontiers in Ecology and Evolution* 11 doi: 10.3389/fevo.2023.1267705: 10 pp. (in English) ["Understanding habitat

requirements of species of conservation concern is central for their conservation and the management of their habitat. Although much of the research attention has been focused on reproductive sites, the understanding of roosting behavior and microhabitat selection, and their potential fitness consequences is also crucial. Here, we assess the roosting behavior of an endangered endemic damselfly *Calopteryx exul* Selys in a lotic habitat of Northeast Algeria. Based on marked individuals, we specifically investigated their vertical and horizontal distribution at roosting sites, as well as the timing of roosting and its correlation with lifespan (as a measure of fitness). We found that individuals were philopatric to roosting sites and less so to vertical stratification. Roosting sites were used for both foraging and roosting. Individuals that occupied lower strata in roosting sites had longer lifespans and ceased roosting earlier. Average temperature of the day affected the timing of roosting such that on warm days roosting started later and ended earlier. Individuals with longer lifespans roosted earlier, suggesting potential scramble competition for roosting sites. Our results suggest that *C. exul* individuals show variability in the vertical and horizontal location as well as the timing of roosting, and these choices potentially have fitness consequences. This study highlights the importance of bank vegetation as roosting sites for lotic insects, and emphasizes the benefits of protecting these sites and including them as integral parts of the conservation plans of species." **22299.** Martínez-Darve Sanz, P.; García Pérez, J. (2023): Confirmación de la reproducción de *Pantala flavescens* (Fabricius, 1798) (Odonata, Libellulidae) por primera vez en las Islas Canarias y en España. Confirmación of the breeding of *Pantala flavescens* for the first time in the Canary Islands and Spain. *Boletín de la Asociación española de Entomología* 47(1-2): 83-86. (in Spanish) ["On November 9, 2022, above some bushes in the South Park of Maspalomas (UTM 10X10 28RDR47), a group of five dragonflies was observed hunting insects on the vegetation. The specimens were visually identified as belonging to the species *P. flavescens*. Subsequently, on November 15, 2022, several groups of four to five individuals were again located feeding in open areas far from water in the same park. During the visit, several isolated individuals were identified that stopped in the vegetation, perching hanging in a vertical position, a rare behavior among European dragonulids, but typical of this taxon (DIJKSTRA et al., 2020). These specimens attracted attention due to their fairly uniform yellowish color, their glassy and shiny wings, without apparent damage, and their pale yellow pterostigmas, instead of reddish as seen in adults.

All these characteristics, together with the absence of south/southeast winds in the previous days, seemed to indicate that these were young individuals that had not arrived from Africa, but had probably emerged on the island of Gran Canaria itself. On November 18, 2022, the area was visited again to try to locate the place of origin of the young specimens. During sampling, in a stony section of the nearby Barranco de Fataga (UTM 10X10 28RDR47), a series of small, practically dry pools were found in which twenty exuviae of *P. flavescens* were collected. All of them were found at a low height above the ground, indifferently on large rocks and dry vegetation. They were recent, as evidenced by the good state of conservation of their thoracic tracheas. Subsequently, on December 29, 2022 and in successive visits in January (days 4 and 13) of 2023, a breeding habitat was discovered in a section of ravine with shallow water next to the Betancores dam in which copulations, laying tandems and larvae in their final stages of development. Finally, during the month of February 2023, up to five newly emerged specimens were found hanging from their own exuvia in the same breeding area, as well as teneral individuals that frequently stopped on the vegetation near the temporary watercourse." **22300.** Mataba, G.R.; Clark, N.W.; Kweka, E.J.; Munishi, L.; Brendonck, L.; Vanschoenwinkel, B. (2023): Interactive effects of dragonfly larvae and *Bacillus thuringiensis* var. israelensis on mosquito oviposition and survival. *Ecosphere* 14(9), e4653: 17 pp. (in English) [Magugu village located at 3°59'05.6" S and 35°46'02.5" E in Manyara region in northern Tanzania. "The biological larvicide *Bacillus thuringiensis* var. israelensis (Bti) is used worldwide to control reproduction of mosquitoes in freshwater habitats. However, its impact on the ecosystem including nontarget species is often unclear. In addition, it is unknown how Bti larvicide may interact with local mosquito predators to shape oviposition site selection of mosquitoes. We used an outdoor mesocosm experiment to investigate the effects of realistic concentrations of the bio-larvicide Bti on *Culex* oviposition, larval density, survivorship, and on densities of nontarget species. We also manipulated the complexity of the community by manipulating the presence of dragonfly larvae [*Pantala flavescens*] as a predator. *Culex* oviposition was unaffected by Bti but the larvicide effectively reduced larval density and survivorship in all treatments. Bti did not affect nontarget insects but stimulated phytoplankton density at the expense of lower herbivore density. The presence of dragonfly larvae in mesocosms did not reduce *Culex* oviposition or larval sensitivity to Bti. We conclude that Bti may effectively reduce the density and survivorship of *Culex quinquefasciatus* mosquitoes in this part of East Africa, but possibly at the cost of higher phytoplankton densities. Bti-treated mesocosms were not more or less attractive for mosquitoes, suggesting that its application would not alter their oviposition behavior in the field." **22301.** Mehdi, H.; Kumar, S.; Gupta, P. (2023): Aerodynamic performance of the corrugated airfoil in gliding mode at ultra-low Reynolds numbers? *AIP Conf. Proc.* 2933, 020014 (2023) <https://doi.org/10.1063/5.0174587>: 9 pp. (in English) ["A micro air vehicle can be as small as 6 cm. Development is driven by military, research, and commercial purposes,

with insect-sized aircraft that may be used in the future. The small aircraft allows for remote observation of hazardous environments, aerial photography, and robotics contests. The CFD simulation of fluid flow and aerodynamic performance of the dragonfly (*Aeshna cyanea*) wing section was examined using FLUENT software at low Reynolds numbers (1000, 1250, and 1500) with various angles of attack (AOA) (0°, 5°, 10°). The numerical solver was based on the SIMPLE algorithm with Green-Gauss Node velocity pressure coupling. With increasing AOA, the mean lift coefficient increased while the drag coefficient decreased, resulting in improved propulsive performance. As the AOA rises, the gliding ratio increases in lockstep. The drag formation has some exciting outcomes. Because viscous effects are more significant at lower Re values, leading skin friction to be the primary contributor to drag reduction, the average drag coefficient in each case drops as the AOA increases." (2023): Keanekaragaman capung (Odonata) pada area Kali Pertambakan desa Bakaran Kulon kecamatan juwana kabupaten Pati [Diversity of dragonfly (Odonata) in the areas of rivers at Bakaran Kulon Village, Juwana sub-district, Pati District]. Webinar biofair pendidikan biologi Universitas PGRI Semarang: 241-251. (in Indonesian) ["Dragonflies have a very important role as aquatic bioindicators. Disruption of the dragonfly's natural habitat causes the dragonfly population to change due to human activity. The purpose of this study was to determine the diversity of dragonflies (Odonata) in the fishpond area of Bakaran Kulon Village. Data collection for dragonflies (Odonata) used the edge roaming method in the pond area. Data collection was carried out by walking at the end of transect 1 to the other end and recording the dragonflies found. Based on the research that had been conducted for 3 days, it was found that 110 individuals of dragonflies were found belonging to two suborders, namely Suborder Zygoptera and Suborder Anisoptera. Suborder Anisoptera found 107 individuals, namely Libellulidae including *Crocothemis erythraea* species with 30 individuals, *Pantala flavescens* 68 individuals, *Orthetrum sabina* 8 individuals, *Diplacodes trivialis* only found 1 individual, Suborder Zygoptera only found one family, namely Family Coenagrionidae found 1 species with a total of 3 individual. The most abundant dragonflies were from the *Pantala flavescens* species." **22305.** Momin, S.G.; Pale, M.; Sarkar, P.; Ahmed, G.; Bhat-tacharya, A. (2023): Prey selection by Pitcher Plant, *Nepenthes khasiana* in Meghalaya, India. Uttar Pradesh Journal of Zoology 44(13): 115-130. (in English) ["*Nepenthes khasiana*, an endangered pitcher plant endemic to Meghalaya and southern Assam, India seems to develop a pitcher for trapping small animals as their prey to supplement the nutrient deficiency which occurs in the soil. A study on the enigmatic meat-eating choice of *N. khasiana* is scarce. Hence, this study was conducted to find out their prey species covering all three hills of Meghalaya, India. A total of 90 pitcher samples (30 from each hill) were collected randomly and preserved in 70% alcohol which was further identified at the lower taxa level. A total of 71 species were identified up to the species level while another five were identified up to their genus level. Among this, 90.8% of species were insects (69 species) while the remaining 9.2% (7 species) were non-insect species. All these seven non-insect species belonged to single order Arachnida. The majority of them (71.1%, 54 species) were capable of flying while the remaining 28.9% (22 species) were incompetent to fly. Those species which were incompetent to fly belonged to orders Araneae, Dermaptera, Diptera, Hemiptera, Lepidoptera, and Odonata. The prey constituted the highest 23 species belonging to the order Hymenoptera followed by 11 species under Coleoptera, 9 species under Diptera, 7 species under Araneae, 6 species each under Hemiptera and Blattodea, 5 species each under Orthoptera and Lepidoptera, 2 species under Odonata and 1 species each under Mantodea and Dermaptera. The orders Hymenoptera and Diptera together contributed 83.3% of the total feeding spectrum. This further indicates the sustainable management of biodiversity securing the abundance of animal prey species for the conservation of pitcher plants in this landscape." (Authors)]

**22306.** Monnerat, C. (2023): Situation actuelle de *Leucorrhinia albifrons* (Burmeister, 1839) en Suisse (Odonata: Libellulidae). Entomo Helvetica 16: 9-25. (in French, with English and German summaries) ["Status of *Leucorrhinia albifrons* (Burmeister, 1839) in Switzerland (Odonata: Libellulidae). A synthesis of the data on *Leucorrhinia albifrons* collected since 2000 documents its reproduction as certain in six localities (two of which are no longer in existence) and probable in a seventh, while single males have been recorded in eight other localities. In the cantons of Aargau, Jura and Graubünden, the species was recorded for the first time, while in the cantons of Bern and Zurich it was seen again after half a century of absence. The data presented

confirm the high dispersal capacity of *L. albifrons*, from several dozen to over 100 kilometers, which has allowed this species to colonise a revitalised high marsh, water bodies created after 1990 and even a natural site in the subalpine zone. However, the number of occupied sites is still very small and they are far apart, which reduces the probability of regular exchanges between sites and increases the risk of extinction. The increased availability of suitable bodies of water through revitalization measures and the creation of new habitats is essential to maintaining sustainable populations of this highly demanding species in Switzerland." **22307.** Morris, R.K.A.; Welch, M.D. (2023): Is invertebrate conservation in Great Britain best achieved by policies that increase species protection? *Journal of Insect Conservation* 27: 527-531. (in English) ["We discuss proposals to extend the list of protected insect species in Great Britain and question whether existing species protection measures are appropriate for insects whose ecology is substantially unknown. We highlight the practicalities of applying such measures to very poorly known taxa, whose identification depends upon highly experienced specialists and a tiny pool of relevant expertise. We propose a seven-point plan that would strengthen invertebrate conservation in Great Britain. Our proposals could be applied to other countries with a protected sites network and a desire to improve habitat-based insect conservation measures. Implications for insect conservation: Our analysis suggests that insect conservation will not be improved by legislation that restricts the potential for ad hoc surveillance that currently provides almost all the data used to monitor rare and threatened insects. We highlight the need for improvements in the understanding of insect micro-habitat requirements amongst conservation managers. Our proposed seven-point plan provides a structured approach to insect conservation that should improve identification of important insect sites, site management and landscape-scale conservation measures." (Authors) The British terrestrial arthropods protected under the Wildlife and Countryside Act (1981) include two. not further specified. Odonata species.] Address: Morris, R.K.A., Scientific Associate, Diptera Section, Natural History Museum, London SW7 5BD, UK. Email: syrphid58@gmail.com

**22308.** Mozhui, L.; Kakati, L.N.; Ao, B.; Kezo, V.; Meyer-Rochow, V.B. (2023): Socio-economic analysis of edible insect species collectors and vendors in Nagaland, North-East India. *Journal of Insects as Food and Feed* (2023); DOI: 10.1163/23524588-20230082: 18 pp. (in English) ["In Nagaland insects like the Eri silkworm *Samia cynthia ricini* and the Indian honey bee *Apis cerana indica* are reared for commercial purposes rather than just household uses. Of the marketed edible insects in India, Hymenoptera contribute 34% followed by Orthoptera (25%), Coleoptera (16%), Hemiptera (12%), and Lepidoptera (9%) while Odonata and Blattodea contribute 2% each. The present study estimates that an insect seller may earn Rs. 600-800 (US \$7.51-10.01) per kg from various types of insects such as grasshoppers, crickets, katydid, water and diving beetles, ants, stink bugs and tent caterpillars. For 1 litre of honey an insect seller may earn Rs. 532-1600 (US \$6.66-20.02) and for 1 kg of wood larvae (largely beetle larvae), carpenter "worms" (= *Cossus* spp. moth larvae) and hornets the vendor can demand Rs. 3,300-3,750 (US \$41.29-56.31). The contribution of the edible insect sector towards the socio-economy and livelihood improvement of the people in both rural and urban communities is highlighted and discussed. Given the insect bio-resource

in the region, the consumption of edible insects, coupled with mass production, processing, and marketing (as successfully implemented in countries like Thailand, Vietnam, and some African countries like Cameroon and Nigeria), can be a boon to Nagaland." **22314.** Nel, A.; Palazzo, G.J.; Aase, A. (2023): A new damselfly from the Lower Eocene Green River Formation (Odonata, Dysagrionidae). *Palaeoentomology* 6(4): 336-339. (in English) ["The Eocene Green River Formation in the USA is well known as a Konservat-Lagerstätte, and has yielded an enormous number of beautifully preserved fossil insects from the Parachute Creek Member of Lake Uinta in Colorado and Utah, USA (Grande, 1984) where insects dominate the fauna. In Fossil Lake deposits, fish dominate the fauna with insects a minor component. This formation spans a 5-my-long period between ca. 53.5 and 48.5 Ma (Smith et al., 2003) in three distinct basins containing lacustrine sediments. Many of these fossils are in an exquisite state of preservation, occasionally even with soft tissues and colour patterns preserved (e.g., Bechly et al., 2020). As this entomofauna is one of the most diverse for the Early Eocene, increasing its knowledge is crucial for the understanding of the evolution of the insects at that time. This is especially the case for the Odonata, a clade that remains poorly known for the Paleocene and early Eocene (Nel & Jouault, 2022). Bechly et al. (2020) provided a first revision of the damselflies from the Green River Formation, but continuing excavation produces new specimens. The specimen described herein was recently discovered while excavating fossil fish in the Fossil Lake deposits of the Green River Formation in southwest Wyoming. This new species of Zygoptera from the Fossil Lake deposits further demonstrates its impressive diversity of Odonata." (Authors)] Address: Nel, A., Lab. Ent. Mus. Natn. Hist. **22315.** Noda, R.; Liu, X.; Hefler, C.; Shyy, W.; Qiu, H.H. (2023): The interplay of kinematics and aerodynamics in multiple flight modes of a dragonfly. *Journal of Fluid Mechanics* 967: (in English) ["This paper presents the effects of wing kinematics on both normal forward flight and escape flight of a dragonfly. A Navier–Stokes-based numerical model has been adopted, and results have been substantiated by experimental data. The wing kinematics of tethered specimens and the prescribed wing morphology of a free-flying dragonfly were used in the simulation. To shed light on the interplay between kinematics and aerodynamics, a parametric study of the kinematics has been conducted. It is found that in escape flight, the dragonfly generates additional lift while the thrust reduces and the overall efficiency drops. Compared with normal forward flight, the escape mode produces larger lift force peaks. When the kinematics change to facilitate escape flight, the aerodynamic forces are affected by not only the flapping kinematics but, in the case of the hindwing, the varied wing–wing vortex interactions. The direction of the resultant force on each wing changes according to the change of the mean of pitching angle and stroke plane angle. We found that in the studied configurations, the varied phasing of the wings has a marginal effect on the aerodynamics of the dragonfly. It reduces lift and increases thrust, and this force modulation is slightly more efficient when the local angle of attack also changes.

On the other hand, the change of angle of attack played a major role in leading-edge vortex formations and directing the resultant forces of the wings. The results can be useful in developing flight control strategies for micro air vehicle design." **22317.** Oelmann, Y.; Fiedler, D.; Michaelis, R.; Leivits, M.; Braun, A.; Gschwind, P.; Neidhardt, H.; Willigalla, C. (2023): Autumn migration of the migrant hawkler (*Aeshna mixta*) at the Baltic coast. *Movement Ecology* 11(Article number: 52): 9 pp. (in English) ["Background: Migratory insects are important for the provision of ecosystem services both at the origin and destination sites but – apart from some iconic species – the migration routes of many insect species have not been assessed. Coastlines serve as a funnel where migrating animals including insects accumulate. Migratory behaviour and captures of dragonflies in bird traps suggest autumn migration of dragonflies along coastlines while the origin and regularity of this migration remain unclear. Methods: Dragonfly species were caught at the bird observatory Kabil at the Baltic coast in Estonia in 2009, 2010 and 2015. For the 2015 data set, we used a stable hydrogen (H) approach to trace the potential natal origin of the migrant hawkler (*Aeshna mixta*). Results: 1079 (2009), 701 (2010) and 88 (2015) *A. mixta* individuals were caught during the study periods (35, 37 and 11 days in 2009, 2010 and 2015, respectively). The migration period lasted from end of August to end of September. Based on the results from our stable isotope analysis, we identified two populations of *A. mixta*: One (range of isotope signatures of non-exchangeable H [ $\delta^2\text{Hn}$  wing]: -78‰ to -112‰) had a local likely origin while the other ( $\delta^2\text{Hn}$  wing: -113‰ to -147‰) migrated from northerly directions even in headwind from the South. The former showed an even sex ratio whereas the actively migrating population was dominated by males. Conclusions: Our results suggest a regular southbound autumn migration of *A. mixta* along the Baltic coast. However, nearly half of the sampled individuals originated from the surroundings

suggesting either no, partial or "leap-frog" migration. Contrary to our expectation, *A. mixta* did not select favourable wind conditions but continued the southbound autumn migration in the flight boundary layer even in case of headwinds. The dominance of males might indicate migration as a result of competition for resources. Further repeated, large-scale studies along the Baltic coast are necessary to pinpoint the migratory pattern and the reason for migration of *A. mixta*. Such studies should also comprise locations north of the known species range of *A. mixta* because of the rapid climate-change induced range expansion." (Authors)] Address: Oelmann, Yvonne, Geoecology, Department of Geosciences, University of Tübingen, 72070 Tübingen, Germany. Email: yvonne.oelmann@uni-tuebingen.de

**22318.** Omary, R.R.; Lalika, M.C.S.; Nguvava, M.; Mjimwa, E. (2023): Macroinvertebrates as bio indicators of water quality in Pinyinyi River, Arusha Tanzania. *Journal of Water Resource and Protection* 15(8): 393-412. (in English) ["This study used macroinvertebrates to assess the impact of anthropogenic activities on the Pinyinyi River during dry and wet season. Abundance of macroinvertebrates, average score per taxon and Shannon Weiner Species Diversity Index were used to state the ecological status of Pinyinyi River. Because the abundance of macroinvertebrates can be affected by change in water quality, some of the physicochemical parameters were also measured. A macroinvertebrates hand net is used to collect the macroinvertebrates per sampling point. DO, temperature, pH, turbidity and TDS were measured in-situ using HI-9829 Multiparameter and BOD was measured in the laboratory using Oxydirect levibond method. A total of 164 macroinvertebrates were collected and identified from Pinyinyi River during dry and wet season. They belong to 13 families. The most abundant taxa were mosquito larva, Diptera (41.07%) and aquatic caterpillar, Lepidoptera (23.21%) during dry season representing about 64.28% of the total macroinvertebrates whereas the least abundant taxa were pouch snail (16.07%) and dragonflies, Odonata (19.64%) during dry season representing about 35.72% of the total macroinvertebrates. The most abundant taxa collected during wet season were aquatic earthworm, haplotaxida (19.44%), midges, Diptera (17.59%), black flies, Diptera (15.74%) and creeping water bugs, Hemiptera (12.96%) whereas the least abundant were pigmy back swimmers, Hemiptera (2.78%), snail (3.7%), predacious diving beetle (4.63%) and coleopteran (4.63%). Average Score per taxon of Pinyinyi River during dry season was 5.25 and 3.6 during wet season. The Shannon Weiner Species Diversity Index was 1.318 during dry season and 2.138 during wet season. Based on the score, Pinyinyi River is moderately polluted during dry season and seriously polluted during wet season. Based on index, Pinyinyi River has low diversity of macroinvertebrates during dry season and highly in diversity of macroinvertebrates during wet season. Moreover, it was found that, agricultural activities, livestock keeping, bathing and washing alter physicochemical parameters of Pinyinyi River and hence change the abundance of macroinvertebrates as well as the quality of water. The study, therefore, recommends that the source of pollutants should be controlled and the river regularly monitored by the relevant authorities." (Authors)] Address: Omary, R.R., Dept of Geography & Environmental Studies, College of Natural & Applied Science (CoNAS), Sokoine Univ. of Agriculture, Morogoro, Tanzania

*Anopheles arabiensis* and *Anopheles funestus* larval survivorship in Homa Bay County Western Kenya. *Malaria Journal* (2023) 22:298: 9 pp. (in English) ["Background: The rise of insecticide resistance against malaria vectors in sub-Saharan Africa has resulted in the need to consider other methods of vector control. The potential use of biological methods, including larvivorous fish, *Bacillus thuringiensis israelensis* (Bti) and plant shading, is sustainable and environmentally friendly options. This study examined the survivorship of *Anopheles arabiensis* and *Anopheles funestus* larvae and habitat productivity in four permanent habitat types in Homa Bay county, western Kenya. Methods: Predator densities were studied in a laboratory setup while habitat productivity and larval survivorship was studied in field setup. Results: Fish were observed as the most efficient predator (75.8% larval reduction rate) followed by water boatman (69%), and dragonfly nymph (69.5%) in predation rates. Lower predation rates were observed in backswimmers (31%), water beetles (14.9%), water spiders (12.2%), mayflies (7.3%), and tadpoles (6.9%). Increase in predator density in the field setup resulted in decreased *Culex* larval density. Larval and pupa age-specific distribution was determined and their survivorship curves constructed. Combined larvae (Stage I-IV) to pupa mortality was over 97% for *An. arabiensis* and 100% for *An. funestus*. The highest larval stage survival rate was from larval stages I to II and the lowest from larval stage IV to pupa. Stage-specific life tables indicated high mortality rates at every developmental stage, especially at the larval stage II and III. Conclusion: Determination of the efficiency of various larval predators and habitat productivity will help with the correct identification of productive habitats and selection of complementary vector control methods through environmental management and/or predator introduction (for instance fish) in the habitats." (2023): Hat *Sympetrum fonscolombii* (Selys, 1840) am Kranichwoog bei Hütschenhausen (Rheinland-Pfalz, Landstuhler Moomiederung) als Larve überwintert (Odonata: Libellulidae)? *Libellula* 42(1/2): 69-78. (in German, with English summary) ["Did *S. fonscolombii* overwinter in the larval stage in the Kranichwoog near Hütschenhausen (Rheinland-Palatinat, Landstuhler Moomiederung)? – The article reports on an overwintering population of larvae of *Sympetrum fonscolombii* in the Kranichwoog near Hütschenhausen (Rheinland-Palatinat, Landstuhler Moomiederung). The adults emerged at the beginning of June 2023. Taking into account the known time of their larval development, phenological evidence of the migration of the species and the available weather data, it is deduced that these adults must have emerged from overwintered larvae. This can be considered as another effect of climate change on the dragonfly fauna." (Author)] Address: Ott, J., L.U.P.O. GmbH, Friedhofstr. 28, 67705 Trippstadt, Germany. Email: ott@lupogmbh.de

**22323.** Patten, M.A.; Benson, B.R. (2023): A broader flight season for Norway's Odonata across a century and a half. *Oikos* 2023: e09882. doi: 10.1111/oik.09882: 11pp. (in English) ["As global climate continues to change, so too will phenology of a wide range of insects. Changes in flight season usually are characterised as shifts to earlier dates or means, with attention less often paid to flight season breadth or whether seasons are now skewed. We amassed flight season data for the insect order Odonata, the dragonflies and damselflies, for Norway over the past century-and-a-half to examine the form of flight season change. By means of Bayesian analyses that incorporated uncertainty relative to annual variability in survey effort, we estimated shifts in flight season mean, breadth, and skew. We focussed on flight season breadth, positing that it will track documented growing season expansion. A specific mechanism explored was shifts in voltinism, the number of generations per year, which tends to increase with warming. We found strong evidence for an increase in flight season breadth but much less for a shift in mean, with any shift of the latter tending toward a later mean. Skew has become rightward for suborder Zygoptera, but not for Anisoptera, or for the Odonata as a whole. We found weak support for voltinism as a predictor of broader flight season; instead, voltinism acted interactively with use of human-modified habitats, including decrease in shading (e.g. from timber extraction). Other potential mechanisms that link warming with broadening of flight season include protracted emergence and cohort splitting, both of which have been documented in the Odonata. It is likely that warming-induced broadening of flight seasons of these widespread insect predators will have wide-ranging consequences for freshwater ecosystems." **22326.** Pyo, J.-Y.; Kim, S.-S.; Park, J.S.; Kim, J.-M.; Song, Y.-K.; Kim, I. (2023): Identification of *Sympetrum depressiusculum* Selys, 1841 in South Korea (Odonata: Libellulidae) according to morphology and genetic markers. *Insects* 2023, 14(9), 733; <https://doi.org/10.3390/insects14090733>: 20 pp. (in English) ["Simple Summary: Two species of *Sympetrum*, namely *S. depressiusculum* and *S. frequens*, have been documented in South Korea. However, the distinction between these two species and their identity within South Korean populations has been a longstanding point of contention. To solve this issue, morphology, two mitochondrial genes, and one nuclear region were analyzed for *S. depressiusculum* samples from The Netherlands and Russia and *S. frequens* samples from Japan, as well as samples of *Sympetrum* from South Korea. Further, available public sequence data for the two species were included. Morphology, sequence divergence, and phylogenetic results all consistently suggest that South Korean populations form a single species. Analyses of haplotype network and gene pool distribution patterns in a nuclear region conducted to better explain the current taxonomic implications indicated changes in the dominant gene pool from The Netherlands and Russia to South Korea and Japan. However, such divergence and subdivision could be explained within the context of within-species diversification patterns, suggesting that South Korean populations constitute one species, *S. depressiusculum*, by applying the senior name. Abstract: In South Korea, both *S. depressiusculum*, which is distributed throughout Europe and from Russia to the Korean Peninsula, and *S. frequens*, which is endemic to Japan, are recorded. However, the identity of South Korean populations and the validity of listing the two species have not yet been settled. In this study, we collected 74 individuals of *Sympetrum* species from South Korea (five localities), Russia, The Netherlands, and Japan. These samples were examined for morphology and sequenced for partial COI, 16S rRNA, and a nuclear internal spacer (ITS) region, after which these molecular data were combined with available public data from Russia, Japan, and The Netherlands. Major morphological characters that have been used to distinguish the two species and phylogenetic, network, and structure analyses all consistently suggest that South Korean populations form a single species. Consequently, it could be valid to treat South Korean populations as one species, *S. depressiusculum*, by applying the senior name. Nevertheless, the validity of maintaining each as an independent species in other countries may need additional study considering that our samples were focused more on South Korea and limited for Europe, Russia, and Japan." **22329.** Raghunandan, K.S.; Anusha V.S.; Prasanna, K.S. (2023): A preliminary checklist on odonates in and around Lingambudhi lake, Mysuru, Karnataka. *Journal of Applied Entomologist* 3(4): 6-11. (in English) ["Odonates are amphibiotic, well-known dominant groups of freshwater and terrestrial insects. A field study was conducted to find out to prepare a checklist of odonates in and around Lingambudhi lake, Mysuru, Karnataka during June to August, 2023. Sampling was done by Direct Encounter Method and Identification of Odonates as per the Standard field guides. Biodiversity indices values were formulated for the observed data. A total 18 Odonate species has been identified, belonging to Anisoptera (n=12) and Zygoptera (n=6) suborders having 7 families. The Libellulidae contribute highest number of Odonate species. It was observed that more anthropogenic activities lead to disturbance of odonates in study area. The study highlights the importance of odonates and provides data which would be useful in future biodiversity conservation." (Authors)] The list includes *Lestes dryas*, a misidentification as can be seen from the specimen documented on plate 1 as fig. L.] Address: Raghunandan, K.S., Guest Faculty, Postgraduate Dept of Applied Zoology, Maharani's Science College for women, Autonomous, JLB Road, Mysuru, Karnataka, India

**22330.** Rahong, P.; Techakijvej, C.; Phalaraksh, C. (2023): Predators as biocontrol agents of mosquito larvae in small and large habitats in Chiang Mai, Thailand. *J. of Vector Ecology* 48(2): 78-88. (in English) ["Controlling mosquito-borne disease is a major global challenge due to the rise of insecticide-resistant mosquitoes. In response, we conducted a study in Chiang Mai Province, Thailand, which is one of the largest and the most popular cities for tourists in Southeast Asia, to explore the potential of local species as biological control agents for mosquito larvae. Mosquito larvae and aquatic predators were sampled from large and small habitats, while relevant physico-chemical parameters were measured. The study identified 560 predators and 1,572 mosquitoes, with most mosquito species belonging to the genus

*Culex*. Additionally, the study identified 16 predator taxa, including four fish taxa and 12 taxa of predatory aquatic insects belonging to four orders: Coleoptera, Hemiptera, Odonata, and Diptera. The study found that several locally occurring predator species, namely *Poecilia*, *Laccophilus*, *Lutzia*, *Toxorhynchites splendens*, *Agrionoptera*, and *Pseudagrion*, shared habitats with mosquitoes, indicating their potential as effective biological control agents for mosquito control. Conductivity, dissolved oxygen, and pH were the important physico-chemical parameters that affect both predators and mosquito larvae. Consequently, promoting native predators and reducing mosquito larvae through habitat management would be a sustainable and ecologically friendly approach in large habitats where it is not possible to remove mosquito oviposition sites. In smaller habitats, releasing local aquatic predators and removing oviposition sites may be a suitable strategy." (Authors)] Address: Rahong, P., Environmental Science Research Center, Faculty of Science, Chiang Mai University, Chiang Mai, 50200, Thailand

**22331.** Rajapaksha, K.A.T.; Hettiarachchi, D.K. (2023): A preliminary assessment of odonate (Insecta: Odonata) diversity and abundance in Mihintale lake and Kaludiya-pokuna in Mihintale, Anuradhapura. *Proceedings of the International Conference on Applied and Pure Sciences (ICAPS 2023-Kelaniya)* Volume 3, Faculty of Science, University of Kelaniya Sri Lanka: 46. (in English) [Verbatim: The odonates of Sri Lanka comprise with 129 known species, including 67 species belongs to 12 families where 56 species (43%) are known to be endemic to the country. These organisms are currently threatened due to increase in human population and activities, climatic change, intensive agricultural practices and pollution and in need of conservation. Having less diversity, richness, abundance and distribution surveys is one of the key obstacles in conservation. There have been less surveys of odonates in dry zone areas. This study intended to prepare an inventory of odonates that inhabit two lotic ecosystems in dry zone. Four sample sites were selected from each lotic habitat. Visual observations of adult odonates were conducted by walking along belt transect of 100 x 3m that are adjacent to the water bodies in all four sample sites in the selected two lotic ecosystems. Observations were taken from 0900 h to 1100 h in the morning and 1500 h to 1600 h in the evening for six months from Kaludiya pokuna and Mihintale lake visiting three times per month to each site. The observed individuals were photographed. A total of 3,343 of individual odonates were recorded. A total of 22 species identified using standard field guides, belong to three families, Coenagrionidae (25.90%), Gomphidae (3.26%) and Libellulidae (70.83%), two vulnerable species *Aciagrion occidentale* and *Ceriagrion cerinorubellum*, two endemic species *Cyclogomphus gynostylus* and *Pseudagrion rubriceps ceylonicum* where one was considered as critically endangered and three nearly threatened species *Orthetrum glaucum*, *Hydrobasileus croceus* and *Rhodothemis rufa* were recorded. The diversity of odonates and abundance was higher in Mihintale lake because Shannon – Weiner diversity index (2.267) and Simpson's diversity index (0.854) and Evenness (0.817) were high for Mihintale lake. The highest number of individuals that observed was *Brachythemis contaminata* in both study sites as a total but in Kaludiya pokuna number of individuals that was observed from this species was higher than Mihintale lake. This study shows odonate diversity is high in both lotic habitats that were studied and in Mihintale lake it is higher than Kaludiya pokuna. This study needs to be further expanded taking micro-habitat parameters, water quality parameters and expanding it over time and area. Further, both lotic and lentic habitats

can be considered with and without/less anthropogenic activities.] Address: Hettiarachchi, D.K., Dept of Biological Sciences, Fac. Applied Sciences, Rajarata Univ. of Sri Lanka, Mihintale, Sri Lanka. Email: dilanikh@as.rjt.ac.lk

**22332.** Raut, A.M.; Banu, A.N.; Akram, W.; Nain, R.S.; Singh, K.; Wahengabam, J.; Shankar, C.; Shah, M.A. (2023): Impact of pesticides on diversity and abundance of predatory arthropods in rice ecosystem. *Applied and Environmental Soil Science* Volume 2023, Article ID 8891070: 10 pp. (in English) ["Rice (*Oryza sativa*) is one of the most important cereal crops with a diverse set of pests and natural enemies. Rice fields often support a high diversity of arthropods which contribute significantly to productivity. This diversity is frequently threatened due to indiscriminate applications of pesticides. Our aim was to emphasize on the predator diversity in agrochemical exposed rice field as well as on the impact of surrounding vegetation on beneficial insect diversity. Natural enemies' data were recorded from randomly selected 10 quadrates by visual observation from each treatment. A total of 5,590 individuals of predators were observed during the study period which included 27 species belonging to 16 families from five orders of arthropods during the kharif season of rice. Statistically, there were no significant differences between the population of general natural enemies such as Odonata, Coleoptera, Hymenoptera, and Araneae in plots with insecticide and control during the different growth stages of rice cultivation. Diversity indices were almost similar in fields where pesticide was sprayed and not sprayed. Our study concluded that natural enemies are conserved by ensuring crop heterogeneity, growing insect-friendly plants (with high levels of nectar and pollen) as border crops, and judicious application of granule insecticide like cartap hydrochloride in a rice agro-ecosystem." (Authors)] Address: Raut, A.M., Dept of Entomology, School of Agriculture, Lovely Professional University, Jalandhar, Punjab, India. Email: ankushento@gmail.com

**22333.** Ruppell, G.; Hilfert-Ruppell, D. (2023): Double function of flight in *Calopteryx splendens* (Odonata: Calopterygidae) males. *International Journal of Odonatology* 26: 172-178. (in English) ["Different flight manoeuvres of males of *Calopteryx splendens* were analysed by means of slow-motion filming. The wingbeat frequencies of males flying in tandem were higher than those of single flying males. A male exhibited the highest frequencies when carrying a Blue Featherleg [*Platynemis pennipes*] tandem over a distance of 20–25 cm. The widest range of variability of values of wingbeat frequencies were recorded in threatening flight, probably due to the simultaneous communicative function of the wings during that behaviour. The upstroke/downstroke ratio of the wings allows to draw conclusions on their aerodynamic effect. It was low in pursuing flight, which is when more thrust is needed, and it was high in flight with an additional load (a Featherleg tandem) when a lot of lift was necessary. Both sexes exhibited wing standstills during forward flight. In males, the variability of the duration of wing standstills was widest, probably due to the communicative function of their blue wings. Because males engage in threatening displays their flight was very irregular and unsteady. In contrast, females were much more regular in their flight, which may explain why they win most pursuit races with males." (Authors)] Address: Ruppell, G., An der Wasserfurche 32, Cremlingen, Germany. Email: georg.rueppell@protonmail.com

**22337.** Sánchez-Campaña, C.; Múrria, C.; Hermoso, V.; Sánchez-Fernández, D.; Tierno de Figueroa, J.M.; González, M.; Millán, A.; Moubayed, J.; Ivkovic, M.; Murányi, D.; Graf, W.; Derka, T.; Mey, W.; Sipahiler, F.; Paøil, P.; Polášková, V.; Bonada, N. (2023): Anticipating where are unknown aquatic insects in Europe to improve biodiversity conservation. *Diversity and Distributions* 29: 1021-1034. (in English) ["Aim: Understanding biodiversity patterns is crucial for prioritizing future conservation efforts and reducing the current rates of biodiversity loss. However, a large proportion of species remain undescribed (i.e. unknown biodiversity), hindering our ability to conduct this task. This phenomenon, known as the 'Linnean shortfall', is especially relevant in highly diverse, yet endangered, taxonomic groups, such as insects. Here we explore the distributions of recently described freshwater insect species in Europe to (1) infer the potential location of unknown biodiversity hotspots and (2) determine the variables that can anticipate the distribution of unknown biodiversity. Location: The European continent, including western Russia, Cyprus and Turkey. Methods: Georeferenced information of all sites where new aquatic insect species were described across Europe from 2000 to 2020 was compiled. In order to understand the observed spatial patterns in richness of recently described species, spatial units were defined (level 6 of HydroBASINS) and associated with a combination of a set of socioeconomic, environmental and sampling effort descriptors. A zero-inflated Poisson regression approach was used to model the richness of newly described species within each spatial unit. Results: Nine hundred and sixty-six recently described species were found: 398 Diptera, 362 Trichoptera, 105 Coleoptera, 66 Plecoptera, 28 Ephemeroptera, 3 Neuroptera, 2 Lepidoptera and 2 Odonata. The Mediterranean Basin was the region with the highest number of recently described species (74%). The richness of recently described species per spatial unit across Europe was highest at mid-elevation areas (between 400 and 1000 m), latitudes between 40 and 50° and in areas with yearly average precipitation levels of 500–1000 mm, a medium intensity of sampling effort and low population density. The percentage of protected areas in each study unit was not significantly related to the richness of recently described species. In fact, 70% of the species were found outside protected areas. Main conclusions: The results highlight the urgent need to concentrate conservation efforts in freshwater ecosystems located at mid-altitude areas and out of protected areas across the Mediterranean Basin. The highest number of newly described species in those areas indicates that further monitoring efforts are required to ensure the aquatic biodiversity is adequately known and managed within a context of growing human impacts in freshwater ecosystems." **22338.** Sentis, A.; Kaunisto, K.; Chari, L.; Morrill, A.; Popova, O.; Pomeranz, J.; Boukal, D.; Tüzün, N.; Stoks, R. (2023): Odonata trophic ecology. In: *Dragonflies and Damselflies*. Second Edition. Edited by A. Córdoba-Aguilar, C.D. Beatty and J.T. Bried, Oxford University Press. 219-232. (in English) ["Trophic interactions are at the core of several key ecological processes and theories as they determine the flow of material and energy within and across communities and habitats. Odonates provide a rich and diverse taxonomic group with several features (e.g. trophic position, hunting behavior, olfaction) that make them a very interesting biological model for the study of trophic interactions in aquatic

and terrestrial habitats. Moreover, odonates undergo incomplete metamorphosis with aquatic larvae and terrestrial adults, which provides opportunities to investigate ontogenetic diet variation and trophic links between aquatic and terrestrial systems. They are also important predators regulating prey populations and mediating community processes such as trophic cascades. Finally, recent studies on odonates have pioneered whether local adaptation and phenotypic plasticity can counterbalance the negative impacts of global change on resource acquisition and fitness. This chapter reviews recent studies investigating the trophic features and role of odonates in aquatic and terrestrial ecosystems as well as their importance for investigating the impact of global change on trophic ecology, local adaptation, and community processes. Many of the insights highlighted in this chapter go beyond odonates and have helped to advance key concepts in trophic ecology." (2023): Odonatas predadores de larvas do mosquito *Aedes aegypti*, no sudoeste da Bahia. In: *XXI Encontro de Zoologia do Nordeste*. Universidade Federal de Pernambuco, Recife-PE, 2023. Disponível em: <<https://www.doity.com.br/anais/resumosezn2023/trabalho/310953>>. Acesso em: 04/11/2023 às 13:49: 4 pp. (in Portuguese) ["Studies to control the *Aedes aegypti* vector are important to reduce the incidence of Dengue, Zika and Chikungunya, responsible for thousands of deaths in Brazil. This study investigated the potential for biological control of the *Ae. mosquito. aegypti* by nymphs of the order Odonata, aiming to combat these diseases. The third and fourth instar larvae of *Ae. aegypti* were obtained from the Natural Insecticide Research Laboratory (LAPIN) of the State University of Southwest Bahia (UESB), Itapetinga Campus, and bred from eggs of the Rockefeller strain, provided by the Toxicology Research Laboratory of the Federal University of Pernambuco (UFPE). The Odonata nymphs were collected in a UESB reservoir on the Vitória da Conquista campus, using an entomological net and placed in containers containing 2 liters of treated and dechlorinated water, where they remained for 24 hours without food before the experiments. These were conducted in the laboratory, using nymphs from the Aeshnidae, Libellulidae and Coenagrionidae families. In the first experiment, nymphs from the Aeshnidae family preyed on 56 *Ae. aegypti* over 9 hours. In the second, nymphs from the Libellulidae family preyed on all 150 *Ae. larvae. aegypti* in 12 hours, while nymphs from the Coenagrionidae family preyed 25. In the third experiment, nymphs from the Libellulidae family preyed 68 *Ae. aegypti*, highlighting the influence of the amount of water on predation. Results support the effectiveness of Odonata nymphs to control *Ae. aegypti*, especially the Aeshnidae and Libellulidae families, offering an economical and sustainable approach to reducing mosquito-borne diseases. However, it is essential to consider ecological factors for the success of biological control. This study highlights the importance of innovations in the fight against *Ae. aegypti* to protect public health and prevent these diseases." **22340.** Staentzel, C.; Schlumberger, O.; Barillier, A.; Valentini, A.; Boyer, F.; Beisel, J.N. (2023): Trophic impact of *Neogobius melanostomus* in a restored site on the Old Rhine

River (France). Aquatic Sciences volume 85, Article number: 46: 15 pp. (in English) ["Habitat changes induced by restoration can favour invasive species, thereby thwarting the main biological objectives of restoration and possibly limiting a project's success. Here, we focus on a study site located along the Old Rhine River that was being restored in 2013 by controlled bank erosion and implementation of artificial transverse groynes. In the Upper Rhine (Franco-German border), the first reports of the bighead goby (*Ponticola kessleri*, Günther 1861) and round goby (*Neogobius melanostomus*, Pallas 1814) were 2010 and 2011, respectively. As the round goby largely dominates the overall goby assemblage, we asked about the consequences of its presence on the restored site. Electrofishing was carried out from 2013 to 2021 in parallel to a benthic macroinvertebrate monitoring conducted from 2014 to 2019. In 2015/2016, we looked at goby's predation by studying their stomach contents through macroscopic visualisation and eDNA metabarcoding analysis. For results, gobies were found in large densities dominated by *N. melanostomus*, increasing over time to the detriment of local fish species. No predation was observed on native fish species but *N. melanostomus* cannibalism reached 9%. Round goby's predation was opportunistic, based on the most abundant benthic macroinvertebrates: (i) low trophic level taxa, and (ii) invasive amphipod crustaceans. If round gobies fed on some insects, they did not prevent the colonization of new taxa on the habitats that appeared after restoration. We stress that the high abundance of *N. melanostomus* has led to profound changes in the food web structure and species interactions in the Old Rhine River, but it is unlikely that it masked the restoration consequences on macroinvertebrates 6 years after the restoration. These results support (i) the importance in carrying out long-term monitoring to confirm that a stronger trophic impact is not ultimately delayed, and (ii) the diversification of habitats as an option for limiting the invasion by gobies." (Authors) Odonate taxa are treated at family level."] Address: Staentzel, Cybill, Université de Strasbourg, UMR 7362 CNRS LIVE, 3, rue de l'Argonne, F-67000 Strasbourg, France. **22341.** Stahl, L. (2023): How does temperature and resource level affect competition in two species of dragonfly larvae? MSc. thesis, Uppsala University, Disciplinary Domain of Science and Technology, Biology, Biology Education Centre.: 23 pp. (in English) ["In the wakes of climate change, the phenology of many species is shifting. This can have many implications for inter-specific competition. In this thesis I studied how temperature affected the larval competition between two species of Odonata, dragonfly: *Lestes sponsa* and *Sympetrum vulgatum*. In addition, I studied how this competition was affected by food resource availability. To do this I performed a laboratory experiment on larvae at two different temperatures (21°C and 24°C) and two different resource densities (low and high). I estimated egg hatching rate, growth rate and survival. Larval competition (growth rate and survival) was studied in sympatry in small containers mimicking a natural environment at a density of 5 individuals of each species during a 10-week period. The results showed that eggs of both species hatched at a slightly higher rate at 24°C, and that *S. vulgatum* started hatching about one day in advance of *L. sponsa*. In general, growth rate was higher: (1) at 24°C compared to 21°C, (2) at high compared to low resource densities, and (3) in *L. sponsa* compared to *S. vulgatum*. Interestingly, at 24°C the higher growth rate of *L. sponsa* was accentuated at the high resource level compared to the low resource level. Hence resource levels affected competition differently depending on

temperature. There was a negative relationship between growth rate and survival suggesting that the higher growth rate of larva was to some degree driven by interspecific predation and/or cannibalism. The results from this thesis suggest that resource levels interact with temperature and cause difference in strength of competition between species. Such effects should be considered in theory predicting changes in species distribution in the light of climate change." **22342.** Swaegers, J.; De Cupere, S.; Gaens, N.; Lancaster, L.T.; Carbonell, J.A.; Sánchez Guillén, R.A.; Stoks, R. (2023): Plasticity and associated epigenetic mechanisms play a role in thermal evolution during range expansion. *Evolution Letters*, qrac007pp. (in English) ["Due to global change, many species are shifting their distribution and are thereby confronted with novel thermal conditions at the moving range edges. Especially during the initial phases of exposure to a new environment, it has been hypothesized that plasticity and associated epigenetic mechanisms enable species to cope with environmental change. We tested this idea by capitalizing on the well-documented southward range expansion of the damselfly *Ischnura elegans* from France into Spain where the species invaded warmer regions in the 1950s in eastern Spain (old edge region) and in the 2010s in central Spain (new edge region). Using a common garden experiment at rearing temperatures matching the ancestral and invaded thermal regimes, we tested for evolutionary changes in (thermal plasticity in) larval life history and heat tolerance in these expansion zones. Through the use of de. and hypermethylating agents, we tested whether epigenetic mechanisms play a role in enabling heat tolerance during expansion. We used the phenotype of the native sister species in Spain, *I. graellsii*, as proxy for the locally adapted phenotype. New edge populations converged toward the phenotype of the native species through plastic thermal responses in life history and heat tolerance while old edge populations (partly) constitutively evolved a faster life history and higher heat tolerance than the core populations, thereby matching the native species. Only the heat tolerance of new edge populations increased significantly when exposed to the hypermethylating agent. This suggests that the DNA methylation machinery is more amenable to perturbation at the new edge and shows it is able to play a role in achieving a higher heat tolerance. Our results show that both (evolved) plasticity as well as associated epigenetic mechanisms are initially important when facing new thermal regimes but that their importance diminishes with time." ### 2006

**22346.** Jensen, E.V. (2006): Cumulative effects monitoring of Okanagan streams using benthic invertebrates, 1999 to 2004. Environmental Protection Division, Ministry of Environment, Penticton, B.C.: 60 pp. (in English) ["Biological monitoring is essential to describing and protecting biological resources. Chemical measurements, or habitat assessments are useful to aquatic resource management, but the primary sentinels and objects requiring protection are organisms living in the stream. The merits of using benthic invertebrate measures as cumulative effects indicators are many. Foremost is that biological condition of the streams is being directly assessed. Benthic invertebrates are useful integrators of various stressors and are acknowledged as useful cumulative effects indicators. Secondly, the ranking of stream condition using a benthic invertebrate index or metric, is a defensible objective statement describing stream health, which may be more readily understood by resource managers and the public, than chemical concentrations or habitat statements. Lastly, this process of regional correlation or calibration of benthic health to watershed condition factors can provide opportunities to collaborate across disciplines and integrate and strengthen cumulative effects assessments

of aquatic ecosystem condition in the Okanagan. In this study, benthic invertebrates were collected from 23 low elevation Okanagan stream sites between 1999 and 2004. Replicate sampling used a Surber net and data analysis followed the Benthic Index of Biological Integrity concept developed by Karr (Karr and Chu, 1999). Streams representing a gradient of conditions from low stress to high stress due to human alteration or use of the watershed were examined. Potential stress levels were established through GIS analysis at the watershed level and at the sampling reach for in-stream and near stream habitat condition. Low stress or reference sites and watersheds had low urban, agriculture, timber harvest factors, as well as low instream and near stream habitat alteration. High stress or high impact sites were chosen in watersheds and locations with high urban and agriculture landuse, and demonstrated degraded near and instream habitat. Categorical ranking by upper and lower relative stressor levels allowed calibration of a benthic index of biological integrity (B-IBI) for Okanagan streams. Five benthic invertebrate measures responded predictably over space and time to cumulative stress in valley bottom stream locations. These metric included total taxa, number of plecoptera taxa, number of ephemeroptera taxa, number of intolerant taxa, and number of clinger taxa. These metrics were found to respond predictably to cumulative watershed disturbance and clearly distinguished urban and highly altered sites from low impact sites. Secondary metrics, which responded predictably but did not clearly distinguish high and low stress categories were: number of trichoptera, Hilsenhoff biotic index, percent tolerant, percent predators and percent dominance. Primary metrics were summed into a multimetric index (B-IBI) and partitioned into excellent, good, fair, poor and very poor stream condition categories. The primary and secondary metrics correspond well to metrics used in B-IBI systems employed elsewhere in the Pacific Northwest. B-IBI scores were highest for stream sites on Equisis, Peachland, Shorts, Whiteman, Ellis upstream of Penticton, Chute, McDougall ups of Hwy 97, Coldstream and Lambly Creek (see Table 6 for site details). These sites were considered good to excellent, having a full range of biological diversity and presence of species sensitive to variety of stressors such as thermal, flow, sediment and toxic contaminants. B-IBI scores were lowest for Kelowna, Ellis near Okanagan River, Vernon at 25th Avenue in Vernon, Trout Creek near Hwy 97, Shuttleworth in Ok Falls, Eneas and Prairie Creeks in Summerland and BX Creek at 30th Avenue in Vernon. These sites were judged to be in poor or very poor condition, having almost half the species diversity as the reference group and very few intolerant taxa. A large number of

stream sites were ranked as fair (see Table 6) and have some loss of biodiversity. Water and sediment chemistry samples were collected during the study to complement the biological sampling. Water quality data indicated that in urban and agriculture settings, bacteriological measures frequently exceeded drinking and recreational water quality guidelines. Aquatic life protection guidelines were rarely challenged. Nitrate nitrogen was often orders of magnitude higher in streams flowing through urban and agriculture settings. Reduced sediment quality was more common in urban streams. Polycyclic aromatic hydrocarbons (PAHs) were often elevated in urban stream sediments of BX, Kelowna, Ellis and Eneas creeks. PAHs in BX Creek at 30th Avenue were consistently above Canadian Council of Ministers of the Environment aquatic life interim sediment guidelines but below probable effects levels. Lead and zinc were higher in BX and Kelowna creek sediments than other streams, and average values were between the CCME interim and probable effect levels. Pesticide analysis of stream sediments in 2003 found DDE (a breakdown product of DDT) above CCME aquatic life probable effects levels in Kelowna and Eneas creeks. Endosulphan was also detected in Eneas Creek. PCBs were not detected in urban sediments above detection limits. Further sampling and analysis would be required to describe variation in water and sediment quality for these study sites. Re-evaluation of the same habitat, water and sediment chemistry, and benthic invertebrate data set was carried out by Perrin (2006) using the Environment Canada's Benthic Assessment of Sediment (BEAST) software in CABIN (Canadian Aquatic Biomonitoring Network). Okanagan streams were classified by BEAST using the Fraser Basin reference groups as either unstressed, potentially stressed, stressed or severely stressed relative to Fraser Basin reference conditions, and then compared to B-IBI scores. BEAST was conservative in showing a better condition for 13% of the sites but a worse condition for 55% of the sites than was determined using the B-IBI process. Complete agreement of BEAST and B-IBI scores occurred for 29% of the sites, and 81% of the sites were within one stress category. No sites were more than 2 stress categories apart. The Okanagan CABIN data set and sediment quality data was further evaluated by Perrin (2006) using cluster analysis and multidimensional scaling. These analyses confirmed the BIBI classification of sites into the upper and lower stressor groups which were used in calibrating the Okanagan benthic index of biological integrity. Discriminant function analysis identified sediment PAH, nickel, manganese and water alkalinity as best discriminants of the reference group and two high stress groups. Polycyclic aromatic hydrocarbons (PAHs) in sediments were identified as the strongest discriminator of benthic community in high impact stations. Cause and effect can not be presumed as other stressors such as impervious surface area or measures of stream flow variation are often associated with deteriorating biological condition. Given the specificity of the CABIN model to the Fraser basin and traveling kick net collection method, the overall agreement between the two methods of analysis is encouraging. The comparability of the B-IBI and CABIN outputs suggests that either the B-IBI or BEAST can be used with confidence on Okanagan low elevation streams. Both methods will detect impairment when applied in riffle habitats. Perrin suggests Surber collected data can be used for BEAST assessment but notes assessment error potentially increases. Data compiled for a BIBI analysis may also be used for more in-depth analysis, including multivariate analysis of habitat variables and anthropogenic stressors. Methods of benthic invertebrate collection and data analysis will continue to evolve. Although metric scoring criteria and metric selection varies somewhat

between areas in the Pacific Northwest (Skeena, Fraser Valley, Puget Sound and Washington Cascade areas) the overall commonality in chosen metrics, enables comparable statements of aquatic ecosystem health among these study areas and could enable broad environmental reporting. Comparability of different methods applied in overlapping or adjacent areas through examination of performance characteristics (e.g., precision, sensitivity) known as a performance-based method system. The demonstrated common response of the Okanagan B-IBI with the Fraser Basin models and CABIN protocols may further allow harmonized reporting of environmental conditions across geographic and methodological boundaries. To this end, focused comparison of kick and surber net collections, and increased sampling of reference sites to develop an Okanagan model within CABIN is recommended. Defining benthic community response to stressors is potentially more powerful when spatial scales are reduced, and linking this work to probabilistic surveys would enable broader estimation of regional stream conditions. While harmonization of collection methods and analysis tools between jurisdictions and across borders is a worthy goal it is equally important to apply available information in a timely manner. Given that the B-IBI method has been calibrated for the Okanagan, it can be used to communicate aquatic ecological health and cumulative effects. Further effort must be made on a provincial scale to translate these and other indicator measurements into socially valued descriptors of the environment. Urban streams in the Okanagan are clearly degraded relative to Okanagan B-IBI reference sites, as well as Fraser Basin reference conditions. Reference condition assessments whether based on B-IBI or RCA may not necessarily require high specificity to be used to differentiate highly stressed sites from reference conditions, and provide better aquatic ecosystem condition definition than chemical measures. This information can be particularly useful to watershed and stormwater management efforts in the Okanagan Basin. As resource, site specificity or consequences of decisions increase, the burden of proof will necessarily rise and more stressor based assessments will be required." **22347.** Ahrenhövel, C. (2007): Die Schutzgebiete der Stadt Weimar: Teil I: Die geschützten Landschaftsbestandteile „Tobritzteich bei Possendorf“, „Seeteich bei Legefild“ und „Erlenwiese“. Thüringer Faunistische Abhandlungen 12: 5-27. (in German, with English summary) [The natural reserves of the town of Weimar (Thuringia) Part I: The protected landscape components "Tobritzteich bei Possendorf", "Seeteich bei Legefild" and "Erlenwiese": The present paper is the start of a series about natural reserves in the urban area of Weimar. This first contribution introduces the protected landscape components "Tobritzteich bei Possendorf", "Seeteich bei Legefild" and "Erlenwiese", their significance as geotopes and the results of the survey of floristic and faunistic species. A total of 158 species of higher plants were proven to exist in the three reserves, among them the existence of the rare and endangered species *Trollius europaeus* and *Carex pseudocyperus*. The fauna of these reserves was investigated especially of the classes Mammalia, Aves and Amphibia among vertebrates; and mollusca, Odonata and Orthoptera among invertebrates. A total of 9 species of mammals, 85 of birds, 5 (+ 2 missing) of amphibians, 29 of molluscs, 20 of dragonflies and 7 of grasshoppers were recorded. The surveyed area is mainly significant as a breeding ground, feeding habitat and resting place for birds, among them 28 in

Thuringia endangered species. It is part of the registered special protected area no. 32 "Ilmtal zwischen Bad Berka und Weimar mit Buchfarter Wald". The small bodies of water have a particular importance for amphibians and dragonflies. In the 1970s and 1980s the tree frog (*Hyla arborea*) and natterjack toad (*Bufo calamita*) still occurred but have become extinct in the present. Of the occurring species of dragonflies, four have to be highlighted since they are considered endangered according to the Red List of Thuringia: *Lestes barbarus*, *L. dryas*, *Sympecma fused* and *Sympetrum flaveolum*. The contribution is supplemented by recommendations for the care and development of the three reserves." (Author)] Address: Arenhövel, C., Stadtverwaltung Weimar: Abt. **22348.** Dethlefs, A. (2007): Untersuchungen zur Räuber-Beute-Interaktion zwischen Libellenlarven (Odonata: Anisoptera) und jungen Edelkrebse (Astacus astacus). Diplomarbeit. Christian-Albrechts Universität Kiel: 123 pp. + Anhang. (in German) ["In summary, it can be stated that the predation of dragonfly larvae on young crabs is limited to the Aeshnidae. In the case of *Anax imperator*, it was shown that they can eat almost all crabs on offer in a short time, but that they do not specialize in them and therefore also accept alternative food. This, as well as hiding places for the crabs, significantly reduces the mortality of the crabs. Once they reach a certain body length, the crabs are predators of the dragonfly larvae. There are a lot of dragonfly larvae in the crayfish breeding ponds. However, it must be noted that some of these larvae (Libellulidae) are not harmful. To show how relevant this is, the data from Figure 36 (p. 68) on the relative occurrence of anisopteran species was repeated differently colored in Figure 40: All species whose larvae have a Libellula-type capture mask are colored blue. These species, which are harmless for crayfish breeding, clearly dominate the dragonfly fauna. The few individuals of the red species are those with the Aeshna-type capture mask. They occur in small numbers. It is important to note that around 250 *Anax imperator* larvae were removed from the ponds in crayfish breeding before the first line taxation. These 250 larvae could not hatch there and therefore cannot be seen in Figure 40. Normally, about 90% of *Anax imperator* larvae survive hatching (Corbet, 1957). This means that approximately 225 adults of this species would dominate the ponds if the larvae had not been removed. The larvae of the species *A. imperator* occur in exceptionally (personal communication from Dr. Dreyer) large numbers. Based on the feeding tests carried out, this species is potentially dangerous to the young crabs. However, it has also been shown that if the larvae are offered alternative food, they will also eat it. So there is no specialization in crayfish. It is difficult to say whether *A. imperator* actually has a major influence on the crayfish population, as only counts before the onset of crayfish and those from the fall are available. According to these counts, the loss is around 50% (personal communication from the breeder). How great the natural loss of crabs is in this breeding is not known." **22352.** Bönsel, A. (2009): Koordination, Datenaufbereitung und Auswertung von Kartierungen im Rahmen des landesweiten Monitoringprogrammes MV: Artengruppe Libellen im Jahr 2009: Verbreitungskartierung: *Leucorrhinia pectoralis* (Große Moosjungfer), *L. albifrons* (Östliche Moosjungfer), *L. caudalis* (Zierliche Moosjungfer), *Aeshna viridis* (Grüne Moosjungfer), *Sympecma paedisca* (Sibirische Winterlibelle), *Gomphus flavipes* (Asiatische Keiljungfer); Monitoring: *Leucorrhinia pectoralis* (Große Moosjungfer) für das Jahr 2009. Im Auftrag Landesamt für Umwelt, Naturschutz & Geologie, Postfach 1338, 18263 Güstrow: II + 36 pp. (in German) ["Summary 1. 25 new cases of *L. pectoralis* were detected in 2009. With this mapping from 2009 and the recordings within the management plans, 246 occurrences of *L. pectoralis* are now known in Mecklenburg-Western Pomerania. 2. Only very isolated exuvia were found in both the state mapping and the mapping for management planning. 3. No new outstanding occurrences with over 50 individuals or more than 50 exuvia per 100 m search distance were found this year. 4. As in previous years, it was found that mesotrophic waters - such as bog waters or waters with marshy subsoil

- appear to be the most favorable locations for *L. pectoralis*. 5. This year 33 measuring table sheets were examined. The number of measuring table sheets examined was higher than in previous years because in some MTBs there are no optimal waters with the habitat requirements of *L. pectoralis* or other FFH dragonfly species and the general examination time per MTB was therefore shortened. 6. In 2009, new occurrences of *L. caudalis* and *A. viridis* were recorded alongside *L. pectoralis*. Despite intensive searches for water bodies, new occurrences of *L. albifrons* and *S. paedisca* could not be discovered based on autecological findings about the species. There was no search for *G. flavipes*, which only occurs on the Elbe in this federal state, in 2009. 7. In total there are 2 occurrences of *G. flavipes*, 9 occurrences of *L. albifrons*, 27 occurrences (with 13 new discoveries in 2009) of *L. caudalis*, 16 occurrences (2 new discoveries in 2009) of *A. viridis* and two old, currently uncontrolled occurrences of *S. paedisca*. 8. For the monitoring of *L. pectoralis*, 11 occurrences were recorded according to the BfN specifications and evaluated according to the BfN parameters. 9. Three of these monitoring sites still had exuvia in 2009. At all other locations either only adults were observed during the state mapping and monitoring of *L. pectoralis* in 2009 or the location was completely abandoned by the species. The reasons for the extinction of the occurrences are discussed in detail for all locations. 10. A site with 12 exuvia per m at the Schwarzer See near Bützow is the largest occurrence to date in the entire distribution area of the species. 11. Recommendations for improvement measures are made for all loss-making locations within the monitoring program. 12. It is recommended to abandon the Mummelsee and Stiegsee monitoring sites in southern MV and instead include occurrences with proof of soil stability as monitoring sites. The replacement sites should be located in the metropolitan area of microhollow forms, as these sites represent the most frequently populated habitats of the species in MV. 13. If it becomes apparent in 2010 that the site near Kamin is no longer inhabited by the species, a replacement will also be recommended. 14. The MTBs, which have not yet been examined, are among the regions in MV that have many potential bodies of water for at least one of the six occurring FFH dragonfly species and are therefore research-intensive. The originally targeted 32 MTBs to be examined per year cannot be assumed. To this end, the number of bodies of water to be examined per MTB increases in order to discover potential occurrences of *L. pectoralis* and/or other FFH dragonfly species. 15. In 2010, 19 MTBs are to be examined for the presence of FFH dragonfly species. Since the monitoring of *L. pectoralis* is to be continued and the monitoring of Appendix IV dragonfly species is to be started, the capacities have been exhausted. 16. There are still 46 MTBs to be examined for the years after 2010, but without additional monitoring. The desired goal of completing the national mapping of *L. pectoralis* on all MTBs in 2013 will remain achievable." **22353.** Galan, C.; Herrera, F.; Rincon, A.; Leis, M. (2009): Diversidad de la fauna cavernícola de los karsts en caliza del norte de Venezuela. Bol. SVE 43: 31 pp. (in Spanish, with English summary) ["We present a comparative study about cave-dwelling fauna diversity in the most significative karstic regions of Northern Venezuela. The study is based in data obtained by mean of detailed surveys, with similar methodology, in three caves representatives of their respective regions: Los Laureles Cave (in Perijá Mountains, Zulia state),

Cueva Grande de Anton Göering (in Mata de Mango karst, Monagas state) and Coy-coy de Uria Cave (in the Sierra of San Louis, Falcon state). We study the ecology, taxonomic diversity, biomass and numeric abundance of the cave populations, which comprises a total number of 288 invertebrates and vertebrates cave-dwelling species. 31 of them are troglobites. More than 20 species are new species in Science. Some troglaphiles and troglobites organisms belong to zoological groups reported for first time for the fauna in the caves of Venezuela or even the Neotropical region. These data are the highest biomass values reported for cave-dwelling fauna around the world, with a biomass weight maximum in Cueva Grande of 3.824 kg (153 kg by 100 m of galleries). The principal factors, abiotic and biotic, which condition the high biodiversity and biomass found in these ecosystems, are discussed." (Authors) The table of results includes one Odonata without further details.] Address: Galán, C., Sociedad Venezolana de Espeleología. Apartado 47.334, Caracas 1041-A, Venezuela. (in German, with English summary) ["Selected results of entomological and botanical excursions in five study areas in the wider area of Lake Kühnauer in the city of Dessau-Roßlau are presented. The study sites are briefly characterized. Records of 55 insect species, including 27 Diptera, 18 Odonata, 10 Buprestidae (Coleoptera) and 198 ferns and flowering plants are listed in tabular form. Particularly rare and endangered species, as well as species documented for the first time locally or nationally, are discussed. The taxa *B. radiata*, *T. paraterminalis*, *Aeshna isoceles* (O.F. Müller, 1767), *Trachys scrobiculatus* Kiesenwetter, 1857 (Coleoptera: Buprestidae), among others, receive detailed discussion. The botanical excursion to the Lobenbreite provides the first floristic survey of the area known to the authors since 1978 and is part of the revision of the flora of Dessau-Roßlau. *Silene otites* (L.) were found on regionally rare, partly endangered plant species. (earspoon catchfly), *Geranium sanguineum* L., *Vincetoxicum hirundinaria* Medik (swallowwort), *Ornithopus*

perpusillus L. (bird's foot) and *Colchicum autumnale* L. (autumn crocus) detected." (Authors/Google translate)] Address: Osterloh, Susanne, Krumbholzstr. 12, 06406 Bernburg/Saale, Germany.

## 2010

**22356.** Agaki, T.N. (2010): The diversity of dragonflies and damselflies (Odonata) at the inlet and outlet of the Sentani Lake (in Bahasa Indonesia). SUGAPA (Suara Serangga Papua) 5(1): 22-25. (in Indonesian, with English summary) ["The aim of this study was to know the diversity of Odonata at the inlet and outlet area of the Sentani Lake. Data were recorded during 32 days (from 19 September till 20 October 2009) in the environment of the Sentani Lake, Jayapura. The analysis of data was done from the end of October till December 2009. The used methods were observation, Count Transect method at Transect Line and documentation. The result of the survey -at all localities both at inlet as at outlet- consists of 449 specimens, representing 44 species in ten families. At the two inlet areas 298 specimens were recorded representing 35 species in 10 families: 16 species of the Family Libellulidae, 11 species of the Coenagrionidae, and 1 species each of the Gomphidae, Aeshnidae, Corduliidae, Calopterygidae, Chlorocyphidae, Protoneuridae, Platycnemididae and Platystictidae. At the single outlet area of the Sentani Lake 151 specimens were recorded representing 30 species in seven families: 13 species of the Family Libellulidae, 9 species of the Coenagrionidae, 3 species of the Protoneuridae, and 1 species each of the Gomphidae, Aeshnidae, Chlorocyphidae, and Platystictidae. The result shows that the diversity of Odonata at the inlet area is higher in comparison with the diversity at the outlet area; the equity of species in inlet and outlet areas is about the same (ISs = 64.61 %). Anisoptera species were more common at open and sunny river sites; Zygoptera were more often found close to bushes and trees at the river banks." **22357.** Lehoux, H. (2010): Limnologie et entomologie tropicales. Pré-projets pour le monitoring des rivières de la région d'Esquinas Costa Rica. Entreprise Centre de recherche Biologique Tropicale, La Gamba, Parque nacional de las Piedras Blancas, Costa-Rica: 41 pp, Annexe (in French, with English summary) ["In today's world, questions about water quality are a constant issue. Agriculture, industry and urban pollution are majorly responsible for the disturbance of lakes and rivers, our freshwater basins. This model study in La Gamba, Costa Rica, shall show the impact of human activities on the biological integrity in the Esquinas' drainage basin. While the first part of the study talks about the geographical structure of the river network as well as the general chemical and physical features of its water, the second, main part of the study assesses the different population structures of dragonflies and damselflies (odonata) in different habitats within the drainage basin. The study took place between April and June 2010, therefore in the beginning of the rainy season. In order to examine the physical structure of the river network, I measured current velocity, depth and width at different spots of nine rivers within the drainage basin. Of the same nine rivers, I took samples to learn about the water features, checking temperature, DO, suspended solids, pH, conductivity, NO<sub>3</sub> and PO<sub>4</sub>. In addition to these measurements, I conducted a more detailed study of the morphology of one of the nine rivers, the Quebrada Negra, analyzing the daily change of water levels as well as level changes caused by rainfall, the sediment structure and the current

velocity throughout a transect of 100 meters. The study of the dragonflies and damselflies' distribution took place in the primary forest (4 sites), at forest margin (2 sites) and in cultivated areas (4 sites). 427 individuals of 26 species were identified during the twenty sampling periods. The species' assemblages were compared, and different sampled parameters were tested, in order to explain the differences in the distribution. In the end, the study leads to a discussion about the suitability of various protocols for the monitoring." (Author)] Address: Lehoux, H., 9, rue Duboys des Sauzais, 35150 Corps-Nuds, France

**22360.** Paternoster, D. (2011): Vegetation und Landschaftswandel der Pöggstaller Senke (südliches Waldviertel, NÖ) als Grundlagen für naturschutzfachliches Management. M.Sc. thesis, Fakultät für Lebenswissenschaften, Ökologie, Universität Wien: 155 pp, Anlagen (in German, with English summary) ["This work deals with vegetation and landscape changes of the Weitenbach-lowland between Pöggstall and Würmsdorf in the southern Waldviertel (Lower Austria). Results provide a basis for conservation issues. During the growing seasons in the years 2006 and 2007, both the vegetation and land use were mapped. 169 relevés were collected using the methodology of Braun-Blanquet (1964). For the survey of actual land use I used the mapping guide of Peterseil & Wrška (2001). The broad valley floor of the investigation area remains the last expanded and connected grassland area in the whole Weitenbach-Valley. For this reason, the phytosociological investigation focuses on characterisation of wet meadows and fen-meadows. Moreover the collected data are also compared with relevant regional literature. Altogether 26 different plant communities and 48 regionally or nationally endangered plant species were detected. Most of these species show preferences for wet meadows and fen-meadows. The chronological change of the landscape is characterized by means of a GIS-based analysis of historical cadastral land registers within an area of five square kilometers. The historical land use situation in 1823 is compared with the recent situation. Results are discussed in context of common signs of landscape change and historical evolution of vegetation in the Waldviertel-biom. The regional landscape change in and around the investigation area is characterized by an increase of forests and settlement areas, on the contrary the area of arable by a decrease. Using vegetation and landscape changes as

fundamentals, a management concept is formulated, which refers to the 44 ha large, broad valley floor between Pöggstall and Würnsdorf. Faunistic findings of former investigations done by the research community LANIUS are incorporated. The definition of management strategies and implementation of precise arrangements require appraisal of basically value-free natural resources, ecosystems, habitats or species. In this case the appraisal refers to plant communities and follows the reproducible and more or less standardized methodology of Plachter (1994). Fen-meadows and sedge reeds demonstrate the premium sites as far as nature conservation is concerned. Based on the appraisal results and in consideration of the historical landscape situation, a conservational overall concept is generated, which represents the target state in the face of nature conservation. According to the composition of vegetation, the management area is divided into three different zones (nature-zone, management-zone and development-zone). On the one hand the apportionment may support design of potential, prospective protected areas, on the other hand it helps to clarify the management requests of particular subjects of protection. Furthermore, a catalogue of measures is defined, that refers to plant communities and habitat types, respectively. In case of need the catalogue could be adapted for the level of parcels by intersection of the regional database with official land registers. In the printable version the phytosociological tables are added as attachments." (Author) Chapter 4.3.4 deals with Odonata. ## 2012

**22362.** Bedjanic, M. (2012): O zeleni devi in vodni škarjici, rumenem porecniku in še cem z daljnega vzhoda Slovenije [About *Aeshna viridis* and *Stratiotes aloides*, *Stylurus flavipes* and something else from the far east of Slovenia]. Trdozy. Bilten slovenskih terenskih biologov in ljubiteljev narave 1(1): 18-19. (in Slovenian) [Verbatim/Google translate: Among Slovenian nature lovers, Mura has a very special, mystical or somewhat romantic place. Of course, because it is the first river in our country that is illuminated by the sun's rays in the morning, but even more so because of the extraordinary diversity of the living world with many habitats and plant and animal species that cannot be found anywhere else in Slovenia. Also from the point of view of the dragonfly fauna, the river landscape along the Mura is one of the most interesting areas in our country, as over 50 species of dragonflies have been recorded here in the last two decades, which is more than 2/3 of the Slovenian odonate fauna. One of the greatest odontological peculiarities of the world along the lower reaches of the Mura in Slovenia is undoubtedly *A. viridis*. In our country, it lives in only a few localities in the vicinity of Petišovci, and in addition, its biology in the company of European species of dragonflies is unprecedented. Its life and development are closely linked to the water shearwater plant (*S. aloides*). Females of *A. viridis* lay their eggs only in the succulent leaves of this plant, and the larvae then live in

its partially submerged leaf rosettes. State of residence or the state of water sedge habitats is thus the best, although of course not the only indirect indicator of the state and prospects for the survival of green camel populations in a certain area. Or to put it another way – if the water sedge disappears in an area, *A. viridis* will certainly disappear as well, but on the other hand, the presence of this very rare and endangered plant in our country is not a direct guarantee of the presence of the equally endangered dragonfly. We first found *S. aloides* in Slovenia only 15 years ago, and to date we have confirmed its development only on the Kapitany Lap, Nagy Parlag and Csiko Legelo wetlands in the vicinity of Petišovci, which are also the most beautiful still-preserved habitats of water sedge in our country. As part of the LIFE+ Nature project entitled Protection and management of freshwater wetlands in Slovenia - WETMAN 2011-2015, in 2011 we carefully investigated the mentioned three localities and, using the method of collecting lions, estimated that almost 600 adults metamorphosed from larvae in the vicinity of Petišovci that year specimens of green trees. Together with the currently still fairly good condition of water sedge habitats, the research gives us hope that the short-term survival of the two highly endangered species in our country is not in question. Unfortunately, due to the natural succession and landfall of dead fish, which no longer occur naturally, and the ever-present threat of inadequate fishing and other human interventions, the story of *A. viridis* and *S. aloides* is unfortunately less optimistic in the long run. In order to ensure a favorable conservation status of the two specialties of the Prekmurian marshes, active conservation measures will undoubtedly be necessary in the coming decades. However, the year 2011 served up another pleasant surprise from the landscape along the Mura. After half a century, we have again found *G. flavipes*, a species of dragonfly that was considered extinct in Slovenia. Luck smiled on us in mid-July at the side of the Mura river in the Murska šuma, southeast of Petišovci. But it wasn't easy - for this venture we had to gather odontologists from Slovenia, Serbia, Croatia, Bosnia and Herzegovina, Italy and Slovakia, who took part in the 1st International Meeting of odontologists of the Balkans BOOM 2011. Right on the team field of this meeting, the Slovakian colleague Dušan Šácha caught a solitary male of this rare and endangered species right next to the Croatian border. The Yellow River is included in the appendices of the Berne Convention and Annex IV of the Habitats Directive and is considered a typical type of larger lowland rivers with at least partially preserved natural river dynamics and diverse structures of the river ecosystem. All of this is undoubtedly fulfilled by Mura in the lower part of its Slovenian route, between Verže and the estuary of the Ledava, or the Hungarian border. If we add to all of the above the findings of many other endangered species of dragonflies, such as *Coenagrion pulchellum*, *Brachytron pratense*, *Epithea bimaculata*, *Aeshna grandis*, *Ophiogomphus cecilia* and *Leucorrhinia pectoralis*, which we observed in the landscape along the Mura in the past season, we can conclude that the diversity of the world of dragonflies here is really extraordinary. At least on paper, the wider area along the Mura River has a formally defined nature conservation status on the basis of the Birds Directive and the Habitats Directive and is included in the European network of Natura 2000 areas of nature conservation importance. the country's inexplicably delayed efforts to declare the Mura Regional Park unfortunately still remain.] Address: Bedjanic, M., M., National Institute of Biology, Vecna pot 111, 1000 Ljubljana, Slovenia. **22363.** Donnelly, N. (2012): Ken Soltesz — An appreciation. *Argia* 24(4): 8-9. (in English) [Verbatim: The recent death of

Ken Soltesz has left a huge hole in the lives of the New York Ode Community. His energy, capacity for really hard work, enthusiasm, and generosity will not be seen around here again for a very long time. Ken contributed heavily to downstate New York records for my first paper on the Odonata of New York (BAO, 1992), and also for the second paper (WDA meeting 1999). His large body of records has been crucial for our knowledge of the odonate fauna of New York (summarized in the New York Dragonfly and Damselfly Survey (2005-2009) report). In fact, Ken's work was the "anchor" for this very important part of the state. Most of us became acquainted with Ken for the first time in 1990, when he organized a DSA Northeastern meeting at the Ward Pound Ridge Reserve in Westchester Co., New York, where Ken was the park naturalist. This was (for me) one of the most enjoyable DSA regional meetings that I have ever experienced, partly because of the marvelous venue and interesting odes, but mainly because of the hospitality of Ken and his wife Joyce. Most of my interaction with Ken in subsequent years involved the Delaware River, where Ken was doing extensive dragonfly surveying. In 1994, he had found exuviae of a strange Gomphus. In 1995, he was paddling down the Delaware River with Joyce and their daughters when their raft sped past a boulder in a rapids. With a "WHAT'S THAT?" shout he actually stopped the raft, hopped out (if that is the word), struggled upstream through the raging current and netted the first adult specimen of *Gomphus septima delawarensis* (Septima's Clubtail Northern form)! A later exercise was an Odonata inventory for West Point Military Reservation. Most people are familiar with the monumental architecture and Hudson River setting of the Military Academy; few are acquainted with a large "wild" area on the Reservation used for artillery (and other military) training of cadets. Ken picked his way warily through this tangle of splintered vegetation and documented an impressive odonate fauna, including an additional (and furthest north) record of *Gomphus rogersi* (Sable Clubtail). My last field trip with Ken and Joyce was in 1999 on the Wallkill River, where he had found a new locality for *Gomphus fraternus* (Midland Clubtail), an uncommon species in New York. By this time, as a result of diabetes, his health had deteriorated seriously. Not long thereafter his vision became very poor and he and Joyce retired to eastern Tennessee, where Ailsa and I had an enjoyable visit with them in 2009. We will all miss Ken a lot. Not only was he a thoroughly self-taught odonatist, but he was also perhaps the most generous person I have ever met. He did not hesitate to give you his time, his knowledge, and his superbly prepared specimens. Ken was a "keeper". We all extend our deepest regrets to Joyce and his daughters Tammy, Cathy, and Susie.] Address: Donnelly, T., 2091 Partridge Lane, Binghamton, NY 13903, USA. E-mail: tdonnel@binghamton.edu

(2012): A brief field report on emergence of Riverine Clubtail (*Stylurus amnicola*) and Arrow Clubtail (*Stylurus spiniceps*) along a sandy bank in northern Connecticut. *Argia* 24(3): 17. (in English) ["In the summer of 2007, a sandy bank on the Connecticut River in East Windsor, Connecticut was visited a total of eight times between 27 June and 4 August. The location is immediately adjacent to the Interstate 91 overpass and is heavily visited by fishermen. The riverbanks in this area consist mainly of fine sand. During my visits to the area I observed many active emergences and eclosures, and countless cases of dragonfly mortality due to bird predation. The steep sandy banks and lack of extensive vegetation made the area ideal for recording emergence distance. Nymphal tracks were evident throughout the area, despite the heavy pedestrian use. A total of 209 *S. amnicola* emergence distances were recorded. Nymphs travelled an average of 10.99 feet from the edge of the river (s.d. 3.73). Fewer *S. spiniceps* (n=29) were observed, but emergence distance was similar (11.03 ft, s.d. = 3.64)." (Author)] Address: Martin, Kirsten, Univ. **22371.** Dullinger, S.; Essl, F.; Rabitsch, W.; Erb, K.-H.; Gingrich, S.; Haberl, H.; Hülber, K.; Jarošík, V.; Krausmann, F.; Kühn, I.; Pergl, J.; Pyšek, P.; Hulme, P.E. (2013): Europe's other debt crisis caused by the long legacy of future extinctions. *Proceedings of the National Academy of Sciences of the United States of America (PNAS)*, April 15, 2013: 6 pp. (in English) ["Rapid economic development in the past century has translated into severe pressures on species survival as a result of increasing land-use change, environmental pollution, and the spread of invasive alien species. However, though the impact of these pressures on biodiversity is substantial, it could be seriously underestimated if population declines of plants and animals lag behind contemporary environmental degradation. Here, we test for such a delay in impact by relating numbers of threatened species appearing on national red lists to historical and contemporary levels of socioeconomic pressures. Across 22 European countries, the proportions of vascular plants, bryophytes, mammals, reptiles, dragonflies, and grasshoppers facing medium-to-high extinction risks are more closely matched to indicators of socioeconomic pressures (i.e., human population density, per capita gross domestic product, and a measure of land use intensity) from the early or mid-, rather than the late, 20th century. We conclude that, irrespective of recent conservation actions, large-scale risks to biodiversity lag considerably behind contemporary levels of socioeconomic pressures. The negative impact of human activities on current biodiversity will not become fully realized until several decades into the future. Mitigating extinction risks might be an even greater challenge if temporal delays mean many threatened species might already be destined toward extinction." (Authors) Red List publications including Odonata were used as data base.] Address: Dullinger, S., Dept für Naturschutzbiologie, Vegetations- & Landschaftsökologie, Univ.Wien, 1030 Wien, Rennweg 14, Austria. **22372.** Erbida, N.; Vinko, D. (2013): Fotografski natečaj Pisani akrobati [Photography competition: Painted acrobats]. *Trdozy. Bilten slovenskih terenskih biologov in ljubiteljev narave* 2(2): 35-36. (in Slovenian) [Verbatim/Google translate: In 2013, within the framework of the Slovenian Odonatological Society, young odonatologists announced a photography competition for all lovers of natural history photography. The purpose of the competition was to show people of all ages the beauty and skill of dragonflies, to stimulate their interest and attract them to participate in our society. The competition, which we named Pisani acrobats, was divided into three age groups: youth, students and adults. During the summer and until the end of September, when the deadline for applications to the competition closed, we received 134 photos from 52 authors. The best photos, some of which are also published in *Trdoživ*, were chosen by a committee composed of: dr. Davorin Tome, Ph.D. Rudi Verovnik, Ph.D. Tomi Trilar, Ph.D.

Alja Pirnat and Ali Šalamun. After the publication of the bulletin, all that remains is the opening of the photography exhibition with the awarding of plaques and prizes, which will take place in early January 2014 at the Biology Department of the Faculty of Biotechnology in Ljubljana. At that time, we will also prepare a short lecture on dragonflies and invite those present to odontology fields intended for the general public, which we will organize in the spring and summer. We will also present a poster about dragonflies that we made as part of the project.] Address: Vinko, D., Slovensko odonološko društvo, Verovškova 56, SI-1000 Ljubljana, Slovenia. E-mail: damjan.vinko@gmail.com

**22373.** Gregoire, S.; Gregoire, J. (2013): Monitoring *Celithemis elisa* (Calico Pennant) emergence: Year 8 and counting. *Argia* 25(1): 16- (in English) [Verbatim: For odonates in central New York, the 2012 season was dismal. During the winter, temperatures were way above normal, resulting in no ice cover on lakes, ponds and streams. Lack of snowmelt and rainfall left all water levels frighteningly low, then a very warm (hot) March and April wreaked havoc on normal phenology. As the season progressed, high temperatures and continuing drought dried up many wetlands by late May. All this culminated just as our study of the emergence season for *C. elisa* was beginning. We have monitored their activity here for seven years and we were eager to see how these adverse conditions affected the population here. As we suspected, emergence began a little earlier than in previous years, but not by much. The trend has been for earlier emergence almost every year, so this was not unexpected. Each year, a peak period of emergence commences immediately, lasts a few days, and then reduces to a slower pace. After the initial burst, emergence continues in lower but steady numbers punctuated with occasional small surges lasting a few days. The pattern continued in 2012, although in low numbers overall. This too, was not unusual. As indicated in the accompanying table, their numbers have fluctuated greatly over the seven-year study period. Normally, emergence extends into late July, sometimes into August. In 2012, only a few emerged in late June and the population produced its last teneral in early July. It seemed very early to us but, accounting for the early beginning, was not beyond the range of total emergence periods we had previously witnessed. In summary, by their Standards, the emergence season for *C. elisa* was successful and normal. Their pond is deep and withstood the heat and drought, although it lost almost four feet in depth overall. Numbers were low, but not the lowest we've seen. With continuing study, we hope to set parameters around what *C. elisa* considers "normal". Each year presents a different set of Standards for us to ponder. As a result of the bad weather in 2012, we do not expect an abundant 2013, but it will no doubt give us something more to think about.] Address: Gregoire, Sue and John, Kestrel Haven Avian Migration Observatory, Burdett, New York 14818, USA. Email: khmo@empacc.net

**22374.** Meurgey, F. (2013): Vagrant Emperor, *Hemianax ephippiger* (Burmeister, 1839), in the New World: Synthesis and comments on recent discoveries. *Argia* 25(1): 5- (in English) [Verbatim: *H. ephippiger* is a well-known Palearctic migrant species originating from Africa that can reach the northernmost island of Iceland in summer. There is no consensus among odonatologists concerning the correct assignment of *ephippiger* to the genus *Anax* or *Hemianax*. Recent studies both on adults and larval characters between the two genera have reinstated the discussion. Rowe (1991) showed that larval characters of *Hemianax ephippiger* are not shared with any other *Anax* species to date. Gentilini et al. (1993), attempting to

map a small number of fossil wings onto extant taxa, place ephippiger and papuensis in the genus *Anax*. But the suppression of *Hemianax* is asserted as fact in the abstract, without any discussion in the text. In her phylogenetic study of the extant Aeshnidae, von Ellenrieder (2002) maintains the genus *Hemianax*. This long debate seems to continue and we choose to keep a conservative point of view in using *Hemianax ephippiger*. *Hemianax ephippiger* in the New World: The first known and documented observation of this Afrotropical aeshnid in the New World dates back to 2002 in French Guiana and constitutes the first record for the New World (Machet & Duquef, 2004). Later in 2006, a single female caught in Guadeloupe in the Lesser Antilles constituted the first record for the West Indies (Meurgey 2006). The following year, additional specimens were seen in the Virgin Islands in the Greater Antilles (Sibley, 2007) and two others (male and female) in Dominica (Meurgey and Weber, 2007) just south of Guadeloupe in the Lesser Antilles. As far as we know, no other record from the West Indies or the New World has been recorded since then (Meurgey & Picard, 2011). Recently, Lionel Dubief and Vincent Lemoine kindly informed us that they found two specimens in Guadeloupe at the same locality as in 2006 and 2007 (northwest of Grande-Terre). The first specimen was caught on 15 October and a second was only observed on 23 October 2012. A few months later, Maurice Duquef (2012) reported the capture of a general female in French Guiana on 21 March 2012, at almost the same locality as in 2002, indicating that the species probably breeds near Sinnamary. Following this, Dennis Paulson (pers. comm.) informed us that the species now breeds with certainty on Curaçao where exuviae were found, and is reported from Aruba where 3 individuals were found on 1-I-2013 by Gert Veurink. The arrival of several individuals in the West Indies in 2012 followed the tropical storm Rafael that originated on the west coast of Africa on 5 October and reached the Caribbean on 13 October. De Marmels (2007) stated that the arrival of African species such as *H. ephippiger* to the West Indies was correlated with the occurrence of tropical storms originating from the coasts of West Africa and was generally associated with large flows of Desert Locusts (*Schistocerca gregaria*). Given that the species has been recorded as breeding in the Caribbean region, we believe the species will extend its distribution in ensuing years throughout the West Indies and establish populations. Future tropical storms originating in Africa subsequently reaching the West Indies may augment populations of this species in the West Indies. The arrival of Afrotropical species to the West Indies (*H. ephippiger* and *Tramea basilaris*) and documented observations provides a unique opportunity to study the colonization of the Caribbean islands by species and to measure their negative or positive impact on native species. We urge visiting and resident odonatists to send us their observations, which will allow us to study and monitor the evolution of the colonization by *H. ephippiger* throughout the West Indies.] Address: Meurgey, F., Muséum d'Histoire naturelle de Nantes, 12, rue Voltaire, 44000 Nantes, France. E-mail: Francois.Meurgey@mairie-nantes.fr

**22375.** Satori, L. (2013): Effects of habitat management and restoration on freshwater ecosystem population dynamics. Tesi di dottorato, Università degli Studi di Milano-Bicocca: 149 pp. (in English) ["Although water quality improvement is generally the primary objective of treatment wetlands, the creation of habitats is an inevitable outcome of these projects. Macroinvertebrate are often early colonists of new created wetlands, with abundance and diversity approaching high levels within a few years from wetland construction. A deeper knowledge of the biodiversity hosted in these environments

is needed to evaluate if newly created ponds are appropriate management tools for biological conservation. The effectiveness of the interventions provided by Parco Pineta di Appiano Gentile e Tradate (a regional park in Lombardy, Italy) in freshwater ecosystem management and restoration has been evaluated, considering a set of natural, artificial and constructed wetlands spread within the park territory. Considering the macroinvertebrate community and analyzing the biodiversity hosted in all the considered wetlands, no significant differences were found between artificial and natural ecosystems. Even the constructed wetlands, which were characterized by low water quality and higher pollutants concentrations, presented a biodiversity level which in some cases exceeded that one present in natural ecosystems. Even though biodiversity was similar between wetland typologies, differences in community compositions have been enlightened. The macroinvertebrate community assemblages seemed to be influenced more by the geographical and hydromorphological variables of the ecosystem rather than the physicochemical water characteristics. In particular, water body area and habitat heterogeneity resulted to be the most important variables that influenced the community composition. Seasonal variations in hydrological conditions and resource availability were the main factors that influenced the macroinvertebrate dispersal, evaluated considering life-strategy groups. Although the considered ponds and wetlands presented different features, they all contributed to the local ecological network even if they were not all equally interconnected together. All the collected information could be useful to design further possible interventions for conservation aims." **22376.** Stalter, D.; Magdeburg, A.; Quednow, K.; Botzat, A.; Oehlmann, J. (2013): Do contaminants originating from state-of-the-art treated wastewater impact the ecological quality of surface waters? PLoS ONE 8(4): e60616. doi: 10.1371/journal.pone.0060616: 10 pp. (in English) ["Since the 1980s, advances in wastewater treatment technology have led to considerably improved surface water quality in the urban areas of many high income countries. However, trace concentrations of organic wastewater-associated contaminants may still pose a key environmental hazard impairing the ecological quality of surface waters. To identify key impact factors, we analyzed the effects of a wide range of anthropogenic and environmental variables on the aquatic macroinvertebrate community. We assessed ecological water quality at 26 sampling sites in four urban German lowland river systems with a 0–100% load of state-of-the-art biological activated sludge treated wastewater. The chemical analysis suite comprised 12 organic contaminants (five phosphor organic flame retardants, two musk fragrances, bisphenol A, nonylphenol, octylphenol, diethyltoluamide, terbutryn), 16 polycyclic aromatic hydrocarbons, and 12 heavy metals. Non-metric multidimensional scaling identified organic contaminants that are mainly wastewater-associated (i.e., phosphor organic flame retardants, musk fragrances, and diethyltoluamide) as a major impact variable on macroinvertebrate species composition. The structural degradation of streams was also identified as a significant factor. Multiple linear regression models revealed a significant impact of organic contaminants on invertebrate populations, in particular on Ephemeroptera, Plecoptera, and Trichoptera species. Spearman rank correlation analyses confirmed wastewater-

associated organic contaminants as the most significant variable negatively impacting the biodiversity of sensitive macro-invertebrate species. In addition to increased aquatic pollution with organic contaminants, a greater wastewater fraction was accompanied by a slight decrease in oxygen concentration and an increase in salinity. This study highlights the importance of reducing the wastewater-associated impact on surface waters. For aquatic ecosystems in urban areas this would lead to: (i) improvement of the ecological integrity, (ii) reduction of biodiversity loss, and (iii) faster achievement of objectives of legislative requirements, e.g., the European Water Framework Directive." (Authors) The list of taxa (in supplementary file) includes *Coenagrion hylas* [sic]. ## 2014

**22377.** Galatowitsch, M.L. (2014): Invertebrate life-history trade-offs and dispersal across a pond-permanence gradient. Doctor of Philosophy (PhD) in Ecology, University of Canterbury. Biological Sciences: 175 pp. (in English) ["Flexible life-history traits and dispersal may allow generalist populations to persist across a range of habitats despite experiencing contrasting selection pressures. Invertebrates exploiting temporary ponds must develop quickly and disperse as adults, or have wide environmental tolerances. Conversely, permanent-pond invertebrates must avoid a suite of predators (e.g., fish and dragonflies). This gradient of pond permanence can result in life-history trade-offs that influence fitness, population dynamics, and genetic structure. In addition, recruitment between habitats may balance juvenile life-history trade-offs and be crucial to sustain generalist invertebrate populations in ponds with unpredictable hydrology. Through a multi-year survey of three pond complexes in the Canterbury high-country and a series of mesocosm experiments using two generalist pond invertebrates, *Xanthocnemis zealandica* damselflies and *Sigara arguta* waterboatmen, I found these two species had alternative life-history strategies that influenced their distributions across the pond-permanence gradient. With longer juvenile development, *X. zealandica* benefited from flexible life-history traits: temporary-pond *X. zealandica* had accelerated development and short-term desiccation tolerance, but were excluded from ponds with long dry periods, whereas, permanent-pond *X. zealandica* had extended development and predator avoidance behaviours (e.g., reduced movement and refuge-use). In contrast, *S. arguta* had an opportunistic life-history strategy with a fixed, rapid development response that allowed them to inhabit more temporary ponds, but they were intolerant of drying and limited to permanent ponds that contained shallow refuges from fish. These results illustrate how alternative life-history strategies enabled two generalist species to achieve broad realised niches. Recruitment between habitats also appeared to be important for balancing trade-offs and maintaining meta-populations across the pond-permanence gradient. To evaluate the importance of *X. zealandica* dispersal among and within pond complexes I used microsatellite analyses. While there was unique genetic population structure between the North and South Islands, at lower spatial scales there was little variability in genetic diversity and limited genetic structure in populations, likely due to gene flow among different habitat types. Overall, this work shows how an interaction of juvenile strategies and adult dispersal could reduce life-history trade-offs, resulting in weak selection pressures across an unpredictable disturbance gradient. Whether increasingly unpredictable hydrological patterns under climate-warming favour generalist species will

likely depend on how well generalist life-history traits and dispersal allow exploitation of a range of habitat types and resilience to variable selection pressures. Higher mean summer rainfall in New Zealand may allow both species to exploit more temporary ponds, whereas longer dry periods between extreme precipitation events could limit *X. zealandica* distributions. Thus, species with generalist strategies are likely to be favoured under warming, but their specific life-history strategies will likely promote or limit their ability to exploit more unpredictable habitats." **22378.** Grutters, M. (2014): Libellen als keurmeesters van de waterkwaliteit. Straatgras 26 [1] 2014 [Zuiderpark Special]: 3. (in Dutch) [Verbatim/Google translate: Dragonflies as inspectors of water quality: The redesign of the Zuiderpark does not seem to have harmed the dragonflies. In the period from 2007 onwards, 23 species were observed, with a maximum of eighteen species annually, compared to a maximum of fifteen species in the period 2000-2003. With the redesign, the water quality improved in a number of places, although this appears to be slowly deteriorating again (Andeweg 2014). It is important for dragonflies that in many places bank revetments have been replaced by natural banks with bank plants. Many species depend at some point in their life cycle on the presence of riparian, floating or submerged aquatic plants. The construction of „wadis“ and a helophyte filter played an important role. Blue damselflies: The monitoring consists of counting all species of Odonata three times a year on 18 counting routes along the banks of various waterways. By far the most common dragonfly species here are small, blue damselflies such as *Ischnura elegans* and *Erythromma viridulum*. These two species alone together account for three quarters of the total number of dragonflies counted. The lantern is seen along almost all waters. This species makes few demands on its habitat. *E. viridulum* is slightly less widespread and is limited to waterways where coarse hornwort (*Ceratophyllum demersum*) is abundant. As with the equally common *Erythromma najas*, eggs are often deposited on yellow wattle (*Nuphar lutea*), a common aquatic plant in the Zuiderpark. „Wadis“ [pools, water bodies]: We saw interesting developments at the wadis. Shortly after its construction, several species characteristic of such barren pioneer environments immediately appeared. These included the beautiful *Libellula depressa* and a number of darter species. For example, *Sympetrum striolatum* likes to reproduce in shallow pools with little vegetation. This dragonfly was often seen near the wadis. Over the years, numbers steadily decreased as the water and soil continued to condense. This allowed *Sympetrum vulgatum*, which is not a pioneer, to conquer territory. In recent years this was the most common darter species in the Zuiderpark. Critical species Among the species that increased is *Aeshna isoceles*. This was not on the species list before the redevelopment, but is now a common sight in the Zuiderpark. It can be seen as an indicator of clean water with richly vegetated banks. It is therefore no coincidence that it is mainly found around the helophyte filter in the western part of the park - the place with the best water quality. *Brachytron pratense* is also such a critical species, but it is rarely seen in the Zuiderpark. In the Kralingse Bos it does show an increase. Although the first pioneers are already a thing of the past, the current dragonfly diversity of the Zuiderpark can be said to be quite good. However, with a slow decline in numbers and distribution, the best times seem to be behind us. Possible future changes in water quality, as can be expected due to the construction of the Blue Connection, could lead to the further expansion

of the various species. Monitoring has shown that dragonflies quickly find the Zuiderpark if there are new suitable waters and that they can expand rapidly through quality improvement. Who knows what the future will bring.] Address: Mark Grutters, ecologist, Bureau Stadsnatuur, The Netherlands. Email: grutters@bureaustadsnatuur.nl]

**22379.** Huber, K. (2014): Libellen im Machland. ÖKO-L 36/2: 13-16. (in German) [The Machland is the Danube lowlands between Mauthausen and the entrance to the Strudengau shortly before Grein. The Machland stretches to the left and right of the Danube. It is therefore divided between Upper and Lower Austria. The spatial unit of the Upper Austrian Machland is given as 114 km<sup>2</sup>. In 2012 and 2013, 43 odonate species were recorded.] Address: Huber, K., Naturschutzbund Österreich, Regionalgruppe Machland, Parksiedlung 22, 3300 Amstetten, Austria

(2014): Environmental diagnoses of two urban streams with bioindicators Goiânia (Go). *Revista Mirante, Anápolis (GO)* 7(2): 109-144. (in Portuguese, with English summary) [Brazil "The present diagnosis was carried out in the municipality of Goiânia on September 16, 2006 (dry period), where 8 sampling stations were demarcated, collecting 4 points from Córrego Botafogo and 4 from Córrego Samambaia, throughout these eight stations, measuring some physicochemical variables. The structure of the aquatic insect community of the aforementioned watercourses was represented by 14 families distributed in the following orders: ... Odonata [Gomphidae], .... The physicochemical variables demonstrated greater impairment of quality in Córrego Botafogo, with Córrego Samambaia presenting better conditions for these parameters." (Authors)] Address: Mota, Eltania, Graduada em Química / UFG - Universidade Federal de Goiás, Goiânia – GO e Especialista em Perícia Ambiental / PUCGO – Pontifícia Univ. Católica de Goiás, Goiânia – GO. taniammota@yahoo.com.br

**22381.** Vidal-Cordero, J.M.; Hemando-Soriguer, A.; Cortés-Merino, S. (2014): Proyecto Técnico: Odonatofauna del Humedal de Padul (Granada, España). *Boletín de la Sociedad Odonatológica de Andalucía* 2: 37-40. (in Spanish) [Verbatim: The Padul wetland, located at the western end of the Sierra Nevada massif, south of Granada and the urban center of Padul, on the very border of two well-differentiated historical regions, the Lecrín Valley and the Temple, is the largest wetland in the province and one of the most important wetlands in the Spanish southeast, mainly due to the faunal diversity it has. This lagoon system forms a unique biotope within the complex ecosystem that makes up the entire Sierra Nevada Protected Space. Currently, it is the remnant of a much larger wetland, which occupied around 500 hectares, and which was drained in the 18th and 19th centuries in order to cultivate the drained land. It has numerous protection figures such as Natural Park, RAMSAR Convention, SPA Zone, etc. This protected area covers about 300 hectares, of which 90 hectares. It covers the swamp area that is divided into two parts, the Aguadero area (to the East), with a total area of about 80 hectares, highlighting the Aguadero lagoon with 25 hectares. and the waterlogged reedbed with about 40 hectares. of approximate surface area, and the Agia area (to the West), formed by a set of three lagoons and flooding areas with a total area of 11 hectares, of which the lagoons occupy 9 hectares. The Padul wetland presents the main elements of large wet complexes, such as areas of free water, flooded areas, flooded and dry reed beds, wet meadows, canals and ditches, springs, etc., giving it enormous ecological value. As a result of this well-conserved water system, a great

wealth of animal species can be found in the wetland that thrive there, not all of which benefit from an exhaustive study of their populations, such as the fortunate case of birds. Most of the monitoring of animal species falls on the ornithofauna and in fact, previous studies carried out by the Padul Ornithological Station Association (E.O.P.) have shown that the Padul wetland constitutes a place of settlement and passage of numerous species of birds. As a non-profit entity, the E.O.P. It is made up of a group of people with a common concern: the study, conservation and dissemination of the natural values of the Padul Wetland. This is why, in addition to working with the ornithofauna of this area, we aim to open the spotlight in relation to other animal groups whose presence and population dynamics in the wetland are less studied. Within the group of insects, odonates, along with butterflies, are those that enjoy a greater degree of admiration and have numerous people interested in observing, studying and photographing them (Herrera et al., 2009). Taking advantage of the intrinsic charisma that this order of insects provides, its ecological importance within the habitats in which it lives and the lack of knowledge of the species and their populations in the Padul wetlands, despite this first approach by Conesa, M. A., 2013, The Technical Project: Odonatofauna of the Padul Wetland was born in the winter of 2012, which aims to characterize the odonotofauna of the Padul Wetland, carrying out an inventory of the dragonflies and damselflies that are distributed in said wetland, as well as obtaining data related to its biology and conservation, involving E.O.P. volunteers. for the realization of said project and offering resulting information available for adequate environmental awareness. The project is being carried out by technicians and volunteers from the E.O.P. together with the technical support of a photographer and the supervision of the station director, for a period of seven months (April-October) and with a view to having continuity for a longer period of time and for a more exhaustive study of its composition, phenology and population dynamics.] Address: Vidal-Cordero, J. M. 1, porphirio\_5@hotmail.com

## 2015

**22382.** Bedjanic, M. (2015): Slovensko odonatološko društvo izdalo jubilejno 30. številko biltena Erjavecia [The Slovenian Odonatological Society published the 30th anniversary issue of the Erjavecia newsletter]. *Trdoziv* 4(2): 10. (in Slovenian) [Verbatim: Erjavecia, named after Fran Erjavec, who was one of the first in our country to use the term "dragonfly" in the first Slovenian natural history textbook, is a newsletter of the Slovenian Odonatological Society. It has been published regularly since 1995. In its twenty years of publication, 30 volumes have already been published, since until 2005 they were published two per year, and since then a single issue for the current year has been published at the end of October. It is our intention and desire to publish as much interesting and valuable odontological information from our area as possible. There are a lot of various odontological tidbits, crackers and quite often quite substantial stories and reports from faunistic, ecological, nature conservation, historical, literary and other fields, which we have touched on so far in a total of more than 1,100 pages of Erjavecia. Even the jubilee issue of the newsletter touches on many interesting topics on 144 pages; among other things, it also brings a substantial odontological bibliography of Slovenia for the period from 1685 to 2015. This includes all known written sources about Slovenian dragonflies. The number of titles cited so far in the collection, which has been continuously updated for two decades, has also risen to almost 1,100. In the Slovenian Odonatological Society, we will continue to strive to ensure that Erjavecia remains

the central place for collecting a wide variety of information about dragonflies in Slovenia and beyond. All members of the Slovenian Odonatological Society and contributors receive the Erjavcica newsletter in printed form. You are welcome to send your field observations, experiences or any odontological notes to [matjaz\\_bedjanic@yahoo.com](mailto:matjaz_bedjanic@yahoo.com).] Address: Bedjanic, M., M., National Institute of Biology, Vecna pot 111, 1000 Ljubljana, Slovenia. Email: [matjaz.bedjanic@nib.si](mailto:matjaz.bedjanic@nib.si)

**22383.** Bedjanic, M. (2015): Intervju: Bostjan Kiauta. Trdoziv 4(2): 23-28. (in Slovenian) [Matjaz Bedjanic, inspiring odonatologist from Slovenia, interviewed Bastiaan Kiauta, founder of journal *Odonatologica* and most influencing person of *Societas Internationalis Odonatologica*. Here we document in English language the questions asked. For the complete interview in Slovenian language see: [https://botanico-drustvo.splet.arnes.si/files/2019/03/Trdoziv08\\_web.pdf](https://botanico-drustvo.splet.arnes.si/files/2019/03/Trdoziv08_web.pdf). I used 'Google translate' to translate the questions into English language. The following questions were asked: "Prof. Kiauta, let's start with a question you've probably answered a thousand times: Why did you choose dragonflies as the central group of your admiration and research? How did you get into research in the first place? It must have been a special challenge in those days. At the beginning of your entomological journey, your uncle, Prof. Ciril Ažman, one of the last Slovenian polyhistorians. You were also in contact a lot with Alfonzo Gspan. I assume that these two men were your main source of information for such a broad knowledge of the development and history of Slovenian entomology. Can you tell us something else about your science activities during your high school years? What was fieldwork actually like in those days? Probably quite unimaginable from today's perspective... For this reason, the weight of your comprehensive faunistic contributions about the dragonflies of the Loka territory, the Triglav National Park, the Kamniška Bistrica basin, etc. so much bigger. In your work *Odonata fauna of Slovenia*, in the sixties of the last century, you recorded species of dragonflies for the territory of Yugoslavia at the time, for the first time, such as *Somatochlora alpestris* etc. ... Did this surprise you or were you specifically looking for them? In 1962 you moved to the Netherlands. Were you forced into this due to the political situation and pressures, or was Slovenia simply "too small" for you? The year 1971 is important in the Netherlands, when the international odontological association *Societas Internationalis Odonatologica* - S.I.O. was founded. You played the main role in this from the very beginning, you were the driving force of the project, and you were surrounded by the majority of active odontologists in the world. It probably opened your odontological horizons even further. If we are talking about journals and their editing, and in this respect we can draw a parallel with the field work that you talked about earlier... Today, the edition of the publication is a "small snack", but in the 70s and 80s of the last century there were no computers, no e-mail, technically it was the "Stone Age" of newspaper publishing back then compared to what is available today. The publication of a new volume every three months, always on time, 1,400 edited articles that had to be partly written, rewritten, edited, communicated with the authors through letters; How have you managed it in 42 years of publishing *Odonatologica*? Such extensive correspondence with many authors requires a lot of time, accuracy, discipline... I read somewhere that your correspondence with many odontologists around the world runs into hundreds of thousands of letters. Just the two of us exchanged several hundred letters in all these years from 1993 onwards. In your archive there is only ten and more meters of correspondence... Let's briefly review other matters that interest you. You have dealt with caves, bats, bears are also your favorite subject... In 2002, the Queen

of the Netherlands named you a Knight of the Order of Orange-Nassau. Can you tell us a bit more about how that came about? They say that behind every successful man is an equally successful woman. For you, this is your wife Marianne, who has been doing extremely important work "behind the scenes" for many years. As I know, you have a new very important occupation at home in the Netherlands, where you have been living on a farm for several years... One last question... Last year and again this year, you published some very interesting odontological contributions for the territory of Slovenia, for example the one about the dragonflies of Ljubljana in the journal *Natura Sloveniae*. In short, can you release us any other project that you plan to work on in the future? Dear Prof. Kiauta, thank you very much for this conversation. We want and hope that we can count on your cooperation and support for many years to come. We are proud that, as an honorary member of the Slovenian Odonatological Society, you are still an active odontologist, and we are glad that you are always ready to help younger colleagues with your knowledge and advice. We wish you and dear Marianne many more healthy, creative and happy years!" **22387.** Gaona, M.J.; Navarrete, F.E. (2015): Nueva cita en la provincia de Cádiz (España) de *Orthetrum nitidinerve* (Selys, 1941), (Odonata: Libellulidae). *Boletín de la Sociedad Andaluza de Entomología* 25: 13-15. (in Spanish) [Verbatim: *O. nitidinerve* is a medium-sized anisopteran; males with the body covered with a grayish-blue pruinosity and orange pterostigma. Its main difference with the rest of the species of the genus lies in the yellow color of the radial and costal veins (Askew, 2004; Dijkstra & Lewington, 2006) (FIG. 1). The species object of this note is an Ibero-Maghrebi element (Torralba Burrial & Ocharan, 2007), distributed mainly throughout the Maghreb (Morocco, Algeria, Tunisia and Libya), reaching the Iberian Peninsula, Sardinia, Sicily and some localities in the Italian Peninsula (Conci & Nielsen, 1956). Most of

the citations are before 1980 (Boudot et al., 2009) In Andalusia it is cited for the first time by McLachlan (1889) in Algeciras (Cádiz) (UTM: 30STF70). Subsequently, it is cited on two more occasions in the province of Cádiz, specifically in Algeciras (30STE79), (Ocharan, 1992) and in the Barbate river basin (30STF31), (Hampe, 2004). Previously in the province of Málaga it is cited in the Arroyo Toquero (30SUF76), (Conesa, M. & García, E. 1983), and in the Arroyo de la Calera. Los Alcornocales, in the province of Cádiz (30STF64), (Cano-Villagas, F. et al. 2012). Recently, in September 2014, a female specimen was also located in Malaga in the Guadaiza river basin (30SUF15), (Conesa-García M. & Rodríguez-Martínez, D. 2015). The first observation of the species in grid 30-STF69 was on 9-IX-2014. Three adult males were observed. On 11-IX-2014, five adult males were counted again. In a new observation on September 15, 2014, 4 males and one female were recorded (FIG.2), all adults. On 30-IV- 2015, continuing sampling in the study area, a male teneral of *O. nitidinerve* was located (FIG. 3). Ten days later, new specimens were still observed, in this case a female (FIG. 4). The habitat where this population was found is a natural watercourse on sandstone soils, in a pasture replacing cork oak with *Teucrium scorodonia* (FIG. 5). Other species of odonates are observed in the sampled area: *Ischnura graellsii*; *Calopteryx haemorrhoidalis*; *Anax imperator*; *Orthetrum chrysostigma* and *O. coerulescens*.] Address: Gaona, J.M., C/Alhóndiga 5-1ºB 11370, Los Barrios, Cádiz, Spain. **22389.** Rache Rodríguez, L. (2015): Caracterización de hábitat y morfología de algunas especies del género *Perithemis* (Odonata: Anisoptera) presentes en la Cordillera Oriental. MSc thesis, Universidad Nacional de Colombia, Facultad de Ciencias, Departamento de Biología, Bogotá, Colombia: 140 pp. (in Spanish) ["Of the genus *Perithemis*, 14 species have been described so far and it is composed of small individuals with amber wings in males that sometimes have dark spots, while in females the wings are completely hyaline or with amber spots. In the present research, 30 bodies of water located on the two slopes of the Colombian eastern mountain range are studied in order to identify the general characteristics of the habitat of *Perithemis lais* and *P. mooma*, as well as establish the relationship between these and the morphology of the at. Because the two species show very different distributions (wide in *P. mooma* and restricted in *P. lais*) it is interesting to determine what factors may condition their presence in a specific region or body of water. Therefore, it was evaluated whether there were quantitative differences between the water bodies inhabited by *P. lais* and *P. mooma* and those in which they do not. As well as, determine if the morphology of the wings is related to the environmental variables of aquatic systems. Four samplings were carried out over a year in each of the selected sites, in which chemical, physical and biological variables of the water bodies were measured, as well as land use in the surroundings. In addition, adult individuals and larvae that were raised in the laboratory were collected in order to examine the morphology of the wings. The cluster and principal component analyzes showed that the water bodies in which the species were collected have

little internal variation and differ from the others. Through logistic regressions it was possible to establish the most important environmental variables for each of the species. In the case of *P. lais* they were temperature, shadow on the water mirror, continuity of the macrophyte belt and conductivity, while for *P. mooma* pH, conductivity, water temperature, free water mirror, oxygen, shadow on the water mirror, width and continuity of the macrophyte belt were selected. For its part, the analysis of the morphology of the wings was done through geometric morphometry, a method in which the shape of a group of organisms can be quantified, separating the effect of size, in order to compare it with others. For *P. mooma* and *P. lais*, the left forewing and hindwing of males collected in the selected water bodies were used. After observing the patterns shown in the principal components and cluster analysis, Manova and Monte Carlo tests were performed to test significant differences between the populations. In addition, multiple regressions were used to establish whether the environmental variables of the water bodies had any relationship with the shape and size of the wings. Very low interpopulation variation was found in the two species and little correlation between the shape of fore and hind wings with environmental variables, while size did show a strong correlation with altitude and temperature. It is proposed that the absence of interpopulation variability in the two species is due to the fact that the shape of the wings is a conservative trait in them and that there is genetic flow between the populations mediated by females that present some traits found in migratory species, which which enables them to travel great distances and allow genetic exchange." **22390.** Rodríguez Martínez, D.; Conesa Garcia, M.A. (2015): Odonatos en los cursos fluviales de la fachada sur-oeste de Sierra Bermeja (Málaga, España): Resultados preliminares. Boletín de la Asociación Odonatológica de Andalucía 3: 28-38. (in Spanish, with English summary) ["Odonata in Rivers of the South-West Facade of Sierra Bermeja (Malaga, Spain): Preliminary Results: This document discloses the results until November 2014 of the sampling campaign that Asociación Odonatológica de Andalucía (AOA) has been developing in river basins of Sierra Bermeja, mainly in rivers Padrón, Castor, Guadalmanza, Guadalmina, Guadaiza and Verde. Among others, three new locations are disclosed for *Macromia splendens*, two for *Oxygastra curtisii*, two for *Gomphus graslinii* and one for *Orthetrum nitidinerve*. Significant progress has also been achieved in the general catalog of Odonata species present in the rivers of Sierra Bermeja, several of which had been poorly prospected to date. The results indicate that Sierra Bermeja is a wilderness area of the first order for the conservation of dragonflies in Andalusia: it has a very significant number of taxa - 42 species recorded so far- and several populations of dragonflies with a high degree of global threat or a very restricted distribution in the Iberian Peninsula and the European Union. Current distribution of some of these protected species, as *Macromia splendens* and *Gomphus graslinii*, could be significantly reduced short-term because the urban projects that develop and will be developed in Sierra Bermeja, incompatible with the conservation of the rivers and the surrounding forest habitats." **22392.** Rodríguez Martínez, D.; Conesa Garcia, M.A. (2015): *Orthetrum nitidinerve* (Sélys, 1841) (Odonata: Libellulidae) en Sierra Bermeja (Málaga, España). *Boletín de la Asociación Odonatológica de Andalucía* 3: 25-27. (in Spanish, with English summary) ["In the course of a series of sampling carried out in Sierra Bermeja (Málaga), in the UTM UF15 grid we found an area of flooding, belonging to the sub-basin of the Daidín stream, a tributary course of the Guadaiza river, which originates in the ravine of the Cuerna and that leaves materials dragged as it passes through a system of terraces, formerly used for agriculture. Thanks to this contribution, several of these terraces are permanently flooded, forming large mudflats. This environment can be associated with index 3270: "River courses with contributions of muddy sediments on the banks, generally during floods, which are colonized by pioneer and nitrophilous species", in the catalog of Habitats of Community Interest, (Manuel, Robles & Tejero, 2009). In this area we found a female *Orthetrum nitidinerve*, on 13-IX-2014; Although the flight period recognized for the species ranges from April to October (Dijkstra & Lewington, 2006), we think that it was at the limit of its flight period, since its left hind wing was very deteriorated. In sampling after September no more individuals were observed. It is possible that the successive findings that have been found of this species in recent years are related to the impulse given by different naturalist associations (A.O.A. and the R.O.L.A.) in the study of dragonflies in Andalusia, considerably increasing the number of observers and the number of grids sampled." ## 2016

**22393.** Bhati, D.; Srivastava, M. (2016): Entomo-fauna as documented employing cage net and light trap in some sewage irrigated agro-ecosystems in and around Bikaner, Rajasthan, India. *International Journal of Basic and Applied Sciences* 5(2): 23-36. (in English) ["During this century, the practice of irrigating agricultural crops with sewage waters in rural and peri-urban areas of our country is becoming a common practice as the soil is very good for cropping. Concern for human health and environment are the most important constraints in the use and before one can endorse this means, a thorough analysis seems to be a pre-requisite from social, economical and ecological standpoint. Looking into this, it was proposed to document information relating to insect status in such sewage irrigated farms and thus the present work was undertaken to study the insect scenario (diversity and density) in some sewage irrigated agro-ecosystems in and around Bikaner, Rajasthan. Indigenously designed cage and light trap were employed for insect collection. The cage net trap collection comprised of ... five odonates [*Lestes* sp., *Agriocnemis femina*, *Rhodischnura nursei*, *Bradinopyga geminata*, *Pantala flavescens*], ... while, in light trap collection order Lepidoptera was represented by thirteen species, order Coleoptera was represented by seventeen species, order Hemiptera was represented by seven species, order Hymenoptera, Orthoptera and Diptera by one species each respectively. Based on density (number), the cage net collection comprised of 6 dominant, 63 frequent and 28 rare species, while, in

light trap collection, based on density (number), 14 were dominant, 17 were frequent and 9 were rare." (Authors)] Address: Srivastava, Meera, Laboratory of Entomology, Post Graduate, Department of Zoology, Government Dungan College, Bikaner 334001, Rajasthan, India

**22394.** Calvao, L.B. (2016): Padrão de distribuição de Odonata (Insecta) em sistemas aquáticos com exploração de madeira na Amazônia Oriental: seleção de microhabitat e características morfológicas das libélulas. Tese (Doutorado) - Universidade Federal do Pará, Museu Paraense Emílio Goeldi, Belém, 2017. Programa de Pós-Graduação em Zoologia: 118 pp. (in Portuguese or English) ["Biological communities are distributed in a spatially structured way in aquatic systems, so that the loss of habitat integrity by anthropic actions and the restrictions imposed by the morphological characteristics of the species contribute to the existing pattern of the meta-community in the environment. The hydric systems constitute good models for identifying the processes that participate in the local distribution of organisms. The tributaries of these systems are arranged in a dendritic network under the restriction of multiple environmental conditions and are very sensitive to the modifications that occur in the drainage basin. These modifications are mainly those resulting from human activities, which generally culminate in the loss of resident biodiversity. In the Amazon region, wood exploitation has been considered one of the main activities that cause high rates of deforestation. To reduce the drastic effects on the environment, some forest management techniques, such as Reduced Impact Management (RIM), have been implemented in order to extract the raw material from the natural environment and promote the conservation of species and processes necessary for the functioning of the ecosystem. On the other hand, uncontrolled exploitation, known as conventional exploitation, alters the channel morphology of aquatic ecosystems, reduces vegetation cover and increases the input of fine sediment, generally altering acceptable physical-chemical-microbiological water parameters. Seeking to evaluate the effects of logging on aquatic biodiversity, we will use the order Odonata as a model organism, due to its sensitivity to modifications in the aquatic environment, high species diversity and being associated with diverse types of aquatic environments, as well as living at the interface with the terrestrial environment. The aim of the thesis is to evaluate the distribution pattern of Odonata species in water systems that are distributed in areas subjected to conventional or reduced impact logging in the Eastern Amazon region. To answer this objective the thesis was divided into three chapters, whose objectives are: (i) To evaluate if Odonata diversity decreases in areas with conventional logging, and, to identify which are the abiotic variables that structure Odonata composition. (ii) To evaluate the intensity of environmental and spatial factors on the distribution of Odonata species in the sampled streams and to verify if a taxonomic turnover of species occurs in natural areas (intact). (iii) To evaluate which are the morphological structures of the Odonata order associated with the environmental gradient in the three treatments (reference (REF), reduced impact management (MIR) and conventional logging (CC))." **22395.** Cho, R. (2016): Odonata in cranberry bogs successions in Manomet, Massachusetts. Senior Thesis, Boston College, Department of Earth and Environmental Sciences: 50 pp. (in English) ["Odonata are robust but due to their aquatic larval life cycle they are sensitive ecological markers. There is much literature on the organisms themselves, but no prior

documentation that they are found in the watery ditches of cranberry bogs. Cranberry bogs are an important part of Massachusetts' agricultural identity and some like Tidmarsh Farms, under conservation efforts, are being put into natural restoration. This study sets to explore Odonata specifically in cranberry systems by examining odonate adult and larval populations in and around the ditches of cranberry bogs followed for different lengths of time. Methods included taking pseudoreplicates of the three bog successions- 0, 5, and 15-year - by dipping for larvae and measuring ditch characteristics of width, depth, and vegetation cover, along with pollard walks to observe adults. I found that the dynamic nature of the bog by ditch characteristics and seasonal variation have an effect on odonate populations and may not adhere specifically to ecological succession theory. This data would hope to contribute to a more expansive longitudinal study of management practices and restoration on cranberry bogs and Odonata ecology as a whole." **22397.** Dhandu, S.R. (2016): Lift & drag analysis of a 3D synthetic dragonfly wing. Master of Engineering thesis, The University of Canterbury: 119 pp. (in English) ["A 3D dragonfly wing is developed by using the Autodesk point cloud methodology, which takes several high definition (HD) pictures of the wing and uploads them into the software which computes all the spatial points and to give a rough matrix of the external structure. The structure is further modified by using Mesh mixer and printed in 3D of Acrylonitrile butadiene styrene (ABS) material. Initially a bending and torsion stiffness test is carried out by cantilevering the wing onto a U shaped frame, where the increasing weights are suspended on the wing tip end to calculate the deflection upon loading at different room temperatures. Keeping the Reynolds and Strouhal numbers constant, a flapping mechanism is de-signed consisting of two smart servo motors connected to the wing root with a fix-tures designed to give the wing four axis degrees of freedom (DOF) maintaining the centre line axis. The servos are programmed by using Arduino Nano board and the whole mechanism is fixed onto two load cells on an apparatus which is connected to a LabView® programme for collecting the data. The data from the load cells is taken and investigated in MatLab® by using Fourier analysis. The maximum deflection of the wing tip as per the literature review is in the range of 3-12 mm depending on the loads acting on the wing during flight. For this thesis the average deflection of the wing tip during the experiment upon applied loading is to be about 3-10 mm. It varies with the forces acting on it and also expected to change for another sample of the model wing which can be produced using flexible PVC which has different properties. These deflection values are used to determine the amount of force acting on the wing tip during

the bottom end of the flap cycle. The torsional deflection of the wing during flight was assumed to be 20 degrees. Where as in the torsional stiffness experiment it is more than 10 degrees for the ABS structure. The values obtained during the experiment is lower compared to the value from the previous literature due to the rigidity of the material. It varies with the forces acting on it and also expected to change for another sample of the model wing which can be produced using flexible PVC which has different properties. The flapping experiment is carried out for various flapping and torsional angles using a flapping test rig. The data is studied for the extraction of the forces acting on the wing and is assumed to give more information on the stable and unstable aerodynamics of the dragonfly wing. It is observed that when the phase difference is changed from 0° to 270° the lift generated value is raised from 0.4N to 0.6N. CL-max is determined as 0.55 and is maximum when the phase difference between the flapping angle, torsion angle is maintained as 270°. It is reducing for lower phase differences of 90° and 0°. For two consecutive experiments with a 180° phase difference CL-max is remaining constant at flapping angle of 60°, 90° while frequency and torsion angle are maintained constant. The CD is observed to be consistently low and reaching maximum of 0.125 within the experiments. This research values can be used as a source for developing a flapping unmanned aerial vehicle (UAV)." (Author)] Address: <https://ir.canterbury.ac.nz/server/api/core/bitstreams/b2377737-fd23-44-11-a820-714ec0c66f66/content>

**22398.** Dolný, A.; Harabis, F.; Bárta, D. (2016): Vážky (Insecta: Odonata) České Republiky. Academia, Praha: 342 pp. ["Dragonflies, which appeared on Earth almost 300 million years ago, stand out with a number of unique features. Due to the relatively low number of species, they belong to the best-studied groups of insects, with regard to their taxonomy, ecology and distribution. In addition, they are enjoying increasing popularity, so besides butterflies and beetles, there are probably not many other groups of insects that have the same positive reception from both the professional and the lay public. Also for these reasons, a new practical picture publication was created, which differs from previous works in many respects. Above all, this atlas can be used very well as a field guide, and at the same time, it also contains general information about the life of dragonflies, their biology and ecology." (Publisher/Google translate)] Address: Dolný, A., Dept of Biology and Ecology, Faculty of Science, University of Ostrava, Chittussiho 10, CZ-710 00 Slezská Ostrava, Czech Republic. **22399.** Ellis, L.E.; Jones, N.E. (2016): A test of the serial discontinuity concept: longitudinal trends of benthic invertebrates in regulated and natural rivers of northern Canada. River Research and Applications 32(3): 462-472. (in English) ["Abiotic and biotic impacts below impoundments within the context of the River Continuum (RCC) and the Serial Discontinuity Concepts (SDC) have been the focus of many lotic studies. Recovery gradients, however, are rarely examined in sufficient detail below dams. Further refinement and understanding are needed to inform science and river managers about regulated river ecology. In this study, we examine longitudinal patterns in abiotic and biotic characteristics in two regulated rivers in Northern Canada. We also examine spatial patterns on two natural rivers: a lake outlet river and a river with no lakes. Direct gradient analysis revealed that increases in periphyton, planktonic drift, primary production, substrate size, and changes in thermal regime at sites closest to the dam drive benthic invertebrate community characteristics. We test the Serial Discontinuity Concept by

comparing predicted functional forms of each environmental variable with the empirically derived forms. Substrate size, periphyton biomass, and drift density increased below dams and recovered quickly within 5 km downstream, following closely with SDC predictions. The response of organic matter and water quality was variable, and benthic invertebrate richness recovered relatively quickly, contrary to SDC predictions. Thermal regime and flow took much longer to recover than most variables and represent a second longer gradient type below dams. Plecoptera, Gomphidae, and Simuliidae were strongly influenced by altered resource and habitat and may be good candidates for indicators and predictive modelling. Our results generally support predictions from the Serial Discontinuity Concept and highlight the need for the further testing and refinement of this concept. ... The recovery of these variables and specific taxa (e.g. Plecoptera and Odonata) can provide river managers a focussed target on assessing the impacts of hydroelectric impoundments on rivers. Future studies could focus on specific environmental requirements of Plecoptera and Odonata to determine indicator capability. In particular, further study on Gomphidae would be especially useful as their presence is linked to riparian vegetation, incorporating lateral floodplain connectivity into river management." **22400.** Erbida, N. (2016): Pisani akrobati. Zelene prestolnice 2016 [Colourful acrobats. Green Capitals 2016]. Trdov: Bilten slovenskih terenskih biologov in ljubiteljev narave 5(2): 49-50. (in Slovenian) [Verbatim/DeepL: Adult dragonflies are agile insects in a rainbow of colours that can be admired especially in the warmer part of the year. When we watch their antics by a marsh, lake or river, we are tempted to take a photo to capture the beautiful colours and their gracefulness. In order to draw the attention of the general public to the photogenic but unfortunately endangered dragonflies, the Slovenian Odonatological Society has launched its second photography competition. The first one was successfully held in 2013 under the name of the Photo Contest "Colourful Acrobats". Between May and September 2016, we collected 136 photographs from 55 authors in three sections, namely A (primary and secondary), B (students) and C (adults). In October, the jury consisted of: Dr Tomi Trilar, an employee of the Natural History Museum of Slovenia, where he works mainly on insects, but also on bioacoustics and photography; Dr Ali Šalamun, an employee of the Centre for Cartography of Fauna and Flora, where he works mainly on dragonflies and on Geographic Information Systems; and Mr Janez Tarman, a professional natural history photographer. The jury selected three winning photographs in each category, which are published in this issue, and the official announcement of the winners took place on 24 November 2016 at the Dept of Biology, Faculty of Biotechnology, University of Ljubljana. Here, the participants were introduced to dragonflies and the reasons why they are endangered, and were presented with symbolic prizes and awards. After the announcement, we opened an exhibition of the selected photographs, followed by a feast of local delicacies. During the project, we also organised photography field workshops in the Ljubljana area, where we showed the participants some techniques for photographing dragonflies. Creative workshops were held at the Ljubljana Zoo, where we worked with visitors to make dragonfly-shaped products, and two workshops were also held at the City Square, where the Green Capital of Europe 2016 Point For You was operating. The Green Capital's Colourful Acrobats photo competition was made possible by the Ljubljana

Municipality's Department of Environmental Protection, the STIKS Association, the Ljubljana School of Art, the Student Organisation of the Faculty of Biotechnology, the Department of Biology at the Faculty of Biology of the University of Ljubljana and the Ljubljana Zoo. The winning photographs are published, with one exception, as part of the article on the next page. **22401.** Erbida, N. (2016): Košèèeni škratec na Ljubljanskem barju [Coenagrion ornatum on the Ljubljana Marshes]. Trdov: Bilten slovenskih terenskih biologov in ljubiteljev narave 5(2): 9. (in Slovenian) [Verbatim/DeepL: C. ornatum... is a habitat specialist, occupying only slow-moving, sunny waters with abundant riparian and aquatic vegetation. In Europe, it occurs in the east and south of the continent. The species is relatively poorly known, while its closest relative, C. mercuriale, is one of the best-studied European dragonfly species. This is mainly due to its distribution in western and central Europe, where dragonfly research is much more active than in the rest of the continent. Although the two species occupy similar habitats, both are threatened and protected in Europe and Slovenia. C. mercuriale does not occur in Slovenia. C. ornatum is found in a good part of Slovenia, but is rare wherever it occurs. Today, the species' habitats are mostly anthropogenic, such as drainage canals. Therefore, based on some previous surveys, we conclude that the largest populations in Slovenia are found in the Ljubljana Marshes and the Vipava Valley, where the canal networks are most extensive. However, we do not know how numerous these populations are, nor is it known how large populations occur elsewhere in Europe. Only a few waters in Slovenia have so far recorded a few tens of individuals, and most have only found a few individuals. Only a few waters in Slovenia have so far recorded a few dozen specimens, but mostly only a few specimens have been found. My Master's thesis Population dynamics of the C. ornatum at a selected location in the Ljubljana Marshes was aimed at determining the population size C. ornatum in the Ljubljana Marshes using the mark-release-recapture (MRR) method. Initially, we wanted to carry out the study over the whole of the Ljubljana Marshes, but it became apparent in the first fieldwork that a single individual could not capture and mark specimens over such a large area. The Ljubljana Marshes is a culturally and nature conservation important area and as such is protected as a landscape park and Natura 2000 site, for which C. ornatum is a qualifying species. We chose a 470 m long canal south-west of Kozlarjeva gošta and north of Matena. In the selected area, all specimens of the Box Turtle Dace were caught on each field day from the beginning of May until mid-July 2013. They were marked on the skirt with an alcohol marker with a permanent and unique mark. Despite the fact that the canal population is not isolated, we expected a higher recapture rate in this study, as the Bone Grebes are relatively poor fliers. The low recapture rate results in a rather imprecise estimate of the population size, but we still obtained a more accurate estimate than has been given in previous field surveys. The estimated population size of the Bactrian Lark for Slovenia as a whole has so far ranged from a few tens to a few hundreds of thousands of individuals. A total of 2,168 individuals were caught in the survey, of which 1,690 were males and 478 were females, with an overall recapture rate of 14%. As expected, more males were caught than females, and the recapture rate of males was also higher. This is because females spend most of their time away from the water, where they feed and produce eggs, and they are more cryptic in colour, making them

harder to spot. Therefore, fewer females than males were captured in the study, which was conducted only near the water. Males, on the other hand, spend most of their time by the water, waiting for females to mate with them just before they lay their eggs in the water. The total estimated population size in the selected canal is 12,617 or between 5,326 and 19,906 individuals. We also found that 79% of the specimens moved less than 100 m from their original capture site. No population study has been carried out in Slovenia on the Bone Bream, so a comparison of population abundance is not possible. However, based on the results and reports of other records of the species in Slovenia, the population in the Ljubljana Marshes is one of the largest in Slovenia. We believe that the planned maintenance of the canals is very important for the conservation of the Bone-nosed Damselfly, as well as for the conservation of other endangered dragonfly species present in this habitat. Further research is needed in the whole area, but we recommend that a larger number of people be mobilised to survey a larger area.] Address: <https://www.dlib.si/details/URN:NBN:SI:DOC-4HUNW72O/?=&query=%27rele%253dTrdo%25c5%25beiv%27&p ageSize=25>

**22402.** Frank, M. (2016): Eiablage von *Anax imperator* auf einer nassen Holzterrasse (Odonata: Aeshnidae). *Libellen in Hessen* 9: 45-50. (in German) ["A female *A. imperator* was observed laying her eggs on a wet wooden terrace in the middle of a residential area and at least two kilometers from the nearest reproductive water. The terrace had previously been cleaned with water and therefore had a surface that was still wet and reflected light. The most likely cause of this egg laying in unsuitable artificial substrate is thought to be a polarotactic response - a known, general ability of dragonflies to detect water surfaces based on reflected horizontally polarized light." **22403.** Joest, R.; Beckers, B. (2016): Libellenfauna des Feuchtwiesenschutzgebietes Ahsewiesen. *Natur in NRW* 1/16: 43-47. (in German) [Nordrhein-Westfalen, Germany "In the Ahsewiesen nature reserve, small bodies of water and lakes were created from 1988 onwards, ditches were dammed and waterlogging measures were carried out in order to improve living conditions, especially for meadow bird species. As part of the success monitoring, the dragonfly fauna was mapped from 1988 to 2003, which was repeated in 2015. The species identified in 2015 were predominantly widespread habitat generalists in still waters. What is remarkable is the relatively high number of individuals in the endangered pioneer species *Ischnura pumilio*. The total number of species has increased from four in 1988 to 27 in 2015. This is due to the creation of numerous small bodies of water and lakes as part of renaturation measures. In addition, supra-regional climatic changes have also enabled the establishment of heat-loving species. The development in the Ahsewiesen shows that the measures implemented to improve the habitat for meadow birds were also beneficial for other groups of species such as the dragonflies examined here. The living conditions for these species can be permanently improved through further measures aimed at increasing and maintaining the water level in the area. In order to maintain the quality of the habitat for specialized species, targeted optimization and maintenance to control the succession of water bodies is also necessary." **22405.** Nair, A.; Agashe, D. (2016): Host-specific spatial and temporal variation in culturable gut bacterial communities of dragonflies. *Current Science* 110(8): 1513-1523. (in English) ["Many microbial communities are associated with specific animal hosts, with major impacts on the ecological and evolutionary dynamics of both partners. We analysed gut microbial communities of eight dragonfly species in southern India. Adult dragonflies are generalist opportunistic predators; thus, we expected to find relatively high individual variation but low host-specific variation in their gut community composition. However, we find that each host species has a distinct gut bacterial community, with sampling location and month playing a small but significant role in shaping community structure. These patterns suggest that dragonflies either specialize on subsets of available prey, or their guts impose differential selective pressures resulting in distinct communities." **22406.** Opaev, A.S.; Panov, E.N. (2016): Space use in territorial and non-territorial male *Calopteryx splendens* (Odonata: Calopterygidae). *Odonatologica* 45(1/2): 57-76. (in English) ["In *Calopteryx damselflies* male territorial and non-territorial alternative mating tactics are identified. Territorial males are believed to secure more copulation. With increasing age, males starve and become non-territorial that only occasionally manage to copulate. However, space use of territorial and non-territorial males is not known in detail. We present the data on space use of individually marked male *C. splendens* ... obtained during two field seasons in Vladimir Oblast, Russia. Each damselfly was captured, marked and the wing length was measured. During observation sessions of 2-4 hours per day, each male was characterised as either territorial or non-territorial and encounter locations were mapped. The probability of being territorial declines with the male's age. Territorial vs non-territorial tactic in a given day strongly influences tactic retention on the next day. We identified the territorial and non-territorial phases in the life of a male, which occur consequently and have roughly similar duration. We define the territorial phase as all days until the last record of a male as a territorial individual. The subsequent days were defined as the non-territorial phase. During the territorial stage, males may (1) occupy a single territory; (2) be non-territorial in some of the days and then return to his previous territory or (3) after staying within a certain territory for several days change it and occupy another territory

on the next day or several days later. The transition from the territorial to the nonterritorial phase is gradual. It may suggest this transition caused by exhaustion. Thus, space use changes predictably during the life of a male. Characteristics of individual lifetime trajectory - number of days when the male was recorded as territorial, - number of territories occupied, etc. - did not depend on wing length." **22407.** Outomuro, D.; Angel-Giraldo, P.; Corral-Lopez, A.; Realpe, E. (2016): Multitrait aposematic signal in Batesian mimicry. *Evolution* 70(7): 1596-1608. ["Batesian mimics can parasitize Müllerian mimicry rings mimicking the warning color signal. The evolutionary success of Batesian mimics can increase adding complexity to the signal by behavioral and locomotor mimicry. We investigated three fundamental morphological and locomotor traits in a Neotropical mimicry ring based on Ithomiini butterflies and parasitized by Polythoridae damselflies: wing color, wing shape, and flight style. The study species have wings with a subapical white patch, considered the aposematic signal, and a more apical black patch. The main predators are VS-birds, visually more sensitive to violet than to ultraviolet wavelengths (UVS-birds). The white patches, compared to the black patches, were closer in the bird color space, with higher overlap for VS-birds than for UVS-birds. Using a discriminability index for bird vision, the white patches were more similar between the mimics and the model than the black patches. The wing shape of the mimics was closer to the model in the morphospace, compared to other outgroup damselflies. The wing-beat frequency was similar among mimics and the model, and different from another outgroup damselfly. Multitrait aposematic signals involving morphology and locomotion may favor the evolution of mimicry rings and the success of Batesian mimics by improving signal effectiveness toward predators." **22408.** Pitts, M. (2016): Damsels in distress: A study of the effect of temperature on damselfly competitive interactions. Biological Sciences Undergraduate Honors Theses. Paper 21: 16 pp. (in English) ["Temperature has a fundamental role in shaping numerous physiological aspects of organisms, such as growth rate, that determine an organism's performance. Due to global climate change, temperature is projected to keep increasing. As temperature increases, so does an organism's growth rate. Also, as competition increases organisms' growth rate decreases. While studies have examined these factors individually, no experiments have assessed the combined impact of temperature and competition on organism's growth rates. The experiment we conducted manipulated temperature and density in order to project what will happen as a result of rising temperatures." **22409.** Serrano Leon, J.P.; Gomez Blazquez, A.I. (2016): Notas sobre la presencia de *Paragomphus genei* (Sélys, 1841) (Odonata: Gomphidae), en la cabecera del río Guadamar, (Sevilla, España). *Boletín Asociación Odonatológica de Andalucía* 4: 15-19. (in Spanish) [Verbatim: *P. genei* is a small gomphid with a yellowish-olive color. It has light blue-gray eyes with greenish upper facets. Its thorax is yellowish-green with thick blurred stripes of brown tones on the sutures;

some specimens have a very greenish hue. On the abdomen you can see brown-mahogany and black spots. Males have lateral leaf expansions in the S8 and S9 segments and very characteristic long, yellowish hook-shaped cercoids (Fig. 1, A). The pterostigmata are yellowish in the center, surrounded by very thickened black veins (Dijkstra & Lewington, 2014). The species, the subject of the note, has been cited in all Andalusian provinces with the exception of Almería and Granada. Specifically in Seville there is a single record of a *P. genei* larva at the head of the Guadamar River near the Castillo de las Guardas (29SQB37), (Ferrerías & Gallardo, 1985). After a chance encounter of a female *Paragomphus genei* on a wild olive tree and an exuvia in the vicinity of the Guadamar River, near Gerena, a selection of different potential points was made (FIG.3) where more specimens could be located. to confirm the current status of the species. Much of the route at the head of the river is located within cattle farms that make sampling difficult. This prevented finding any point that confirms the presence on the UTM 10x10 km 29SQB46 grid. This circumstance is repeated when passing through Las Cortecillas (29SQB38). Sampling at each of the points was carried out between 12 and 5 p.m., since these are the main hours of activity for adults, between 30 or 60 minutes depending on the location. Transects were carried out on both banks, in search of the presence of both adults in flight and exuviae (Table 1) that ensured the presence and/or reproduction of the species at said points. These transects were extended to at least 50 meters from the water points so as not to underestimate the population. The adult specimens were photographed and all the exuviae found during sampling were cataloged and preserved for later confirmation. The species associated with each of the observation points were also noted. Point 1: 29SQB3777, Río Guadamar – Hacienda El Castillo. Sandy bed with a maximum channel width of 4 or 5 meters. Temporary course that is dry most of the year. On the second visit there was no longer any water flowing, leaving only isolated shallow pools. Abundant shrub and tree plant presence on the banks Point 2: 29SQB3775, Río Guadamar – El Castillo de las Guardas. (Fig. 4) Bed made up of a mixture of coarse sand, gravel and large rocks. Temporary course with bed width between 5 and 8 meters. Pools that are maintained throughout the year. Very abundant riparian vegetation on the banks with a large presence of *Nerium oleander*, *Typha* sp. and trees with roots submerged in water. Point 3: 29SQB4471, Guadamar River – El Alisar. Bed composed of gravel, rocks and coarse sand banks. Temporary course with an approximate width of 8 meters with a nearby irrigation dam. Shrub river-side vegetation composed mainly of *Typha* sp. and *Nerium oleander*. Point 4: 29SQB4857, Río Guadamar- Gerena. Bed 10 to 15 meters wide composed of coarse and fine sand. Water all year round with large water ponds. Shrub vegetation dominated by *Nerium oleander* with the presence of *Arundo donax* and *Typha* sp. Point 5: 29SQB4540, Río Guadamar-Sanlúcar la Mayor. Bed composed of silt, clay and sand. It has water and current throughout the year, although during the summer it is usually minimal. Tree and shrub vegetation in sections dominated by *Phragmites* sp., *Arundo donax*, *Scirpus* sp. and *Juncus* sp. Exuviae of *Paragomphus genei* were found in three of the five points sampled and adult specimens in two of them. *Paragomphus genei* was cited for the first time by Ferreras & Gallardo (1985), for the province of Seville, and was not cited again in subsequent sampling after the Aznalcóllar mine spill (Ferrerías, Cano & Salamanca, 2004). With the specimens and exuviae found in this work, the presence and reproduction of *Paragomphus genei* is reaffirmed in the headwaters of the Guadamar River in the province of Seville. Other species of odonates present in the studied area were the following: *Chalcolestes viridis*, *Ischnura*

**22410.** Siepielski, A.M.; Nemirov, A.; Cattivera, M.; Nickerson, A. (2016): Experimental evidence for an eco-evolutionary coupling between local adaptation and intraspecific competition. *The American Naturalist* 187(4): 447-456. (in English) ["Determining how adaptive evolution can be coupled to ecological processes is key for developing a more integrative understanding of the demographic factors that regulate populations. Intraspecific competition is an especially important ecological process because it generates negative density dependence in demographic rates. Although ecological factors are most often investigated to determine the strength of density dependence, evolutionary processes such as local adaptation could also feed back to shape variation in the strength of density dependence among populations. Using an experimental approach with damselflies, a predaceous aquatic insect, we find evidence that both density-dependent intraspecific competition and local adaptation can reduce per capita growth rates. In some cases, the effects of local adaptation on reducing per capita growth rates exceeded the ecological competitive effects of a doubling of density. However, we also found that these ecological and evolutionary properties of populations are coupled, and we offer two interpretations of the causes underlying this pattern: (1) the strength of density-dependent competition depends on the extent of local adaptation, or (2) the extent of local adaptation is shaped by the strength of density-dependent competition. Regardless of the underlying causal pathway, these results show how eco-evolutionary dynamics can affect a key demographic process regulating populations." **22411.** Slugaski, C. (2016): Structure and function of dragonfly looming-sensitive neurons. *The FASEB Journal* 30(1, Supplement) [Federation of American Societies for Experimental Biology]. *Experimental Biology 2016 Meeting Abstracts*, April 2016: 760.3 - (in English) [Verbatim: "In this project, I aim to identify specific neurons in the dragonfly brain that respond selectively to looming stimuli. In the dragonfly nerve cord, there are large visual neurons, called Target Selective Descending Neurons (TSDNs). These neurons respond selectively to small moving stimuli, which mimic the movements of dragonfly prey. The response of these neurons is the steering movement of the dragonfly's wings, allowing them to predict the location of their prey for accurate interception. A subset of the TSDNs show large and precisely timed responses to the expanding image of an approaching object. I will be studying these "looming-sensitive" neurons, researching what visual information they are sending to the flight system. This material will allow for the analysis of the anatomical structure in the dragonfly brain. The visual responses of these dragonflies suggests that the looming-sensitive neurons are the specific TSDNs called MDT3 and DIT3, but in order to confirm this prediction, we must visualize the anatomy of the brain. With the use of a dye called Lucifer yellow, we can trace the response of the looming stimuli to a specific area of the brain. By injecting the dye with a recording microelectrode, we can positively identify these specific neurons." (Author)] Address: Slugaski, Clara, Biology, Union College, Schenectady, NY, USA

**22412.** Johnson, J. (2017): The spread of *Libellula saturata* (Flame Skimmer) through Oregon and its appearance in Washington. *Argia* 29(2): 6-7. (in English) ["In 2015, *L. saturata* was observed at wetlands in the middle of Portland such as Tanner Springs Park (OC 434573) and Westmoreland Park (OC 435648). By 2016, the species was conspicuous at Salish Ponds (report by Bonnie Comegys on the Western Odonata Facebook group) — within a dragonfly's easy flight of the Columbia River. On 10 September 2016, I observed a male and photographed an ovipositing female at Soapstone Lake, Clatsop Co. (OC 455310). This became the northernmost record in Oregon, and, because of the meandering route of the lower Columbia River, this was further north than most of Clark County, Washington. This really seemed like the year to finally find the species at my local ponds in the Vancouver area. I've been checking Kline Pond just north of Vancouver, Clark Co., Washington, on a somewhat regular basis throughout the odonate season — always thinking about the probability of eventually finding *L. saturata*. That finally happened on 14-IX-2016. I found a lone male alternately flying back and forth as it chased other odonates and perching in the sun along the pond's northern shore. I obtained several photos during a few brief moments that it perched (OC 455577). I returned on 16 and 21 September, and on each of those days I found a lone male *L. saturata* appearing intermittently along the same stretch of shoreline on the north side of the pond. More photos were obtained both days (OC 455705, 456155, 456159)." (Author)] Address: Johnson, J.T., 3003 Unander Avenue, Vancouver, WA 98660, USA. E-mail: gomphusjim@gmail.com

**22415.** Tamm, J. (2017): Zum Vorkommen der Gestreiften Quelljungfer (*Cordulegaster bidentata*) im östlichen Taunus (Odonata: Cordulegasteridae). *Libellen in Hessen* 10: 57-67. (in German) ["*C. bidentata* was found in nine locations in the eastern Taunus, Gessen, Germany. Eight of these locations were identified as part of a species-focused imaginal mapping exercise in this region in 2016, which covered 109 head-water streams. The populated streams were mainly in the Hochtaunus and Vordertaunus, while only two occurrences were found in the Hintertaunus. These were also in the Pferdeskopf area, which is immediately north of the Hochtaunus and, as a high mountain range, is more similar to it than the rest of the Hintertaunus. *C. bidentata* was not found in the hilly region of the Hintertaunus proper. In the Hochtaunus and Vordertaunus, the colonization frequency of *C. bidentata* was 20% and reached a maximum of 36% in the deciduous forests of the Vordertaunus south of Eppstein. This is comparable to the peak values for the species in other parts of Hesse and Germany. The very different settlement densities seem to be based primarily on structural differences in the streams in the sub-regions. The populated streams were characterized by a clear gradient and a diggable loose sediment, at least in places. These circumstances are rare in the Hintertaunus. In the study area, *C. bidentata* is primarily affected by the large-scale cultivation of spruce in the Hochtaunus, especially where the most favorable stream structures for the species are otherwise present. The conservation of the dragonfly in the eastern Taunus is likely to depend above all on solving this problem." (Author/Google translate)] Address: Email: jochen.tamm@t-online.de

**22419.** Ehira, K. (2018): Interspecific copulation between male *Calopteryx japonica* and female *Mnais pruinosa*. *Tombo* 60: 104-105. (in Japanese, with English summary) ["A case of interspecific copulation between male *Calopteryx japonica* and a female *Mnais pruinosa* was observed at Kurino, Yusui town, Aira district, Kagoshima prefecture. Following action by the connected male just like intramale sperm translocation, the copula position was smoothly attained. During copulation, however, no rhythmical movement of the few basal segments of the male abdomen was observed. Subsequently, the male ceased copulation and tandem position and flew away. It took about three minutes from detection of the couple to the end of copulation." (Author)] Address: Email: menpo@hotmail.com

**22420.** French, S.K.; McCauley, S.J. (2018): Canopy cover affects habitat selection by adult dragonflies. *Hydrobiologia* 818(1): 129-143. (in English) ["The mechanisms structuring aquatic communities across environmental gradients are often difficult to distinguish from one another and can produce similar patterns of species distributions. In freshwater systems, the amount of canopy cover from surrounding trees is often associated with transitions in local community structure. These community changes could be driven by habitat selection prior to colonization of the aquatic habitat and/or species-sorting post-colonization. To assess the contributions of pre- versus post-colonization processes in structuring larval dragonfly assemblages, we tested the impact of artificial and natural canopy cover on the selection of experimental aquatic mesocosms by adult dragonflies, and monitored the performance (i.e. growth and survival) of larval dragonflies that were placed in mesocosms under a gradient of natural canopy cover. We found that greater levels of canopy cover resulted in fewer adult visits to mesocosms, and more natural canopy cover decreased the species richness of visitors. There were no effects of canopy cover on the growth and survival of larvae added to the mesocosms. Our results suggest that adult habitat selection plays a dominant role in structuring larval dragonfly assemblages across a canopy cover gradient, and that canopy cover can be an important environmental filter on species distributions." (Authors)] Address: French, Sarah, Dept Biol., Univ. Toronto Mississauga, Mississauga, Canada

**22421.** Futahashi, R.; Miyahata, T.; Yokoi, N. (2018): Distribution of species of the genus *Mnais* (Zygoptera: Calopterygidae) in northern Kanto district, C. Honshu, Japan. *Tombo* 60: 116-120. (in Japanese, with English summary) ["We surveyed the distribution of the genus *Mnais* in northern Kanto district, C. Honshu, based on nuclear ITS sequences. The distribution of the genus was found to be complex in Gunma Prefecture, whereas only *M. costalis* was recorded from Fukushima and Ibaraki Prefectures. Two larvae of interspecific hybrid were also recorded from Gunma Prefecture." **22422.** Futahashi, R.; Okude, G.; Sugimura, M.; Ugai, S. (2018): Interspecific hybrids in Japanese Odonata. *Tombo* 60: 1-49. (in Japanese, with English summary) ["After Asanina's 1974 paper, more than 150 papers have reported on interspecific hybrid of Japanese Odonata. Combination of interspecific hybrids can be directly confirmed by analyzing biparentally inherited nuclear DNA and maternally inherited mitochondrial DNA. Based on nuclear and mitochondrial DNA analyses, we identified the following 21 combinations of interspecific hybrids in Japanese Odonata: (1) *Mnais costalis*

x *Mnais pruinosa*, (2) *Paracercion sieboldii* x *Paracercion melanotum*, (3) *Ischnura senegalensis* x *Ischnura elegans*, (4) *Anax parthenope* x *Anax nigrofasciatus*, (5) *Anax parthenope* x *Anax guttatus*, (6) *Anax parthenope* x *Anax panbeus*, (7) *Somatochlora uchidai* x *Somatochlora graeseri*, (8) *Sympetrum darwinianum* x *Sympetrum maculatum*, (9) *Sympetrum frequens* x *Sympetrum depressiusculum*, (10) *Sympetrum eroticum* x *Sympetrum baccha*, (11) *Sympetrum eroticum* x *Sympetrum parvulum*, (12) *Sympetrum eroticum* x *Sympetrum kunckeli*, (13) *Sympetrum eroticum* x *Sympetrum pedemontanum*, (14) *Sympetrum croceolum* x *Sympetrum speciosum*, (15) *Sympetrum croceolum* x *Sympetrum uniforme*, (16) *Tramea virginia* x *Tramea basilaris*, (17) *Tramea virginia* x *Tramea transmarina*, (18) *Zygomma obtusum* x *Zygomma petiolatum*, (19) *Orthetrum albistylum* x *Orthetrum japonicum*, (20) *Orthetrum melania* x *Orthetrum pruinosum*, (21) *Libellula quadrimaculata* x *Libellula angelina*. Among them, more than 50 individuals have been recorded in the following 3 combinations: *Anax parthenope* x *Anax nigrofasciatus*, *Sympetrum frequens* x *Sympetrum depressiusculum*, and *Sympetrum eroticum* x *Sympetrum baccha*, and among the former two combinations, F2 hybrids have been also obtained by breeding eggs derived from hybrid females. *Sympetrum eroticum* was involved in the 4 different hybrid combinations as paternal species in all examined individuals. Among 203 Japanese Odonata species, the following 2 combinations cannot be distinguished by nuclear ribosomal DNA including internal transcribed spacer (ITS) region: *Pseudocoptera annulata* vs *Pseudocoptera tokyoensis* and *Rhyothemis variegata* vs *Rhyothemis phyllis*. Additionally, the following 7 combinations cannot be distinguished by mitochondrial DNA probably due to mitochondrial introgression through hybridization: (1) *Mnais costalis* vs *Mnais pruinosa*, (2) *Paracercion hieroglyphicum* vs *Paracercion melanotum*, (3) *Anax parthenope* vs *Anax nigrofasciatus*, (4) *Trigomphus melampus* vs *Trigomphus ogumai* vs *Trigomphus interruptus*, (5) *Sympetrum frequens* vs *Sympetrum depressiusculum*, (6) *Sympetrum croceolum* vs *Sympetrum uniforme*, and (7) *Tramea virginia* vs *Tramea transmarina* vs *Tramea loewii*. In this review paper, we describe the morphological characteristics of above 21 combinations or interspecific hybrids in Japanese Odonata and list the records comprehensively." **22431.** Liu, Y.; Luo, X.-J.; Huang, L.-Q.; Yu, L.-H.; Mai, B.-X. (2018): Bioaccumulation of persistent halogenated organic pollutants in Insects: Common alterations to the pollutant pattern for different insects during metamorphosis. *Environ. Sci. Technol.* 52(9): 5145-5153. (in English) ["Few studies have examined the accumulation and fate of persistent halogenated organic pollutants (HOPs) in insects. We measured HOPs, including dichlorodiphenyltrichloroethanes (DDTs), polychlorinated biphenyls, and halogenated flame retardants, in insects from four taxonomic groups collected from an e-waste site. Dragonfly larvae collected from a pond contained the highest concentrations of all chemicals except DDTs, while the litchi stinkbugs contained the lowest. Different insect taxa exhibited different contaminant patterns which could be attributed to their habitats and feeding strategies. Bioaccumulation factors for dragonfly larvae and biomagnification factors for moth and grasshopper larvae were significantly positively correlated with the octanol-water partition coefficient of the chemicals ( $\log KOW < 8$ ). Common nonlinear correlations between the ratio of larval to adult concentrations and  $\log KOW$  were observed for all taxa studied. The ratio of concentrations decreased with increasing values of  $\log KOW$  ( $\log KOW < 6-6.5$ ), then increased ( $6 < \log KOW < 8$ ) and decreased again ( $\log KOW > 8$ ). This result implies that the mechanism that regulates organic pollutants in insects during metamorphosis is common to all the taxa studied." (Authors)] Address: Luo, X.-J., State Key Lab. **22435.** Okuyama, H., M. Kawanaka, A. Hara, A. Takeuchi, R. Suzuki, S. Sasaki, K. Watanabe, K. Osaki, K. Hirano, T. Kiyoshi, J. Takahashi (2018): The genetic diversity of a threatened skimmer species, *Nannophya pygmaea* (Odonata: Libellulidae): a report on the population in Kanagicho, Hamada City, Shimane Prefecture, Japan). Tombo 60: 90-95. (in Japanese, with English summary) ["A decline in the genetic diversity of *N. pygmaea* is likely to occur as a result of habitat destruction. *N. pygmaea* is considered vulnerable (VU) in Shimane Prefecture, Japan. In this study, we analyzed the genetic diversity of a *N. pygmaea* population in Kanagicho, a town in Hamada City located in Shimane Prefecture, was found in 2010, using the mitochondrial DNA 16S rDNA (503 bp) and nuclear DNA ITS 1(234 ~ 248 bp) and ITS2 (307 bp) partial regions. For 16S rDNA, ITS1 and ITS2 regions, two, ten and two haplotypes were identified, respectively. The nucleotide diversities were 0.00103, 0.00550 and 0.00013 and the haplotype diversities were 0.517, 0.676 and 0.038, respectively. As a result of phylogenetic analysis, this population belonged to the same clade as other Japanese, Chinese, Taiwanese and Malaysian populations. In this population, 90 % haplotypes for ITS1 region and 50% haplotypes for 16S rDNA and ITS2 regions were endemic. Thus, the present study suggests that *N. pygmaea* Shimane Prefecture population is important as a conservation population because this population maintains the genetic diversity and characteristic.] Address: Okuyama, H., Faculty of Life Sciences, Kyoto Sangyo University, Kamigamo, Motoyama, Kita-ku, Kyoto, Japan. **22436.** Prescott, V.A.; Eason, P.K. (2018): Lentic and lotic odonate communities and the factors that influence them in urban versus rural landscapes. *Urban Ecosystems* 21(4): 737-750. (in English) ["Habitat alteration via urbanization has very different effects on even closely related taxa. Most research investigating the ecological effects of urbanization has focused on birds or mammals, resulting in a relatively poor understanding of how the species richness and community composition of invertebrates may change. We quantified differences in species richness of adult odonates at lentic and lotic sites in urban and rural landscapes, and we examined environmental factors that might drive the differences in community composition that we observed. For lotic sites, species richness did not differ between urban versus rural sites for either dragonflies or damselflies. For lentic sites, urban and rural sites contained similar dragonfly species richness, but damselfly species richness was significantly lower at urban sites than at rural sites. Differences in lentic odonate community composition were associated with the amount of urban development within 150 m of each site, mean algal coverage, and distance to the urban center. At lotic sites, water temperature and distance to the urban center were correlated with differences in odonate community composition. The differing responses to urbanization observed in this study were probably

a consequence of differences between lentic versus lotic ecosystems and between dragonflies versus damselflies in dispersal capability and habitat specificity. Given that different environmental factors affected these taxa differently in lentic and lotic sites, maintaining the highest level of odonate diversity possible across a landscape will require the use of different management practices for each ecosystem type." **22445.** Alemneh, T.; Ambelu, A.; Zaitchik, B.F.; Bahrdorff, S.; Mereta, S.T.; Pertoldi, C. (2019): A macroinvertebrate multimetric index for Ethiopian highland streams. *Hydrobiologia* 843: 125-141. (in English) ["Headwater streams in the highland regions of Ethiopia are exposed to severe human disturbances because of rapid population growth. Protection and management of headwater streams require the development of informative indices that can capture disturbance and assess streams water quality in highland regions. Therefore, we developed a multimetric index based on macroinvertebrate communities, to assess the ecological condition of the headwater streams in the Ethiopian highlands. We reviewed 38 potential metrics, representing various aspects of the macroinvertebrate assemblages, and selected four of them [total family richness, Simpson index, percentage of shredder, and family richness of EOT (Ephemeroptera, Odonata, and Trichoptera)] as final core metrics. A trisection inter-quartile range system was applied to derive scores for each core metric at impaired and reference sites. The macroinvertebrate multi-metric index (MMI) distinguished well between impaired and reference stream sites and was negatively correlated with the degree of disturbance. The results suggest that the MMI is robust measure of disturbance and can be used as a sensitive tool for evaluating the ecological condition of headwater streams in Ethiopian

highlands." (Authors)] Address: Alemneh, Temesgen, Dept of Earth & Planetary Sciences, Johns Hopkins Univ., Baltimore, MD 21210, USA. Email: tyimani1@jhu.edu

**22447.** Guillermo-Ferreira, R.; Bispo, P.C.; Appel, E.; Kovalev, A.; Gorb, S.N. (2019): Structural coloration predicts the outcome of male contests in the Amazonian damselfly *Chalcopteryx scintillans* (Odonata: Polythoridae). *Arthropod Structure & Development* 53, November 2019, 100884: 10 pp. (in English) ["Highlights: • Structural coloration in an Amazonian damselfly is a result of a multilayered structure. • Male damselflies use the dorsal wing coloration during territorial contests. • Color hue seems to be the wing trait that predicts contest outcome. • Angle dependent structural coloration may be an adaptation to Rainforest light environment. Abstract: Iridescence is an optical effect that produces angle dependent coloration in animals. Recently, studies have attempted to unveil structures behind such elaborated visual signals and associated behaviors in Odonata. Here, we studied males of *C. scintillans*, which have hindwings that exhibit pronounced iridescence. This optical feature is used by the damselflies for intra-specific communication during territorial fights and courtship. The main question we addressed was whether male wing structural coloration may predict the outcome of male-male contests. We also studied the wing ultrastructure, in order to reveal the mechanisms that are responsible for wing coloration. Using various microscopical and spectroscopical techniques, we demonstrate that hindwing coloration is derived from two main effects: (1) light interference in the cuticle multilayer and (2) a specific angle dependent light scattering and antireflective properties of the epicuticular wax coverage. The results of our field experiment show that wing pigmentation and the hue of the dorsal surface of the hindwings is correlated with the outcome of territorial contests. This is one of the first studies showing that structural coloration derived from multilayer interference may influence the outcome of intrasexual agonistic interactions. This indicates that multicomponent structural coloration in visually guided insects may be under selective forces of male-male competition for resources and females." **22449.** Kemabonta, K.A.; Essien, R.; Adu, B.W.; Ogbogu, S.U.; Iyasa, A.; Uche-Dike, R. (2019): Abundance and distribution of odonates (dragonflies and damselflies) In Akwa Ibom State, Nigeria. *Pan African Journal of Life Sciences* 1: 33-38. (in English) ["Introduction: Odonates are used as bio-

indicators for monitoring habitat degradation both on terrestrial and aquatic ecosystem because of their sensitivity to anthropogenic activities. They serve an important role in the ecological food chain by consuming aquatic larvae and being in turn consumed by birds and various amphibians. This study is part of the ongoing research on the diversity of Odonate species of Nigeria. The objective is to determine the abundance and distribution of odonates in Akwa Ibom State and to compare the species diversity across the various sites in Akwa Ibom State. Methodology: Akwa Ibom state was divided into six areas namely Ikot Akpaden, Obio Akpa, Ikot Okoro, Ikot Udofia, Urua Udofia and Obio Ndot using biotypes and a study site was randomly selected in each area. Adult members were captured using a sweep net and were preserved for identification using morphological features. Results: A total of 767 odonates were collected at the six study sites representing 24 species, 16 genera and four families namely Libellulidae (77%), Coenagrionidae (21%), Calopterygidae (>1%) and Chlorocyphidae (>1%). Most of the species collected were members of family Libellulidae (77%) with *Palpopleura lucia* having the highest occurrence (41%) and found in all the sites. Family Calopterygidae and Chlorocyphidae had less than 1% population of the total individuals collected. Ikot Okoro had the highest number of individuals (238) and the least evenness ( $e^H/S=0.3292$ ) while Ikot Akpaden, which had the least effect of anthropogenic intrusion had the largest diversity of Odonata species ( $H'=2.387$ ). Obio Ndot had the most evenly distributed Odonata species ( $e^H/S=0.8028$ ). There was no statistical difference in the occurrence of dragonflies across all study sites ( $p=0.238$ ). Conclusion: The high occurrence of family Libellulidae which are anthropogenic tolerant, and the absence of more highly localized species indicate that most of the study sites have been degraded and may not be fit for species with narrow niches. It is therefore vital to conserve the Odonata community by implementing proper forest management techniques." **22450.** Ousterhout, B.H.; Serrano, M.; Bried, J.T.; Siepielski, A.M. (2019): A framework for linking competitor ecological differences to coexistence. *Journal of Animal Ecology* 88(10): 1534-1548. (in English) ["1. Not all ecological differences among competing species affect their ability to locally coexist. Rather, the differences that promote stable coexistence can be those which cause each species to experience stronger intraspecific than interspecific competition. Recent approaches have established how to detect the demographic signature of these competitive effects, but alone they cannot elucidate the ecological differences among species that yield these patterns. 2. Here, we present a unifying experimental and observational framework that identifies potential ecological differences among species shaping their responses to intra- and interspecific competition. We first describe a conceptual model establishing why the strength of intra- and interspecific competitive interactions should vary along environmental gradients related to species ecological differences. We then show how to apply the framework using *Enallagma* damselflies [*E. exulans*, *E. traviatum*, *E. vesperum*], a diverse group of predatory aquatic insects. 3. To determine how species responded to intra- and interspecific competition along environmental gradients, we experimentally manipulated the relative abundances of three species and replicated this across five lakes which varied in environmental conditions affecting larval damselfly per capita growth and mortality rates – key vital rates regulating their populations. 4. Results suggest *Enallagma* are ecologically differentiated in ways that in some communities can result in intraspecific

competition exceeding interspecific competition. However, in many cases the opposite was true, or the effects of intra- and interspecific competition were equivalent via growth and mortality responses. Moreover, these effects tended to be weak and asymmetrical among competitors, which suggests that differential responses of larval growth and mortality to intra- and interspecific competition may not contribute strongly to the maintenance of *Enallagma* diversity. Different environmental factors appear to shape these demographic responses to competition, providing insight into the ecological mechanisms regulating damselfly assemblages. 5. This framework can be broadly applied to identify the ecological differences among species that may promote coexistence, advancing knowledge of the mechanisms underlying coexistence, and overcoming some limitations of purely phenomenological approaches." **22451.** Rivas-Torres, A.; Lorenzo-Caballa, M.O.; Sánchez-Guillén, R.A.; Cordero-Rivera, A. (2019): Variation in intraspecific sperm translocation behaviour in a damselfly and its consequences for sperm viability. *Animal Behaviour* 156: 51-55. (in English) ["Highlights: • Males reused vesicle sperm when copulating 15 min after sperm translocation (ST). • The proportion of males that repeated ST increased over time. • Female fertility decreased with increasing time between ST and copulation. • Males seem to be able to detect whether their sperm vesicle is full or not. Sperm quality and viability affect both male and female fitness. Most dragonfly and damselfly males translocate sperm from the testis to the seminal vesicle before each copulation, a behaviour known as intramale sperm translocation (ST). However, some published observations indicate that odonate males can occasionally skip ST prior to copulation. Our aim was to determine the circumstances under which males skip ST and how this might affect sperm viability. We allowed males of *Ischnura graellsii* to perform ST (interrupting the copulation at this stage) and we studied ST behaviour during subsequent copulation. Males were randomly assigned to four treatments, which consisted of allowing the experimental male to copulate again 15 min or 1–3 days after his last ST. Fertility of females mated with the experimental males was analysed as a proxy for sperm viability. All males used the sperm that they translocated previously when the second mating took place 15 min after the manipulation, while the proportion of males that repeated ST increased steadily over time. Both treatment (time elapsed since last ST) and the interaction between treatment and ST (yes/no) had a significant effect on fertility, which decreased only in males that did not perform ST immediately before copulation. Additional experiments with damselflies of the genus *Calopteryx* showed also that males did not repeat ST when the time to the next copulation was less than a day. Our results suggest that sperm quality decays over time in odonates, and that males can choose whether to keep and reuse the sperm in the seminal vesicle or to discard it. We conclude that the special anatomical disposition of odonate males might increase selective pressures to maximize sperm viability and/or repeated intramale ST behaviour." **22452.** Vinko, D. (2019): Identity card: Temni slanišear (Selysiothemis nigra). *Trdozy. Bilten slovenskih terenskih biologov in ljubiteljev narave* 8(2): 41, 52- (in Slovenian) ["*S. nigra* is a dragonfly from the family Libellulidae. It is easily distinguished from the rest of the species; the base of the wings is without a spot, the pterostigma and the thinner veins of the

wings are pale gray. The posterior and anterior veins of the pterostigma are thicker and black, reminiscent of the "=" equation. His wings resemble the fluttering of a flag even in a slight flutter. Males (fig. 1) are dark, almost black (fig. 2), often with a slightly bluish tinge. Females (Fig. 3) and young males (Fig. 4) are mostly sandy-colored, with dark brown programs on the breast and a dark pattern on the back. Most of the time, it rests on solitary twigs or plants near the water habitat, often with its rear slightly raised (Fig. 5). Larvae (Fig. 6), which grow up relatively quickly, live on aquatic vegetation and can tolerate high salt concentrations. It is a migratory and nomadic species. It is found near shallow ponds and lakes and reservoirs, also near brackish waters and in karst fields. *S. nigra* can be recognized by their characteristic well-developed dorsal and lateral spines (Fig. 7). We have recorded this small winged dragonfly, measuring only about 3 cm, only three times. It was observed twice in 2012 in the Škocjan Bay, and in 2019 adults and egg-laying were observed near Sermin (Fig. 8). It has recently been "naturalized" in the Gulf of Trieste and is apparently expanding its range, which is linked to climate change. It is scattered throughout the Mediterranean, in North Africa and in the east as far as the Arabian Peninsula and South-West Asia." **22453.** Voronin, M. Yu. (2019): Long-term monitoring of macrozoobenthos in the reservoir-cooler of Balakovo NPP. *Izv. Saratov Univ. (N. S.), Ser. Chemistry. Biology. Ecology* 19(4): 461-472. (in Russian, with English summary) ["For 8 years (2011–2018) macrozoobenthos samples were taken at the permanent stations in the reservoir-cooler of Balakovo NPP. Sampling stations were located in a highly heated part of the reservoir-cooler of the Balakovo NPP, and poorly heated part, in the adjacent water area of the Saratov reservoir. Differences were revealed: species richness and diversity; numbers and biomass; saprobity indices of the areas of these reservoirs; a positive or negative trend of long-term dynamics of the studied indicators macrozoobenthos. Over the study period the composition of benthic invertebrates of the reservoir-cooler of Balakovo NPP showed 42 species of aquatic organisms: ... Odonata [*Ischnura elegans*, *Orthetrum cancellatum*, *Platycnemis pennipes*] ... The species richness, abundance and biomass of macrozoobenthos of the highly heated thermal water part of the cooling reservoir of the Balakovo NPP is significantly lower compared to the cold-water one. The water reservoir-cooler of Balakovo NPP can be described as  $\alpha$ -mesosaprobic (moderately polluted, the 3rd quality class). Adjacent to the reservoir-cooler an area of the Saratov reservoir can be described as  $\alpha$ -mesosaprobic (contaminated, 4th class of quality). There was no statistically significant increase or decrease (from 2011 to 2018) in the number, or biomass of macrozoobenthos and saprobity of the studied reservoirs. A statistically significant increase in the number of macrozoobenthic species in the cooling reservoir of the Balakovo NPP was found. Due to the fact that by 2018, some restoration of submerged vegetation (previously depleted *Ctenopharyngodon idella*) and, accordingly, the phytophilic group of benthos began to be observed." **22455.** Zurek, R.; Bas, G.; Dumnicka, E.; Gloab, M.; Profus, P.; Szarek-Gwiazda, E.; Walusiak, E.; Cieczac, K. (2019): Plaszów pond in Kraków - biocenoses. *Chronmy Przyr. Ojcz.* 75(5): 345-362. (in Polish, with English summary) ["In 2017, a wildlife inventory was carried out for selected elements of the Plaszow Pond (Staw Plaszowski) biocoenosis and its surroundings. The species richness is relatively high, despite the fact that the fauna and flora of this water body are strongly affected by human activity in the highly urbanised environment, while the land development and busy streets significantly reduce the possibility of migration for many animal species. Aquatic and wetland plants were represented by 17 species, mainly common ones; the great horsetail *Equisetum telmateia* and common bladderwort *Utricularia vulgaris* were moderately abundant. In addition to bladderwort, the underwater meadows were composed of stoneworts from the genera *Chara* and *Nitellopsis* as well as filamentous yellow-green algae *Vaucheria* sp. A total of 21 zooplankton species, numerous zoobenthos taxa and seven fish species were found in the pond. Of the 24 identified dragonfly species, at least half are breeding in the pond. Only two amphibian taxa and three reptile species were recorded, including an alien (non-indigenous) species in our fauna, i.e. Cumberland slider *Trachemys scripta troostii* - a turtle coming from the USA. ... Nonetheless, the biological richness of the pond is endangered and certain measures should be taken to preserve it. ... Dragonflies: The tank is characterized by a typical, average odonata-fauna in terms of both the number and species composition. 24 species of vases were found, including one protected species - *Sympecma paedisca*. In addition, two southern species were observed: *Sympetrum fonscolombii* and *Crocothemis erithrea*. No representatives of the Lestidae family were found. In the case of the presence of two river species, *Calopteryx splendens* and *C. virgo* were probably individuals that flew from nearby watercourses. Probably, most of the species found were growing in the Plaszowski pond, but based on the presence of adolescent and observed reproductive behavior, they were able to confirm the reproduction only for half of them." **22456.** Carbonell, J.A.; Stoks, R. (2020): Thermal evolution of life history and heat tolerance during range expansions toward warmer and cooler regions. *Ecology* 101(10). e03134: 11 pp. (in English) ["Species' range edges are expanding to both warmer and cooler regions. Yet, no studies directly compared the changes in range-limiting traits within the same

species during both types of range expansions. To increase our mechanistic understanding of range expansions it is crucial to disentangle the contributions of plastic and genetic changes in these traits. The aim of this study was to test for plastic and evolutionary changes in heat tolerance, life history and behaviour, and compare these during range expansions toward warmer and cooler regions. Using laboratory experiments we reconstructed the thermal performance curves (TPCurves) of larval life history (survival, growth and development rates) and larval heat tolerance (CTmax) across two recent range expansions from the core populations in southern France toward a warmer (southeastern Spain) and a cooler (northwestern Spain) region in Europe by *Ischnura elegans*. First-generation larvae from field-collected mothers were reared across a range of temperatures (16 - 28 °C) in incubators. The range expansion to the warmer region was associated with the evolution of a greater ability to cope with high temperatures (increased mean and thermal plasticity of CTmax), faster development and partly a faster growth indicating a higher time constraints caused by a shorter time frame available for larval development associated with a transition to a greater voltinism. Our results thereby support the emerging pattern that plasticity in heat tolerance alone is inadequate to adapt to new thermal regimes. The range expansion to the cooler region was associated with faster growth indicating countergradient variation without a change in CTmax. The evolution of a faster growth rate during both range expansions could be explained by a greater digestive efficiency rather than an increased food intake. Our results highlight that range expansions to warmer and cooler regions can result in similar evolutionary changes in the TPCurves for life history, and no opposite changes in heat tolerance." **22457.** Dalal, J.; Sharma, S.; Bhardwaj, T.; Dhattarwal, S.K.; Verma, K. (2020): Seasonal study of the decomposition pattern and insects on a submerged pig cadaver. *Journal of Forensic and Legal Medicine* Volume 74, August 2020, 102023: 9 pp. (in English) ["Research on studying the decomposition pattern in aquatic habitat is very sparse worldwide. Due to this void, assessment of the postmortem submersion interval (PMSI) of drowned and submerged cadavers is still inaccurate and imprecise. The current work focused on studying the decomposition pattern and insects associated with submerged pig (*Sus scrofa*) carcasses during various seasons (winter, spring, summer, and rainy) for two years. The total postmortem submersion interval (PMSI) from the fresh stage till the sunken remains stage varied from 25 days for rainy season (624.5 ADD) to 78 days (1890.5 ADD) for winter season. The spring season at 44 days (1067.5 ADD) and summer season at 31 days (763.5 ADD) had moderate PMSI. During this time interval, five stages of decomposition were studied: submerged fresh, early floating, floating decay, advanced floating decay, and sunken remains. A total of 2385 insect specimens were found to be associated with different decomposition stages. The terrestrial activity during the first stage (submerged fresh) was almost nil as the carcasses were submerged. During the early floating stage (2nd stage), various terrestrial insect species visited the carcass and laid their eggs along with the presence of Chironomidae, Coenagrionidae, Lestidae, Aeshnidae families were also found associated with this stage. In the floating decay (3rd stage), the insects visiting and colonizing the carcass were from Coenagrionidae, Gomphidae, Aeshnidae, Gomphidae, Libellulidae, Chironomidae families along with Calliphoridae (Diptera). Species from the group of scavenging aquatic beetles (Hydrophilidae), *Enochrus esuriens*, *Regimbartia attenuata* (Fab),

Helochaeres sp. and burrowing water beetles, *Canthydrus laetabilis* (Family: Noteridae) and some terrestrial species of beetles, i.e. *Saprinus* sp., *Saprinus pensylvanicus* and *Necrobia rufipus* (Family: Histeridae) were also present during the 3rd, 4th and 5th stages. During advanced floating decay (4th stage) and sunken remains (5th stage), many hemipteran species such as *Ranatra digitata* and *Ranatra filiformis* (Fab) along with many coleopterans were found visiting the corpse." **22458.** Desjonquères, C.; Gifford, T.; Linke, S. (2020): Passive acoustic monitoring as a potential tool to survey animal and ecosystem processes in freshwater environments. *Freshwater Biology* 65(1): 7-19. (in English) ["\* Biodiversity in freshwater habitats is decreasing faster than in any other type of environment, mostly as a result of human activities. Monitoring these losses can help guide mitigation efforts. In most studies, sampling strategies predominantly rely on collecting animal and vegetal specimens. Although these techniques produce valuable data, they are invasive, time-consuming and typically permit only limited spatial and temporal replication. There is need for the development of complementary methods. \* As observed in other ecosystems, freshwater environments host animals that emit sounds, either to communicate or as a by-product of their activity. The main freshwater soniferous groups are amphibians, fish, and macroinvertebrates (mainly Coleoptera and Hemiptera, but also some Decapoda, Odonata, and Trichoptera). Biophysical processes such as flow or sediment transport also produce sounds, as well as human activities within aquatic ecosystems. \* Such animals and processes can be recorded, remotely and autonomously, and provide information on local diversity and ecosystem health. Passive acoustic monitoring (PAM) is an emerging method already deployed in terrestrial environments that uses sounds to survey environments. Key advantages of PAM are its non-invasive nature, as well as its ability to record autonomously and over long timescales. All these research topics are the main aims of ecoacoustics, a new scientific discipline investigating the ecological role of sounds. \* In this paper, we review the sources of sounds present in freshwater environments. We then underline areas of research in which PAM may be helpful emphasising the role of PAM for the development of ecoacoustics. Finally, we present methods used to record and analyse sounds in those environments. \* Passive acoustics represents a potentially revolutionary development in freshwater ecology, enabling continuous monitoring of dynamic bio-physical processes to inform conservation practitioners and managers." **22459.** DuBois, R.B. (2020): Odonata drift: a reassessment. *International Journal of Odonatology* 23(4): 381-396. (in English) ["More than 400 scientific journal articles and gray literature reports that addressed macroinvertebrate drift were reviewed and 63 articles were found that reported on the natural drift of Odonata at some taxonomic level. Forty-three species and 44 genera within 15 families (nine Zygoptera; six Anisoptera) were documented in the drift. Drift of another 13 species and eight genera was inferred from indirect evidence. The mean drift density reported was  $0.03 \text{ m}^{-3}$  (range  $<0.001\text{--}0.153 \text{ m}^{-3}$ ), which is relatively low, but not unexpected because benthic densities of Odonata are often lower than those of the macroinvertebrate taxa that occur more frequently in the drift. Percent composition of odonates in the

total drift was invariably  $<10\%$  and usually  $<1\%$ , but the percent was slightly higher if expressed as biomass or volume because odonate larvae are relatively large. Most odonates that drifted were not full grown. High flows were often associated with drift of Odonata, but not exclusively so; drift was highest at night and during summer months. Accidental (catastrophic) drift and active, behavioral drift to colonize new habitats and reduce crowding are thought to be the primary causes of Odonata drift, but its ecological significance would benefit from more research. The presumption that Odonata have a low predisposition to drift is probably not uniformly accurate. Use of drift nets specifically to collect odonates is unlikely to be as efficient as other collection methods in most circumstances, but it should not be entirely dismissed because drift nets are easy to set, relatively clean to operate, do not destroy habitats, and provide integrated samples of various habitats where it might be difficult or unsafe to use other methods." **22461.** Franke, S.; Brandl, R.; Heibl, C.; Mattivi, A.; Müller, J.; Pinkert, S.; Thorn, S. (2020): Predicting regional hotspots of phylogenetic diversity across multiple species groups. *Diversity and Distributions* 26(10): 1305-1314. (in English) ["Aim: The protection of phylogenetic diversity has become a priority in conservation biology, but its achievement requires a detailed understanding of (a) hotspots of phylogenetic diversity on a management-relevant scale and (b) the land use and climate factors determining local phylogenetic diversity. In this study, we identified spatial patterns of taxonomic and phylogenetic diversity and their environmental drivers. Location: Bavaria, Germany. Methods: To map the cross-taxon phylogenetic diversity, we combined species distribution data obtained from country-wide monitoring programmes and phylogenetic trees of birds, bats, dragonflies, grasshoppers and butterflies and calculated the phylogenetic diversity standardized by species richness. Generalized additive models were used to test the effects of land use and climate on phylogenetic diversity. We identified hotspots of phylogenetic diversity and assessed the extent to

which established protected areas in Bavaria cover these hotspots. Results: High coverage by urban areas, arable land and water bodies negatively affected the phylogenetic diversity of most species groups. The phylogenetic diversity of birds increased with increasing meadow cover. Climate did not influence the phylogenetic diversity of the studied groups. We identified 10 regional hotspots that contained the highest standardized phylogenetic diversity across the examined species groups. There was a strong mismatch between hotspots of phylogenetic diversity among the species groups. Protected areas (national parks, natural reserves and areas of the Flora-Fauna-Habitat Directive) overlapped only to ~9.6% with these hotspots of standardized phylogenetic diversity. Main conclusions: Cross-taxon approaches are required to identify hotspots of phylogenetic diversity at a management-relevant scale. At regional scales, land use was more important than climate in determining phylogenetic diversity. Our study highlights the importance of involving land users into strategies for protecting phylogenetic diversity." **22464.** Kagimoto, B. (2020): A report on the Conservation of *Orthetrum poecilops* Ris, 1919. Tombo 62: 20-22. (in Japanese, with English summary) ["*O. poecilops* is a very rare species of dragonfly which is found only in Miyajima, Japan and in Fujian and Guangdong in China, including Hong Kong. At Miyajima the habitat is curiously a marsh near the

sea shore, where sea water flows in on a spring tide. Such a habitat is very vulnerable to any pressure of development. However Miyajima has been a forbidden island to develop as "God's island" because the God of Shinto is believed to reside there. In 2005 the Conservation committee started. This committee comprised staff from the Ministry of Environment, Hiroshima Prefectural Government, Hatsukaicm City and consisted mainly of specialists in insects. The project was to build fences to exclude invading wild bore around habitats in all 4 areas in Miyajima, so that the number of specimens of *O. poecilops* could be assessed, and to breed larvae from eggs artificially and so on. Thanks to these activities, the number of *poecilops* is increasing. From 2018 a new project has begun. The Conservation committee attempted to create a 5th habitat on the island. There are two big problems for Conservation. One is a lack of funds for everything. Another is pollution from scrap plastic. Fortunately the latter has little influence on the habitat at present. Thanks to such activities by the Conservation committee, *O. poecilops* has been able to survive on Miyajima Island." (Author)] Address: Email: miyajimatono@yahoo.co.jp

**22465.** Kita, H.; Suda, S. (2020): Habitat and Conservation Status of *Paracercion plagiosum* (Needham, 1930). Tombo 62: 9-12. (in Japanese, with English summary) ["*P. plagiosum* is designated as Endangered Class B (EN) in the Ministry of the Environment Red List category. Recently, many of the existing production areas have been lost and many of them are in crisis. The authors looked at the current status of habitats and conservation. To date, *P. plagiosum* has been found in ten prefectures in Tohoku and Kanto regions, of which Kanagawa Prefecture has become extinct and many habitats in other areas are at risk. It is important that this species inhabits abundant aquatic plants that serve as spawning substrates, but *P. plagiosum* tends to decline when aquatic plants decrease due to deteriorating water quality. Although many efforts have been made for *P. plagiosum*, such as habitat conservation and selection of important wetlands, the degradation of its habitat and the decline of this species are progressing at a faster speed. It shows how difficult it is to conserve this species, which is locally distributed only on human-sensitive plains and has high environmental preference." **22466.** Koch, L. (2020): Libellen als Indikatoren für den ökologischen Zustand einer Region. *Natur und Umwelt im Pannonschen Raum* 30(2): 7. (in German) [Verbatim/Google translate: Dragonflies as indicators of the ecological condition of a region The Seewinkel region is one of Austria's "dragonfly hotspots": Of the 78 dragonfly species currently in Austria, around 50 are found here. Despite the extinction of insects, dragonflies are important indicators of the ecological condition of a region. The time of the impressive giant dragonflies with a wingspan of up to 70 cm in the Carboniferous period is over, but dragonflies still fascinate many people to this day. Due to the high diversity of different habitats, the Seewinkel region in Burgenland is home to around 50 species of dragonflies. The region offers, among other things, one of the rare Central European inland occurrences of the dark rush damselfly (*Lestes macrostigma*), which in the Seewinkel occurs primarily on salt lakes with brackish reed beds. Studies from 2008 showed that species that prefer to spend time on salt lakes appear to be experiencing a decline in their populations. This is due, among other things, to large-scale lowering of groundwater, which results in a change in the water regime and thus promotes the plants to dry out earlier in the season. The good news: Through renaturation measures in

bodies of water, former habitat losses can usually be quickly compensated for, as many dragonflies are known to quickly return to their former habitats. *Libellula depressa* and *Orthetrum coerulescens* are positive examples of this. Although these species were considered endangered in Burgenland until the 1980s, they are now benefiting from the improvement in water quality in gravel pits and rivers, so that their populations are now considered stable and, in the case of the *C. coerulescens*, are even increasing. Two thirds of the dragonfly species found in Austria are now endangered. Many of them are on the red list. Preserving as large a variety of dragonflies as possible is particularly important from a nature conservation perspective, as the presence or absence of a particular dragonfly species in a body of water can provide essential information about the ecological quality of their environment: dragonflies act as so-called bioindicators; i.e. indicator organisms that are used in conservation biology to obtain information about the ecological status of a habitat. It remains questionable whether an improvement in general water quality will be sufficient in the long term to protect dragonfly species that have become rare. Due to the current climate crisis, there are winners among dragonflies, who are expanding their range due to climate change, and losers, whose populations are expected to decline over the next few years. Nevertheless, habitat renaturation measures are extremely important, as they ultimately benefit the preservation and improvement of our fantastic nature and environment, of which these fascinating little animals are certainly the best proof.] Address: Koch, Laura, Naturschutz und Biodiversitätsmanagement sowie Zoologie an der Universität Wien

**22467.** Li, L.; Park, Y.-S. (2020): Habitat availability and environmental preference drive species range shifts in concordance with climate change. *Diversity and Distributions* 26(9): 1343-1356. (in English) ["Aim: A progressive increase in air temperature is recognized as the most important mechanistic driver of species range shifts. However, only a few studies have simultaneously considered the influence of both extrinsic and intrinsic mechanistic drivers; there are still no studies on the roles of extrinsic and intrinsic drivers that regulate such species changes. We investigated how species will shift their geographical ranges to cope with future climate change and analysed the relative importance of the mechanistic drivers in governing species range shifts. Location: 16 countries in South, West and North Europe. Methods: We used ensemble species distribution models on the European continental scale to predict 105 odonate species in response to climate change in the future decades until 2080s under three emission scenarios. We evaluated the projected changes in four community metrics (distribution area, optimum position, leading edge and trailing edge) and investigated how these changes are driven by extrinsic and intrinsic factors. Results: The odonate species were predicted to shift their range margins poleward, with a higher migration rate towards the trailing edge (2.38-10.34 km/year) than the leading edge (1.13-2.00 km/year). Contrary to the assumption that the response of the odonate species to climate change will linearly accelerate over time, the distribution areas of odonate species were predicted to increase until 2050s and then decline until 2080s under RCP 2.6 (representative concentration pathway). However, their distributions under RCP 4.5 and RCP 8.5 were predicted to decrease over time, with a higher rate under RCP 8.5. Overall, environmental preference and habitat override dispersal ability govern the range shift of odonate species. Main conclusions: Quantifying the relative importance of extrinsic and intrinsic factors across a large spatial scale under different emission scenarios can help understand the mechanistic processes to facilitate species range shifts."]

(2020): Importation of dragonfly nymphs (Odonata: Anisoptera) to control mosquito larvae (Diptera: Culicidae) in southern Maine. *Northeastern Naturalist* 27(2): 330-343. (in English) ["A long-standing program in Maine promotes stocking of dragonfly (Odonata) nymphs for biological control of nuisance and vector mosquitoes. Currently the only sources of dragonflies for stocking are out-of-state biological supply companies. In 2 dragonfly shipments from suppliers in Massachusetts and North Carolina, we determined that 6.8% and 38.5% of species, respectively, were not native to Maine. In an experiment of stocking efficacy, we introduced 4, 2, or 0 dragonfly nymphs into artificial pools in a forest habitat and found no differences in mosquito larvae counts among treatments. While the motivation for using dragonflies as biological control agents is commendable, the practice may be ineffective, and risks accidental introductions of non-native aquatic plants and animals in water used for shipping." Follow journal DOI: 10.1088/1742-6596/1725/1/01-2035: 6 pp. (in English) ["We investigated the diversity and distribution of Odonata inhabiting lakes at Universitas Indonesia, Depok, West Java in November 2017. The Study aimed to characterize the lakes based on the occurrence of some Odonata species. There were six study sites: Lake Agathis, Lake Kenanga, Lake Mahoni, Lake Puspa, Lake Salam, and Lake Ulin. Species of Odonata encountered within the study sites were caught using sweep nets, photographed and then released. A total of 16 species of Odonata were found including 12 dragonflies and 4 damselflies. The dragonflies were represented by two families. Of the 12 species of dragonflies recorded, 11 were from the family Libellulidae and 1 was from the family Gomphidae. *Brachydiplax chalybea* and *Orthetrum testaceum* were the most widely distributed species. However, the abundant species were *O. testaceum* and *Zygomma obtusum*. Damselflies were poorly represented, with only four species from two families, Coenagrionidae and Platycnemididae. Based on the species composition of Odonata from six lakes at Universitas Indonesia we conclude that most species are eurytopic or generalist that are widespread and tolerant to a wide range of environmental variables. In the current study, we consider that all lakes at Universitas Indonesia are disturbed habitats which are generally unsuitable for specialist or stenotopic species." **22479.** Dada, O.C. (2021): Ecological studies on the diversity of Odonata (Insecta) in Ipogun, Ifedore local government area, Ondo state, Nigeria. M.Tech. thesis, Environmental Biology & Public Health, Federal University of technology,

Akure, Ondo State, Niveria: (in English) ["Odonata are particularly good indicators of freshwater ecosystem health. The constant disturbance of freshwater habitats can result in reduction of Odonata species diversity. Changes in Odonata diversity are influenced by human activities such as urbanization, agriculture and input of pollutants in water. This study assessed the abundance and diversity of Odonata along River Aponmu in Ipogun. A total of 906 individuals representing 64 species and 16 genera in seven families (Coenagrionidae, Lestidae, Platycnemididae, Chlorocyphidae, Calopterygidae, Libellulidae and Gomphidae) were collected and identified. Of the 906 individuals, Libellulidae had the highest percentage composition (44%) with 395 individuals out of which *Trithemis arteriosa* (a pollution tolerant species) had the highest number of individuals (225) and Gomphidae had the lowest percentage composition (0.03%) with 1 individual. Most of the species collected had tolerance for disturbed environment including *Pseudagrion melanicterum*, *Paragomphus genoi* and *Orthetrum julia*. Aponmu area had the highest species diversity ( $H' = 2.312$ ) while Idi area had the least species diversity ( $H' = 2.021$ ). Alaasin area had the highest Simpson\_d value (0.8557) and the best taxa distribution (Evenness=0.524; Equitability\_J= 0.7764) which made the area a more pristine site than the other sites while Aponmu area had the least distribution (Evenness=0.3365; Equitability\_J= 0.6798). Cluster analysis revealed a close similarity between the Odonata assemblages at Alaasin and Aponmu areas while that of Idi area was quite different. Analysis of variance (ANOVA) of physico-chemical parameters revealed that temperature ( $^{\circ}\text{C}$ ), pH, Dissolved Oxygen (DO), turbidity (NTU), Biochemical oxygen demand (BOD), Nitrate ( $\text{NO}_3$ ) and Phosphate ( $\text{PO}_4$ ) did not show significant difference at the three sites while Electrical Conductivity ( $\mu\text{S}/\text{cm}$ ) and Total dissolved solids (mg/L) which had moderately high mean values indicated significant difference at Aponmu area ( $p < 0.05$ ). *Trithemis arteriosa* exhibited a weak negative correlation to both temperature and Dissolved Oxygen (DO). This study has provided information on Odonata assemblage and physico-chemical parameters at River Aponmu and therefore infers that some parameters influence the abundance of some Odonata species and River Aponmu is somewhat polluted as it receives more pollutants resulting from human activities around it and could be unsafe for drinking." **22482.** Dolný, A.; Pyszko, P.; Šigitová, H. (2021): Community changes in odonate monitoring: why are long-term studies so relevant? *Insect Conservation and Diversity* 14(5): 597-608. (in English) ["1. Most ecological studies involving insects are based on medium- and short-term observations; however, the extent to which such data captures reality remains unclear. 2. We investigated the long-term dynamics of two Odonata communities (disturbed and undisturbed sites) over 18 years and analysed the differences in the short- and long-term results. We also focused on the sampling methodology to enhance the efficacy and objectivity of long-term monitoring involving Odonata. 3. During one year, we captured only 53% of the overall species richness; during three consecutive sampling years, it was 65%. To capture 95%, we needed 16 years. Changes in quantitative similarity (Renkonen index, P) were more pronounced within sites over time than between sites. Species constancy significantly increased with the maximum abundance class but decreased with increasing fluctuation ratio and specialisation (Dragonfly Biotic Index). Based on exuviae, we detected half of the species compared to adults, but the species accumulation curves peaked after a few sampling years. 4. Long- and short-term monitoring yield different results, both qualitatively (species richness, specialisation) and quantitatively (abundance, dominance). Ideal sampling should be sequential, lasting at least 10 years (capturing >80% of species). Intermittent sampling (one-year interspersed with pauses), allowing the inclusion of multiple sites in monitoring programme, may also provide satisfactory results when performed over a longer period. 5. Over the long term, sampling adults semi-quantitatively and exuviae qualitatively provided sufficient information, while being feasible in terms of both personnel and costs, thereby overcoming the main pitfalls of long-term monitoring programmes." **22484.** Erasmus, J.H.; Lorenz, A.W.; Zimmermann, S.; Weperner, V.; Sures, B.; Smit, N.J.; Malherbe, W. (2021): A diversity and functional approach to evaluate the macroinvertebrate responses to multiple stressors in a small subtropical austral river. *Ecological Indicators* 131, November 2021, 108206: 11 pp. (in English) ["Highlights: • Hex River is subjected to multiple stressors i.e. mining, industrial and urban effluents. • Water chemistry variables were main drivers of macroinvertebrate community changes. • Mining impacted community features differently than urban impacts. • Combined macroinvertebrate approaches were able to differentiate stressor groups. Abstract: Aquatic macroinvertebrates are considered effective bioindicators of ecosystem health due to their different sensitivities to habitat alteration and pollution. Macroinvertebrate community structures can be assessed using commonly used diversity-based approaches, however, functional trait-based approaches are increasingly introduced into bioassessments. The Hex River is subjected to intensive mining activities, while urban and industrial effluents, as well as treated and untreated sewage also contributes to pollution in the river. The present study aimed to assess macroinvertebrate responses to different stressors (nutrient and chemical, especially metal pollutants), determine whether diversity-based or trait-based approaches provide a better indication of responses and, to evaluate the relationship between metal bioaccumulation and macroinvertebrate responses to this multi-stressor environment. The mining impacts, in combination with urban, industrial and sewage effluent, altered the macroinvertebrate community structure of the Hex River. The species richness significantly decreased from reference conditions (39 species) to impacted conditions (24 species), while the total number of individuals in tolerant species gradually increased. The diversity-based approach indicated a clear difference between reference and impacted conditions but did not clearly differentiate between different stressors, while the trait-based approach distinguished the urban, industrial and sewage effluent sites from mining impacted sites. The use of both approaches is, therefore, recommended as both complement each other. From the present study, it is evident that macroinvertebrates can be considered as both reliable accumulation-, and response bioindicators to pollution from mining, as well as urban and industrial activities. ... The species response curves revealed that metals from mining activities (Cr, Ni, Pt) had a significant negative effect on ... Odonata species (Nothiothemis sp., Trithemis sp.). In contrast, ... Odonata species (Pseudagrion sp.) increased in response to higher metal concentrations (Supplementary data, Fig. S2 and S3). ... Nothiothemis sp. had a significant negative response to Cl<sup>-</sup>. Chemical oxygen demand (mg/L), Electrical conductivity (µS/cm), Ni in the water and sediment, SO<sub>4</sub><sup>2-</sup>, as well as Total hardness (mg/L)." (Authors) In the supplemental material, the following taxa are listed: *Lesites* sp., *Ellatoneura glauca*, *Platycypha caligata*, *Pseudagrion* sp., *Enallagma glaucum*, *Agriocnemis pinheyi*, *Notogomphus* sp., *Ceratogomphus* sp., *Paragomphus* sp., *Onychogomphus* sp.,

*Aeshna* sp., *Anax* sp., *Tetrathemis* sp., *Acisoma* sp., *Nothiothemis* sp., *Orthetrum* sp., *Bradinopyga* sp., *Pantala* sp., *Trithemis* sp., and *Sympetrum fonscolombii*.] Address: Erasmus, J.H., Water Research Group, Unit for Environmental Sciences and Management, North-West University, 11 Hoffman St, Potchefstroom 2520, South Africa. **22485.** Eslami Barzoko, Z.; Ebrahimi, M.; Kiany, M.; Sadeghi, S. (2021): Ecological drivers of Odonata beta diversity in arid and semi-arid regions of the Central Plateau of Iran. *Insect Conservation and Diversity* 14(1): 40-51. (in English) ["1. Freshwater habitats are among the most threatened and least studied habitats in arid regions of Iran. Discovering factors responsible for the spatial variation of biodiversity are one of the main considerations in conservation biology. As a first step towards developing conservation strategies, we aimed to investigate the beta diversity and response of Odonata assemblages to climate and landscape variables in arid and semi-arid regions of Iran. 2. A total of 120 water bodies were surveyed. The beta diversity distance matrices were calculated for Odonata, Anisoptera, and Zygoptera, using the Jaccard dissimilarity coefficient. Also, the replacement and richness difference components of Odonata beta diversity were computed. Each of the five dissimilarity matrices was modelled by generalised dissimilarity modelling (GDM). 3. We recorded 58 species of Odonata that represent 58% of the Odonata species in Iran. The average total beta diversity was high (0.873). GDMs results showed that the most influential variables varied between the replacement and richness difference components of Odonata beta diversity as well as between the two Odonata suborders. Anisoptera were most strongly affected by the temperature annual range, while the most important variable for Zygoptera was the average wind speed in April. 4. Our results suggest that the studies of the drivers of biodiversity patterns benefit from beta diversity partitioning also from comparing species groups with different ecological preferences. The high biodiversity of the studied water bodies as well as the anthropogenic and climate threats that they are faced with, make these ecosystems a conservation priority." **22486.** Fujita, Y.; Lima, M. (2021): Unsteady lift generation of corrugated wing by lambda vortex collapse. *Bulletin of the American Physical Society, 74th Annual Meeting of the APS Division of Fluid Dynamics, Sunday–Tuesday, November 21–23, 2021; Phoenix Convention Center, Phoenix, Arizona, Session P13: Biological Fluid Dynamics: Flying Insects. 4:05 PM–6:41 PM, Monday, November 22, 2021, Room: North 127 ABC:* (in English) [Verbatim: "Dragonfly wing is not smooth but corrugated; its vertical cross-section consists of connected series of line segments. Some previous studies suggest that the aerodynamic performance of the corrugated wing is higher than that of the flat wing at the low Reynolds numbers ( $Re \sim O(10^3)$ ). However, the details are not fully investigated. In particular, the aerodynamic characteristics and flow property during unsteady wing motion has not been studied in detail because of the complicated flow characteristics. In this study, we analyzed flow around two-dimensional corrugated wing model that started impulsively by direct numerical simulations. We focused on a period between the generation of the leading-edge vortices (LEVs) and subsequent interactions, and its detachment. For the flat wing, so-called lambda vortex with the sign opposite to LEV. On the other hand, for the corrugated wing, the lambda vortex collapsed and stuck in the valleys of the corrugated

structure in a parameter range. The lambda vortex collapse changes the LEV dynamics to encourage the instantaneous lift enhancement of the corrugated wing. In the presentation, we will discuss the details." (Authors)] Address: Fujita, Yusuke, Program of Mathematical & Life Sciences, Graduate School of Integrated Sciences for Life, Hiroshima University

**22487.** Goldner, J. (2021): Investigating metapopulation responses to landscape-level habitat changes. PhD thesis, Faculty of Purdue University, Department of Entomology, West Lafayette, Indiana: 122 pp. (in English) ["The study of landscape structure and configuration is firmly established as integral to the continued advancement of ecology. The configuration of resource patches can have far-reaching implications for biodiversity, metapopulation dynamics, community structure, and habitat quality. Human activities, such as forestry, agriculture, and residential construction alter patch configuration by breaking larger patches into smaller fragments. This frequently results in pronounced, unforeseen consequences for species. The fragmentation and shrinking of habitat patches can lead to changes in the environmental conditions within the remaining patches (e.g., degradation), prompting responses from local populations. These responses can, in turn, cause changes to the metapopulation structure on large spatial scale. I examined the relationship between the degree of habitat fragmentation (edge density), and foraging lengths of *Calopteryx maculata*. I used correlated random walks to determine the biologically relevant landscape area over which forest fragmentation was calculated. Then, I used Moran's I to determine the spatial scale of wing length response to fragmentation. I found that wing lengths increased with edge density. I also found that wing lengths were spatially autocorrelated at distances below 5 Km. These findings suggest that damselflies adapt to changes in forest fragmentation at a relatively small spatial scale. Next, I assessed the slime mold *Physarum polycephalum*'s usefulness as a microcosm of dispersal in fragmented landscapes. Slime mold plasmodia were placed in dishes with oat patches of varying sizes and distances. The probability of each patch type being colonized first was compared to predictions of patch occupancy based on *C. maculata*. Patches that were nearer or larger were likely to be colonized before patches that were more distant, or smaller. Observed patch occupancy matched model predictions when only patch distance was varied, but not when patch size was varied. These results suggest that *P. polycephalum* has the potential to serve as a useful microcosm of dispersal in patchy landscapes. However, more testing is needed to develop the microcosm system. Finally, a lesson plan was developed to teach high school students about the concepts of landscape ecology and connectivity. An emphasis was placed on using active learning techniques, which have been demonstrated to result in greater understanding than traditional lecture formats. The lesson plan incorporates an education boardgame, *Humans & Habitats*, that I developed to illustrate how the conflicting goals of resource managers impact habitat connectivity. It also incorporates a scientific inquiry activity that uses *P. polycephalum* to test predictions about the effect of altered connectivity. The lesson plan and materials will be available to members of the public, free of charge." **22488.** Hasik, A.Z. (2021): Host-parasite interactions within food webs. PhD thesis, University of Arkansas, Fayetteville: 141 pp. (in English) ["Parasitism is one of the most common life history strategies employed in nature, yet the effects of

parasites are often thought to be minimal, and the vast majority of studies fail to consider parasites and their effects on host organisms. This is likely a problem, as the magnitude of parasite-mediated effects on their hosts can be quite large. Additionally, the effects of parasites are known to extend beyond the host to affect other species interactions. I used a series of approaches to gain a more integral understanding of host-parasite interactions by studying (1) the effects of parasites on biotic interactions that hosts engage in, (2) how biotic interactions such as predation and competition can affect host immune defense, and (3) how abiotic and biotic factors within the local environment affecting the host can further mediate parasitism dynamics. Specifically, in Chapter 1 I conducted a phylogenetically informed meta-analysis of the effects of parasites on species interactions (i.e., predation, competition, mutualism, and reproduction). I found that despite a strong overall negative effect on species interactions, the effects of parasites surprisingly ranged from being strongly beneficial to strongly deleterious on host species interactions. In Chapter 2 I used larval damselflies and their dominant fish predator to test how cascading effects of predators on host competitive interactions and resource acquisition affected a critical component of damselfly immune function, the phenoloxidase (PO) cascade. I found that neither direct density-mediated effects, indirect, trait-mediated effects, nor combined effects of predators via natural selection affected total PO activity. Instead, PO levels increased with resource availability, implying resource limitation. Finally, in Chapter 3 I used two field experiments and a detailed observational study to investigate how host, abiotic, and biotic factors within the local environment affected the relationships between *Enallagma* spp. hosts and their water mite (*Arrenururs* spp.) ectoparasites. I found that parasitism was species-specific and did not vary with host density or host condition (i.e., immune function). Instead, parasitism was largely predicted by abiotic factors (i.e., pH). Collectively, my results indicate that parasites are key players in the complex web of species interactions that compose food webs. Furthermore, host-parasite interactions are mediated by many of the same ecological factors as other species interactions, which has implications for parasitism dynamics within ecological communities. Future studies of food webs must incorporate parasites into their experimental and theoretical designs, and future studies of host-parasite interactions must expand beyond the focal relationship and consider the ecology of both the host and parasite." **22489.** Hojaji, M.; Soufivand, M.R.; Lavimi, R. (2021): An experimental comparison between wing root and wing tip corrugation patterns of dragonfly wing at ultra-low Reynolds Number and high angles of attack. *Journal of Applied and Computational Mechanics* 8(4): 1176-1185. (in English) ["This study presents the empirical comparison between the wing root and wingtip corrugation patterns of dragonfly wing in the newly-built wind-tunnel at the IAUN. The main objective of the research is to investigate the effect of wingtip and wing root corrugations on aerodynamic forces and the flow physics around the cross-sections at  $Re=10000$  and the angle of attack of  $0^\circ$  to  $30^\circ$ . For this aim, two cross-sections are extracted from wing root (first cross-section) and wingtip (second cross-section). The first cross-section has corrugations with higher density than the second cross-section. The comparison of lift coefficients obtained from pressure distribution and force measurement indicates an acceptable agreement between the results. Also, Particle Image Velocity (PIV) technique is used to measure the velocity field. The

results show that all corrugation patterns do not have positive effects on the aerodynamic forces. The second cross-section can generate considerable aerodynamic forces compared to the first cross-section. At  $\alpha=25^\circ$ , the lift coefficient generated by the second cross-section is 90% and 25% higher than that of the first cross-section and the flat plate, respectively. Based on results, corrugations in the wing root's vicinity have a crucial role in the solidity of insect wings; however, corrugations in the wing tip's vicinity play a vital role in generating adequate aerodynamic forces. The comparison conducted in the current research reveals the second cross-section is an appropriate replacement for the flat plate in MAVs due to generating more essential forces for flight." **22490.** Komaki, S. (2021): Widespread misperception about a major East Asian biogeographic boundary exposed through bibliographic survey and biogeographic meta-analysis. *Journal of Biogeography* 48(9): 2375-2386. (in English) ["Aim: The Watase line, a major biogeographic boundary between Palearctic and Oriental realms in East Asia, is generally drawn between Akuseki and Kodakara Islands of the Northern Ryukyu archipelago, Japan. However, no evidence can be found to support the positioning of the boundary between these two tiny volcanic islands. This study aimed to confirm whether and where the biogeographical boundary should be drawn. Location: East Asia. Taxon: Land snail, ant, dragonfly, butterfly, amphibian, reptile, bird and plant. Methods: A bibliographic survey was carried out to revisit an original definition of the Watase line and its usage. Biogeographic and meta-analyses were also performed using a Simpson dissimilarity index calculated from published distribution data to test whether and where any biogeographic boundary exists. To ensure the validity of the study design, similar surveys and analyses were conducted in another region of Southern Ryukyu, where a reliable biogeographic boundary has been proposed as a positive control. Results: The bibliographic survey showed that the Watase line had been described without specifying the precise position. No revised definition has been proposed for the boundary to date. Biogeographic analyses do not support the existence of a boundary between Akuseki and Kodakara Islands. Meanwhile, the presence of a boundary in Southern Ryukyu was endorsed by both the bibliographic survey and biogeographic analyses, supporting the validity of this study's design. Main conclusions: This study revealed that the major biogeographic boundary is widely used with deviations from the original definition. Presumably, ideas based on inappropriate evidence, such as the distribution of a symbolic species and unpublished data, have been referred to without being questioned and led to the current widespread misunderstanding. Misunderstandings like these could occur at any biogeographic boundaries around the world, and thus, systematic reviews of all boundaries are needed for an appropriate understanding of biodiversity." **22491.** Liu, C.; Du, R.; Li, F.; Sun, J. (2021): Bioinspiration of the vein structure of dragonfly wings on its flight characteristics. *Microscopy Research and Technique* 85(3): 829-839. (in English) ["Dragonflies have excellent flight characteristics, which are inextricably related to the characteristics of their wings. Their wings not only support a variety of loads during flight but also maintain high-efficiency flight characteristics. In this study, the forewing of *Pantala flavescens* was

used as a research object to explore the microstructure of the surface, cross section, and the vein distribution. Three-dimensional models of three different structures of the forewing vein, including an oval-shaped hollow tube, a circular hollow tube, and a circular solid tube, were established. Fluid dynamics analysis of these three forewing models under different angles of attack during gliding was carried out by FLUENT software, and subsequently, the influence of the dragonfly forewing vein structure on its flight characteristics was analyzed. The numerical simulation results indicated that the vein structure has a considerable influence on the lift, drag, and lift-drag ratio of the *P. flavescens* forewing. It was indicated that among the tested models, the forewing model with oval-shaped hollow tubular veins has better flight efficiency and aerodynamic characteristics. The results of this study may provide the basis for a novel bionic concept of flapping wing microaircraft design." **22493.** Ryu, S.; Zhang, H.; Salcedo, M.; Socha, J.J.; Pass, G. (2021): Circulatory flow patterns in a dragonfly wing elucidated from a microfluidic model. *Bulletin of the American Physical Society. 74th Annual Meeting of the APS Division of Fluid Dynamics. Sunday–Tuesday, November 21–23, 2021; Phoenix Convention Center, Phoenix, Arizona. Session P13: Biological Fluid Dynamics: Flying Insects. 4:05 PM–6:41 PM, Monday, November 22, 2021, Room: North 127 ABC*: (in English) [Verbatim: "Insect wings consist of a network of tubular veins and thin inter-connected membrane. Within these veins are hemolymph (blood), tracheal branches (oxygen delivery), and nerves connected to vital sensory organs on the wing. Since blood flow supplies water and nutrients to the sensory organs and other tissues and removes waste products, veins and hemolymph flow are crucial for stability, flexibility, and functionality of the delicate wing blade. However, the relationship of wing venation on hemolymph circulation remains poorly studied. Previous experiments tracking hemocytes (blood cells) in transparent veins of living specimen gave some insight into some flow patterns. To investigate detailed hemodynamics in complex wing venation, we used photo/soft-lithography to create a microfluidic wing vein model of *Anax junius*. Blood flow was simulated by injecting dyed water into the veins using a range of flow velocities and input locations. Microbeads were used to characterize local flow patterns within the veins. Visualized flow patterns suggested that advection dominates near the wing

base, whereas diffusion dominates toward the wing tip. Biomimetic wing vein devices allow for further investigation into the insect wing's unique circulatory system and transport phenomena." (Authors)] Address: not stated

**22496.** Strausfeld, N.J. (2021): The lobula plate is exclusive to insects. *Arthropod Structure & Development* Volume 61, March 2021, 101031: (in English) ["Highlights: • Six specific neuroanatomical traits define the holometabolan lobula plate. • Neuropils claimed as lobula plates in malacostracans do not share any of those traits. • Traits identified in Odonata correspond to three traits defining holometabolan lobula plates, suggesting possible homology. Abstract: Just one superorder of insects is known to possess a neuronal network that mediates extremely rapid reactions in flight in response to changes in optic flow. Research on the identity and functional organization of this network has over the course of almost half a century focused exclusively on the order Diptera, a member of the approximately 300-million-year-old clade Holometabola defined by its mode of development. However, it has been broadly claimed that the pivotal neuropil containing the network, the lobula plate, originated in the Cambrian before the divergence of Hexapoda and Crustacea from a mandibulate ancestor. This essay defines the traits that designate the lobula plate and argues against a homologue in Crustacea. It proposes that the origin of the lobula plate is relatively recent and may relate to the origin of flight." **22500.** Mahmoud, M.M.; Younes, A.A.; El-Sherif, H.A.; Gawish, F.A.; Habib, M.R.; Kamel, M. (2022): Predicting the habitat suitability of *Schistosoma* intermediate host *Bulinus truncatus*, its predatory aquatic insect Odonata nymph, and the associated aquatic plant *Ceratophyllum demersum* using MaxEnt. *Parasitology Research* 121: 205-216. (in English) ["Schistosomiasis is one of the most important parasitic diseases in tropical and subtropical areas. Its prevalence is associated with the distribution of freshwater snails, which are their intermediate hosts. Thus, control of freshwater snails

is the solution to reduce the transmission of this disease. This will be achieved by understanding the relationship between the snails and their habitats including natural enemies and associated aquatic plants as well as the factors affecting their distribution. In this study, Maximum Entropy model (MaxEnt) was used for mapping and predicting the possible geographic distribution of *Bulinus truncatus* snail (the intermediate host of *Schistosoma haematobium*), Odonata nymph (predatory aquatic insect), and *Ceratophyllum demersum* (the associated aquatic plant) in Egypt based on topographic and climatic factors. The models of the investigated species were evaluated using the area under receiver operating characteristic curve. The results showed that the potential risk areas were along the banks of the Nile River and its irrigation canals. In addition, the MaxEnt models revealed some similarities in the distribution pattern of the vector, the predator, and the aquatic plant. It is obvious that the predictive distribution range of *B. truncatus* was affected by altitude, precipitation seasonality, isothermality, and mean temperature of warmest quarter. The presence of *B. truncatus* decreases with the increase of altitude and precipitation seasonality values. It could be concluded that the MaxEnt model could help introducing a predictive risk map for *Schistosoma haematobium* prevalence and performing better management strategies for schistosomiasis." **22501.** Paz, L.E.; Rodriguez, M.; Gulloc, B.; Rodrigues Capitulo, A. (2022): Impacts of urban and industrial pollution on functional traits of benthic macroinvertebrates: Are some traits advantageous for survival? *Science of The Total Environment* Volume 807, Part 2, 10 February 2022, 150650: (in English) ["Highlights: • Urbanization and industrialization decrease functional richness and Rao diversity. • Gills, grazers, and crawlers are sensitive traits to these disturbances. • Spiracles, resistance forms and cylindrical body are related to these disturbances. Abstract: Urbanization and industrialization produce substantial changes in biodiversity and in the functionality of ecosystems. However, little is known about how anthropic pressures might drive these changes and about their functional consequences. We aimed to determine the responses of macroinvertebrate biological traits to urban and industrial pollution and assess the impacts of these disturbances on the functional diversity of these assemblages. We sampled benthic macroinvertebrates in 27 sites of four basins with different urban disturbance gradients (rural, peri-urban, and urban-industrial), among them the Matanza-Riachuelo River, one of the most polluted basins in the world. We classified macroinvertebrates into 11 traits and 56 categories. Then, we performed an RLQ analysis and computed functional richness, evenness, divergence and Rao diversity indexes for each site and community weighted means for each trait category. The urban and industrial sites (mainly low and middle Matanza-Riachuelo River Basin) showed high concentrations of ammonium, SRP, conductivity, COD, BOD, and organic matter, as well as the lowest values of DO. The functional richness and Rao index of these sites were significantly lower than that of the other sites. Macroinvertebrate traits associated with urban and industrial sites were aerial respiration (spiracles), forms of resistance (eggs or statoblast), cylindrical body shape, oviparity, feeding on macroinvertebrates, and full water swimmers. These traits potentially enabled tolerant species persistence at polluted sites while gills, grazers, and crawlers were sensitive to these disturbances. Urban and industrial activities influence biological traits, producing the disappearance or dominance of certain traits in macroinvertebrate assemblages. As a consequence,

extreme pollution caused predictable trait-based community changes resulting in reduced functional diversity, and potentially altered the ecosystem function." (2022): Differential efficacy of edaphic traps for monitoring arthropods diversity in subtropical regions. *Journal of King Saud University – Science* 34 (2022) 101686: 7 pp. (in English) [Installation of traps in the agricultural field is an economically important and cheaper technique to observe arthropods diversity. Cost-effective ecological monitoring of arthropods by traps has been gaining interest in the field of environmental entomology since last few decades. This study explains the effectiveness of four different types of traps (pitfall, yellow-sticky, pan and barrier traps) to monitor the arthropod diversity in summer and winter seasons. These traps were installed in different mango orchards located in Punjab, Pakistan. diversity of captured arthropods was 1.5 times higher in summer than in winter season. However, among the traps, pitfall traps were most effective than others for trapping edaphic arthropods in both seasons. The pan traps were found most effective in the summer season, while sticky traps in the winter season. The pitfall traps exhibited highest taxa richness index values (8.00 for summer and 5.00 for winter season), while the lowest values were recorded for barrier traps (5.00 for summer and 3.00 for winter season). Moreover, the pitfall were the most effective traps for the capture or collection of Arachnida, Coleoptera, Hymenoptera, Lepidoptera, Orthoptera and other arthropods. The PVC barrier and sticky traps were found most effective for Dipteran and Hemipteran's insects, respectively, and hence, are recommended for the ecological monitoring of these arthropod groups in future studies. ... Pan trap type was most effective for the capture of Odonata order ( $F = 1.89$ ;  $P = 0.085$ )."] (Authors)] Address: Sial, M.U., Institute of Plant Protection, Muhammad Nawaz Shareef University of Agricultural, Multan, Pakistan

(2023): Identifikasi Tingkat Serangan Serangga Penggerek (*Hypothenemus hampei*) Taman Kopi dan musuh Alaminya Nur Apriani, Hasna UI Maritsa, Hesti Riany [Identification of the attack level of borer insects (*Hypothenemus hampei*) in coffee gardens and their natural enemies]. *Organisms* 3(2): 8 pp. (in Indonesian, with English summary) ["*H. hampei* is the main pest of coffee plants. *H. hampei* uses coffee fruit and beans as a shelter, lay eggs, eats, reproduces and metamorphoses. This causes damage to coffee plants thereby reducing the quality of the coffee. The aim of this research was to determine the level of attack by the *Hypothenemus hampei* insect on coffee plants and identify its natural enemies. The method for measuring the level of attack was done by counting the coffee cherries that are attacked by the *Hypothenemus hampei* pest on 3 branches of the coffee tree and the enemy and calculating it using the pest attack intensity formula. Natural enemies were collected by direct observation and identified by matching their morphological characteristics with reference books. The percentage of *H. hampei* pest attacks on Liberica Coffee reached 12.35-61.97%, while the percentage of *H. hampei* pest attacks on Robusta Coffee reached

5.83-35.48%. The natural enemies found were weaver ants (*Oecophylla smaragdina*), wolf spiders (*Pardosa pseudoannulata*), and dragonflies (*Neurothemis fluctuans*)." **22504.** Babik, W.; Dudek, K.; Marszalek, M.; Palomar, G.; Antunes, B.; Sniegula, S. (2023): The genomic response to urbanization in the damselfly *Ischnura elegans*. *Evolutionary Applications* 16: 1805-1818. (in English) ["The complex and rapid environmental changes brought about by urbanization pose significant challenges to organisms. The multifaceted effects of urbanization often make it difficult to define and pinpoint the very nature of adaptive urban phenotypes. In such situations, scanning genomes for regions differentiated between urban and non-urban populations may be an attractive approach. Here, we investigated the genomic signatures of adaptation to urbanization in *Ischnura elegans* sampled from 31 rural and urban localities in three geographic regions: southern and northern Poland, and southern Sweden. Genome-wide variation was assessed using more than 370,000 single nucleotide polymorphisms (SNPs) genotyped by ddRADseq. Associations between SNPs and the level of urbanization were tested using two genetic environment association methods: Latent Factors Mixed Models and BayPass. While we found numerous candidate SNPs and a highly significant overlap between candidates identified by the two methods within the geographic regions, there was a distinctive lack of repeatability between the geographic regions both at the level of individual SNPs and of genomic regions. However, we found "synapse organization" at the top of the functional categories enriched among the genes located in the proximity of the candidate urbanization SNPs. Interestingly, the overall significance of "synapse organization" was built up by the accretion of different genes associated with candidate SNPs in different geographic regions. This finding is consistent with the highly polygenic nature of adaptation, where the response may be achieved through a subtle adjustment of allele frequencies in different genes that contribute to adaptive phenotypes. Taken together, our results point to a polygenic adaptive response in the nervous system, specifically implicating genes involved in synapse organization, which mirrors the findings from several genomic and behavioral studies of adaptation to urbanization in other taxa." (2023): New data on biodiversity and chorology of aquatic insects of Tazekka National Park (Middle Atlas, Morocco) I: Odonata, Coleoptera, and Hemiptera. *Transactions of the American Entomological Society* 149(3): 261-297. (in English) ["Aquatic insects play a crucial role in freshwater ecosystems, and their diversity and distribution are important indicators of ecosystem health. In this study, we present old and new faunistic and distributional data on three orders of aquatic insects (Odonata, Hemiptera, and Coleoptera) in the Tazekka National Park, located in the Eastern Middle Atlas. An annotated list of 85 species is provided, of which 53 were identified from 1023 specimens collected seasonally between summer 2018 and summer 2019 at a total of 19 sampling sites. The remaining 32 species were identified from the literature but were not captured in this study. The 85 species are classified into 47 genera and 24 families, which are divided into 8 species of Odonata, 14 species of aquatic Hemiptera, and 63 species of aquatic Coleoptera. 18 of the captured species are new to the Tazekka National Park. A chorological analysis shows that most species are essentially Mediterranean (63%), whilst those whose distribution is wider in Palearctic (25%) or extends into Nearctic, Australian, or Afrotropical regions (12%) are clearly less represented. This chorotype pattern is similar to that observed for OCH in other national parks in northern Morocco." (2023): Prioritizing

the reassessment of data deficient species on the IUCN Red List. *Conservation Biology* e14139: 16 pp. (in English, with Spanish summary) ["Despite being central to the implementation of conservation policies, the IUCN Red List of Threatened Species is hampered by the 14% of species classified as Data Deficient (DD), either because information to evaluate these species' extinction risk was lacking when they were last assessed or because assessors did not appropriately account for uncertainty. With limited funds and time for reassessment, robust methods are needed to identify which DD species are more likely to be reclassified in one of the data sufficient Red List categories. Here we present a reproducible workflow to help Red List assessors prioritise reassessment of DD species, and tested it with 6,887 DD species of mammals, reptiles, amphibians, fishes, and Odonata. Our workflow provides for each DD species: (i) the probability of being classified in a data sufficient category if reassessed today, (ii) the change in such probability since last assessment, and (iii) whether the species might qualify as threatened based on the recent rate of habitat loss. Combining these three elements, our workflow provides a priority list for reassessment of species more likely to be data sufficient, thus ultimately improving knowledge of poorly known species and the comprehensiveness and representativeness of the IUCN Red List." **22510.** Cerini, F.; Vignoli, L.; Blust, M.; Strona, G. (2023): Functional traits predict species co-occurrence patterns in a North American Odonata metacommunity. *Ecosphere* 14(12), e4732: 11 pp. (in English) ["The probability of occurrence of a given species in a target locality and assemblage is conditioned not only by environmental/climatic variables but also by the presence of other species (i.e., species co-occurrence). This framework, already complex in nature, becomes even more complicated if one considers the functional traits of species that, in turn, might influence the structure of metacommunities in various ways. Depending on the ecological and environmental setting, functional similarity (i.e., convergence in morphological and ecological traits) between species might either reduce their co-occurrence due to high niche overlap driving negative interactions or promote it if the similar traits are associated with local habitat suitability. Similarly, functional divergence might either promote species co-occurrence by limiting negative interactions through niche separation or reduce it through trait mediated environmental filtering. Therefore, discriminating between these alternative scenarios—predicting whether two species will tend to co-occur or not based on their traits—is extremely challenging. Here, we develop a novel protocol to tackle the challenge, and we demonstrate its effectiveness by showing that ecological species traits can predict species co-occurrence in a large dataset of North American Odonata. To this end, we first used the Hierarchical Modeling of Species Communities framework to quantify the pairwise species co-occurrence after controlling for environmental and climatic factors. [Body length, Body coloration type, Flight mode, Body color, Presence of wing pigment, Habitat openness, Aquatic habitat type, Body color pattern, Hindwing length] Then, we used machine learning to generate models which proved capable of predict accurately the observed co-occurrence patterns from species functional traits. Our approach offers a generalizable analytical framework with the potential to clarify long-standing ecological questions." (2023):  $\beta$ -diversity of odonate community of the Ganga River: partitioning and insights from local and species contribution. *Wetlands Ecology and Management* 31: 899-912. (in English) ["The  $\beta$ -diversity studies reveal diversity patterns at a spatial scale and strengthen the process of regional diversity conservation. The aim of the current study was to understand the pattern of local contribution to  $\beta$ -diversity (LCBD) and species contribution to  $\beta$ -diversity (SCBD) of odonates in the Ganga River. We selected 27 sites along the banks of the Ganga River for the study, with an average distance between sites of 75 km, and recorded 30 species of odonate (species richness between 5 and 24) at these sites. Using  $\beta$ -regression analysis, we examined the impact of species richness and habitat variables on the LCBD. The LCBD was found to be negatively correlated with species richness and influenced by creeping macrophytes, water temperature, dissolved oxygen and salinity. We found that species with high SCBD scores (above 0.05) had intermediate occupancy (between 10 and 16 sites), including 5

species of dragonfly and 5 species of damselfly, and that the second-degree term the relationship between SCBD and the number of declared locations better stocked with species than in the first degree. Since the SCBD is responsible for identifying species that make the greatest contribution to  $\beta$ -diversity and the LCBD is responsible for identifying sites with particular combinations of species, the combined approach using both should be included for ecological assessments, river biodiversity restoration and maintenance plans." **22516.** Dewangan, N.K.; Pang, J.; Zhao, C.; Cao, C.; Yin, B.; Weng, S.; He, J. (2023): Host and transmission route of *Enterocytozoon hepatopenaei* (EHP) between dragonfly and shrimp. *Aquaculture* 574, 739642: (in English) ["*Enterocytozoon hepatopenaei* (EHP) is a shrimp pathogen that causes huge economic losses. In the present study, the hosts of EHP were investigated using polymerase chain reaction (PCR) in an aquaculture farm located in Maoming, China. EHP was detected in *Litopenaeus vannamei*, *Penaeus monodon*, *Varuna litterata*, *Mytilopsis leucophaeata*, and three dragonfly species (*Anax parthenope*, *Pantala flavescens*, and *Ischnura senegalensis*). In the histopathological examination using hematoxylin–eosin (HE) staining, EHP spores were found in nymphs and adult dragonflies naturally infected with EHP that were collected from the shrimp farm. Fluorescence in situ hybridization (FISH) results showed a positive signal for

EHP infection in the fat body of dragonfly nymphs. Immature and mature microsporidian spores and late sporogonial plasmodium were observed in the cytoplasm of dragonfly nymphs using transmission electron microscopy (TEM). The transmission of EHP from shrimp to dragonfly nymphs was confirmed via cohabitation challenge experiments in which EHP-free dragonfly nymphs were cohabited with EHP-infected shrimp, and the transmission of EHP from dragonfly nymphs to shrimp was demonstrated via the cohabitation of EHP-infected dragonfly nymphs with EHP-free shrimp and oral administration challenge experiments. This study confirms that dragonflies can act as natural EHP hosts, and a novel EHP horizontal transmission route exists between dragonflies and shrimp." **22517.** Dou, X.; Jurenka, R. (2023): Pheromone biosynthesis activating neuropeptide family in insects: a review. *Front. Endocrinol.* 14:1274750. 10 pp. (in English) ["Neuropeptides are involved in almost all physiological activities of insects. Their classification is based on physiological function and the primary amino acid sequence. The pyrokinin (PK)/pheromone biosynthesis activating neuropeptides (PBAN) are one of the largest neuropeptide families in insects, with a conserved C-terminal domain of FXPRLamide. The peptide family is divided into two groups, PK1/diapause hormone (DH) with a WFGPRLa C-terminal ending and PK2/PBAN with FXPRLamide C-terminal ending. Since the development of cutting-edge technology, an increasing number of peptides have been sequenced primarily through genomic, transcriptomics, and proteomics, and their functions discovered using gene editing tools. In this review, we discussed newly discovered functions, and analyzed the distribution of genes encoding these peptides throughout different insect orders. In addition, the location of the peptides that were confirmed by PCR or immunocytochemistry is also described. A phylogenetic tree was constructed according to the sequences of the receptors of most insect orders. This review offers an understanding of the significance of this conserved peptide family in insects." (Authors)] The study includes references to Odonata.] Address: Jurenka, R., Dept of Plant Pathology, Entomology, Microbiology Iowa State University, Ames, IA, USA. Email: rjurenka@iastate.edu

**22518.** Duanmu, D.; Li, X.; Huang, W.; Hu, Y. (2023): Soft finger rehabilitation exoskeleton of biomimetic dragonfly abdominal ventral muscles: Center tendon pneumatic bellows actuator. *Biomimetics* 2023, 8, 614. 16 pp. (in English) ["The development of soft robotics owes much to the field of biomimetics, where soft actuators predominantly mimic the movement found in nature. In contrast to their rigid counterparts, soft robots offer superior safety and human-machine interaction comfort, particularly in medical applications. However, when it comes to the hand rehabilitation exoskeletons, the soft devices have been limited by size and material constraints, unable to provide sufficient tensile strength for patients with high muscle tension. In this paper, we drew inspiration from the muscle structure found in the tail of dragonflies and designed a novel central tendon-based bellows actuator. The experimental results demonstrated that the central tendon-based bellows actuator significantly outperforms conventional pneumatic bellows actuators in terms of mechanical output. The tensile strength of the central tendon-based bellows actuator exceeded that of pneumatic actuators more than tenfold, while adding only 2 g to the wearable weight. This finding suggests that the central tendon-based bellows actuator is exceptionally well-suited for applications

demanding substantial pulling force, such as in the field of exoskeleton robotics. With tensile strength exceeding that of pneumatic bellows actuators, this biomimetic design opens new avenues for safer and more effective human-machine interaction, revolutionizing various sectors from healthcare to industrial automation." **22522.** Gomez-Llano, M.; Boys, W.A.; Ping, T.; Tye, S.P.; Siepielski, A.M. (2023): Interactions between fitness components across the life cycle constrain competitor coexistence. *Journal of Animal Ecology* 92(12): 2297-2308. (in English) ["Numerous mechanisms can promote competitor coexistence. Yet, these mechanisms are often considered in isolation from one another. Consequently, whether multiple mechanisms shaping coexistence combine to promote or constrain species coexistence remains an open question. Here, we aim to understand how multiple mechanisms interact within and

between life stages to determine frequency-dependent population growth, which has a key role stabilizing local competitor coexistence. We conducted field experiments in three lakes manipulating relative frequencies of two *Enallagma* species to evaluate demographic contributions of three mechanisms affecting different fitness components across the life cycle: the effect of resource competition on individual growth rate, predation shaping mortality rates, and mating harassment determining fecundity. We then used a demographic model that incorporates carry-over effects between life stages to decompose the relative effect of each fitness component generating frequency-dependent population growth. This decomposition showed that fitness components combined to increase population growth rates for one species when rare, but they combined to decrease population growth rates for the other species when rare, leading to predicted exclusion in most lakes. Because interactions between fitness components within and between life stages vary among populations, these results show that local coexistence is population specific. Moreover, we show that multiple mechanisms do not necessarily increase competitor coexistence, as they can also combine to yield exclusion. Identifying coexistence mechanisms in other systems will require greater focus on determining contributions of different fitness components across the life cycle shaping competitor coexistence in a way that captures the potential for population-level variation." (2023): Testing for relationships between animal personality traits, activity level and voracity, and the underlying influence of body size in the dragonfly predator, *Epiplatys canis*. Senior Theses, Trinity College, Hartford, CT 2023. Trinity College Digital Repository. 40 pp. (in English) ["Animal personality, defined as among-individual variation in behavior, is taxonomically widespread, but its ecological implications remain unclear. While associations between animal personality and ecological traits have been examined, methodological shortcomings, such as lack of repeated measurements, limit the insights these studies provide. Here, I measured the repeatability of activity level and feeding rate behaviors in the nymph stage of the dragonfly predator, *Epiplatys canis*, taking 10 repeated measurements of each trait over a 10-week period. Moreover, I tested for a relationship between among-individual variation in activity level and feeding rate while accounting for the underlying influence of nymph body size. While nymph feeding rate was highly repeatable across short and long timescales (i.e., individuals exhibited differences in voracity), activity level was not correlated with voracity. This lack of relationship between activity level and voracity was likely due to the low repeatability of activity level. However, dragonfly nymph body size influenced voracity, with larger nymphs consuming more *Daphnia magna* prey. Even after accounting for the positive relationship between body size and voracity, voracity was still shown to be highly repeatable. Overall, my findings suggest the personality of dragonfly activity level may only occur over short timescales, which limits its ecological effects on predator-prey interactions. Yet, individual differences in voracity can influence predator-prey interaction strength, and thus improving our understanding of voracity drivers as an important topic for future studies." **22524.** Guerzon, V.M.; Burias, N.A.R.; de la Cruz, I.N.B. (2023): Records of Odonata in the riparian system of Andanan Watershed Forest Reserve, Philippines. *Journal of*

Ecosystem Science and Eco-Governance 5(1): 15-23. (in English) ["The Odonata fauna is a good biological indicator of freshwater ecosystems. This research aims to provide a record inventory of both dragonflies and damselflies occurring in the riparian ecosystem of Andanan Watershed Forest Reserve. Field collection using sweep nets was done in three locations along the riparian area. Odonatans (n=79) were recorded belonging to 19 species, comprising 58% dragonflies and 42% damselflies. Out of 19 species recorded in the area, one species of dragonfly and six species of damselfly are endemic to the Philippines, with 36.84% endemism in the area. All dragonflies documented are ground skimmers with a high tolerance for anthropogenic disturbances in freshwater systems. The genus *Orthetrum* is relatively abundant and obtained the highest number of species. On the other hand, the genus *Euphaea* in damselflies, was recorded to have the highest abundance. The genus *Risicnemis* has the highest species richness. All species of *Risicnemis* were also reported endemic. Despite the high diversity ( $H'=2.77$ ;  $H'/H_{max}=0.94$ ) of the Odonata fauna in Andanan Watershed Forest Reserve, human activities and intervention were still observed around the riparian ecosystem. The results shown in the current study may be utilized as primary information to allow local conservation efforts for odonatans found in the watershed and its tributaries." (2023): Genetic variation and population structure of a widely distributed damselfly (*Ischnura senegalensis*). *Archives of Insect Biochemistry and Physiology* 114(2): 14 pp. (in English) ["*I. senegalensis* is among the most widespread damselfly species in the world. Unlike dragonflies with strong migration abilities, *I. senegalensis* have limited dispersing abilities. Gene flow among *I. senegalensis* populations may be greatly influenced by anthropogenic disturbance, fragmented suitable habitats, sea straits, or even global warming. In this study, to investigate the genetic diversity of *I. senegalensis* populations, we sequenced and collected 498 cytochrome oxidase I sequences across the Old World. Haplotype network analysis showed 51 haplotypes and *I. senegalensis* could be grouped into four regions (Afrotropical region, Oriental region, main Islands of Japan, and the Ryukyu Islands), each of which contains different dominant haplotypes. Based on molecular variance analysis, we found that populations from

the Afrotropical region have quite a low gene flow with the Asian populations (except Yemen). Furthermore, rice cultivation may aid the dispersion of *I. senegalensis* in the oriental region. Populations from the Ryukyu Islands show the highest genetic diversity, which may be due to the geological separation among islands. Our results prove that *I. senegalensis* has great genetic diversity among different populations across the world." **22529.** Kashyap, O.N.; Madhu, P. (2023): Study of flow around bio-inspired corrugated aerofoil at different angle of attacks in low Reynolds number regime. *AIP Conf. Proc.* 2399, 030031: 9 pp. (in English) ["MAVs operate in the region of low Reynolds-Number i.e 8000-10000. The use of scaled down models of traditional NACA aerofoil for the same have proven to be ineffective. This can be resolved by bio-mimicking the corrugated aerofoil structure found in the wings of the insects like Locusts and Odonata. The corrugated aerofoils can delay the flow separation and give higher lift to drag ratio than the traditional symmetric aerofoils at higher angle of attacks in region of low Reynolds Number, thus facilitating complex maneuverability. Keeping this as the objective of study, simulation analysis of flow over three different models of bio-inspired corrugated aerofoil at low Reynolds Number of 8000 has been carried out by varying the height and position of the corrugations. From this study it is evident that, by changing the height and position of the corrugations, the flow remains attached to the surface of the aerofoil at higher angles of attacks and delaying stall by limiting flow recirculation to only 0.3%C from the trailing edge, indicating stable flight during complex maneuvers and MAVs when implemented." (Authors)] Address: Kashyap, O.N., Mechanical Dept, BNM Institute of Technology, Karnataka, India. Email: omkarnkashyap@gmail.com

**22530.** Kathan, B. (2023): Larvalhabitate der Gestreiften Quelljungfer *Cordulegaster bidentata* im Raum Tübingen: Bestandsveränderungen, Umweltassoziationen und ein Methodentest. MSc thesis, Mathematisch-Naturwissenschaftlichen Fakultät der Eberhard Karls Universität Tübingen: 110 pp. (in German) ["Due to the very large populations, especially in the south of the country, Germany bears a special responsibility for the protection of *C. bidentata*, which is listed in the Habitats Directive as a character species for tufa springs. However, the lack of standardization of the larval recording method and the underrepresentation in routine dragonfly mapping results in incomplete knowledge about their current distribution and thus the degree of threat. Above all, anthropogenic changes to the source ecosystems and longer periods of drying as a result of climate change are considered to be the main causes of danger. Suitable habitats may already be rare regionally, which means that the distribution is viewed as heterogeneous, especially depending on the geology. The aim of the work was to contribute to a better understanding of the local distribution and threat using a universally applicable standard method and the assessment of the status of the target species in the Tübingen area. In 2022, more than 100 spring rivulets were examined for larvae between May and December and around 30 environmental parameters were recorded. In addition, a comparison of the presence/absence of the larvae from the years 2001 and 2022 was carried out, in which exactly the same spring rivulets (comparison bodies of water) were examined in order to be able to determine and interpret changes in distribution. In addition, additional habitats were sampled in order to be able to generate a more comprehensive picture (additional water bodies) and a principal component analysis was used to determine whether relevant environmental parameters correlated with both the presence of the larvae and the mean number of larvae per spring stream as response variables. In 2022, a total of 806 larvae of *C. bidentata* and 38 larvae of *C. boltonii* were detected in 65 of 78 water-bearing spring rivulets, of which 760 and 33 were in the comparison waters and 40 and 5 in the additional waters. Positive evidence was found in 28 habitats in which no larvae were found by H. Henheik in 2001. In 2001, Henheik recorded a number of 248 larvae that was 3.3 times smaller, with a time expenditure of around 2.5 times less. In 2022, only the suitability of isolated habitats was medium or high, as was the abundance of larvae. More than 50% of the rivulets exhibited anthropogenic disturbances. The probability of colonization or presence of the larvae correlated significantly with the first principal component associated with the habitat suitability and size (proportion of suitable flow stretches, proportion of fine debris, absolute length of the flow stretch), while the mean number of larvae across all sample locations of a spring stream correlated significantly with the first main component also with Rot.PC2, which was associated with the specific flow parameters "flow speed, number of impairments, stone content and continuity of the water flow". The method tested in this work was successfully established as a potential, universally applicable, future standard method because, depending on the length of the habitat, it proved to be very effective with up to 10 sampling sites with a sampling duration of 7 minutes each. A maximum of 10 larvae per sampling site and 39 larvae per spring stream were recorded. To save time and money, the number of sample sites for qualitative verification using identical methodology could also be reduced to 5. As measures to protect species, the dismantling of the pipework and stone frames is recommended and the use of optimal flow obstacles or the creation of new, flooded habitats using solar-powered deep water pumps are discussed. Future mapping of *C. bidentata* larvae, both in the study area and in principle, should include population genetic analyzes in order to be able to examine the genetic

diversity and the range of action of the species. In the appendix, the work contains detailed raw data tables with information on all relevant recorded variables per spring stream, including data on the parallel recorded occurrences of the fire salamander (*Salamandra salamandra*) as well as sketches of potentially ideal flow obstacles for testing and further development." **22532.** Knowles, S.; Dennis, M.; McElwain, A.; Leis, E.; Richard, J. (2023): Pathology and infectious agents of unionid mussels: A primer for pathologists in disease surveillance and investigation of mortality events. *Veterinary Pathology* 60(5): 510-528. (in English) ["Freshwater mussels are one of the most imperiled groups of organisms in the world, and more than 30 species have gone extinct in the last century. While habitat alteration and destruction have contributed to the declines, the role of disease in mortality events is unclear. In an effort to involve veterinary pathologists in disease surveillance and the investigation of freshwater mussel mortality events, we provide information on the conservation status of unionids, sample collection and processing techniques, and unique and confounding anatomical and physiological differences. We review the published accounts of pathology and infectious agents described in freshwater mussels including neoplasms, viruses, bacteria, fungi, fungal-like agents, ciliated protists, Aspidogastrea, Digenea, Nematoda, Acari, Diptera, and Odonata. Of the identified infectious agents, a single viral disease, *Hyriopsis cumingii* plague disease, that occurs only in cultured mussels is known to cause high mortality. Parasites including ciliates, trematodes, nematodes, mites, and insects may decrease host fitness, but are not known to cause mortality. Many of the published reports identify infectious agents at the light or ultrastructural microscopy level with no lesion or molecular characterization. Although metagenomic analyses provide sequence information for infectious agents, studies often fail to link the agents to tissue changes at the light or ultrastructural level or confirm their role in disease. Pathologists can bridge this gap between identification of infectious agents and confirmation of disease, participate in disease surveillance to ensure successful propagation programs necessary to restore decimated populations, and investigate mussel mortality events to document pathology and identify causality." **22533.** Koehnsen, A.; Gorb, S.N.; Büsse, S. (2023): A switchable joint in the head of dragonfly larvae (Insecta: Odonata) as key to the multifunctionality of the prehensile labial mask. *Journal of Experimental Zoology Part A: Ecological and Integrative Physiology* 339(7): 644-654. (in English) ["Odonata larvae capture prey by rapid protraction of a raptorial mouthpart, based on a modified labium. Yet, in insects with biting-chewing mouthparts, the labium has an essential role in food handling. These two distinct functions -prey capturing and handling—lead to a mechanical problem in Odonata larvae: while the labium is always protracted in a straight line during prey capture, food handling requires more dexterity. In this study, we investigate the role of the labium in the feeding process and analyse the mechanics of the labial joints in the larva *Anax imperator*. Our results show that the labium features a multiaxial joint connecting the basal segment (postmentum) and the head. During feeding, a combination of rotations around different axes is used to handle and orient prey, which is unique among biting-chewing mouthparts. Furthermore, we identified structures at the joint which likely restrict lateral motion during the predatory strike. Our results provide a further understanding of the unique prey-capturing apparatus of odonate larvae capable of controlling a 'switchable' multiaxial to a restricted monoaxial joint. This concept highlights the evolution of a highly modified raptorial mouthpart appendage where the degrees of freedom can be actively restricted to allow for the respectively needed functionality. Research Highlights: \* Kinematics and functionality of the raptorial appendage in odonate larvae at joint level. \* First assess to the multifunctionality of the prehensile labial mask. \* Presenting a 'switchable' multiaxial to restricted monoaxial joint." **22540.** Mahdjoub, H.; Zebba, R.; Kahalerras, A.; Amari, H.; Bensouilah, S.; Samways, M.J.; Khelifa, R. (2023): Condition-dependent survival and movement behavior in an endangered endemic damselfly. *Scientific Reports* 13, 21819: 10 pp. (in English) ["Movement is essential for the maintenance of populations in their natural habitats, particularly for threatened species living in fluctuating environments. Empirical evidence suggests that the probability and distance of movement in territorial species are context-dependent, often depending on population density and sex. Here, we investigate the movement behavior of the spring cohort of an endangered endemic damselfly *Calopteryx exul* in a lotic habitat of Northeast Algeria using capture-mark-recapture of adults. By sampling 10 gridded river stretches across a 2 km section of the watercourse, we were able to estimate the distance of movement throughout individual lifespans and estimate movement probability for both males and females.

We used multistate models to examine whether individual density and sex ratio influence survival and movement probability. We found that males and females had similar movement kernels with most individuals moving short distances (83% performing movements of < 100 m and only 1% > 1000 m). Of the 547 marked individuals, 63% were residents, and 37% were movers (moved at least 50 m from one sampling occasion to another). Survival probability showed higher estimates for females and was slightly density-dependent (i.e., lower survival probabilities were associated with high male densities). Survival probability did not show a marked difference between residents and movers. Movement probability and distances were positively correlated with individual density, but were not or slightly correlated with sex ratio, respectively. These results are not in line with the hypotheses of sex-biased movement and survival costs of movement. Our results suggest that the species performs mostly short-distance movements that are dependent on intraspecific interactions." (Authors)] Address: Khelifa, R., Institute for Resources, Environment, and Sustainability, University of British Columbia, 2202 Main Mall, Vancouver, BCV6T 1Z4, Canada. **22541.** Maneechan, W.; Prommi, T.O. (2023): Proximate composition, fatty acid profile, and microplastic contamination of edible odonate larvae (Aeshnidae: *Anax* sp.) in rice fields. *Jordan Journal of Biological Sciences* 16(4): 649-654. (in English) ["Although the human consumption of edible insects is a culturally well documented practice, the nutritional literature of aquatic insects has not been completely covered. The present study was conducted with the aim of evaluating the proximate composition, fatty acid profiles, and microplastic contamination of edible odonate larvae (*Anax* sp.). Nutrient analysis showed that the proximate composition was a good source of protein (65.70 g/100g dry weight). The major fatty acids were oleic (1.08 g/100g DW) and palmitic acid (1.01 g/100g DW). The long-chain polyunsaturated fatty acid profile showed an abundance of linoleic, alpha-linolenic, and eicosapentaenoic acids. Total microplastics content found 694 items in the gastrointestinal tract, with a mean abundance of 11.57 items/individual. Five distinct polymers, including polyethylene, polyamide, polypropylene, polyethylene terephthalate, and cellulose, were identified through chemical analysis of FTIR spectra. Future research should be conducted regarding a comprehensive nutritional study to as method for a nutritional reference on food safety and security." **22542.** Manu, M.K.; Ashiagbor, G.; Issah Seidu, I.; Groen, T.; Gyimah, T.; Toxopeus, B. (2023): Odonata as bioindicator for monitoring anthropogenic disturbance of Owabi wetland sanctuary, Ghana. *Aquatic Insects* 44(2): 151-169. (in English) ["This study proposes a method for assessing anthropogenic disturbance in the Owabi wetland sanctuary in Ghana using Odonata. Uniqueness of a species to specific land use (LU) class and its tolerance to environmental conditions served as the criteria for the monitoring. 29 species were identified from the families Aeshnidae, Libellulidae, Chlorocyphidae, Calopterygidae and Coenagrionidae. A Kruskal-Wallis's test suggest significant difference in species richness across the anthropogenic disturbance regimes. *Pantala flavescens* was identified as an indicator of high anthropogenic disturbance; *Orthetrum abbotti* and *Africallagma vaginale* were indicators of moderate anthropogenic disturbance; and *Tramea limbata*, *Olpogastra lugubris*, *Neodythemis klingi*, *Brachythemis*

leucosticta, Chlorocypha curta, C. luminosa, C. radix, Gynacantha bullata and Agriocnemis sp. were identified as indicators of low anthropogenic disturbance." **22543.** Mavromati, E.; Kemitzoglou, D.; Tsiaoussi, V. (2023): Does littoral substrate affect macroinvertebrate assemblages in Mediterranean lakes? *Aquatic Ecology* 57: 667-679. (in English) ["The objective of this study was to investigate the effects of substrate type in macroinvertebrate assemblages in Mediterranean lakes. Samplings have taken place in the littoral zone of 21 lakes in Greece, between 2015 and 2018. We compared benthic macroinvertebrate assemblages among three substrate types of their littoral zones; sandy, covered with macrophytes and stony substrate. Benthic macroinvertebrate assemblages at sites with extended macrophyte cover differed only slightly in composition and abundance from the ones found in stony and sandy substrates. Coenagrionidae were indicative of sites covered with macrophytes and Oligochaeta and Erpobdellidae were representative of stony substrates. The type of substrate proved to be a statistically significant factor influencing the number of benthic macroinvertebrate taxa, the relative abundance of Oligochaeta and the relative abundance of Odonata. In the context of designing site-adapted management measures, priority could be given to the conservation and restoration of aquatic vegetation in lake littoral zones, which host rich macroinvertebrate assemblages with abundant taxa of Odonata." **22545.** Mohammed, H.; Adamu, K.M.; Adamu, A.K.; Mohammed, Y.M.; Usman, B. (2023): Anthropogenic impact on macroinvertebrates distribution and physicochemical characteristics of a tropical stream in north-central Nigeria. *Tropical Freshwater Biology* 32(1): 1-17. (in English) ["Emu is a tropical stream in Northcentral Nigeria that serves as the water source for drinking and other domestic activities for Kusotachin communities, Niger State, Nigeria. This study evaluates the impact of anthropogenic activities on the ecological health of the stream using physicochemical parameters and macroinvertebrate assemblages. Macroinvertebrates were collected for a period of 8 months (July 2021 to February 2022)

using modified kick sampling techniques, and the physicochemical parameters were determined using standard sampling and analytical procedures. Samples were collected from four different stations which are characterized by various anthropogenic activities across the stream bed. With the exception of depth, the measured physicochemical parameters showed no significant ( $P > 0.05$ ) difference between the sampling stations. However, there were significant ( $P < 0.05$ ) differences in air temperature, pH, electrical conductivity, total alkalinity, total hardness, dissolved oxygen, chemical oxygen demand, phosphate, and nitrate between the sampling months. A total of 506 individuals, from 30 species in eight groups of macroinvertebrates were identified. Hemiptera were the most represented group with 57.07% abundance, followed by Odonata with 27.44%, Arachnida (4.14%), Coleoptera (3.93%), Ephemeroptera (2.55%), Diptera (2.17%), Mollusca (1.38) % and the least abundance was 0.19% observed in Decapoda and Oligochaeta. The Canonical correspondence analysis (CCA) showed little or no correlations between the determined macroinvertebrates and physicochemical parameters. CCA axis 1 accounted for 44.94% of the variation of the macroinvertebrates data set with an Eigenvalue of 0.30. CCA axis 2 accounts for 30.5% of data set of macroinvertebrates and an Eigenvalue of 0.20 while CCA axis 3 accounts for 24.55% variation in data set with an Eigenvalue of 0.16. Overall, the low abundance of Ephemeroptera and the absence of other pollution-sensitive macroinvertebrate groups such as Plecoptera and Trichoptera, combined with deteriorating surface water quality, is an indication of pollution stress caused by various anthropogenic activities as the vegetative nature of the stream was the primary factor responsible for the macroinvertebrate assemblage structure." **22546.** Moore, M.P.; Khan, F. (2023): Relatively large wings facilitate life at higher elevations among Nearctic dragonflies. *Journal of Animal Ecology* 92(8): 1613-1621. (in English) ["Determining which traits allow species to live at higher elevations is essential to understanding the forces that shape montane biodiversity. For the many animals that rely on flight for locomotion, a long-standing hypothesis is that species with relatively large wings should better persist in high-elevation environments because wings that are large relative to the body generate more lift and decrease the aerobic costs of remaining aloft. Although these biomechanical and physiological predictions have received some support in birds, other flying taxa often possess smaller wings at high elevations or no wings at all. To test if predictions about the requirements for relative wing size at high elevations are generalizable beyond birds, we conducted macroecological analyses on the altitudinal characteristics of 302 Nearctic dragonfly species. Consistent with the biomechanical and aerobic hypotheses, species with relatively larger wings live at higher elevations and have wider elevation breadths—even after controlling for a species' body size, mean thermal conditions, and range size. Moreover, a species' relative wing size had nearly as large of an impact on its maximum elevation as being adapted to the cold. Relatively large wings may be essential to high-elevation life in species that completely depend on flight for locomotion, like dragonflies or birds. With climate change forcing taxa to disperse upslope, our findings further suggest that relatively large wings could be a requirement for completely volant taxa to persist in montane habitats." **22549.** Palomar, G.; Wos, G.; Stoks, R.; Sniegula, S. (2023): Latitude-specific urbanization effects on life history traits in the damselfly *Ischnura elegans*. *Evolutionary Applications* 16: 1503-1515. (in English) ["Many species are currently adapting to cities at different latitudes. Adaptation to urbanization may require eco-evolutionary changes in response to temperature and invasive species that may differ between latitudes. Here, we studied single and combined effects of increased temperatures and an invasive alien predator on the phenotypic response of replicated urban and rural populations of *I. elegans* and contrasted these between central and high latitudes. Adult females were collected in rural and urban ponds at central and high latitudes. Their larvae were exposed to temperature treatments (current [20°C], mild warming [24°C], and heat wave [28°C; for high latitude only]) crossed with the presence or absence of chemical cues released by the spiny-cheek crayfish (*Faxonius limosus*), only present at the central latitude. We measured treatment effects on larval development time, mass, and growth rate. Urbanization type affected all life history traits, yet these responses were often dependent on latitude, temperature, and sex. Mild warming decreased mass in rural and increased growth rate in urban populations. The effects of urbanization type on mass were latitude-dependent, with central-latitude populations having a greater phenotypic difference. Urbanization type effects were sex-specific with urban males being lighter and having a lower growth rate than rural males. At the current temperature and mild warming, the predator cue reduced the growth rate, and this independently of urbanization type and latitude of origin. This pattern was reversed during a heat wave in high-latitude damselflies. Our results highlight the context-dependence of evolutionary and plastic responses to urbanization, and caution for generalizing how populations respond to cities based on populations at a single latitude." **22551.** Pineda-Alarcón, L.Y.; Cañón Barriga, J.E. (2023): Modelación de la relación predador-presa para la comunidad de macroinvertebrados en el litoral del Lago de Tota - Modeling the predator-prey relationship for the macroinvertebrate community on the shore of Lake Tota. *Acta Biológica Colombiana* 28(2): 189-203. (in Spanish, with English summary) ["High Andean lakes are ecosystems affected by multiple anthropogenic pressures that alter water quality and biotic communities, and aquatic macroinvertebrates are excellent bioindicators for these ecosystems. The present work analyzes the dynamics of the macroinvertebrate community associated with *Egeria densa*, the relationship with physicochemical variables, biotic indices, and predator-prey interaction in the littoral of Lake Tota. This work was developed in three campaigns on nine sampling stations on the perimeter of the lake. Among the findings, *Hyallela* sp. (30 %) and *Dicrotendipes* sp. (27 %) are the most abundant and dominant taxa of the study, being bioindicators of the presence of decomposing organic matter and decrease in water quality. ANOVA analysis of the physicochemical variables of water and nutrients of *Egeria densa* showed significant differences at the temporal level. The biotic indices showed differences in water quality, determining a possible zoning of this parameter along the coast. Finally, to identify community relationships, a predator-prey model is presented, with *Hyallela* sp. as prey and *Ischnurasp.* as predator through the Lotka-Volterra equations, finding that there is agreement between the behavior of measured and simulated abundances. In this way, the trophic dynamics contribute to understand the communities and their projection in time in relation to the environmental conditions of the littoral zone." (Authors)] The study includes *Coryphaeschna* sp. and *Ischnura* sp.] Address: Pineda-Alarcón, Ludy, Grupo GAlA, Facultad de Ingeniería, Universidad de Antioquia, Calle 67 No. 53 - 108, Medellín, Colombia. **22552.** Priyadarshana, T.S.; Slade, E.M. (2023): A meta-analysis reveals that dragonflies and damselflies can provide effective biological control of mosquitoes. *Journal of Animal Ecology* 92(8): 1589-1600. (in English) ["Odonata naiads have the potential to control mosquitoes, and indirectly the diseases they carry, due to their extensive predation on mosquito larvae. Experimental studies have measured the effectiveness of individual dragonfly/damselfly naiads in controlling mosquitoes by introducing them to mosquito larvae and counting the number of larvae eaten in a given time period (i.e. predation success). Without a quantitative synthesis, however, such individual measures are unable to provide a generalized estimation about the effectiveness of Odonata as biological mosquito control agents. To achieve this, we assembled a database containing 485 effect sizes across 31 studies on predation successes of 47 species of

commonly found Odonata naiads on nine species of mosquito larvae belonging to *Aedes*, *Anopheles* and *Culex*. These studies covered 14 countries across Asia, Africa and South and North America, where mosquitoes are the vectors of Chikungunya, Dengue, Japanese encephalitis, Lymphatic filariasis, Malaria, Rift Valley fever, West Nile fever, Yellow fever and Zika. Using this database, we conducted a meta-analysis to estimate the average predation success per day by a single individual dragonfly/damselfly naiad on these mosquito larvae as a generalized measure of the effectiveness of Odonata for mosquito control. We also built an interaction network for predator-Odonata and prey-mosquitoes and the diseases they vector to understand the functioning of this important predator-prey network. Our results showed that mosquito larvae were significantly reduced through predation by Odonata naiads. Within experimental containers, a single individual Odonata naiad can eat on average 40 (95% confidence intervals [CIs] = 20, 60) mosquito larvae per day, equivalent to a reduction of the mosquito larval population by 45% (95% CIs = 30%, 59%) per day. The average predation success did not significantly vary among *Aedes*, *Anopheles* and *Culex* mosquitoes or among the four (I–IV) mosquito larval stages. These results provide strong evidence that Odonata can be effective biological control agents of mosquitoes, and environmental planning to promote them could lower the risk of spreading mosquito-borne diseases in an environmentally friendly and cost-effective manner." **22556.** Samraoui, B.; Touati, L.; Samraoui, F. (2023): Life cycle and seasonal regulation of the Ibero-Maghrebian endemic *Onychogomphus costae* across an altitudinal gradient (Insecta, Odonata). *Hydrobiologia* 850: 4891-4905 (in English) ["The emergence and life cycle of the Ibero-Maghrebian endemic *O. costae*, was studied over an altitudinal gradient of the Seybouse River in northeastern Algeria. The asynchronous and protracted emergence period showed a "summer" pattern, extending from late April to mid-August and lasting about three and a half months. The proportion of the total emergence period, EM50, at sea level was unusually long, varying annually between 44 and 66 days. No differences in emergence sex ratios were observed in 2015, but in 2016 there was a statistically significant deviation from a 1:1 ratio in favour of females. In both years, the body size of female exuviae at emergence was consistently larger than that of males. The long flight and oviposition period of *O. costae* extends throughout spring and summer and is responsible for the phenotypic plasticity of the larvae and the asynchrony of their development. Larval growth and development of *O. costae* are consistent with regulated development and a semivoltine life cycle across the entire altitudinal gradient of the Seybouse River. Nevertheless, some voltinistic flexibility is evident at low elevations, with some individuals exhibiting a univoltine life cycle." **22557.** Saxton, N.A.; Powell, G.S.; Bybee, S.M. (2023): A story of vicariance? How the geology of oceanic archipelagos influenced the evolutionary history of endemic damselflies. *Molecular Phylogenetics and Evolution* 186, 107831: 10 pp. (in English) ["South Pacific islands provide an ideal study system to explore patterns of speciation, specifically examining the role of dispersal versus vicariance. Dispersal is often the suggested mechanism of diversification in the South Pacific, specifically among remote island chains. Here, we provide a phylogeny of several related genera of Coenagrionidae from the South Pacific, based on five molecular loci, in order to examine patterns of speciation in the region. We used the endemic damselfly genera *Nesobasis*, *Nikulabasis*, and *Vanuatubasis* found across both Fiji and Vanuatu. Knowledge of the geologic history of the region was used to inform our understanding of the evolution of these genera. Both archipelagos used to be part of the Vitiac arc which spanned from the Solomon Islands to Tonga and began to break apart 10-12 Ma. Results of our divergence-time estimations and biogeographic reconstructions support that the breakup of this arc acted as a significant vicariance event in the evolution of these taxa. Specifically, it led to the extant generic diversity seen in these damselflies. We find that

within the archipelago of Vanuatu, that Espiritu Santo served as an important source for dispersal to other islands with Malekula acting as a stepping stone to Efate." **22559.** Silina, A.E.; Sushchik, N.N.; Gladyshev, M.I.; Kurina, E.M.; Kolmakova, A.A.; Seleznev, D.G. (2023): Emergence of amphibious insects from an old beaver pond in the Upper Kholer Valley under conditions of the forest steppe. *Contemporary Problems of Ecology* 16: 790-806. (in English) ["This work presents the results of studies of the emergence of amphibiotic insects from the old beaver pond on the Yuzhnaya River of the Privolzhskaya Lesostep Nature Reserve in the Upper Kholer basin. The parameters of abundance, biomass, and frequency of occurrence are given for insects from 34 families and 8 orders; the timing of their emergence in different parts of the pond is indicated. The dominant and common species are identified: chironomids *Paramerina cingulata* (Walk.) and *Cricotopus silvestris* (F.), biting midges (*Bezzia bicolor* (Mg.)), chaoborids *Chaoborus flavicans* (Mg.), and mayflies *Cloeon inscriptum* (Bgts.). The intensity of the emergence of insects is 12.10 individuals/m<sup>2</sup> per day; the average daily transfer of biomass is 49.23 mg/m<sup>2</sup> per day. The analysis of the fatty acid composition and content of the main biogenic elements in adults of amphibiotic insects is carried out. The results of calculations of the energy and matter transfer, including biogenic elements (carbon, phosphorus, and nitrogen) and polyunsaturated fatty acids (PUFAs) during the emergence of insects from various orders (Ephemeroptera, Odonata [*Gomphus vulgatissimus*, *Coenagrion puella*], Trichoptera, and Diptera) into adjacent terrestrial ecosystems, are presented. The transfer of wet biomass from water to land is 7.385 g/m<sup>2</sup> per year and, in dry weight, 2.216 g/m<sup>2</sup> per year; transfer of the main nutrients is carbon, 1.21 g/m<sup>2</sup> per year; nitrogen, 0.25 g/m<sup>2</sup> per year; and phosphorus, 0.03 g/m<sup>2</sup> per year. PUFA transfer is 24.16 kg/km<sup>2</sup> per year. ... Odonata were represented exclusively by Anisoptera [?] (genera *Sympetrum* and *Aeschna*) emerging in the second half of summer (from July 28 to August 25). Due to their large forms, they played a major role in the transfer of

biomass during this period, despite their low occurrence (FO = 1.9%). The proportion of dragonflies in the total transfer of bio mass by insects from the pond was 14.8%." (Authors)] Address: Silina, A.E., Belogorye Nature Reserve, 309342, Borisovka, Belgorod oblast, Russia

**22560.** So, J.; Choe, D.-H.; Rust, M.K.; Trumble, J.T.; Lee, C.-Y. (2023): The impact of selenium on insects. *Journal of Economic Entomology* 116(4): 1041-1062. (in English) ["Selenium, a naturally occurring metalloid, is an essential trace element for many higher organisms, including humans. Humans primarily become exposed to selenium by ingesting food products containing trace amounts of selenium compounds. Although essential in these small amounts, selenium exhibits toxic effects at higher doses. Previous studies investigating the effects on insects of order Blattodea, Coleoptera, Diptera, Ephemeroptera, Hemiptera, Hymenoptera, Lepidoptera, Odonata, and Orthoptera revealed impacts on mortality, growth, development, and behavior. Nearly every study examining selenium toxicity has shown that insects are negatively affected by exposure to selenium in their food. However, there were no clear patterns of toxicity between insect orders or similarities between insect species within families. At this time, the potential for control will need to be determined on a species-by-species basis. We suspect that the multiple modes of action, including mutation-inducing modification of important amino acids as well as impacts on microbiome composition, influence this variability. There are relatively few studies that have examined the potential effects of selenium on beneficial insects, and the results have ranged from increased predation (a strong positive effect) to toxicity resulting in reduced population growth or even the effective elimination of the natural enemies (more common negative effects). As a result, in those pest systems where selenium use is contemplated, additional research may be necessary to ascertain if selenium use is compatible with key biological control agents. This review explores selenium as a potential insecticide and possible future directions for research. ... The orders Odonata, Orthoptera, Coleoptera, and Blattodea have comparatively limited literature available regarding sublethal effects on behavior. Most of the available studies measure feeding behavior. For example, a common dragonfly, *Sympetrum corruptum* increased feeding on *C. quinquefasciatus* when grown in a selenate solution compared to nymphs maintained in an untreated solution (Jensen 2006)." (2023): From extremely acidic to alkaline - aquatic invertebrates in forest mining lakes under the pressure of acidification. *Hydrobiology* 108(1-3): 5-16. (in English) ["Human activities, including the mining industry, have considerably degraded water habitats worldwide. Acidification has severely affected aquatic environments and biodiversity by altering food webs and reducing species richness. The study area in southern Poland is unique in addressing the effects of mining-related acidification on biodiversity in freshwater ecosystems along a broad pH gradient (2.4-9.6) in mining lakes. Study was design to test for effect of human induced

acidification. Using multivariate ordination techniques, we analyzed how variations in invertebrate composition are related to environmental factors. The results indicated that pH, hardness, total dissolved solids, and the content of ammonia and calcium were significantly associated with the distribution of invertebrates in the studied mining lakes. The highest iron content, relatively high values of conductivity and chlorides were found in the extremely acidic mining lakes. A clear trend in decreasing density with decreasing pH was observed for taxa such as Oligochaeta, Chironomidae, Glossiphoniidae and certain taxa of snails. However the density of other taxa such as Lestidae, Libellulidae, Caenidae, Sialidae, Helodidae, Hydrophilidae and Polycentropodidae increased with decreasing pH. Specific communities were found with increasing acidity. Therefore, a further increase in acidity will probably cause a stronger decline in most of taxa and their density, and on water chemistry (e.g., calcium concentration, nitrites, hardness). The data yielded offer an opportunity to fill knowledge gaps on acidic stress concerning less-studied environments like mining lakes and link environmental pollution with communities, which is especially important because aquatic forest habitats are especially exposed to different climatic factors and threats." **22563.** Suárez-Tovar, C.M.; Rocha-Ortega, M.; Córdoba-Aguilar, A. (2023): Is body condition of Mexican rubyspot (*Odonata*: Zygoptera) associated with urbanization? *Journal of Insect Conservation* 27: 961-969. (in English) ["Urbanized areas can impose selective pressures on insects which can be identified at the individual level based on animal physiological condition. Physiological condition can be measured from variables such as body size, body mass or energetic budget of individuals. We examined whether body mass, wing spot size and energy reserves (proteins, lipids and carbohydrates) were reduced as urbanization increases, using adults of two damselflies, *Hetaerina americana* and *H. vulnerata*, in Central Mexico. We used a Habitat Integrity Index to assess the degree of urbanization in our sampled sites, considering biophysical attributes and the impact of anthropogenic activities. We did not find relation of above individual variables with urbanization degree. These results support possible resilience of rubyspot damselflies in the face of radical changes such as urbanization. Our finding echoes other results in damselflies research. Implications for insect conservation: Our results highlight the resilience of these damselflies species in the face of urban disturbances. Thus design cities considering not only requirements of humans is essential to promote the presence and conservation of these and other species of insects in cities." (2023): Chemical cannibalistic cues make damselfly larvae hide rather than hunt. *Scientific Reports* 13, Article number: 13556: 13 pp. (in English) ["Adopting cannibalism substantially affects individual fitness, and recognizing the presence of other cannibals provides additional benefits such as the opportunity to prepare for hunting or defense. This recognition can be facilitated by perceiving conspecific chemical cues. Their role in cannibalistic interactions is less studied than in interspecific predation and it is unclear whether these cues inform individuals of danger or of food

availability. Interpretation of these cues is crucial to balance the costs and benefits of anti-predator and feeding strategies, which can directly influence individual fitness. In this study we aimed to test whether damselfly larvae shift towards bolder and more exploratory (cannibalistic) behavior, or become more careful to avoid potential cannibals (as prey) in response to such cues. We conducted behavioral and respiratory experiments with *Ischnura elegans* larvae to investigate their response to chemical cues from older and larger conspecific larvae. We found that *I. elegans* larvae decrease their activity and shift their respiratory-related behavior, indicating activation of anti-predator defense mechanisms in response to conspecific chemical cues. Our findings indicate that individuals exposed to conspecific chemical cues balance catching prey with staying safe." (Authors)] Address: Sysiak, Monika, Dept of Hydrobiology, Inst. (2023): Past and present: changes in the Odonata fauna of small lowland watercourses. *Biodiversity Data Journal* 11(6): 24 pp. (in English) ["Small lowland watercourses, strongly exposed to anthropogenic activities and climate change, have received negligible odonatological attention. This study provides a revised checklist of three typical lowland small watercourses (Kállai-folyás, Konyári-Kálló and Ölyvös) within the Pannonian Lowland and presents the changes in their diversity over the past decades. Results revealed a significant biodiversity loss, with a 31.6% decline in Odonata fauna over the last 53 years. The upper and middle sections degraded the most, where the habitats have dried out or become intermittent. However, a diverse Odonata assemblage (1,277 individuals of 27 species) was observed at the 14 sampling sites of the three watercourses, containing protected and sensitive species (*Somatochlora flavomaculata*, *Orthetrum brunneum*, *Aeshna isoceles*, *Libellula fulva*). However, the low abundance of larval and exuvial forms (59 individuals of 13 species) suggests that the majority of the observed adults were developed in other watercourses. While recolonisation from nearby habitats is still possible, a parallel degradation of adjacent waterbodies could lead to an irreversible biodiversity loss." (2023): Wetland biodiversity of Ramaroshan Lake complex: a need for conservation. *Journal of Threatened Taxa* 15(12): 24299-24320. (in English) ["The Ramaroshan Lake Complex, situated in the mid-hills of Sudurpaschim Province, is renowned for its scenic beauty, yet there is a notable dearth of information regarding its biodiversity and ecological status. This study represents the first systematic examination of seasonal variations in water quality parameters and biodiversity encompassing aquatic macroinvertebrates, fishes, birds, herpetofauna, mammals, and macrophytes, as well as the surrounding vegetation within the complex, spanning the winters and summers of 2018 and 2019. Among the twenty water quality parameters investigated, thirteen displayed significant seasonal differences across the lakes ( $p < 0.05$ ), with Batula and Ramaroshan lakes exhibiting elevated nutrient levels. Lamadaya Lake stood out with a highly diverse macroinvertebrate community compared to other lakes, while overall, the study recorded 45 aquatic macroinvertebrate families, three fish species, 79 bird species, 12 herpetofauna species, 12 mammal species, and 26 macrophyte species within the

complex. Additionally, the surrounding vegetation comprised 193 distinct plant species. Notably, the complex currently hosts 14 IUCN Red List species, including Near Threatened (5), Vulnerable (5), Critically Endangered (1), and Endangered (3) species, as well as five migratory wetland bird species, underscoring its significance for wildlife conservation. Given the diverse and cross-cutting nature of wetlands, the development of science-based policies and coordinated efforts among central, provincial, and local governments are essential for the preservation and sustainable management of these vital ecosystems." (Authors) Odonate taxa are treated at family level.] Address: Tachamo-Shah, R.D., Dept of Life Sciences, School of Science, Kathmandu Univ., Dhulikhel 45200, Nepal; Aquatic Ecology Centre, School of Science, Kathmandu University, Dhulikhel 45200, Nepal.

(2023): Predictive saccades and decision making in the beetle-predating saffron robber fly. *Current Biology* 33: 13 pp. (in English) ["Internal predictions about the sensory consequences of self-motion, encoded by corollary discharge, are ubiquitous in the animal kingdom, including for fruit flies, dragonflies, and humans. In contrast, predicting the future location of an independently moving external target requires an internal model. With the use of internal models for predictive gaze control, vertebrate predatory species compensate for their sluggish visual systems and long sensorimotor latencies. This ability is crucial for the timely and accurate decisions that underpin a successful attack. Here, we directly demonstrate that the robber fly *Laphria saffrana*, a specialized beetle predator, also uses predictive gaze control when head tracking potential prey. *Laphria* uses this predictive ability to perform the difficult categorization and perceptual decision task of differentiating a beetle from other flying insects with a low spatial resolution retina. Specifically, we show that (1) this predictive behavior is part of a saccade-and-fixate strategy, (2) the relative target angular position and velocity, acquired during fixation, inform the subsequent predictive saccade, and (3) the predictive saccade provides *Laphria* with additional fixation time to sample the frequency of the prey's specular wing reflections. We also demonstrate that *Laphria* uses such wing reflections as a proxy for the wingbeat frequency of the potential prey and that consecutively flashing LEDs to produce apparent motion elicits attacks when the LED flicker frequency matches that of the beetle's wingbeat cycle." **22569.** Termaat, T. (2023): Trending Dragonflies assessing and explaining trends and threats on different scales. PhD thesis, Wageningen University, Wageningen, NL: 206 pp. (in English, with Dutch summary) ["Monitoring biodiversity is necessary to keep track of the progress towards conservation targets and to measure the success of conservation strategies. However, adequate biodiversity monitoring programmes are not easy to achieve. They require enough data on species occurrence over a longer period of time, and a scientifically sound method for data analysis to derive robust, unbiased trend information. Monitoring programmes that meet these requirements are scarce and often cover only a small geographic area. In Europe, only two species groups currently are covered by monitoring programmes that have resulted in pan-European biodiversity indicators: birds and butterflies. Evidently, these two species groups do not sufficiently represent total biodiversity. Dragonflies (Odonata, including damselflies) may be a suitable additional indicator group. They are likely sensitive to other aspects of ecosystem quality than birds and butterflies and due to their strong dispersal capacities they may quickly respond to environmental change. The number of amateur naturalists watching dragonflies has greatly increased in recent decades, leading to a sharp rise in available distribution records throughout Europe. The majority of these records, however, are opportunistic', that is, collected without a standardised field protocol and without a design ensuring the geographical representativeness of sampled sites. Using these records requires a new method for data analysis that successfully corrects for unequal observation efforts. The aim of the research covered in this thesis is to find and test such a method, and use it to derive trends in the distribution of dragonflies at different spatial scales in Europe. Subsequently, it examines how the obtained trends can be explained and which consequences this has for dragonfly conservation. Chapter 2 of this thesis explores if occupancy models (also known as site-occupancy models) may be helpful to reduce biases in estimating trends based on opportunistic data, caused by temporal variation of observation effort and by incomplete reporting of sightings. Occupancy models estimate the probability of sites to be occupied while taking into account imperfect detection of a species, via the deduction of 'detection histories' from replicated visits. Such models were applied to three opportunistic datasets of dragonfly species (1999–2007) in the Netherlands: (1) one-species records, (2) short species day-lists and (3) comprehensive species day-lists. The resulting trend estimates were compared to trend estimates based on presence-absence records collected at fixed monitoring transects, via the standardised field protocol of the Dutch Dragonfly Monitoring Scheme (the 'golden standard'). In addition, conventional logistic regression analyses were applied to test if occupancy models performed better. Occupancy trends based on comprehensive species day-lists in combination with occupancy models were similar to those based on standardly collected data, while trends based on single-species records and short day-lists were too imprecise. Application of logistic regression models led to less realistic trend estimates than application of occupancy models. Thus, analysing comprehensive day-lists of opportunistic records with occupancy models can be a suitable and feasible alternative for dragonfly monitoring based on standardised observations. The monitoring method described in Chapter 2 can of course be used in other countries than the Netherlands as well, provided that these countries have sufficiently large datasets of opportunistic dragonfly records. However, to infer dragonfly

trends on a supranational scale, a method is needed to combine trends from different countries while taking into account the unequal geographical occupation of surveyed sites. Chapter 3 describes a pilot study for *Calopteryx splendens*. Opportunistic distribution records were collected from five countries (Ireland, Great Britain, the Netherlands, Belgium and France), covering the period 1990–2008. Occupancy trends were first estimated for each country separately. Then the countries were weighted according to the number of sites surveyed and the range of the species per country. These weights were then applied during the aggregation of the national trends into a supranational trend. This showed that the distribution of *C. splendens* increased significantly in the five countries combined. The pilot demonstrated that supranational occupancy trends can be successfully calculated, which opens new perspectives for international monitoring of biodiversity. Chapter 4 investigates how the dragonfly fauna of the Netherlands has developed in the period 1991–2013, using both standardised monitoring data on abundance and opportunistic data on distribution. Trends of dragonfly species from different habitat types are compared, as are trends of species with southern vs. northern distributions in Europe. Many species had declined prior to 1990, due to environmental pollution and habitat loss. Since the 1980s, stricter environmental regulations and habitat restoration projects led to improvements in freshwater habitats and many dragonfly species were able to quickly recover, leading to more positive conservation statuses. Species of running waters benefitted more than species of standing waters, and southern species had more positive trends than northern species, suggesting that climate change has contributed to the recovery. These outcomes support the suitability of dragonflies as indicators of freshwater habitat condition. However, dragonflies recovered more strongly in the Netherlands than many other aquatic or terrestrial insects (e.g. stoneflies, caddisflies, mayflies, butterflies, moths), likely because of their higher dispersal abilities or different habitat requirements. Following the method for supranational trend assessment in Chapter 3 and the explanations for the Dutch dragonfly trends found in Chapter 4. Chapter 5 explores how the occurrence of dragonflies has changed at a European level, in the period 1990–2015. Based on distribution data from 10 European geographic regions, occupancy indices were calculated for 99 (69%) of the European species. 55 of them increased in distribution at European level, 32 species remained stable, and none declined. Trends for 12 species were uncertain. To determine whether the changes found in dragonfly communities are driven by climate warming, Species Temperature Indices (STI) were calculated. STI is a simple measure of a species' preferred temperature regime, expressed as the mean annual temperature in the species' European range. Based on these STI, all species were categorised as either being cold-dwelling or warm-dwelling and Multi-species Indicators (MSI) were compiled. MSI of cold-dwelling and warm-dwelling species differed in some of the regions, but increased at a similar rate at European level. Furthermore, Community Temperature Indices (CTI) were calculated, as the average STI of all species in a region, weighted by species occupancies. CTI increased in all regions, except Cyprus. The European CTI increased slightly, but lagged behind the increase in temperature itself. This implies that dragonflies have accumulated a 'climate debt', meaning that problems for cold-dwelling species can still be expected after 2015. Dragonflies proved to be a suitable species group for monitoring changes in communities, both at regional and continental level. For effective species conservation it is not only important to notice early that a species is declining, but also to properly understand the causes of its decline. Furthermore, as insects may respond rapidly to environmental changes, it is necessary to

discriminate between former and current threats and to focus conservation efforts on the latter. Chapter 6 describes a study on the habitat requirements of *Coenagrion hastulatum*, an endangered species in the Netherlands, and investigates what has caused the progressive loss of its populations during the 20th and beginning of 21st century. Historically, habitat loss and changes in anthropogenic use of moorland pools and bogs were the most prominent causes. In the second half of the 20th century, strongly elevated atmospheric deposition of sulphur and nitrogen compounds, leading to acidification and eutrophication, was the main culprit. Sites where *C. hastulatum* disappeared between 2001 and 2015 had lower cover of essential vegetation structures. This suggests that they never fully recovered, despite the strong reduction in sulphur and moderate reduction in nitrogen deposition since the 1980s. Most recently, more populations have been lost as a direct result of prolonged droughts, a consequence of climate change. Thus, the most relevant pressures have indeed changed over time. Restoration of groundwater systems and rewetting measures are now first priorities for the conservation of *C. hastulatum* and other cold-adapted species of moorland pools and bogs. Chapter 7 contains an overall synthesis. It draws general conclusions, addresses implications for dragonfly conservation and discusses future prospects. At national level in the Netherlands, dragonflies reacted negatively to environmental problems in the 20th century, but most species quickly recovered as these problems were overcome or mitigated. However, climate change now has a dominant effect, both positive on warm-adapted species and negative on cold-adapted species. This is also true at a European level: the 'climatic debt' that dragonfly communities accumulated is now being paid, as many cold-adapted species have started to decline and will be listed as threatened on the updated IUCN Red List of European Odonata. Conservation efforts should prioritise the protection of oligo-mesotrophic freshwater habitats in northern Europe as areas of refuge for cold-adapted species. Halting human exploitation of these ecosystems and consolidating surface and groundwater levels are the most important measures. Protection of watersheds in southern and southeastern Europe is also pressing, as multiple dragonfly species in those regions are at risk due to desiccation of streams and rivers, including some range-restricted European endemics. This thesis supports the suitability of dragonflies as biodiversity indicators. Since dragonflies react to environmental change almost instantly, both positively and negatively, they inform us on the current condition of freshwater ecosystems. Due to their strong dispersal ability, habitat fragmentation plays a limited role. Dragonfly trends therefore have an 'early signalling' function and may be used as predictors of the future trends of other freshwater organisms that respond less rapidly. Furthermore, this thesis proves that it is feasible to start a European dragonfly monitoring programme right away, by compiling distribution data that are already available in many countries, and analysing those data with occupancy models. The resulting species indices and trends could form the basis of a freshwater biodiversity indicator, narrowing the gap in the availability of indicators currently employed by the European Environmental Agency." (2023): Exploring chromosome evolution in 250 million year old groups of dragonflies and damselflies (Insecta: Odonata). *Molecular Ecology* 32: 5785–5797. (in English) ["Using recently published chromosome-length genome assemblies of *Ischnura elegans*,

*Platycnemis pennipes*, *Pantala flavescens* and *Tanypteryx hageni*, we demonstrate that the autosomes of Odonata have undergone few fission, fusion, or inversion events, despite 250 million years of separation. In the four genomes discussed here, our results show that all autosomes have a clear ortholog in the ancestral karyotype. Despite this clear chromosomal orthology, we demonstrate that different factors, including concentration of repeat dynamics, GC content, relative position on the chromosome, and the relative proportion of coding sequence all influence the density of syntenic blocks across chromosomes. However, these factors do not interact to influence synteny the same way in any two pairs of species, nor is any one factor retained in all four species. Furthermore, it was previously unknown whether the microchromosomes in Odonata are descended from one ancestral chromosome. Despite structural rearrangements, our evidence suggests that the micro-chromosomes in the sampled Odonata do indeed descend from an ancestral chromosome, and that the micro-chromosome in *P. flavescens* was lost through fusion with autosomes." (Authors) T. hageni, P. flavescens, I. elegans, P. pennipes, Hetaerina americana, Rhinocypha anisoptera, Calopteryx splendens, Ladona fulva.] Address: Tolman, E.R., Division of Invertebrate Zoology, American Museum of Natural History, New York City, NY 10024, USA. **22571.** Tsavdaridou, A.I.; Doxa, A.; Mazaris, A.D. (2023): Towards achieving a twenty-fold increase in the coverage of freshwater species distributions within protected areas in Europe. *Biological Conservation* 285, 110233: 9 pp. (in English) ["Freshwater ecosystems are threatened worldwide, with 1/3 of freshwater species being under extinction risk. Yet, systematic conservation planning has received little attention as a means to prioritize freshwater conservation areas. Here, we develop a comprehensive approach to spatially delineate key areas for freshwater conservation across Europe, considering directed-connectivity, climate change and human-related disturbances. We assess the adequacy of the current reserve network in protecting European freshwater ecosystems and provide guidelines for expansion. We conducted 13 prioritization scenarios for 18,300 sub-basins across Europe, accounting for the distribution of 1,668 freshwater species [including 131 odonate species]. Connectivity properties, metrics of climatic stability and human induced pressures were incorporated into the spatial prioritization framework. We highlight the critical importance of specific regions in Central and Southern Europe, the Mediterranean Basin, and parts of the Balkan Peninsula for future freshwater conservation efforts. However, our analysis also reveals the complete inadequacy of the current reserve network, as protected sub-basins only cover 4 % of the study area and encompass on average only 3 % of freshwater species distributions. In contrast, expanding current reserves to cover the top 17 % of high priority areas across Europe could substantially improve the overall coverage of species distributions, reaching an average of 61.5 % for all freshwater species and even exceeding 93.1 % for species of conservation interest (critically endangered, endangered and vulnerable species). The priority freshwater conservation network derived from the analysis provides specific spatial recommendations to help achieve conservation goals if the current reserve network is appropriately expanded." (2023): Modeling dragonfly population data with a Bayesian bivariate geometric mixed-effects model. *Journal of Applied Statistics* 50(10): 2171-2193. (in English) ["We develop a generalized linear mixed model (GLMM) for bivariate count responses for statistically analyzing dragonfly population [*Aeshna viridis*] data from the Northern Netherlands. The populations of the threatened dragonfly species *A. viridis* were counted in the years 2015–2018 at 17 different locations (ponds and ditches). Two different widely applied population size measures were used to quantify the population sizes, namely the number of found exoskeletons ('exuviae') and the number of spotted egg-laying females were counted. Since both measures (responses) led to many zero counts but also feature very large counts, our GLMM model builds on a zero-inflated bivariate geometric (ZIBGe) distribution, for which we show that it can be easily parameterized in terms of a correlation parameter and its two marginal medians. We model the medians with linear combinations of fixed (environmental covariates) and random (location-specific intercepts) effects. Modeling the medians yields a decreased sensitivity to overly large counts; in particular, in light of growing marginal zero inflation rates. Because of the relatively small sample size ( $n = 114$ ) we follow a Bayesian modeling approach and use Metropolis-Hastings Markov Chain Monte Carlo (MCMC) simulations for generating posterior samples." in networks of conservation corridors. *Biodiversity and Conservation* 32: 3991-4005. (in English) ["Complementarity is crucial when prioritizing sites for biodiversity conservation. Networks of conservation corridors (CCs) can contribute to regional representativeness by complementing biodiversity features included in existing protected areas (PAs). We ask whether criteria important for CC management and design are effective at prioritizing complementary sites, and how the consideration of species represented in PAs influence criteria performance. We focused on species turnover of generalist and specialist dragonflies across 88 riverine sites. Criteria assessed included site-level estimates of dragonfly species richness, estimates of local habitat quality and corridor width. Measures of local habitat quality were based on either dragonfly indicator species or proportion of alien vegetation. Results showed that CCs complement dragonfly diversity in PAs by contributing unrepresented generalist species. Of the criteria, corridor width was the most efficient at prioritizing complementary sites, while prioritization based on dragonfly indicator species or species richness underperformed. When aiming to prioritize CC sites that also complement sites situated in established PAs, wide corridors with low levels of alien vegetation should be favoured.] Address: van Schalkwyk, Julia, Dept of Conservation Ecology & Entomology, Stellenbosch University, Private Bag X1, Matieland 7602, South Africa. **22576.** van Staveren, D.; Vergeer, P.; Meertens, H.; Huperichs, L.; van den Berg, L. (2023): Habitat restoration at the Kasteelhoeve Cartils Estate. *Natuurhistorisch Maandblad* 112(7): 181-187. (in Dutch, with English summary) ["The 'Kasteelhoeve Cartils' estate is located in the Eyserbeek valley, near the mouth of the Eyserbeek brook, between Eys and Gulpen in the south of the Dutch province of Limburg. The estate extends from a higher slope of the Ubachsberg Plateau (i.e. the Biesberg hill) to the low-lying village of Cartils. In 2010, the landowner of 'Kasteelhoeve Cartils' decided to transform large parts of the land into nature areas or manage them by means of an agri-environmental management approach. Since then, habitats have been restored on a large scale. The restoration efforts were explicitly aimed at restoring various types of habitat and the natural and unique gradients from dry to wet and from calcareous to acidic. By now, 14 of the 33 hectares have been transformed into a nature reserve because of their high potential for the development of calcareous grassland, mesotrophic flower-rich grasslands and calcareous marsh. The coming years will be marked by further development through appropriate management of the restored landscape. Eventually, the ecosystem approach to restoration that is being used will, in combination with effective management, create another jewel in the landscape of southern Limburg, in which the entire abiotic gradient from the edge of the plateau to the valley of the river Geul will be reflected in a unique, characteristic semi-natural vegetation." **22577.** van't Hof, A.E.; Fincke, O.M. (2023): Novel hatching cue in the neotropical damselfly *Megaloprepus caerulatus*: larval adaptation and maternal constraint. *International Journal of Odonatology* 26: 153-163. (in English) ["The evolution of sibling cannibalism as a maternal strategy is particularly challenging to explain when nurseries are shared among multiple females. Such is the case for *Megaloprepus caerulatus*,

whose females lay eggs in bark above the water line in large, water-filled tree holes. Asynchronous egg hatching appears to be a maternal bet-hedging strategy to increase the chances that cannibalistic offspring hatch during windows of opportunity, which occur after the remaining large larvae emerge, having eaten all others. We investigated the proximate causes of asynchronous hatching. By monitoring the pattern of egg hatching under ambient temperature in an insectary, we found that egg hatching co-occurred with lower ambient temperatures, which decreased with increasing rainfall. Treating fully developed eggs to a lower temperature for two hours triggered increased hatching relative to controls at ambient temperature. Dissection of control clutches indicated that embryonic development of siblings was asynchronous. Results suggested that the hatching trigger is adaptive. Rainfall assures a recharge of the larval habitat with water and provides wet conditions essential for neonate mobility on bark. Only 40% of neonates in a 4-day drying treatment survived; none survived the 8- and 14-day treatments. This novel hatching trigger should increase the number of neonates entering the nursery after rains, constraining a mother's control over the timing of egg hatch, while increasing the competition among related and unrelated offspring for limited windows of opportunity in the shared nursery." **22578.** Vejříková, I.; Vejřík, L.; Cech, M.; Blabolil, P.; Peterka, J. (2023): Variable diet plasticity in Eurasian perch (*Perca fluviatilis*): Current versus seasonal food uptake. *Ecology of Freshwater Fish* 32: 795-803. (in English) ["Diet plasticity is often studied in Eurasian perch (*Perca fluviatilis*), a species commonly described as having generalist populations composed of specialised individuals. Perch diet was examined using gut content analysis (GCA) and stable isotope analysis (SIA), and individual specialisation was calculated in two study lakes within 2 years. Mostly only one diet category was present in the perch stomach, with more variation in the diet in the Most lake compared to the Milada lake between 2013 and 2014. The calculated degree of individual specialisation indicated higher specialisation in the Most lake. Interestingly, despite the different or almost uniform diet composition between the years, the total niche width (based on SIA) of the population remained similar in both lakes. This suggests that the overall variation in the sources utilised by the entire population remained consistent between the years. GCA mostly indicated zooplankton as the prevailing food source, whereas SIA indicated significant utilisation of YOY fish earlier that year, an information that was completely missed by the GCA of fish caught in September. The differences between GCA and SIA results could be attributed to the different time intervals reflected by the methods, but possibly to the conversion of the diet into the body tissues that is reflected by SIA and may depend on the diet's nutritional values rather than the proportion of different prey consumed." (Authors) No details on Odonata are given.] Address: Vejříková, I., Biology Centre of the Czech Academy of Sciences, Institute of Hydrobiology, České Budejovice, Czech Republic

**22581.** Vilela, D.S.; Reis dos Santos, M.; Heldt Junior, R.; Monteiro, R.T.; Pereira de Gouvêa, T.; de Souza, M.M. (2023): Odonata (Insecta) in high-altitude fields and associated ecosystems in the Poços de Caldas Plateau, Brazil. *Revista Chilena De Entomología* 49(4): 843- 860. (English, with Spanish summary) ["The High Altitude Fields (HAF) are unique phytosociological features that occur only in certain regions of the Atlantic Forest. It is composed of herbaceous and shrubby vegetation and shallow soils that promote local water infiltration and recharge. Occurring on top of hills, the HAF are isolated units in the landscape, connecting with the matrix through associated ecosystems (springs with riparian forests and "capões de mata", which are natural islands of arboreal vegetation, commonly associated with rural vegetation, such as high-altitude fields, located above 1,200 m in phytogeographic domains of the Atlantic Forest, Cerrado or Caatinga). These areas have great species endemism, and studies concerning the order Odonata are still scarce. Thus, we aimed to evaluate the ecological responses (richness, diversity, specificity) of adult odonates in these ecosystems. The study was conducted from November 2020 to March 2021 in three areas in the Poços de Caldas Plateau, Minas Gerais state, Brazil. A total of 45 species (247 specimens) were collected, with the highest total richness being recorded for Anisoptera. Among the sampled areas, there was no difference in Anisoptera communities, but there was a difference in Zygoptera species composition. In general, the most preserved remnant of HAF, the greater it presents greater richness of Odonata and harbors a regional pool of species." **22582.** Viza, A.; Garcia-Raventós, A.; Riera, J.L.; Maynou,

X.; Martín, R.; Prunier, F.; El Haissoufi, M.; Múrria, C. (2023): Species-specific functional traits rather than phylogenetic relatedness better predict future range-shift responses of odonates. *Insect Conservation and Diversity* 16(5): 574-587. (in English) ["Climate change has the potential to modify habitat characteristics and, consequently, induce species responses to ongoing environmental changes. Functional traits determine both if a species can persist and maintain stable population sizes in particular ecological conditions, and its capacity to disperse to more favourable habitats. Given that functional traits evolve over time, one could expect closely related species to show similar responses to climate change, which should identify vulnerable lineages. Alternatively, species-specific functional traits may anticipate species responses to climate change, and therefore, trait composition should be a strong predictor. We compiled a comprehensive dataset of functional traits of 84 Iberian and Moroccan odonates species and built a phylogenetic tree to determine if dissimilarity of traits and phylogenetic relatedness are relevant to better discriminate species range-shift responses to climate change. Modelling results for 66 species showed clear impacts of the increase in temperature and drought events on their potential distribution. The traits that best-discriminated species that expanded their ranges were multivoltinism, short-life cycles and preference for temporary habitats, whereas species with a reduced and displaced potential distribution were mostly semivoltine, with a short flying season, oviposition on gravel and restricted to permanent streams, small rivers or oligotrophic lakes. Trait conservatism was rejected and phylogenetic relatedness was a poor predictor of range shifts. Considering odonates as model organisms, traits such as voltinism, beginning and prolongation of flight period and preference of temporal habitats should be examined to anticipate range-shift responses of freshwater insects to climate change." **22584.** Walia, G.K.; Dhillon, G.K. (2023): Phylogenetic analysis of *Aciagrion* Selys (Odonata: Coenagrionidae). *Journal of Natural History* 57(37-40): 1610-1628. (in English) ["Odonates are useful biological indicators of environmental health because of their pollution-free habitat requirements and amphibiotic life cycle. Due to habitat destruction by industrial development, there is a need to name these odonates and obtain their genetic data to be used in understanding their evolutionary history for biodiversity conservation. *Aciagrion* is a poorly known and taxonomically difficult genus of oriental damselflies. Species of this genus cannot be distinguished on the basis of morphological characters alone as they are morphologically similar to the damselflies of other genera (*Ischnura* and *Amphialagma*) and may also be referred to

as cryptic species. Here, therefore, molecular studies are carried out to distinguish the species of this genus. The phylogenetic relationships of five species of genus *Aciagrion* have been explored using molecular (based on concatenated sequences of mitochondrial genes- COI, ND1 and 16S rRNA genes) as well as external morphological characters. Single-linkage cluster analysis of morphological data sets did not explain the relationships appropriately among the species of this genus as outgroup species were also retrieved within in-group species. Interspecific genetic divergence, conserved, variable, parsimony-informative sites, nucleotide base composition and transition/transversion bias based on concatenated gene sequences have been calculated for these species. It is found that a multigene concatenation approach interprets phylogeny more appropriately than the morphological data alone. Presently, a COI gene fragment sequence for one species (the endemic *Aciagrion hisopa*), 16S rRNA gene fragments for four species and ND1 gene fragments for five species have been submitted for the first time to GenBank, and phylogenetic relationships based on three genes have also been determined for the first time. *Aciagrion migratum* is a new record from India." of short-term temporal variability on the efficacy of dragonfly larvae as mercury biosentinels. *Science of The Total Environment* 867, 161469: 9pp. (in English) ["Highlights: • Spatial variation in Hg exceeded temporal variability. • Temporal patterns in Hg differed among sites in the same region. • %MeHg is consistent over time. • Relationship between abiotic and biotic Hg varies over time. Abstract: Mercury (Hg) exposure to fish, wildlife, and humans is widespread and of global concern, thus stimulating efforts to reduce emissions. Because the relationships between rates of inorganic Hg loading, methylmercury (MeHg) production, and bioaccumulation are extremely complex and challenging to predict, there is a need for reliable biosentinels to understand the distribution of Hg in the environment and monitor the effectiveness of reduction efforts. However, it is important to assess how temporal and spatial variation at multiple scales influences the efficacy of specific biosentinels. Seasonal and interannual variation in total Hg (THg) concentrations of dragonfly larvae were examined in relation to spatial variability among 21 sites in two U.S. national parks with contrasting ecologies Hg deposition patterns. Dragonfly THg differed among sampling events at 17 of the 21 sites, but by an average of only 20.4% across events, compared to an average difference of 52.7% among sites. Further, THg concentrations did not follow consistent seasonal patterns across sites or years, suggesting that the observed temporal variation was unlikely to bias monitoring efforts. Importantly, for a specific site, there was no difference in %MeHg in dragonflies among sampling events. Finally, there was significant temporal variability in the biogeochemical factors (aqueous inorganic Hg, aqueous MeHg, DOC, SO<sub>4</sub>, and pH) influencing dragonfly THg, with the importance of individual factors varying by 2.4 to 4.3-fold across sampling events. Despite these results, it is noteworthy that the observed temporal variation in dragonfly THg concentrations was neither large nor consistent enough to bias spatial assessments. Thus, although this temporal variation may provide insights into the processes influencing biological Hg concentrations, it is unlikely to impair the use of dragonflies as biosentinels for monitoring spatial or temporal patterns at scales relevant to most mitigation efforts." (2023): The genomics and evolution of inter-sexual mimicry and female-limited polymorphisms in damselflies. *Nature Ecology & Evolution*: 15 pp, suppl. (in English) ["Sex-limited morphs can provide profound insights into the evolution and genomic architecture of complex phenotypes. Inter-sexual mimicry is one particular type of sex-limited polymorphism in which a novel morph resembles the opposite sex. While inter-sexual mimics are known in both sexes and a diverse range of animals, their evolutionary origin is poorly understood. Here, we investigated the genomic basis of female-limited morphs and male mimicry in *Ischnura elegans*. Differential gene expression between morphs has been documented in damselflies, but no causal locus has been previously identified. We found that male mimicry originated in an ancestrally sexually dimorphic lineage in association with multiple structural changes, probably driven by transposable element activity. These changes resulted in ~900 kb of novel genomic content that is partly shared by male mimics in a close relative, indicating that male mimicry is a trans-species polymorphism. More recently, a third morph originated following the translocation of part of the male-mimicry sequence into a genomic position ~3.5 mb apart. We provide

evidence of balancing selection maintaining male mimicry, in line with previous field population studies. Our results underscore how structural variants affecting a handful of potentially regulatory genes and morph-specific genes can give rise to novel and complex phenotypic polymorphisms." **22590.** Worthen, W.B.; Harrell, M.D. (2023): Differences in perch height and response to intruders for territorial and non-territorial *Calopteryx maculata* (Odonata: Calopterygidae). *International Journal of Odonatology* 26: 145-152. (in English) ["In *C. maculata*, territorial males court potential mates and guard ovipositing females near the surface of the water. We conducted a survey and an experiment to determine whether there was a relationship between territoriality (site fidelity and agonistic behavior) and perch height. In the survey, males were captured, numbered, and released, and their perch height and location along a stream was noted for two weeks. Mean perch height was positively correlated with total distance travelled and negatively correlated with the number and percentage of times observed at the same site. Males that travelled less than 4 m had a significantly lower mean perch height than males that travelled more than 4 m. We conclude that males with greater site fidelity perch lower than males that travel widely. To test for a relationship between agonistic behavior and perch height, live male and female decoys, and a stick control, were run along a 20 m zip-line at two heights (25 cm and 75 cm), and the responses of resident males were recorded. Resident males that perched low (< 1 m high) approached decoys more often than resident males that perched high, and low-flying decoys were approached more than high-flying decoys. We conclude that territorial males—identified by greater site fidelity and agonistic behavior—perch lower than other males and are particularly responsive to low flying intruders. The benefits and costs of perching low and responding to low-flying intruders are discussed." (Authors)] Address: Worthen, W.B., Biology Dept, Furman University, Greenville, SC, 29613, USA

**22592.** Yan, H.; Sun, F.; Zhang, Y. (2023): Scientific and technical analysis of lead-barium glaze dragonfly eye beads from the Late Warring States period in China. *Heritage Science* (2023) 11:186: 9 pp. (in English) ["This paper analyzed five dragonfly eye beads excavated from M176 of the Hejia Cemetery in the Late Warring States period (around 3rd c. BC) by using a super depth of field 3D microscope system (OM), scanning electron microscope-energy dispersive spectrum (SEM-EDS) and Raman spectroscopy. The analytical results confirmed that all the beads were glazed pottery and the glaze material belongs to the lead-barium-silicate (PbO-BaO-SiO<sub>2</sub>) system. The color component of the glaze is Chinese Blue (BaCuSi<sub>4</sub>O<sub>10</sub>). Three beads, M176-2, M176-3, and M176-4, were formed with an inner core support and were made in the same batch. Additionally, two weathering products, CuPb<sub>4</sub>(SO<sub>4</sub>)<sub>2</sub>(OH)<sub>6</sub> and PbCO<sub>3</sub>, were detected on the glaze layer surface. The results of scientific and technological analysis show that these beads have differences in the composition of the body and glaze, and the color composition in the glaze layer is relatively rare in previous studies. The discovery of lead-barium glazed pottery beads from the Late Warring States period in northern China provides new evidence for further exploration into the origins and evolution of early glazed pottery. The identification of weathering products formed on the beads' surface within an alkaline burial environment holds valuable implications for the study of weathering and deterioration in silicate artifacts. .... Dragonfly eye beads are a type of bead imitating the structure of a dragonfly's compound eye by inlaying different colored-glass onto the base [1, 2]. It first appeared in ancient Egypt during the 18th dynasty (1550–1307 BC) [3], then became widely popular on the Mediterranean coast and the Iranian plateau [4, 5], and came into China through trade at a later time. However, the exact route of transmission has not been found clearly. Many different shapes of dragonfly eye beads have been excavated from various sites in China. ...." (2023): Little bits of dragonfly history repeating exemplified by a new Pennsylvanian family. *Royal Society Open Science* 10: 230904. <https://doi.org/10.1098/rsos.230904>: 13 pp. (in English) ["During its 320 Myr evolution, Odonata wing morphology underwent intense modifications. The resulting diversity prompted comparative analyses focusing on phylogeny. However, homoplasy proved to plague wing-related characters. Concurrently, limited benefits were obtained from considering fossil taxa, similarly impacted. Herein, we investigate two aspects

particularly affected by convergence, namely the acquisition of vein-like structuring elements derived from regular cross-venation, termed conamina; and the evolution of butter knife wing shape. Conamen implementation is found to be consistently linked with vein curvature sharpening, itself generating potential breaking points. Conamina therefore likely evolved to address wing integrity issues during ever-more-demanding flight performance. Moreover, an existing conamen is likely to trigger the acquisition of further, associated conamina. As for butter knife shape, previously documented in the extinct Archizyoptera and among damselflies, we report a new, 315 Ma occurrence with the rare species *Haidilaozhen cuiiae* gen. et sp. nov. (family Haidilaozhenidae fam. nov.), from the Xiaheyan locality (China). The repeated acquisition of butter knife-shaped wing can be related to slow speed flight and, in turn, predator avoidance. In both cases of iterated regularities, the unique 'network-and-membrane' wing design proper to insects is found to compose a strong, constraining factor." **22597.** Zeng, Z.; Chen, X.-Y.; Yu, X. (2023): Stability of diagnostic morphological characters in *Ceriagrion* larvae (Odonata: Zygoptera). *Acta Hydrobiologica Sinica* 47(10): 1659-1668. (in Chinese, with English summary) ["Although dragonfly larvae can be good bioindicators in fresh water environment

assessments, their identification based on morphological characteristics is still a tough work, especially at species level. In the present study, 116 larvae of two Chinese widespread damselfly, *Ceriagrion fallax* Ris and *Ceriagrion auranticum* Fraser, were identified depending on sequence data of the mitochondrial genes Cytochrome Oxidase I (COI) and nuclear ribosomal genes ITS. The stability of two important morphological characters, caudal gills and mandibles, was discussed. For molecular analysis, LCO1490d (TTTCTAC-WAACCAYAAAGATATTGG) and HCO2198d (TAACTTC-WGGRTGTCC AAARAATCA) were used as COI primers, and Vrain2F (CTTTGTACACACCGCCCGTCGCT) and Vrain2R (TTTCACTCGCCGTTACTAAGGGAATC) as ITS primers. The reaction systems were 31.0  $\mu$ L: DNA template 3.0  $\mu$ L, upstream and downstream primers 2.0  $\mu$ L each, Mix 15.0  $\mu$ L (Jiangsu ComWin Biotech Co., Ltd's 2xEs Taq Master Mix), ddH<sub>2</sub>O 9.0  $\mu$ L. Take 5.0  $\mu$ L PCR amplification products and detect them by electrophoresis using 1.5% agarose gel. The amplification products with detected by electrophoresis, and then sent to Chongqing Tsingke Xingye Biotechnology Co to sequence. Neighbor-Joining (NJ) trees and genetic distance method were using for the molecular identification of larvae, with the help of identified adults' sequences as conference. Relative large size of larval specimens, *C. fallax* (n=110) and *C. auranticum* (n=6), were dissected and photographed using LY-WN-OPLENC ultra-clear microphotographic system. Detailed comparative morphological examination was conducted focusing on two typical morphological features, caudal gill and mandibles. Our result showed that: (1) the presence or absence, numbers, and color of the black spots on the caudal gill were unstable, which have nothing to do with populations and sex; (2) characters of mandibles were also variable even within the same population. The discovery of the instability of the two typical diagnostic morphological characters indicates that characters of caudal gills and mandibles, at least, in these two species should be used with caution latterly in taxonomy. Our result also suggests that the similar instability may exist in other diagnostic morphological characteristics in other odonate species. The idea and methodology of this study can be instructive to future morphological studies on insect taxonomy." **22598.** Zhang, H. (2023): Bio-inspired superhydrophobic surface based on hierarchical periodic surface structures of titanium by ultrafast laser. *Proceedings Volume 12793, International Conference on Mechatronics and Intelligent Control (ICMIC 2023); 127931P (2023)* <https://doi.org/10.1117/12.3006756>: 7 pp. (in English) ["Metallic materials are widely used in various industrial scenarios but they often suffer from different issues such as icing, corrosion, and damage, which negatively impact the safety and performance of equipment. Superhydrophobic materials, characterized by an apparent contact angle greater than 150° have been extensively studied as potential solutions to these problems. This paper introduces the basic theory of surface wettability, discusses applications of metallic surfaces and two main strategies for obtaining superhydrophobic surfaces. Inspired by the structure of dragonfly wings, we present an experimental method using a Ti:sapphire ultrafast laser system to fabricate superhydrophobic surfaces on TC4 titanium alloy samples. Scanning electron microscopy (SEM) and energy dispersive spectrometer (EDS) analysis reveal the ultrafast laser pulse can induce micro-scale groove structures and nano-scale laser induced periodic surface structures (LIPSS) on the morphology of titanium and will cause a significant change in the

surface chemistry. The resulting superhydrophobic behavior can be attributed to a combination of surface roughness and low surface energy, which has potential applications in fields such as self-cleaning surfaces, microfluidics, and anti-corrosion coatings." (Author)] Address: not stated

**22599.** Zhang, X.; Zheng, D.; Li, Y.; Song, S.; Zhang, H. (2023): Discovery of *Sinaeschnidia heishankowense* Hong, 1965 (Odonata: Aeschniidae) from the Lower Cretaceous of Baiwan Basin, southwestern Henan, China: biogeographic implications. *Cretaceous Research* 147, July 2023, 105513: (in English) ["The Jehol Biota is the best-preserved Cretaceous terrestrial biota and one of the most important treasures housing exceptionally-preserved fossils in the world. The Jehol Biota *sensus stricto* is found distributed in northern Hebei, western Liaoning and southeastern Inner Mongolia, northeast China, while the Jehol Biota *sensu lato* is distributed in most of East Asia. The three-stage evolution of the Jehol Biota suggests that the biota extended south to the Qinling-Dabie mountains at its second stage, including western and southern Henan. Here the adult dragonfly *Sinaeschnidia heishankowense* Hong, 1965 is reported for the first time from the Baiwan Formation of the Baiwan Basin, Zhenping County, southwestern Henan, China. *S. heishankowense* is one of the representatives of the second stage of the Jehol Biota, previously only recorded in the Lower Cretaceous Yixian Formation in western Liaoning and southeastern Inner Mongolia, and the equivalent strata in China. This finding confirms that the Jehol Biota reached southwestern Henan at its second stage, and that the Baiwan Formation in the Baiwan Basin could be generally correlated with the Yixian Formation in western Liaoning, assigned to a middle Barremian age (Lower Cretaceous) rather than to the Upper Jurassic as previously considered." **22600.** Zheng, H.; Mofatteh, H.; Habcicsek, M.; Akbarzadeh, A.; Akbarzadeh, M. (2023): Dragonfly-inspired wing design enabled by machine learning and Maxwell's reciprocal diagrams. *Advanced Sciences* 2023, 2207635: 15 pp. (in English) ["This research is taking the first steps toward applying a 2D dragonfly wing skeleton in the design of an airplane wing using artificial intelligence. The work relates the 2D morphology of the structural network of dragonfly veins to a secondary graph that is topologically dual and geometrically perpendicular to the initial network. This secondary network is referred as the reciprocal diagram proposed by Maxwell that can represent the static equilibrium of forces in the initial graph. Surprisingly, the secondary graph shows a direct relationship between the thickness of the structural members of a dragonfly wing and their in-plane static equilibrium of forces that gives the location of the primary and secondary veins in the network. The initial and the reciprocal graph of the wing are used to train an integrated and comprehensive machine-learning model that can generate similar graphs with both primary and secondary veins for a given boundary geometry. The result shows that the proposed algorithm can generate similar vein networks for an arbitrary boundary geometry with no prior topological information or the primary veins' location. The structural performance of the dragonfly wing in nature also motivated the authors to test this research's real-world application for designing the cellular structures for the core of airplane wings as cantilever porous beams. The boundary geometry of various airplane wings

is used as an input for the design procedure. The internal structure is generated using the training model of the dragonfly veins and their reciprocal graphs. One application of this method is experimentally and numerically examined for designing the cellular core, 3D printed by fused deposition modeling, of the airfoil wing; the results suggest up to 25% improvements in the out-of-plane stiffness. The findings demonstrate that the proposed machine-learning-assisted approach can facilitate the generation of multiscale architectural patterns inspired by nature to form lightweight load-bearing elements with superior structural properties." (2024): Environmental and aquatic macroinvertebrates metrics respond to the Eucalyptus afforestation gradient in subtropical lowland streams. *Hydrobiologia* 851(2): 343-365. (in English) ["Eucalyptus afforestation may affect stream ecosystems, but the magnitude of these effects on water quality and biota in subtropical lowland streams is little understood. We evaluated the potential effects of Eucalyptus afforestation on water quality and macroinvertebrate assemblage. Water quality parameters and macroinvertebrate assemblages were sampled in summer and winter in 30 streams covering an afforestation gradient (from 0.05 to 96% of the catchment area) and tested their relationship. We analyzed the taxa density distribution in afforestation and water parameters using the Thresholds Indicator Taxa Analyses (TITAN). Nutrient concentrations, conductivity, and total dissolved solids showed positive responses to the increase of afforestation, but the responses varied among seasons. Macroinvertebrate metrics showed negative (Ephemeroptera-Trichoptera-Plecoptera (EPT), sensitive families, scrapers), and positive (Chironominae, Oligochaeta) responses to the afforestation. Densities of sensitive taxa (mostly EPT) decrease with an increase in Eucalyptus afforestation, which is also related to water quality and possibly to habitat changes attributed to afforestation management. The use of water quality parameters in combination with macroinvertebrates assemblage contributes to managing these streams under catchment afforestation." (Authors) Taxa include Odonata, and are treated at family or genus level.] Address: Barrios, M., Depto Ecología y Gestión Ambiental, Centro, Univ. (2024): How pondscapes function: connectivity matters for biodiversity even across small spatial scales in aquatic metacommunities. *Ecography* 2023: e0696. 12 pp. (in English) ["Habitat loss and fragmentation are growing global threats to natural habitats and their networks, posing significant challenges to biodiversity conservation. Globally, ponds are sharply declining in number because their small size makes them highly vulnerable to land use changes. While it is generally agreed that connectivity in habitat networks is crucial for sustaining biodiversity, the effect of connectivity on biodiversity patterns over small-scaled habitat networks has so far received less attention given the general assumption that metacommunities lack spatial structuring on small scales. In this study, we tested whether this holds for multiple passively and actively dispersing organism groups in a well-

delineated pond metacommunity of 54 bomb crater ponds situated within 1 km. We investigated the influence of space and environment on species richness and metacommunity structure in these ponds, which share similar age, size, and shape and are subject to strong environmental gradients, making it an ideal study system. We specifically examined the impact of network centrality on taxonomic richness and eigenvector-based spatial arrangement on metacommunity structure across different organism groups, including prokaryotes, microeukaryotes, zooplankton, macroinvertebrates, and amphibians. We found that while environmental filtering is the primary driver of community dynamics, there is also a significant spatial signal, particularly for passively dispersing groups, demonstrating the role of the central-peripheral connectivity gradient. These findings highlight the importance of studying and protecting ponds as parts of a network rather than focusing on individual ponds." **22604.** Malacarne, T.J.; Machado, N.R.; Moretto, Y. (2024): Influence of land use on the structure and functional diversity of aquatic insects in neotropical streams. *Hydrobiologia* 851: 265-280. (in English) ["Although many studies show the negative impacts of agricultural activities on aquatic ecosystems, few relate functional and structural characteristics of the biota. We evaluate the structure and functional dynamics of aquatic insects in headwater streams with different degrees of land cover and in different hydrological periods, in a hydrographic basin where agriculture and livestock predominate. Three diversity indices were measured: functional richness (FRic), functional equitability (FEve) and functional dispersal (FDis), with the highest values recorded for Trichoptera, Diptera, Coleoptera and Odonata. From the results, the abundance was higher in the dry season and some families were exclusive to this period. In the rainy season, there was a decline in total abundance and richness of families and an increase of Diptera in urban streams. In rural streams, we registered an occurrence of Odonata, Coleoptera and EPT and a reduction of Diptera. The recorded data confirm that urbanization has negative effects on ecosystem functioning, since urban streams showed lower richness, dispersion and functional evenness. Furthermore, the increase in taxonomic diversity was accompanied by an increase in functional diversity, which reinforces the importance of the combined approach of functional and structural traits to better understand the impacts of anthropic changes in neotropical streams." **22605.** Munyai, L.F.; Liphadzi, T.; Mutshekwa, T.; Mutoti, M.I.; Mofu, L.; Murungweni, F.M. (2024): Water and sediment

chemistry as drivers of macroinvertebrates and fish assemblages in littoral zones of subtropical reservoirs. *Water* 2024, 16, 42. <https://doi.org/10.3390/w16010042>: 15 pp. (in English) ["Reservoirs are human-made ecosystems with diverse purposes that benefit humans both directly and indirectly. They however cause changes in geomorphological processes such as sediment cycling and influence the composition and structure of aquatic biota. This study aimed to identify water and sediment quality parameters as drivers of macroinvertebrates and fish communities during the cool-dry and hot-wet seasons in the littoral zones of three subtropical reservoirs (Albasini, Thathe and Nandoni). Macroinvertebrates and fish were collected from three sites (n = 3 from each site) in each reservoir. A total of 501 and 359 macroinvertebrates and fish individuals were collected throughout the sampling period, respectively. The present study employed a two-way ANOVA in conjunction with redundancy analysis (RDA) to assess the relationships that exist between water and sediment variables, macroinvertebrates diversity and species abundances across seasons. Based on the two-way ANOVA model, significant differences were observed across reservoirs for evenness, Simpson's diversity, and total abundance, while seasonal differences were observed for most metrics, with exception for evenness. The RDA results identified four water variables (i.e., water temperature, oxidation–reduction potential, pH and conductivity) and one sediment metal (Mg) as the most important parameters in driving the fish community structure. Field observations and metal results attest that the Nandoni reservoir shows high concentrations of metals in sediments as compared to other reservoirs, suggesting that anthropogenic activities such as car washing, brick making, recreation, fishing, wastewater treatment work and landfill site may be the major contributor of metals to the Nandoni reservoir, which accumulate in the littoral zones. Findings of this study highlight the need to analyze reservoir ecological conditions at several scales. The study of macroinvertebrates and fish, water, and sediment chemistry in the littoral zone laid the groundwork for proposing measures for conserving aquatic ecosystems. A total of 501 macroinvertebrate individuals belonging to 21 families and 7 orders were identified within three selected water bodies (Table 3). In terms of orders, Hemiptera (28.6%) was the dominating order followed by Odonata (23.8%) and Coleoptera (14.3%)." **22606.** Musters, C.J.M.; Honkoop, H.P.; de Snoo, G.R. (2024): Well known indicator groups do not predict the decline of insects. *Ecological Indicators* 158, January 2024, 111458: 8 pp. (in English) ["Highlights: • Random Forests were trained with species samples to predict the decline of insect. • Training with random species samples resulted in prediction accuracy of 0 to 0.4. • Training with taxonomic samples resulted in low accuracy of prediction of decline. • Using taxonomic indicator groups is advised against in case of insects. Abstract: In decision making for insect conservation, one depends largely on knowledge of the relationship between changes in environmental factors and abundance of a very limited number of species. The species we have knowledge on cannot be regarded as a representative sample of all insects. How accurately do changes in the abundance of these species predict the changes in other species? To answer this question, we studied 373 insect species belonging to the Apidae (bees), Lepidoptera (butterflies), Orthoptera (grasshoppers), Ephemeroptera (mayflies), Trichoptera (caddisflies), Odonata (dragonflies), and Plecoptera (stoneflies),

with known population trends and attributes in the Netherlands. The 78 attributes included morphological and demographic trait values, as well as habitat requirements of species. We trained Random Forests (RFs) with random samples and with taxonomic groups to predict the decline of the species based on their attributes. Then we used the trained RFs to predict the decline of the species outside the training groups and checked the accuracy of the predictions. The results showed that accuracy of the predictions of the RFs trained by the random samples increased from 0 to 0.20 (maximum 0.40, on a scale of 0 to 1) with sample size increasing from 10 to 90% of the insects. Moreover, we found that the accuracy of the predictions by the RFs trained with the taxonomic groups were zero in case of butterflies and grasshoppers, and low in other groups (maximum 0.37, in case of bees predicting terrestrial insects). Accuracy depended significantly on the size of the taxonomic group. Large over- or underestimation of number of declining species occurred in all cases. Further, we found that the taxonomic groups had few attributes important for predicting in common. The attribute 'Active dispersion' had the highest importance when all insects were used for training the RF. Using 'indicator groups' for predicting the decline of insects has a high risk of over- or underestimating the actual number of declining species and should therefore be advised against unless the indicator group is sure to be representative." **22607.** Schuijt, L.M.; van Drimmelen, C.K.E.; Buijse, L.L.; van Smeden, J.; Wu, D.; Boerwinkel, M.-C.; Belgers, D.J.M.; Matser, A.M.; Roessink, I.; Beentjes, K.K.; Trimbos, K.B.; Smidt, H.; Van den Brink, P.J. (2024): Assessing ecological responses to exposure to the antibiotic sulfamethoxazole in freshwater mesocosms? *Environmental Pollution* 343, 123199: 12 pp. (in English) ["Highlights: • Environmentally relevant concentrations did not impair aquatic communities. • Combining DNA tools and morphological identification provided complementary information. • We observed inconsistent results between studies using comparable concentrations. Abstract: Antibiotics are a contaminant class of worldwide concern as they are frequently detected in aquatic ecosystems. To better understand the impacts of antibiotics on aquatic ecosystems, we conducted an outdoor mesocosm experiment in which aquatic communities were exposed to different concentrations of the antibiotic sulfamethoxazole (0, 0.15, 1.5, 15 and 150 µg/L). These concentrations include mean (0.15 µg/L) and maximum detected concentrations (15 and 150 µg/L) in aquatic ecosystems worldwide. Sulfamethoxazole was applied once a week for eight consecutive weeks to 1530 L outdoor mesocosms in the Netherlands, followed by an eight-week recovery period. We evaluated phytoplankton-, bacterial- and invertebrate responses during and after sulfamethoxazole exposure and assessed impacts on organic matter decomposition. Contrary to our expectations, consistent treatment-related effects on algal and bacterial communities could not be demonstrated. In addition, sulfamethoxazole did not significantly affect zooplankton and macroinvertebrate communities. However, some effects on specific taxa were observed, with an increase in *Mesostoma* flatworm abundance (NOEC of <0.15 µg/L). In addition, eDNA analyses indicated negative impacts on the insects Odonata [*Enallagma*] at a sulfamethoxazole concentration of 15 µg/L. Overall, environmentally relevant sulfamethoxazole concentration did not result in direct or indirect impairment of entire aquatic communities and ecological processes in our mesocosms. However, several specific macroinvertebrate

taxa demonstrated significant (in)direct effects from sulfamethoxazole. Comparison of the results with the literature showed inconsistent results between studies using comparable, environmentally relevant, concentrations. Therefore, our study highlights the importance of testing the ecological impacts of pharmaceuticals (such as sulfamethoxazole) across multiple trophic levels spanning multiple aquatic communities, to fully understand its potential ecological threats." **22608.** Silva, L.F.R.; Castro, D.M.P.; Juen, L.; Callisto, M.; Hughes, R.M.; Hermes, M.G. (2024): Ecological thresholds of Odonata larvae to anthropogenic disturbances in Neotropical savanna headwater streams. *Hydrobiologia* 851: 313-326. (in English) ["We evaluated whether ecological thresholds could be detected along gradients of disturbances by using larval Odonata genera. Morphological, physiological, and behavioral differences between Odonata suborders may be reflected in different thresholds to anthropogenic disturbance. Therefore, we hypothesized that larval Zygoptera genera would have narrower ecological thresholds in response to increased levels of stream disturbance and would be considered sensitive to anthropogenic disturbances, and the opposite for larval Anisoptera genera, which would have wider ecological thresholds and would be considered tolerant to anthropogenic disturbances. We assessed 30 larval Odonata genera collected from 186 headwater stream sites in the Neotropical Savanna. Threshold Indicator Taxa Analysis detected ecological thresholds in seven Odonata genera (*Argia*, *Brechmorhoga*, *Cacoides*, *Gomphoides*, *Phyllocyba*, *Progomphus* and *Hetaerina*) revealing them as robust bio-indicators (purity and reliability = 0.85). Most Zygoptera were associated with less-disturbed sites and most Anisoptera were associated with more-disturbed sites, but not all genera corresponded to this pattern. Therefore, we recommend using Odonata larvae at the genus-level, versus the suborder level, for constructing improved biomonitoring tools and obtaining more accurate impact assessments of Neotropical stream sites." **22609.** Suárez-Tovar, C.M.; Pereira, J.L.; Rocha, T.; Rivera-Duarte, J.D.; Juen, L.; Córdoba-Aguilar, A. (2024): Fierce city hunters: more effective predation of dragonflies and damselflies in urbanized areas. *Animal Behaviour* 208: 51-58. (in English) ["One area of animal behaviour of growing interest is related to the behavioural traits that favour species' survival in rapidly changing environments (e.g. cities). In this regard, one animal group that is resilient to urbanization is that of odonate insects. These animals are formidable generalist predators that exhibit large behavioural flexibility. Here we tested whether adult odonate communities show differences in behavioural traits associated with reproduction, foraging and thermoregulation in relation to an urbanization gradient. Our results indicate that individuals were more efficient at capturing prey in more urbanized places. More effective predation in cities may occur because of changes in the environment, changes in odonate behaviour or modifications in prey communities whose characteristics influence the success rate of odonates during hunting."
