**16911.** Mujumdar, N.; Thakuria, D.; Halali, D.; Koparde, P. (2018): Observations on underwater oviposition in *Pseudagrion indicum* Fraser (Odonata: Coenagrionidae): an endemic species from the Western Ghats. *Halteres* 9: 39-44. (in English) ["Opportunistic records from two localities in Northern and Southern Western Ghats highlight the lack of data on breeding biology of these odonates. Observations presented here throw light on the need for documentation of breeding season of these species, which appears to be the post-monsoon season for *P. indicum*. Our work concludes that more emphasis should be given on ecological studies of these insects, especially endemic species that can provide valuable

inputs in designing conservation strategies for potential areas." (Authors)] Address: Mujumdar, Neha, Bombay Natural History Society, Shaheed Bhagat Singh Road, Colaba, Mumbai - 400001, Maharashtra, India. E-mail: nehadm02@gmail.com

**16912.** Nakanishi, K.; Yokomizo, H.; Hayashi, T.I. (2018): Were the sharp declines of dragonfly populations in the 1990s in Japan caused by fipronil and imidacloprid? An analysis of Hill's causality for the case of *Sympetrum frequens*. *Environmental Science and Pollution Research* 25(35): 35352-35364. (in English) ["Neonicotinoids and fipronil are the most widely used insecticides in the world. Previous studies showed that these compounds have high toxicity to a wide taxonomic range of non-target invertebrates. In rice cultivation, they are frequently used for nursery-box treatment of rice seedlings. The use of fipronil and neonicotinoid imidacloprid is suspected to be the main cause of population declines of red dragonflies, in particular *S. frequens*, because they have high lethal toxicity to dragonfly nymphs and the timing of the insecticides' introduction in Japan (i.e., the late 1990s) overlapped with the sharp population declines. However, a causal link between application of these insecticides and population declines of the dragonflies remains unclear. Therefore, we estimated the amount of the insecticides applied for nursery-box treatment of rice seedlings and analyzed currently available information to evaluate the causality between fipronil and imidacloprid usage and population decline of *S. frequens* using Hill's causality criteria. Based on our scoring of Hill's nine criteria, the strongest lines of evidence were strength, plausibility, and coherence, whereas the weakest were temporality and biological gradient. We conclude that the use of these insecticides, particularly fipronil, was a major cause of the declines of *S. frequens* in Japan in the 1990s, with a high degree of certainty. The existing information and our analyses, however, do not allow us to exclude the possibility that some agronomic practices (e.g., midsummer drainage or crop rotation) that can severely limit the survival of aquatic nymphs also played a role in the dragonfly's decline." (Authors) imidacloprid = Neonicotinoid] Address: Hayashi, T.I., 1. National Institute for Environmental Studies, Ibaraki, Japan

**16913.** Nautiyal, P. (2018): Diet components, dietary habits, resource and its use in the coexisting catfish species. *J. Inland Fish. Soc. India*, 50(1): 9-20. (in English) ["In over last six decades fisheries of the Ganga river System in general and the Ganga R. in particular have witnessed a radical change in dominance from the carp to catfish and now to invasive exotic species. Has this happened due modified river environment (natural flows, pollution) or have the species modified the food-web of the river is an issue that should be addressed in deep earnest intent. Among many facets that need to be answered, we should know the food resources base available in the river environment, preferences of fish species, if it is selective and the extent of overlap among the sympatric and co-existing species. The present investigation precisely examines this for the co-existing catfish species, *Rita rita* and *Bagarius bagarius*. *R. rita* feeds with greater intensity than *B. bagarius*. In *R. rita* intensity was high in pre-

monsoon (January to May) compared to *B. bagarius* where intensity was higher in post monsoon (October to December). *R. rita* showed +ve preference for chironomid-Diptera and variety of Trichoptera among insects. Others include crustaceans and gastropod molluscs. In contrast *B. bagarius* shows preferences for a consortium of Diptera (Simuliidae), Trichoptera (Glossosomatidae), Ephemeroptera (Heptageniidae), Coleoptera and Odonata among insect food. It has high preference for fish elements. Both species select these items. There is a biologically significant diet overlap but these species avoid competition not only by selecting different items from the common food resource base but also by seasonal variation in feeding intensity. Such studies need to be extended to fish within and among feeding guilds." (Author)] Address: Nautiyal, P., Dept of Zoology & Biotechnology, H.N.B. Garhwal Univ., Srinagar 246174, Uttarakhand, India. E-mail: pn.mahseer@gmail.com

**16914.** Nel, A.; Prokop, J.; Pecharová, M.; Engel, M.S.; Garrouste, R. (2018): Palaeozoic giant dragonflies were hawked predators. *Scientific Reports* 8:12141 | DOI:10.1038/s41598-018-30629-w: 5 pp. (in English) ["The largest insects to have ever lived were the giant meganeurids of the Late Palaeozoic, ancient stem relatives of our modern dragonflies. With wingspans up to 71 cm, these iconic insects have been the subject of varied documentaries on Palaeozoic life, depicting them as patrolling for prey through coal swamp forests amid giant lycopsids, and cordaites. Such reconstructions are speculative as few definitive details of giant dragonfly biology are known. Most specimens of giant dragonflies are known from wings or isolated elements, but *Meganeurites gracilipes* preserves critical body structures, most notably those of the head. Here we show that it is unlikely it thrived in densely forested environments where its elongate wings would have become easily damaged. Instead, the species lived in more open habitats and possessed greatly enlarged compound eyes. These were dorsally hypertrophied, a specialization for long-distance vision above the animal in flight, a trait convergent with modern hawked dragonflies. Sturdy mandibles with acute teeth, strong spines on tibiae and tarsi, and a pronounced thoracic skewness are identical to those specializations used by dragonflies in capturing prey while in flight. The Palaeozoic Odonoptera thus exhibited considerable morphological specializations associated with behaviours attributable to 'hawkers' or 'perchers' among extant Odonata." **16915.** Nichols, J. (2018): An assessment of Odonata abundance and impacts from urbanization in La Crosse County, WI. Undergraduate Thesis, Environmental Science: Conservation and Ecology, Carthage College, Kenosha, Wisconsin: 28 pp. (in English) ["Knowledge of the relationships between urbanization and the ecology and distribution of odonates enhances our ability to effectively assess conditions of aquatic ecosystems and nearby terrestrial habitats. With this project, the terrestrial adult Odonata populations and species dynamics between urban and nonurban river

habitats of La Crosse County, WI were assessed using data received by the Wisconsin Odonata Survey. Using the counts of odonates by species from 2009 to 2015, calculations for general odonate abundance as well as species abundance were generated. It was expected that nonurban habitats would yield both more overall numbers of odonates as well as a more species, though the results showed little difference between the two types of locations. There were on average about 1 more individual odonates counted in urban locations. However, a t-test of these means yielded the data to not be considered statistically different (p-value 0.06). There was also little change in species counts for urban habitats, but there was a spike in counts of nonurban locations from 2009 – 2012, where there were 16 counted in 2009 up to 38 in 2012. Though the r-squared values of the corresponding trendlines suggest a low goodness of fit (< 0.001 and 0.27 for nonurban and urban locations), the low values were to be expected, given the variability of the data in terms of how uneven the counts were performed. The data itself was not gathered with regard to a study, as it has been the culmination of citizen scientists recording their own findings as they visited locations. The low values could reflect the bias toward sampling done for the survey, where the surveyor frequented more urban locations. Despite this, research done with regard to adult odonate ecology and 3 distribution is helping to broaden the lacking knowledge we currently have with regard to odonate population ecology, as well as increase our knowledge of the effects on urbanization on populations and habitats." (Authors)] Address: not stated

**16916.** Nourbakhsh, H.Z.; Obeidi, R. (2018): Analysis of the diet of the *Liza abu* (Heckel, 1843) in Mond River in Bushehr seaport. *Advances in BioResearch* 9(3): 140-144. (in English) ["During the fishing season, 765 *Liza abu* were collected from Mond River and the contents of their digestive system were examined. The minimum and maximum length of the collected fish was 45 and 350 mm, respectively. In addition, the gut length to body length ratio (RLG) of the one-year and five-year fish was 4 and 2.2, respectively. The highest frequency of nutrients in the river belonged to the Ephemeroptera, but the feeding preference of this fish was Plecoptera and Odonata in both rivers. The research results revealed that this fish is an omnivorous species given its feeding habits." **16921.** Ottonello, D.; Oneto, F.; Vignone, M.; Rizzo, A.; Salvidio, S. (2018): Diet of a restocked population of the European pond turtle *Emys orbicularis* in NW Italy. *Acta Herpetologica* 13(1): 89-93. (in English) ["Recently several projects have been implemented for the conservation of *E. orbicularis*, but few aspects of the captive-bred animals released into the wild have been described. In this note we report about the trophic habits of a small restocked population of the endemic subspecies *E. o. ingauna* that is now reproducing in NW Italy. Faecal contents from 25 individuals (10 females, 11 males and 4 juveniles) were obtained in June 2016. Overall, 11 taxonomic categories of invertebrates were identified, together with seeds and plant remains. Plant material was present in 24 out of 25 turtle faecal contents, suggesting that ingestion was deliberate. There were no differences between the dietary habits of females and males, and the trophic strategy of adult individuals was characterised by a relatively high specialization on dragonfly nymphae. These findings suggest that captive bred turtles are adapting well to the wild and that restocked individuals assumed an omnivorous diet, a trophic behaviour typical of other wild turtle populations living in similar habitats." (Authors)] Address: Salvidio, S., DISTAV, Univ. degli Studi di Genova, Corso Europa 26, 16132 Genova, Italy. E-mail: salvidio@dipteris.unige.it

**16922.** Panorel, P.A.; Maglasang, J.C. (2018): Experimental and computational investigation of corrugated dragonfly airfoil performance in small wind turbine applications. *Asia-Pacific Journal of Science, Mathematics and Engineering* 4(2): 4-8. (in English) ["Small wind turbines suffer performance degradation due to its inherent low Reynolds number flow. The flow is initially laminar and is prone to separate even under a mild adverse pressure gradient. Recent studies revealed the capability of corrugated Dragonfly airfoil in delaying flow separation against streamlined airfoils in the low Reynolds number regime. Hence, this paper aims to improve the performance of small wind turbines by leveraging the capabilities of Corrugated Dragonfly airfoil. Experimental results have shown that small wind turbines made from corrugated dragonfly, NACA 4412, and flat plate airfoil had a coefficient of performance of 0.191, 0.284 and 0.099, respectively."] Address: Panorel, P.A., Dept of Mechanical Engineering, MSUlligan, Institute of Tech., Iligan City, Philippines. **16924.** Parker, K.; Fuller, C. (2018): Effects of Roundup on feeding behavior of larval Blue Dashers, *Pachydiplax longipennis*. 2018 - Spring Scholars Week (April 16-20): (in English) [Verbatim: "Herbicides are widely used, and prior research has shown that many herbicides are harmful to organisms and the environment. Herbicides enter aquatic environments through runoff or aerial dispersion from fields. The objective of this study was to determine if Roundup (active ingredient Glyphosate) causes negative effects on feeding behavior of larval *Pachydiplax longipennis*. Larvae were captured from rainwater-filled mesocosms at Hancock Biological Station in Murray, KY. Larvae were exposed to one of four concentrations of Roundup (0mg/L, 2.5mg/L, 5mg/L, or 10mg/L). *Daphnia* consumption trials were conducted at 7 and 14 days post-exposure. There were no significant differences among treatments for whether or not larvae ate offered *Daphnia* for Day 7 ( $c^2 = 1.195$ ,  $df = 3$ ) or Day 14 ( $c^2 = 1.283$ ,  $df = 3$ ). For the trials on Day 7, Roundup concentration did not have a significant effect on the time it took the larvae to consume 1, 2, or 4 *Daphnia*; however, exposure significantly increased the time it took the larvae to consume three *Daphnia* ( $P=0.036$ ). For the trials on Day 14, concentration did not have a significant effect on the time it took to consume 1 or 2 *Daphnia*; however, Roundup significantly increased the time it took to consume 3 ( $P=0.050$ ) or 4 *Daphnia* ( $P=0.029$ ). Thus, Roundup slowed prey consumption, suggesting that it could have a negative impact on larval dragonfly predation and, consequently, their overall quality of life. More time to capture and consume food suggests higher energy usage during predation." (Authors)] Address: Parker, Kayleen, Biology Dept, Murray State University, Murray, KY 42071

**16925.** Parr, A.J. (2018): Migrant and dispersive dragonflies in Britain during 2017. *J. Br. Dragonfly Society* 34(2): 79-88. (in English) ["In Britain, the year 2017 proved to be a highly eventful one for migrant and dispersive dragonflies;

indeed it was to be one of the best years on record. Several dispersive species showed notable range expansions (e.g. the first record of *Libellula fulva* for Wales was made at Porthkerry Country Park, Glamorgan, on 7 June), and many of our recent colonist species fared well. The major highlights, however, referred to longer distance migrants, with immigration being noted throughout much of the year. Significant arrivals of *Anax ephippiger* were noted both in early spring 2017 and again in autumn. *Anaxparthenope* had a good year, with records from over 30 sites during the summer, and presumed immigrant *Aeshna affinis* were seen at a few localities in southern England well away from the species' breeding stronghold around the greater Thames Estuary. Perhaps the most significant events of the year involved various members of the Libellulidae. *Sympetrum fonscolombii* appeared in very good numbers, with records from almost 100 sites around the UK. Many individuals stayed around to breed, and a locally-bred second generation was noted during late summer/ autumn at sites as far north as Yorkshire, though productivity was in general low. The other highlights relate to *Crocothemis erythraea*, where a male was present at Longham Lakes in Dorset over 8-9 July; this followed late news, only recently received, of a male seen at Hickling Broad in Norfolk on 5 July 2016. These are the first confirmed British records for over a decade." (Authors)] Address: Parr, A.J., 10 Orchard Way, Barrow, Bury St Edmunds, Suffolk, IP29 5BX, UK

**16936.** Piersanti, S.; Reborá, M. (2018): The antennae of damselfly larvae. *Arthropod Structure & Development* 47(1): 36-44. (in English) ["The larval antennal sensilla of two Zygoptera species, *Calopteryx haemorrhoidalis* and *Ischnura elegans* are investigated with SEM and TEM. These two species have different antennae (geniculate, setaceous) and live in different environments (lotic, lentic waters). Notwithstanding this, similarities in the kind and distribution of sensilla are outlined: in both species the majority of sensilla types is located on the apical portion of the antenna, namely a composed coeloconic sensillum (possible chemoreceptor), two other coeloconic sensilla (possible thermo-hygroreceptors) and an apical seta (direct contact mechanoreceptor). Other mechanoreceptors such as filiform hairs sensitive to movements of the surrounding medium or bristles positioned to sense the movements of the flagellar segments are present on the antenna. Similarities in the antenna sensilla types and distribution are observed also with other dragonfly species, such as *Onychogomphus forcipatus* and *Libellula depressa*. A peculiar structure with an internal organization similar to that of a gland is observed in the apical antenna of *C. haemorrhoidalis* and *I. elegans* and it is present also in *O. forcipatus* and *L. depressa*. The possible function of this structure is at the moment unknown but it deserves further investigations owing to its widespread presence in Odonata larvae." **16937.** Pinto, A.P.; Kompier, T. (2018): In honor of conservation of the Brazilian Atlantic Forest: description of two new damselflies of the genus *Forcepsioneura* discovered in private protected areas (Odonata: Coenagrionidae). *Zoologia* 35: e21351: 19 pp. (in English) ["Two new Brazilian Protoneurinae damselflies, *Forcepsioneura regua* sp. nov. (holotype ♂ deposited in DZRJ: Brazil, Rio de Janeiro State, Cachoeiras de Macacu municipality, RPPN Reserva Ecológica de Guapiaçu) and *Forcepsioneura serrabonita* sp. nov. (holotype ♂ deposited in DZRJ: Brazil, Bahia State, Camacan municipality, RPPNs Serra Bonita), are described, illustrated and diagnosed based on males and females. The bluish and smaller *F. regua* sp. nov. has been confused with at least three previously described species, being very similar to the type species of *Forcepsioneura*, *F. garrisoni* Lencioni, 1999, but lacking a defined tubercle-like process on the posterolateral margin of the median lobe of the prothorax in both sexes, which allows it to be distinguished from all other known species. The shape of the cercus of the male of *F. serrabonita* sp. nov. is similar to that of *F. grossiorum* Machado, 2001 and *F. lucia* Machado, 2000, two species with very short ventrobasal process. However, it differs from them mainly by the mediobasal process of the cercus, which is rounded in dorsal view and almost not

visible in lateral view. The taxonomic status of *Forcepsioneura* is discussed and a comparison with the other species of the genus is provided. Based on size, habitat and coloration, *Forcepsioneura* can be informally divided into two groups: (1) large, orange-black and montane species, including *F. grossiorum*, *F. itatiaiae* (Santos, 1970), *F. lucia* and *F. serrabonita* sp. nov.; (2) small, bluish and lowland species, including *F. garrisoni*, *F. haerteli* Machado, 2001, *F. regua* sp. nov. and *F. sancta* (Hagen in Selys, 1860). Our findings highlight the urgency in directing collecting efforts to unexplored areas, as well as the importance of private preserves that harbor the type localities as guardians of the threatened and diverse Atlantic Forest diversity. Together these two localities surveyed account for more than 210 species of odonates, representing almost 24% of the number of Brazilian species. Brazil has the greatest number of known species of odonates in the world. This study shows that further research is required in order to fully understand the diversity of *Forcepsioneura*." **16940.** Rajabi, H.; Stamm, K.; Appel, E.; Gorb, S.N. (2018): Micro-morphological adaptations of the wing nodus to flight behaviour in four dragonfly species from the family Libellulidae (Odonata: Anisoptera). *Arthropod Structure & Development* 47(4): 442-448. (in English) ["Highlights: •The shape and material composition of the nodus in percher and flier dragonflies are adapted to their flight behaviour. •The area proportion of the soft, resilin-dominated cuticle is found to decrease from typical perchers to typical fliers. •The presence of a knot-shaped protrusion in the nodus of percher dragonflies is likely to avoid large wing displacements. •We suggest a framework for future research on the relationship between wing morphology and flight behaviour in dragonflies. Abstract: Adult dragonflies can be divided into two major groups, perchers and fliers, exhibiting notably different flight behaviour. Previous studies have yielded conflicting results regarding the link between the wing macro-morphology and flight style in these two groups. In this study, we present the first systematic investigation of the micro-morphological differences of wings of percher and flier dragonflies in four closely related species from the family Libellulidae. Our results suggest that the shape and material composition of wing microstructural components and, in particular, the nodus are adapted to facilitate the specific wing functioning in fliers and perchers. The findings further indicate a decreasing trend in the area proportion of the soft resilin-dominated cuticle in the nodus in the series of species from typical perchers to typical fliers. Such a reduction in the resilin proportion in the nodus of fliers is associated with an increase in the wing aspect ratio. The knot-shaped protrusion at the nodus of perchers, which becomes notably smaller in that of strong fliers, is likely to act as a mechanical stopper, avoiding large wing displacements. This study aims to develop a novel framework for future research on the relationship between wing morphology and flight behaviour in dragonflies." **16942.** Rampola, R.B.; Nuñez, O.M.; Villanueva, R.J.T. (2018): Species diversity and distribution of Odonata in selected river systems of North Cotabato, Philippines. *Proceedings of the 23rd International Forestry and Environment Symposium 2018 of the Department of Forestry and Environmental Science, University of Sri Jayewardenepura*: 1 p. (in English) [Verbatim: Odonata has long been studied as an insect order that plays an important role in the balance of aquatic environment. The order represents one set of insects that is potential in indicating environmental quality. In this study, the species diversity and distribution of Odonata in selected river systems of North Cotabato, Mindanao, Philippines was assessed. Four rivers were sampled in the study: Mirasol River in Alamada and Nicaan River in Libungan which are relatively disturbed and Raradangan River in Alamada and Kimarayag River in Pigcawayan which are relatively undisturbed. Opportunistic sampling was employed through sweep netting in visual encounter surveys. The association of environmental factors to species distribution was evaluated using Canonical Correspondence Analysis (CCA). Geographic Information System (GIS) was used to create a distribution map of Odonata species in the sampling sites. Fifteen species belonging to five families were recorded of which four (26.67%) species are Philippine endemic. High species diversity ( $H' = 2.13$ ) was recorded in Raradangan River (Site 1). Kimarayag River (Site 4) is considered high in diversity ( $H' = 2.02$ ) next to site 1. Moreover, Sites 2, Mirasol River ( $H' = 1.62$ ) and site 3, Nicaan River exhibited moderate diversity ( $H' = 1.53$ ) in spite of the human disturbances. The Oriental species, *Pseudagrion p. pilidorsum* (Brauer) is the most abundant distributed in all sampling sites. The values for all the parameters (water temperature, pH, dissolved oxygen and relative humidity) in all sampling sites are within the Philippine standard of water quality. Eight species were identified to be affected by high dissolved oxygen, three species were positively affected by relative humidity, and four species were found to have tolerance to change in water temperature. GIS mapping clearly showed spatial aggregation of species within the surrounding habitat. Results indicate that Odonata appears to be associated with habitat variables.] Address: Villanueva, R.J.T., D3C Gahol Apartment, Lopez Jaena St., PH-8000 Davao, Philippines. **16944.** Ribi, W.; Zeil, J. (2018): Diversity and common themes in the organization of ocelli in Hymenoptera, Odonata and Diptera. *Journal of Comparative Physiology A* 204(5): 505-517. (in English) ["We show in a comparative analysis that distinct retinal specializations in insect ocelli are much more common than previously realized and that the rhabdom organization of ocellar photoreceptors is extremely diverse. Hymenoptera, Odonata and Diptera show prominent equatorial fovea-like indentations of the ocellar retinae, where distal receptor endings are furthest removed from the lens surface and receptor densities are highest. In contrast, rhabdomere arrangements are very diverse across insect groups: in Hymenoptera, with some exceptions, pairs of ocellar retinular cells form sheet-like rhabdoms that form elongated rectangular shapes in cross-section, with highly aligned microvilli directions perpendicular to the long axis of cross-sections. This arrangement makes most ocellar retinular cells in Hymenoptera sensitive to the direction of polarized light. In dragonflies, triplets of retinular cells form a y-shaped fused rhabdom with microvilli directions oriented at 60° to each other. In Dipteran ocellar retinular cells microvilli directions are randomised, which destroys polarization sensitivity. We suggest that the differences in ocellar organization between insect groups may reflect the different head attitude control systems that have evolved in these insect groups, but possibly also differences in the mode of locomotion and in the need for celestial compass information." (2018): A diverse suite of pharmaceuticals contaminates stream and riparian food webs. *Nature Communications* volume 9, Article number: 4491 (2018): 9 pp. (in English) ["A multitude of biologically active pharmaceuticals contaminate surface waters globally, yet their presence in aquatic food webs remain largely unknown. Here, we show that over 60 pharmaceutical compounds can be detected in aquatic invertebrates and riparian spiders in six streams near Melbourne, Australia. Similar concentrations in aquatic invertebrate larvae and riparian predators suggest direct trophic transfer via emerging adult insects to riparian predators that consume them. As representative vertebrate predators feeding on aquatic invertebrates, platypus and brown trout could consume some drug classes such as antidepressants at as much as one-half of a recommended therapeutic dose for humans based on their estimated prey consumption rates, yet the consequences for fish and wildlife of this chronic exposure are unknown. Overall, this work highlights the potential exposure of aquatic and riparian biota to a diverse array of pharmaceuticals, resulting in exposures to some drugs that are comparable to human dosages." **16948.** Rodrigues, M.E.; De Oliveira Roque, F.; Guillermo-Ferreira, R.; Saito, V.S.; Samways, M.J. (2018): Egg-laying traits reflect shifts in dragonfly assemblages in response to different amount of tropical forest cover. *Insect Conservation*

and Diversity 12(3): 231-240. (in English) ["1. Oviposition site selection by aquatic insects is usually influenced by both aquatic and terrestrial cues. Landscape changes (e.g. native vegetation loss) can affect the level of the reproductive success in aquatic insects, changing local species composition and richness. 2. We investigate whether forest cover loss around streams influences the number of species with exophytic (species which lay eggs directly on the water surface), endophytic (species which lay their eggs directly into plant tissue), or epiphytic (species which lay eggs on the exposed surface of rocks, leaves, trunks or other substrates protruding from the stream surface) oviposition behaviour in dragonfly assemblages. 3. We sampled adult dragonflies in 116 streams in a Neotropical savanna region in Brazil. The relationship between species richness for each behavioural category, and the proportion of forest cover around the streams, was tested using regression analysis. 4. We collected 2413 Anisoptera and Zygoptera individuals, belonging to 8 families, 30 genera, and 63 species. Of these, 25 species were classified as exophytic, 28 as epiphytic, and 10 as endophytic. Our results show that the number of species with exophytic or epiphytic behaviour was strongly related to riparian forest loss. 5. Forest loss changes the habitat, and here, specifically changes site suitability for oviposition. We highlight the importance of using behavioural traits as a bioindicator tool for the assessment of anthropogenic impacts on tropical forest." **16955.** Sánchez-Guillén, R.A.; Ott, J. (2018): Genetic consequences of range expansions along several fronts in *Crocothemis erythraea*. *International Journal of Odonatology* 21(2): 81-91. (in English) ["Global warming has altered the ranges of many species, especially those of insects and other ectotherms that are particularly susceptible to rising temperatures. Four decades ago, *C. erythraea* began to demonstrate northern range expansion in Germany, as well as in Belgium, the Netherlands, Poland and the UK. The rapid range expansion of *C. erythraea* has highlighted the capacity of this dragonfly for dispersal, making this species a good model to investigate the genetic consequences of expansions from several fronts. We predict that the recently established populations of *C. erythraea* in central Europe (Germany & Switzerland) will show only a minimal reduction in genetic diversity (because founders may derive from a broader set of core populations) with respect to populations from core regions of this species, and an increase in the genetic differentiation (given the multiple independent expansion axes along the broad front). To test our hypothesis, we compared genetic variation, in terms of genetic diversity and genetic differentiation using two mitochondrial genes (cytochrome b and NADH dehydrogenase), between central Europe and three core regions (south-west Europe, Italy and Africa). Results were in concordance with our hypothesis: populations from central Europe did not show a significant reduction in the overall genetic diversity but were highly differentiated from Africa, Italy and south-west Europe populations." **16956.** Sanchez Herrera, M.; Beatty, C.; Nunes, R.; Re-alpe, E.; Salazar, C.; Ware, J.L. (2018): A molecular systematic analysis of the Neotropical banner winged damselflies (Polythoridae: Odonata). *Systematic Entomology* 43(1): 56-67. (in English) ["The Neotropics are a hotspot of global diversity for many groups of organisms, including the dragonflies and damselflies (Insecta: Odonata). While the number of biodiversity surveys and new species descriptions for Neotropical odonates is increasing, diversity in this region is still under-explored, and very few studies have looked at the genetic and morphological diversity among (and within) species. Here, we present an overview of the evolutionary history of the Neotropical damselfly family Polythoridae. The family comprises 57 species across seven genera: Chalcopteryx, Chalcothore, Cora, Euthore, Miocora, Polythore and Stenocora. Using a multi-locus approach, mitochondrial (COI, ND1, 16S) and nuclear (18S, 28S, EF1-alpha) genes were concatenated to estimate phylogenetic relationships. Our results support five monophyletic clades, which were not always congruent with the genera previously considered to be

monophyletic. Only Polythore was recovered as monophyletic, and within it there was geographical structure. We propose the following new genus-level classification: Chalcothore, Chalcopteryx, Cora s.s., Cora s.l., Miocora, Euthore s.l and Polythore. In addition, we proposed the following new combinations: Miocora aurea comb.n., Miocora chiripa comb.n., Euthore confusa comb.n., Euthore klenei comb.n., and Euthore terminalis comb.n., based on our phylogenetic analyses, our evaluation of morphological characters and their geographical distribution: these data each support the monophyletic entities we recover here." **16959.** Schmidt Dalzochio, M.; Renner, S.; Sganzerla, C.; Prass, G.; Ely, G.J.; Salvi, L.C.; Dametto, N.; Périco, E. (2018): Checklist of Odonata (Insecta) in the state of Rio Grande do Sul, Brazil with seven new records. *Biota Neotropica* 18(4): e20180551: 14 pp. (in English, with Portuguese summary) ["The regional knowledge of species diversity and distribution is important to support conservation strategies for species and their habitats. The main goal of this work is to present a checklist of Odonata species in the state of Rio Grande do Sul, as well as their known locations in the municipalities. The preparation of the list was based in data gathered from collections of Museu de Ciências da Universidade do Vale do

Taquari (UNIVATES), Laboratório de Ecologia e Evolução da Universidade do Vale do Taquari (UNIVATES), Museu de Ciências Naturais da Fundação Zootânica, Museu de Zoologia da Universidade do Vale do Rio dos Sinos (UNISINOS) plus data extracted from 65 publications and the sites SpeciesLink, All Odonata and Puget Sound University. A total of 182 Odonata species were recorded, spanning nine families and 57 genera. The most representative family was Libellulidae (80 species) followed by Coenagrionidae (41 species) and seven species are new records for Rio Grande do Sul. The list of species presented here is a significant advance compared to previous counts for Rio Grande do Sul, however, our list is by no means a final one. Some regions of the state remain poorly explored, such as the border to Uruguay also in the northernmost part of the state. Several families remain poorly sampled, especially those that inhabit small forested streams and probably there are many specimens which are not cataloged and identified yet in scientific collections, both in the state and in the country." (Authors)] Address: Schmidt Dalzochio, Marina, Universidade do Vale do Taquari, Laboratório de Ecologia e Evolução, Lajeado, RS, Brasil. E-mail: mahsdalzochio@gmail.com

**16960.** Schmitz, M. (2018): Veränderungen der Odonatenfauna im FFH-Gebiet Heisinger Ruhraue von Mitte der 1980er Jahre bis 2015. *Libellula* 37(3/4): 55-78. (in German, with English summary) ["Changes in the Odonata fauna of the Heisinger Ruhraue from the mid 1980s to 2015 - In the Heisinger Ruhraue Odonata surveys were carried out in the mid 1980s. The results are compared to those of field studies in 1999-2007 and 2009-2015, covering a period of more than 30 years in all. The Heisinger Ruhraue is a Special Area of Conservation under the European Union's Habitats Directive. It consists of the river Ruhr and its floodplain with different types of standing water bodies. From 2003 to 2005 new habitats were created through the implementation of compensation measures. 36 Odonata species have been recorded so far, for 29 breeding was proven or is strongly suspected. The total number of species rose over the years and comprises species of all dragonfly associations described for riverine habitats. The Heisinger Ruhraue is an especially valuable habitat for dragonflies close to the metropolitan Ruhr area and of importance beyond that and neighbouring regions. The highest number of (breeding) species was recorded in 1999-2007. Dragonflies increased due to recolonisation by species inhabiting rivers and streams (following improvement of water quality), the occurrence of Mediterranean species expanding their ranges (climatic changes) and as a consequence of the newly created habitats, supporting thermophile species of shallow open water bodies. The new habitats were subject to vegetative succession and after a few years partly overgrown by higher plants and trees. As a result of vegetative growth and eutrophication at the newly created and other water bodies several species decreased or have not been recorded in the last years. The natural dynamic is restricted in the Stretch of the river Ruhr where the Heisinger Ruhraue is situated. Thus more measures for river development and renaturation are needed to maintain suitable habitats for the different species of dragonfly." (Author)]

**16961.** Schneider, T.; Ikemeyer, D.; Dumont, H.J. (2018): *Crocothemis sanguinolenta* new for Iran – an example of influx of African Odonata across the Strait of Hormuz (Odonata: Libellulidae). *Odonatologica* 47(3/4): 219-228. (in English) ["On 14-vii-2018, *C. sanguinolenta* (Burmeister, 1839) was found in a ditch with clear, cold, fast flowing water near Khabr in Kermān, southern Iran (28.7241°N, 56.3298°E; 1 979 m a.s.l.). A male was observed perching on a stone in the water and a pair in the wheel was collected. To our knowledge *C. sanguinolenta* is new for Iran and new for Asia outside of the Arabian Peninsula and the Levant. As winters are cold in the Hazaran Mountain region, reproduction may fail. We speculate that both *C. sanguinolenta* and *Zygonyx torridus* regularly establish bridgeheads across the Strait of Hormuz between Oman and southern Iran, supported by favourable weather during summer." (Authors)] Address: Schneider, T., Arnold-Knoblauch-Ring 76, 14109 Berlin-Wannsee, Germany. E-mail: thomas.rs@gmx.de

**16962.** Schorr, M.; Kosterin, O.E.; Borisov, S.N.; Marinov, M. (2018): *Anormogomphus kiritshenkoi* Bartenev, 1913 (Odonata: Gomphidae): a literature review of the variable spelling of the species epithet, choice of the correct spelling and notes on the type locality of the species. *Zootaxa* 4370(4): 439-445. (in English) ["The spelling of the specific name of an *Anormogomphus* species in its original description by Bartenev (1913) was variable, *kiritshenkoi* (5 times) vs *kiritschenkoi* (1 time). Bartenev himself did not mention this species in his further publications. Later authors proceeded to use different spelling versions of this name, including those not in the original paper. According to the International Code of Zoological Nomenclature (ICZN), the valid spelling should be chosen by the First Reviser. Acting as such, we choose as valid the name spelling *Anormogomphus kiritshenkoi* Bartenev, 1913, since it predominates in the original description, appears in the species subtitle, and is a proper transliteration from Cyrillic to Latin. It also corresponds to the spelling of his name used by A.N. Kiritshenko himself. Information of the type locality of the species is provided." (Authors)] Address: Kosterin, O.E., Institute of Cytology and Genetics, Siberian Branch, Russian Academy of Sciences, Lavrentiev Ave 10, RUS-630090 Novosibirsk, Russia. **16965.** Seehausen, M. (2018): „H. Sauter s Formosa-Ausbeute" und weitere Libellen aus Asien und Papua-Neuguinea im Übersee-Museum Bremen (Insecta: Odonata). *TenDenZen* 2014 (2018), Jahrbuch XXII, Übersee-Museum Bremen: 103-118. (in German, with English summary) ["The Odonata from Asia and Papua-New Guinea in the collection of the Übersee-Museum Bremen/Germany were determined and catalogued. The biggest part from one source is a collection of Taiwanese dragon- and damselflies from Hans Sauter which were not published before. Furthermore there are Asian specimens from Borneo, China, India, Malaysia, Sri Lanka, Thailand, Japan and Java. Most remarkable is the re-discovery of an excollection of M. E. de Selys Longchamps which was given to Bremen in 1875. Additionally some specimens of *Neurothemis stigmatizans* collected in Papua New-Guinea are listed. *Lestes cf. concinnus*, *Orthetrum luzonicum*, *Pseudothemis zonata* and *Sympetrum baccha arenot* mentioned by F. Ris in his publications about the taiwanese specimens of Hans Sauter. The female of *Prodasineura croconota* was labeled by Erich Schmidt as "Allotype" in 1931. Because there was no publication about a description of this female and Ris described two male specimens from different places this status is wrong. Very rare to be found in collections is *Aristocypha fulgipennis*. Unfortunately there is a wrong label at this specimen with ("Java") as supposed finding locality. This species is only known from Vietnam, Laos and Cambodia. Two specimens of original syntype series were found in the duplicate collection of Selys: *Dysphaea dimidiata* ("race *limbata*") and *Rhinocypha trifasciata*. These have been published more detailed before with a catalogue of the complete ex-collection. Also published before was the first record of *Matrona basilaris* from Hongkong. They were, together with specimens of *Euphaea opaca*, collected by J. T. Lauts between 1878 and 1907. Of *E. opaca* there was only

one historical record before. Also not often to be found in collections is *Epophthalmia vittata*. This species was collected, together with some others, by Tiefermann who was inmate at the British detention center Ahmednagar in India between 1914 and 1918. One specimen of *Macromia moorei* which was mentioned by M.A. Liefstinck could not be found and must be declared as lost. Also there are records of four dragonfly species collected offshore on board of a ship in the Andaman Sea between Andaman-Islands and Mergui Archipelago in the collection." **16968.** Sellam-Bouattoura, N.; Attou, F.; Arab, A.; Samraoui, B. (2018): Odonata of the Mazafran hydrosystem: distribution and community structure. *Revue d'Ecologie* 73(4): 537-549. (in English, with French summary) ["One of the objectives of our study is to increase our knowledge of the Odonata in the Mazafran hydrosystem, located in the centre of northern Algeria. This unexplored region in terms of Odonatology, is characterized by its sub-humid Mediterranean climate, and a dry period spread over six months, from May to the end of October. The prospection of 19 sites distributed along the Mazafran hydrographic system during 24 months, from April 2013 to March 2015, allowed us to identify 948 adults involving 15 species. *Calopteryx haemorrhoidalis* (33.1 %) and *Platycnemis subdilatata* (20.5 %) were the most abundant and frequent species.

The results revealed the presence of *Ischnura pumilio*, which is currently relatively rare in the overall Maghreb. Both the physicochemical and climatic characteristics of the various wadi influenced the Mazafran hydrographic system. The seasonal change of flow rate led to a dramatic increase in water temperature and had a considerable impact on sites located at low elevation. Cumulative effects of urban and industrial effluents, river bed degradation, illegal pumping of water for agricultural purpose and reduction of riparian canopy influence the Odonata community and lead to a decrease of species richness and diversity. We urge decision-makers to take urgent steps for the restoration of the natural state and functioning of wadi systems throughout Algeria before their irreversible destruction." ] Address: Sellam-Bouattoura, Nassima, Laboratory of Dynamics and Biodiversity, FSB, USTHB, LP 32 El Alia, Bab Ezzouar. **16970.** Serdar, O.; Verep, B. (2018): The investigation of water quality of Iyidere and Çiftekavak streams using physicochemical and biotic indexes. *Int. J. Pure Appl. Sci.* 4(1): 61-71. (in English) ["An investigation was carried out on the streams of Çiftekavak and Iyidere in Rize between April 2010 and March 2011. Water samples were taken monthly from the station which chosen six sample points on Iyidere and two sample point on Çiftekavak Stream. Water quality was evaluated with the standard physicochemical analysis (water temperature, pH, dissolved oxygen, oxygen saturation, electrical conductivity, suspended solid, total hardness, Ca hardness, Mg hardness, biological oxygen demand, nitrite nitrogen, total phosphate) like parameters were determined according to the Inland Water Resources Criteria, Water Pollution Control Regulation. With this study, it was aimed to determine the water quality of 8 stations at Iyidere and Çiftekavak Streams. It had been determined that the physicochemical data were not contaminated with Iyidere grade. However, Çiftekavak Stream had been determined that the pollution be under threat at the level. Benthic macroinvertebrates were analysed and compared with the measurement of parameter. In this study, as biomarker indexes, seven different biotic index such as SI (Saprob Index), FBI (Family Biotik Index), BMWP (Biological Monitoring Index Scores), BBI (Belgium Biotic Index), ASPT

(Medium Taxon Index) and EPT (Ephemeroptera Per Taxon) taxon number were used in evaluation. During the period of this study, 27 taxas which belong to Ephemeroptera, Amphipoda, Tricladida, Coleoptera, Decapoda, Rhynchobdellida, Odonata, Diptera, Trichoptera, Plecoptera, Tubificida and Arthropoda were identified. The Ephemeroptera taxa was the highest abundance values in benthic macroinvertebrates. With this study, it was aimed to determine the water quality at 8 stations at Çiftekavak and Iyidere. Both biologic and physicochemical yields were found to result in unpollution of the Iyidere Stream level. However, Çiftekavak stream was found to be under the threat of pollution." **16974.** Shi, G.C.; Wang, M.L.; Zhu, Y.Y.; Shen, L.; Ma, W.L.; Wang, Y.H.; Li, R.F. (2018): Dragonfly wing decorated by gold nanoislands as flexible and stable substrates for surface-enhanced Raman scattering (SERS). *Scientific Reports* 8, Article number: 6916: 11 pp. (in English) ["A flexible and

stable biomimetic SERS substrate was successfully fabricated by depositing gold (Au) nanoislands on the dragonfly wings (DW) via a simple DC magnetron sputtering system. Characterizations of the Au/DW nanostructure indicated that the optimum Au/DW-45 (sputtering time was 45 min) substrate owns high sensitivity, good stability and outstanding reproducibility. The limit of detection (LOD) for Rhodamine 6 G (R6G) was as low as  $10^{-7}$  M and enhancement factor (EF) was calculated to be  $2.8 \times 10^6$ . 70-day-duration stability tests showed that Raman intensity of R6G reduced only by 12.9% after aging for 70 days. The maximum relative standard deviations (RSD) of SERS intensities from 100 positions of Au/DW-45 substrate were less than 8.3%, revealing outstanding uniformity and reproducibility. Moreover, the flexible Au/DW-45 bioscaffold arrays were employed to solve the vital problem of pesticide residues. By directly sampling from tomato peels via a "press and peel off" approach, cypermethrin has been rapidly and reliably determined with a LOD centered at  $10^{-3}$  ng/cm<sup>2</sup> and a correlation coefficient (R<sup>2</sup>) of 0.987. The positive results demonstrated that the Au-based DW biomimetic arrays may offer an efficient SERS platform for the identification of various pesticide residues on real samples." **16979.** Solano, E.; Hardersen, S.; Audisio, P.; Amorosi, V.; Senczuk, G.; Antonini, G. (2018): Asymmetric hybridization in *Cordulegaster* (Odonata: Cordulegasteridae): Secondary postglacial contact and the possible role of mechanical constraints. *Ecology and Evolution*. 2018 DOI: 10.1002/ece3.4368: 15 pp. (in English) ["Two *Cordulegaster* dragonflies present in Italy, the Palaearctic and northern distributed *C. boltonii* and the endemic to the south of the peninsula *C. trinacriae*, meet in central Italy and give rise to individuals of intermediate morphology. By means of mitochondrial and nuclear markers and of Geometric Morphometrics applied to sexual appendages, we defined i) the geographical boundaries between the two species in Italy and ii) we determined the presence, the extent, and the genetic characteristics of the hybridization. Genetic data evidenced asymmetric hybridization with the males of *C. trinacriae* able to mate both interspecifically and intraspecifically. The results contrast with expectations under neutral gene introgression and sexual selection. This data, along with the morphological evidence of significant differences in size and shape of sexual appendages between the males of the two species, seem indicative of the role of mechanical constraints in intraspecific matings. The origin of the two species is dated about to 1.32 Mya and the hybridization resulted related to range expansion of the two species after Last Glacial Maximum and this led to the secondary contact between the two taxa in central Italy. At last, our results indicate that the range of *C. trinacriae*, a threatened and protected species, has been moving northward probably driven by climate changes. As a result, the latter species is currently intruding into the range of *C. boltonii*. The hybrid area is quite extended and the hybrids seem well adapted to the environment. From a conservation

point of view, even if *C. trinacriae* has a strong genetic identity, the discovery of hybridization between the two species should be considered in a future species management." **16980.** Solis, M.; Bonetto, C.; Marrochi, N.; Paracampo, A.; Mugni, H. (2018): Aquatic macroinvertebrate assemblages are affected by insecticide applications on the Argentine Pampas. *Ecotoxicology and Environmental Safety* 148: 11-16. (in English) ["Highlights: •Land use in the basin affects the macroinvertebrate assemblages in Pampas streams. •Nutrient concentrations are higher in streams adjacent to crops. •Endosulfan was measured in sediments from cropped streams; a stream with a buffer strip contained lower concentrations. •Macroinvertebrate assemblages in the agricultural streams were different from those in the livestock and reserve streams. Abstract: Agriculture intensification in Argentina has increased agrochemicals consumption in the last decades and might represent an environmental risk for adjacent water bodies. The objective of the present work was to assess the effect of land use on water quality and invertebrate assemblages in the Argentine Pampas streams. Eight streams were sampled on 4 occasions during the 2013/14 growing season. Three streams are located within a biosphere reserve, two drain basins with extensive livestock fields, and three run through intensively cultivated plots; one of them contained a 30 m wide uncultivated grass-covered strip between the crop and the stream. Macroinvertebrates were sampled from emergent vegetation by means of a D-net with a 500 µm pore size, and 30 cm diameter. Higher nutrient concentrations were measured in the agricultural streams. Endosulfan was measured in sediments of the agricultural streams, concentrations being significantly lower in the stream with the buffer strip. Invertebrate assemblages in the cropped streams were significantly different from those in the livestock and reserve streams, those in the latter not being different from each other. Ampullariidae (*Pomacea canaliculata*) and Planorbidae (*Biomphalaria peregriana*) were the taxa best represented in the agricultural streams. Hyalellidae (*Hyalella curvispina*), Zygoptera and Planorbidae (*B. peregriana*) were the taxa best represented in the reserve and livestock streams. Present evidence suggests that the observed differences in the invertebrate composition in the agricultural streams were related with the impact of agrochemicals and that buffer strips represent a useful attenuation practice. Cattle breeding on natural pastures represented a land use with low impact on the invertebrate assemblages." (Authors)] Address: Solis, Marina, ILPLA (Instituto de Limnología "Dr. Raúl A. Ringuelet"), UNLP, FCNyM, CONICET, Boulevard 120 y 62, La Plata, Buenos Aires, Argentina. E-mail: marinasolis@ilpla.edu.ar

**16981.** Somwanshi, N.R.; Sonawane, A.R.; Khandagle, A.J. (2018): New report of *Zygomma petiolatum* (Rambur, 1842). Odonates from Daund Tehsil, MS: India. *International Conference on Frontiers in Life and Earth Science* 5(1): 143-146. (in English) ["Morphological similarity often complicates field identification in insects, leading to data analysis on the basis

of geographic distribution over planet. Still working on morphometrical data analysis on some endemic or rare species it's really challenging job with conservation status, that's the reason for taxonomical analysis done in August to October 2017 on *Z. petiolatum*. The Indian dragonfly genus *Zygomma* is a difficult group to identify on field due to their extreme occurrence during mild sunny evening time with higher flier conditions, and shortest information on identification keys, geographical distribution and natural history. *Z. petiolatum* is commonly known as brown dusk hawk. Primarily based upon the hypothesis that collected specimen may be dragonfly or damselfly as due to showing both characteristic such as, slender abdomen looks like damselfly and spreading of wings, compound eyes, bulgy thorax shown in case of dragonfly. After carefully observing the specimen it showed 8 abdominal segments which were characteristic features of dragonfly." **16983.** St. Clair, C.R.; Fuller, C.A. (2018): Atrazine exposure influences immunity in the Blue Dasher Dragonfly, *Pachydiplax longipennis* (Odonata: Libellulidae). *Journal of Insect Science* 18(5): 1-7. (in English) ["Agricultural runoff containing herbicide is known to have adverse effects on freshwater organisms. Aquatic insects are particularly susceptible, and herbicide runoff has the potential to affect immunity in this group. Here we examined the effect of ecologically relevant levels of atrazine, an herbicide commonly used in the United States, on immune function in larvae of *P. longipennis* during a long-term exposure at ecologically relevant concentrations. Larvae were exposed to concentrations of 0, 1, 5, and 10 ppb atrazine for 3 or 6 wk. Hemocyte counts, hemolymph phenoloxidase (PO) activity, cuticular PO, and gut PO were measured at the end of each trial period as indicators of immune system strength. Atrazine concentration had

a significant effect on hemocyte counts after controlling for larval size. There was a significant interaction between time and concentration for hemolymph PO, cuticular PO, and a marginal interaction for gut PO. The effect of atrazine on the measured immune parameters was often nonmonotonic, with larger effects observed at intermediate concentrations. Therefore, atrazine affects both hemocyte numbers and PO activity over time in *P. longipennis*, and the changed immune function demonstrated in this study is likely to modify susceptibility to pathogens, alter wound healing, and may decrease available energy for growth and metamorphosis." **16984.** Start, D. (2018): Animal behavior and algal camouflage jointly structure predation and selection. *Journal of Evolutionary Biology* 31(5): 773-778. (in English) ["Trait variation can structure interactions between individuals, thus shaping selection. While anti-predator strategies are an important component of many aquatic systems, how multiple anti-predator traits interact to influence consumption and selection remains contentious. Here, I use a common larval dragonfly (*Epithea canis*) and its predator (*Anax junius*) to test for the joint effects of activity rate and algal camouflage on predation and survival selection. I found that active and poorly camouflaged *Epithea* were more likely to be consumed, and thus survival selection favored inactive and well camouflaged individuals. Notably, camouflage dampened selection on activity rate, likely by reducing attack rates when *Epithea* encountered a predator. Correlational selection is therefore conferred by the ecological interaction of traits, rather than by opposing selection acting on linked traits. I suggest that anti-predator traits with different adaptive functions can jointly structure patterns of consumption and selection." (Authors)] Address: Start, D., Toronto, ON, Canada. **16985.** Stewart, S.S.; Vodopich, D.S. (2018): Seasonal and annual variations on wing shape and wing size of eight damselfly species (Odonata: Calopterygidae, Coenagrionidae). *Odonatologica* 47(3/4): 245-266. (in English) ["This study examined the effects of seasonal and annual variations on wing shape and wing size of eight damselfly species in central Texas. Comparisons included i) populations collected early in the flight season versus those collected late in the flight season, and ii) populations collected from the same locations during several annual flight seasons. We found widespread differences in both wing shape and body size in males and females among most species examined. Wing shape of male and female damselflies collected early varied significantly from those collected late in the flight season for all locations and years sampled. Damselflies emerging early in the flight season were significantly larger than those emerging late, except for *Enallagma civile* showing opposite results. Populations of six species sampled in different years at the same location were compared, and significant differences in wing shape and size occurred in no females and in males of only two species. Our results suggest that differences in seasonal

and year-to-year environmental conditions frequently influence wing shape and body size in multiple damselfly species." (Authors)] Address: Stewart, Sherry, Dept Biol., Baylor Univ., Waco, Texas 76798-7388, USA. E-mail: Sherry\_Stewart@baylor.edu

**16987.** Subrero, E.; Sforzini, S.; Viarengo, A.; Cucco, M. (2018): Exposure to anti-mosquito insecticides utilized in rice fields affects survival of two non-target species, *Ischnura elegans* and *Daphnia magna*. *Paddy and Water Environment* 17: 1-11. (in English) ["Insecticides are commonly utilized to control mosquito larvae in rice fields. They can, however, have negative effects on both vertebrates and non-target invertebrate species. In this study, we examined the effects of pulse exposition to different concentrations of cypermethrin (0.15, 0.015, 0.0015 mg/L) and diflubenzuron (0.15, 0.015, 0.0015 mg/L) on egg hatching rate, larval growth, and larval survival in *Ischnura elegans*, and on survival of a crustacean, *Daphnia magna*. Insecticide exposure had significant negative effects on hatching rate in damselfly eggs. Exposed damselfly larvae also grew less and showed a higher mortality than control larvae. In *Daphnia*, the acute toxicity test (ISO 6341 in Water quality—determination of the inhibition of the mobility of *Daphnia magna* Straus (Cladocera, Crustacea)—acute toxicity test, Int Organ Stand Geneva, Geneva, 2012) showed an increased inhibition of mobility in the presence of insecticides. We observed a proportional response in relation to insecticide concentration, such that the highest exposure levels showed the largest reduction of vital performances. Our highest tested values correspond to those currently employed in agriculture. This study suggests that exposure to two common insecticides strongly affects non-target invertebrates even at very low concentration levels (cypermethrin 0.0015 mg/L and diflubenzuron 0.0015 mg/L)." **16989.** Supekar, S.C.; Gramapurohit, N.P. (2018): Larval skipper frogs recognise kairomones of certain predators innately. *Journal of Ethology* 36(2): 143-149. (in English) ["Recognising potential predators is critical for the survival and reproduction of prey animals. However, prey animals may possess an innate ability to recognise the signature odours (kairomones) of only certain native, sympatric predators, while requiring learning to recognise others. Our observations have shown that larval skipper frogs (*Euphylyctis cyanophlyctis*) fail to recognise kairomones of dragonfly nymph, a common predator of amphibian tadpoles with a cosmopolitan distribution. Hence, we wanted to determine if larval skipper frogs totally lack an innate mechanism to recognise kairomones of all aquatic predators, or have an innate ability to recognise kairomones of only certain predators. In a series of experiments, we tested the antipredator response of larval skipper frogs to kairomones of dragonfly nymph (*Bradinopyga geminata*); walking catfish (*Clarias batrachus*); Mozambique tilapia (*Oreochromis mossambicus*); two species of predatory tadpoles, Indian bullfrog (*Hoplobatrachus tigerinus*) and Jerdon's bullfrog (*Hoplobatrachus crassus*); and the checkered keel back snake (*Xenochrophis piscator*). The results clearly indicate that larval skipper frogs have the innate ability to recognise kairomones of the walking catfish, both species of larval bullfrog and checkered keel back snake. However, they lack the innate ability to recognise kairomones of dragonfly nymph and Mozambique tilapia. Prey choice of the Mozambique tilapia and gape-limitation of dragonfly nymphs could be responsible for the lack of innate responses of larval skipper frogs to them. The study provides empirical evidence for the notion that prey can innately recognise certain predators." (Authors)] Address: Supekar, S.C., Dept Zool., Savitribai Phule Pune Univ., Pune, India

**16990.** Sybertz, J. & M. Reich (Hrsg.) (2018): Tierarten im Klimawandel in Harz und Lüneburger Heide. *Natur und Raum* 10, Schriftenreihe Institut für Umweltplanung, Leibniz Universität Hannover: 7-56. (in German, with English summary) ["Within the KLIFF research project, the sensitivity of 227 Red List species (breeding birds, reptiles, amphibians, dragonflies and damselflies, grasshoppers and crickets, and butterflies) to climate change impacts within the "Harz" and "Lüneburger Heide und Wendland" ecoregions, in Lower Saxony, was evaluated. This assessment included the sensitivity of the species towards specific climatic changes as well as their general sensitivity towards environmental changes. Based on

the climate projections for these regions up to the end of the 21st century, increasing mean temperatures, an increase of hot extremes, a decrease of cold periods and a shift in annual precipitation regimes (including a decrease of precipitation in summer and an increase of precipitation in winter) can be expected. About half of the examined species are probably not sensitive towards these climatic changes and most of the sensitive species are sensitive to a low to moderate degree. Overall, more species seem to be affected by a decrease of summer precipitation than by an increase of mean temperatures. On average, the examined species are more sensitive towards environmental changes in general than towards specific climatic changes. As assessments of climate change impacts on species are linked with uncertainties, it is important to take these uncertainties into account when developing nature conservation strategies adapted to climate change. Regarding management strategies, the conservation and restoration of wetlands, as well as the promotion of wildlife corridors and habitat connectivity, are of high importance." (Authors)] Address: Reich, M., Inst. für Umweltplanung, Leibniz Univ. Hannover, Herrenhäuser Str. 2, 30419 Hannover, Germany

(2018): Come to the dark side: habitat selection of larval odonates depends on background visual patterns. *Ecological Entomology* 43(5): 640-646. (in English) ["1. Determining which environmental traits enable animals to inhabit and choose preferred habitats is key to understanding ecological processes. Habitat complexity and background colour patterns can act as selective pressures on animal behaviour, and ultimately affect habitat choice. 2. To investigate the role of environmental features on habitat selection, this study looked at whether dragonfly and damselfly larvae show a preference between dark/light or complex environments. Last-instar larvae of *Micrathyrina didyma* and *Acanthagrion lancea* were collected in the Neotropical savanna, and five experiments in laboratory conditions were subsequently carried out. The first experiment tested the preference of larvae for leaves in contrast to a white background. The second experiment compared a preference for white and black backgrounds. As both experiments showed a significant preference for darker backgrounds, a predator was included in the black background in the third experiment, and a macrophyte was included in the white background in the fourth experiment. In this way, favourable and unfavourable conditions were included in the habitat of choice. The fifth experiment tested the influence of environmental complexity on habitat choice. 3. The results of these experiments showed that larvae choose darker backgrounds independently of predation risk, and that macrophytes are as attractive as a dark background. They also suggest that the coenagrionid, but not the libellulid, prefer more complex environments. 4. Overall, these findings suggest that larvae exhibit behavioural preferences for background colour and complexity, which may ultimately drive habitat occupation." **16995.** Thakkar, N.R.; Verma, P.R.; Andrew, R.J. (2018): Breeding behaviour of the Coromandel Marsh Dart Damselfly (Zygoptera: Coenagrionidae: *Ceragrion coromandelianum* (Fabricius)) in central India. *Journal of Threatened Taxa* 10(3): 11443-11449. (in English) ["*C. coromandelianum* is one of the most common damselflies in the Indian subcontinent. It flies

among bushes and breeds in stagnant pools, small garden tanks, tubs and ornamental cement ponds containing submerged and/or floating vegetation. The oviposition behaviour of *C. coromandelianum* was observed at the botanical garden of Hislop College, Nagpur, India, where small underground cement tubs are utilized to grow macrophytes. *C. coromandelianum* displays a refined hierarchy of preferences for oviposition and chooses floating leaves of *Nymphaea nouchali* (69%) over *Lemna paucicostata* (23%) and submerged *Hydrilla verticillata* (8%). In an uninterrupted oviposition bout, the female deposits 283 eggs in 16 rows (N=5) on the under surface of the *N. nouchali* leaf. The tiny leaves of *L. paucicostata* holds 7.8 eggs in 4.8 rows (N=10). In *H. verticillata*, the internode region of the stem can house 25.4 eggs (N=10). One or two eggs are also found neatly inserted in the thin leaf base of *H. verticillata*. Decaying plant material is never used for oviposition. The present investigation also clearly demonstrates that the choice of oviposition substrate not only depends upon the presence of aquatic species in the water body but also on the spatial location of the oviposition site." **17003.** Truong, V.K.; Vongsvivut, J.; Geeganagamage, N.; Tobin, M.J.; Luque, P.; Baulin, V.; Wemer, M.; Maclaughlin, S.; Crawford, R.J.; Ivanova, E.P. (2018): Study of melanin localization in the mature male *Calopteryx haemorrhoidalis* damselfly wings. *Journal of Synchrotron Radiation* 25: 874-877. (in English) ["*C. haemorrhoidalis* exhibiting black wings are found in the western Mediterranean, Algeria, France, Italy, Spain and Monaco. Wing pigmentation is caused by the presence of melanin, which is involved in physiological processes including defence reactions, wound healing and sclerotization of the insect. Despite the important physiological roles of melanin, the presence and colour variation among males and females of the *C. haemorrhoidalis* species and the localization of the pigment within the wing membrane remain poorly understood. In this study, infrared (IR) microspectroscopy, coupled with the highly collimated synchrotron IR beam, was employed in order to identify the distribution of the pigments in the wings at a high spatial resolution. It was found that the melanin is localized in the procuticle of the *C. haemorrhoidalis* wings, distributed homogeneously within this layer, and not associated with the lipids of the epicuticle." **17004.** Tsutsui, M.H.; Kobayashi, K.; Miyashita, T. (2018): Temporal trends in arthropod abundances after the transition to organic farming in paddy fields. *PloS one* [11 Jan 2018, 13(1):e0190946]: 13 pp. (in English) ["Organic farming aims to reduce the effect on the ecosystem and enhance biodiversity in agricultural areas, but the long-term effectiveness of its application is unclear. Assessments have rarely included various taxonomic groups with different ecological and economic roles. In paddy fields with different numbers of years elapsed since the transition from conventional to organic farming, we investigated changes in the abundance of insect pests, generalist predators, and species of conservation concern. The abundance of various arthropods exhibited diverse trends with respect to years elapsed since the transition to organic farming. Larval lepidopterans, Tetragnatha spiders, and some planthoppers and stink bugs showed non-linear increases over time, eventually reaching saturation, such as the abundance increasing for several years and then becoming stable after 10 years. This pattern can be explained by the effects of residual pesticides, the lag time of soil mineralization, and dispersal limitation. *Ischnura asiatica* did not show a particular trend over time, probably

due to its rapid immigration from source habitats. Unexpectedly, both planthoppers and some leafhoppers exhibited gradual decreases over time. As their abundances were negatively related to the abundance of Tetragnatha spiders, increased predation by natural enemies might gradually decrease these insect populations. These results suggest that the consideration of time-dependent responses of organisms is essential for the evaluation of the costs and benefits of organic farming, and such evaluations could provide a basis for guidelines regarding the length of time for organic farming to restore biodiversity or the economic subsidy needed to compensate for pest damage." **17006.** Uboni, C.; Merluzzi, P.; Poldini, L.; Riservato, E.; Pizzul, E. (2018): First data on the reproduction of the Vagrant Emperor Anax ephippiger in North-Eastern Italy, Friuli-Venezia Giulia Region (Odonata Aeshnidae). *Bollettino della Società Entomologica Italiana* 150(3): 101-106. (in English, with Italian summary) ["A. ephippiger, is a migrant dragonfly species from Africa and Middle East; in Europe only summer generation are known, without evidence of overwintering larvae. In August 2010 a reproductive breeding site for this species was found in the Friuli-Venezia Giulia Region (north-eastern Italy). This discovery represents the first proof of reproduction for the species in north-eastern Italy. With the aim of increasing the knowledge on the species requirements, a study to delineate the emerging habitat was conducted: dragonfly community (adult and exuviae), vegetation, chemical and physical water parameters were sampled. This yielded data about larval tolerance toward salinity. This new data proves a northward move for the species, which may also have been facilitated by global warming." (Authors)] Address: Uboni, Costanza, Dept of Life Science, Univ. Trieste, Italia. E-mail: costanza.uboni@gmail.com

**17007.** Ueno, D.; Mizukawa, H.; Inanami, O.; Nagasaka, H.; Tatsuta, N.; Narazaki, Y.; Fujino, T.; Watanabe, I.; Kameda, Y.; Nakai, K. (2018): "Caddisfly watch," a biomonitoring program using *Stenopsyche* larvae to determine radioactive cesium contamination in rivers following the Fukushima nuclear disaster. *Landscape and Ecological Engineering* 14(1): 29-35.

(in English) ["The "Caddisfly Watch" program proposes the use of larvae of the caddisfly genus *Stenopsyche* (Trichoptera: Stenopsychidae) to monitor the radioactive cesium ( $^{137}\text{Cs}$ ) pollution, including that of suspended solids, in river environments, as a simple method was essential for this following the Fukushima nuclear disaster in March 2011. A variety of aquatic organisms were collected from rivers in Japan in 2012 and their levels of radioactive Cs measured. Amongst all the organisms collected, the highest concentrations of  $^{137}\text{Cs}$  were observed in caddisfly larvae. These larvae occur at a high density and can be collected at regular intervals in most rivers throughout Japan. It is proposed that caddisfly larvae can be used as bioindicators of radioactive Cs contamination in rivers, as their temporal and spatial changes are easily assessed." The study includes data on *Orthetrum albistylum* and *Sympetrum infuscatum*. (Authors) ] Address: Ueno, D., Dept of Environmental Sci., Fac. of Agriculture, Saga Univ., Saga, Japan. **17010.** Verheyen, J.; Temmerman, K.; De Block, M.; Stoks, R. (2018): Voltinism-associated differences in winter survival across latitudes: integrating growth, physiology, and food intake. *Oecologia* 186(4): 919-929. (in English) ["Species that span large latitudinal gradients face strong differences in voltinism and in winter conditions within their range. Latitudinal gradients in winter survival and especially their underlying mechanisms and association with voltinism patterns are poorly stud-

ied. We tested in *Enallagma cyathigerum* whether high-latitude populations were better in dealing with the longer winters compared to central- and low-latitude populations and whether this was associated with changes in voltinism. We thereby evaluated whether higher initial levels and/or lower reductions during winter of energy storage (measured as fat content) and investment in immune function [measured as the activity of phenoloxidase (PO)], and/or stronger compensatory responses in food intake contributed to the higher winter survival in high-latitude populations. To this end, we simulated a long high-latitude winter at 4 °C under manipulated food conditions. Across food levels, winter survival was highest in Swedish larvae, intermediate in Belgian larvae, and lowest in Spanish larvae, indicating latitude-specific thermal adaptation that could be partly linked to differences in voltinism. The semi-voltine Swedish larvae were growing slower before winter and as a result accumulated the highest fat content and PO activity when the winter started compared to the univoltine, faster growing Belgian, and Spanish larvae. Fat content and PO activity declined during the winter, yet equally across latitudes, and were not buffered by compensatory food intake. Our data identified possible underlying physiological mechanisms of winter survival and support the hypothesis that widespread latitude-associated voltinism shifts may be a selective factor contributing to latitudinal shifts in winter survival." **17016.** Walia, G.K.; Katnoria, N. (2018): Morphological variation in the chromosome complement of *Neurobasis chinensis chinensis* of family Calopterygidae (Odonata: Zygoptera). *International Journal of Life Sciences Research* 6(4): 260-266. (in English) ["Chromosome complement of *N. chinensis chinensis* has been characterized by conventional staining and C-banding. The specimens were collected from Sadhupul (Solan), Ghumarwin (Bilaspur) of Himachal Pradesh and Lachhiwala (Dehradun) of Uttarakhand states of India. The species possesses  $2n=23$  as the diploid chromosome number with XO-XX sex determination. Morphological variation in the chromosome complement has been observed in the species collected from different localities. In the spermatogonial metaphase, two large sized autosome pairs are present in specimens of Lachhiwala (Dehradun) and Sadhupul (Solan) and one large pair and other smaller than it are seen in specimens of Ghumarwin (Bilaspur). Similarly, in the diakinesis, two equal sized, large autosomal bivalents possess two interstitial and terminal chiasmata in the specimens of Lachhiwala (Dehradun) and Sadhupul (Solan). On the other hand, one extra large autosomal bivalent shows terminal and interstitial chiasmata, while second small bivalent reveals terminal chiasmata as remaining bivalents in the specimens of Ghumarwin (Bilaspur). These variations have also been confirmed by C-banding. In the diakinesis, C-bands are mostly present at the terminal ends of all the bivalents, while both the autosomal bivalents of Lachhiwala (Dehradun) and Sadhupul (Solan) specimens and one extra large autosomal bivalent of Ghumarwin (Bilaspur) specimens possess terminal as well as interstitial C-bands. X chromosome is C-positive throughout the length in all the specimens." (Authors)] Address: Kaur Walia, Gurinder, Dept of Zoology and Environmental Sciences, Punjabi University, Patiala, India

**17017.** Walia, G.K.; Katnoria, N.; Gill, J.K. (2018): Chromosomes of *Libellago lineata lineata* (Chlorocyphidae: Odonata). *Indian Journal of Entomology* 80(3): 737-740. (in English) ["Linear characterization and course of meiosis in the zygopteran *Libellago lineata lineata* (Chlorocyphidae) are described by conventional staining, C-banding, silver nitrate staining and sequence specific staining. There are two complements  $n=12$  and  $n=13$ , without m chromosomes. Increase in chromosome number is due to the fragmentation of medium sized autosome pair. Dark terminal C-bands are present on 9 autosomal bivalents, while remaining 3 bivalents and X chromosome show less amount of C-heterochromatin; 10 autosomal bivalents show terminal NOR-bands; while X chromosome is NOR-negative. All the autosomes and X chromosome possess less intense DAPI and bright CMA3 signals, which indicate complement is rich in GC rich regions than AT rich regions." (Authors)] Address: Walia, Gurinder Kaur, Dept of Zoology & Environmental Sciences, Punjabi University, Patiala 147002, Punjab, India

**17018.** Walia, G.K.; Chahal, S.S.; Somal, D.S. (2018): Chromosome observations based on C-banding, Ag-NOR and

sequence-specific staining in two *Anax* species from India (Odonata: Aeshnidae). *Odonatologica* 47(1/2): 145-160. (in English) ["The previously known male karyotypes ( $2n = 27$ ,  $m; n = 14, m; X0$  sex determination) of *Anax immaculifrons* and *A. nigrofasciatus nigrolineatus* from Himachal Pradesh are redescribed, based on conventional staining and are described for the first time using three other staining techniques. In the two species, C-bands occur on chiasmatic/non-chiasmatic bivalent ends, there is a C-positive X, while the m bivalent is C-negative in *A. immaculifrons* and C-positive in *A. nigrofasciatus*. The other details are given in the text and micrographs are provided." (Authors)] Address: Kaur Walia, Gurinder, Dept Zool. & Environ. Sci., Punjabi Univ., Patiala-147002, Punjab, India. **17019.** Wang, J.; Wang, C.; Zhao, M.; Feng, Y. (2018): Mercury absorption, enrichment and water-land transfer by aquatic insects. *Biotic Resources* 40(6): 507-511. (in Chinese, with English summary) ["Mercury is a non-essential and toxic heavy metal element of the human body. Global mercury pollution has attracted much attention because of its damage to human health. Most of the mercury in nature enters aquatic ecosystems through river runoff and the deposition of rain and snow dust, with at least 10, 000 tons of mercury entering the aquatic ecosystem each year. As an important consumer animal, aquatic insects are an important part of the aquatic ecological food network and play an important role in the material cycle of aquatic ecosystems. This paper introduces the related research between aquatic insects and mercury in recent years, focusing on the absorption and enrichment of mercury by aquatic insects, and analyzing the role of aquatic insects in the water-land transfer of mercury. The research data show that the degree of mercury absorption by aquatic insects is related to environmental factors and is transferred to terrestrial ecosystems through different pathways, which poses a certain threat to the organisms in the upper food chain of terrestrial ecosystems. At the same time of development and utilization of aquatic insects, whether the mercury exceeds the standard should be considered." (Authors)] Address: Wang, J., Res. Inst. of Resource Insects, Chinese Acad. Forestry, Kunming 650233, Yunnan, China. E-mail: jdwang666@163.com.

**17021.** White, J.C.; House, A.; Punchard, N.; Hannah, D.M.; Wilding, N.A.; Wood, P.J. (2018): Macroinvertebrate community responses to hydrological controls and groundwater

abstraction effects across intermittent and perennial headwater streams. *Science of the Total Environment* 610-611: 1514-1526. (in English) ["Intermittent rivers comprise a significant proportion of river networks globally and their spatial extent is predicted to increase with rising water abstraction pressures. Despite this, the ecological implications of hydrological modifications within intermittent rivers have received limited research attention. This paper examines macroinvertebrate assemblages across intermittent and perennial sections of headwater streams within the Hampshire Avon catchment (United Kingdom) over a five-year period. The composition of faunal assemblages was quantified in relation to four hydrological metrics: the duration of flowing conditions, the geographical proximity to the nearest perennial source along each watercourse (two observed flow parameters) and two modelled groundwater abstraction influences. The results highlight that macroinvertebrate communities inhabiting sites which dry periodically and are positioned at greater distances (>c. 2.5km) above the perennial source (the most upstream point of permanent flow within a given year) possessed the highest conservation values. These sites supported species that are rare in many areas of Europe (e.g. Ephemeroptera: *Paraletophlebia weneri*) or with limited geographical distribution across the United Kingdom (e.g. Trichoptera: *Limnephilus bipunctatus*). A range of faunal community diversity indices were found to be more sensitive to the antecedent flow duration and distance from the perennial source, rather than any effects of groundwater abstraction. Taxonomic richness responded most strongly to these observed flow parameters and varied more markedly with the distance from the perennial source compared to the antecedent flow duration. Several taxa were significantly associated with the observed flow parameters, particularly those predominantly inhabiting perennially flowing systems. However, the distance that such fauna could migrate into intermittent reaches varied between taxa. This research demonstrates the overriding importance of antecedent flow durations and the geographical proximity to perennial sources on macroinvertebrate communities within intermittent and perennial headwater streams." *Calopteryx splendens* is the only odonate species mentioned (Authors)] Address: White, J.C., Dept of Geography, Loughborough Univ., Loughborough, Leicestershire LE11 3TU, UK. **17023.** Wiszniowska, M.; Buczynski, P. (2018): Późne stwierdzenie *Anax ephippiger* (BURMEISTER, 1839) (Odonata: Aeshnidae) w Polsce południowej A late record of *Anax ephippiger* (BURMEISTER, 1839) (Odonata: Aeshnidae) in southern Poland. *Odonatrix* 14\_4 (2018): 4 pp. (in Polish, with English summary) ["A male of *A. ephippiger* was recorded on 8-X-2018 at the "Górnik" Pond in Katowice-Giszowiec (S Poland, 50°12'56" N, 19°04'31" E, UTM: CA66). One of the latest in both Poland and central-eastern Europe, this record is discussed in the context of this species' distribution and biology. A third generation can be ruled out, because the second generation in Poland emerges late (2nd half of July – 1st half of August) and larval development takes at least 80-90 days. The options considered are: (1) direct, late migration from the south; (2) the exceptionally late emergence of the 2nd generation in Poland, possibly resulting from later migration from the south than usual; (3) the return migration of an individual from a population that reproduced farther north. It is worth noting that the date of this Katowice record coincides with the return migration period in central Asia." (2018): The mitochondrial genome of *Atrocalopteryx melli* Ris, 1912 (Zygoptera: Calopterygidae) via Ion Torrent PGM NGS sequencing. *Mitochondrial DNA Part B* 3(1): 115-117. (in English) ["The mitochondrial genome of *Atrocalopteryx melli* was sequenced and assembled via Next-Generation Sequencing (NGS) and iteratively assembly process with a reference seed. This genome is 15,562 bp long and A + T biased (71%), with 37 genes arranged in common order of Odonata. All protein-coding genes are initiated by typical "ATN" codon, and 9 genes are terminated with a complete stop codon, except *nad4*, *nad5*, *cox2*, and *cox3*, which are terminated with an incomplete codon "T(aa)". The S5 intergenic spacer is absent in this genome, supporting that lacking of S5 as a specific character for damselflies. The A + T rich region of *A. melli* is 267 bp longer than that of *A. atrata*. This mitogenome provides new molecular information for understanding of *A. melli* and *Atrocalopteryx*." **17025.** Yamaguchi, Y.; Okubo, T.; Matsushita, M.; Wataji, M.; Iwasaki, S.; Hayasaka, K.; Akizawa, K.; Matsuo, J.; Shimizu, C.; Yamaguchi, H. (2018): Analysis of adult damselfly fecal material aids in the estimation of antibiotic-re-

sistant Enterobacterales contamination of the local environment. PeerJ 6:e5755 <https://doi.org/10.7717/peerj.5755>: 19 pp. (in English) ["Because damselflies are ubiquitously but focally present in natural environments and play a critical role as predators of other insect species, the fecal matter of damselflies may be useful for investigating antibiotic-resistant bacterial populations, including human pathogens, in local environments. We therefore examined the prevalence of antibiotic-resistant bacteria, including Enterobacterales, in fecal material from 383 damselflies (adults and larvae) collected from seven locations around Sapporo City, Japan, in 2016 and 2017. Fecal samples were plated on soybean casein digest (SCD) agar plates with and without antibiotics (SCD-A and SCD-w/o, respectively) to identify environmental bacteria and gut bacteria, respectively, and on MacConkey agar plates with antibiotics (MacConkey-A) to select for Gram-negative bacteria, including human pathogenic Enterobacterales species. The prevalence of colonies on each of the plates was compared, and representative colonies on MacConkey-A plates were identified to the species level using an API 20E kit and the MALDI Biotyper system. Overall, SCD-w/o plates showed a gut bacterial load of approximately 108 colony-forming units per adult damselfly or larva. There was a significant difference between the prevalence of colonies on the SCD-A and MacConkey-A plates, and a significantly increased prevalence of antibiotic-resistant bacteria on MacConkey-A plates was observed in samples collected from Shinoroshinkawa. Cluster analysis based on minimum inhibitory concentration values of 59 representative isolates from MacConkey-A agar plates revealed that samples from Shinoroshinkawa contained a higher prevalence of Enterobacterales than those from other sampling locations. Thus, fecal materials discharged by adult damselflies could be used in future studies as a simple tool for estimating antibiotic-resistant bacteria, including Enterobacterales species, in the local environment." **17026.** Yapo, M.L.; Tuo, Y.; Koné, M.; Atse, B.C.; Kouassi, P. (2018): Diversity and distribution of odonata larvae in some tropical fish farm ponds (Southern Côte D'ivoire, West Africa). *Jour. Sci. Res. Allied Sci.* 3(4): 51-64. (in English) ["Diversity and distribution of Odonata larvae collected in some fish farm ponds of Southern Cote d'Ivoire were studied. In each pond, samples were collected in the water column using a 350 µm mesh hand-net and in the sediment using a van Veen grab. Environmental variables such as transparency, temperature, pH, dissolved oxygen, and conductivity were measured in situ. Water samples were taken and conducted to the laboratory where analyses of dissolved inorganic nutrients were carried out. A total of 11 taxa belonging to 3 families (Coenagrionidae, Libellulidae, and Gomphidae) were recorded. Odonata fauna was qualitatively dominated by Coenagrionidae and Libellulidae. Quantitatively this fauna was dominated by Coenagrionidae. *Pseudagrion wellani* was the most abundant taxa within the Odonata assemblage. Azaguie recorded the highest species richness and the highest abundance. This station recorded the maximum values of Shannon-Wiener diversity index and evenness. Odonata can be used as a potential

instrument in future ecology studies in Ivorian aquatic ecosystems." (Authors)] Address: Yapo, M. L., Dépt de Biologie Animale, UFR Sciences Biologiques, Université Peleforo Gon Coulibaly, Korhogo, BP 1328 Korhogo, Côte d'Ivoire

**17027.** Yeo, D.; Puniamoorthy, J.; Ngiam, R.W.J.; Meier, R. (2018): Towards holomorphology in entomology: rapid and cost-effective adult-larva matching using NGS barcodes. *Systematic Entomology* 43(4): 678-691. (in English) ["In many taxa the morphology of females and immatures is poorly known because species descriptions and identification tools have a male bias. The root causes are problems with matching life-history stages and genders belonging to the same species. Such matching is time-consuming when conventional methods are used (e.g. rearing) and expensive when the stages are matched with DNA barcodes. Unfortunately, the lack of associations is not a trivial problem because it renders a large part of the phenome of insects unexplored, although larvae and females are useful sources of characters for descriptive and phylogenetic purposes. In addition, many collectors intentionally avoid females and immature stages, which skews survey results, interferes with collecting life-history information, and makes it less likely that rare species are discovered. These problems even exist for well-studied taxa like Odonata, where obtaining adult-larva matches relies largely on rearing. Here we demonstrate how the matching problem can be addressed with cost-effective tagged amplicon sequencing of a 313-bp segment of *cox1* with next-generation sequencing (NGS) ('NGS barcoding'). We illustrate the value of this approach based on Singapore's odonate fauna which is of a similar size as the European fauna (Singapore, 122 extant species; Europe, 138 recorded species). We match the larvae and adults of 59 species by first creating a barcode database for 338 identified adult specimens representing 83 species. We then sequence 1178 larvae from a wide range of sources. We successfully barcode 1123 specimens, which leads to adult-larva matches for 59 species based on our own barcodes (55) and online barcode databases (4). With these additions, 84 of the 131 species recorded in Singapore have now been associated with a species name. Most common species are now matched (83%), and good progress has been made for vulnerable/near-threatened (55%), endangered (53%), and critically endangered species (38%). We used nondestructive DNA extraction methods in order to be able to use high-resolution imaging of matched larvae to establish a publicly available digital reference collection for odonates which is incorporated into 'Biodiversity of Singapore' (<https://singapore.biodiversity.online/>). We suggest that the methods described here are suitable for many insect taxa because NGS barcoding allows for fast and low-cost matching of well-studied life-history stages with neglected semaphoronts (eggs, larvae, females). We estimate that the specimen-specific amplicons in this study (c. 1500 specimens) can now be obtained within eight working days and that the laboratory and sequencing cost is c. US\$600 (<US\$0.40 per specimen)." (Authors)] Address: Meier, R., Department of Biological Sciences, National University of Singapore, 14 Science Drive 4, #05-20 Singapore, 117543. **17030.** Yoshida, M.; Kawata, N.; Uchida, S. (2018): Dragonflies (Insecta: Odonata) in and around the Yakusa Campus of Aichi Institute of Technology, central Honshu, Japan. *Aichi Institute of Technology Research Report* 53: 85-93. (in Japanese, with English summary) ["Records of dragonflies in and around the Yakusa Campus of Aichi Institute of Technology, central Honshu, Japan, were reviewed, and dragonfly nymphs and adults were collected eight times from April to November in 2016 at five ponds in and around the campus. We found the records of 58 dragonfly species (including two species newly found in 2016) since 1970's in the literature, but only 35 dragonfly species were collected in 2016. This decrease of species richness can be caused by the predation on dragonfly nymphs by the invasive fishes; largemouth bass, *Micropterus salmoides* and bluegill, *Lepomis macrochirus* and by the invasive crayfish, *Procambarus clarkii*, inhabiting four of the five ponds. We propose removal of these invasive predators from the four ponds to enrich the species diversity of dragonflies." (Authors)] Address: not translated

**17031.** Zhang, S.; Sunami, Y.; Hashimoto, H. (2018): Deformation behavior of dragonfly-inspired nodus structured wing in gliding flight through experimental visualization approach.

*Scientific Reports* 8:5751 | DOI:10.1038/s41598-018-24237-x: 7 pp. (in English) ["Dragonfly has excellent flight performance and maneuverability due to the complex vein structure of wing. In this research, nodus as an important structural element of the dragonfly wing is investigated through an experimental visualization approach. Three vein structures were fabricated as, open-nodus structure, closed-nodus structure (with a flex-limiter) and rigid wing. The samples were conducted in a wind tunnel with a high speed camera to visualize the deformation of wing structure in order to study the function of nodus structured wing in gliding flight. According to the experimental results, nodus has a great influence on the flexibility of the wing structure. Moreover, the closed-nodus wing (with a flex-limiter) enables the vein structure to be flexible without losing the strength and rigidity of the joint. These findings enhance the knowledge of insect-inspired nodus structured wing and facilitate the application of Micro Air Vehicle (MAV) in gliding flight." **17032.** Zhang, Z.; Zhang, L.; Yu, Z.; Liu, J.; Li, X.; Liang, Y. (2018): In-situ mechanical test of dragonfly wing veins and their crack arrest behavior. *Micron* 110: 67-72. (in English) ["Highlights: •Dynamic fracture process of dragonfly wing was detected by in-situ tensile device. •The nano-mechanical test and in-situ tensile test combined. •The trend of elastic modulus and nano-hardness was consistent with the tensile test. •Veins and the membranes played a different role on function of crack prevention. Abstract: In natural biological systems, many insects in complex environments exhibit exemplary mechanical properties. Dragonfly wings are light and strong enough to withstand wind loading. Their rigid veins play supporting and strengthening roles to enhance resistance to fatigue. To explore the effect of veins on arresting cracking in the wing, the costa, subcosta, radius R1, and two areas of dragonfly hind wings were samples for in situ tensile tests. The fracture process of the samples was observed with a high-speed camera and a scanning electron microscope. The mechanical properties of the veins and the results of nanomechanical tests on the wings were analyzed. The costa was stiffer and more resistant to deformation than the subcosta and radius, but it was less tough. The results of this study may provide inspiration for the design of mechanical structures and materials." **17044.** Abdel-Hamza, A.K.; Ward Shaher, K. (2019): Insect order that the blue-cheeked bee-eater *merops superciliosus persicus* Pallas, 1773 (Coraciiformes: Meropidae) chicks feed on in the provinces of Baghdad and Babylon. *Plant Archives* 19(2): 4121-4124. (in English) ["This study was conducted in Jadiriya, Baghdad and the Emam, Babil provinces during 2017-2018. Results showed that there were significant

differences in the order of insects that birds feed on in the nestling during the day and between the weeks. The highest insect rate was in the first week for order Odonata in Babylon and Baghdad when scored 7 and 10 insect in the morning period respectively. Whereas it scored 7 - 8.4 insects) and (5.3 - 6 insects) in the afternoon and evening respectively. The order Orthoptera scored the lowest rate with 1.3 - 1, 0.6 - 0.6 and 0.3 - 1.3 insects for the morning, afternoon and evening periods, respectively. The number of insects orders started increasing during the second, third and fourth week when the Odonata scored (19.3, 44.3 and 61.6 insects), (14.3, 34.3 and 53.3 insects) for the morning Respectively, (11, 20.3 and 16.6 insects) (8, 15.6 and 19.6 insects) for the afternoon respectively (15.3, 35.3, 45 lactation), 12, 30 and 40.6 insects respectively for the evening period, respectively and the lowest for Orthoptera (1.3, 0.6 and 2.2 insects) (0.6, 1.6 and 1.3 insects), 0.6, 0.6 insect (respectively), 1.3 (1.3, 1.6 insect) and 0.6, 0.3 and 0.6 respectively 2 insects) for the evening. We conclude that the number of insects that chicks feed on the increase with age and prefer large insects, especially dragonflies for feeding." **17045.** Abdillah, M.; Millah, N.; Arroyan, N.; Alifudin, F.; Peritiwi, W. (2019): Correlation between Libellulidae diversity and vegetation diversity at Sumber Clangap Village of Puncu, Sub-district of Puncu, District of Kediri. The proceedings of the international symposium of remediation, biomaterial, revegetation and conservation 2018: 56-62. ["Libellulidae are the largest family in Ordo Odonata. Odonata has an antenna with olfactory function. The Odonata olfactory can be used for detecting chemical material in environmental. The environment including vegetation has role on keeping the ground water content. It statement indicate that the vegetation has role on organic material cycle including Libellulidae life. Sumber Clangap is the cold lava flow of Mount Kelud that affected by the eruption in 2014. This study was aimed to know the correlation between Libellulidae diversity and vegetation diversity at Sumber Clangap. There were 7 species of Libellulidae with the highest diversity index at third sampling plots. There were 72 plant species noted at Sumber Clangap with the highest diversity index at the first sampling plots. The paired T-test analysis showed that Libellulidae diversity significantly correlated with vegetation diversity." (Authors)] Address: Abdillah, M., Dept of Biology, Islamic State Univ. Sunan Ampel Surabaya, Jl. A. Yani, No. 117, Kota Surabaya, Indonesia

**17046.** Abdillah, M.M.; Prakarsa, T.B.P.; Tyastirin, E. (2019): Odonata diversity at Sumber Clangap and Sumber Mangli Puncu Village sub district of Puncu district of Kediri. Jurnal Biodjati 4(2): 236-243. (in English) ["Sumber Clangap and Sumber Mangli are geographically located at the Mount Kelud steeps. Administratively located at Puncu Village, Puncu Sub-district and District of Kediri. They provided hab-itat for the flora than fauna especially Odonata that never been studied before. We aimed to study Odonata diversity at Sumber Clangap and Sumber Mangli area. The method used in this study was natural snapshot experiment that conducted by Odonata

monitoring. Micro-climate parameter including air temperature and humidity were noted. Odonata activity and behavior noted for analysis. Collected data were analyzed using Shannon-Wiener heterogeneity index. The results showed that there were 17 species from the whole location. There was *Euphaea variegata*, *Vestalis luctuosa*, *Rhinocypha anisoptera*, *Pericnemis stictica*, *Pseudagrion pruinatum*, *Coeliccia membranipes*, *Gynacantha subinterrupta*, *Idionyx montana*, *Paragomphus reinwardtii*, *Heliogomphus drescheri*, *Neurothemis fluctuans*, *Orthetrum glaucum*, *O. pruinatum*, *O. sabina*, *Pantala flavescens*, *Trithemis festiva* and *Zygonyx ida*. Based on the Shannon-Wiener heterogeneity index the value, Sumber Clangap had heterogeneity index higher ( $H' = 1.97$ ) than Sumber Mangli ( $H' = 1.39$ ). Sumber Mangli has a Java endemic species *P. reinwardtii* and *R. anisoptera* that is spread only at Sumatera and East Java." (Authors)] Address: Abdillah, M.M., Biol. Dept, Fac. Sci. & Tech. **17047.** Agrawal, A. (2019): Passive flow control mechanism in a bio-inspired corrugated hydrofoil. SN Applied Sciences (2019) 1:1505: 17 pp. (in English) ["Corrugated hydrofoils are lately getting attention because of their superior aerodynamic performance compared to engineered hydrofoils at low Reynolds numbers ( $Re$ ). A particle image velocimetry (PIV) based study on corrugated hydrofoil is conducted here to understand the flow dynamics around it at ultralow Reynolds numbers ( $Re = 280-11,700$ ). Seven different angles of attack ( $\alpha$ ) are considered in this study ranging from  $-15^\circ$  to  $15^\circ$ . Load cell measurements are undertaken to obtain the force coefficients and further these are compared with the results obtained from PIV data using wake survey method. The wake velocity profiles are examined to understand the variation in force coefficients in a better way. Vortices are found to be trapped in the valley of the corrugations. The lift coefficient increases as the number of vortices increases on the top (suction) surface. A temporal analysis of the data shows that the partially merged co-rotating vortices give higher lift as compared to the fully merged vortices. The maximum aerodynamic performance is obtained at  $-5^\circ$  angle of attack for  $Re = 6760$ . The asymmetry in the geometry combined with asymmetry in the flow helps create relatively high lift for a corrugated wing. The performance of positive and negative angles of attack are compared and it is found that the fluctuation in lift coefficient is comparatively higher. It is hypothesized that the merging of trapped vortices with each other gives the effect of fluid roller bearings; this fluid roller bearing produces a travelling wave, which avoids the formation of boundary layer, thereby leading to high gliding ratio. These detailed results, covering the entire Reynolds number and angle of attack range of dragonfly flight, provide useful insights into the secret of dragonfly flight which will help in better design of micro air vehicles." **17049.** Aljjanovna, B.T. (2019): Review of insect fauna of urbanocenoses Kerki of the Republic of Turmenistan. XXV International scientific conference: 15-18. (in Russian, with English summary) ["The article presents some results of the study of species composition and structure of entomofauna of agrocenoses in the Eastern part of the Republic of Turkmenistan. The object of the study was the collection of imago insects living on the territory of Kerky and its surroundings. The study revealed 14 species of insects belonging to 7 groups. Dominant species and ecological groups of insects on the basis of trophic relations are revealed." *Sympetrum vulgatum* is the single odonate species listed. (Author)] Address: not stated

**17050.** Alves, R.J.V.; Costa, L.A.A.; Soares, A.; Silva, N.G.; Pinto, A.P. (2019): Open ocean nocturnal insect migration in the Brazilian South Atlantic with comments on flight endurance. *PeerJ* 7:e7583 DOI 10.7717/peerj.7583: 15 pp. (in English) ["We observed a nocturnal insect swarm aboard the oceanographic ship *Cruzeiro do Sul* of the Brazilian Navy, while conducting a survey of the Montague guyot (seamount), 389 km distant from the nearest land in the South Atlantic. The insects came from open sea toward the ship from all directions, attracted by the powerful light of the deck. Most insects collided with the hull and fell into the ocean, but we managed to capture and determine 17 (13 Hemiptera of a single species, three Lepidoptera of three species and one Odonata). With one exception, we are certain that none of the specimens caught originated from the ship. The geographic origin, most likely the coast of Brazil, and flight endurance of these insects were inferred using data on wind speed and direction, provided by the crew of the ship, and were reconstructed using Hysplit modeling of air current trajectories." (Authors) 1. *Anax amazili* (Burmeister, 1839). Material examined. One female (MNRJ ODO-0012, subsequently lost in the fire). Remarks. Species of *Anax* are known as migratory. They spend many weeks in migration routes undertaking distinct behaviors such as foraging (cf., May, 2013). *Anax amazili* is a New World species widespread in the entire American continent occurring from the USA (Needham, Westfall & May, 2000) through central America and the Caribbean Islands (Calvert, 1905) to southern Argentina (von Ellenrieder & Muzón, 2008). It also occurs as a resident species in the Pacific archipelago of Galápagos, about of 1,000 km from the coast (Calvert, 1905; Peck, 1992). The site of capture was about 380 km from the Brazilian coast and almost 800 km west of the closest archipelago, Trindade & Martin Vaz, from which Alves et al. (2019), *PeerJ*, DOI 10.7717/peerj.7583 5/15 only two different Odonata were recorded to date (MNRJ):

*P. flavescens* and *Rhionaeschna* sp. (see Santos, 1981). The pantropical Libellulidae glider *P. flavescens* in the best-known migrant dragonfly species (Samways & Osborn, 1998). The hypothesis that this species forms a global panmictic population has received recent support (Troast et al., 2016). However, it is not known if there is a regular migration route among these land masses.] Address: Alves, R., Depto de Botânica, Museu Nacional, Universidade Federal do Rio de Janeiro, Rio de Janeiro, Rio de Janeiro, Brazil

**17051.** Alves-Martins, F.; Calatayud, J.; Medina, N.G.; De Marco, P.; Juen, L.; Hortal, J. (2019): Drivers of regional and local diversity of Amazonian stream Odonata. *Insect Conservation and Diversity* 12(3): 251-261. (in English) ["1. Large Amazonian rivers may act as dispersal barriers for animals with low dispersal abilities, limiting their distribution to certain interfluves. Consequently, the distribution of these taxa would be less affected by macroclimatic gradients. Conversely, high-dispersal taxa would be less constrained by large rivers and may track suitable climates. 2. We evaluate whether Zygoptera and Anisoptera, two Odonata suborders with different dispersal abilities, show differences in distribution patterns across Amazonian interfluves. We further assess the relative importance of macroclimatic and habitat factors in their community assembly. 3. We used network modularity analyses to identify biogeographic species pools and spatial buffers to define metacommunity species pools. Then, we used structural equation models to estimate the relative importance of multi-scale factors on species richness patterns. 4. Zygoptera communities are more similar in species composition within than between interfluves, suggesting that large Amazonian rivers indeed limit the distribution of Zygoptera species. Conversely, the distribution of Anisoptera extends across Amazonian interfluves. Seasonality has a strong positive effect on Odonata richness across scales. In addition, habitat integrity is negatively correlated with the regional species richness and abundance of Anisoptera and positively correlated with Zygoptera local richness. 5. The contrasting effects of habitat integrity on Anisoptera and Zygoptera suggest that the former is favored in open habitats, whereas the latter is so in forests. Despite these differences, both suborders appear to follow similar community assembly mechanisms in Amazonia, with a strong climatic control across scales and an effect of habitat filters on local communities." **17055.** Assandri, G. (2019): A critical review of the odonate fauna of Trentino: annotated check-list and new relevant data for Italy (Insecta: Odonata). *Fragmenta Entomologica* 51(1): 75-88. (in English) ["By the first half of the Twentieth Century, the Odonate fauna of Trentino (Oriental Alps, Italy) was quite well known; subsequently, few surveys on dragonflies were carried out, resulting in a limited update of the knowledge on this taxon. The aim of this study is to provide a critical and annotated check-list of the Odonata of this province for the period from 1851 to 2018. This synthesis is based on a total of 3814 records obtained from the literature (955 records), revision of collections (1048 records), and unpublished recent data (1811 records). An updated and comprehensive Odonatological bibliography of the region is also provided. Overall, 61 species were confirmed to occur (or have occurred) in Trentino. These represent the 64% of the species recorded in Italy and the 43% of the species recorded in Europe. Presence of five additional species (*Ceriagrion tenellum*, *Coenagrion lunulatum*, *C. ornatum*, *Ophiogomphus cecilia*, and *Epithea bimaculata*) should be considered doubtful for Trentino. Further two species (*Platycnemis latipes* and *Onychogomphus uncatatus*) have to be excluded from the fauna of the study area. 45 species were recorded also after 2000, whereas seven species were not confirmed after this year (*Lestes dryas*, *L. virens*, *L. barbarus*, *Sympetma paedisca*, *Coenagrion scitulum*, *Brachytron pratense*, and *Sympetrum flaveolum*). Several

new records resulting from this study (referred to: *Erythromma najas*, *Aeshna subarctica*, *A. caerulea*, *A. grandis*, *Leucorrhinia pectoralis*) have a conservation or biogeographical relevance which transcends the borders of the study area, being noteworthy from an Italian or Alpine perspective and are thus commented in detail. Taxonomic notes on subspecies are also given when relevant." (Author)] Address: Assandri, G., Sezione Zoologia dei Vertebrati, MUSE - Museo delle Scienze, Corso del Lavoro e della Scienza, Trento, Italy. E-mail: giacomo.assandri@gmail.com

**17056.** Assandri, G.; Franceschini, A.; Lencioni, V. (2019): Dragonfly biodiversity 90 years ago in an Alpine region: The Odonata historical collection of the MUSE (Trento, Italy). *Biodiversity Data Journal* 7: e32391. <https://doi.org/10.3897/BDJ.7.e32391>: 13 pp. (in English) ["Background: Historical collections of natural science museums play a fundamental role in documenting environmental changes and patterns of biodiversity transformation. This considered, they should have a pivotal role to plan conservation and management actions. The MUSE - Science Museum of Trento is an Italian regional museum preserving about 5.5 million items (organised in 297 collections). About one million of them are invertebrates, 70% of which are of local origin, gathered in the collection "Miscellanea Invertebrati". Odonata account for a minor part of this collection; however, most of them are of local or regional relevance. A complete catalogue of this collection does not exist to date. New information: The collection was studied in 2017-2018 and this contribution aims to present the Catalogue of the historic collection of Odonata of the MUSE - Museo delle Scienze of Trento (Italy). In all, 836 specimens of adult dragonflies and damselflies are found in the collection referring to an overall 56 species. The collection covers a period between 1924 and 1957 and refer to 74 defined localities, all located in northern Italy (most of them in Trentino - Alto Adige Region). The samples conserved in the collection are, for several species, the only indisputable confirmation of their former occurrence in that region." **17058.** Baba, Y.G.; Kusumoto, Y.; Tanaka, K. (2019): Positive effect of environmentally friendly farming on paddy field odonate assemblages at a small landscape scale. *Journal of Insect Conservation* 23: 467-474. (in English) ["Odonata species can be used to indicate the effects of anthropogenic disturbance on agrobiodiversity. In Japan, populations of some odonate species inhabiting rice paddy fields have decreased strongly owing to their high susceptibility to insecticides, and they therefore need to be conserved. To identify effective conservation strategies, we investigated how agricultural practices (conventional vs. environmentally friendly: EF) and surrounding landscape (area of forest at three spatial scales, namely 50, 100 and 200 m from the edge of the paddy field) influenced the abundance of odonates in rice paddies in Tochigi Prefecture, Japan. Generalized linear mixed-effect models revealed that EF farming increased the abundance of odonate adults and the number of nymphal exuviae, suggesting a strong negative effect of insecticides. The influence of forest area at the local scale on the numbers of odonate adults and nymphal exuviae was small, with the exception of a strong negative influence on adult *Symptetrum infuscatum*: the presence of a large area of forest within 200 m of the edge of the paddy field reduced their abundance, probably reflecting this dragonfly's oviposition site preference. Our results suggest that EF farming could generally support the conservation and recovery of local populations of odonates, but its effectiveness potentially varies depending on the ecological aspects of each species." (in English) ["*Gomphidia podhigai* nov. spec. is described from southern Western Ghats, India based on a male specimen. The new species is very distinct from all the known species of *Gomphidia* from Indian subcontinent. Revised keys to the males and known females of *Gomphidia* of India and Sri

Lanka are provided." (Authors)] Address: Subramanian, K.A., Zoological Survey of India, Southern Regional Centre, Santhome High Road, Chennai-600 028, Tamil Nadu, India. E-mail: subbuka.zsi@gmail.com

**17061.** Bashinskiy, I.V.; Senkevich, V.A.; Stoyko, T.G.; Katsman, E.A.; Korkina, S.A.; Osipov, V.V. (2019): Forest-steppe oxbows in limnophase — Abiotic features and biodiversity. *Limnologica* 74: 14-22. (in English) ["The aim of our study was to identify the main abiotic factors that influence the biodiversity of forest-steppe oxbows in limnophase. Experiments were performed in 2016–2017 in Penza oblast, Central Russia. In addition to disturbed water exchange, isolated oxbows experienced such human influence as logging and plowing on watersides, and the construction of roads and mounds. Under those conditions, some water bodies became unstable and temporal, while others remained stable and were relatively unaffected. Higher light intensity in unstable oxbows led to higher plant diversity because of the mass occurrence of helophytes. However, the diversity of hydrophytes in stable oxbows remained higher, which contributed to higher vegetation coverage. This resulted in increased zooplankton diversity, which was also influenced by lower fluctuations in water level and oxygen level. Disturbed water regimes impacted organisms with a full aquatic life cycle (phyto- and zooplankton, fish). The diversity of unstable oxbows decreased due to their isolation from the river and from drying. The absence of fish may positively affect the abundance and biomass of benthos; however, we found no influence on zooplankton. Instability and high fluctuations in water level may lead to the high diversity of organisms that spawn in water. The higher diversity of benthos may also be influenced by the abundance of amphibian larvae which are a necessary food resource. In addition to predation, amphibians are at risk of mass larval mortality because of drying. Although the degradation of oxbows in limnophase is an undesirable consequence of anthropogenic impact, the coexistence of all types of oxbows is necessary to conserve the freshwater biodiversity of foreststeppes." **17062.** Batty, P.M (2019): Recent observations of *Aeshna caerulea* (Azure Hawker) in Scotland. *J. Br. Dragonfly Society* 35(1): 1-17. (in English) ["The population of *A. caerulea* in Scotland has been inferred as undergoing a decline. However, many of the apparent gains and losses are likely to be attributable to recording effort. This study revisits sites that have not been recorded from for 10 years or more and investigates other potential bog pools for breeding data through surveying for larvae. Two important breeding populations were found in Glen Garry and above Loch Quoich, extending the known range. These could be part of a much larger complex in the whole area. Breeding pools were also found at Rannoch Moor and Corroul. Recent surveys confirm the importance of higher-level upland blanket bog pools as the breeding habitat for this species. The lack of large larvae underlined the low productivity of the species and a large area may be needed to sustain the population. An update is also given

on the current situation for *A. caerulea* from other sources since 2012, which was the approximate cut-off date for data for the Atlas of British and Irish Dragonflies (Cham et al, 2014). The range of *A. caerulea* is expanding in the Highlands. However, after extensive survey work, it appears possible that the species may have been lost from its most southerly site. More survey work is needed to investigate other, older records and to locate breeding areas." (Author)] Address: Batty, Patricia, Kirnan Farm, Kilmichael Glen, Lochgilphead, Argyll PA31 8QL, UK

**17063.** Bechly, G.; Rasmussen, J.A. (2019): A new genus of hawker dragonfly (Odonata: Anisoptera: Aeshnidae) from the Early Eocene Fur Formation of Denmark. *Zootaxa* 4550(1): 123-128. (in English) ["*Parabaissaeshna ejerslevense* gen. et sp. nov. (Aeshninae: Allopataliini), is described from the Early Eocene Fur Formation (Mo-clay) of the island of Mors, northern Denmark. Its position among traditional "gomphaeschnine" dragonflies is discussed, and it is attributed to the tribe Allopataliini as close relative to the Cretaceous genus *Baissaeshna*, documenting the survival of this lineage through the K-Pg mass extinction. The Recent genus *Boyeria* and the Eocene genus *Anglogomphaeschna* are also transferred to Allopataliini." (2019): Rapid recovery of macroinvertebrates in a South African stream treated with rotenone. *Hydrobiologia* 834: 1-11. (in English) ["South Africa's Cape Fold Ecoregion supports a unique freshwater fish assemblage with many endemics. To mitigate impacts of alien invasive fishes on this unique assemblage, nature conservation authority CapeNature used rotenone to remove smallmouth bass (*Micropterus dolomieu*) from the Rondegat River. We investigated whether the rotenone treatments had an adverse impact on the aquatic macroinvertebrate community over the long-term, the first study of its kind in Africa. We monitored macroinvertebrates within treated and untreated (control) sites on multiple sampling events for 2 years before and 2 years after two rotenone treatments. We analysed the difference in invertebrate abundance between treatment and control sites before and after treatment, using generalised linear mixed models with sampling event as a random factor to partition out natural fluctuations in abundances over time. Populations fluctuated widely in control and treatment sites over the study period, and we found no effect that could be clearly attributed to rotenone. We conclude that macroinvertebrates recovered rapidly after treatment, probably through drift from untreated areas upstream, with no long-term adverse effects. We recommend that the presence of uninhabited upstream refuges that may provide demographic rescue be used as a key discriminating factor for future conservation purposed rotenone deployments." (Authors)] Address: Bellingan, T.A., Dept of Entomology and Arachnology, Albany Museum, Grahamstown, South Africa

of the Owabi Wildlife Sanctuary, Kumasi, Ghana was characterized into different disturbance gradients to assess water quality in the reserve. A total of 207 individuals from 25 species were recorded in the study area. Of these, 105 individuals belonging to 12 species and 102 individuals in 13 species were recorded as Odonata respectively. The forest habitat exhibited the largest damselfly assemblages while the disturbed habitat exhibited the largest dragonfly assemblages.] Address: Hadeeza Bemah. E-mail: hadeezahbemah@yahoo.com]

**17066.** Bhardwaj, M.; Soanes, K.; Lahoz-Monfort, J.J.; Lumsden, L.F.; van der Ree, R. (2019): Little evidence of a road-effect zone for nocturnal, flying insects. *Ecology and Evolution* 9: 65-72. (in English) ["Roads and traffic may be contributing to global declines of insect populations. The ecological effects of roads often extend far into the surrounding habitat, over a distance known as the road-effect zone. The quality of habitat in the road-effect zone is generally degraded (e.g., due to edge effects, noise, light, and chemical pollution) and can be reflected in species presence, abundance, or demographic parameters. Road-effect zones have been quantified for some vertebrate species but are yet to be quantified for insects. Investigating the road-effect zone for insects will provide a better understanding of how roads impact ecosystems, which is particularly important given the role insects play as pollinators, predators, and prey for other species. We quantified the road-effect zone for nocturnal flying insects along three major freeways in agricultural landscapes in southeast Australia. We collected insects using light traps at six points along 2-km transects perpendicular to each highway (n = 17). We sorted the samples into order, and dried and weighed each order to obtain a measure of dry biomass. Using regression models within a Bayesian framework of inference, we estimated the change in biomass of each order with distance from the road, while accounting for environmental variables such as temperature, moon phase, and vegetation structure. The biomass of nine of the ten orders [including Odonata] sampled did not change with distance from the freeway. Orthoptera was the only order whose biomass increased with distance from the freeway. From our findings, we suggest that the impacts of roads on insects are unlikely extending into the surrounding landscape over a distance of 2 km. Therefore, if there are impacts of roads on insects, these are more likely to be concentrated at the road itself, or on finer taxonomic scales such as family or genus level." **17069.** Bláha, M.; Grabicova, K.; Shaliutina, O.; Kubec, J.; Randák, T.; Zlabek, V.; Buric, M.; Veselý, L. (2019): Foraging behaviour of top predators mediated by pollution of psychoactive pharmaceuticals and effects on ecosystem stability. *Science of the Total Environment* 662: 655-661. (in English) ["Highlights: •Functional response approach was utilized as an endpoint of contaminant exposure. •WWTP effluent with real mixture of PhACs was tested. •Predator feeding behaviour was affected by all tested compounds. •WWTP effluent strengthens interaction strength by increased maximum feeding rate. •Single tested PhACS displayed decreased maximum feeding rate. Abstract: Although pharmaceuticals are recognized as a major threat to aquatic ecosystems worldwide, little is known about their ecological effect on aquatic biota and ecosystems. Drug-induced behaviour changes could have a substantial impact on consumer-resource interactions influencing stability of the community and ecosystem. We combined laboratory experiments and functional response modelling to investigate effects of real wastewater treatment plant (WWTP) effluent, as well as environmentally relevant concentrations of the antidepressants citalopram and opioid pain medication tramadol, on trophic interactions. Our biological system consisted of *Aeshna cyanea* larvae as predator of common carp *Cyprinus carpio* fry. Exposure to WWTP effluent significantly increased *A. cyanea* maximum feeding rate, while those parameters in tramadol and citalopram-exposed larvae were significantly lower from unexposed control group. This suggested the potential of all tested pollutants to have an effect on consumer-resource equilibrium in aquatic ecosystems. While WWTP effluent strengthened interaction strength (IS) of consumer-resource interaction dynamics making the food web more vulnerable to fluctuation and destabilization, tramadol and citalopram could inhibit the potential oscillations of the consumer-resource system by weakening the IS. Similar studies to reveal the potential of pervasive pharmaceuticals to change of consumer-resource interactions

dynamics are needed, especially when real WWTP effluent consisting of mixture of various pharmaceuticals displayed very different effect from single compounds tested." **17073.** Bos-Groenendijk, G.I.; Grunsvan, R.H.A. van; Poot, M.J.M. (2019): Mogelijkheden voor aantalsmonitoring en verspreidingsonderzoek rivierrombout. Rapport VS2019.025, De Vlinderstichting, Wageningen: 15 pp. (in Dutch) ["*Stylurus flavipes* is species that lives in the large rivers (Waal, Rijn, IJssel). The species had disappeared from the Netherlands for a long time, but was rediscovered in 1996. Due to improvements in water quality, the Dutch rivers had become suitable habitats again. The species is now found in large parts of the river area. The river snake is listed in Annex IV of the European Habitat Directive and thus enjoys a legally protected status. The species is therefore a target species within the Ecological Monitoring Network (NEM). However, it is difficult to monitor and because of its way of life it does not fit into the standard method of the dragonfly monitoring network. This report describes the current situation in terms of distribution and number monitoring of the river hummingbird and how monitoring could develop further. In 2019, number monitoring of the river scallop was started for the first time. This was a pilot project to find out whether a good picture of the population developments of the species could be obtained in this way. Based on observations from the NDFF, two locations were selected where potentially many skinks could be found. At both locations different routes are set out according to the method of the dragonfly monitoring network. These routes were visited three times and the skins of the river hawk were sought. The pilot project has produced good results at Loevestein Castle. We expect that this method will provide long-term insights into the population development of the river scoter and therefore recommend continuing this form of monitoring." **17076.** Bried, J.T.; Hinchliffe, R.P. (2019): Improving taxonomic resolution in large-scale freshwater biodiversity monitoring: an example using wetlands and Odonata. *Insect Conservation and Diversity* 12(1): 9-17. (in English) ["1. Immature aquatic insects are a major source of taxonomic difficulty in large-scale freshwater biodiversity monitoring. Adult stages could improve taxonomic resolution for assessing distributions and trends of biodiversity. Odonata have accessible adult stages that should greatly enhance the amount of species-level information. 2. We used Odonata and a wetland monitoring programme in Alberta, Canada to illustrate how much taxonomic information can be lost in larval collections, and an extensive adult records database to estimate what could be gained from adult surveys. 3. Despite processing 22 638 odonate specimens from 975 wetlands throughout Alberta, larval monitoring failed to collect or identify almost 60% of the lentic breeding Odonata species known from adult records. A total of 25 lentic-breeding dragonfly species and 12 lentic-breeding damselfly species were present in adult records and not the larval data, including species of conservation concern. Due to the abundance of early instars, a substantial 82% of the processed damselfly collection and 62% of the processed dragonfly collection was left at suborder. 4. We recommend supplementing aquatic sampling with adult rearing, collecting, and observing (at least Odonata) to improve the basic inventory and overall status assessment in large-scale freshwater biodiversity monitoring. This is especially true when aquatic sampling is restricted to a suboptimal time of year for species identifications." **17077.** Buczynska, E.; Buczynski, P. (2019): Aquatic insects of man-made habitats: Environmental factors determining the distribution of caddisflies (Trichoptera), dragonflies (Odonata), and beetles (Coleoptera) in Acidic Peat Pools. *Journal of Insect Science* 19(1): 1-15. (in English) ["As degradation of sensitive habitats like *Sphagnum* L. (Sphagnales: Sphagnaceae) peatbogs is endangering their invertebrate fauna, artificial peat pools may offer peatbog insect fauna a chance of survival. The entomofauna of seven peat pools in a peatbog and its surrounding natural marginal zone in SE Poland was investigated at the level of species, assemblages and faunistic metrics, indicating the key environmental drivers of the insect distribution and their implications for the biodiversity and potential conservation of these habitats. The species composition, specialists, and insect assemblages of the peat pools were linked with the fauna typical of both peatbogs and dystrophic pools

with an open water surface. The most specialized fauna was found in the pools with the largest Sphagnum cover: only typhobionts, of all the ecological elements, significantly discriminated the fauna of peat pools and the marginal zone. Sphagnum cover was the key structural factor affecting the distribution of all the insects. Additionally, dragonflies were dependent on pH, beetles on temperature, and caddisflies on dissolved oxygen; however, structural factors—apart from Sphagnum cover—pool perimeter and emergent vegetation cover were predominant. Our results show that appropriate management of the structural factors of peat pools, especially Sphagnum cover, and the provision of different successional stages, can enhance biodiversity and help to maintain a valuable specialist fauna. Even along small environmental gradients and in a homogeneous area, the response of insects is highly differentiated. Dragonflies probably best represent the conservation value of the overall invertebrate fauna of Sphagnum bogs." **17081.** Bylak, A.; Rak, W.; Wójcik, M.; Kukula, E.; Kukula, K. (2019): Analysis of macrobenthic communities in a post-mining sulphur pit lake (Poland). *Mine Water and the Environment* 38(3): 536-550. (in English) ["The objective of the study was to define the primary environmental factors affecting the composition of the macrobenthic community in an abandoned open cast sulphur mine pit lake that had been filled with water from a nearby river. We investigated habitats at various depths and the macrobenthic communities; samples were collected by scuba divers. Although rush and submerged vegetation in the subsaline pit lake was abundant and provided potentially good habitat conditions for mayflies, caddisflies, coleopterans, or damselflies, the native insects were scarce. The taxa do not have many representatives in waters with elevated salinity, so those present in the Machów pit lake were mainly euryhaline species. Chironomids were the most abundant macroinvertebrates in shallower zones, whereas non-native zebra mussels were the quantitatively dominant taxon in deep-water zones. Moreover, these non-native mussels were the dominant biomass of invertebrates at all sites in all seasons. The current composition of the invertebrate assemblage was probably primarily determined by the salinated water, which limited the abundance of native species and gave non-native species an edge." **17084.** Calvao, L.B.; Juen, L.; Barbosa de Oliveira, J.M.; Batista, J.D.; De Marco, P. (2019): Land use modifies Odonata diversity in streams of the Brazilian Cerrado. *Journal of Insect Conservation* 22(5–6): 675–685. (in English) ["The presence of riparian vegetation provides microclimatic regulation of stream conditions [e.g. luminosity (lux), air temperature ( $^{\circ}$ C) and relative humidity (%)], which varies naturally throughout the day. These variables explain the diurnal behaviour patterns of ectotherms such as Odonata in natural areas. However, human land uses (e.g. pastures) modify the abiotic conditions of riparian environments, favouring the presence of disturbance-tolerant species. In this context, we assess relationships between riparian land use (control streams-natural areas and pasture), abiotic conditions habitat integrity index (in control and pastures streams), (air temperature, luminosity and humidity in control streams), and Odonata diversity (between pasture and control streams and throughout the time of day) in Brazilian savannah (Cerrado) streams. First, the control streams had higher habitat integrity index than pasture. Higher abundance and difference in composition of Odonata species were observed in streams surrounded by pasture relative to natural areas. The conversion of natural areas to pasture near streams was also accompanied by an increase in overall body size of Odonata species. Odonata species richness and abundance in natural areas varied throughout the day, but peaked around 12:00 h, coinciding with changes in air temperature and luminosity. Our study highlights that changes in the physical characteristics of streams through conversion of natural habitats to pasture will change environmental conditions and act as a filter on the distribution and persistence of Odonata species in Cerrado streams." **17086.** Cannings, R.A. (2019): Odonata of Canada. *ZooKeys* 819: 227–241. (in English) ["Since Corbet's thorough 1979 overview of Canadian Odonata, hundreds of regional works on taxonomy, faunistics, distribution, life history, ecology and behaviour have been written. Canada records 214 species of Odonata, an increase of 20 since the 1979 assessment. Estimates of unrecorded species are small; this reflects the well-known nature of the fauna. A major impetus for surveys and analyses of the status of species is the work of the Committee on the Status of Endangered Wildlife in Canada which provides a scientifically sound classification of wildlife species potentially at risk. As of 2017, six species have been designated "Endangered" and two "Special Concern" (only five of which are officially listed under the Federal Species at Risk Act (SARA)). The Order provides a good example of molecular barcoding effort in insects, as many well-accepted morphological species in Canada have been barcoded to some degree. However, more barcoding of accurately identified specimens of many species is still required, especially in most of the larger families, which have less than 70% of their species barcoded. Corbet noted that the larvae of 15 Canadian species were unknown, but almost all larvae are now well, or cursorily, described. Extensive surveys have greatly improved our understanding of species' geographical distributions, habitat requirements and conservation status but more research is required to better define occurrence, abundance and biological details for almost all species." **17089.** Cao, L.-z.; Wu, K.-m. (2019): Genetic diversity and demographic history of Globe Skimmers (Odonata: Libellulidae) in China based on microsatellite and mitochondrial DNA markers. Scientific Reports 9( 8619): 8 pp. (in English) ["To analyze genetic characters of migratory dragonflies, we used 10 microsatellite markers and a partial sequence of the mitochondrial gene *Cytb* to investigate genetic diversity and demographic history among 19 populations of *P. flavescens* in eastern the monsoon region of China. In a Bayesian clustering analysis of the microsatellite data, three distinct clades were present, and each population consisted of a mixture of individuals from the three clusters. An AMOVA of the data from both the microsatellite loci and *Cytb* revealed that genetic variation was mainly within each population. For the 543 individuals from the 19 regions, 77 unique haplotypes were obtained by DnaSP 4.0, and a median-joining network showed no obvious geographical pattern and displayed high gene flow and minimal population genetic structure among the 19 populations. According to a Mantel test, there was no significant association between genetic distance and geographic distribution and no isolation by distance. Mismatch distribution and neutrality tests showed no demographic expansion for the 19 populations. Microsatellite and mitochondrial DNA data suggested there was high gene flow and low differentiation among the populations. These results will help provide valuable information to study the migratory route of insects, especially important agricultural pests." **17090.** Casanueva, P.; Sharifi, F.S.; Hernández, M.A.; Campos, F. (2019): Colour of the gonapophyses in *Cordulegaster boltonii* (Golden-ringed Dragonfly) can help determine the stage of metamorphosis in female final instar larvae. J. Br. Dragonfly Society 35(1): 33-38. (in English) ["The degree of darkening of the gonapophyses in female final instar (F-0) larvae of *C. boltonii* is compared with the four stages (here referred to as 1 - 4) of metamorphosis described by Ferreras-Romero & Corbet (1999) in this species. There is a reasonable degree of correlation, with larvae showing no darkening of the gonapophyses falling mainly in stages 1 and 2, whereas those with more than 25% of darkening fall almost exclusively

into stages 3 and 4. The method described in the current study is a simple method for determining the stage of metamorphosis but it is suggested that, for maximum accuracy, both methods should be used." **17091.** Catalano, S.; Nadler, S.A.; Fall, C.B.; Marsh, K.J.; Leger, E.; Sened, M.; Priestnall, S.L.; Wood, C.L.; Diouf, N.D.; Ba, K.; Webster, J.P. (2019): *Plagiorchis* sp. in small mammals of Senegal and the potential emergence of a zoonotic trematodiasis. IJP: Parasites and Wildlife 8: 164-170. (in English) ["Trematodes of the genus *Plagiorchis* have a wide geographical distribution and can exploit a variety of hosts. The occurrence and zoonotic potential of *Plagiorchis* spp. have been characterised across several countries in Asia; in contrast, information on *Plagiorchis* parasites in Africa remains anecdotal. We isolated a previously undescribed *Plagiorchis* species from the biliary tract and small intestine of 201 out of 427 small mammals collected in the region of Lake Guiers, Senegal, with local prevalence ranging from 38.6% to 77.0%. Conversely, *Plagiorchis* isolates were not observed in the 244 small mammals sampled in and around the town of Richard Toll, Senegal. Molecular phylogenetics of the internal transcribed spacer region, nuclear ribosomal DNA, and of the cytochrome c oxidase subunit 1 gene, mitochondrial DNA, supported the monophyly and multi-host spectrum of this newly discovered West African *Plagiorchis* species. Sequencing of individual cercariae shed by *Radix natalensis* (Gastropoda: Lymnaeidae) suggested that these freshwater snails may act as suitable first intermediate hosts. Phylogenetic analysis yielded a highly resolved topology indicating two different clades, one composed by *Plagiorchis* spp. infecting rodents, insectivores, and birds, while the other included parasites of bats. Our findings showed the low host specificity and high prevalence of the isolated *Plagiorchis* sp. in the Lake Guiers region, with Hubert's multimammate mice (*Mastomys huberti*) appearing to play a primary role in the epidemiology of this parasite. The results raise concern about the zoonotic potential of *Plagiorchis* sp. in local communities of the Lake Guiers region, and highlight food-borne trematodiasis and their link to land-use change as a neglected public health issue in regions of West Africa." **17093.** Chelmick, D. (2019): *Coenagrion mercuriale* (Southern Damselfly) at Povington, Isle of Purbeck, Dorset. *J. Br. Dragonfly Society* 35(1): 18-32. (in English) ["*C. mercuriale* is found very locally in Southern Britain where it breeds in base rich, slow flowing streams and mires; its two year larval life cycle in the UK requires permanent waters. On the Isle of Purbeck, Dorset, *C. mercuriale* has been found in six sites, only one of which (Harland Moor) is currently thriving. One of the sites, at Povington, which is on MOD land, was discovered in May 1992, and in 1995 the colony was thought to comprise approximately 1500 adults and was the most important in Purbeck. Since that time the colony has declined and in 2016 only one adult was seen. This was the last sighting of this species at Povington. On behalf of the British Dragonfly Society, the author undertook a study of the habitat to investigate the decline. In summary: The colony at Povington came about as a result of changing water flows associated with clay workings, probably in the 1980s. In 1996 it was proposed that the water flows would be diverted entirely away from the site. Following negotiations, a compromise solution was made, allowing some water to continue to flow through the site. Unfortunately, this compromise has provided insufficient water to maintain the colony. Although the water flow has improved, the reduced grazing of the area has led much of the habitat to become overgrown. The problems with water flow and grazing mean that it is unlikely that *C. mercuriale* survives at Povington." (Authors)] Address: Chelmick, D., Macromia Scientific 31 High Beech Lane, Haywards Heath RH16 1SQ, UK. E-mail: david.chelmick@gmail.com

**17094.** Chertoprud, M.V.; (2019): Macrofauna communities in the mountain streams of Sri Lanka (Ceylon). *Inland Water Biology* 12(2): 199-209. (in English) ["The rheophilic macrobenthic communities of the mountainous part of the island of Sri Lanka have been studied based on the material of 170 quantitative stations of small rivers and streams. Thirteen types of communities are described by taxonomic structure (mainly at the genus level) and habitats; similarities with other regions are also shown. A difference between the communities in the lowland (tropical) and highland (subtropical) zones is observed. This paper provides a taxonomic review of the macrofauna sampled and a description of the regional features of its ecology and diversity. Characteristics of the oriental tropical rheophilic communities in comparison with subtropical and boreal Palearctic communities, the influence of altitudinal zonation, the effect of the island on the community structure, and the biogeographic position of Sri Lanka are discussed." **17095.** Chien, W.-C.; Li, M.-H.; Li, H.-J. (2019): Appropriate management practices help enhance odonate species richness of small ponds in peri-urban landscapes. *Urban Ecosystems* 22: 757-768. (in English) ["Adult odonate biodiversity was investigated to understand their relationship with pond management practices and environmental conditions in a

rapidly urbanized landscape. Twenty-four farm ponds in Taoyuan City were selected and classified into five pond groups based on pond management practices. In total, 21 species, 17 genera, and 6 families of odonates were recorded for a total of 5701 individuals between June 2014 and July 2015. The abundance of Odonata was unrelated to pond size or distance to the nearest pond; however, odonate species richness was negatively and significantly correlated with pond size. Pond management practices considerably affected pond aquatic macrophytes and dike construction materials. Ecology park ponds under intense human management and undisturbed ponds without any human management had higher species richness than did the ponds in the other three fish farming groups. Species richness was highest in small and human-modified ponds. By contrast, species richness was lowest in two fish farming pond groups. These results suggest that pond management practices can increase or reduce odonate species richness depending on the alteration of pond microhabitat features. Our observations suggest that the enhanced habitat quality of small ponds provides an opportunity to protect freshwater biodiversity for local governmental civil servants in urbanized landscapes." **17099.** Conze, K.-J. (2019): In memoriam of Prof. Dr. Eberhardt Schmidt, 20 July 1935 to 9 July 2018. *Agrion* 23(1): 5. (in English) [Verbatim: In July 2018 Prof. Dr. Eberhardt Schmidt died after a severe illness but in the good custody of his family. Nearly all his life he was an odonatologist, from early beginnings as a pupil in Berlin to more than seventy years of experience in his later years. He published more than 250 scientific papers, around 180 of them about dragonflies! In 1971 he was involved in the foundation of the SIO (Societas Internationalis Odonatologica) and for several years he also worked on the board of this international scientific community of odonatologists from around the world. Together with Rainer Rudolph he founded the GdO (Gesellschaft deutschsprachiger Odonatologen) and for a long time he was the 'guiding spirit' of this society. Early on he gave advice on how to determine and document dragonflies by photographs; this knowledge is even today still very helpful and necessary. Also from the start of GdO he proclaimed long-term monitoring as an important task for odonatologists. We should certainly learn from him! But his huge body of work for the sake of the dragonflies is now a significant part of our baseline knowledge. Many of his papers produced ideas to be followed up and developed further e.g. using dragonflies as bioindicators for nature conservation of watercourses. No doubt, Ebi (as his friends called him) will always stay in our memory! The GdO is now preparing a dedicated supplement of *Libellula* to honour Eberhardt Schmidt.] Address: Klaus-Jürgen Conze. Cordero-Rivera, A.; Romeo Barreiro, A.; Cabana Otero, M. (2019): *Forcipomyia paludis* (Diptera: Ceratopogonidae) in the Iberian Peninsula, with notes on its behaviour parasitizing odonates. *Boletín de la Sociedad Entomológica Aragonesa* 64: 243-250. (in English, with Spanish summary) ["The adults of Odonata are parasitized by the ceratopogonid dipteran *F. paludis*, which is widely distributed in Europe, but has not been formally cited in the Iberian Peninsula, although it has been cited in the Balearic Islands. However, its presence in photographs stored in citizen science websites, books on odonates, as well as the finding of this species in Galicia in at least two locations, indicate that its distribution in the Iberian Peninsula is wide, particularly on the Mediterranean

coast. A detailed map of the distribution of *F. paludis* in the Iberian Peninsula is provided, as well as photographs under the scanning electron microscope, to facilitate its identification. In Galicia it has been found for several years parasitizing odonates in the lagoon of Doniños (Ferrol), where its main hosts are *Enallagma cyathigerum* and *Ischnura elegans*, although always at very low frequencies. Other species occasionally parasitized in this lagoon were *Sympetrum sanguineum*, *Erythromma viridulum* and *Lestes virens*, in these last two cases a newly emerged individual. Likewise, several adults of *F. paludis* have been observed attacking an individual of *Onychogomphus uncatatus* at the time of the emergence, in this case on the Ulla river, a behaviour that is described and discussed." **17100.** Cordero-Rivera, A.; Sanmartín-Villar, I.; Sánchez Herrera, M.; Rivas-Torres, A.; Encalada, A. C. (2019): Survival and longevity in neotropical damselflies (Odonata, Polythoridae). *Animal Biodiversity and Conservation* 42.2: 293-300. (in English, with Spanish summary) ["Survival and longevity in neotropical damselflies (Odonata, Polythoridae). Longevity among insect orders varies greatly, and has mainly been studied in insects in temperate biomes, where seasonality determines high synchronization of reproductive activities and limits lifespan. Most forest damselflies in tropical regions have low population densities and are almost never observed in copula. We hypothesized that selection will favour a high survival rate and hence high lifespan, allowing the animals to be ready for the occasional events that favour reproduction. We studied *Polythore mutata* and *P. derivata*, in Ecuador, using mark-recapture methods. We found that sex affected the rate of recapture, but daily survival rate was affected by sex only in one population. We found evidence that suggests stabilizing or directional selection on body size. The maximum lifespan was 54–63 days. We conclude that the survival rate of *Polythore* damselflies in tropical forests is comparable to that of similar damselflies in temperate zones." **17103.** Crane, A.L.; Bairos-Novak, K.R.; Jefferson, D.M.; Chivers, D.P.; Ferrari, M.C.O. (2019): Survival, behaviour, and morphology of larval wood frogs, *Lithobates sylvaticus*, under threat from an exotic crayfish predator, *Orconectes virilis*. *Aquatic Ecology* 53(3): 383-392. (in English) ["There are numerous examples of species introductions that have caused declines in native populations. In many cases, exotic species are predators of native prey which do not respond correctly to these new and often much different threats. Amphibians, as a group, have been strongly affected by introductions of fish and other aquatic predators such as crayfish. Our goal in this study was to explore the potential impacts of exotic crayfish on the behaviour, morphology, and survival of native wood frog tadpoles, *L. sylvaticus*. In mesocosms, groups of tadpoles were exposed to either a native predator (larval beetle or dragonfly nymph) or an exotic crayfish, *Orconectes virilis*. Tadpoles were the largest following exposure to dragonflies, indicating that dragonflies were selecting smaller tadpoles. Vertical space use of tadpoles was highest in the presence of crayfish, suggesting that tadpoles were learning to avoid crayfish in the benthos. Mortality was highest in the presence of beetles and lowest with crayfish, and hence in isolation, exotic crayfish were poorer predators of wood frog tadpoles. However, half way through the experiment, we replaced each predator with a new predator of either the same species or a different species to assess how the impact of the new predator was affected by experience with the first predator. When crayfish were added following beetles, the mortality due to crayfish increased significantly, possibly due to differences in predator space use and foraging mode." **17104.** Cuellar-Cardozo, J.A.; Lozano-Bernal, M.F.; Díaz-Guamán, J.-W. (2019): Estudio, curaduría y nuevos registros de odonatos presentes en la colección del Museo de La Salle. *Revista de la Academia Colombiana de Ciencias Exactas, Físicas y Naturales* 43(168): 489-493. (in Spanish, with English summary) ["Study, curation and new records of odonates present in the collection of the Museum of La Salle. Colombia is the fifth country with the most Odonata species in Latin America totaling 437 distributed among 11 families, which represent 7.2% of the world's richness. This is reflected in a large number of specimens present in many collections in the country.

The collection of the Museum of La Salle has records since 1968 and it evidences problems in the taxonomic identification and the preservation mode that can put at risk the specimens and the information they represent in the long term. Taking into account this, the objective of this project was to carry out a taxonomic update and to improve the storage conditions of the odonates deposited in the museum. For this, the specimens were identified up to the minimum possible taxonomic level and, at the same time, we undertook curative conservation and storage optimization actions. As a result, a total of 903 individuals were identified belonging to 81 species distributed in 14 departments, Huila being the most representative with 363 specimens, most of them collected between 2010 and 2017. Through a bibliographic review, we found new records for several departments of the country, Cundinamarca being the one with the largest amount. We concluded that the collection of the Museum of La Salle has valuable pieces of information regarding the spatial and temporal distribution of Odonata species in the country. Likewise, we highlight the importance of using the correct technique for specimen preservation and storage." (Authors)] Address: Cuéllar-Cardozo, J.A., Bioprospección y Conservación Biológica, Univ. de La Salle, Bogotá, D.C., Colombia. E-mail: josecuellar1094@gmail.com

**17105.** Cunha, D.L.; Mendes, M.P.; Marques, M. (2019): Environmental risk assessment of psychoactive drugs in the aquatic environment. *Environmental Science and Pollution Research* 26(1): 78-90. (in English) ["The consumption of psychoactive pharmaceuticals has increased worldwide, and wastewater treatment plants are not able to eliminate them from the effluent. An extensive review was carried out to assess the environmental risk (ERA model) based on secondary data about potential impacts on non-target organisms of seven psychoactive drugs consumed worldwide (alprazolam, bromazepam, citalopram, clonazepam, diazepam, lorazepam, and oxazepam). Risk quotients (RQs) were calculated according to the European Medicines Agency (EMA) on ERA of Medicinal Products For Human Use based on (i) the predicted and measured environmental concentrations (PEC and MEC, respectively) of the psychoactive drug in surface water, groundwater, and wastewater effluent and (ii) the predicted no-effect concentration (PNEC) derived from ecotoxicological assays or ECOSAR software. Furthermore, this study reviews and discusses non-standardized ecotoxicity assays, such as sublethal and behavioral effects on different organisms. In total, 903 MEC entries of psychoactive drugs and 162 data on ecotoxicological assays were gathered from the literature survey addressing behavioral effects (115), acute/chronic effects (35), and sublethal effects (12). Citalopram and diazepam were the only substances that are likely to pose an environmental risk (RQ > 1) to surface waters. Even though there is considerable amount of data on behavioral effects of psychoactive drugs to aquatic species, results are currently not integrated into the EMA risk assessment framework. The large amount of data on psychoactive drug concentrations and effects on nontarget organisms collected, interpreted, and discussed in the present study should be used as a baseline for future improvement of ERA strategies." **17108.** da Silva, M.H.; Teixeira-Gamarra, M.C.; Rodrigues, M.E.; Aoki, C. (2019): Survey of odonate fauna (Insecta:

Odonata) in a stretch of the Maracaju Hills, State of Mato Grosso do Sul, Brazil. *Oecologia Australis* 23(4): 961-968. (in English) ["The scarcity of studies on fauna inventories, especially those addressing insects, is a large problem in many regions of Brazil. To contribute to taxonomic knowledge and broaden the distribution of the order Odonata, we present a survey of odonate fauna of the Maracaju Hills in the state of Mato Grosso do Sul, Brazil. Ten samplings were performed between September 2013 and April 2015, totaling 38 h of active searches. A total of 386 individuals belonging to five families, 21 genera and 37 species were collected. Eleven species belonged to the suborder Zygoptera and 26 belonged to the suborder Anisoptera. The family Libellulidae was the richest and most abundant (25 species; 285 individuals), followed by Coenagrionidae (nine spp.; 81 individuals). Lestidae, Gomphidae and Calopterygidae were each represented by a single species and totaled little more than 5% of the overall sample. Among the genera, *Erythrodiplax* stood out in terms of richness (eight spp.), followed by *Erythemis* (three spp.). The most abundant species were *Erythrodiplax paraguayensis* (N = 75), *E. famula* (n = 50), *Ischnura fluviatilis* (N = 48) and *Micrathyria spuria* (N = 45). The sampling effort represented by the species accumulation curve indicated that the richness of Odonata is close to actual richness, since the curve approached the asymptotic one. *Aphylla molossus*, *Erythemis mithroides* and *Oxyagrion basale* constitutes new records for the state of Mato Grosso do Sul, raising the richness of the state to 212 species." (Authors)] Address: Maria Helena da Silva, Univ. **17110.** David, S.; Sacha, D. (2019): The annotated Odonata Checklist of the Slovak Republic. *Ochrana prírody, Banská Bystrica* 33: 49-78. (in Slovakian, with English summary) ["Since 1977, when Teyrovský published first Checklist of Odonata of then existing Czechoslovakia, several papers have been published putting forward Odonata checklists for

Slovakia. Some of them hard to acquire since published in regional journals, some as table annexes of faunistic reports on dragonflies and overall not widely used. Dragonfly research has intensified in Slovakia over the last decades, leading to confirmation of new species, e.g. *Coeangrion armatum*, *Anax ephippiger*, *Cordulegaster heros*, *Somatochlora meridionalis*, *Leucorrhinia rubicunda*. Other species were confirmed to have been wrongly reported from Slovakia, based on misidentifications, e. g. *Nehalania speciosa*, *C. mercuriale*, *Aeshna caerulea*, *Gomphus pulchellus*, *G. simillimus*, *C. boltonii*. In this paper we present all 79 taxa of the Odonata, which have ever been reported from Slovakia. Out of them, reports of 9 taxa were based solely on misidentifications and they do not occur in Slovakia (*Lestes macrostigma*, *C. mercuriale*, *C. boltonii*, *Ischnura elegans* subsp. *pontica*, *A. caerulea*, *Gomphus simillimus*, *G. pulchellus*, *Lindenia tetraphylla*). From among 69 taxa with solid evidence of their occurrence, 64 have permanent populations, while 5 species do not have any reproducing population here (*Chalcolestes parvidens*, *Sympecma paedisca*, *A. ephippiger* and *L. albifrons*). One species (*C. lunulatum*) was only observed in 1959 and is considered missing in Slovakia. Transitional forms between species *Ch. viridis* and *Ch. parvidens* and *Orthetrum coerulescens* and *O. coerulescens* subsp. *anceps* are mentioned in the paper. With taxa dubiously reported from Slovakia, historical records and taxa whereby evidence of their occurrence (specimens) is missing, we add brief comments. Overview of synonymous names and notes on nomenclature are also added, as appropriate." (Authors)] Address: David, S., Katedra ekológie a environmentalistiky, FPV UKF v Nitre, Trieda A. **17121.** Dow, R.A. (2019): Odonata from Sri Aman Division south and west of the Lupar River and from the Kelinggang Range, Sarawak. International Dragonfly Fund - Report 137: 1-26. (in English) ["Records of Odonata from the southwest of Sri Aman Division and the extreme east of Serian Division in Sarawak are presented. The sampled areas are interesting not only because they are poorly known for Odonata but also because many are just to the south and west of the Lupar Line which is a division between the ancient Sunda shelf and more recent geological formations. Differences between the odonate faunas on either side of the Lupar Line are discussed. Eightyfive species of Odonata were recorded during the surveys reported on. The single most notable record is that of *Coeliccia southwelli* Dow & Reels, 2011, which represents a considerable extension to the known range of this species. Other interesting records include *Telosticta dupophila* (Lieftinck, 1933), *T. species cf longigaster* Dow & Orr, 2012, *Podolestes parvus* Dow & Ngiam, 2019 and *Helio gomphus species cf olivaceous* Lieftinck, 1961. Variation in the markings of *Stenagrion dubium* (Laidlaw, 1912) across its range is discussed and a gene tree using the COI marker is presented to illustrate the high variability of this species in this marker. However the variability in COI does not appear to be correlated with other characters." 516. (in English) ["*Podolestes parvus* sp. nov. is described and illustrated from both sexes from Sarawak, Malaysian Borneo (holotype ♂ Maludam National Park, Betong Division, Sarawak, 10 vii 2012, deposited in RMNH). The new species is closest to *P. atomarius* Lieftinck, 1950 and is the smallest species yet known in its genus. A full set illustrations of *P. atomarius* is provided for comparison."] (Authors)] Address: Dow, R.A., 6 Bramley Avenue, Coulsdon, Surrey, CR5 2DP, UK. E-mail: rory.dow@virgin.net

**17123.** Dressler, P.E. (2019): Gut content analysis of aquatic macroinvertebrates using DNA-based methods. Winthrop University; <https://digitalcommons.winthrop.edu/source/SOURCE2019/posterpresentations/40/>; (in English) [Verbatim: With the great deal of complexity associated with aquatic food webs, many questions regarding species interactions remain unanswered. One such question of importance is: Who is eating whom? This is a question that morphologically based analysis techniques have failed to answer with great accuracy. However, with the advent of DNA-based analysis methods, this question can be answered. DNA-based analysis methods allow for greater certainty in taxonomic identification, because specific gene regions can be targeted using group-specific primers as a means for DNA detection. This approach was used to analyze dragonfly (Odonata, Anisoptera) gut contents using group-specific primers for midges (Chironomidae) and mosquitoes (Culicidae) as potential prey groups. Specimens were collected in Big Dutchman Creek and Winthrop Lake in Rock Hill, South Carolina. DNA was extracted from gut contents of collected specimens. A polymerase chain reaction was performed on each of the extracted samples in order to amplify DNA concentrations. Gel electrophoresis was used as a presence-absence test for DNA from target prey groups. We found that one individual of the genus *Progomphus* contained DNA from the family Chironomidae, but not Culicidae. A second *Progomphus* individual tested negative for both families, illustrating individual variation in feeding. These refined methods will allow for testing of more *Progomphus* individuals and potential prey groups as well as other aquatic macroinvertebrate predators.]

**17124.** Drury, J.P.; Barnes, M.; Finneran, A.E.; Harris, M.; Grether, G.F. (2019): Continent-scale phenotype mapping using citizen scientists' photographs. *Ecography* 42: 1436-1445. (in English) ["Field investigations of phenotypic variation in free-living organisms are often limited in scope owing to time and funding constraints. By collaborating with online communities of amateur naturalists, investigators can greatly increase the amount and diversity of phenotypic data in their analyses while simultaneously engaging with a public audience. Here, we present a method for quantifying phenotypes of individual organisms in citizen scientists' photographs. We then show that our protocol for measuring wing phenotypes from photographs yields accurate measurements in two species of Calopterygid damselflies. Next, we show that, while most observations of our target species were made by members of the large and established community of amateur naturalists at iNaturalist.org, our efforts to increase recruitment through various outreach initiatives were successful. Finally, we present results from

two case studies: 1) an analysis of wing pigmentation in male smoky rubyspots *Hetaerina titia* showing previously undocumented geographical variation in a seasonal polyphenism, and 2) an analysis of variation in the relative size of the wing spots of male *Calopteryx splendens* in Great Britain questioning previously documented evidence for character displacement. Our results demonstrate that our protocol can be used to create high quality phenotypic datasets using citizen scientists' photographs, and, when combined with metadata (e.g. date and location), can greatly broaden the scope of studies of geographical and temporal variation in phenotypes. Our analyses of the recruitment and engagement process also demonstrate that collaborating with an online community of amateur naturalists can be a powerful way to conduct hypothesis-driven research aiming to elucidate the processes that impact trait evolution at landscape scales."] (Authors)] Address: Drury, J.P., E-mail: jonathan.p.drury@durham.ac.uk

**17126.** Dwivedi, Y.D.; Sudhir Sastry, Y.B. (2019): An experimental flow field study of a bio-inspired corrugated wing at low Reynolds Number. *INCAS Bulletin* 11(3): 55-65. (in English) ["The present paper examined experimentally the glide flight flow visualization and boundary layers of a bio-inspired corrugated dragonfly wing performing a comparison with the results obtained with a flat plate, at low to moderate range of chord Reynolds numbers. The experimental work is performed in an open-end low speed subsonic wind tunnel at different angles of attack ranging from 0 to 120 and Reynolds number  $2.25 \times 10^5$ . The boundary layer measurements were done at a fixed chord location ( $0.7 x/c$ ) and three different semi span locations such as 30%, 60% and 90% of the wing's semi span from the right side of the longitudinal axis of the wing. The flow patterns were visualized by using colored tufts, placed at different span locations. The flow reversal was observed at selected Reynolds numbers and angles of attack only. The boundary layer measurements demonstrated that there exists a clear distinction on the pressure and velocity parameters in all the three tested locations on both types of the wings. The corrugated wing showed significant delay in stall and flow separation compared with the flat plate. The visualization of flow in both wings showed that there subsists a spanwise flow moving from wing tip to root, indicating three dimensional natures of airflows."] (Authors)] Address: Dwivedi, Y.D., Dept of Aeronautical Engineering, Institute of Aeronautical Engineering, Dundigal, Hyderabad, 500043, Telangana, India. **17127.** El-Latif, M.E.A.; Elsayed, K.; Abdelrahman, M.M. (2019): Aerodynamic study of the corrugated airfoil at ultra-low Reynolds number. *Advances in Mechanical Engineering* 11(10): 1-18. (in English) ["In this study, *Aeshna cyanea*

dragonfly forewing mid-cross-section corrugated airfoil was simulated at ultra-low Reynolds number. The corrugated airfoil was compared with its smooth counterpart to study the effect of the corrugations upon the aerodynamic performance. Unsteady two-dimensional laminar flow was solved using FLU-ENT. This study was divided into gliding phase and flapping phase. In the gliding phase, the corrugated airfoil produced a higher lift force with respect to the profiled airfoil at both tested Reynolds numbers (1400, 200) with comparable drag coefficient for all the tested angles of attack. In the flapping phase, both the corrugated airfoil and the flat-plate have a very similar flow behavior which yields a very similar aerodynamic performance at  $Re=1400$ . A structural analysis was performed to compare the corrugated airfoil with the flat-plate. The analysis revealed the superiority of the corrugated airfoil over the flat-plate in decreasing the deflection under the applied load. The reduced frequency was varied to study its impact on the aerodynamic performance. By increasing the reduced frequency, the thrust and the lift forces increased by 82% and 75%, respectively. Any increase in the reduced frequency will increase lift and thrust forces, but the propulsive efficiency will deteriorate." (2019): Komposisi Odonata di Kabupaten Bangka Selatan. *Ekotonia: Jurnal Penelitian Biologi, Botani, Zoologi dan Mikrobiologi* 4(2): 31-36. (in Bahasa Indonesian, with English summary) ["The existence and diversity Odonata in an area could reflect the quality of a habitat's environment such as pH, temperature, light intensity, conditions of chemical and availability of water and foods. The purpose of this study was to record the composition Odonata in Regency of Southern Bangka. This research was conducted in two habitats namely natural in the form of rivers and artificial in the form of tin mining lakes in Regency of Southern Bangka. The method used was the transect line with a transect length of 100 m. Odonata was captured using an insect net then the number of species is recorded. Abiotic factors measured include temperature, light intensity and pH of water. Result showed that 1,166 individuals Odonata that were found at the study site consisted of 18 species which belong to four family and two suborder. Both the species number and individual found around the river was greater than the tin mining lake. The highest number of species found in the river was 17 and the lowest found tin mining lake was 10. The highest number of individuals found in the river was 694 and the lowest found tin mining lake was 472. The highest diversity indices was at Sebagin river (2.20) and the highest evenness indices was at Nyelanding tin mining lake (0.9639)." **17130.** Fleck, G.; Juillerat, L. (2019): The genus *Navicordulia* Machado & Costa, 1995 (Insecta: Odonata: Corduliidae s.str.): new species, identification key for males and data on ecology and distribution. *Zoosystema* 41(27): 553-565. (in English, with French summary) ["Based on male specimens a new species of the genus *Navicordulia* Machado & Costa, 1995 is described from South French Guiana. This is the second species of the genus recorded for this country. The male of *Navicordulia pascali* n. sp. can be easily separated from all known males of the other species of the genus by the presence of a remarkable large ventral tooth at the base of the cerci. *Navicordulia pascali* n. sp. is a forest dwelling species inhabiting hilly landscape at low altitude. Adults seem to be on flight during the rainy season. The new species is most closely related to *N. errans* (Calvert, 1909) and *N. leptostyla* Machado & Costa, 1995, both from Cerrado of central Brazil. Affinities with the Venezuelan lowland *N. vagans* (De Marmels, 1989) are also probable. A differential diagnosis is given, and a key for *Navicordulia* species based on male characters is provided. The distributions are also given for all species of the genus. Aspects of ecology and biogeography are discussed." (Authors)] Address: Fleck, G., Entomologiste indépendant, F-07150 Lagorce, France. **17131.** Fontenla, J.L. (2019): Libélulas (Insecta: Odonata) de Playas del este, La Habana, Cuba/ Dragonflies and damselflies (Insecta: Odonata) of Playas del Este, La Habana, Cuba. *Poeyana* 509: 1-7. (in Spanish, with English summary) ["Odonata species composition at eight sites of Eastern Beaches was determined. The observations were made between November 2014 and July 2019. Distances traveled among sites fluctuated between 450m and 1200m. There were observed two species of Zygoptera and 15 species of Anisoptera. Species richness among sites varied between two and 11 species. The most frequent species were *Erythrodiplax umbrata*, *Orthemis ferruginea*, *Erythemis vesiculosa* and *Crocothemis servilia*. In general sense, species composition is characterized by widespread species. Spatial distribution adopted a nested pattern, and species were concentrated in sites that presented temporal ponds of pluvial origin. It is emphasized the presence of rare species in Cuba, like *Celithemis eponina* or habitat specialists like *Erythrodiplax berenice*. This landscape

may represent an important reservoir for biodiversity in urbanized areas with intense flow of people." (Author)] Address: Fontenla, J.L., Instituto de Ecología y Sistemática, carretera Varona 11835, Rpto. Parajón, Boyeros, 11900, La Habana, Cuba. E-mail: fontenla@ecologia.cu

**17132.** Foo Tse Fen, V.; Lim, K.K. (2019): Malayan spineleg dragonfly at Upper Seletar Reservoir. *Singapore Diversity Records* 2019: 104. (in English) [Verbatim: "Subject: *Merogomphus femoralis*. Subject identified by: Lim Kim Keang and Robin Ngiam. Location, date and time: Singapore Island, Central Catchment Nature Reserve, Upper Seletar Reservoir; 11-VIII-2019; around 1145 hrs. Habitat: Secondary forest edge, at the shore of a freshwater lake. Observers: Lim Kim Keang and Veronica Foo Tse Fen. Observation: On a hot and sunny morning, an example estimated to be around 4 cm body length was observed perched for a few minutes on a leaf of a *Syzygium* tree at about 5 m from the ground. A dorso-lateral view of the dragonfly is shown in the accompanying photograph. Remarks: In Singapore, this rare and 'critically endangered' dragonfly is known only from Nee Soon swamp-forest (Soh et al., 2019: 15) which is located at the southern shore of the Upper Seletar Reservoir. The female is apparently undescribed (Tang et al., 2010: 119). The featured dragonfly is believed to be a female of the *M. femoralis*. Compared to the male (see Tang et al., 2010: 119), it has thicker abdominal segments with broader whitish bands. The first abdominal segment also has a single greenish whitish side bar next to the dorsal bar. The male *M. femoralis* has a total body length of 45 mm (Tang et al., 2010: 119). Without the specimen in hand, it is not possible to gauge the female's exact size from the photograph." (Authors)] Address: veronfoo@yahoo.com

**17133.** Fulan, J.A.; Dos Anjos, M.R. (2019): Variation of the rainfall regime in the northern region and its effect on the Odonata (Insecta) in Been River, Amazonas, Brazil. *Acta zoológica mexicana* N.S. 35: 1-6. (in English, with Spanish summary) ["The goal of this work was to know the effect of precipitation in four periods (Rising, Flood, Lowing and Dry) on Odonata larvae living near to the macrophyte *Salvinia auriculata* Aubl., in Been River, Amazonas, Brazil. The biological material was collected in the Been river in the section near the river Madeira, state of Amazonas, Brazil. Sampling was conducted in stands of three macrophytes *S. auriculata* in four periods: rising (November 2012), flood (February 2013), lowing (May 2013), and dry (August 2013). A total of 286 Odonata larvae were identified in the river studied. Six families and 14 genera were identified. The flood period showed the highest abundance in the studied period. *Acanthagrion* presented a positive correlation with flood period in axis 1 and *Telebasis* also positive, but in the dry period. In conclusion, although there are few studies on Odonata larvae associated with floating macrophytes in the Amazon, the results of this work showed the importance of knowing the distribution of larval abundance throughout the year. Flood and dry period showed to be the period with the highest abundance of Odonata genera. In addition, the principal component analysis showed that some species are more sensitive to the periods of the year, *Telebasis* in the dry period and *Acanthagrion* in the flood period." (2019): Molecular basis of wax-based color change and UV reflection in dragonflies. *eLife* 2019;8:e43045 doi: 10.7554/eLife.43045: 24pp. (in English) ["Many animals change their body color for visual signaling and environmental adaptation. Some dragonflies show wax-based color change and ultraviolet (UV) reflection, but biochemical properties underlying the phenomena are totally unknown. Here we investigated the UV-reflective abdominal wax of dragonflies, thereby identifying very long-chain methyl ketones and aldehydes as unique and major wax components. Although little wax was detected on young adults, dense wax secretion was mainly found on the dorsal abdomen in mature males of *Orthetrum albistylum* and *O. melania*, while pruinose wax secretion was identified on the ventral abdomen in mature females of *O. albistylum* and *Sympetrum darwinianum*. Comparative transcriptomics demonstrated drastic upregulation of *ELOVL17* gene, a member of the fatty acid elongase family, whose expression reflected the distribution of very long-chain methyl ketones. Synthetic 2-pentacosanone, the major component of dragonfly's wax, spontaneously formed light-scattering scale-like fine structures with strong UV reflection, suggesting its potential utility for biomimetics." **17143.** Giuliano, D.; Bogliani, G. (2019): Odonata in rice agroecosystems: Testing good practices for their conservation. *Agriculture, Ecosystems & Environment* 275: 65-72. (in English) ["Highlights: •Rice crops have recently lost their original value as surrogate wetland habitat. •Ditches may be insufficient to improve paddy suitability for breeding Odonata. •Odonata benefit from a well-developed vegetation, especially on paddy banks. •Semi-natural wetlands are essential to achieve Odonata conservation in rice crops. •Low frequency and rotational mowing should be implemented on paddy and canal banks. Abstract: Paddy systems have recently lost their original value as surrogate habitat for several wetland species due to rice farming intensification. Changes in water regimes largely compromised the survival of many aquatic organisms formerly abundant in rice fields, such as Odonata, inducing the introduction of new agricultural practices supposed to mitigate the negative impacts of intensive rice cultivation on biodiversity. For instance, the construction of a water retention structure (ditch) within paddies has been incentivized in Italy, in order to reduce the detrimental effects of

drying periods on aquatic organisms. In this research, we investigate the effects of ditch occurrence and dimensions on Odonata diversity in rice fields, and furthermore we evaluate the response of these insects to vegetation height on paddy and canal banks, as an approximation of grass management intensity. Field surveys revealed that ditch occurrence may not be sufficient to improve the suitability of rice fields as breeding habitat for Odonata, especially for sensitive species. Paddies with ditches of larger dimensions supported more abundant adult populations than other field types, but no clear differences have been observed concerning larval stages. Conversely, the occurrence of a well-developed bank vegetation produced clear benefits for these insects in rice fields, while a not significant effect have been observed along irrigation canals. In order to achieve Odonata conservation in rice agroecosystems, together with the excavation of large ditches within paddies, the creation of a network of semi-natural wetlands should be encouraged, as well as the implementation of extensive grass management strategies on rice field and canal banks." (Authors)] Address: Giuliano, D., Dept of Earth and Environmental Science, University of Pavia, Via Ferrata 9, 27100 Pavia, Italy. E-mail: [davide.giuliano@alice.it](mailto:davide.giuliano@alice.it)

**17144.** Goertzen, D. (2019): Parkteiche als Lebensraum für Libellen – Einfluss von Wasservögeln und Fischen auf die Libellendiversität. *Libellula Supplement 15*: 71-91. (in German, with English summary) ["City park ponds as habitats for dragonflies – Impact of waterfowl and fish on dragonfly diversity – City park ponds are characterized by high abundances of waterfowl and fish, poor littoral and aquatic vegetation, and artificial shorelines. I investigated how these factors affect dragonfly diversity at city park ponds by conducting experiments at four park ponds in Dortmund (North Rhine Westphalia, Germany) in 2011 and 2012. (1) I investigated the effects of fish and waterfowl predation as well as the presence of submerged vegetation on the diversity of dragonfly larvae by using enclosures. Protection against predators did not have any effect, but the presence of submerged plants promoted diversity. (2) I compared survival and growth rates of larvae of *Coenagrion puella* and *Ischnura elegans* kept in enclosures in two of the ponds, of which one was almost free of dragonfly larvae, while the other was inhabited by a population of *I. elegans*. Both species survived and grew in both ponds. (3) I assessed the effects of shoreline treatment by comparing the diversity of adult dragonflies along transects of different littoral structures (sealed area, mowed lawn, reeds, and aquatic vegetation), including one experimental transect type in which lawn mowing was intermitted for one season. The presence of reeds as well as of aquatic vegetation were essential for increased diversity of adults. These were also the only shoreline structures where reproduction behaviour was observed. From my experiments, I conclude that the degraded littoral zone with often poor vegetation is probably the major reason for depleted dragonfly diversity in city park ponds. This degradation is connected with high waterfowl and fish density, causing eutrophication, turbid water conditions, and grazing, and additionally, with physical pressures (trampling, artificial structures) exerted by recreational use of the ponds." **17146.** Golab, M.J.; Johansson, F.; Sniegula, S. (2019): Let's mate here and now – seasonal constraints increase mating efficiency. *Ecological Entomology* 44(5): 623-629. (in English) ["1. Latitudinal climatic conditions shape the length of the mating season and could thus influence reproductive traits. Knowledge of how animals behave along latitudinal clines will increase understanding of the impact of climate on sexual selection and might help in the prediction of whether peripheral populations will spread or shrink in response to changes in climate. 2. This study investigated variation in the mating efficiency of a temperate insect, *Lestes sponsa*, under semi-natural field conditions along a latitudinal gradient covering three regions of the species' distribution: south, central and north. 3. A comparison was done of the proportion of copulating males, the proportion of males that formed tandems but did not copulate (unsuccessful males), and the proportion of males that did not attempt to form a tandem (passive males) in these three regions. 4. It was found that the proportion of copulations was significantly higher at northern latitudes than in the southern and central regions. Southern latitudes had a higher proportion of successful copulations compared with central latitudes. The northern region had a significantly lower frequency of passive males. The southern region had an intermediate proportion of passive males, and the central region had the highest proportion. The proportion of unsuccessful males did not differ between regions. The population density across sites did not affect these results. 5. The study shows that damselflies inhabiting northern populations mate more intensively than individuals from southern and central populations. This suggests that more restrictive environmental conditions during a brief mating season select for higher mating efficiency." (Authors)] Address: Golab, Maria, Institute of Nature Conservation, Polish Academy of Science, 31-120 Krakow, Poland. E-mail: [marysiagolab@gmail.com](mailto:marysiagolab@gmail.com)

**17147.** Gorb, S.N. (2019): Wing surface in the damselfly *Mecistogaster ornata* (Zygoptera, Pseudostigmatidae): interactions between nanoscale wax and sticky spider webs. *International Journal of Odonatology* 22(1): 51-57. (in English) ["The representatives of the damselfly family Pseudostigmatidae are known for their ability to catch small orb web spiders, or in some cases small kleptoparasitic spiders in the webs of other spiders. In this paper, I demonstrate that the nanoscopic crystalline wax coverage of wings in *M. ornata* is partially

altered due to the presence of fluid-contaminated spots corresponding in their shapes and distribution to the typical beads-on-a-string (BOAS) geometry of sticky threads of orb web spiders. The spider fluid has the ability to wet superhydrophobic crystalline wax coverage. Also residues of the sticky threads were revealed in high quantities on the wing surface. The data suggest that the pseudostigmatid damselflies, due to their specific prey capturing method, have some costs and risks of being trapped by the sticky spider webs. However, high resolution SEM images revealed that the crystalline wax coverage of wings, in spite of its wettability by the spider glue, functions as a sacrificial anti-adhesive layer protecting the damselfly surface against spider adhesive traps." **17148.** Grand, D.; Marinov, M.; Jourdan, H.; Cook, C.; Rouys, S.; Mille, C.; Theuerkauf, J. (2019): Distribution, habitats, phenology and conservation of New Caledonian Odonata. *Zootaxa* 4640: 1-112. (in English, with French summary. ["Compared to other archipelagos of the Pacific, the New Caledonian Odonata fauna is rich and diverse with 56 valid species or subspecies (23 endemics, 41%) from eight families (four Zygoptera: Argiolestidae, Coenagrionidae, Isostictidae, Lestidae, and four Anisoptera: Aeshnidae, Corduliidae, Synthemitidae, Libellulidae) and 31 genera (including four endemics, 13%). In Zygoptera, we record 19 species including 12 endemics (63%), and among Anisoptera, we record 37 species or subspecies, including 11 endemics (30%). We removed five species from the list that had been erroneously recorded as occurring in New Caledonia: *Tamea carolina*, *Austroargiolestes icteromelas*, *Ischnura torresiana*, *Xiphagrion cyanomelas* and *Hemicordulia oceanica*. The occurrence of *Tamea limbata* appears also doubtful, but we were unable to clarify to which taxon this record referred hence we excluded it from our update. From a biogeographic perspective, the New Caledonian fauna has mostly Australian affinities with some connections with south-east Asia and the Pacific region. We provide for each species, whenever information was available, a distribution map with a brief review of its known ecology, behaviour and phenology. We also evaluated each species' conservation status, in light of known threats (range restriction, scarcity and human activity including altered water flow). We consider 17 species (30%) endangered. The most immediate threats concern water pollution including alteration to the flow of water courses caused by mining, deforestation and fires. Invasive species, such as alien fish, may be predators of concern for Odonata larva, although this has not yet been proven in New Caledonia." **17153.** Günther, A. (2019): Reproductive behaviour of *Chlorocyphidae*. Part 1. Genus *Sclerocypha* Fraser, 1949 (Odonata). *Odonatologica* 48(3/4): 285-304. (in English) ["The reproductive behaviour of *S. bisignata* was studied in various

fast flowing streams in mountainous regions of Central Sulawesi. Using high speed cinematography males were shown to exhibit protracted threatening flights with a stationary display of the fore wings. In steady threatening flight the abdomen was held horizontally and the stroking of the hind wings paused briefly and regularly every 2-5 wing beats. These flights were interrupted periodically by short bursts of increased intensity where males arched their abdomens upwards and the hind wing beat was continuous. This flight style differs in several respects from any chlorocyphid species yet studied. During courtship the males presented all three pairs of legs; as courtship intensified they briefly raised their abdomen and presented stationary fore wings. Oviposition took place with the female completely submerged. Unlike most Chlorocyphidae, oviposition sites and male display sites were well separated and ovipositing females were unguarded." **17154.** Gunnarsson, K.; Ekblom, R. (2019): Review of the diet specialisation of the Blue-cheeked bee-eater (*Merops persicus*). *Journal of Ornithology* 160(1): 275-279. (in English) ["Ecological specialisation, e.g. in terms of prey preferences, can have important implications for population biology. Bee-eaters are considered diet specialists; they hunt aerial insects, particularly hymenopterans. However, *M. persicus* has been considered a special case, as it preferentially feeds upon dragonflies. Here we review current literature on the diet of *M. persicus*, and conclude that this species is not as restricted to dragonflies as previously suggested. Instead, populations in different parts of the breeding and wintering ranges seem to specialise on various types of insects (such as wasps, bees, dragonflies, butterflies and mosquitoes)."] (Authors)] Address: Gunnarsson, K., Dept of Ecology & Genetics, Uppsala Univ., Uppsala, Sweden

**17155.** Haber, W.A. (2019): *Gynacantha vargasi* (Odonata: Anisoptera: Aeshnidae) sp. nov. from Costa Rica. *Zootaxa* 4612: 58-70. (in English, with Spanish summary) ["The male and female of *G. vargasi* sp. nov. are described from three sites on the Caribbean slope of Costa Rica. The species is distinguished from its congeners by lime-green lateral thoracic stripes, orange-brown hind femur tipped with black, dorsal side of the hind tibia yellow, unique cercus shape, diurnal behavior, and barcode analysis. A key to all species of *Gynacantha* recorded from Mexico and Central America is provided."] (Author)] Address: Haber, W.A., Apdo. 50-5655, Monteverde, Costa Rica. E-mail: bill.haber01@gmail.com

**17156.** Hadjadjia, S.; Amari, H.; Bouiedda, N.; Guebailia, A.; Boucenna, N.; Mayache, B.; Houhamdi, M. (2019): Emergence ecology and body size dimorphism in *Sympetrum fonscolombii* and *S. meridionale* (Odonata: Libellulidae). *Zoology and Ecology* 29(1): 8 pp. (in English) ["The study of dragonfly emergence provides insights into the understanding of their life history, ecology, and adaptation to abiotic and biotic factors. Here we investigate the emergence ecology and body size of two congeneric dragonflies (*S. fonscolombii*, and *S. meridionale*) in Northeast Algeria, highlighting the seasonal

pattern, sex ratio at emergence, sexual size dimorphism (SSD), and vertical stratification. We found that both species, *S. fonscolombii* in particular, showed quite asynchronous emergence. In both species, and especially in the larger *S. meridionale*, sex ratio was found to be female-biased, which is in line with the hypothesis of a negative relationship between SSD and sex ratio. There was no seasonal pattern of body size observed in both species. In *S. meridionale*, SSD with regard to both body and wing sheath length was male-biased, while in *S. fonscolombii*, it was male-biased with regard to body length and female-biased with regard to wing length. Vertical stratification depended on support height (the higher the support, the higher the height of exuvia fixation) but had a complex relationship with the body size. The biological significance and implications of the vertical stratification-body size relationship are discussed." **17158.** Harabiš, F.; Rusková, T.; Dolný, A. (2019): Different oviposition strategies of closely related damselfly species as an effective defense against parasitoids. *Insects* 10(1), 26; <https://doi.org/10.3390/insects10010026>: 9 pp. (in English) ["Parasitoidism is one of the main causes of insect egg mortality. Parasitoids are often able to detect eggs using semiochemicals released from eggs and disturbed plants. In response, female insects adopt a wide variety of oviposition strategies to reduce the detectability of eggs and subsequent mortality. We evaluated the proportion of parasitized and undeveloped eggs of three common damselfly species from the family Lestidae, the most diverse group of European damselflies, in terms of oviposition strategies, notably clutch patterning and the ability to utilize oviposition substrates with different mechanical properties. We assumed that higher costs associated with some oviposition strategies will be balanced by lower egg mortality. We found that the ability of *Chalcolestes viridis* to oviposit into very stiff substrates brings benefit in the form of a significantly lower rate of parasitoidism and lower proportion of undeveloped eggs. The fundamentally different phenology of *Sympetma fusca* and/or their ability to utilize dead plants as oviposition substrate resulted in eggs that were completely free of parasitoids. Our results indicated that ovipositing into

substrates that are unsuitable for most damselfly species significantly reduces egg mortality. Notably, none of these oviposition strategies would work unless combined with other adaptations, such as prolonging the duration of the prolarval life stage or the ability to oviposit into stiff tissue." **17159.** Hardersen, S.; Toni, I. (2019): Proposal for a time-based standard sampling method for the monitoring of *Gomphus flavipes* (Charpentier, 1825) and *Ophiogomphus cecilia* (Fourcroy, 1785) (Odonata: Gomphidae). *Fragmenta Entomologica* 51(1): 55-62. (in English) ["Monitoring of conservation status is an obligation arising from Article 11 of the Habitats Directive for all species of community interest. However, the development of monitoring methods for invertebrate species has received relatively little attention. *G. flavipes* and *Ophiogomphus cecilia* are two dragonfly species, listed in the annexes of the Habitats Directive, which suffered severe declines in the last century and have since recovered. Methods for the monitoring of these two gomphids have been proposed, but these have not been extensively tested and no abundance classes have been proposed for the evaluation of the conservation status of these species. A time-based standard sampling method is proposed for both species and results from numerous sites in Lombardy, northern Italy, are presented. Applying the standard method revealed that it is common for rivers that high water levels preclude sampling of exuviae through the summer and it is better to allow for two seasons when planning the monitoring. A further result is the fact that it was not always possible to sample the same stretches as the dynamic nature of the rivers and fluctuations in water level lead to some river banks becoming unsuitable for sampling during some visits. In these cases the time-based approach was advantageous, as the method did not need to be modified in response to the original bank section becoming unsuitable." **17161.** Hayasaka, D.; Kobashi, K.; Hashimoto, K. (2019): Community responses of aquatic insects in paddy mesocosms to repeated exposures of the neonicotinoids imidacloprid and dinotefuran. *Ecotoxicology and Environmental Safety* 175: 272-281. (in English) ["Pesticides are one of major threats

to wetland environments and their communities, and thus the information about ecological impact assessment of agrochemicals on ecosystems is essential for future effective pesticides management. Here, effects of the yearly application of two neonicotinoids, imidacloprid and dinotefuran on aquatic insect communities of experimental rice fields were assessed during two years of monitoring. Both neonicotinoid-treated fields and controls were monitored biweekly throughout the 5-month experimental period until harvest (late October) in each year. Maximum concentrations of imidacloprid (157.5 ig/l in 2014 and 138.0 ig/l in 2015) and dinotefuran (10.54 ig/l in 2014 and 54.05 ig/l in 2015) in water were relatively similar in both years, but maximum residues of imidacloprid (245.45 ig/kg) and dinotefuran (419.5 ig/kg) in the sediment in the second-year were 18 and 175 times higher than in the first year, respectively, with great variability of concentrations among sampling dates. In addition, remaining soil residues of both neonicotinoids were approximately 1 ig/kg (ppb) at the start of the second-year. A total of 6265 individuals of 18 aquatic species belonging to 7 orders were collected. No differences in the number of species between controls and the two neonicotinoids-treated paddies were found between years. However, clear differences in community structures of aquatic insects among the imidacloprid- and dinotefuran-treated mesocosms, and controls and between years were shown by PRC analysis. In particular, imidacloprid likely decreased *Crocothemis servilia mariannae* nymphs, Chironominae spp. larvae, and *Aedes albopictus* larvae, whereas dinotefuran tended to decrease *Guignotus japonicus*, *Orthetrum albistylum speciosum* nymphs, and Tubificidae spp. In addition, long-living species of Coleoptera and Odonata were most sensitive to both neonicotinoids. Changes in composition of feeding functional groups (FFGs) of aquatic insects were more prominent in the first year and became subtler in the second year. One of the possibilities of this phenomenon may be functional redundancy in which species that had low sensitivity to imidacloprid and dinotefuran replaced the vacant niche caused by decreases of other species with high susceptibility within the same feeding functions, although further studies are needed to verify this explanation. Thus, feeding functional traits can be a good indicator for evaluation of changes in ecosystem processes under pesticides exposures. Consequently, the current study emphasized that more realistic prediction of community properties after the repeated application of agrochemicals in successive years should consider for 1) long-term population monitoring, 2) cumulative effects at least over the years, and 3) species' functional traits." **17163.** He, Z.; Zhao, M.; Wang, C.Y.; Sun, L.; Jiang, Y.Y.; Feng, Y. (2019): Purine and uric acid contents of common edible insects in Southwest China. *Journal of Insects as Food and Feed* 5(4): 1-8. (in English) ["Edible insects have recently been considered as a potential food source that may solve problems of malnutrition and starvation worldwide. However, studies exploring insects as food sources are mainly focused on entomophagy and nutrition rather than the potential risks of excessive metabolite contents, such as purine and uric acid. In this study, we analysed guanine, hypoxanthine, xanthine, adenine and uric acid concentrations in 11 species of edible insects from Yunnan and Guizhou provinces in Southwest China, including 5 species of dragonfly, 3 species of wasp and a single species of locust, mealworm and silkworm. Purine and uric acid contents differed distinctly between these insects, and guanine and xanthine were the dominant purines in all samples. The proportions of 4 purines in the total purine content of these insects differed markedly from those in meat samples from poultry and livestock, and uric acid contents varied significantly between aquatic insects and terricolous insects, such as silkworm pupa. Taken together, the present data show that most edible insects are potent food sources of purine." **17164.** Hedberg, R. (2019): Biodiversity of aquatic invertebrates in urban ponds: effects of land use. Bachelor thesis, Uppsala University, Disciplinary Domain of Science and Technology, Biology, Biology Education Centre. (Department of Ecology and Genetics): 17 pp. (in English) ["Urban ponds have the potential to hold large abundance and diversity of aquatic invertebrates, which could maintain an overall high biodiversity in the urban landscape. Little is known about how aquatic systems, such as ponds, are affected by the fast rate of urbanisation caused by an increasing human population together with the expansion of cities. The aim of this study was to investigate how landscape variables affect the abundance of six invertebrate groups. Thirty ponds in Stockholm, Sweden, were studied by sampling aquatic invertebrates of the taxonomic groups: Bivalvia, Gastropoda, Odonata, Trichoptera, Coleoptera and Hemiptera. The percentage of open land, developed land, forest and other water bodies around the ponds were investigated to examine possible correlations with invertebrate abundances. In addition, the relationship between the ponds distance to the city centre and invertebrate abundances were examined. The results indicate that the surrounding landscape has an important effect on the abundance of aquatic invertebrates living in the urban ponds. Odonata abundances showed increasing abundances with percentage of forest cover and decreasing abundances with more developed land. Bivalvia and Trichoptera abundances together with Odonata were found positively correlated with distance to the city centre. No significant results were found for Coleoptera, Hemiptera and Gastropoda. Since the taxonomic groups were affected differently by the landscape variables in the urban area, further investigation on how landscape variables affect the diversity of aquatic invertebrates are

needed. Such knowledge would contribute to understand how the landscape variables should be optimised to maintain a high biodiversity in urban ponds." (Author)] Address: not stated

**17166.** Hjalmarson, E.A.; Patten, M.A. (2019): Win-win urban ecology: near-home fishing promotes diversity of Odonata. *Urban Ecosystems* 22(6): 1201-1206. (in English) ["It is generally thought that increased human activity or infrastructure automatically translates to decreased wildlife activity or abundance. We surveyed Odonata at 14 urban parks with water features to determine factors that promote or hinder species richness or overall abundance. We constructed basic decision trees with either richness or abundance as a response variable and a suite of park characteristics (e.g., size, footprint of the water feature(s), habitat heterogeneity, presence and extent of infrastructure) as predictors. We found that the key predictor of both higher odonate richness and higher odonate abundance was the presence and extent of fishing activities. Despite higher human use at parks that promoted angling, as well as more infrastructure and increased management at these parks—factors that typically are thought to be correlated negatively with biodiversity—odonates and humans benefit from maintaining them and, we suggest, ensuring proper water quality persists. If it is good for fish, it is good for aquatic insects." (Authors)] Address: Hjalmarson, Emily, Oklahoma Biological Survey and Department of Biology, University of Oklahoma, Norman, USA

**17167.** Hoess, R. (2019): Erstnachweis einer zweiten Jahresgeneration von *Orthetrum brunneum* (Odonata: Libellulidae) für Mitteleuropa. *Libellula* 38(1/2): 97-102. (in German, with English summary) ["First evidence of a second annual generation of *O. brunneum* in Central Europe – In a rice field at Schwadernau (Switzerland), a teneral female of *O. brunneum* and its exuvia were found in August 2018. The rice field was created in April 2018. As there is no hint of larval displacement, a bivoltine development is likely. A second annual generation is therefore evidenced for this species for the first time in Central Europe. Larval development is assumed to have lasted about 75 days." **17168.** Holtmann, L.; Brüggeshemke, J.; Juchem, M.; Fartmann, T. (2019): Odonate assemblages of urban stormwater ponds: the conservation value depends on pond type. *Journal*

of Insect Conservation 23(1): 123-132. (in English) ["Urbanisation is among the most severe drivers of the recent biodiversity crisis. It has been shown that stormwater ponds have a high value for the conservation of Odonata in urban areas. However, information on the relevance of different types of stormwater ponds is lacking so far. The aim of this study was to compare the Odonata assemblages of three types of urban stormwater ponds (n per type=?10): (i) ponds only containing temporary water bodies (TEMP), (ii) ponds with temporary and small perennial water bodies (TEMP/PERE) and (iii) ponds with one large perennial water body (PERE). We observed distinct differences in environmental conditions and Odonata assemblages among the three types of stormwater ponds. In particular, vegetation structure and the partly interrelated microclimate differed considerably between TEMP on the one hand, and TEMP/PERE and PERE on the other hand. Odonate species richness and exuviae density of threatened species differed, too. Due to their early successional stages with low cover of riparian woodland and shallow water bodies, TEMP were characterised by a warmer microclimate than TEMP/PERE and PERE. Odonate species richness and exuviae density of threatened species were highest in TEMP and lowest in PERE. Moreover, indicator species were only identified for TEMP. Our study showed that stormwater ponds with a temporary hydroperiod play an important role for the conservation of odonates in urban areas. This is especially the case for specialised threatened species, such as *Libellula depressa* and *Ischnura pumilio*." (2019): An experimental mechanism of a tandem flapping wing for micro aerial vehicle. *Journal of Physics: Conference Series* 1349 (2019) 012014; doi:10.1088/1742-6596/1349/1/012014: 4 pp. (in English) ["Micro Aerial Vehicles, otherwise known as MAVs, is defined as an aerial vehicle that has a 15cm or less wingspan with a take off weight of less than 200g. Its miniature size and manoeuvrability allows it to fly in confined space at low Reynolds number flight conditions (100 – 100,000). In this study, an entothopter design inspired by dragonfly wings was investigated using a subsonic wind tunnel to see the effect of tandem wing configuration on the lift generation. The study was done at different flapping frequency (5-11Hz) and at different flight speed (5m/s, 7m/s, and 9m/s). It was observed that in phase flapping configuration produces better lift for all flapping frequency and all flight speed." (Authors)] Address: Ismail, N.I., Fac. of Mechanical Engineering, Univ. **17182.** Jonsson, M.; Andersson, M.; Fick, J.; Brodin, T.; Klaminder, J.; Piovano, S. (2019): High-speed imaging reveals how antihistamine exposure affects escape behaviours in aquatic insect prey. *Science of The Total Environment* 648: 1257-1262. (in English) ["Highlights: •High-speed imaging was successful at capturing fast escape responses. •Antihistamine exposure altered prey escape responses. •The changed behaviour indicates a reduced ability to evade predator attacks. •High-speed imaging should be used in environmental risk assessment. Abstract: Aquatic systems receive a wide range of pharmaceuticals that may have adverse impacts on aquatic wildlife. Among these pharmaceuticals, antihistamines are commonly found, and these substances have the potential to influence the physiology of aquatic invertebrates. Previous studies have focused on how antihistamines may affect behaviours of aquatic invertebrates, but these studies probably do not capture the full consequences of antihistamine exposure, as traditional recording techniques do not capture important animal movements occurring at the scale of milliseconds, such as prey escape responses. In this study, we investigated if antihistamine exposure can impact escape responses in aquatic insect, by exposing damselfly (*Coenagrion hastulatum*) larvae to two environmentally relevant concentrations (0.1 and 1 µg L<sup>-1</sup>) of diphenhydramine. Importantly, we used a high-speed imaging approach that with high-time resolution captures details of escape responses and, thus, potential impacts of diphenhydramine on these behaviours. Our results show overall weak effects of antihistamine exposure on the escape behaviours of damselfly larvae. However, at stage 2 of the C-escape response, we found a significant increase in turning angle, which corresponds to a reduced swimming velocity, indicating a reduced success at evading a predator attack. Thus, we show that low concentrations of an antihistamine may affect behaviours strongly related to fitness of aquatic insect prey – effects that would have been overlooked using traditional recording techniques. Hence, to understand the full consequences of pharmaceutical contamination on aquatic wildlife, high-speed imaging should be incorporated into future environmental risk assessments." **17188.** Kelly, R.S.; Nel, A. (2019): Revision of some damsel-dragonflies (Odonata, Liassophlebiidae and Anglophlebiidae new family) from the Triassic/Jurassic of England and Antarctica. *Journal of Paleontology* 92(6): 1035-1048. (in English) ["Fossil insects from the Triassic-Jurassic boundary of England could provide an important resource for investigating the severity of extinction events in the terrestrial realm of the uppermost Triassic. However, the fossil record is poorly understood for this period even though there are abundant historical collections. Many of these collections are still in need of taxonomic revision before they can be used to reconstruct past entomofaunas and make inferences about diversity change through time. This paper is part of a larger project to revise the taxonomy of insects across the Triassic-Jurassic boundary of England to better understand changes in insect diversity through the Triassic-Jurassic boundary and associated extinction period. Herein, the damsel-dragonfly family Liassophlebiidae Tillyard, 1925 is revised and an additional specimen from the Early Jurassic of Antarctica is included. *Rossiphlebia* new genus is erected for *Liassophlebia jacksoni* Zeuner, 1962; *L. batheri* Tillyard, 1925 is considered nomen dubium and another specimen originally attributed to *L. batheri* is identified as *L. withersi* Tillyard, 1925. *Liassophlebia* (?) *clavigaster* Tillyard, 1925 and *L. (?) hopei* (Brodie, 1845) are considered incertae sedis at the generic level. *Liassophlebia gigantea* Zeuner, 1962 is based on a fragmentary specimen but has several unique key characteristics. We redescribe it in *Anglophlebia* new genus and tentatively in *Anglophlebiidae* new family in Heterophlebioptera. Also discussed are *L. magnifica* Tillyard, 1925, *L. withersi*, and *L. pseudomagnifica* Whalley, 1985, which are redescribed with updated figures. *Caraphlebia antarctica* Carpenter, 1969 was originally described from the Early Jurassic of Antarctica as being closely related to *Liassophlebia*; it is herein confirmed in *Selenothemistidae* Handlirsch, 1939." An investigation of the influence of habitat type on macroinvertebrates assemblages structure was conducted in July 2016. Nine (9) sampling sites were selected based on sediment type, water condition, and aquatic vegetation type. Macroinvertebrates attributes including density, biomass, and four diversity indices (Simpson diversity index, Margalef richness index, Shannon-Weiner index, and Pielou evenness index) were assessed. A total of 53 taxa were collected during the study period, with the highest density dominated being from aquatic insects and gastropods. *Bellamyia purificata* and *Expalaeon annandalei* were the most dominant among all the species. The results showed that the assemblages structure of macroinvertebrates in different habitats was significantly different. Also, the results with PCA showed that the higher values of invertebrates density, biomass, diversity indices, and species richness had a greater association with the habitat types of silt-humus sediment, closed lentic area, and submerged-floating-emergent vegetation.] Address: Liu, M., College of Wildlife Resources, Northeast Forestry University, Harbin 150040, China. **17192.** Kim, I.; Su, Y.J.; Min, J.K. (2019): Complete mitochondrial genome sequence of Bekko Tombo Libellula angelina Selys, 1883 (Odonata: Libellulidae). Mitochondrial DNA Part B 4(2): 2201-2203. (in English) ["L. angelina has been listed as a critically endangered species by the International Union for Conservation of Nature and is also an endangered insect in South Korea. We sequenced the whole genome (15,233 bp) of L. angelina species, which included a set of typical genes and one major non-coding AT-rich region with an arrangement identical to that observed in most insect genomes. The A + T-rich region harbored one identical repeat composed of 65 bp and two tRNA-like structures (trnF and trnK-like sequences) with proper anticodon and clover-leaf structures. Phylogenetic reconstruction using the concatenated sequences of 13 protein-coding genes (PCGs) and two rRNAs of the representative odonate mitogenomes utilizing both Bayesian inference and maximum-likelihood methods revealed a strong support for the monophyletic Zygoptera and a moderate to high support for the monophyletic Anisoptera suborders. Unlike that in conventional phylogenetic analysis, a relatively strong sister relationship was revealed between the suborders of Anisozygoptera and Zygoptera." **17193.** Kipping, J.; Clausnitzer, V.; Fernandes Elizalde, S.R. F.; Dijkstra, K.D.B. (2019): Chapter 9. The Dragonflies and Damselflies of Angola: An Updated Synthesis. In: B. J. Huntley et al. (eds.), Biodiversity of Angola: 141-165. (in English) ["Prior to 2012, only 158 species of Odonata were known from Angola. Surveys in 2012 and 2013 added 76 species and further additions in 2016 brought the national total to 236 species. This was published earlier in 2017 as the checklist of the dragonflies and damselflies (Odonata) of Angola by the same authors (Kipping et al. Afr Invertebr 58 (1):65-91) on which this chapter is based. Records obtained in 2017 and 2018 and a survey by two of the authors in December 2017 led to the discovery of 25 additional species, of which several are undescribed. We provide a revised checklist here comprising 260 species

and discuss the history of research, the biogeography of the fauna with endemism and the potential for further discoveries. The national total is likely to be above 300 species. This would make Angola one of the richest countries for Odonata in Africa." (Authors)] Address: Kipping, J., BioCart Ökologische Gutachten, Taucha/Leipzig, Germany. E-mail: biocartkipping@email.de

**17194.** Kloen, J.-F. (2019): Habitat preference of the Green Hawker (Aeshna viridis). Brachytron 20(2): 94-102. (in Dutch, with English summary) ["A. viridis has strict habitat requirements. In the Netherlands, this species only occurs in vegetations with Water Soldier (Stratiotes aloides) and a good water quality. The following habitat characteristics are important for Aeshna viridis. The water must be at least three meters wide; the vegetation in the water and on the banks should be rich in species; the water has to be sheltered by trees, bushes or reed; the water should be clear without many algae or rotting organic material. The S. aloides plants should be tall, with leaves reaching at least 19 centimeters above the surface, a total leaf length of at least 34 centimeters and the heart of the plant at least 19 centimeters below the surface." **17195.** Klymko, J.; Weigensberg, M.; Blaney, C.S. (2019): First records of the Lilypad Forktail (Ischnura kellicotti) (Odonata: Coenagrionidae) for the Canadian Maritimes and the Southern Pygmy Snaketail (Lanthus vernalis) (Odonata: Gomphidae) for Nova Scotia. J. Acad. Entomol. Soc. 15: 21-23. (in English) ["The Odonata fauna of the Canadian Maritime provinces has received much attention in recent years. A comprehensive overview was presented by Brunelle (2010), and additions to the Maritimes or individual provinces were reported by Klymko (2011), Klymko and Robinson (2013), McAlpine et al. (2017), and Makepeace et al. (2017). Here we add to this body of work with the first reports of I. kellicotti for the Canadian Maritime provinces and the first report of L. vernalis for Nova Scotia. Most of the occurrences documented in this note are based on specimens collected during a dragonfly exuvia survey of the St. Mary's River, Nova Scotia, in 2011 (Klymko & Robinson 2011) and a damselfly survey of south-western New Brunswick lakes done in 2017 (Klymko and

Weigensberg 2018). Voucher specimens have been deposited in the New Brunswick Museum (NBM) and the Canadian National Collection of Insect (CNCI)." (Authors)] Address: Klymko, J., Atlantic Canada Conservation Data Centre, PO Box 6416, Sackville, NB, Canada E4L 1G6. E-mail: jklymko@mta.ca

**17196.** Knight, S.M.; Pitman, G.M.; Flockhart, D.T.T.; Norris, D.R. (2019): Radio-tracking reveals how wind and temperature influence the pace of daytime insect migration. *Biology Letters* 15(7): 5 pp. (in English) ["Insects represent the most diverse and functionally important group of flying migratory animals around the globe, yet their small size makes tracking even large migratory species challenging. We attached miniaturized radio transmitters (less than 300 mg) to monarch butterflies (*Danaus plexippus*) and common green damer dragonflies (*Anax junius*) and tracked their autumn migratory movements through southern Ontario, Canada and into the United States using an automated array of over 100 telemetry towers. The farthest estimated distance a monarch travelled in a single day was 143 km at a wind-assisted ground-speed of 31 km h<sup>-1</sup> (8.7 m s<sup>-1</sup>) and the farthest estimated distance a green damer travelled in a single day was 122 km with a wind-assisted groundspeed of up to 77 km h<sup>-1</sup> (21.5 m s<sup>-1</sup>). For both species, increased temperature and wind assistance positively influenced the pace of migration, but there was no effect of precipitation. While limitations to tracking such small animals remain, our approach and results represent a fundamental advance in understanding the natural history of insect migration and environmental factors that govern their movements." **17197.** Kolar, V.; Boukal, D.S.; Sentsis, A. (2019): Predation risk and habitat complexity modify intermediate predator feeding rates and energetic efficiencies in a tri-trophic system. *Freshwater Biology* 64(8): 1480-1491. (in English) ["(1) To understand the effects of environmental changes on ecosystems, it is important to determine the factors and mechanisms influencing the strength of species interactions in food webs. However, joint effects of predation risk and additional environmental factors on species interaction strengths in multitrophic systems remain largely unexplored, leaving a substantial gap in our understanding of the links between local environmental characteristics and food web properties. (2) To fill this gap, we investigated the effects of habitat complexity and predation risk by top predatory dragonfly larvae (*Aeshna cyanea*) on feeding rates and energetic efficiency (i.e. the ratio of acquired and expended energy) of the larvae of three intermediate predatory odonate species (*Libellula quadrimaculata*, *Sympetrum sanguineum*, and *Ischnura elegans*) preying on cladocerans. (3) We hypothesised that predation risk would decrease the feeding rate, especially in the structurally simple habitat, and increase the metabolic rate of all intermediate predators. We also expected higher feeding rates of intermediate predators using aquatic vegetation as a perching site (i.e. *Sympetrum* and *Ischnura*) in the structurally complex habitat. Finally, we expected to observe habitat- and predation risk-dependent energetic efficiencies of

the intermediate predators driven by changes in feeding and metabolic rates. (4) The effect of predation risk on feeding rates was species specific and differed between the structurally simple and complex habitat. Habitat complexity increased feeding rates but only in the absence of predation risk. Moreover, predation risk signalled by chemical cues significantly increased *S. vulgatum* feeding rates but did not influence the feeding rates of the two other intermediate predators. (5) Metabolic rates varied among the three intermediate predators but were not affected by predation risk. Estimated energetic efficiency decreased with intermediate predator body mass and depended, to a lesser extent, on the interactive effect of habitat complexity and predation risk. (6) Our results imply that the effects of habitat complexity and predation risk on trophic interactions are likely to be determined by traits related to foraging and defence of the intermediate predators and their habitat domains, and that energetic efficiency is mainly determined by predator mass. Given that habitat complexity and predation risk can vary substantially across habitats, we conclude that it is important to consider habitat complexity and predation risk to better understand and predict the effects of environmentally driven variations on trophic interaction strength and metabolic rates that underlie the energetic efficiency of individual consumers. This has important implications for population and community dynamics as well as ecosystem functioning." **17199.** Koparde, P.; Dawn, P.; Darshetkar, A. (2019): Odonates across a tropical urbanization gradient (Mula River, Pune, Maharashtra, India). *International Dragonfly Fund Report* 128: 1-13. (in English) ["Globally urban wetlands are under high anthropogenic pressure of degradation. Urban wetlands are hotspots for species losses and rapid turnover in species assemblages. Therefore, studying such wetlands may provide an estimate of the pace of local extinction, concerning wetland-dependent species such as odonates. We undertook a study to document odonate species across a tropical urbanization gradient. We sampled six localities across the gradient across the Mula River that flows through the Pune City, India. We sampled adult odonates using a newly devised Halfcircle Point Count method from September 2016 to March 2017. We took multiple temporal replicates per site. We also sampled larvae across six sites once in November 2016. We measured site characteristics such as canopy cover, solid waste, and water turbidity to understand

the level of disturbance at each site. We recorded 41 odonates, six species (primarily Gomphidae members) exclusively from the larval sampling. We did not find the localization of species in a particular site across the urbanization gradient, possibly because we sampled a relatively short stretch of the river to capture the variation. Here, we update the Odonata list of Pune including data on larvae. We demonstrate that larval sampling complements Odonata surveys, especially in recording Gomphids. We recommend future research to include a longer timespan and extensive sampling area." **17202.** Krieger, A.; Fartmann, T.; Poniowski, D. (2019): Restoration of raised bogs—Land-use history determines the composition of dragonfly assemblages. *Biological Conservation* 237: 291-298. (in English) ["Even though bogs function as the most important terrestrial carbon store on Earth and play a crucial role in the conservation of highly endangered species, the area covered by peatlands is declining globally. Consequently, numerous restoration efforts within degraded bogs have been realized. In many cases, however, it is unknown whether the conservation measures have been successful. We used Odonata (hereafter referred to as dragonflies) as ecological indicators to evaluate the restoration success of rewetting measures in central European degraded raised bogs. Depending on their land-use history (rewetted industrial peat cuts with and without former agricultural use), two types of bog restoration were compared with rural peat cuts (control). Our study demonstrated that restored bogs are important habitats for dragonfly conservation. Both types of restored bogs

were as diverse in overall species richness as the control plots. However, land-use history had a strong effect on restoration success. All raised-bog species of the study area were able to recolonize at least some of the nutrient-poor restored bogs. The situation was different for the nutrient-rich restored bogs. Due to the high nutrient content – caused by the former agricultural use – the characteristic dragonfly fauna of raised bogs will be unlikely to be able to recolonize in these locations in the long term. Nevertheless, the nutrient-rich restored bogs represent an important secondary habitat, especially for transition-bog species. In conclusion, the conducted restoration measures created a network of small oligo- to mesotrophic water bodies, which fosters aquatic macroinvertebrate diversity in bogs." **17203.** Kumar, D.; Mohite, P.M.; Kamle, S. (2019): Dragonfly inspired nanocomposite flapping wing for Micro Air Vehicles. *Journal of Bionic Engineering* 16(5): 894-903. (in English) ["The current research is aimed towards the development of dragonfly inspired nanocomposite flapping wing for micro air vehicles (MAVs). The wing is designed by taking inspiration from the hind wing of *Anax parthenope julius*. Carbon nanotubes (CNTs)/polypropylene nanocomposite and low-density polyethylene are used as the wing materials. The nanocomposites are developed with varying CNTs' weight percentage (0% – 1%) and characterized for dynamic mechanical properties, which revealed that the 0.1 weight percentage case produces highest storage modulus values throughout the frequency range (1 Hz – 90 Hz). It is also observed that the storage modulus values are in the range of Young's modulus of veins and membrane of natural insect wings. This is useful to achieve true biomimicking. Advanced manufacturing technique such as photolithography is used for wing fabrication. The length, weight and average thickness of the fabricated wing are ~44 mm, 26.22 mg and 187 µm, respectively. The structural dynamic properties of the fabricated wing are obtained experimentally and computationally using DIC and ANSYS, respectively. The developed dragonfly inspired wing showed a natural frequency of 29.4 Hz with a bending mode shape which is close to the characteristic frequency of its natural counterpart." **17204.** Lan, D.-Y.; Shen, S.-Q.; Cai, Y.-Y.; Wang, J.; Zhang, J.-Y.; Storey, K.B.; Yu, D.-A. (2019): The characteristics and phylogenetic relationship of two complete mitochondrial genomes of *Matrona basilaris* (Odonata: Zygoptera: Calopterygidae). *Mitochondrial DNA Part B* 4(1): 1745-1747. (in English) ["The relationship of *Matrona* and *Atrocalopteryx* is still unclear. To better understand the phylogenetic relationship of *Matrona* and *Atrocalopteryx*, we sequenced and annotated two complete mitochondrial genomes of *Matrona basilaris* sampled from two different locations. The length of the two complete mitochondrial genomes of *M. basilaris* is 16,149 bp and 15,893 bp for the specimens collected in

Jinhua, Zhejiang Province and Tianmushan, Zhejiang Province, China, respectively. The two mitochondrial genomes include the typical invertebrate set of 37 genes: 13 protein-coding genes (PGCs), 22 tRNA genes, and 2 rRNA genes. The nucleotide composition of the mitogenome is similar to other odonates with high content of A + T (68.9%) and all PCGs use ATN as the start codon. Tandem repeats were detected in the control regions of the two *M. basilaris* samples that accounted for the different sequence lengths of the mitochondrial genomes from the two locations. Finally, BI and ML phylogenetic analysis based on the concatenated nucleotide sequences of the 13 PCGs supported the conclusion that *M. basilaris* is a sister clade to *A. melli*." **17205.** Lee, S.-D. (2019): Proposition of dragonfly's appropriate survey period inhabited in temperate zone. *Korean Journal of Environment and Ecology* 33(1): 16-27. (in Korean, with English summary) ["This study was identified the survey period and emergence of main species of dragonfly species, an indicator species that can identify the characteristics of wetland ecosystem. I surveyed the species and population of dragonflies once every two weeks from May 2015 to October 2016 (29 times). From January to March, November and December were excluded from the cluster classification because the dragonflies were not observed. In April and October, the species was emerged but it was not suitable because it could not represent the time of the seasons. When we divide by month, it was able to judge from April to June as spring. Except the May, there were some changes due to rainfall and temperature, and sometimes June was included in the summer season. June, July and August correspond to summer, and September and October fall in autumn. In June and October, the change was expected due to the effects of temperature and so it was judged as a partial fit. Looking at the change of the species, *Coenagrion johanssoni* and *Paracercion calamorum* were increase at the spring, and then *Crocothemis servilia mariannae*, *P. calamorum*, *Anax nigrofasciatus*, *Lyriothemis pachygastra*, *Orthetrum melania* were abruptly enlarge in summer. At last, *Sympetrum kunckeli*, *Lestes temporaris* tended to be higher in autumn." (Author)] Address: Lee, S.-D., Dept. Landscape Archit., Gyeongnam Nat. Univ. Science & Technology, 52725, Korea

**17206.** Lim, D.; Lee, Y. (2019): Fish fauna and the population of a Korean endangered freshwater fish, *Brachymystax lenok tsinlingensis*, in Korea: Bonghwa Habitat. *Environ. Eng. Res.* 24(4): 638-645. (in English) ["This research was an evaluation of the fish fauna and the habitat for *B. lenok tsinlingensis* for 11 stations at the Bonghwa-gun sanctuary. The predominant species in this research area was *Zacco koreanus*. *B. lenok tsinlingensis*, which has been designated as an endangered freshwater fish in Korea, was found in the Bonghwa sanctuary zone, except at stations 5 and 6. The *B. lenok* individuals were shorter in length than 400 mm. In total, 13 endemic species were found, including *Coreoleuciscus splendidus* and *Iksookimia longicorpus*. Specimens of *Koreocobitis*

*naktongensis*, a first grade endangered species, were also collected. The benthic macroinvertebrates consisted of four divisions, four classes, seven orders, 30 families, 60 species, and 10,344 individuals and were distributed among the orders Ephemeroptera (55.9%), Diptera (18.2%), Trichoptera (12.4%), Plecoptera (2.1%), and Odonata (0.3%)." **17207.** Lin, C.-Y.; Hsu, Y.-H.; Wang, J.-F.; Lin, C.-P. (2019): New damselfly hosts and species identification of an aquatic parasitoid *Hydrophylita emporos* (Hymenoptera: Trichogrammatidae) in Taiwan. *Journal of Natural History* 53(35-36): 2195-2205. (in English) ["The host-parasitoid relationship and species identity of aquatic parasitoids of *Coeliccia cyanomelas* and *Psolodesmus mandarinus dorothea* from Fushan and Lienhuachih in Taiwan were studied using morphological characters and DNA barcoding sequences. The parasitoids reared from the damselflies' eggs, and the field-collected parasitoids, were morphologically identified as *H. emporos*, a recently described parasitoid of the damselfly *P. m. mandarinus* from Northern Taiwan. The CO1 (cytochrome c oxidase I) gene tree supported the identification as *H. emporos*, as well as all parasitoid samples from *C. cyanomelas*, *P. m. dorothea* and *P. m. mandarinus*. The sampled *H. emporos* populations did not differ genetically despite their different host associations. However, some genetic differences were found between *H. emporos* populations from Northern and Central Taiwan, indicating that the dispersal of *H. emporos* may be limited by geographical distances. Our results suggest that *H. emporos* can parasitise not only closely related sister subspecies, *P. m. mandarinus* and *P. m. dorothea*, but also phylogenetically distant species of another damselfly family, *C. cyanomelas*. This is the first record of multiple damselfly hosts for the aquatic parasitoid genus *Hydrophylita*. This finding implies that the host range of *H. emporos* and congeneric species may be broader than previously thought." (Authors)] Address: Lin, C.-Y., Dept of Life Science, Nat. Taiwan Normal Univ., Taipei, Taiwan. E-mail: treehopper@ntnu.edu.tw

**17208.** Liu, X.; Zhang, J.; Shi, W.; Wang, M.; Chen, K.; Wang, L. (2019): Priority pollutants in water and sediments of a River for Control Basing on benthic macroinvertebrate community structure. *Water* 2019, 11(6), 1267; <https://doi.org/10.3390/w11061267>: 16 pp. (in English) ["Understanding the drivers of macroinvertebrate community structure is fundamental for adequately controlling pollutants and managing ecosystems under global change. In this study, the abundance and diversity of benthic macroinvertebrates, as well as their chemical parameters, were investigated quarterly from August 2014 to April 2015 in four reaches of the Huai River basin (HRB). The self-organizing map (SOM) algorithm and canonical correspondence analysis (CCA) were simultaneously applied to identify the main factors structuring the benthic community. The results showed that the benthic community structure was always dominated by gastropoda and insecta over seasons and presented obvious spatial and temporal heterogeneity along different pollution levels. The insects were always the top contributors to number

density of the benthic community, except for the summer, and the biomass was mainly characterized by mollusca in all seasons. Statistical analysis indicated that TN and NH<sub>3</sub>-N in water, as well as Hg, As, Cd, and Zn in sediments, were the dominant factors structuring the community, which determined the importance of sediment heavy metal concentrations in explaining the benthic community composition in comparison with other factors. These major factors should be given priority in the process of river pollutant control, which might be rated as a promising way to scientifically improve river health management and ecological restoration." **17212.** Mangahas, R.S.; Murray, R.L.; McCauley, S.J. (2019): Chronic exposure to high concentrations of road salt decreases the immune response of dragonfly larvae. *Front. Ecol. Evol.* | doi: 10.3389/fevo.2019.00376: 6 pp. (in English) ["Salinization of freshwater ecosystems, due to the application of road salts, is recognized as a potential threat to aquatic communities. Much of the research on the impact of salinity has focused on performance metrics in vertebrates, including respiration and osmoregulation. Here we focus on immune function in of the dragonfly *Anax junius*, a top predator in fishless aquatic habitats. Impacts on this top predator have the potential to cascade through the community, and immune function is known to be both plastic and sensitive to stress. We injected larvae with monofilaments (simulating a parasite) and placed them in one of three environmentally relevant concentrations of deicing road salt: control (dechlorinated tap water with no added salt), low (1000 mgL<sup>-1</sup>), or high salt (3000 mgL<sup>-1</sup>), for either acute (24hr) chronic or (96hr) exposures. We hypothesized that elevated salinity would suppress the immune response and that longer exposure magnifies this effect. As predicted, chronic exposure to high salt concentrations resulted in a significantly reduced larval immune response, however, there was no detectable treatment effects in larvae exposed to low concentrations of road salt or to acute high concentrations. Our results demonstrate that prolonged exposure to high levels of road salt can compromise the immune response of dragonfly larvae. Our findings suggest that insects in aquatic environments that experience sustained environmental salt pollution will be more susceptible to parasites and pathogens, which in turn may affect the impact of this major predator on aquatic community dynamics." **17215.** Marinov, M.; Jacq, F.A.; Ramage, T.; Doscher, C. (2019): Contribution to the Odonata fauna of the Society Islands, French Polynesia (Insecta: Odonata). Faunistic Studies in South East Asian and Pacific Island Odonata 28: 1-37. (in English) ["Following field studies in 2018 the Odonata fauna of Society Islands, French Polynesia is reviewed and the validity of all records analysed. An updated species list is provided, bringing the number of breeding species recorded from this island group to ten. Field studies targeted *Hemicordulia* Selys, 1870 specimens for inclusion in the revision of the Pacific representatives of the genus. Samples were taken mainly from Tahiti and Raiatea, with some additional specimens collected from Bora Bora and Huahine. Only the Society Islands endemic *H. oceanica* Selys, 1871 was encountered on all four islands, being recorded from Bora Bora for the first time. At least one new species of *Hemicordulia* has been reported from the high mountain areas of Tahiti (Jacq et al. 2009, 2014). The present study also emphasises the need for a revision of Zygoptera records from the French Polynesia and the rest of the Pacific. Presently, about 25 endemic species provisionally assigned to *Ischnura* Charpentier, 1840 and *Hivaagrion* Hämäläinen & Marinov, 2014 are known from the Society, Austral and Marquesas island groups (R. Englund, J. Jacq, T. Ramage, D. Polhemus, per. comm.). Only seven of them have been described so far. Detailed morphological and molecular analyses will likely prove the separate generic status of some of the species presently included under *Ischnura*." **17219.** Mellal, M.K.; Bensouilah, M.; Houhamdi, M.; Khelifa, R. (2019): Reproductive habitat provisioning promotes survival and reproduction of the endangered endemic damselfly *Calopteryx exul*. Journal of Insect Conservation 22(3-4): 563-570. (in English) ["Effective habitat management is predicted to have positive effects on populations and species of conservation concern. Although studies have shown that

ecological processes such as colonization can be promoted after habitat management, we still need more information on the survival and reproductive consequences at the individual level in order to reach positive conservation outcome. Here we assess the effects of reproductive habitat supplementation (host oviposition plant) on survival and mating success of *C. exul*, using capture-mark-recapture data. We first determined that the species prefer to oviposit on floating leaves of *Potamogeton* spp. Based on Cormack-Jolly-Seber modeling, we found that recapture and survival probabilities were positively affected by the number of the host oviposition patches of the host plant. Moreover, we showed a strong positive relationship between adult lifespan and lifetime mating success. Our results suggest that host-plant provisioning for reproduction not only increases the survival of individuals, but also increases the number of matings per lifetime. The procedure of supplying reproductive sites may enhance population growth of threatened odonates and other aquatic insects." (Authors)] Address: Mellal, M.K., Lab. Entomol.* 116: 269-280. (in English) ["Insect larval development affects adult traits but the biometric relationships are usually poorly understood, including large odonates. In this study, measurements of morphological traits of larvae, exuviae and adults of *A. imperator* were recorded. They were used to investigate the effects of early development on adult morphology. Results showed an increase in larval length during the final instar and the length of its exuviae significantly exceeded that of the larva. Length and body mass of teneral adults were strongly related to the length of their exuviae. Adult males were significantly longer than adult females, while both had the same body mass at emergence. Length of teneral adults was negatively related to the date of emergence in both sexes. During maturation, body mass of males only increased slightly whereas that of females increased greatly. Mature specimens were also significantly longer than teneral individuals. Body mass of mature males and length of mature females were both associated with the date of capture. Wing length did not differ between sexes or from data available from Great Britain. This study underscores the importance of taking into account larval growth in order to better understand the adult traits of odonates." **17225.** Moore, M.P.; Lis, C.; Gherghel, I.; Martin, R.A. (2019): Temperature shapes the costs, benefits and geographic diversification of sexual coloration in a dragonfly. *Ecology Letters* 22(3): 437-446. (in English) ["The environment shapes the evolution of secondary sexual traits by determining how their costs and benefits vary across the landscape. Given the thermal properties of dark coloration generally, temperature should crucially influence the costs, benefits and geographic diversification of many secondary sexual colour patterns. We tested this hypothesis using sexually selected wing coloration in a dragonfly. We find that greater wing coloration heats males – the magnitude of which improves flight performance under cool conditions but dramatically reduces it

under warm conditions. In a colder region of the species' range, behavioural observations of a wild population show that these thermal effects translate into greater territorial acquisition on thermally variable days. Finally, geo-referenced photographs taken by citizen scientists reveal that this sexually selected wing coloration is dramatically reduced in the hottest portions of the species' range. Collectively, our results underscore temperature's capacity to promote and constrain the evolution of sexual coloration." (Authors)] Address: Moore, M.P., Dept Biology Case Western Reserve Univ. **17226.** Moskowitz, D.; May, M.L. (2019): Nymph ecology, habitat, and emergence-site selection of *Cordulegaster erronea* Hagen (Tiger Spiketail Dragonfly) in New Jersey with implications for conservation. *Northeastern Naturalist* 26(1): 141-154. (in English) ["*C. erronea* is of conservation concern throughout much of its range; yet only a single study on the nymphs has been conducted, and many aspects of the species' life-history are poorly understood. The present study evaluated the size, age structure, and density of Tiger Spiketail nymphs at a stream on the Schiff Reservation Natural Lands Trust (Schiff) in Mendham Township, Morris County, NJ. We investigated the habitat and surrounding landscape characteristics of this stream and a second stream containing Tiger Spiketails at Schiff. We collected and measured 137 Tiger Spiketail nymphs during this study—82 in the spring and 55 in the fall—representing pre- and postadult emergence. We found 24 exuviae along both study streams and an additional 8 exuviae along 3 other streams in New Jersey, Connecticut, and Delaware. We are aware of only 1 other published report of Tiger Spiketail exuvia, which documented a single specimen. Our data and habitat assessment indicate that the Tiger Spiketail has a long nymphal stage and may be dependent upon high quality, fish-free, perennial headwater streams flowing through extensive forests. This information may assist resource managers in developing conservation strategies and habitat-protection measures for this species." (Authors)] Address: Moskowitz, D., EcolSciences, Inc., 75 Fleetwood Drive, Suite 250, Rockaway, NJ 07866, USA. E-mail: dmoskowitz@ecolsciences.com.

**17227.** Müller, O.; Schumann, V.-F. (2019): Terrestrische Migration der Larven von *Stylurus flavipes* (Odonata: Gomphidae). *Libellula Supplement* 15: 113-120. (in German, with English summary) [Terrestrial Migration of Larvae of *S. flavipes* – *S. flavipes* is a character species of lowland rivers. Its larvae inhabit shallow river banks that contain fine-grain sediments. Though most of these rivers are radically regulated in Europe, there are some less regulated ones, such as the River Elbe or the River Oder, that were able to sustain relatively natural tide dynamics. In summer, the water levels often decrease drastically with the impact on the shallow parts of the river banks drying out within a few hours. Emerging pools that are swiftly separated from the river can become traps for larvae. Would larvae be able to leave the pools if these pools were completely separated from the river? The paper at hand describes the phenomenon of terrestrial migration of larvae for the first time. In our

experiment, some of the larvae left the artificial pools. There seemed to be a specific adaptive behaviour between different instars. Whereas larvae ready to emerge tended to move ashore, the younger ones tended to move towards the river.] Address: Müller, O., Städtisches Gymnasium Carl Friedrich Gauß, Mathematisch-naturwissenschaftlich-technische Spezialschule, Friedrich-Ebert-Str. 52, 5234 Frankfurt (Oder), Germany. **17229.** Mukherjee, S.; Blaustein, L. (2019): Effects of predator type and alternative prey on mosquito egg raft predation and destruction. *Hydrobiologia* 846: 215-221. (in English) [oas 47 "For a vector species, understanding their egg raft predation (consumption) or destruction is essential for both ecological and human health reasons since it directly influences its fitness. In a mesocosm experiment, we assessed differences in *Culiseta longiareolata* egg raft predation/destruction by three aquatic predators *Notonecta maculata* (backswimmers), *Sympetrum fonscolombii* and *Ommatotriton vittatus* (newts), both in the presence and absence of an alternate prey (*Culex* larva). Egg raft predation and destruction significantly differed between predators types, and strongly influenced by the presence of alternate prey. Backswimmers attacked and destroyed (broke down) all egg rafts until they disintegrated and sank in water regardless of whether an alternate prey was present. Egg raft predation by dragonflies was common in the absence of alternative prey, but rare when alternative prey was present. Predation by newts was rare regardless of whether there was an alternative prey. The number of alternate prey consumed also significantly differed between predators ( $P < 0.001$ ) with backswimmers being the most effective predator. Relatively few studies have tested for egg raft predation/destruction. Hence it is crucial that we conduct similar trials in other landscapes since such predators can prove to be key agents for the biological control of mosquitoes." **17240.** Ohtsu, K. (2019): Acute toxicity test method, dragonfly, Fipronil, Imidacloprid, Japanese common meadowhawk, Paddy field nursery bed insecticides, Pesticide sensibility, *Sympetrum frequens*. *Jpn. J. Environ. Toxicol.* 22(2): 31-40. (in Japanese, with English summary) ["*Akiakane* (*S. frequens*), a Japanese common meadowhawk, is widely distributed in Japan. The larvae hatch in paddy water in a season of rice planting. In recent years in Japan, insecticides for nursery-box application are widely used. As these insecticides include a long-acting type, it is concerned about affecting the growth of *S. frequens* larvae. The objective of this study is to develop acute toxicity test method for 2nd instar larvae of *S. frequens* to some typical insecticides for nursery-box application (Fipronil, Imidacloprid) and compare the sensitivity of these insecticides. A 48-hour acute toxicity test method using a 48-well plate was established. Susceptibility to 2nd instar larvae of *S. frequens* was 48 times higher for fipronil than for imidacloprid. For effective hatching of larvae, it was necessary to treat the eggs at low temperature for at least 4 weeks. The temperature during the acute toxicity test was preferably 21°C. rather than 26°C." (Author)] Address: Ohtsu, K., Institute for Agro-Environmental Sciences, NARO / 3-1-3 Kannondai, Tsukuba City, Ibaraki 305-8604, Japan. Email: [kazu02@affrc.go.jp](mailto:kazu02@affrc.go.jp)

**17241.** Okuyama, H.; Kiyoshi, T.; Takahashi, J.-I.; Tsubaki, Y. (2019): Complete mitochondrial genome sequence of the broad-winged damselfly, *Mnais pruinosa* Selys, 1853 (Odonata:

Calopterygidae). *Mitochondrial DNA Part B* 4(2): 3101-3103. (in English) ["The mitochondrial genome of *M. pruinosa* was identified as a circular molecule of 15,494 bp, and was found to be similar to that of other damselfly species. It was predicted to contain 13 protein-coding (PCG), 22 tRNA, and two rRNA genes, as well as one A+T-rich control region. The genes ATP8 and ATP6 shared seven nucleotides, ATP6 and COIII shared one nucleotide, ND4 and ND4L shared seven nucleotides, and ND6 and Cytb shared one nucleotide. The initiation codon ATG was found in eight genes, ATC in four, and ATT in one; the termination codons TAA, TAG, incomplete TA, and single T were observed in seven, one, two, and three genes, respectively. All the tRNA genes possessed a cloverleaf secondary structure, except for tRNA-His that lacks the TWC loop. The average AT content of mitochondrial genome was 66.18%." (Authors)] Address: Okuyama, H., Fac. Life Sciences, Kyoto Sangyo Univ., Kamigamo, Motoyama, Kita-ku, Kyoto, Japan. E-mail: [k5533@cc.kyoto-su.ac.jp](mailto:k5533@cc.kyoto-su.ac.jp)

**17242.** Okuyama, H.; Kiyoshi, T.; Takahashi, J.-I.; Tsubaki, Y. (2019): A comparison of complete mitochondrial DNA sequences of *Mnais costalis* Selys, 1869 (Odonata: Calopterygidae) from three different populations (one allopatric and two sympatric). *Mitochondrial DNA Part B* 4(2): 3104-3105. (in English) ["In Japan, two closely-related damselflies, *Mnais costalis* and *M. pruinosa* Selys-Longchamps, 1853, coexist, and they exhibit geographic variations in wing color, body size, and habitat preference. In this study, we analyzed the complete mitochondrial genome of *M. costalis* from Saga Prefecture, Japan (sympatric populations that exhibit wing color polymorphism), and compared the genome with *M. costalis* that exhibit monomorphic orange wing color. The mitochondrial genome of *M. costalis* from Saga Prefecture was identified as a circular molecule of 15,488 bp, similar to that found in other *M. costalis* populations. It was predicted to contain 13 protein-coding (PCG), 22 tRNA, and two rRNA genes, along with one A + T-rich control region. Among the PCGs, ATP8 and ATP6, ATP6 and COIII, ND4 and ND4L, and ND6 and Cytb shared seven, one, seven, and one nucleotides, respectively. The initiation codon ATG was found in eight genes, ATC in four, and ATT in one, while the termination codons TAA, TAG, TA, and T were observed in seven, one, two, and three genes, respectively. All the tRNA genes possessed a cloverleaf secondary structure, except for tRNA-His that lacks the T C loop. The average AT content of mitochondrial genome was 66.06%. From a phylogenetic analysis, the loss of wing color polymorphism in monomorphic sympatric populations is likely to occur with the coexistence of two *Mnais* species." (Authors)] Address: Okuyama, H., Faculty of Life Sciences, Kyoto Sangyo Univ., Kamigamo, Motoyama, Kita-ku, Kyoto, Japan. E-mail: [k5533@cc.kyoto-su.ac.jp](mailto:k5533@cc.kyoto-su.ac.jp)

**17243.** Olumukoro, J.O.; Anani, O.A. (2019): Evaluation of aquatic macro-invertebrate populations: a model for emergent bio-monitoring guide for quantifying uncleanness of some Rivers in Northern Central Nigeria. *Nigerian Journal of Technological Research* 14(2): 54-62. (in English) ["The objectives of this study are to examine the composition, abundance and distribution of benthic macroinvertebrate

communities, assess the health status and evaluate the spatial relationships of some selected Rivers. A total of 1251 individuals of macroinvertebrate taxa was recorded in this study. The percentage composition of the taxonomic groups obtained from the 22 stations were: Chironomidae (Diptera) (40.85%), Ephemeroptera (14.95%), Oligochaeta (9.83%), Amphibian (7.99%), Ceratopogonidae (Diptera) (7.11%), Mollusca (4.00%), Hemiptera (3.44%), Coleoptera (2.56%), Ostracoda (2.24%), Zygoptera (1.44%), Nematoda (1.12%), Decapoda (0.80%), Trichoptera (0.56%), Anisoptera (Odonata) (0.48%), Polychaeta (0.32%), Lipdoptera (0.08%) and Hydrachnidae (0.08%). The findings of this study indicated that Omeme, Kpansi Afara and Etsu rivers were classified as very poor category; exceeding the set benchmark. Etsu 11 and Afara Rivers were within the fair category. The Bray-Curtis indices revealed that there was similarity in all the stations Sustainable anthropogenic activities are recommended to avoid displacement of benthic communities." **17244.** Ong'wen, F. (2019): Additive effects of dragonfly (*Pantala flavescens*) nymph and fungus (*Beauveria bassiana*) on development and survival of Malaria Mosquito (*Anopheles gambiae*). Thesis, Maseno University: (in English) ["Malaria continues to be a world-wide human health problem. Insecticide resistance challenge efficacy and sustainability of malaria control programs and therefore call for sustainable malaria control strategies. Environmental factors affect mosquito development and survival and should be considered when designing these strategies. However, there is limited knowledge on mosquito ecology, especially on interactions with predator such as *P. flavescens* nymph and parasite such as *B. bassiana* fungus across stages. This study focused on investigating additive effects of *P. flavescens* and *B. bassiana* on *Anopheles gambiae*. Specific objectives were to determine: predation efficacy of *P. flavescens* nymph against *A. gambiae* larvae; development rate of *A. gambiae* larvae reared in presence of varying densities of *P. flavescens* nymphs; efficacy of *B. bassiana* against *A. gambiae* larvae; and survival of adult mosquitoes exposed to fungus after predator and/or parasite pre-exposure at larval stage. All experiments consisted of survival bioassays quantified either as pupation day or dead larvae and adults. Mosquito eggs were obtained from The Center for Global Health Research, KEMRI; dragonfly nymphs from Ahero Irrigation Scheme, Kenya; and *B. bassiana* spores (IMI- 391510) provided by IN2CARE®, The Netherlands. Predation efficacy investigation involved four replicates of 30 larvae exposed to 1 dragonfly nymph. Development rate investigation involved exposing four replicates of 30 larvae to varying numbers (0-4) of constrained dragonfly nymphs. Four replicates of 30 larvae were exposed to varying spore concentration (0-12 mg) to determine fungal efficacy. Three replicates of 30 adults pre-exposed to predator and/or fungus were exposed to same fungus for adult survival. Predation efficacy test showed significant difference in mean number of dead larvae ( $Z=-12.667$ ,  $P<0.001$ ). Development rate test showed significant difference ( $P<0.001$ ) for groups exposed to 1 or 2 nymphs but

group exposed to 4 nymphs ( $P=0.227$ ) was not significantly different. Fungal efficacy test showed that larvae exposed to 3, 6 and 12 mg of fungus had HR, 2.0, 2.5 and 3.5, respectively. In adult survival test, adults not pre-exposed to any factor, those pre-exposed to predator, parasite or both predator and parasite had HR of 45.8, 67.4, 50.9 and 112.0, respectively. It is clear that single and additive effects of the predator and/or parasite affect mosquito development and survival, because it affects mosquito physiology and immunity. However, field studies should be done to prove consistency in the field. The knowledge can then be employed by Ministry of Health for malaria control in areas with *P. flavescens*." Cuatro Ciénegas Basin: An Endangered Hyperdiverse Oasis. Springer, Cham: 117-128. (in English) ["A summary of the present knowledge on the diversity of Odonata occurring in the Cuatro Ciénegas Basin (CCB) is presented. The work is based on published records, and the results from samplings are carried out between the years 2009 and 2013 in 23 sites. A list of the 67 Odonata species from the CCB is provided including 19 new state records.

Finally, the biogeographic affinities, conservation status, and major threats are discussed." (Authors)] Address: Ortega-Salas, H., Posgrado en Ciencias Biológicas, Univ. Nacional Autónoma de México Ciudad de México, Mexico. E-mail: hector\_os@ciencias.unam.mx

**17248.** Oteman, B.; de Vries, H.H. (2019): Beoordeling van habitatkwaliteit op basis van satellietdata: een pilot met de groene glazenmaker. Rapport VS2019.029, De Vlinderstichting, Wageningen: 30 pp. (in Dutch) ["The rare *Aeshna viridis*, is strongly dependent on the water plant, crabbush. In order to gain more insight into the availability of suitable habitat for the green hawker, this pilot project analyses satellite images for two South Holland polders: Polder Kromme, Geer and Zijde and Polder Nesse. In different satellite images, from 2014, 2017 and 2019, a search for crabgrass was carried out. For this purpose, a spectral profile of crabgrass was drawn up through fieldwork. This profile was then applied to the satellite images. The prediction based on the 2019 satellite image was then validated in the field. This showed that crabgrass, under favourable conditions, can be determined with a 93% accuracy. The best period to use satellite images to detect crabgrass is June-July. For brown crabgrass this is the first half of September. Applying the calculated spectral profile to other satellite images showed that depending on the sensor of the satellite an additional calculation step might be necessary (further calibration). The method with a spectral analysis seems to offer more than enough perspective to be applied in other areas. However, this will require some calibration, possibly through additional field visits. The spatial comparison between 2014, 2017 and 2019 shows that the decline in crabgrass is not spatially clustered. The problem is not limited to a few watercourses or plots, the decline is area-wide." (Authors) Translated with www.DeepL.com/Translator (free version)] Address: not stated

**17249.** Ott, J. (2019): Libellen als Indikatoren für eine Flussrenaturierung – Ergebnisse der dritten Erfolgskontrolle an der Oster (Insecta: Odonata). *Libellula Supplement* 15: 147-162. (in German, with English summary) ["Dragonflies as indicators of the restoration of the river Oster – results of the third success-control-study (Insecta: Odonata) – After 1991, 1996, and 2003, a 4 km long restored stretch of the river Oster (German federal state "Saarland") was investigated for a third time in 2017 and 2018 regarding the dragonfly fauna. This study was part of a so called "Entwicklungs- und Erprobungsvorhaben" (Development and testing project) of the German Federal Agency for Nature Conservation (BfN). The increase of dragonfly diversity and abundances in 1996 and 2003, which was regarded as a success of the restoration project although typical anisopteran species of running waters had not yet appeared, could not be confirmed in the more recent study. *Calopteryx virgo* was the only species of running waters present in a considerable population. The reasons for the present deficiency is the still existing waste water pollution, the impact of fine organic material, as well as the lack of morphodynamics, the effects of the dense riparian alder vegetation, and the immigration of the invasive signal crayfish. Finally, measures for ecological improvement are proposed." (Author) Address: Ott, J.,

**17250.** Ožana, S.; Burda, M.; Hykel, M.; Malina, M.; Prášek, M.; Bárta, D.; Dolný, A. (2019): Dragonfly Hunter CZ: Mobile application for biological species recognition in citizen science. *PLoS ONE* 14(1): e0210370. <https://doi.org/10.1371/journal.pone.0210370>: 13 pp. (in English) ["Citizen science and data collected from various volunteers have an interesting potential in aiding the understanding of many biological and ecological processes. We describe a mobile application that allows the public to map and report occurrences of the Odonata species found in the Czech Republic. The application also helps in species classification based on observation details such as date, GPS coordinates, and the altitude, biotope, suborder, and colour. Dragonfly Hunter CZ is a free Android application built on the open-source framework NativeScript using the JavaScript programming language which is now fully available on Google Play. The server side is powered by Apache Server with PHP and MariaDB SQL database. A mobile application is a fast and accurate way to obtain data pertaining to the Odonata species, which can be used after expert verification for ecological studies and conservation basis like Red Lists and policy instruments. We expect it to be effective in encouraging Citizen Science and in promoting the proactive reporting of odonates. It can also be extended to the reporting and monitoring of other plant and animal species." **17251.** Pahari, P.R.; Mandal, S.S.; Maiti, S.; Bhattacharya, T. (2019): Diversity and community structure of Odonata (Insecta) in two land use types in Purba Medinipur District, West Bengal, India. *Journal of Threatened Taxa* 11(6): 13748-13755. (in English) ["The present study recorded a total of 45 species of Odonata, of which one species, *Ischnura mildredae*, was recorded for the first time from West Bengal in India. 38 species were found in Tamluk Municipality as compared to 21 species in Haldia Industrial Belt (IB), with 14 species common to both the localities. Index of similarity revealed that the two localities were slightly dissimilar in odonate faunal composition as only 47% of species were shared. In both the localities, Anisoptera was more abundant, comprising over 69% of the total odonates. Libellulidae was the most abundant Anisopteran family in both the localities, comprising over 66% of the total odonates. Coenagrionidae was the most abundant Zygopteran family in both the localities. 13 species of Anisoptera and 11 species of Zygoptera were found only in Tamluk whereas two species of Anisoptera and five species of Zygoptera were found only in Haldia IB. *Crocothemis servilia*, *Pantala flavescens*, and *Ceriagrion coromandelianum* were the dominant species in Tamluk while *Brachythemis contaminata* and *Orthetrum sabina* were the dominant species in Haldia IB. Based on the values of Shannon index, Tamluk was considered unpolluted (=3.16) and Haldia IB moderately polluted (=2.43). Higher equitability index (J=0.87) and very low dominance index (0.06) in Tamluk indicated homogeneity in community composition and relatively

stress-free equitable environment. The present investigation suggests that Odonata can be used as bioindicators of industrial pollution." (Authors)] Address: Pahari, P.R., Dept Zoology, Tamralipta Mahavidyalaya, Tamluk, Purba Medinipur, West Bengal 721636, India

**17253.** Parr, A. (2019): Migrant and dispersive dragonflies in Britain during 2018. *J. Br. Dragonfly Society* 35(2): 48-60. (in English) ["In the UK, 2018 will go down as one of the most spectacular years in modern history for migrant and dispersive dragonflies. *Somatochlora flavomaculata* was recorded as new to Britain when a male was photographed at Carton Marshes near the Suffolk coast on 2 July, while only the fourth ever record of *Leucorrhinia pectoralis* was made elsewhere in Suffolk on 27 May. As well as these great rarities, large scale arrivals of many of the currently less unusual migrant species were also reported, though *Sympetrum fonscolombii* had a rather more low-key year. *Anax ephippiger* appeared in numbers during October and was even seen ovipositing, while it was the second best year ever for *Anax parthenope* in the UK with records from over 40 sites. A substantial arrival of *Aeshna affinis* was noted in southern England during July and early August, and *A. isocetes* also produced a number of unexpected sightings away from breeding sites. Most notable of these was a record from the Exminster Marshes, Devon, on 12 July. In addition to these migratory movements, significant internal dispersal by species such as *Orthetrum caerulescens* was seen during the year. Many of our recent colonist damselflies also had a productive season. *Erythromma viridulum* was noted on the Lizard Peninsula in Cornwall during early July, some 100 km away from previously known UK sites for the species and thus perhaps indicative of a fresh immigration event. Continued immigration by *Lestes barbarus* was also detected during 2018, while the first ever inland breeding site for the species was discovered in Buckinghamshire." **17254.** Pastorino, P.; Bertolia, M.; Squadrone, S.; Brizio, P.; Piazza, G.; Oss Noser, A.G.; Prearo, M.; Cesarin, M.; Pizzul, A.E. (2019): Detection of trace elements in freshwater macrobenthic invertebrates of different functional feeding guilds: A case study in Northeast Italy. *Ecohydrology & Hydrobiology* 19(3): 428-440. (in English) ["Trace elements are common contaminants in aquatic ecosystems; their detection in biota yields information on their availability in the environment and provides an indirect indication of freshwater ecological status. We analyzed samples of freshwater macrobenthic invertebrates from six watercourses in Friuli Venezia-Giulia

(Northeast Italy) to verify whether trace elements accumulation is related to their ecological status sensu Water Framework Directive (WFD), and to determine tropic level influences on the accumulation of 18 trace elements in macrobenthic communities. Observed concentrations could be in line with results of ecological status assessment defined by the WFD, in fact two sites classified as "Moderate" had the highest trace elements content. The genus *Calopteryx* (predator) was positively correlated with Be, Cr, Fe, Mn, Mo, Ni, Sn, and V (S range 0.777–0.844). Positive correlations were also determined for the genus *Rhyacophila* (Trichoptera, predator) with Cu (?S = 0.757), suggesting bioaccumulation in macroinvertebrate tissue. Ephemeroptera of the genus *Caenis* (collector-gatherers) were positively correlated with Be, Fe, Mn, Pb, Sb, and V (ps range 0.757–0.802), indicating that ingestion of sediment is the most effective uptake of these metals. Results of this study, albeit preliminary, showed that trace elements detection in aquatic macrobenthic invertebrates is a useful analysis for obtaining information about the status of freshwater course. Our study provides evidence for a greater accumulation of trace elements in predators and collector-gatherers, suggesting that the tropic level of macrobenthic communities influence the accumulation of trace elements." **17255.** Patel, S. (2019): Proteins: Sustainable source, processing and applications. Chapter 2 - Insects as a Source of Sustainable Proteins: 41-61. (in English) ["Ensuring nutritious food for the ever-growing world population is one of the foremost challenges. As pressure on land and water is mounting, these resources are getting depleted in alarming manner. So, energy and resource-efficient ways of food productions are being searched for. In this regard, insects, the members of phylum Arthropoda, appear very promising as their life cycle is short while turnover rate and biomass conversion rate are high. Entomophagy, the practice of ingesting insects, is an ancient way of feeding but it has mostly been confined to poorer economic strata. Not all, but certain insects such as bees, termites, ants, caterpillars, water bugs, flies, beetle larvae, crickets, grasshoppers, katydids, cicadas, and dragonflies are rich in proteins, fat, and minerals, are nontoxic, and are free of offensive aftertaste. These insect members are candidates for staple human foods. However, food neophobia and the lack of safety assurance are barriers that need to be surmounted before insects become a popular food item. Adequate research and public perception change regarding entomophagy can eradicate food insecurity, while causing a low ecological footprint. This chapter reviews the available literature on edible insects, presents the latest developments in this field, discusses their scope to food security, and proposes the pros and cons of this emerging food trend." (Author)] Address: Patel, Seema, Bioinformatics & Medical Informatics Research Center, San Diego State Univ., San Diego, CA, USA

**17256.** Pattanayak, A.; Pahari, P.R.; Deen, S.Y. (2019): Diversity and abundance of Odonata larvae in a fresh water lentic system of Purba Medinipur District, West Bengal, India.

Journal of Pharmacognosy and Phytochemistry 2019; SP5: 32-36. (in English) ["In total 19 species of Odonata larva have been recorded from a weed infested manmade Freshwater large lentic system near Tamluk, West Bengal (22017'52.56"N, 87055'16.72"E), India. Libellulidae were numerically the most abundant group comprising 66.04 % of the total Odonata larva followed by Coenagrionidae (31.92%) and Gomphidae (2.04%) respectively. Libellulidae represented by 12 species while Coenagrionidae represented by only 6 species and Gomphidae was represented by only one species. Urothemis and Rhodothemis were largest and lowest number of individuals recorded respectively. The water quality was fairly good during the 11 month study period of 2017-18. Various diversity indices were calculated in different seasons and the result shows maximum diversity and abundance during post-monsoon and minimum was in pre-monsoon. Diversity and evenness indices were fluctuated during study period due to seasonal changes of environmental conditions." (Authors)] Address: Pattanayak, A., PG, Dept Zool., Magadh Univ. **17270.** Polovic, L.; Miliša, M.; Dražina, T.; Špoljar, M. (2019): The role of dragonflies as the peak predators and indicators

of the health of the Mediterranean ponds. Simpozij o biologiji slatkih voda (SOBS). Zagreb, Hrvatska, 15.02.2019: (in English) [Verbatim: Mediterranean freshwater ponds are specific, sometimes man-made freshwater habitats on islands and coast. Since they're mainly isolated freshwater habitats in the arid and marine environment, they represent precious habitats with high freshwater species diversity. They are sensitive to weather and detrimental human effects due to their properties (e.g. small volume, low depth, karst base, proximity to the sea). These ponds undergo washing of nutrients, toxins and soil from surrounding areas, salinization, water level fluctuations and are often semi-permanent or temporary. Benthic macroinvertebrates are sentinel indicators of water ecological state as well as changes therein. Thus, across the Dugi otok island macroinvertebrates in 10 ponds were sampled. For productivity assessment, head capsule width was measured and 13 instars were distinguished and separated. Benthic community was comprised of 41 taxa of which the top predators - dragonflies were dominant, in biomass and in abundance. Therefore, further research was focused on dragonflies, specifically genera *Sympetrum* and *Anax*. Their presence differed among ponds, depending on the macrophyte coverage, salinity and the dragonfly prey size in the pond. *Sympetrum fonscolombii* was the most abundant species, with the highest biomass and thus it was the best choice for life cycle study. Taking into account the broad taxonomic structure of the benthic community, its trophic composition, and standing stock biomass of the top predator these habitats (although in a rather high trophic state) indicated healthy and stabile ecosystems. Hence, we encourage further protection and research of these curious and precious habitats.] Address: Maria Špoljar: maria.spoljar@biol.pmf.hr

**17271.** Poma, G.; Liu, Y.; Cuykx, M.; Tang, B.; Luo, X.-J.; Covaci, A. (2019): Occurrence of organophosphorus flame retardants and plasticizers in wild insects from a former e-waste recycling site in the Guangdong province, South China. *Science of The Total Environment* 650: 709-712. (in English) ["Highlights: •Large quantities of e-waste are generated worldwide and often inappropriately dismantled. •Occurrence of PFRs was investigated in wild insects from an e-waste recycling site (China). •TEHP was the most abundant PFR, followed by TPHP, TCIPP, TCEP, EHDPHP and TCP. •Odonata were more contaminated, followed by Lepidoptera, Orthoptera, Hemiptera, Coleoptera. •PFR contamination patterns could be explained by insect habitats and feeding habits. Abstract: Due to the fast growth of the electronic industry, a large quantity of electronic waste (e-waste) is generated worldwide and then often inappropriately dismantled and disposed of. In a pilot study, the occurrence of organophosphorus flame retardants and plasticizers (PFRs) was investigated for the first time in several wild insect species collected from a former e-waste recycling site in the Guangdong province, South China. TEHP was the most abundant PFR (average concentration of 5.8 ng/g ww), followed by TPHP (2.5 ng/g ww), TCIPP (2.2 ng/g ww), TCEP (0.8 ng/g ww), EHDPHP and TCP (both 0.1 ng/g ww). Dragonfly nymphs were the most contaminated insects, with total PFR concentrations of 68 ng/g ww, followed by moth adults (26? g/g ww) and terrestrial stinkbug (17 ng/g ww). The different contamination patterns observed in the analyzed insects could

be explained by their different habitats and feeding habits. This study shows that e-waste recycling areas can be an important local source of contamination with PFRs, mainly caused by inadequate recycling activities." (Authors)] Address: Covaci, A., Toxicol. **17272.** Poschmann, M.; Nel, A.; Schindler, T. (2019): Erster Nachweis von Riesen-Urilibellen (Odonatoptera: Meganisoptera: Meganeuridae) im Permokarbon des Saar-Nahe-Beckens (Rheinland-Pfalz, SW-Deutschland). *Mainzer naturwissenschaftliches Archiv* 56: 71-86. (in German, with English summary) [First record of giant griffenflies (Odonatoptera: Meganisoptera: Meganeuridae) in the Permocarboniferous of the Saar-Nahe Basin (Rhineland-Palatinate, SW-Germany). A wing fragment from lake deposits of the Meisenheim Formation (Lower Rotliegend, Autunian) near Obermoschel is the first record of giant griffenflies for the Permo-Carboniferous of the Saar-Nahe Basin. With a reconstructed wing span of at least 60 centimetres the animal was comparable in size to the iconic *Meganeura monyi* from the Stephanian of Commeny/France and is currently the largest known insect from Germany. The increased partial pressure of oxygen in the Upper Carboniferous to mid-Permian is discussed as a possible factor controlling the maximum size of griffenflies. The palaeoenvironment of Lake Obermoschel was characterized by large lakes and fluvial systems that provided the open spaces preferred by meganeurids, which were probably agile hawk predators." **17274.** Rae, J.; Murray, D. (2019): Pathogen vs. predator: ranavirus exposure dampens tadpole responses to perceived predation risk. *Oecologia* 191(2): 325-334. (in English) ["There is increasing interest in how animals respond to multiple stressors, including potential synergistic or antagonistic interaction between pathogens and perceived predation risk (PPR). For prey that exhibit phenotypic plasticity, it is unclear whether infection and PPR affect behaviour and morphology independently, or in an antagonistic or synergistic manner. Using a 2 × 2 factorial experiment involving green frog (*Lithobates clamitans*) tadpoles exposed to ranavirus (FV3) and larval *Anax* spp., we assessed whether anti-predator responses were affected by infection. We found that activity and feeding were reduced additively by both stressors. Body mass of tadpoles from FV3-exposed tanks was lighter relative to control and PPR-only tanks, while metabolism was comparable

across treatments. We found that FV3 exposure compromised morphometric responses to PPR in an antagonistic manner: tadpoles exposed to both treatments had restricted changes in tail depth compared to those receiving singular treatment. We conclude that multiple stressors can have complex and substantive effects on organisms, and that interactions between stressors may yield a range of responses depending on the level of exposure and sensitivity of the organism. Additional work should more fully determine mechanisms underlying the complex interplay between infection and predation risk, across a range of environmental conditions." **17276.** Rajapaksha, S.; Kandambi, H.K.D.; Dayawansa, P.N. (2019): Comparison of Faunal Wealth of a Selected Oil Palm Plantation and a Rubber Plantation in the Wet Zone of Sri Lanka. *Proceedings of the 24th International Forestry and Environment Symposium 2019 of the Department of Forestry and Environmental Science, University of Sri Jayewardenepura, Sri Lanka*: 61. (in English) ["A rapid increase in oil palm plantations has been evident in the low country wet zone of Sri Lanka as it is an economically profitable crop. Nevertheless, oil palm receives an immense resistance by the public claiming diminution of the water table and biodiversity wealth. Rubber plantations, which are often replaced by oil palm are claimed to be more environmentally friendly than oil palm plantations. The current study was designed to reveal the faunal wealth of selected oil palm plantations (OPP) and rubber plantations (RP) with reference to microclimatic conditions. It was hypothesized that there is no difference in faunal wealth of OPP and RP as measured by species richness, abundance and diversity indices. Three OPP and two RP in Agalawatta (N 6° 32' 50" E 80° 14' 01"-N 6° 32' 50" E 80° 13' 55") were selected for the study. Species richness and abundance of selected faunal groups were determined with reference to environmental factors (ambient temperature, relative humidity, soil moisture, litter depth, light intensity and canopy cover) from March to September 2018. Species richness and abundance of invertebrates (butterflies and dragonflies) and vertebrates (amphibians, reptiles, birds and mammals) were studied using line transects, circular plot counts, visual encounter survey technique, quadrat cleaning technique, live trapping

and hair tube sampling. Shannon-Weiner Diversity Index (H) was determined for different faunal groups inhabiting OPP and RP. Soil moisture content in OPP was significantly higher than that of RP (t-test  $p < 0.05$ ) while litter depth was significantly higher in RP ( $p < 0.05$ ). Ambient temperature, relative humidity, light intensity and canopy cover did not differ significantly between the two plantations. Species richness of fauna of OPP and RP were 54 (Endemic 16) and 30 (Endemic 5) respectively. Vertebrate diversity did not differ significantly between OPP ( $H = 2.68$ ) and RP ( $H = 2.53$ ), however, invertebrate diversity of OPP ( $H = 2.26$ ) was significantly higher than that of RP ( $H = 0.95$ ) (t-test  $p < 0.05$ ). Diversity of birds and reptiles were higher in RP than OPP while diversity of amphibians and small mammals were higher in OPP. Rare point endemic bush frog *Polypedates ranwellai* was found in oil palm plantations, which is considered as a range extension. This preliminary study revealed that overall faunal wealth of oil palm plantations is slightly higher than that of rubber plantations and this could be attributed to the availability of microhabitats." (2019): An annotated check list of Hong Kong dragonflies and assessment of their local conservation significance. *Faunistic Studies in Southeast Asian and Pacific Island Odonata* 30: 1-49. (in English) ["Dragonflies were surveyed at 33 sites across the territory of Hong Kong Special Administrative Region over the period 2016-2017. Surveys included identification of larvae, exuviae and adults, and involved 92 separate site visits. The chosen sites covered the whole spectrum of dragonfly habitats in Hong Kong, with the exception of actively managed fish ponds and reservoirs. 22 of the study locations had been identified as key dragonfly sites by Wilson (1997a). An annotated check list of Hong Kong Odonata was compiled, listing 128 taxa. Comparison of local distribution of dragonflies during the present study with that recorded by Wilson (1997a) indicated that only three species had undergone significant decline in the intervening two decades, while several others (including the conservation significant *Mortonagrion hirosei* Asahina, 1972 and *Orthetrum poecilops* Ris, 1919) had considerably extended local distributions. 28 species of particular conservation importance for Hong Kong were identified and ranked, using a species conservation value assessment metric." **17280.** Reid, D.J.; Tippler, C. (2019): Access to natural substrates in urban streams does not counter impoverishment of macroinvertebrate communities: a comparison of engineered and non-engineered reaches. *Water Air Soil Pollut.* (2019) 230:8: 15 pp. (in English) ["Urban streams are degraded through multiple mechanisms, including severely altered flow regimes, elevated concentrations of waterborne contaminants, removal of riparian vegetation and the loss of a mosaic of heterogeneous aquatic habitats. Engineering of urban stream reaches using concrete is a widespread and extreme case of deliberate alteration of flow regimes and concomitant habitat simplification. To assess the effect of such engineering practices on stream ecosystems, we compared aquatic macroinvertebrate communities from concrete-lined engineered urban reaches, nonengineered urban reaches with natural substrates and reference reaches flowing through minimally disturbed forested subcatchments and with natural substrates, in the Sydney metropolitan region, Australia. The communities from all urban reaches were impoverished and distinctly different from more diverse communities in forested reference reaches. Despite low aquatic habitat heterogeneity, engineered urban reaches had very high abundances of Diptera and some other tolerant taxa. Diptera and/or Gastropoda were dominant in nonengineered urban reaches. Multivariate community structures were dissimilar between the urban reaches and forested reference reaches and between nonengineered and engineered urban reaches. However, the low family-level richness and SIGNAL scores in both urban reach types indicated they were severely ecologically impaired, whether engineered or not. Most macroinvertebrate taxa in the regional pool that were hardy enough to inhabit urban reaches with natural substrates were also present in nearby concreted reaches. The results add weight to the growing evidence that in urban landscapes, regional-scale changes in water quality and flow regimes limit the establishment of diverse macroinvertebrate communities, which cannot be addressed through the provision of increased reachscale habitat heterogeneity." **17284.** Romero-Lebrón, E.; Gleiser, R.M.; Petrulevicius, J.F. (2019): Geometric morphometrics to interpret the endophytic egg-laying behavior of Odonata (Insecta) from the

Eocene of Patagonia, Argentina. *Journal of Paleontology* 93(6): 1126-1136. (in English) ["Although the order Odonata has a rich fossil record, many questions about its reproductive biology remain unanswered. There are two strategies of egg laying among odonates, exophytic and endophytic, the latter being one of the most revealing vestiges of plant–insect association in the fossil record. We assessed whether geometric morphometrics based on elliptical series of Fourier allow expression of variability of shape in traces of Odonata eggs within a leaf of *Eucalyptus chubutensis* (Berry) González (in part), González, 2009 (Myrtaceae) from Laguna del Hunco (Chubut, Argentina) (early Eocene) and whether this variability is consistent with the ichnotaxonomy of this material. We found that the largest variation corresponds to the compression of the shape while the remaining two components reflect variations in the apex position and its curvature, which changed according to the relative position of the traces in the leaf. There was no evidence that the hardness of the leaf would affect the shape of the egg trace. We postulate that these traces could have been produced by one single female: Variations in the pattern observable in the fossil of an originally three-dimensional structure are consistent with differences in the position of the eggs inserted by a single female who has flexed her abdomen to insert the eggs as she approaches the apex of the leaf (behavior observed also in extant dragonflies). For the first time, endophytic egg traces are analyzed with geometrical morphometrics, and this allows us to make inferences on the oviposition behavior of a female that lived around 52 million years ago." **17287.** Salami, E.; Ward, T.A.; Montazer, E.; Ghazali, N.N.N. (2019): A review of aerodynamic studies on dragonfly flight. *Proceedings of the Institution of Mechanical Engineers, Part C: Journal of Mechanical Engineering Science* 233(18): 6519-6537. (in English) ["In the recent decades, the design and development of biomimetic micro air vehicles have gained increased interest by the global scientific and engineering communities. This has given greater motivation to study and understand the aerodynamics involved with winged insects. Dragonflies demonstrate unique and superior flight performance than most of the other insect species and birds. They are capable of sustained gliding flight as well as hovering and able to change direction very rapidly. Pairs of independently controlled forewings and hindwings give them an agile flying ability. This article presents a review of all published journal articles, listed in the Thomson-Reuters Web-of-Science database (1985–2018), that are related to the flight aerodynamics of dragonflies or micro air vehicles that biomimic them. The effects of dragonfly wing motions and interactions (between forewing and hindwing) that are necessary to generate the appropriate aerodynamic forces in different flight modes are described. The associated power requirements of these modes are also addressed. This article aims to provide a valuable reference to the aerodynamic design and control of dragonfly-inspired biomimetic micro air vehicles." **17288.** Sampa, T. (2019): The first larval record of *Sympetrum fonscolombii* from Kawasaki city, Kanagawa Prefecture. *Tombo* 61: 51-52. (in Japanese, with English summary) ["In 2018, a larva of *S. fonscolombii* was collected from an elementary school's swimming pool in Kawasaki city, Kanagawa Prefecture. The larva of this species is here recorded

for the first time from Kanagawa Prefecture. It is suggested that this species chooses not only natural water areas but artificial water areas such as swimming pools for an oviposition site. In addition, it is shown that the larva of this species is able to pass the winter in Kawasaki city." (Author)] Address: not stated in English

**17289.** Samraoui, B.; Touati, L.; Samraoui, F. (2019): Slow and steady wins the race: Life cycle and seasonal regulation of *Gomphus lucasii* (Odonata: Gomphidae). *Odonatologica* 48(3/4): 229-246. (in English) ["We investigated the emergence and life cycle of the endangered Maghrebian endemic *G. lucasii* at the Seybouse River in north-eastern Algeria. Starting in mid-April, their emergence, typical of spring species, was highly synchronized and was achieved within two to three weeks. EM50 was reached in three days. Larval sampling indicated that the synchrony was achieved through larvae overwintering in the F-0 stage. Noteworthy was the concomitant presence of a junior cohort throughout the year demonstrating that the species completes a generation in two years. Thus, contrary to what has been reported previously, we argue that *G. lucasii* is a semivoltine species with a 'slow' developmental rate congruent with its distribution in high-risk permanent habitats. This finding has important conservation implications for this threatened endemic species which is facing severe anthropogenic pressures in the context of global changes." (Authors)] Address: Samraoui, B., Laboratoire de Conservation des Zones Humides, Université 8 Mai 1945 Guelma, Algeria. E-mail: bsamraoui@gmail.com

**17290.** Sánchez-Bayoa, F.; Wyckhuys, K.A.G. (2019): Worldwide decline of the entomofauna: A review of its drivers. *Biological Conservation* 232: 8-27. (in English) ["Biodiversity of insects is threatened worldwide. Here, we present a comprehensive review of 73 historical reports of insect declines from across the globe, and systematically assess the underlying drivers. Our work reveals dramatic rates of decline that may lead to the extinction of 40% of the world's insect species over the next few decades. In terrestrial ecosystems, Lepidoptera, Hymenoptera and dung beetles (Coleoptera) appear to be the taxa most affected, whereas four major aquatic taxa (Odonata, Plecoptera, Trichoptera and Ephemeroptera) have already lost a considerable proportion of species. Affected insect groups not only include specialists that occupy particular ecological niches, but also many common and generalist species. Concurrently, the abundance of a small number of species is increasing; these are all adaptable, generalist species that are occupying the vacant niches left by the ones declining. Among aquatic insects, habitat and dietary generalists, and pollutant-tolerant species are replacing the large biodiversity losses experienced in waters within agricultural and urban settings. The main drivers of species declines appear to be in order of importance: i) habitat loss and conversion to intensive agriculture and urbanisation; ii) pollution, mainly that by synthetic pesticides and fertilisers; iii) biological factors, including pathogens and introduced species; and iv) climate change. The latter factor is particularly important in tropical regions, but only affects a minority of species in colder climates and mountain settings of temperate zones. A rethinking of current

agricultural practices, in particular a serious reduction in pesticide usage and its substitution with more sustainable, ecologically-based practices, is urgently needed to slow or reverse current trends, allow the recovery of declining insect populations and safeguard the vital ecosystem services they provide. In addition, effective remediation technologies should be applied to clean polluted waters in both agricultural and urban environments. ... Odonata comprise a relatively small order of insects that depend on water bodies for their larval development. Both nymphs and imagoes are predators of aquatic organisms and flying insects respectively, and they play an important role in controlling nuisance mosquitoes and agricultural pests, e.g. of rice. Of the 118 aquatic species of endangered insects listed by the IUCN, 106 are Odonata, although it is clear that other aquatic taxa are underrepresented due to insufficient knowledge. A recent IUCN assessment indicates that 10% of the world's Odonata are threatened with extinction, although that study only covered a quarter of all species known and acknowledged data gaps for 35% of species, particularly those from tropical and Australasian regions. Given the above, 15% of all species may be threatened. In the USA, recent surveys at 45 sites across California and Nevada were compared to historical records from 1914 to 1915. Occurrence rates of 52 species of Odonata (65% of all recorded) have declined over the 98-year period while those of 29 species have increased. Two generalist and pollution-tolerant species that were not recorded in 1914–1915 greatly expanded their range into California and became common, particularly in urban areas. At least nine species declined significantly, including four species (*Sympetrum danae*, *S. costiferum*, *Ophiogomphus occidentis* and *Libellula nodisticta*) that were also rare in early surveys. Declines occurred mostly among habitat specialists, whereas increases were recorded for generalist and migratory species that replaced the losses at the same sites. Specialist species included those with overwintering diapause, which appear to have declined due to an increase of minimum temperature over the period. While species richness has not declined, Odonata assemblages have become more homogeneous in species composition, which is typically an effect of urbanisation. In Europe, 15% of the 138 Odonata species are currently threatened, with two damselflies (*Ceriatagrion georgifreyi* and *Pyrrhosoma elisabethae*) and one dragonfly (*Cordulegaster helladica* sp. *kastalia*) critically endangered in the Balkan Peninsula. A quarter of all species (33) are declining in population numbers and distribution, whereas 10% of them are increasing and about half remain stable. Major declines took place during post-1960 agricultural intensification, with canalisation of rivers for irrigation and water pollution by urban runoff, pesticides and fertilisers (i.e. eutrophication) being the main drivers of population extinctions over large areas. Ubiquitous species such as *Coenagrion puella* and *Sympetrum striolatum*, however, increased and shifted their range some 300 km northwards in Britain between 1960 and 1970 and 1985–1995. In central Finland, populations of 20 common species of Odonata were surveyed at 34 small creeks over 1995–1996, and their distribution patterns were compared with historic records from 1930 to 1975. Two specialist and lentic dragonflies, *Coenagrion johanssoni* and *Aeshna caerulea* have disappeared

from streams, and 45% of the 219 surveyed populations vanished. Local extinctions occurred in peat bogs and dynamic waters upstream, which are habitats for lentic-specialist species, whereas downstream water bodies had lower losses. Generalist species (i.e., those that breed in both lentic and lotic waters) were less likely to become locally extinct. The construction of agricultural ditches and habitat fragmentation from forestry further impacted on populations of rare species. In Japan, 57 out of 200 Odonata species are declining, with 23 being vulnerable and 19 endangered. The largest drops in abundance and distribution are among lentic species once common in rice paddy fields (e.g., *Lestes japonicus*, *Libellula angelina*, *Sympetrum maculatum* and *S. uniforme*). Island endemics are next in the extinction list, whereas those of lotic habitats of mountain streams are the least affected. The sharp decline in populations of red dragonflies (*Sympetrum* spp.) since the mid-1990s has been linked to the use of fipronil and neonicotinoid insecticides, which affect the aquatic nymphal stages by curtailing the emergence of adults. Of the 155 Odonata species recorded in South Africa, 13 are declining and four are extinct. The protection of rare species in nature reserves of that country does not necessarily guarantee their survival, as current livestock management and other human activities negatively impact on these aquatic insects." **17295.** Scheurer, S. (2019): Einfluss von polarisiertem Licht auf Insekten und ihr Eiablageverhalten in der Landwirtschaft. Bachelor thesis, ZHAW Zürcher Hochschule für Angewandte Wissenschaften: 45 pp. ["Linearly polarized light provides crucial visual information to water-seeking insects. Normally, the light reflected off water surfaces is polarized and can therefore be used to recognise the surface as water. At present more and more man-made artificial surfaces with similar reflective properties can be found, which can lead to fatal decisions by insects. In agriculture, for example, woven polypropylene mulch is used, which has corresponding properties. In a pumpkin field in Bütschwil, in the Bernese Seeland, as well as another in Steffisburg near Thun, this mulch is used in the cultivation process. As such, these fields were able to serve as location for field observations. With a focus on Odonata, several field surveys were carried out during the 2019 season and the behaviour of the dragonflies and their species was recorded. Furthermore, a theoretical background for these dragonfly species and the polarization of light is provided. In addition, measurements of different woven polypropylene products with respect to their polarization properties were performed and further possible sources for linearly polarized light were investigated. In both study areas, various dragonflies with species-specific behaviour could be observed, which is typically seen in their reproductive waters. These measurements on the aforementioned ribbon fabrics showed very similar reflective properties to those on water surfaces and only one white fabric had a limited polarizing effect. In addition, research revealed many other possible sources of polarized light, some of which are presented, and possible solutions are discussed. Further study approaches are recommended and a proposal for the introduction of the topic into the study of environmental engineering at the ZHAW is made." (Author)] Address: not stated

["Emerging damselflies are vulnerable to predator attacks and considered to be at high risk at this stage of their life cycle. We filmed bird and frog attacks on damselflies ready to emerge in slow motion and analysed their reactions. Pharate damselfly larvae that had left the water reacted to approaching wagtails and frogs by disengaging from the substrate, dropping with flipping movements back into the water and trying to swim away rapidly thus escaping these predators. It is inferred that until immediately before eclosion, pharate larvae that have left the water are able to recognize approaching predators and to react adaptively. Death feigning only occurs after physical contact with the predator." (Authors)] Address: Schneider, B., Wolfbühlstr. 34A, 8408 Winterthur, Switzerland. E-mail: beatsch@bluemail.ch

(2019): Meat eating in wild hamadryas baboons: Opportunistic trade-offs between insects and vertebrates. *American Journal of Primatology* 2019; e23029: 12 pp. (in English) ["Insects made up 0.5% of the baboons' annual diet, ranging from 0% to 2% of monthly diets (Figure 2). The baboons' insect consumption consisted primarily of locusts and dragonflies). Most of this feeding occurred when swarms of these organisms passed through the Filoha region. In almost all of these cases, most members of the band simultaneously fed on these insects, chasing and jumping up to capture and eat them. Predation success was high with the baboons catching an insect during the majority of attempts; the very large numbers of these insects during outbreaks allowed the baboons to repeatedly catch insects over a period of time generally lasting from 30 min to 1 hr. Almost all insect eating occurred in Acacia scrubland habitat where they spent almost half of their time, although the baboons fed on dragonflies a few times when a swarm passed through their sleeping cliff. (2019): Benthic macroinvertebrate diversity and functional feeding groups in relation to physicochemical factors in Sanjiang plain wetlands, northeast China. *Applied Ecology and Environmental Research* 17(2): 3387-3402. (in English) ["Sanjiang plain wetland is the largest freshwater ecosystem in northeast China, and with its richness in animal and plant species, it displays a high biodiversity. This study provides information about benthic macroinvertebrate diversity and functional groups in association with physicochemical parameters in wetland habitats of Sanjiang plain. Benthic macroinvertebrate samples were collected using a D-frame aquatic net. Shannon-Wiener, Simpson and Pileou's evenness indices were calculated in terms of abundance. The relationship between measured physicochemical variables and benthic

macroinvertebrate functional feeding groups (FFGs) was explored using CCA. A total of 57 macroinvertebrate taxa were collected from the 16 sampling sites. Aquatic insects were the most abundant with 11 families, Dytiscidae, Chironomidae, Leptophlebiidae, Belostomatidae, Corixidae, Geridae, Corduliidae, Gomphidae, Macromiinae, Libellulidae and Phryganeidae. Chironomids were the most diverse and abundant with 26 taxa. The metrics of abundance, Shannon-Wiener, Simpson and Pileou's evenness indices differed significantly among the 16 sampling sites ( $p = 0.0163$ ,  $p = 0.0092$ ,  $p = 0.0474$ ,  $p = 0.0222$ , respectively). The findings showed that these 57 benthic macroinvertebrate taxa were categorized in six functional feeding groups, including 19 predators, 15 gathering-collectors, 7 scrapers, 6 filtering-collectors, 5 omnivores and 5 shredders. CCA results displayed that benthic macroinvertebrate functional feeding groups had strong relationships with the physicochemical characteristics in the wetlands of Sanjiang plain." (2019): Studies on the reproductive behaviour of *Ischnura nursei* Morton (Odonata: Insecta) at Asan reservoir, District Dehradun, Uttarakhand, India. *Bio Bulletin* 5(2): 14-17. (in English) ["The reproductive behaviour of *I. nursei* was studied four times at Asan Reservoir, District Dehradun, Uttarakhand during June-July, 2019. Courtship is well marked and male demonstrate a circular territory with a radius of about 0.5-1 meter and defended it from the intruding intra or some inter specific male by warning signals like wing vibration or abdomen raising. As female entered into the territory, the male starts following her and forms a tandem link, catching hold of her prothorax by his anal appendages. The before wheel tandem lasted for 5-8 minutes and during this period intramale sperm translocation from the gonopore to the vesicular spermalis took place 2-3 times of 30-50 seconds duration. The courtship wheel lasts for about 6-10 minutes and is performed of perching on vegetation near the reservoir. After wheel tandem lasted for 5-8 minutes. Oviposition is endophytic among the aquatic vegetation and lasts for 7-12 minutes. The female in tandem climbs down underwater and uses her ovipositor to deposit eggs in the submerged vegetation. During oviposition the male in tandem and after release of grip hovers around the female, to defend her from intruding intra- or inter-specific males. The duration of reproductive behaviour lasts for 22-38 minutes." (2019): The impact of deformation on the aerodynamics of flapping dragonfly wings. *AIAA Scitech 2019 Forum, AIAA SciTech Forum*, (AIAA 2019-1378), <https://doi.org/10.2514/6.2019-1378>: 18 pp. (in English) ["As unmanned aerial vehicles continue to decrease in size, the use of flexible wings, imitating those found in nature, is becoming more prevalent. In order to better understand the effects of flexibility 011 the aerodynamics of dragonfly wings, measurements of wing deformations during the free flight of dragonfly specimens were conducted. The OVER-TURNS CFD solver was then modified to simulate the motion of both rigid and deforming wings, following the same bulk kinematics, so that the associated forces and flow fields produced could be compared. The deformation for both fore-

and hindwings resulted in camber during the body-relative downstroke and twist during the upstroke. This pattern of deformation was consistent even when the dragonflies were flying while inverted. Comparing the forces from the simulations revealed that deforming wings produce more lift and a comparable amount of thrust at a much higher efficiency than the rigid wings. This indicates that wings on the MAV scale can have improved efficiency if they are designed to allow a particular deformation pattern." (Authors)] Address: Shumway, N., Univ. Maryland, College Park; Stuart J. Laurence, Univ. of Maryland, College Park

**17308.** Shumway, N.M. (2019): Wing kinematics, deformations, and aerodynamics of dragonflies in free flight. Ph.D. thesis, Faculty of the Graduate School, University of Maryland, College Park: 131 pp. (in English) ["The development of Micro Aerial Vehicles (MAVs) has led researchers to study insects in order to better understand aerodynamic mechanisms and wing kinematics that achieve high performance flight at small scales. Dragonflies in particular are a good candidate for study, as their size is comparable to the target size of MAVs and they are able remain stable while flying in highly variable conditions. To better understand undisturbed steady flight and gust response of dragonflies, experiments were conducted to measure detailed wing kinematics and deformations in free flight both through a quiescent environment and when encountering a lateral gust. A custom testing environment was developed in which dragonflies would fly through an enclosed area with high-speed cameras capturing both their body motion and that of markers placed on their wings. Due to the nature of the setup and how the dragonflies were released, they would frequently fly while inverted rather than upright and a comparison between upright and inverted flight is included in this work. During inverted flight the tested specimens flew in such a way that their wings had a similar orientation in the global reference frame to that of the wings in the upright flights. The two primary kinematic variables that were changed to produce this result were the wing pitch angle and the body elevation angle. In addition, the dragonflies modulated the amount of time spent in the downstroke versus the upstroke so that in either case their wings spent more time moving down in the global frame. When dragonflies encountered a lateral gust, they increased the pitching of their windward wings, using left-right asymmetric kinematics to maintain a straight flight path through the disturbance. From these experimental data, models were developed for both the wing kinematics and the wing deformations, and these were incorporated into flapping wing simulations using the OVERTURNS computational fluid dynamics (CFD) code. Two sets of such CFD simulations were run: one of rigid wings and the other of deforming wings. For both rigid and deforming wings, the interaction between the fore- and hindwing increased the force production on both wings when compared to fore- and hindwings in isolation. The largest differences between isolated and tandem wings were seen for the hindwing as it passed through the wake of the forewing. The wing deformations slightly decreased the total force production, compared to the rigid wings, by reducing the amount of flow separation on the bottom of the wing during the upstroke. The impact of the camber deformation, during the body-relative downstroke, was

dependent on the specific wing kinematics. Though the total force produced decreased, the wing deformations substantially increased the efficiency for both wings." (Author)] Address: not stated

**17309.** Sibley, F.; Paseka, J.; Beckemeyer, R (2019): The Dragonflies and Damselflies of Nebraska. Zea E-Books. 78: III, 95 pp. (in English) ["The Nebraska odonate list has 109 species in Zygoptera with 47 species and Anisoptera with 62 species. Nebraska had been very poorly surveyed prior to 2005 and 63 counties had fewer than 10 records. By 2017 the number of county records had nearly quadrupled, to over 3000 records, the average county total had increased from 9 to 33 and all counties had at least 21 records. An effort was made to collect data more or less uniformly from all 93 Nebraska counties. The areas with intense corn and soybean farming, eastern and southcentral areas, are low in diversity (21-30 species per county), the southeast and western half of the state are higher (31-40 species) and the northwestern and northern Sandhill counties are the richest with more than 50 species per county. The present state list of 109 species represents 12 additions since 1998. Eleven additional species have been reported from the state, but are considered invalid or have been re-identified. This paper presents a short history of odonate study in Nebraska and an analysis of the data for the 109 species recorded in Nebraska to date. Distribution maps by county are included for each identified species." (Authors)] Address: Fred Sibley: fcsibley@empacc.net

**17313.** Slimani, N.; Sánchez-Fernández, D.; Guilbert, E.; Boumaïza, M.; Guareschi, S.; Thioulouse, J. (2019): Assessing potential surrogates of macroinvertebrate diversity in North-African Mediterranean aquatic ecosystems. *Ecological Indicators* 101: 324-329. (in English) ["Highlights: •Macroinvertebrate taxa are assessed as surrogates of aquatic biodiversity in Africa. •We found congruence among their patterns of species richness and composition. •Higher-taxa (mainly genus) can be used to predict species diversity. •We propose the use of Ephemeroptera and Coleoptera at genus level as surrogates. Abstract: The need to use surrogates of biodiversity is quite relevant in threatened habitats harboring high values of biodiversity, such as the Mediterranean aquatic ecosystems. In this study, we assess the performance of eight macroinvertebrate groups (Coleoptera, Heteroptera, Odonata, Trichoptera, Plecoptera, Ephemeroptera, Crustacea, and Mollusca) as surrogates of the whole aquatic macroinvertebrate assemblage in 49 localities from Northern Africa (Tunisia). Specifically, we aimed to test i) the congruence of the patterns of species richness and composition among these eight groups (at species level) in order to propose which groups could be accurate as indicators of diversity of the whole community, and ii) if higher-taxon levels (genera or families) are suitable for predicting overall species richness and composition in these ecosystems. In total, we found 72 families, 157 genera and 280 species. Our results show a high congruence between the patterns of species richness and composition of Ephemeroptera, Coleoptera (even at higher taxonomic levels, especially genus) and the whole community. Thus, we recommend the use of these two groups as surrogates of macroinvertebrate diversity in inland aquatic ecosystem in the study area. They can be used for both i) the rapid and inexpensive monitoring of biodiversity in aquatic ecosystems and ii) conservational studies in order to identify areas

with the highest values of freshwater biodiversity in Mediterranean areas. Finally, high values of congruence among taxonomic levels were found suggesting that, in general, higher taxa can be used as biodiversity surrogates for cost-effective practical survey in Mediterranean aquatic ecosystems from Northern Africa." **17314.** Smith, G.R.; Harmon, J.J. (2019): Differential oviposition and offspring success of gray treefrogs in the presence of an invasive fish. *Ecosphere* 10(2). Article e02612: 9 pp. (in English) ["Females often decide where to place their eggs or offspring based on the relative risks and benefits of a location. One trade-off may be between ovipositing with predators and ovipositing with competitors. Many amphibians show risk-sensitive oviposition and select oviposition sites based on offspring performance. We examined differential oviposition and offspring success by gray treefrogs (*Hyla versicolor*) in response to the presence of caged or free-ranging invasive western mosquitofish (*Gambusia affinis*) using cattletank mesocosms as experimental ponds. Our experiment sought to answer these questions by comparing the number of eggs laid and tadpoles produced among the experimental treatments: (1) Do gray treefrogs exhibit risk-sensitive oviposition? and (2) What is the relative importance of pre-colonization and post-colonization consumptive and trait-mediated effects of western mosquitofish? Gray treefrogs laid more eggs in control and caged predator mesocosms than in free-ranging predator mesocosms. At the end of the experiment, there were more tadpoles in control and caged predator mesocosms than in free-ranging predator mesocosms. Proportional yield was lower in free-ranging predator mesocosms than control and caged predator mesocosms. Eggs were laid 7.8 d earlier in control mesocosms than caged and free-ranging predator mesocosms. Western mosquitofish therefore had a negative effect on the successful colonization of experimental ponds by gray treefrogs, most likely through direct physical interactions. Our results also suggest gray treefrogs shift oviposition preferences as the number of conspecifics reaches a threshold where competition risk outweighs predation risk. Western mosquitofish therefore have great potential to affect the distribution of gray treefrogs through pre- and post-colonization effects." **17315.** Sniegula, S.; Nsanzimana, J.; Johansson, F. (2019): Predation risk affects egg mortality and carry over effects in the larval stages in damselflies. *Freshwater Biology* 64(4): 778-786. (in English) ["1. The non-consumptive predator effect may incur physiological costs that affect growth and development and ultimately survival. While studies have shown that the effect can affect development and growth in organisms with complex life cycles, we have limited knowledge on the effect in the egg and early larval stage. 2. Here, we used a laboratory experiment to examine how the presence of chemical cues, a non-consumptive predator effect, from an aquatic predator,

perch, affected hatching success of larvae in three species of damselfly, *Ischnura elegans*, *Coenagrion pulchellum*, and *Enallagma cyathigerum*. In addition, we examined how exposure to predation risk in the early larval stages affected growth in the late larval stages of *I. elegans*. 3. We found that the presence of chemical predator cues (1) increased egg mortality in all three species, (2) caused earlier hatching of eggs in one species, no change in a second species and a delay in egg hatching in a third species. We also found that predator cues have the potential to cause a carryover effect from early larval stages to late larval stages in terms of larval growth rate. 4. The addition of non-consumptive predator cues in the form of fish water caused higher algal growth than in the control experimental containers, and we suggest that this algal growth has the potential to confound predator stress cues. 5. Our results show that the non-consumptive predator effects affect survival and growth, and hence they have the potential to affect predator-prey dynamics in natural systems. Future studies on such effects in aquatic systems should consider confounding stressors, such as algae, fungi, oxygen, and nutrients levels, that might come with the addition of predation cues in water and thus add additional stress." **17316.** Solis, M.; Arias, M.; Fanelli, S.; Bonetto, C.; Mugni, H. (2019): Agrochemicals' effects on functional feeding groups of macroinvertebrates in Pampas streams. *Ecological Indicators* 101(6): 373-379. (in English) ["Highlights: • Nutrients and endosulfan concentrations were higher in streams adjacent to crops. • Total invertebrate abundance and taxonomic richness were lower in cropped sites. • Shredders were dominant at the reserve and livestock streams. • Scrapers and predators were dominant at the cultivated sites. • Land use is causing change in functional feeding groups' composition. Abstract: The use of agrochemicals in Argentina has increased over the last decades and may represent an environmental risk for adjacent water bodies. In this work we study the invertebrate assemblages in nine streams sampled at 11 sites with different land use on the adjacent plots in the years 2011–2014. Four sites were located inside a biosphere reserve, 4 sites were located adjacent to livestock plots and the other 3 sites were adjacent to cropped plots. The taxa composition was assessed and sorted into functional feeding groups: shredders, gatherers, filterers, scrapers and predators. Significant differences were detected among the functional feeding groups according to the use given to the adjacent land. Total density and taxonomic richness were significantly higher in the streams next to the reserve and livestock sites than in those adjacent to cropped plots; there were no differences between the first two. Gatherers and shredders density was significantly higher in the reserve and livestock than in the cropped sites. Scrapers and predators were the best represented at the cropped sites. Nutrient concentrations in water and endosulfan concentrations in the bottom sediments were also higher at the cultivated sites, suggesting that agrochemical loads from land cultivation caused the observed differences in composition." **17317.** Spyra, A.; Strzelec, M. (2019): The implications of the impact of the recreational use of forest mining ponds on benthic invertebrates with special emphasis on gastropods. *Biologia* 74: 981-992. (in English) ["The relationships between the distribution and diversity patterns of benthic invertebrates in forest ponds used for different recreational activities were examined in this study. The study was based on sampling of benthic invertebrates, plant coverage, physical and chemical analysis of water samples and multivariate species analysis. Mining ponds varied in their solution chemistry and plant cover, with those used for recreation having significantly lower invertebrate occurrences (755 ind. m<sup>-2</sup>) compared to ponds with no recreational use (2629 ind. m<sup>-2</sup>). Statistically significant differences were also observed in the density of Oligochaeta, Hirudinea, Coleoptera, Trichoptera and Diptera between the two types of ponds. Overall, gastropods were more diverse and abundant in ponds not used for recreation. This appeared to relate strongly to plant cover, since cover was greatly reduced in recreational ponds, although plant diversity was enhanced. Density and diversity of benthic invertebrates was also observed to differ in relation to the kind of recreational use involved (recreational angling, swimming, power boating) although this was not quantified. The occurrence of freshwater snails primarily depended on the Ca concentration, the conductivity of the water and plant cover, but recreational disturbance appeared to reduce abundance where it occurred and was related to a reduction in overall plant cover." **17318.** Sreelekshmi, S.; Abhilash, R. (2019): A preliminary study on the odonate diversity of Randapuncha wetland, Kulanada, Patanamthitta district, Kerala. *Science Chronicle* 8 (1&2): 1-8. (in English) ["A study was carried out to assess the Odonata fauna of Randam Puncha wetland near Kulanada in Pathanamthitta district from the first week of April to second week of June 2016. A total of 18 species of Odonates representing 3 families (Libellulidae, Gomphidae, Coenagrionidae) were recorded from Randam Puncha, Kulanada during the study period. *Acisoma panorpoides*, *Aethrimanta brevipennis*, *Brachydiplax chalybea*, *Rhyothemis variegata* and *Orthetrum sabina* were the common dragonflies spotted on the site. On the basis of total number of individuals recorded, Libellulidae was the most dominant family. The Shannon-Weiner diversity index recorded a higher value of 2.405 in Randam Puncha and the Margalef species richness was 2.409. The values of Pielou's evenness index 0.652 showed medium even distribution of species; the dominance index recorded was 0.895. Even though any rare or endangered species were not recorded in the present study, the Randam Puncha wetland showed rich odonate diversity and abundance." **17320.** Stavenga, D.G.; Wilts, B.D. (2019): Measuring the refractive index dispersion of (un)pigmented biological tissues by Jamin-Lebedeff interference microscopy. *AIP Advances* 9, 085107 (2019); <https://doi.org/10.1063/1.5113485>: 9 pp. (in English) ["Jamin-Lebedeff interference microscopy is a powerful technique for measuring the refractive index of microscopically-sized solid objects. This method was classically used for transparent objects immersed in various refractive-index matching media by applying light of a certain pre-designed wavelength. In previous studies, we demonstrated that the Jamin-Lebedeff microscopy approach can also be utilized to determine the refractive index of pigmented media for a wide range of wavelengths across the visible spectrum. The theoretical basis of the extended method was however only precise for a single wavelength, dependent on the characteristics of the microscope setup. Using Jones calculus, we here present a complete theory of Jamin-Lebedeff interference microscopy that incorporates the wavelength-dependent correction factors of the half- and quarter-wave plates. We show that the method can indeed be used universally in that it allows the assessment of the refractive index dispersion of both unpigmented and pigmented microscopic media. We illustrate this on the case of the red-pigmented wing of the damselfly *Hetaerina americana* and find that very similar refractive indices are obtained whether or not the wave-plate correction factors are accounted for." **17321.** Storari, A.P.; Pereira, D.; Furieri, K.S. (2019): New occurrences of dragonflies in the Atlantic Forest fragments of Santa Teresa, Espírito Santo, Brazil. *Revista Brasileira de Gestão Ambiental e Sustentabilidade* 6(13): 481-497. (in Eng-

lish, Portuguese) ["One of the greatest obstacles to biodiversity conservation is the lack of information to prioritize efforts on practical actions. This lack of information comes mainly from absence of inventories in many areas where few groups have reasonably complete databases. The distribution of the dragonfly fauna of Brazil is little known - only 29% of the Brazilian territory presents data about the richness of Odonata. In this contribution, a database of Odonata species of Santa Teresa Municipality was built, Espírito Santo State, Brazil. The database has 627 specimens registered, 77 species distributed in eight families and 38 genera, 40 of these species are common, one endemic of the State of Espírito Santo, and 19 endemic of Brazil. In relation to the measure of conservation, four species are present in the category Insufficient Data (DD), one present in the Nearly Endangered (NT) category, three species in the Vulnerable category (VU) and one in the category In Danger (EN). 25 species are considered new occurrences for the city. These results suggest that the fauna of the studied region deserves attention and points to the interest in implanting future conservation units in the region of Santa Teresa municipality." **17322.** Stretz, P.; Anderson, T.L.; Burkhart, J.J. (2019): Macroinvertebrate foraging on larval *Ambystoma maculatum* across ontogeny. *Copeia* 107(2): 244-249. (in English) ["Understanding community interactions, such as predator-prey dynamics, is vital for determining species viability. Outside of larger macroinvertebrate predators, such as crayfish and dragonfly larvae, there is a paucity of information regarding the effectiveness of other macroinvertebrate predators in consuming larval amphibians, especially caudate larvae, during aquatic life-stages within pond communities. In this study, we tested the ability of a suite of macroinvertebrate predators to consume Spotted Salamander larvae (*Ambystoma maculatum*) at two points during larval development. We tested the ability of macroinvertebrate predators belonging to the genera *Belostoma*, *Lestes*, *Notonecta*, and *Ranatra*, the families *Aeshnidae*, *Dytiscidae*, *Gomphidae*, *Gyrinidae*, *Hirudinae*, *Libellulidae*, and *Notonectidae*, or order *Trichoptera*, as well as larvae of *Rana clamitans*, to consume *A. maculatum* immediately after hatching and several weeks into their larval period across four separate experiments. We tested for significant differences in percent survival of *A. maculatum* among predator treatments using ANOVA. Across all trials, we found a significant effect of predator treatment. Both hatchling and larval *A. maculatum* were susceptible to predation by *Aeshnidae* and *Notonectidae*. In all other treatments, we observed low or zero mortality of hatchlings of *A. maculatum* and 100% survival of larvae of *A. maculatum*. As *Aeshnidae* and *Notonectidae* are both gape unconstrained predators, the increase in larval size did not appear to increase survival of *A. maculatum* due to increased escape performance. Overall, rates of predation are low for *A. maculatum* for most macroinvertebrates during the tested life stages, suggesting that predation by only a handful of invertebrate taxa and vertebrates contribute to high mortality

rates within this system." (Authors)] Address: Stretz, P., Division Biological Sciences, Univ. of Missouri, Columbia, Missouri 65211-7400, USA. Email: pipermstretz@gmail.com

**17323.** Takahashi, M.; Takahashi, Y.; Kawata, M. (2019): Candidate genes associated with color morphs of female-limited polymorphisms of the damselfly *Ischnura senegalensis*. *Heredity* 122: 81-92. (in English) ["Many Odonata species exhibit female-limited polymorphisms, where one morph is similar to the conspecific male in body color and other traits (andromorph), whereas one or more other morphs differ from the male (gynomorphs). Here we investigated the differentially expressed transcripts (DETs) among males and two female morph groups (gynomorphs and andromorphs) using RNA-seq to identify candidate transcripts encoding female-limited polymorphisms in *I. senegalensis*. Seven DETs that had significantly different expression levels between males and gynomorphs, but not between males and andromorphs, were identified. The expression levels of four of these candidate genes, doublesex (*dsx*), black, ebony, and chaoptin (*chp*), were selected for further analysis using qRT-PCR. Sequence analysis of the *dsx* amplicons revealed that this gene produced at least three transcripts. Two short transcripts were mainly expressed in males and andromorphs, whereas the long transcript was specifically expressed in both morph female groups; that is, the expression pattern of the *dsx* splice variants in andromorphs was an intermediate between that of males and gynomorphs. Because the *dsx* gene functions as a transcription factor that regulates the sex-specific expression of multiple genes, its splice variants in *I. senegalensis* may explain why the andromorph is female but exhibits some masculinized traits. Because we did not detect different coding sequences of the candidate genes among the different morphs, a diallelic genomic region controlling alternative splicing of *dsx*, thus determining female-limited polymorphism in *I. senegalensis* most likely lies in a non-coding region of the *dsx* gene or in a gene upstream of it." **17325.** Tennessen, K.J. (2019): Dragonfly nymphs of North America. An identification guide. Springer: 620 pp. (in English) ["This monograph is the first of its kind devoted entirely to the dragonfly nymphs of North America north of Mexico,

the focus being accurate identification of the 330 species of Anisoptera that occur in the region. Nymphal external morphology is described and illustrated in detail, and all terms needed to navigate the dichotomous keys are defined. Species are tabulated with references that provide the most detailed, accurate descriptions for each; species that are inadequately described are so indicated. The key separating the seven families in the region contains several new characters. The families are then covered separately: Aeshnidae (13 genera), Gomphidae (17 genera), Petaluridae (2 genera), Cordulegastridae (2 genera), Macromiidae (2 genera), Corduliidae (7 genera), and Libellulidae (29 genera). Each family is further characterized, followed by a generic key. A drawing of the habitus and diagnostic details for each genus are provided, along with additional diagnostic remarks and notes on habitat and life cycle; for each genus, a map shows its geographic distribution in North America. Full-grown nymphs of all known species of each genus are keyed and diagnosed; characters that apply to earlier instars are noted. Morphological variation in character states was analyzed in order to assess the reliability of previously utilized characters and to discover new characters. Most of the characters used to distinguish all levels of taxa are illustrated; a total of 702 figures, comprising 1,800 original drawings, along with selected photographs where necessary for clarity, accompany the keys. Measurements of total length, head width, and other variables for each species are provided in tables. Difficulties with past keys and descriptions, including errors, omissions and other shortcomings, are addressed. The importance of nymph characters in helping solve generic and specific distinctions and their role in phylogenetic studies is emphasized. Methods for collecting, rearing, and preserving dragonfly nymphs and exuviae are presented. The final chapter discusses research opportunities on North American Anisoptera nymphs, including taxonomic needs, studies on structure and function, life history and microhabitat, water quality indices and conservation efforts. The habitus drawings of all genera are arranged according to family in five plates (Appendix I); although the book is intended as a lab manual, these plates conveniently allow for comparison based on nymph shape making field identification to genus possible in many cases. Appendix II contains a brief history of dragonfly nymph studies in North America. A glossary and an index to scientific names are included." **17326.** Termaat, T.; van Strien, A.J.; van Grunsven, R.H.A.; De Knijf, G.; Bjelke, U.; Burbach, K.; Conze, K.-J.; Goffart, P.; Hepper, D.; Kalkman, V.J.; Motte, G.; Prins, M.D.; Prunier, F.; Sparrow, D.; van den Top, G.G.; Vanappelghem, C.; Winterholter, M.; Wallis DeVries, M.F. (2019): Distribution trends of European dragonflies under climate change. *Diversity and Distributions* 25 (6):936–950. ["Aim: Poleward range shifts of species are among the most obvious effects of climate change on biodiversity. As a consequence of these range shifts, species communities are predicted to become increasingly composed of warm-dwelling species, but this has only been studied for a limited number of taxa, mainly birds, butterflies and plants. As species groups may vary considerably in their adaptation to climate change, it is desirable to expand these studies to

other groups, from different ecosystems. Freshwater macroinvertebrates, such as Odonata, have been ranked among the species groups with highest priority. In this paper, we investigate how the occurrence of dragonflies in Europe has changed in recent decades, and if these changes are in parallel with climate change. Location: Europe. Methods: We use data from 10 European geographical regions to calculate occupancy indices and trends for 99 (69%) of the European species. Next, we combine these regional indices to calculate European indices. To determine if changes in regional dragonfly communities in Europe reflect climatic warming, we calculate Species Temperature Indices (STI), Multi-species Indicators (MSI) and Community Temperature Indices (CTI). Results: 55 of 99 considered species increased in occupancy at European level, 32 species remained stable, and none declined. Trends for 12 species are uncertain. MSI of cold-dwelling and warm-dwelling species differ in some of the regions, but increased at a similar rate at European level. CTI increased in all regions, except Cyprus. The European CTI increased slightly. Main conclusions: European dragonflies, in general, have expanded their distribution in response to climate change, even though their CTI lags behind the increase in temperature. Furthermore, dragonflies proved to be a suitable species group for monitoring changes in communities, both at regional and continental level." **17328.** Thaokar, N.R.; Verma, P.R.; Andrew, R.J. (2019): Moulting pattern and mortality during the final emergence of the Coromandel Marsh Dart Damselfly *Ceragrion coromandelianum* (Zygoptera: Coenagrionidae) in central India. *Journal of Threatened Taxa* 11(13): 14672-14680. (in English) ["The final emergence of *C. coromandelianum* was studied for 50 days (22 January–12 March, 2011) from the botanical garden of Hislop College, Nagpur, India, (a semi controlled site) where

small underground cement tubs/tanks are used to grow macrophytes by the Botany department. In *C. coromandelianum* emergence is asynchronous, diurnal and occurs between 07.00h and 18.00h. Stage-I starts when the ultimate instar nymph of *C. coromandelianum* leaves the water body, searches for a suitable place and then begins to shudder its body to detach the trapped pharate from the nymphal exuvia. The pharate exerts pressure on the thoracic tergites to split the cuticle. Stage-II starts when the head and thorax of the pharate emerges out of the split exuvia. The pharate struggles to remove its trapped body from the nymphal exuvia. During Stage-III, the wings expand but are opaque; pigmentation of the body occurs simultaneously all over the body. Soon the whole body develops its species specific coloration while the expanding wings gain transparency, unfold and separate out and now the imago is ready for its maiden flight. Stages I, II, and III occupy 31.66%, 11.73%, and 56.60% of the total moulting period, respectively. A total of 243 emergences occurred during the observation period, 158 emergences occurred in tanks containing *Pistia stratiotes*, while 65 emergences in tubs containing *Nymphaea nouchali* indicating that *C. coromandelianum* prefers *P. stratiotes* over *N. nouchali* for oviposition. 20 deaths were recorded during the present observation. Failure to moult (15%) and failure to emerge completely out of the exuvia (85%) were the two reasons for mortality." (in Spanish, with English summary) ["Odonata of the Sierra Nevada de Santa Marta, Colombia: A preliminary list. We raised a list of Odonata species and genera from eight rivers of the Sierra Nevada of Santa Marta (SNSM) after the revision of scientific articles, theses, and specimens deposited in the Centro de Colecciones de la Universidad del Magdalena (CEBUMAG). We found 38 species distributed in 35 genera and eight families. The Libellulidae family presented the greatest richness (14 genera) and the widest range of altitudinal distribution (between 50 and 2,800 m a.s.l.) found in all vegetable coverages. The Gaira River exhibited the greatest wealth among the revised rivers with 26 genera of which eight are exclusive to the basin while in the Ranchería River only *Progomphus* was registered. *Argia* and *Brechmorhoga* had a wide spatial distribution as they were recorded in six rivers. The review revealed the lack of studies on the eastern and southwestern slopes of the Sierra Nevada de Santa Marta, so it is recommended to carry out taxonomic and biodiversity work to contribute to the knowledge of Odonata in the Colombian Caribbean." (2019): Experiencia de aprendizaje no-formal para alumnado de Educación Primaria y Secundaria sobre libélulas (Insecta: Odonata) en el marco de la Semana de la Ciencia. *Boletín de la Sociedad Entomológica Aragonesa* 65: 227-230. (in Spanish, with English summary) ["Science and Technology Week is probably the largest event of scientific communication to society in Spain. A non-formal learning activity on the dragonflies was included among the activities proposed by the University of Oviedo in three academic years for Primary and Secondary Education in Asturias. The experience is described; the contributions presented by the Primary Education students are analysed in order to assess their concept of dragonfly and the diagnostic characteristics of odonates and those species that they considered most interesting, their behaviour and habitats. The students' questions and their learning interests about these insects are discussed, especially in the final years of Primary Education and in Secondary Education, as well as possible ways of motivating biodiversity learning as suggested by their questions. Student participation was higher in Primary Education and the first years of Secondary Education (especially when there had been a previous directed inquiry), and very low in the final years of Secondary Education." (in English) ["An extensive survey of odonates were conducted in Khulna University Campus from August 2014 to August 2018. In total 40 species belonging to 24 genera and 4 families of odonates were recorded. Anisoptera contributed with 25 species belonged to 17 genera and two families and Zygoptera contributed with 15 species of 7 genera and two families. Libellulidae found most dominant family of odonates by contributing 24 species over Coenagrionidae, Platycnemididae, and Gomphidae. Species richness increased in monsoon

and 95% of the total species count were recorded in June-October. In winter, species richness declined at lowest number." (Authors)] Address: Md. Sajjad Hossain Tuhin, Forestry & Wood Technology Discipline Khulna Univ., Khulna, Bangladesh

**17337.** Tuskavetska, I. (2019): Diversity and modern study of Odonata in the territory of Lubny district. Education and Science 1(26): 63-70. (in Ukrainian, with English summary) ["The article outlines the main river biocenoses of Lubny district (Ostapivka village, Bopodarivka village, Pisky tillage and Brovarky village), meadows, swamps, marshy lakes, coastal areas of the Sula and Viazovets rivers. The quality of representativeness of the species diversity of the Odonata fauna has been estimated by calculating their dominant index and distribution index in the main biotopes of the studied territory. 25 species of Odonata were caught with 6 families (Libellulidae, Calopterygidae, Coenagrionidae, Gomphidae, Lestidae, Aeshnidae). The most widespread species of this area are Coenagrion puella, C. pulchellum, Calopteryx splendens; common - Ischnura elegans, Lestes virens, L. sponsa, Libellula depressa, Aeshna grandis; rare are Aeshna juncea, Sympetrum danae and Libellula quadrimaculata. The most rich in species composition of the estates of the study area are the coastal areas of the river Viazovets and floodplain meadows with Bohodarivka, and the least numerous - forest glades, coastal areas of the Sula river in the village of Brovarky. Actively fly in the spring-summer period Calopteryx virgo, C. splendens, Coenagrion puchellum, C. puella, and the least in the summer-autumn - Sympetrum vulgatum and S. sanguineum." **17338.** Tyrell, M. (2019): Hatching of submerged eggs of Chalcolestes viridis (Vander Linden) (Willow Emerald Damselfly). J. Br. Dragonfly Society 35(2): 39-47. (in English) ["C. viridis showed a major expansion of range in 2016 (Parr, 2017), resulting in its discovery at a small pond in Finedon Pocket Park, Northamptonshire in October of that year. In 2017 adults and oviposition were recorded at Finedon into a set of Willow trees (Salix spp.) growing in the water. During the very wet winter of 2017-2018, the pond flooded and the Willows were completely submerged such that no sign of them was obvious by April 2018. Adults were again recorded in 2018 and, during routine recording, some empty scars from 2017 were noted on previously submerged Willow branches. Images taken of these scars alongside those of fresh egg scars and those known to have hatched outside of the water confirmed that the eggs of this species can tolerate submersion during hatching and therefore hypoxic conditions are not required to stimulate egg hatching; neither do they inhibit it. Other observations suggest that egg hatching in C. viridis is stimulated by photoperiod and/or temperature." (Author)] Address: Tyrell, M., 8 Warwick Close, Raunds, Northamptonshire, NN9 6JH

**17339.** Tyrell, M. (2019): Coenagrion pulchellum (Vander Linden) (Variable Damselfly) in Northamptonshire VC32: A review of preferred breeding habitats. J. Br. Dragonfly Society 35(2): 70-78. (in English) ["The habitat preferences of C. pul-

chellum are not well understood, with apparently suitable habitat not selected for breeding. In Northamptonshire, this is a rare species, known from only three sites, one longstanding (Maxey Pits), one discovered in 2018 (Weldon Woodland Park) and the third discovered in 2019 (Wicksteed Park). This review examines the habitats chosen by C. pulchellum and finds that there are many characteristics that are shared with other sites that do not host this species, but that one feature - the presence of flowering lillies (Nymphaea spp.) - is common to all three of the host sites but rare at other sites. C. pulchellum appears to use these exclusively for oviposition, suggesting that the habitats in Northamptonshire, despite its rich matrix of well-vegetated gravel pits, are not suitable unless they possess this type of lilly pad." **17340.** Üveges, B.; Szederkényi, M.; Mahr, K.; Móricz, A.M.; Krüzselyi, D.; Bókony, V.; Hoi, H.; Hettyey, A. (2019): Chemical defense of toad tadpoles under risk by four predator species. Ecology and Evolution. 2019: 13 pp. (in English) ["Many organisms use inducible defenses as protection against predators. In animals, inducible defenses may manifest as changes in behavior, morphology, physiology, or life history, and prey species can adjust their defensive responses based on the dangerousness of predators. Analogously, prey may also change the composition and quantity of defensive chemicals when they coexist with different predators, but such predator-induced plasticity in chemical defenses remains elusive in vertebrates. In this study, we investigated whether tadpoles of the common toad (Bufo bufo) adjust their chemical defenses to predation risk in general and specifically to the presence of different predator species; furthermore, we assessed the adaptive value of the induced defense. We reared tadpoles in the presence or absence of one of four caged predator species in a mesocosm experiment, analyzed the composition and quantity of their bufadienolide toxins, and exposed them to free-ranging predators. We found that toad tadpoles did not respond to predation risk by upregulating their bufadienolide synthesis. Fishes and newts consumed only a small percentage of toad tadpoles, suggesting that bufadienolides provided protection against vertebrate predators, irrespective of the rearing environment. Backswimmers consumed toad tadpoles regardless of treatment. Dragonfly larvae were the most voracious predators and consumed more predator-naive toad tadpoles than tadpoles raised in the presence of dragonfly cues. These results suggest that tadpoles in our experiment had high enough toxin levels for an effective defense against vertebrate predators even in the absence of predator cues. The lack of predator-induced phenotypic plasticity in bufadienolide synthesis may be due to local adaptation for constantly high chemical defense against fishes in the study population and/or due to the high density of conspecifics." with English summary) ["A mature female specimen of *S. darwinianum* with a deformed abdomen was captured in Oki island, Shimane prefecture. Forth to eighth abdominal segments of the specimen are abnormally short, while the other segments, including the genital organs, are normal. It is interesting that such a deformed individual is able to survive in a natural environment." (Author)] Address: not stated.

**17342.** Uz, A.G. (2019): A research of intra-species wing variations in *Orthetrum brunneum* (Fonscolombe, 1837) (Insecta: Odonata). Hitit University, Graduate School of Natural and Applied Sciences: XIII + 49 pp. (in Turkish, with English summary) ["Geographical and ecological diversity positively affect in-species diversity in different populations of the same species. Dozens of a ecological barrier, especially in Turkey to investigate the effect of Anatolia Diagonale terms of biodiversity has increased in recent years. The aim of this study is to determine the variations of wing morphology of *O. brunneum* species in different populations by using geometric morphometry method. For this purpose, intra-species wing variations of three different *O. brunneum* populations collected from Tunceli province to the east of Anatolia Diagonale and Yozgat province to the west of Anatolia Diagonale and Western Mediterranean Region were investigated. Statistical analysis (Tukey HSD) showed that a large number of biometric characteristics differed statistically among these taxa ( $P < 0.05$ ). According to Principal Component Analysis (PCA), 4 components with total variance Eigen value over 1 can be explained among these groups and samples of Tunceli population are separated from other populations by Discriminant Function Analysis (DFA). These findings support the idea that Anatolian Diagonale may be a barrier for populations of *O. brunneum*. Therefore, it is necessary to study and take into account the variational situations of Anatolian samples." (Author)] Address: not stated

**17343.** Vandromme, M.; Trekels, H.; Ruiz, N.S.; Somarriba, E.; Vanschoenwinkel, B. (2019): Exploring the suitability of bromeliads as aquatic breeding habitats for cacao pollinators. *Hydrobiologia* 828: 327-337. (in English) ["Bromeliads are common plants in the Neotropics. Being epiphytic, they are often incorrectly considered as parasites and removed from agroforestry systems. However, their water-filled leaf axils provide habitats for a diverse group of aquatic organisms, potentially including cacao pollinating dipterans which could be beneficial to local farmers. Thus far, it is unclear how frequently and abundantly potential pollinators occur in bromeliads in cacao plantations. Therefore, we investigated the aquatic fauna in different types of bromeliads in Nicaraguan cacao agroforestry systems. Our main goal was to study the impact of bromeliad morphology and vertical position on aquatic biodiversity with particular attention for larvae of presumed cacao pollinators. Aquatic biodiversity was higher in larger bromeliads and in bromeliads positioned closer to the ground. Particularly invertebrates without flying life stages were deficient in elevated bromeliads suggesting dispersal limitation. Potential cacao pollinators occurred in 66% of the bromeliads and were most abundant in bromeliads with larger tanks that were located higher in the canopy rather than on the plantation floor. We conclude that larvae of cacao pollinators can be common and relatively abundant inhabitants

of tank bromeliads in cacao trees, and it is likely that preserving these habitats could boost local pollinator abundances." (Authors)] Address: Vandromme, M., Community Ecology Lab, Dept of Biology, Vrije Univ. Brussel (VUB), Brussels, Belgium

**17344.** Vary, P.; Sansault, E. (2019): Première observation de *Trithemis annulata* en région Centre-Val de Loire (Odonata: Libellulidae). *Martinia Tome* 34(1-2): 56. **17346.** Verheyen, J.; Stoks, R. (2019): Temperature variation makes an ectotherm more sensitive to global warming unless thermal evolution occurs. *Journal of Animal Ecology* 88(1): 624-636. (in English) ["1. To assess long-term impacts of global warming on species there is growing interest in latitudinal intra-specific patterns in thermal adaptation. Yet, while both mean temperatures and daily temperature fluctuations (DTFs) are expected to increase under global warming, latitudinal differences in the effects of DTFs have not been documented. 2. We tested whether low-latitude populations of an ectotherm deal better with greater DTF than high-latitude populations, especially at a high mean temperature close to the optimal temperature for growth where DTF causes exposure to extreme high temperatures. We evaluated the impact of DTFs when assessing the effect of gradual thermal evolution at the high latitude with a space-for-time substitution. 3. We compared effects of both mean temperatures (20°C and 24°C) and DTFs (constant = 0°C, low = 5°C and high = 10°C) on growth rates between low-latitude and high-latitude populations of *Ischnura elegans* in a common-garden experiment. 4 DTFs, if anything, reduced growth and were generally stressful as indicated by reductions in body condition, antioxidant defense and metabolic rate, and increases in oxidative damage. Most negative effects of DTFs were only present at a mean of 24°C when

too high temperatures were reached during a daily cycle. Notably, while 4°C warming was beneficial in terms of growth rate at both latitudes at a constant temperature regime, this changed in a negative effect at high DTF. Moreover, this modulating effect of the mean temperature by DTF differed between latitudes indicating local thermal adaptation. While 4°C warming at low DTF still caused faster growth in low-latitude larvae, it already slowed growth in high-latitude larvae. This supports the emerging insight that warming would increase growth in high-latitude larvae in absence of DTF, yet would decrease growth in the more realistic scenarios with DTF. In contrast, a space-for-time substitution approach suggested that under gradual thermal evolution, the evolved high-latitude larvae would no longer suffer a growth reduction in the presence of DTF. 5. Our study provided important proof-of-principle that jointly integrating gradual thermal evolution and the expected increase in DTF generates opposing predictions of effects of global warming on this ectotherm." **17351.** Villalobos-Jiménez G.; Hassall, C. (2019): Wing shape patterns among urban, suburban, and rural populations of *Ischnura elegans* (Odonata: Coenagrionidae). *International Journal of Odonatology* 22(1): 37-49. (in English) ["Odonata are among the most efficient flying insects. However, fragmentation of the landscape can increase distance between habitats and affect costs of dispersal, thus shaping phenotypic patterns of flight-related traits, such as wing shape, wing loading and wing size. Urban landscapes are highly fragmented, which limits dispersal among aquatic habitats. Hence, strong selective pressures can act upon urban populations in favour of individuals with increased flight performance or may lead to the reduction in dispersal traits. Here, we explore differentiation in morphological flight-related traits among urban, suburban, and rural populations of *I. elegans*, which is one of the most abundant species in both urban and rural ponds in Europe. We sampled 20 sites across Leeds and Bradford, UK, in an urban-to-rural gradient from June to August 2014 and 2015 (Nmales = 201, Nfemales = 119). We compared wing shape

among different land use types using geometric morphometrics. Other wing properties analysed were wing aspect ratio, wing loading and wing centroid size. Unexpectedly, no significant effect of urban land use was found on wing shape. However, wing shape differed significantly between males and females. Additionally, females showed significantly larger wing centroid sizes ( $P < 0.001$ ), increased wing loading (forewings:  $P = 0.007$ ; hind wings:  $P = 0.002$ ) and aspect ratio ( $P < 0.001$ ) compared to males across all land use types. Possible mechanisms driving these results are further discussed." (Authors)] Address: Hassall, C., School of Biology, Univ. of Leeds, Woodhouse Lane, LS2 9JT, Leeds, UK. **17352.** Villalona, V.C. (2019): Diversidad e importancia económica de las libelulas (Insecta: Odonata) en la Escuela Agrícola Panamericana a Zamorano, Honduras. Proyecto especial de graduación presentado como requisito parcial para optar al título de Ingeniera Agrónoma en el Grado Académico de Licenciatura. Escuela Agrícola Panamericana, Zamorano, Honduras: V + 34 pp. (in Spanish, with English summary) ["Dragonflies are primary or secondary predators that can be beneficial or detrimental specific to the environment in which they are found. The research taking place within the thesis seeks to find diversity within the Odonata order in Zamorano, study its importance on campus and create an identification guide that facilitates the recognition of some of the species. All data from field collections and reviews of the reference material of the Insects Collection will be specified within the body paragraphs of the thesis. The collection was carried out in lotic and lentic ecosystems during the months of May through August. For 10 weeks, eight hours per week per ecosystem was put forth by two people, where specimens were collected with an entomological network. Within the Insect Collection, the data of all the specimens collected in Zamorano was captured by registering all the information on the collection labels. We found a total of 57 species of dragonflies in Zamorano, 17 of which were obtained within the field collections. Of the species collected (11 Anisoptera and 6 Zygoptera), three of the Anisoptera and one of the Zygoptera species were not reported for Zamorano. The Anisoptera include *Brachymesia furcata*, *Erythemis peruviana*, *Erythrodiplax basifusca* and the one Zygoptera was *Argia joergenseni*. Species such as *Pantala flavescens* and *Brachmesia furcata* are threats in the livestock sector. Anisoptera are vulnerable to *Prosthogonimus* spp, a trematode known for being able to affect birds in pastures. An identification guide is presented for the collected species that helps the knowledge of insect diversity in Zamorano ecosystems." (Authors) Address: not stated

**17353.** Wang, J.-D.; Wang, C.-Y.; Zaho, M.; He, Z.; Feng, Y. (2019): The complete mitochondrial genome of an edible aquatic insect *Epophtalmia elegans* (Odonata: Corduliidae) and phylogenetic analysis. *Mitochondrial DNA Part B*, 4:1: 1381-1382. (in English) ["*E. elegans* is one of edible aquatic insects in Southwest China. In this study, the complete mitochondrial genome *E. elegans* was determined. The mitogenome is 15,719 bp in size (GenBank accession number MK522522), including 13 protein-coding (PCGs), 22 transfer RNAs, 2 ribosomal RNAs

genes, and a noncoding D-loop region. The overall base composition of *E. elegans* mitogenome is 40.40% for A, 15.09% for C, 33.18 for T, and 11.33% for G, with a high AT bias of 73.58%. This mitogenome data can contribute to our understanding of the phylogeny and evolution of *E. elegans*." **17355.** Wang, Z.J.; Melfi Jr, J.; Leonardo, A. (2019): Dragonfly's Righting Reflex. *Bulletin of the American Physical Society*; 72nd Annual Meeting of the APS Division of Fluid Dynamics. Saturday–Tuesday, November 23–26, 2019; Seattle, Washington. Session G27: Biological Fluid Dynamics: Insect Flight II. 3:48 PM–5:32 PM, Sunday, November 24, 2019. Room: 609. Abstract: G27.00001: ["Insects must right themselves in air so as not to fall. Exactly how insects manage to right themselves via a succession of neural-motor actions is a large mystery in neural behavior of animals. The goal of our work is to find clues about their internal actions through careful measurements and analyses of their aerial acrobatics, in the case of a dragonfly. A dragonfly falling upside down can right itself in about 200ms. During this brief episode, not only it has to sense its perilous condition, it also has to respond with proper muscle actions so to modulate the flapping wing motions such that to generate enough aerodynamic torque in order to correct its orientation. Here, we measure the intricate wing modulations of all four wings that a dragonfly employs to make such a maneuver. We further develop a computational model to simulate the righting maneuver so to tease out the key wing asymmetry that leads to a successful recovery. By analyzing the falling trajectory, we calculate the muscle torque dragonfly used to drive the body rotation. We further conjecture a sensory motor pathway during the dragonfly's righting reflex in response to the perceived horizon.] (Authors) Address: not stated

**17356.** Wehmann, H.-N.; Heepe, L.; Gorb, S.N.; Engels, T.; Lehmann, F.-O. (2019): Local deformation and stiffness distribution in fly wings. *Biology Open* (2019) 8, bio038299. doi: 10.1242/bio.038299: 15 pp. (in English) [Mechanical properties of insect wings are essential for insect flight aerodynamics. During wing flapping, wings may undergo tremendous deformations, depending on the wing's spatial stiffness distribution. We here show an experimental evaluation of wing stiffness in three species of flies using a micro-force probe and an imaging method for wing surface reconstruction. Vertical deflection in response to point loads at 11 characteristic points on the wing surface reveals that average spring stiffness of bending lines between wing hinge and point loads varies ~77-fold in small fruit flies and up to ~28-fold in large blowflies. The latter result suggests that local wing deformation depends to a considerable degree on how inertial and aerodynamic forces are distributed on the wing surface during wing flapping. Stiffness increases with an increasing body mass, amounting to ~0.6 Nm.1 in fruit flies, ~0.7 Nm.1 in house flies and ~2.6 Nm.1 in blowflies for bending lines, running from the wing base to areas near the center of aerodynamic pressure. Wings of house flies have a ~1.4-fold anisotropy in mean stiffness for ventral versus dorsal loading, while anisotropy is absent in fruit flies and blowflies. We present two numerical methods for calculation of local surface deformation based on surface symmetry and wing curvature. These data demonstrate spatial deformation patterns under load and highlight how veins subdivide wings into functional areas. Our results on wings of living animals differ from previous experiments on detached, desiccated wings and help to construct more realistic mechanical models for testing the aerodynamic consequences of specific wing deformations." **17357.** Wibowo, S.S.; Basukriadi, A.; Winarni, N.L. (2019): Dragonfly species diversity (Odonata) in three Telaga on the highland freshwater, West Java. *IOP Conf. Ser.: Earth Environ. Sci.* 394 012007: 1-8. (in English) ["Odonata was very selective to the habitat selection. Their sensitivity toward environment makes them be good indicator species. Information of species diversity of Odonata in the highland of tropical freshwater lakes is still rare. The purpose of this research was to compare species diversity of Odonata in Telaga Biru Mount Gede Pangrango National Park, Telaga Warna, Nature Park, and Telaga Saat, West Java. Data of Odonata population were collected using fixed point count method. The results showed that species diversity of Odonata in Telaga Saat is higher than Telaga Warna, Nature Park and Telaga Biru, Mount Gede Pangrango National Park. Species diversity indices of Odonata in the three of lakes ranged between 0.78 – 1.75 and were categorized medium and low diversity. Jaccard index of similarity showed that Telaga Warna and Telaga Saat had the similar communities of Odonata. The high index of species diversity of Odonata in Telaga Saat was probably due to the higher intensity of light, which created the higher air temperature at the lake. Species richness, diversity and Shannon index of Odonata was the highest in Telaga Saat compared two other sites." (Authors)]

**17359.** Wildermuth, H.; Jödicke, R.; Schröter, A.; Borkenstein, A. (2019): Death feigning in sexual conflict between dragonflies (Odonata): does it exist? *Odonatologica* 48(3/4): 211-228. (in English) ["Death feigning, sometimes designated as thanatosis, reflex immobilization, tonic immobility or faking death is generally assumed a last-resort antipredator defence, attempting to avoid being killed and consumed. Recently, faking death has also been claimed to exist with respect to sexual conflict in Odonata. Here we review a number of published cases in Anisoptera that describe how non-receptive females during oviposition escape male harassing by fleeing, plunging into vegetation, freezing immediately and remaining motionless in random body position, no longer being noted by the male hovering nearby. We argue that this reaction of the female does not match the definition of death feigning and propose a new term for it: 'drop and stop' behaviour. In this context it is reasoned how and under what circumstances males, if at all, are able to recognize immobile females and react to them. The adaptive value of 'drop and stop' is discussed and it is suggested that this behaviour in sexual conflict could have evolved from a predator avoiding tactic." **17360.** Wildermuth, H. (2019): Altersbedingte Veränderungen des Farbmusters während des Imaginalstadiums von *Leucorrhinia pectoralis* (Odonata: Libellulidae). *Libellula* 38(1/2): 117-125. (in German, with English summary) ["Age-related changes of the colour pattern during the imaginal stadium of *L. pectoralis* – In dragonflies, changes during the imaginal stadium become mainly manifest in the colour pattern of the thorax and abdomen. Based on photographs of *L. pectoralis* that were taken during 12 years of flight seasons, the sequence of age-related changes in colouration was judged and reconstructed. After emergence, males and females are deep black with large bright yellow spots on thorax and abdomen. By maturation the males additionally turn red on the dorsum of the thorax and the first abdominal segments. In the course of the reproductive period the spots darken in both genders, turning brown. Only the spot on the seventh abdominal segment, characteristic for the species, remains bright yellow. Maturing and aging in Libellulidae are discussed in respect to their presumptive

physiological and genetic causes." (Authors)] Address: Wildermuth, H., Haltbergstrasse 43, 8630 Rüti, Switzerland. E-mail: hansruedi@wildermuth.ch

**17361.** Wildermuth, H.; Borkenstein, A.; Jödicke, R. (2019): Robert's watercolour of *Sympetrum striolatum* and the ambiguity of the thermoregulatory obelisk posture (Odonata: Libellulidae). *Notulae odonatologicae* 9(3): 83-90. (in English) ["In his 1958 book the well-known Swiss artist and odonatologist Paul-André Robert depicted a male *S. striolatum* adopting obelisk posture that might be interpreted as either warming-up or avoiding heat. We analysed the watercolour based on circumstantial evidence such as direction of irradiation, landscape, locality and season and we conclude that Robert painted the dragonfly in warm-up posture. The same posture was observed in a male held in a non-heated greenhouse on a cold morning. Similar postures were found on various photographs taken in the field at known temperatures. On the other hand, among 1164 analysed photos from our own archives, from other photographers and from the Internet only five pictures exhibited unambiguous heat avoiding posture. Compared with other European *Sympetrum* spp. *S. striolatum* rarely adopts warm-up posture and only exceptionally heat avoiding posture. This species presumably avoids overheating mainly by seeking shade in woods." (Authors)] Address: Wildermuth, H., Haltbergstrasse 43, 8630 Rüti, Switzerland; hansruedi@wildermuth.ch

**17362.** Wildermuth, H. (2019): Färbungsvarianten bei den Weibchen von *Coenagrion puella* (Odonata: Coenagrionidae). *Mercuriale* 18/19: 17-26. (in German, with English summary) ["Colour variants in female *C. puella* – In general, two colour forms of *C. puella* are distinguished: the common green (gynochromatypic or heteromorph) and the usually rare blue (androchromatypic or homeomorph) form. A field study based on photographs of tandems and copulation wheels in the eastern Swiss Plateau revealed that various transitional forms exist, whereby green, blue and rarely also yellow as ground colour occur in different combinations and the black patterns vary as to their extension and shape. It is discussed to what certainty the females of *C. puella* can be identified and assigned to one of the variants on the basis of photographs only." **17366.** Wood, C.; Fitt, R.N.L.; Lancaster, L.T. (2019): Evolving social dynamics prime thermal tolerance during a poleward range shift. *Biological Journal of the Linnean Society* 126(3): 574-586. (in English) ["Cold tolerance plays a critical role in determining the geographical range limits of species. Previous studies have found that range shifts in response to climate warming are facilitated, paradoxically, by cold acclimation capacities, due to increasingly colder and variable weather at high latitudes. However, the evolutionary dynamics of this process are poorly understood. In this study we combined experiments and field studies to investigate the social and

ecological factors affecting cold tolerances in range-shifting populations of the female-polymorphic *Ischnura elegans* in north-east Scotland, and their consequences for evolutionary change. In the field, we observed both environmental and social effects on cold tolerance and female colour morph frequencies. This process results in a latitudinal cline in female morph frequencies, due to positive feedback between social stress and thermal tolerances. Density manipulations in the laboratory provide experimental evidence that social interactions directly impact cold tolerance. Reciprocal effects of social environments on thermal acclimation may be important but commonly overlooked aspects of allee effects that contribute to the formation of range margins. Moreover, there is a wider need to consider the role of evolving social dynamics to reciprocally shape both the thermal physiology of individuals and the thermal niches of species." (2019): Numerical investigation of geometrical corrugation influence to vortex flowfields at low Reynolds number. *Journal of Fluid Science and Technology* 14(3): 1-8. (in English) ["Corrugated wings, which are cross-sectional

shapes of dragonfly wing, are expected to improve aerodynamic performance due to vortices generated by irregular shapes at low Reynolds number region. It is difficult to observe the influence of vortices generated from the unevenness of the shape by experiments. In this research, the flowfields around corrugated wings were calculated using Cartesian mesh-based Computational Fluid Dynamics (CFD), Building-Cube Method (BCM). The simulation grasped the detailed flowfield, which was difficult to be visually observed by the experiment. From the visualization result, it is found that the flow circulation velocity inside the concave and convex surface is not accelerated but slow. The result indicates that the improvement in aerodynamic performance is caused by the shape and position of unevenness." Dissertation of Department of Chemical Engineering, Zhongxing University: 98 pp. (in Chinese, with English summary) ["In this study, large-area and single-layer non-closed stacks silica colloidal crystal/Shape Memory Polymer composite were fabricated on polyethylene terephthalate (PET) substrates by spin coating technology using 90 nm, 180 nm, and 240 nm silica colloidal particles. The silica colloidal crystal/Shape Memory Polymer composite is etched with the reactive ion etching, and the dragonfly wing inspired structure with different sizes can be fabricated on the PET substrate by different etching time. The graded refractive index, by measuring the optical properties, shows that the dragonfly wing inspired structure is in the visible wavelength range, which can reduce the reflection of the larger light incident angle and improve the transmission. In addition, by studying the characteristics of shape memory polymer, deionized water was applied to the dragonfly wing inspired structure after etching, and the structure collapsed and aggregated, and its transmission decreased from 91.5% to 73.8%, and then acetone solution was applied. The dragonfly wing inspired structure was recovered, and its transmission raised from 73.8% to 91.2%. So, it shows the structure has property of shape memory. Therefore, it is a structure with property of omnidirectional anti-reflection and shape memory." (Author)] Address: not stated

**17378.** Zhang, X.-l.; Jiao, S.-w.; Wu, M.; Saho, X.-x.; Ye, X.-q.; Yan, Y.-n. (2019): Diet of two passerine birds during breeding season in reed wetland of Hangzhou Bay. Chinese Journal of Ecology 38(6): 1810-1816. (in Chinese, with English summary) ["Information on the bird's diet composition is essential to understand how wetland reclamation affects diversity of passerine birds. Samples of feathers of Reed Parrotbill (*Paradoxornis heudei*) and Oriental Reed Warbler (*Acrocephalus orientalis*) and samples of potential dietary insects were collected in the southern Hangzhou Bay (Shangyu, Shaoxing City), during the breeding season from July to August in 2017. Food sources were analyzed by measuring  $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$  values in bird feathers and insect samples. The results showed that the contribution of various diet composition of Reed Parrotbill ranked as: Noctuidae pupa > Lepidoptera > Arachnida > Hymenoptera > Homoptera. The contribution of various diet composition of Oriental Reed Warbler ranked as: Hymenoptera > Arachnida > Odonata > Lepidoptera > Coleoptera > Homoptera. The value of feeding niche breadths of Reed Parrotbill and Oriental Reed Warbler was 5.21 and 5.95, respectively. There was no significant difference in the  $\delta^{13}\text{C}$  values between the two species, indicating an overlap between their feeding niches ( $P > 0.05$ ). However, there was a significant difference in the value of  $\delta^{15}\text{N}$ , with feeding niche overlap being 6.25, suggesting some differences of nutritional levels ( $P < 0.01$ ). Lepidoptera, Arachnida, Hymenoptera, and Homo-

ptera were overlapping food-source insects for the two passerine species. The narrower niche breadth of Reed Parrotbill was inferior, and the loss of reed habitat had greater impacts on Reed Parrotbill." **17379.** Zhao, G.; Yuan, Y.; Zhang, P.; Zang, C.; Zhang, J.; Tao, L.; Zhang, G.; Zhou, H. (2019): Effects of laser-processed unit distribution density on wear resistance of biomimetic 6082 aluminum alloy. *Optics & Laser Technology* 112: 175-182. (in English) ["Highlights: •Bionic surface with various units distribution was prepared on 6082 Al alloy. •The unit present superior microstructure and hardness. •The wear resistance of Al alloy was increased by 53.43%. •An optimal unit distribution interval was obtained to resist wear. •The wear resistance mechanism was analyzed and the stress was simulated. Abstract: Biomimetic coupling units with different distribution densities were produced on the surface of 6082 aluminum alloy first by imitating the non-smooth wearproof surfaces of natural living things and then by simulating their soft-hard alternated surfaces with the laser surface melting technology. The effects and optimal level of unit distribution density on the abrasive resistance of 6082 aluminum alloy were analyzed via wear tests and simulation analysis. It was found biomimetic coupling units considerably improved the wear resistance of 6082 aluminum alloy. Stress analysis and experiments showed the wear resistance of 6082 aluminum alloy was optimized and enhanced by 53.43% from non-treated alloy when the density distribution coefficient of units was 0.4. Moreover, the wearproof mechanism of biomimetic coupling units was experimentally analyzed and discussed." **17381.** Zheng, D.; Wang, B.; Nel, A.; Jarzembowski, E.A.; Zhang, H.; Chang, S.-C. (2019): Mesostictinae subfam. nov., an archaic group of platystictid damselflies (Odonata: Zygoptera) from mid-Cretaceous Burmese amber. *Journal of Systematic Palaeontology* 17(1): 1-8. (in English) ["Odonatans are quite rare in the fossil record compared with the other insects, especially in Cretaceous amber inclusions. The extant family Platystictidae is one of the most diverse Zygoptera, but short of fossil records. In this paper, a new species, *Mesosticta davidattenboroughi* sp. nov., is described from mid-Cretaceous Burmese amber, representing the third-known fossil

species of Platystictidae. *M. davidattenboroughi* sp. nov. has a long IR1 beginning one cell distal of the base of RP2, confirming the previous attribution of *Mesosticta* Huang, Azar, Cai & Nel, 2015 to Platystictidae. It differs from other species of *Mesosticta* in having a long IR1 and a basally crossed subdiscoidal cell. The fossil genus *Mesosticta* shares the diagnostic characters of the modern platystictid genera, viz. a basally recessed 'CuP' (shared by all species), a very long IR1 (only in *M. davidattenboroughi* sp. nov.), and a specialized subdiscoidal area mostly rhomboidal in shape (only in *M. electronica* Zheng, Zhang, Chang & Wang, 2016). Based on the platystictid damselflies from Burmese amber, a new subfamily Mesostictinae subfam. nov. is established. Mesostictinae subfam. nov. represents the first fossil group of modern platystictid damselflies, documenting the appearance of Platystictidae as early as mid-Cretaceous. It differs from modern Platystictidae by the presence of fewer postnodal and postsubnodal crossveins, a short MP, the base of RP2 being nearer to the subnodus and the nodus lying more distally." (Authors)] Address: Nel, A., Lab. Ent.. Mus. Natn. Hist. Nat., 45 rue Buffon, F-75005 Paris, France. E-mail: anel@cimrs1.mnhn.fr

**17382.** Zheng, D.; Wang, B. (2019): The second hemiphlebiid damselfly (Odonata: Zygoptera) from mid-Cretaceous Burmese amber. *Alcheringa* 43(2): 257-260. (in English) ["*Burmahemiphlebia zhangi* Zheng et al. 2017 is the dominant damselfly found in Burmese amber. Here, a new hemiphlebiid damselfly, *Burmahemiphlebia hui* sp. nov., is described representing the second *Burmahemiphlebia* species discovered in Burmese amber. *Burmahemiphlebia hui* sp. nov. differs from *B. zhangi* in having more postnodal cross-veins, CuP and the separating point of AA from AP basal of  $A \times 1$ , Arc aligned with  $A \times 2$ , RP2 base closer to N than to Pt, and IR1 five cells distal of RP2 base. The new damselfly is extremely rare and the only one known from Burmese amber, unlike *B. zhangi*." (Authors)] Address: Zheng, D., State Key Lab. Palaeobiology & Stratigraphy, Nanjing Inst. Geology & Palaeontology & Center for Excellence in Life & Paleoenvironment, Chinese Acad. of Sciences, 39 East Beijing Road, Nanjing 210008, PR China. E-mail: dranzheng@gmail.com

**17383.** Zheng, D.; Wang, H.; Nel, A.; Dou, L.; Dai, Z.; Wang, B.; Zhang, H. (2019): A new damsel-dragonfly (Odonata: Anisozygoptera: Campteropteroptidae) from the earliest Jurassic of the Junggar Basin, northwestern China. *Alcheringa*: 43(4): 563-567. (in English) ["A new genus and species of campteropteroptid damsel-dragonfly, *Jurassophlebia xinjiangensis* gen. et sp. nov., is described from the Lower Jurassic Badaowan Formation in the Junggar Basin, northwestern China. *Jurassophlebia* differs from all other campteropteroptid genera in having PsA in the same orientation as the distal branch of AA, and in its uniquely open subdiscoidal cell with very acute apical angle in the hind wing. The new discovery adds to the Asian diversity of damsel-dragonflies in the earliest Jurassic." (Authors)] Address: Zheng, D., State Key Lab. Palaeobiology & Stratigraphy, Nanjing Institute of Geology & Palaeontology & Center for Excellence in Life & Paleoenvironment, Chinese Academy of Sciences, 39 East Beijing Road, Nanjing 210008, PR China. **17391.** Bae, Y.J.; Yum, J.H.; Kim, D.G.; Suh, K.I.; Kang, .H. (2020): *Nannophya koreana* sp. nov. (Odonata: Libellulidae): A new dragonfly species previously recognized in Korea as the endangered pygmy dragonfly *Nannophya pygmaea* Rambur. *Journal of Species Research* 9(1): 1-10. (in English) ["*N. koreana* sp. nov., is described from Korea on the basis of morphology and mitochondrial cytochrome oxidase c subunit I (COI) gene sequences. *Nannophya* materials from Korea and other areas in Southeast Asia were compared. The new species was previously recognized in Korea as the endangered *N. pygmaea* Rambur, 1842, which is widely distributed in insular and peninsular Southeast Asia. However, male adults of the *Nannophya* population in Korea could be distinguished from other *N. pygmaea* populations by the presence of a thick, incomplete black stripe on the lateral synthorax that terminated at half-length (vs. continuous to wing base), light orange (vs. red) anal appendages, and 4-5 (vs. 2-3) black teeth on the ventral superior appendages. In addition, the body length of *N. koreana* was generally larger (1.2-1.4 times) than that of *N. pygmaea*, regardless of life stage. COI gene sequences from the two groups exhibited substantial genetic differences (>12%), thereby sufficiently substantiating their differentiation. The taxonomic status, distribution, and habitat of the new species are discussed." (Authors)] Address: Bae, Y.J., National Institute of Biological Resources, Ministry of Environment, Incheon, Republic of Korea. nibrpresident@korea.kr

**17392.** Beddiar, M.; Benchalel, W.; Boucetta, S.; Bouslama, Z.; Elmsellem, H. (2020): Physico-chemical and biological evaluation of the quality of surface water in the Wadi El-Melha watershed (North-East Algeria). *Maroccan Journal of Chemistry* 8(2): 486-496. (in English) ["This environmental study targeted the ecological assessment and classification of the waters' state of health at the level of the Wadi El-Melha watershed flowing from Lake Mellah (northeast of Algeria) through Physico-chemical parameters measured in situ and measured in the laboratory, and the biological quality achieved through Odonates as bio indicators of ecological potential in watercourses. The aim is to conserve the potential of the ecosystem (biotope, habitat and reproduction of species, flow of water, rambling of the bed). The waters' quality of the Wadi El-Melha watershed seems to be generally good at the end of this study despite some recognized disturbances in some sections, which are essentially linked to alterations by, nitrites nitrates and phosphates which in places influence the quality of the surveyed river. In terms of biological quality which was assessed using ecological indices, the results revealed a stability of the stand during the study period. The odonatological procession is diverse (Shannon index  $H' = 2.26$ ), and it is in equilibrium (equitability index  $E = 0.90$ ).

Based on the classification proposed by [1], Wadi El-Melha is among the "middle" rivers, meaning a "moderately polluted" classification. ... The overall relative frequency revealed that the species *Ischnura graellsii* is the most frequent, representing 24.57% of the total population, followed by *Orthetrum coerulescens* with 15.69% *Calopteryx haemorrhoidalis* (12.13%). The other nine species (*Ceriatagrion tenellum*; *Anax imperator*; *Platycnemis subdilatata*; *Chalcolestes viridis*; *Gomphus lucasii*; *Crocothemis erythraea*; *Trithemis annulata*; *Sympetrum striolatum*; *Boyeria irene*) are represented by the respective percentages of 8.36%; 7.84%; 7.12%; 5.21%; 5.16%; 3.82%; 3.66% and 2.89%." **17395.** Benchalel, W.; Beddiar, M.; Boucetta, S.; Bouslama, Z. (2020): Bioecology of *Calopteryx haemorrhoidalis* (Zygoptera, Odonata) in response to environmental factors in the Brabtia sector streams, El-Kala, Algeria: implications for ecohydrological biomonitoring. *Studia Universitatis Vasile Goldis Seria Stiintele Vietii (Life Sciences Series)* 30(1): 21-32. (in English) ["Aspects of the phenology, reproductive biology and larval cycle of natural populations of *C. haemorrhoidalis* are described. Populations of this species in Brabtia sector (eastern Numidia, North-East Algeria) were studied between March 2017 and April 2018. An overview of the current state of the population is provided. The streams of Eastern Numidia have suffered over recent years from major disturbances including the effects of 20 rapid climate changes. Although the status of autochthony is preserved in the site, the populations are currently diminished compared to that recorded two dec-

ades ago. Aspects of the species reproductive behavior, biology, and ecology are reported. The species is univoltine with a direct development in 12 larval stages. The effects of some climatic conditions, particularly air temperature, included an extension of the adult phenology period. The species is unable to tolerate a certain amount of stress similar to stagnant water species. The correlation established between the abundance of *C. haemorrhoidalis* and the physico-chemical parameters from the principal correspondence analysis (PCA) shows an ecological gradient, in the distribution of the species, significantly ( $P < 0.001$ ) explained by a requirement for dissolved oxygen, both temperatures and pH." (Authors)] Address: Beddiar, M., Laboratory of Ecology of Terrestrial and Aquatic System «EcoSTaq», Badji Mokhtar University, Annaba, Algeria. E-mail: Beddiar\_marwa@yahoo.com

**17396.** Bhatti, H.; Panhwar, W.A.; Zia, S.A. (2020): Study on the dragonfly (Anisoptera: Odonata) fauna of district Larkana Sindh, Pakistan. *Journal of Entomology and Zoology Studies* 8(2): 619-623. (in English) ["A detailed odonatalogical field investigations were carried out to capture the dragonfly fauna of Larkana district, during March 2018 to October 2018 from various sites. Total of 215 samples recognized into 9 species under 5 genera pertaining to two families. The family Libellulidae was found most dominant with record of 8 species pertaining to 4 genera while family Aeshnidae was recorded with single species. Family Libellulidae showed its wide diversity and over all percentage of Libellulidae was recorded significantly highest (81.39%) and lowest that of family Aeshnidae (18.60%). Beside this, identification keys were also provided for easily isolation of families and genera." **17399.** Brito, J.; Louback-Franco, N.; Mendoza, C.; Nonato, F.; Juen, L. (2020): After 10 years the myth of *Crotalaria* spp. and dragonflies remains alive. *Biota Neotropica* 20(2): 6 pp. (in English, with Portuguese summary) ["The struggle to control insect-borne diseases can lead to make rash decisions. For instance, the controversial method of planting of *Crotalaria* spp. to attract predatory dragonflies can be used to control insect vectors of dengue fever and several other medically significant insect-borne diseases. Nevertheless, there is no scientific support for this assumption. Despite the lack of evidence, in Brazil, there remains a multitude of online articles and grey literature sources still promote *Crotalaria* planting as a means to prevent dengue fever. Here we discuss the reasons why Odonata would not be attracted by *Crotalaria* and, therefore, it cannot not be considered as an efficient method for vector control. Finally, the best practice to avoid the spread of insect-borne diseases in the tropics is to avoid the accumulation of standing water in urban areas." (Authors) fake news] Address: Juen, L., Univ. Fed. do Pará, Lab. de Ecol. e Conservação, Belém, PA, Brasil. E-mail: leandrojuen@ufpa.br

**17400.** Buczynski, P.; Stasiak, K. (2020): *Sympetma paedisca* (BRAUER, 1877) (Odonata: Lestidae) caught in a light trap. *Odonatrix* 16\_6 (2020): 3 pp. (in Polish, with English summary) ["A female of *S. paedisca* was caught on 23.07.2013 in a light trap in a forest near the village of Gołab in east-central Poland ( $51^{\circ}30'N$ ,  $21^{\circ}55'E$ ; UTM: EC60). This odonate was collected during research on the food resources of the Nightjar (*Caprimulgus europaeus*). However, it was probably an individual roosting away from its breeding site, which was stimulated to activity by the strong light from the trap. This species is therefore unlikely to be a potential food item of the Nightjar. But this record is interesting because *S. paedisca* is rare in the Mazovian Lowland and protected by law in Poland." **17402.** Buczynski, P.; Buczyńska, E.; Baranowska, M.; Lewniewski, L.; Góral, N.; Kozak, J.; Tarkowski, A.; Szykut, K.A. (2020): Dragonflies (Odonata) of the city of Lublin (Eastern Poland). *Polish Journal of Entomology* 89(3): 153-180. ["The authors discuss the dragonfly fauna of Lublin based on fragmentary historical data and the results of their own research from the period 1992-2019. A total of 54 dragonfly species were recorded: 17 in the historical period and 53 contemporarily. Although the Lublin area is a hot spot of odonate species richness in both the Lublin Upland and central and eastern Poland, it is of little importance for habitat specialists and also endangered and protected species. The species composition of the fauna was analysed in three zones of the city: the outskirts, the urbanized area and the City Centre. The diversity and numbers of dragonflies decreased significantly along this urbanization gradient and some groups of stenotopic species disappeared. The importance of anthropogenic water bodies in maintaining the diversity of dragonflies in urban areas, in particular stormwater ponds and garden ponds, is emphasized." (Authors)] Address: Buczynski, P., Dept of Zoology & Nature Protection, Institute of Biological Sciences, Maria Curie-Skłodowska University, Akademicka 19, 20-033 Lublin, Poland. E-mail: pawbucz@gmail.com

**17403.** Buczynski, P.; Bobrek, M.; Bobrek, R. (2020): An interesting record of the accidental introduction of the exotic dragonfly *Pseudagrion microcephalum* (RAMBUR, 1842) (Odonata: Coenagrionidae) to Poland. *Odonatrix* 16\_5 (2020): 6 pp. (in Polish, with English summary) ["One female of the Australian-Oriental *P. microcephalum* emerged in a pet shop with fish aquaria containing tropical plants in Kraków (UTM: DA24) (S Poland) in February 2020. It probably entered the aquarium as an egg or a larva on aquatic plants originating from south-east Asia. This is the fourth known case of the accidental introduction of an exotic odonate to Poland: the earlier ones involved *Mecistogaster* sp., *Crocothemis servilia* and *Ischnura senegalensis*. The case of *P. microcephalum* is particularly interesting, because the plants came from a greenhouse complex in Poland, to which no new plants had been imported for around half a year. Given the larval development time in tropical Coenagrionidae, this indicates the persistence in heated greenhouses of a population of *P. microcephalum* that has been present for at least three or four generations. This is probably the first confirmed information of this kind from Europe. Systematic studies on the existence of reproducing populations of dragonflies in greenhouses cultivating exotic aquarium plants are worth undertaking." **17404.** Burwell, C.J.; Theischinger, G.; Leach, E.C.; & Burwell-Rodriguez, A.I. (2020): Dragonflies and damselflies (Odonata) of the Eungella region, central coastal Queensland, Australia. *Proceedings of The Royal Society of Queensland* 125: 33-42. (in English) ["We collate records of species of

Odonata from the broader Eungella region within the Clarke Range, central coastal Queensland, Australia, comprising the Eungella plateau, the upper Pioneer Valley as far east as Gargett, and the area around Eungella Dam on the western side of the Clarke Range. Records are based on specimens collected on Griffith University and Queensland Museum surveys of the region in 2013 and 2014, specimen records in museum collections, and observational records sourced using the Atlas of Living Australia and accompanied by identifiable photographs. A total of 58 species are recorded from the Eungella region: 37 dragonflies and 21 damselflies, representing 12 families. Four species appear to be endemic to the Clarke Range. Another six are southern species that occur as far north as Eungella and the broader Clarke Range but do not cross the Burdekin-Lynd Barrier. Two species are essentially confined to northern Queensland and occur south of the Burdekin-Lynd Barrier but only as far south as the Eungella region. The majority of the region's species are widespread, occurring from northern to southern Queensland and often far beyond." (Authors)] Address: Burwell, C.J., Biodiversity Program, Queensland Mus., PO Box 3300, South Brisbane, Queensland, Australia. E-mail: chris.burwell@qm.qld.gov.au

**17405.** Cabana Otero, M.; Barreiro, A.R.; Cordero-Rivera, A. (2020): Primera cita de *Aeshna isocles* (Müller, 1767) (Odonata: Aeshnidae) para la provincia de Lugo y situación de la especie en Galicia (noroeste de la Península Ibérica). *Boletín de la Sociedad Entomológica Aragonesa* 67: 399-400. (in Spanish, with English summary) ["The first record of *A. isocles* from Lugo province is reported, as well as new observations from A Coruña province. The situation of this dragonfly in Galicia (north-western Spain) is briefly described and discussed." **17406.** Cardoso, F. (2020): Ângelo Machado - In memoriam (1934-2020). *Arquivos de Neuro-Psiquiatria* 78(5): 316-317. (in English) ["Professor Ângelo Barbosa Monteiro Machado, MD-PhD was born in Belo Horizonte City on the 25th of May, 1934). He graduated from the Medical School of Universidade Federal de Minas Gerais (UFMG) but never practiced Medicine. Despite this fact and paradoxically, as we shall see, he exerted a profound and lasting influence over Medicine, particularly in the fields of Neurology and Neurosurgery. Immediately after graduating, he became part of the faculty at the Anatomy Department of UFMG, where received his PhD title in 1963. From 1965 to 1967, he was a research post-doctoral fellow at the Morphology Department of Northwestern University in Chicago, IL. Upon his return to Brazil, in partnership with his main collaborator and wife, Professor Conceição Ribeiro da Silva Machado (1936-2007), he founded the Laboratories of Electron Microscopy and Neurobiology at the Institute of Biological Sciences of Universidade Federal de Minas Gerais (Laboratórios de Microscopia Eletrônica e Neurobiologia do Instituto de Ciências Biológicas, ICB-UFMG). After retiring as a Professor at the Morphology Department in 1987, he returned to work at the same ICB-UFMG, but this

time at the Laboratory of Insects Systematic of the Zoology Department (Laboratório de Sistemática de Inseto do Departamento de Zoologia). After compulsory retirement in 2004, he became Professor Emeritus at ICB-UFMG in the following year. His most significant contributions in the field of Neurobiology were to elucidate the formation of norepinephrine containing synaptic vesicles from the smooth endoplasmic reticulum as well as several aspects of involvement of the autonomic nervous system in experimental models of Chaga's disease. In the field of Entomology, his area of expertise was dragonflies. He described the astonishing number 98 species and 11 genres of these insects. By the way, Professor Ângelo loved dragonflies so much that the tiles marking the rim of the water of the swimming pool at his house were illustrated with drawings of dragonflies. The third intellectual activity to which he was involved was environmentalism. At an age when this was an issue that deserved at best rare footnotes, he vigorously engaged himself on the defense of the environment. Moreover, he developed a late interest in literature, writing dozens of plays and books. Most of them targeted children and teenagers. In 1993, he received the Jabuti Award for the book *O velho da montanha, uma aventura amazônica*. The Jabuti Award is the most prestigious award in Brazilian letters, comparable to the Pulitzer Prize in the USA. His indelible legacy for Neurology had an almost serendipitous nature. Already an assistant to Professor João Afonso Liberato Didio, MD-PhD, then Professor and Chief of Anatomy at UFMG, always tongue-in-cheek, he thought that "there was no future in dissecting". He moved to the sector of Neuroanatomy. With his remarkable didactic skills, he rendered intelligible a subject that was virtually inaccessible to Medical students. Up to that time, they were forced to study thick and hermetic foreign textbooks. The students started copying the lectures, typed them, bounded them together and created a makeshift book that circulated among them semester after semester. After that, Professor Ângelo curated the text and this is how the first edition of the textbook *Functional Neuroanatomy (Neuroanatomia Funcional)* gained life. There is a fastidious overuse of the adjective seminal. Yet in this particular case it is fitting to associate this book with a reproductive function: there are very few Brazilian neurologists that have not fallen in love with the nervous system and decided to pursue a career in Neurology after reading such work. I regret for those who did not have the privilege of meeting Professor Ângelo Machado. To be born in an aristocratic family with plenty of towering figures in Medicine (Lucas Machado), Politics (Cristiano Machado), and Literature (Maria Clara Machado and Abílio Machado) may be an easy way to have one's talent blocked. However, and fortunately, this never happened to him. Aside his intellectual prowess, he was an eccentric and deliciously funny man, warmly called "Angelim" by his peers and students. He also had many other scientific and non-scientific interests. Among these, he was endowed with an unmatched skill for foreign languages; he was a talented amateur comic actor during the Medical School and was a nocturnal flâneur in the bohemian scene of Belo Horizonte. His retirement of the latter (by the way, bitterly regretted by his fellow bohemians!) was caused by the most fateful event of his life: passion for and marriage with Professor Conceição née

Ribeiro Machado, resulting not only in a highly productive scientific partnership, but also in the birth of Lúcia (neuro-pediatrician), Flávia (intensivist), Paulo (biologist) and Eduardo (employee of the Brazilian Central Bank). Professor Ângelo Machado died on the 6th of April 2020." (Author)] Address: Cardoso, F., Univ. Federal de Minas Gerais, Medical School, Internal Medicine Dept, Neurology Service, Movement Disorders Unit, Belo Horizonte MG, Brazil

**17407.** Chan, K.S.; Tan, J.; Goh, W.L.; Earl of Cranbrook (2020): Diet profiling of house-farm swiftlets (*Aves*, Apodidae, *Aerodramus* sp.) in three landscapes in Perak, Malaysia, using high-throughput sequencing. *Tropical Ecology* 60: 379-388. (in English) ["In Peninsular Malaysia, from the 1980s there has been progressive expansion of an industry based on specially designed buildings to house colonies of edible-nest swiftlets (*Apodidae*, *Collocaliini*). The structures are termed house-farms and the birds, house-farm swiftlets. Genetic research has so far failed to establish affinity with any wild form of swiftlets that builds 'white' edible nests; we therefore identify house-farm swiftlets only as *Aerodramus* sp. The diet profiles of house-farm swiftlets were compared in different landscapes in Perak State, Malaysia, using a high-throughput sequencing of total DNA extracted from faecal samples collected at six house-farms, located at Beruas, Gopeng, Ipoh and Pantai Remis, in the month of October 2017. Landscape profiles of the presumed foraging area within 6 km radius of these six sites were estimated using Google MyMaps, and categorised as urban, monocrop or mixed-use. Based on the partial mitochondrial cytochrome oxidase I region (ca. 218-bp), 4852 operational taxonomic units (OTUs) were recovered, of which 266 belonged to arthropods. Overall, the diets of house-farm swiftlets assessed in this study mainly comprised Diptera (64.49%), followed by Hemiptera (16.73%), Coleoptera (13.47%), Lepidoptera (2.04%), Hymenoptera (1.63%), Blattodea (0.82%) and Odonata (0.82%). Ipoh (urban landscape) and Pantai Remis (mixed) recorded the highest diversity of dietary insects. Presence of the aquatic insect families in these diets may reflect extensive freshwater bodies in the urban landscape. Coleoptera and Hemiptera were found to be dominant in the swiftlet diets at two monocrop landscapes Beruas OP1 and Beruas OP2, but did not include the weevil *Elaeidobius kamerunicus*, an important pollinator of oil palm. Results confirm that house-farm swiftlets are opportunistic feeders, so that variation in the diet profiles in Perak reflected the availability of insect prey within the landscapes of the foraging ranges." (Authors)] Address: Chan, K.S., Dept of Biological Science, Faculty of Science, Univ. Tunku Abdul Rahman, Jalan Universiti, Kampar, Malaysia

**17408.** Chiari, C. (2020): Prima segnalazione di *Selysiothemis nigra* (Van der Linden, 1825) (Anisoptera: Libellulidae) per la provincia di Brescia (Pianura Padana, Lombardia). *Natura Bresciana - Ann. Mus. Civ. Sc. Nat., Brescia* 43: 141-143. (in Italian, with English summary) ["First report of *S. nigra* in the Brescia Province (Po Plain, Lombardy). This note documents the finding of a small population of *S. nigra* in a former quarry basin in the municipality of Poncarale (BS). This is the first recorded report for the province of Brescia and for Lombardy

where this species, notoriously nomadic and endowed with migratory capacity, had never been reported." (Author)] Address: Chiari, C., via Donatello 261, 25124 Brescia (Bs), Italy. E-mail: carlo.emidio@gmail.com

**17409.** Chiari, C.; Piglia, A.; Sacchi, F.; Sand, M.L. (2020): Presenza di *Trithemis annulata*, *Obelisco violetto* (Palisot de Beauvois, 1805) (Anisoptera: Libellulidae) in provincia di Brescia nel 2018. *Natura Bresciana - Ann. Mus. Civ. Sc. Nat., Brescia* 43: 145-148. (in Italian, with English summary) ["Presence of *T. annulata* in Brescia Province in 2018. At the beginning of August 2018 some individuals of *T. annulata*, a male and a female, were observed for the first time in province of Brescia at the Fishing Club Laghi Mella in the municipality of Poncarale (UTM WGS84: 32T593473.5034238, 98 m). These former quarry basins are now used for sport fishing. Subsequently, since the beginning of September, an important reproductive population has been identified in the same place where hundreds of adult individuals have been observed intent on mating, oviposition and defence of the territory by conspecifics and by *Orthetrum cancellatum*, *O. albistylum*, *Crocothemis erythraea*, *Anax imperator* and *A. parthenope*. At the same time other groups, composed of small populations and single individuals, were identified in six other artificial basins originating from former gravel and sand quarries located in the upper and lower Brescia plain and located in the municipalities of: Brescia, Montirone, Bagnolo Mella, Roncadelle, Travagliato and Provaglio d'Isèo. The station with the presence of *Trithemis annulata*, located further north in the province of Brescia, was located in Provaglio d'Isèo in the "Lame" of the SIC-ZPS – "Torbiere del Sebino", former peat quarries." **17411.** Chovanec, A. (2020): Die Libellenfauna (Odonata) eines naturnahen metarhithralen Gewässers im niederösterreichischen Alpenvorland. *Mercuriale* 20: 15-32. (in German,

with English summary) ["The dragonfly fauna (Odonata) of the pristine metarhithron Piesting in the Alpine Foothills of Lower Austria. – In the years 2019 and 2020 a total of six field trips were carried out at a metarhithron stretch of the Piesting, a river situated in the Alpine Foothills of Lower Austria, and a small adjacent backwater, to record the representative spectrum of Odonata species. Investigations focused on the detection of teneral and adult specimens as well as on the observation of reproductive behaviour. The study revealed an inventory of 19 species, 11 of them were certainly, probably or possibly autochthonous. The pristine status of this river section is reflected in the records of river-type specific reference species: the first-degree indicators *Calopteryx virgo* and *Onychogomphus forcipatus*, both probably autochthonous, and the second-degree indicators *Pyrrhosoma nymphula* (certainly autochthonous) and *Orthetrum brunneum*. At the Piesting itself 7 species were found. The backwater comprised a spectrum of 17 species with remarkable records of *Lestes virens* and *Coenagrion ornatum*: both species are "critically endangered" according to the Austrian Red List, *C. ornatum* also is listed in Annex II of the Habitats Directive 92/43/EEC." (Author)] Address: Chovanec, A., Krotenbachgasse 68, 2345 Brunn am Gebirge, Austria. E-Mail: andreas.chovanec@bmlrt.gv.at

**17412.** Chovanec, A. (2020): Zur Aussagekraft unsystematisch erhobener Libellendaten (Insecta: Odonata) aus einem gewässerlosen Garten. *Beiträge zur Entomofaunistik* 21: 181-210. (in German, with English summary) ["The informative value of dragonfly records (Insecta: Odonata) unsystematically gathered in a private garden without water bodies. – In the period 2009–2019, dragonflies appearing in the author's garden in Lower Austria were unsystematically recorded. Despite the fact, that there is no water body in this 300 m<sup>2</sup> garden, 26 species (one third of the Austrian Odonate fauna) were found, including for example *Coenagrion scitulum* and *Sympetrum meridionale*, both species "critically endangered" in Austria. *S. striolatum* accounts for 42 % of the total sum of 467 records. Studies carried out at running and standing waters in the surroundings of the garden revealed an inventory of 37 taxa belonging to the seven dragonfly associations ("ecologic guilds"), which are described for the bioregion where the garden is situated. The species detected in the garden are representative of the species spectrum recorded in the surrounding area because all associations are also represented by the species found in the garden. *Orthetrum albistylum* was seen only in the garden and not at the waters situated in its surrounding area. The highest number of specimens appearing on one day in the garden was 13, the highest number of species four. The records in the garden also reflect characteristic phenological patterns of winter-, spring-, early/midsummer- as well as midsummer/autumn-species." **17415.** Chovanec, A. (2020): Die Libellenfauna der Krems in Ansfelden / Oberaudorf (Oberösterreich) mit einem individuenreichen Vorkommen von *Erythromma lindenii* (Selys, 1840) (Odonata: Coenagrionidae). *Beiträge zur Entomofaunistik* 21: 3-31. (in German, with English summary) ["In the year 2019, 28 Odonate species were recorded at the rehabilitated section of the River Krems in Ansfelden / Oberaudorf (Upper Austria), 22 of them were classified as certainly, probably or possibly autochthonous (reproducing in the investigation area). 21 species (18 of them autochthonous) belong to the inventory of reference species, which is typical of the biocoenotic region of the River Krems in this area, the hyporhithron / epipotamon transition zone. Thus, the dragonfly-based ecological status of this river section was classified as "high". The different hydrological and morphological characteristics of lotic and lenitic sub-sections are reflected by the Odonate fauna and by the results of the assessment procedures: Lotic sub-sections were classified as "high" and "good", lenitic ones as "good" and "moderate". The record of the largest population of the *E. lindenii* ever detected in Austria has to be emphasized. The comparison of the results of the present study with an odonatological investigation of the same study area carried out in 2013 revealed higher total species numbers and higher numbers of rivertype-specific reference species in 2019. The abundances of those species occurring in both years were higher in 2019." (Authors)] Address: Chovanec, A., Krottenbachgasse 68, 2345 Brunn am Gebirge, Austria. E-Mail: andreas.chovanec@bmlrt.gv.at

**17416.** Corso, A.; Penna, V. (2020): *Orthetrum chrysostigma* (Burmeister, 1839): new for the Italian fauna (Odonata Libellulidae). *Biodiversity Journal* 11(2): 359-362. (in English) ["Details about the first Italian record of *O. chrysostigma*, obtained in south-western Sicily, are reported. One mature male

was collected in the province of Agrigento in August 2014." (Authors)] Address: Corso, A., Via Camastra 10, 96100 Siracusa, Italy. E-mail: zoologywp@gmail.it

**17417.** Costa Natividade, D.; Ferreira Santana, Q.C.; Silva Pinto, N. (2020): Weight determines the outcome in territorial contests of *Erythrodiplax fusca* Rambur, 1842 (Odonata: Libellulidae). *Rev. Biol. Neotrop. / J. Neotrop. Biol.* 17(2): 103-109. (in Portuguese, with English summary) ["*E. fusca* ... defend their territories close to rivers, lakes and swamps. Disputes over access to females or breeding sites usually occur during flight activities. The objective in this work was to analyze the disputes over territories between males and to evaluate if the winners are heavier than losers. The study was conducted at the Morro Feio Experimental Farm, located in the municipality of Hidrolândia, state of Goiás, Brazil. First, an inspection was carried out to find points on the bank of the stream that males commonly dispute to establish their territories. After the identification of these points, all disputes for territory were counted and at the end of the conflict the two males were collected (winner and loser) and weighed. 74 individuals of *E. fusca* (37 winners and 37 losers) were collected. The fresh weight was decisive to win the dispute, with winner males 10% heavier than losing males. Therefore, this work corroborates the hypothesis that the weight of the males of *E. fusca* is related to increases in probability of victory in disputes over territories." **17422.** de Carvalho, G.; Cozzer, G.D.; Rezende, R.; Magro, J.D.; Simões, D.A. (2020): Efeito Sinérgico do BTI e predacion sobre a mortalidade de larvas do mosquito *Aedes aegypti* (Linnaeus, 1762). *Revista Acta Ambiental Catarinense* 17(1): 10-16. ["This study objective was to evaluate the effect of use of predatory Libellulidae larvae associated with BTI on larval reduction of mosquitoes. Our tested hypothesis seeks to answer whether there would be an increase in the mortality of *A. aegypti* larvae caused by the synergistic effect of BTI along with the predator. The microcosms consisted of 300mL containers containing 100mL of water with densities of 100, 200, and 300 larvae of *A. aegypti* and one predator larva. The BTI and BTI + Predator treatments received 0.01ppm BTI. Control received only *A. aegypti* larvae. The results showed a significant effect on BTI + Predator treatment in the density of 1 larva / mL, while in the densities of 2 and 3 larvae / mL the same effect

was not observed, partially corroborating the hypothesis of BTI and predation synergistic effect in larval mortality. Increasing larval density increased predation rate, while the effect of BTI on mortality decreased. Our results show that the synergistic effect exists, but that density-dependent factors may hide such effect." As a result of the survey studies, 261 samples belonging to the Odonata order were collected. Seven species ... were determined: *Brachythemis fuscopallata*, *Crocothemis erythraea*, *Orthetrum albistylum*, *O. brunneum*, *O. coerulescens*, *Platycnemis dealbata*, *Ischnura elegans*. Six of the 7 species identified in the study are the first records for the Diyarbakır insect fauna." (Authors)] Address: Bolu, H. E-mail: besni@dicle.edu.tr

**17424.** Dow, R.A. (2020): Revision of the genus *Coeliccia* Kirby in Borneo part III: Two new species from the *C. membranipes*-group from Sarawak and Brunei (Odonata: Zygoptera: Platycnemididae). *Zootaxa* 4890(4): 473-492. (in English) ["*C. junis* sp. nov. (holotype ♂ from Borneo, Sarawak, Bintulu Division, Planted Forest Project, Bukit Mina Wildlife Corridor, "Day 4" stream near Bukit Nyegoh and Bukit Jugam, near small brown water pool, 10 viii 2018, deposited in the Naturalis Biodiversity Center, Leiden, the Netherlands) and *Coeliccia roberti* sp. nov. (holotype ♂ from Borneo, Sarawak, Miri Division, Lambir Hills National Park, small stream on Oil Well Trail, 22 iv 2011, deposited in the Naturalis Biodiversity Center, Leiden, the Netherlands) are described from Borneo. Both new species belong to the *Coeliccia membranipes*-group and bring the number of named species known from the group from Borneo to nine and the total number of named species from Borneo currently placed in *Coeliccia* to 15. *Coeliccia junis* is only known from a small area in Sarawak, *C. roberti* is also known from Brunei. Both species are considered likely to be closely allied with *C. macrostigma* Laidlaw." (Author)] Address: Dow, R.A., Naturalis Biodiversity Center, P.O. Box 9517, 2300 RA Leiden, The Netherlands. E-mail: rory.dow230@yahoo.co.uk

**17425.** Dow, R.A.; Zhang, H.-m. (2020): Two new species of *Coeliccia* Kirby from Yunnan, China (Odonata: Zygoptera: Platycnemididae). *Zootaxa* 4838(4): 491-502. (in English) ["Two new species of *Coeliccia* Kirby are described from Yunnan, China: *Coeliccia tongbiguan* sp. nov. and *Coeliccia yunnanensis* sp. nov. (holotype ♂ for both from Tongbiguan National Nature Reserve, Yingjiang County, Yunnan). *C. tongbiguan* is allied to *C. hoanglienensis* Do, known only from Vietnam. *C. yunnanensis* appears to be closely allied to the *Coeliccia hayashii*-group, also from Vietnam. The fifteen named species of *Coeliccia* now known to occur in China are listed, twelve of them occur

in Yunnan, the presence of *C. didyma* in the country is confirmed." (Authors)] Address: Dow, R.A., 6 Bramley Avenue, Coulsdon, Surrey, CR5 2DP, UK. E-mail: rory.dow@virgin.net

**17426.** Dow, R.A.; Price, B.W. (2020): A review of *Megalogomphus sumatranus* (Krüger, 1899) and its allies in Sundaland with a description of a new species from Borneo (Odonata: Anisoptera: Gomphidae). *Zootaxa* 4845(4): 487-508. (in English) ["*M. sumatranus* and its allies in Sundaland are reviewed. The accessory genitalia of the males of this genus, hardly considered previously, are found to be taxonomically informative. The taxon from Borneo previously treated as *M. sumatranus* is described from both sexes as *M. buddi* sp. nov. (holotype ♂ Sungai Datai, Nanga Bloh, Lanjak Entimau Wildlife Sanctuary, Kapit Division, Sarawak, Malaysia, 22 viii 2013, leg. J. anak Awan & M. anak Adau; deposited at the Naturalis Biodiversity Center, Leiden, the Netherlands). *M. borneensis* (Laidlaw, 1914), described as a subspecies of *M. icterops* (Martin, 1903) and subsequently relegated to the synonymy of that species, is considered to be a distinct species. *M. icterops* is however considered to be a junior synonym of *M. sumatranus*. A re-description of the holotype of *M. borneensis* is provided as is the first description of the female. Descriptive notes with illustrations of *M. sumatranus* are given." (Authors)] Address: Dow, R.A., 6 Bramley Avenue, Coulsdon, Surrey, CR5 2DP, UK. E-mail: rory.dow@virgin.net

**17427.** Dow, R.A.; Phan, Q.T.; Choong, C.Y. (2020): *Protosticta joepani* sp. nov. from Borneo with notes on *P. kinabaluensis* Laidlaw, 1915 (Odonata: Zygoptera: Platystictidae). *Zootaxa* 4729(3): 371-387. (in English) ["*P. joepani* sp. nov. is described from Malaysian Borneo (holotype ♂ Bario, Kelabit Highlands, Miri Division, Sarawak, Malaysia, deposited in the Naturalis Biodiversity Center, Leiden). It is the sister species of *P. kinabaluensis* Laidlaw, 1915; some descriptive notes and a set of illustrations are provided of the latter species. A COI gene tree for both species is provided. The placement of both *P. joepani* and *P. kinabaluensis* is discussed, but although it is very unlikely that they belong in *Protosticta sensu stricto*, the issue is left open here." **17430.** Faradilla, A.R.; Uthami, M.; Andini, B.; Rachman, H.T. (2020): The life history and microhabitat ecology of a phyto-tem-breeding damselfly *Pericnemis stictica* in Jateviulyo Forest, Yogyakarta. *Treubia* 47(1): 63-75. (in English, with Indonesian abstract) ["This study aims to understand the life history and microhabitat ecology' of a phytotelmata-breeding species. *Pericnemis stictica*. Data was collected at 46 breeding sites in the Jatimulyo Forest. Kulonprogo. Several parameters were recorded from each breeding site. Le. plant species, diameters, depth, water depth, water volume, water pH. and water turbidity'. Naiads and imagoes of *P. stictica* were measured morphometrically'. The data taken was analyzed descriptively using Minitab 19. The results showed that 17 naiads of *P. stictica* were found in 13 bamboo stumps. The bamboo species most commonly used by *P. stictica* as a breeding site was *Dendrocalamns asper*. Naiads of *P. stictica* were found in the same habitat as mosquito larva from genera *Toxorhynchites*, *Aedes*, *Armigeres*. and *Culex*. During the rearing process, it was recorded that *P. stictica* naiads can eat more than ten mosquito larvae a day'. Four males and one female imagoes of *P. stictica* were found. The imagoes were mostly' found in a secondary' forest with shady' ravine areas. Imago's average total length was 7.19 cm Naiad's final instar average size

was 16.7 mm. Water depth, water temperature, bamboo depth, bamboo volume, and humidity' were all positively correlated to *P. stictica*'s phytotelmata-breeding behavior." **17433.** Feng, R.-Q.; Luo, F.-Z.; Zhang, L.-J.; Li, M.; Cao, Y.; Yuan, M.-L. (2020): The complete mitochondrial genome of *Sympetrum striolatum* (Odonata: Libellulidae) and phylogenetic analysis. *Mitochondrial DNA Part B Resources* 5(2): 1677-1678. (in English) ["Here, we sequenced and annotated the complete mitogenome of *S. striolatum*. This mitogenome is 15,435 bp in length, consisting of 13 protein-coding genes (PCGs), 22 transfer RNA genes (tRNAs), 2 ribosomal RNA unit genes, and a large non-coding region (putative control region). The *S. striolatum* mitogenome with an A + T content of 71.54% presented a positive AT-skew (0.081) and a negative GC-skew (-0.127). Twelve PCGs started with a typical ATN codon, the remaining one PCG started with TTG (nad1). All tRNAs had a typical secondary cloverleaf structure, except for tmS1 which lacked the dihydrouridine arm. The Bayesian phylogenetic tree of 29 Odonata species based on the concatenated nucleotide sequences of 13 PCGs supported the monophyly of Libellulidae and a closer relationship of *S. striolatum* and *Brachythemis contaminata*." (Authors)] Address: Feng, R.-Q., State Key Lab. of Grassland Agro-Ecosystems, Lanzhou University, Lanzhou, People's Republic of China.

**17434.** Ferwer, W.; Nel, A. (2020): A new damselfly genus and species from Baltic amber (Odonata: Zygoptera: Euphaeidae). *Bulletin de la Société Géologique de France* 191(12): 4 pp. (in English, with French summary) ["The new euphaeid genus and species, *Wolfgangeuphaea ferweri* Nel, are described from the Middle Eocene Baltic amber. It belongs to the Paleogene subfamily Eodichrominae. This new discovery confirms to remarkable past diversity of this family that contains now as many extinct genera and recent ones. They were distributed in North America and Europe, while the family is now-a-day only present in the Old World. There seems to have been a "replacement" of the Euphaeidae by the Calopterygidae during the latest Oligocene and the Neogene." - 17444.** Girardin, V.; Grung, M.; Meland, S. (2020): Polycyclic aromatic hydrocarbons: bioaccumulation in dragonfly nymphs (Anisoptera), and determination of alkylated forms in sediment for an improved environmental assessment. Scientific Reports 10(1) (10958): 15 pp. (in English) ["Road runoff carries a mixture of contaminants that threatens the quality of natural water bodies and the health of aquatic organisms. The use of sedimentation ponds is a nature-based solution for the treatment of road runoff. This study assessed the concentration of polycyclic aromatic hydrocarbons (PAHs) and their alkylated homologues in sediment from seven highway sedimentation ponds and three natural urban ponds. In addition, the study explored the bioaccumulation of PAHs in dragonfly nymphs (Anisoptera). Finally, biota-sediment accumulation factors (BSAFs) were estimated. The results revealed a significant difference in the concentrations of 16 priority PAHs in sediment, with overall higher levels in sedimentation ponds (2,911 ig/kg on average) compared to natural urban ponds (606 ig/kg on average). PAH levels increased substantially once alkylated homologues were considered, with alkylated comprising between 42 and 87% of the total PAH in sediment samples. These results demonstrate the importance of alkylated forms in the environmental assessment of PAHs. The bioaccumulation assessment indicates that dragonfly nymphs bioaccumulate PAHs to a certain degree. It is not clear, however, whether they metabolize PAHs. BSAF results ranged from approx. 0.006 to 10 and indicate that BSAFs can be a powerful tool to determine the functionality of sedimentation ponds." (Authors)] Address: Girardin, Viviane, Norwegian Institute for Water Research (NIVA), Gaustadalléen 21, 0349 Oslo, Norway. E-mail: viviane.girardin@niva.no
- 17445.** Golab, M.J.; Brodin, T.; Sniegula, S. (2020): Two experimental designs generate contrasting patterns of behavioral differentiation along a latitudinal gradient in *Lestes sponsa* — Common-garden not so common after all? Ecology and Evolution 10(18): 10242-10253. (in English) ["Understanding why and how behavioral profiles differ across latitudes can help predict behavioral responses to environmental change. The first response to environmental change that an organism exhibits is commonly a behavioral response. Change in one behavior usually results in shifts in other correlated behaviors, which may adaptively or maladaptively vary across environments and/or time. However, one important aspect that is often neglected when studying behavioral expressions among populations is if/how the experimental design might affect the results. This is unfortunate since animals often plastically modify

their behavior to the environment, for example, rearing conditions. We studied behavioral traits and trait correlations in larvae of a univoltine damselfly, *Lestes sponsa*, along its latitudinal distribution, spreading over 3,300 km. We compared behavioral profiles among larvae grown in two conditions: (a) native temperatures and photoperiods or (b) averaged constant temperatures and photoperiods (common-garden). We hypothesized latitudinal differences in behavioral traits regardless of the conditions in which larvae were grown, with northern populations expressing higher activity, boldness, and foraging efficiency. When grown in native conditions, northern larvae were bolder, more active and more effective in prey capture than central and low latitude populations, respectively, as well as showed the strongest behavioral correlations. In contrast, larvae reared in common-garden conditions showed no differences between regions in both individual traits and trait correlations. The results suggest different selective pressures acting on the studied traits across populations, with environment as a central determinant of the observed trait values. Common-garden designed experiments may evoke population-dependent levels of plastic response to the artificial conditions and, hence, generate results that lack ecological relevance when studying multi-population differences in behavior." (Authors)] Address: Golab, Maria, Institute of Nature Conservation PAS, 31-120 Kraków, Poland. E-mail: marysiagolab@gmail.com

**17446.** González, A.; Barnes, C.L.; Wilder, S.M.; Long, J.M. (2020): Differences in macronutrient content of common aquatic macroinvertebrates available as prey for young-of-the-year Scaphirhynchus sturgeons in the lower Missouri River. *Journal of Freshwater Ecology* 35(1): 191-202 (in English) ["Nutrient availability in prey items can have important consequences for the growth, reproduction, survival, and recruitment into adulthood of juvenile fish. For young of the year sturgeon, which are highly dependent on macroinvertebrates as prey, knowing the nutritional content across various prey items within their habitats can help managers during habitat restoration. The objective of this study was to test for differences in the macronutrient composition of major invertebrate groups commonly consumed by young of the year sturgeon in the lower Missouri River in the summer, when sturgeon habitat assessments occur. Potential prey vary considerably in size. In addition, there were significant differences in the concentrations of nutrients. The lowest concentration of lipid was found in Odonata ( $2.36 \pm 1.83 \text{mg } 100 \text{mg}^{-1}$ ; mean  $\pm$  pooled variance standard error) and the highest was in Diptera ( $14.49 \pm 3.30 \text{mg } 100 \text{mg}^{-1}$ ). The lowest concentration of protein was found in Ephemeroptera ( $58.98 \pm 1.90 \text{mg } 100 \text{mg}^{-1}$ ) and the highest concentration was in Trichoptera ( $70.07 \pm 3.26 \text{mg } 100 \text{mg}^{-1}$ ). Some spatial differences were found in energy derived from protein in Ephemeroptera in the lower Missouri River, but not in energy derived from lipid. Our findings provide useful information that can contribute to adaptive management efforts for sturgeons in the lower Missouri River." **17447.** Gonzalez, I.G.; Núñez-Avellaneda, M.; Zúñiga, M. (2020): Los macroinvertebrados acuáticos de la región andino-amazónica colombiana: Camino Andakí, departamento de Caquetá. *Revista Colombia Amazonica* 12: 191-202. (in Spanish, with English summary) [This study was carried out in the Pescado river basin where the so-called "Camino Andakí" is located, an ancestral route used by indigenous populations between the low areas of the Caquetá department and the Andes. Within the framework of the "ColombiaBio Expedition to biodiversity in the Andean-Amazon transition of the department of Caquetá", an initiative of COLCIENCIAS and the Instituto Amazónico de Investigaciones Científicas -SINCHI, between January and February 2017, a sampling campaign was carried out for aquatic macroinvertebrates. Twelve stations were established between 410 and 1468 masl and 6290 individuals were collected, distributed in 109 genera. The most diverse order was Coleoptera and the most abundant was Ephemeroptera. Odonata expands the distribution of 11 genera for the department of Caquetá (*Palaemnema*, *Heteragrion*, *Enallagma* \*, *Rhionaeschna* \*, *Archaeogomphus* \*, *Epigomphus* \*, *Gomphoides* \*, *Brachymesia*, *Elga* and *Elasmothemis*\*) and six of them (\*) are new report for the Colombian Amazon basin. The similarity cluster analysis established three groups of taxa that were correlated with the altitude ranges of stations that were clustered in upper, upper middle, and lower middle. The station at Pescado river, Los Angeles village (E-12), showed the lowest affinity in its taxonomic composition compared to the rest of the assembly, an aspect influenced by the rise in the altitudinal range and the replacement of taxa. Ten of the genera found this zone, did not appear in any other sampling station. It is important to continue these studies in areas with little available information, such as the Andean-Amazon region that presents biogeographic elements and important components of the country's and continent's biodiversity." **17450.** Günther, A. (2020): Reproductive behaviour of *Chlorocyphidae*. Part 2. Genus *Disparocypha* Ris, 1916 (Odonata). *Odonatologica* 49(1/2): 85-106. (in English) ["The reproductive behaviour of *Disparocypha biedermanni* was studied in various streams, mainly in the Lake Poso area of Sulawesi. Flight styles of males were analysed in detail for the first time using high speed cinematography. Protracted threatening flights were particularly common between territorial neighbours. Males flew with regular counter-stroking wing beats and the abdomen held horizontally. Occasionally one of the males performed short ascending flights, pausing the wing beat. These threatening flights were interrupted periodically by short bursts of increased intensity with higher stroke frequency where males arched their abdomens. The escalated threat display could be intensified by tremulous horizontal changes in position. Unlike most *Chlorocyphidae*, mating took place without courtship and oviposition was in vertical mossy structures well above the water. The female was guarded by the male only at the start of oviposition. Possibly the mating system evolved in such a way as to avoid interspecific competition with other *Chlorocyphidae* but this needs more supporting evidence." **17453.** Haring, E.; Fischer, I.; Sittenthaler, M.; Wolf, P.; Koblmüller, S.; Sattmann, H.; Beqiraj, S.; Pešić, V.; Zangl, L. (2020): Intraspecific genetic diversity in selected widespread dragonfly species (Insecta: Odonata). *Acta ZooBot Austria* 157: 239-256. (in English, with German summary) ["Dragonflies inhabit a wide range of habitats, with different species having different species-specific habitat requirements and corresponding niches. Therefore, they are very well suited as indicator species for habitat quality and conservation. Especially in the fields of taxonomy and phylogenetics new insights in odonatology have been gained through molecular genetic methods. Using "DNA barcodes" (DNA sequences of a standardised gene segment, in this case the cytochrome c oxidase 1 gene (COI)), the intraspecific genetic distances of 14 dragonfly species from 18 countries were analysed. We investigated whether there are general differences in intraspecific genetic variability between common species of Zygoptera and Anisoptera. In addition, we examined how DNA sequences with missing data and the different handling of such data in genetic analyses can affect the calculated distances and thus the interpretation of results. Our data show that the dragonfly species studied here generally show very little genetic variation over very large geographical distances, regardless of their assignment to Zygoptera or Anisoptera. The presumably lower active dispersal potential of Zygoptera obviously does not lead to an increased genetic structure. Although these results were consistent across all calculation methods, there were sometimes considerable differences in the way incomplete data were handled. For better comparability, we recommend documenting all parameters in detail in similar studies." **17454.** Hirai, N.; Morioka, T. Ishii, M. (2020): Species diversity of Odonata in Nakaikemi Marsh, Fukui Prefecture, Japan. *Jpn. J. Environ. Entomol. Zool.* 31: 1-12. (in English, with Japanese summary) ["Nakaikemi Marsh was designated as a wetland of international importance under the Ramsar Convention on Wetlands in 2012 because of its rich species diversity and the presence of threatened and endangered animal

and plant species. Although the marsh had been maintained using traditional methods for centuries as rice paddy fields, land use has changed since the abandonment of cultivation in the 1990s. In this study, species diversity of Odonata in the marsh was investigated once a month between April and November 2012 using line-transect and point-census methods for adults and a netting method for larvae. We recorded adults and larvae of 50 Odonata species; a total of 2093 adults from 47 species and 503 larvae from 27 species were observed in the eight surveys. Most of the species found in this study were those recorded in the past, but *Aeschnophlebia longistigma*, *A. anisoptera*, and *Nannophya pygmaea*, which had been continuously observed in the early 1990s, were not recorded. In contrast, we found increased numbers of *Rhyothemis fuliginosa*, *Ischnura senegalensis*, and *Sympetrum croceolum* around the newly formed Sasahana Pond. A population analysis using Kimoto's similarity index ( $C\pi$ ) revealed that the odonatan assemblage around the pond differs from those in other areas in Nakaikemi Marsh. It is possible that the Sasahana Pond has become one of the most important odonatan habitats in the marsh. We found several endangered species and the second highest species richness and diversity in the Ushirodani Valley adjoining the marsh, where traditional methods are used to maintain paddy fields. Invasive alien plant and animal species such as *Solidago altissima* and *Procambarus clarkii* were widespread across the whole area and are considered to harm native vegetation and aquatic animals in the marsh. Our findings indicate that *P. clarkii* density has a significant negative effect on the species diversity of Odonata larvae in the marsh." **17455.** Hong, S.-J. ; Cheong, S.-W. (2020): A Study on the Community Characteristics and Changes of Benthic Macroinvertebrates in the Conservation Area of the Shinbulsan Wetland. *Journal of Environmental Science International* 29(11): 1079-1088. (in Korean, with English summary) ["The Shinbulsan wetland, located in Yangsan-si, Gyeongsangnam-do, South Korea, was designated as a conservation area in 2004. The area was monitored from 2015 to 2019 to investigate the community characteristics and changes of benthic macroinvertebrates. Between 2015 and 2016, several insects of the orders Ephemeroptera, Odonata, and Hemiptera were identified, but their numbers decreased significantly in 2017 and 2018 following the loss and recovery of the moor owing to drought. During this period, there were relatively more insects of the order Diptera. Within this order, three functional feeding groups, gathering-collectors, plant-piercers, and predators were investigated. Predator species were the most abundant (83.3%), whereas gathering-collectors accounted for the largest proportion of individual insects (50.5%). Between 2015 and 2016, when the moors were stable, groups I and III had the highest community stability. After 2017, when the moors had dried up, group III effectively disappeared because of its lower relative resistance and resilience, and only taxa belonging to group I remained. The results of this study indicate that benthic macroinvertebrates that adapt early during moor formation inhabit the Shinbulsan wetland." (Authors)] Address: Cheong,

S.-W., Dept of Biology & Chemistry, Changwon National University, Changwon 51140, Korea

**17456.** Hulo, I., Aleksic, S.; Lovas, G. (2020): Results of the preliminary faunistic research of dragonflies (Insecta: Odonata) of northern Bracka. *Museon* 18: 129-167. (in Serbian, with English summary) ["Results of a preliminary survey of Odonata fauna conducted from 2016 to 2020 are presented. The aim of the research was to map possible habitats in the territory of Northern Backa suitable for the life and reproduction of these insects, as well as to detect the presence or absence of dragonfly species at certain localities. During the research, adult (imago) dragonflies were detected and identified by methods of observation and taking and then analysing of digital photographs. 26 sites with potential dragonfly habits were mapped, out of which 20 sites at standing and 6 sites at flowing waters. A total of 38 species were registered in these habitats, with 37 species observed at standing waters and 22 species at flowing waters. Among the recorded species on the territory of Northern Bačka, the following stand out as rare: *Lestes macrostigma*, *Coenagrion scitulum* and *Sympetrum depressusculum*. The localities with a noticeable diversity of dragonflies are Lake Kelebija, Bački Vinogradi-Ruža majur and Palic-Tresetište, where more than 20 species were registered. However, in many localities significant habitat degradation has been observed due to anthropogenic influence. Besides field surveys, based on examined material in collections, the presence of *S. pedemontanum* in Vojvodina has been established for the first time. This research also confirmed the importance of artificial aquatic habitats that gradually take over the role of extinct or degraded natural biotopes and provide the possibility of survival for certain species of dragonflies. The results of this research provide a basis and an encouragement for further studies and protection activities to save the fauna of dragonflies in this area." **17458.** Iannella, M.; Console, G.; D'Alessandro, P.; Cerasoli, F.; Mantoni, C.; Ruggieri, F.; Di Donato, F.; Biondi, M. (2020): Preliminary analysis of the diet of *Triturus carnifex* and pollution in mountain karst ponds in Central Apennines. *Water* 2020, 12(1), 44: 15 pp. (in English) ["Mountain karst ponds are sensitive environments, hosting complex trophic networks

where amphibians play a major role, often as top predators. The diet of the Italian crested newt (*Triturus cristatus*) is still poorly known for populations occupying mountain karst ponds. These are traditionally used as livestock's watering points, leading to water pollution due to excreta and wading behavior. The aim of this paper is to understand the relationship between *T. cristatus* diet composition, assessed through the stomach flushing technique, and physical and chemical characteristics in mountain ponds, focusing on parameters altered by livestock pressure, such as ammonium concentration and dissolved oxygen. The high diversity of prey items found within the newts' gut contents confirms the generalist diet even in mountain ponds. The number of prey taxa, their relative abundance and Shannon–Wiener diversity index show variations among the sampled sites, related to livestock organic pollution. Moreover, we report the very first European records of microplastic items in amphibians' stomach content, which also represent the first evidence for Caudata worldwide. Our findings suggest that livestock pressure directly influences *T. cristatus* diet and highlight that the emerging issue of plastics is a threat even in remote high-altitude environments. ... Prey items were counted and classified in 19 different taxa, namely Crustacea (4750 prey items), Diptera (1800), Haptotaxida (328), Odonata (220), Hemiptera (191), Mollusca (135), Ephemeroptera (75), Coleoptera (53), Araneae (35), Acarina (17), Hymenoptera (13), Dermaptera (five), Caudata (four), Trichoptera (three), Tricladida (three), Lepidoptera (two), Julida (two), Neuroptera (one) and Mermithida (one). A total of 641 items could not be determined, due to the high level of deterioration; 161 fragments of plants, 93 particles of inorganic sediments probably deriving from the bottom, 59 microplastic items in the form of fibres, splinters and other undeterminable fragments were also found. " (Authors)] Address: Iannella, M., Dept of Life, Health & Environmental Sciences, Environmental Sciences Sect., Univ. of L'Aquila, Via Vetoio, Coppito, 67100 L'Aquila, Italy

**17459.** Ilahi, I.; Yousafzai, A.M.; Rahim, A.; Haq, T.U.; Wahab, S.; Ali, H.; Halimullah; Farooq, M.; Muhammad, H.; Ullah, F.; Ahmad, B.; Ullah, S.; Hussain, S. (2020): Sensitivity of odonate nymphs to different classes of agricultural insecticides, frequently applied in Swat Valley Pakistan. *Applied Ecology and Environmental Research* 18(3): 4115-4136. (in English) ["The sensitivity of *Ischnura elegans* and *Trithemis aurora* nymphs to six different insecticides were studied during 48-hour exposure in the laboratory conditions. Lambda cyhalothrin was found to be the most toxic. Chlorpyrifos was found least toxic. The highest concentrations of deltamethrin, cypermethrin, lambda-cyhalothrin, chlorpyrifos, dichlorvos and acetamiprid that caused no mortality of *I. elegans* were 0.0078, 0.0039, 0.00048, 0.0078, 0.0039 and 0.00195 ppm, respectively. The highest concentrations of deltamethrin, cypermethrin, lambda-cyhalothrin, chlorpyrifos, dichlorvos and acetamiprid that caused no mortality of *T. aurora* were 0.0039, 0.00195, 0.00048, 0.0156, 0.0078 and 0.000975 ppm, respectively. The lowest concentrations of deltamethrin, cypermethrin, lambda-cyhalothrin, chlorpyrifos, dichlorvos and acetamiprid that caused 100% mortality of *I. elegans* were 0.5, 0.5, 0.0156, 1.0, 0.5 and 0.25 ppm, respectively. The lowest concentrations of deltamethrin, cypermethrin,

lambda-cyhalothrin, chlorpyrifos, dichlorvos and acetamiprid that caused 100% mortality of *T. aurora* were 0.25, 0.25, 0.0312, 2, 1 and 0.125 ppm, respectively. Significantly ( $P < 0.05$ ) lowest LC90 values were observed for lambda cyhalothrin (LC90 against *I. elegans* = 0.01 ppm, LC90 against *T. aurora* = 0.018 ppm). Next to the lambda cyhalothrin, significantly ( $P < 0.05$ ) lowest LC90 values were observed for acetamiprid (LC90 against *I. elegans* = 0.122 ppm, LC90 against *T. aurora* = 0.093 ppm). From the findings of the present study, it was concluded that *I. elegans* and *T. aurora* nymphs are highly sensitive to lambda cyhalothrin and acetamiprid." **17460.** Ito, H.C.; Shiraishi, H.; Nakagawa, M.; Takamura, N. (2020): Combined impact of pesticides and other environmental stressors on animal diversity in irrigation ponds. *PLoS ONE* 15(7): e0229052. <https://doi.org/10.1371/journal.pone.0229052>: 20 pp. (in English) ["Rice paddy irrigation ponds can sustain surprisingly high taxonomic richness and make significant contributions to regional biodiversity. We evaluated the impacts of pesticides and other environmental stressors (including eutrophication, decreased macrophyte coverage, physical habitat destruction, and invasive alien species) on the taxonomic richness of freshwater animals in 21 irrigation ponds in Japan. We sampled a wide range of freshwater animals (reptiles, amphibians, fishes, mollusks, crustaceans, insects, annelids, bryozoans, and sponges) and surveyed environmental variables related to pesticide contamination and other stressors listed above. Statistical analyses comprised contraction of highly correlated environmental variables, best-subset model selection, stepwise model selection, and permutation tests. Results showed that: (i) probenazole (fungicide) was a significant stressor on fish (i.e., contamination with this compound had a significantly negative correlation with fish taxonomic richness), (ii) the interaction of BPMC (insecticide; also known as fenobucarb) and bluegill (invasive alien fish) was a significant stressor on a "large insect" category (Coleoptera, Ephemeroptera, Hemiptera, Lepidoptera, Odonata, and Trichoptera), (iii) the interaction of BPMC and concrete bank protection was a significant stressor on an "invertebrate" category, (iv) the combined impacts of BPMC and the other stressors on the invertebrate and large insect categories resulted in an estimated mean loss of taxonomic richness by 15% and 77%, respectively, in comparison with a hypothetical pond with preferable conditions." - 17466.** Jedro, M.; Jedro, G. (2020): New localities of Sedgling *Nehalennia speciosa* (Charpentier, 1840) (Odonata: Coenagrionidae) in the Slupia Valley Landscape Park. *Odonatrix* 16\_4 (2020): 7 pp. (in Polish, with English summary) ["*N. speciosa* is a stenotopic species that inhabits mainly small primary water bodies supporting mud sledge *Carex limosa*. To date, over a dozen sites of this species have been discovered in the province of Pomerania, two of which are protected as buffer zones. Sedglings were discovered in the Slupia Valley Landscape Park in July 2017, at two peatbog localities close to the villages of Lipieniec [UTM XA61] and Skotawsko [XA62] in the commune of Czarna Dąbrówka. The central points of both bogs are dystrophic water bodies with mats of *Sphagnum* moss and *Carex* sp. tussocks. Teneral specimens and copulating pairs of the species were present. The populations are stable, with more than 100 individuals at each site. Apart from Sedgling, 16 and 17 other dragonfly species, respectively, were recorded in the two peatbogs, including: *Leucorrhinia dubia*, *L. pectoralis*, *L. albifrons* and *Cordulegaster boltonii*. In addition, the rare, red-listed European sundew moth *Buckleria paludum* (Pterophoridae) was discovered at Skotawsko. Forest buffer zones are crucial for *N. speciosa*: they influence water chemistry and vegetation composition, and also act as windshields. Deforestation, eutrophication, drainage and pesticides are the main factors endangering this species. Protective buffer zones extending up to 100 m around these two localities are planned. Cooperation between officials of the Regional Directorate for Environmental Conservation, foresters, Landscape Park staff and local naturalists is therefore essential for the creation and subsequent maintenance of these two buffer zones and to minimize the adverse, anthropogenic impact on these localities." - 17467.** Joshi, S.; Agashe, D. (2020): Ontogenic colour change, survival, and mating in the damselfly *Agriocnemis pygmaea* Rambur (Insecta: Odonata). *Ecological Entomology* 45(5): 1015-1024. (in English) ["1. Damselflies often show intra-specific colour variation, which may represent genetic polymorphism or age-related (ontogenic) colour changes. 2. Such variation has distinct implications for the species' ecology and evolution. Colour variation in females of the damselfly *Agriocnemis*

pygmaea was studied, which range from blue male-like individuals (andromorphs) to those with a distinct red colour (heteromorphs). From preliminary observations, it was hypothesised that this species exhibits ontogenetic colour change from heteromorph to andromorph coloration. 3. Mark–recapture experiments and egg counts of dissected females suggested that immature females are heteromorphic and gradually begin to resemble males as they attain sexual maturity. 4. Reflectance spectra of field-caught individuals indicated that, although males are indistinguishable from andromorphs, they could be easily differentiated from heteromorphs. 5. Finally, field observations and mate choice experiments showed that males rarely attempt to mate with heteromorphic females and prefer andromorphs. Together, this study's results suggest that the observed colour variation in *A. pygmaea* females is ontogenetic and is associated with sexual maturity." (Authors)] Address: Joshi, S., Res. **17485.** Krieg, M.; Mohseni, K. (2020): Transient pressure modeling in jetting animals. *Journal of Theoretical Biology* 494, 7 June 2020, 110237: 14 pp. (in English) ["Highlights: • A circulation based model calculates internal pressure dynamics in jellyfish, dragonfly larvae, and squid much more accurately than standard models. • The model is validated for low-inter-

mediate Reynolds numbers. • Body motions of a jellyfish species are optimized for acceleration at the onset of jetting for survival purposes, whereas, velar morphology towards the end of jetting decreases energetic cost. • Impulsive velocity programs in squid improve efficiency by offsetting peaks in pressure and boundary surface velocity thus decreasing total energetic cost. • Dragonfly larvae hindgut geometry reduces refilling work by inducing impingement prior to generation of negative thrust. Abstract: There are many marine animals that employ a form of jet propulsion to move through the water, often creating the jets by expanding and collapsing internal fluid cavities. Due to the unsteady nature of this form of locomotion and complex body/nozzle geometries, standard modeling techniques prove insufficient at capturing internal pressure dynamics, and hence swimming forces. This issue has been resolved with a novel technique for predicting the pressure inside deformable jet producing cavities (M. Krieg and K. Mohseni, *J. Fluid Mech.*, 769, 2015), which is derived from evolution of the surrounding fluid circulation. However, this model was only validated for an engineered jet thruster with simple geometry and relatively high Reynolds number ( $Re$ ) jets. The purpose of this manuscript is twofold: (i) to demonstrate how the circulation based pressure model can be used to analyze different animal body motions as they relate to propulsive output, for multiple species of jetting animals, (ii) and to quantitatively validate the pressure modeling for biological jetting organisms (typically characterized by complicated cavity geometry and low/intermediate  $Re$  flows). Using jellyfish (*Sarsia tubulosa*) as an example, we show that the pressure model is insensitive to complex cavity geometry, and can be applied to lower  $Re$  swimming. By breaking down the swimming behavior of the jellyfish, as well as that of squid and dragonfly larvae, according to circulation generating mechanisms, we demonstrate that the body motions of *Sarsia tubulosa* are optimized for acceleration at the beginning of pulsation as a survival response. Whereas towards the end of jetting, the velar morphology is adjusted to decrease the energetic cost. Similarly, we show that mantle collapse rates in squid maximize propulsive efficiency. Finally, we observe that the hindgut geometry of dragonfly larvae minimizes the work required to refill the cavity." **17486.** Lancer, B.H.; Evans, B.J.E.; Wiederman, S.D. (2020): The visual neuroecology of Anisoptera. *Current Opinion in Insect Science* 42: 14-22. (in English) ["Highlights: • Dragonflies are highly successful aerial predators that rely almost exclusively on vision to drive behaviour. • Regional specialisations of the dragonfly eye assist in different behaviours. • The neuronal target tracking system is finely tuned for predicting the location of small targets in both background visual clutter and swarming conditions filled with distractors. • Once a target has been observed, the dragonfly may implement a number of distinct pursuit strategies for target capture. Dragonflies belong to the oldest known lineage of flying animals, found across the globe around streams, ponds and forests. They are insect predators, specialising in ambush attack as aquatic larvae and rapid pursuit as adults. Dragonfly adults hunt amidst swarms in condi-

tions that confuse many predatory species and exhibit capture rates above 90%. Underlying the performance of such a remarkable predator is a finely tuned visual system capable of tracking targets amidst distractors and background clutter. The dragonfly performs a complex repertoire of flight behaviours, from near-motionless hovering to acute turns at high speeds. Here, we review the optical, neuronal, and behavioural adaptations that underlie the dragonflies' ability to achieve such remarkable predatory success." **17487.** Lee, S.-D.; Bae, S.-H.; Lee, G.-G. (2020): Understanding the impact of environmental changes on the number of species and populations of Odonata after creating a constructed wetland. *Korean Journal of Environment and Ecology* 34(6): 515-529. (in Korean, with English summary) ["Constructed wetlands undergo biological and physical changes such as an increase in the proportion of arid plants due to the natural succession process after formation. It can adversely affect not only the purification function but also the habitat of species. As such, this study aims to identify environmental factors affecting biodiversity and propose management plans based on the monitoring results of physical environmental changes and the emergence of species in seven constructed wetlands selected based on the water depth and surrounding conditions among the lands purchased by the Nakdong River basin. We examined the environmental conditions and emergence of the Odonata, which is a wetland-dependent species, to predict the trend of changes in biodiversity and abundance. The results showed that the open water area decreased as the emergent plants spread to the deep water in 2015 compared to 2012 when they were initially restored to a depth of 0.2 to 1 m. While a total of 54 dragonfly species were observed, the habitat diversity, such as vegetation, water surface, and grassland, remained similar to the initial formation of the wetlands despite the expansion of the emergent plants. On the other hand, the number of Agrionidae species, which prefer areas with fewer aquatic plants, decreased between 2012 and 2015 due to the diminished water surface. The p-values of the differences in the number of species and population between wetlands by year were 2.568e-09 and 1.162e-08, respectively, indicating the statistically significant differences. The decrease in open water surface was found to have the greatest effect on the biodiversity and habitat density of dragonflies. The time-series survey of constructed wetlands confirmed that the spread of *Phragmites communis*, *P. japonica*, *Typha orientalis*, etc., caused a decrease in species diversity. It suggests that environmental management to maintain the open water surface area is necessary." (Authors) ] Address: Lee, S.-D., Dept. of Landscape Architecture, Gyeongnam National University of Science & Technology, 52725, Korea. E-mail: ecoplan@gntech.ac.kr

**17488.** Legros, V.; Rochat, J.; Reynaud, B.; Strasberg, D. (2020): Known and unknown terrestrial arthropod fauna of La Réunion Island, Indian Ocean. *Journal of Insect Conservation* 24: 199-217. (in English) ["A major part of La Réunion Island has been included on the World Heritage List of the

United Nations Educational, Scientific and Cultural Organization (UNESCO) for its unique landscapes and its outstanding biodiversity. However, there is a lack of knowledge on the arthropod diversity. For this reason, an up-to-date census of Réunion's terrestrial arthropods was undertaken. Of the 3369 species that are reported from Réunion (23 Odonata), 31% are endemic to the island and 40% are endemic to the Mascarenes. A diversity ratio between the numbers of described and expected species in the world was established and then applied to the numbers of reported species in Réunion to estimate the total expected numbers of species on the island. The results predict that between 6751 and 10,812 species of terrestrial arthropods are present in Réunion and that 62% of species remain to be discovered. However, some groups appear underrepresented as expected for Darwinian islands that should be originally composed by species with abilities to colonize remote places. Considering the global biodiversity decline and the numerous threats on Réunion's natural habitats, this article emphasizes the crucial need for conservation of terrestrial arthropods and strongly encourages an increase in the list of protected arthropods." **17491.** Lis, C.; Moore, M.P.; Martin, R.A. (2020): Warm developmental temperatures induce non-adaptive plasticity in the intrasexually selected colouration of a dragonfly. *Ecological Entomology* 45(3): 663-670. (in English) ["1. When the breeding environment fluctuates across generations, reproductive traits may evolve plasticity that optimises the balance between survival and mating success for the prevailing environment. 2. For sexually selected colouration, this balance can depend on environmental temperatures. Accordingly, breeding colouration often co-varies with temperature through space and time. However, whether such traits exhibit plasticity in response to environmental temperatures is poorly understood. 3. In the present study, *Pachydiplax longipennis* was reared under ambient or experimentally warmed conditions and tested for plasticity in its intrasexually selected wing colouration. Although wing colouration improves male territorial success, these advantages are smaller under warmer conditions than cooler conditions. It was therefore predicted that males reared under the ambient thermal conditions of the study site (Cleveland, Ohio) would develop more wing colouration than those reared under experimentally warmed conditions. 4. Contrary to this prediction, males reared in warm larval temperatures produced more wing colouration. Thus, although the secondary sexual colouration of this species displays some thermal plasticity, it does not appear to be adaptive relative to the known thermal variation of intrasexual selection in this population. 5. Given that the environment often determines the strength and direction of sexual selection, future studies should consider the potential for non-adaptive, and even maladaptive, developmental plasticity in the sexually selected traits of insects." **17494.** López-Estrada, E.K.; Barona Fernández, J.; Cardo-Maeso, N.; Montejano, S.T.; Díaz-Martínez, C. (2020): *Onychogomphus cazuma* sp. nov. from Spain: Molecular and morphological evidence supports the discovery of a new European dragonfly species (Odonata: Gomphidae). *Odonatologica* 49(1/2): 125-154. (in English) ["*Onychogomphus cazuma* Barona, Cardo & Díaz sp. nov. is described from the mountainous inland area of Valencia in central-eastern Spain. The new species presents a combination of morphological characters that distinguishes it from all other species of the genus and can be readily identified by the morphology of the male appendages and the female vulvar scale, and by the shape of the median lobe of the prementum and the labial palps of the exuvia. Molecular analysis of two genetic markers, one nuclear and one mitochondrial (PRMT and COII), supports the full species rank for this new taxon, which is sister to the north-western African endemic *O. boudoti*. Despite its small known distribution and the vulnerability of its habitat, available data are still insufficient to place this new species into an IUCN Red List of Threatened Species category." **17495.** Akçakaya, R.; Hochkirch, A.; Bried, J.T.; van Grunsven, R.H.A.; Simaika, J.P.; De Knijf, G.; Henriques, S. (2021): Calculating population reductions of invertebrate species for IUCN Red List assessments. *Journal of Insect Conservation* 25: 377-382. (in English) ["Population reductions are often used to assess extinction risk of species in the IUCN Red List. Guidelines for Red List assessments describe specific methods for calculating the amount of reduction for species with strongly fluctuating populations. Recently, an alternative approach that involves expert opinion has been suggested for calculating population reduction in insect species. We argue that, while populations with high temporal variability do present challenges, the alternative suggestion is unnecessary, and inconsistent with the IUCN Red List Categories and Criteria. Implications for insect conservation Consistent application of standardized methods for calculating population reductions allows robust and objective assessment of extinction risk faced by invertebrate species." **17496.** Akhtar, Z.R.; Tariq, K.; Mavian, C.; Ali, A.; Ullah, F.; Zang, L.-S.; Ali, F.; Nazir, T.; Ali, S. (2021): Trophic transfer and toxicity of heavy metals from dengue mosquito *Aedes aegypti* to predator dragonfly *Tamea cophysa*. *Ecotoxicology* 30(4): 1108-1115. (in English) ["Heavy metal pollution in aquatic habitats can be detrimental to both prey and predators in a food web. To investigate the potential for bio-transfer and bioaccumulation of heavy metals between specific trophic levels, 3rd instar larvae of *Aedes aegypti* were exposed to mercury (Hg), lead (Pb), cadmium (Cd), copper (Cu), and zinc (Zn) for three consecutive generations and fed to dragonfly (*Tamea cophysa*) nymphs. Exposure to Hg caused the highest mortality in *A. aegypti* larvae and *T. cophysa* nymphs. Bioaccumulation and life-history parameters of *A. aegypti*, including egg hatching time, larval and pupal duration, male and female life span, and fecundity, were also evaluated after metals exposure. All life-history parameters

except larval duration were significantly affected by heavy metal treatments. Bioaccumulation of metals in *A. aegypti* larvae and adults gradually and significantly increased from 1st to 3rd generation. To the best of our knowledge, this is the first study describing the acute toxicity of heavy metals to mosquitoes. Our study shows that heavy metals cause dietary toxicity to an aquatic predator, dragonfly, via trophic transfer, which could have considerable consequences on aquatic ecosystems." **17498.** Anupama, V.S.; Raj, S.; Devi, S.S., Kumar, A.B. (2021): Diet of exotic *Pirapitinga Piaractus brachypomus* (Cuvier, 1818) from Vembanad-Kole Wetland, India, as inferred from gut content analysis and DNA barcoding. *Asian Fisheries Science* 34: 47-55. (in English) ["Gut contents of the exotic characid fish *Piaractus brachypomus* (Cuvier, 1818) that escaped into the Vembanad-Kole Wetland, India, during the floods were examined for their gut food spectrum. The qualitative analysis of gut contents showed that

the fish is an omnivore with detritus (27 %) as the most dominant food item followed by, plant matter (25 %), crabs (16 %), molluscs (12 %), fish (11 %) and insects (7 %), respectively. DNA barcoding of the gut contents revealed taxa such as *Puntius mahecola* (Valenciennes, 1844) (Cyprinid fish), *Bellamaya* sp. (Mollusca, Gastropoda, Viviparidae), *Spiralothelphusa* sp. (Crustacea, Brachyura, Gecarcinucidae) and *Ictinogomphus* sp. (Insecta, Odonata, Gomphidae) among diet contents. Ontogenic diet shift was not recorded, and none of the fishes showed empty guts, indicating the higher feeding rate and abundance of food in the habitat. The most predominant food item of *P. brachypomus* in the Vembnad-Kol wetland system is crabs in terms of percentage occurrence, percentage number, percentage volume, index of preponderance, and index of relative importance. *Piaractus brachypomus* showed greater variations in diet spectrum from their frugivorous nature in the home range (Amazon basin) to a more generalist heterogeneous feeding nature in the introduced ecosystem. The study found that in a highly biodiverse ecosystem, the introduced alien fish may compete with native fish and feed on native organisms. The paper suggests a precautionary approach in flood plain aquaculture, especially with the increase in extreme climatic events and holistic studies on invasion biology to manage invasive species." **17499.** Araujo, B.R.; Pinto, A.P. (2021): Dragonflies (Insecta: Odonata) from Mananciais da Serra, a Tropical-Araucaria Forest ecotonal remnant in the southern Atlantic Forest, state of Paraná, Brazil. *Zoologia* 38: e55283: 18 pp. (in English) ["This study provides a comprehensive checklist of Odonata species from the protected area of Mananciais da Serra. The survey was conducted in the endangered Atlantic Forest domain at the southern Serra do Mar mountain chain within a well-preserved area in the municipality of Piraquara, state of Paraná, Brazil. Adults and larvae were sampled between June 2017 and March 2020 using different techniques in numerous mesohabitats, including phytotelmata, pools, small streams, and large reservoirs. A total of 1,708 specimens from 9 families, 43 genera and 84 species were sampled resulting in 53 new records for the state of Paraná, almost doubling the known occurrence records for dragonflies and damselflies in that state. Furthermore, two hitherto undescribed females from the genera *Planiplax* and *Heteragrion*, four ultimate stadium larvae from *Planiplax*, *Neocordulia*, *Heteragrion*, and *Acanthagrion*, and five undescribed species were detected, one each from the genera *Heteragrion*, *Progomphus*, *Brechmorhoga*, *Erythrodiplax*, and *Dasythemis*. The estimated richness of odonates in this area is greater than 100 species, while the observed richness corresponding to almost 10% of all Odonata species in Brazil, the species-richest country in the world. These results reiterate the need to investigate under-sampled areas to improve knowledge on diversity, taxonomy, and distribution of neotropical species. Finally, taxonomic notes for some species, including the rare cordulid

*Neocordulia mambucabensis* Costa & T.C. Santos, 2000, are provided." (Authors)] Address: Araujo, B.R., Laboratório de Sistemática de Insetos Aquáticos, Depto de Zoologia, Univ. Federal do Paraná, Caixa Postal 19020, 81531-980 Curitiba, PR, Brazil. E-mail: breno.rda94@gmail.com

**17500.** Archibald, S.B.; Cannings, R.A. (2021): A new genus and species of Euphaeidae (Odonata, Zygoptera) from the early Eocene Okanagan Highlands locality at Republic, Washington, U.S.A.. *Zootaxa* 4966(3): 392-400. (in English) ["We describe *Republica weatbrooki*, a new genus and species of damselfly (Odonata, Zygoptera, Euphaeidae, Eodichromatinae) from the early Eocene (Ypresian) fossil locality at Republic, Washington, U.S.A. Its single specimen is the sole damselfly known from the Okanagan Highlands series of localities in far-western North America." **17501.** Archibald, S.B.; Cannings, R.A.; Erickson, R.J.; Bybee, S.M.; Mathewes, R.W. (2021): The Cephalozygoptera, a new, extinct suborder of Odonata with new taxa from the early Eocene Okanagan Highlands, western North America. *Zootaxa* 4934(1): 1-133. (in English) ["We describe the Cephalozygoptera, a new, extinct suborder of Odonata, composed of the families *Dysagrionidae* and *Sieblosiidae*, previously assigned to the Zygoptera, and possibly the *Whetwhetaksidae* n. fam. The Cephalozygoptera is close to the Zygoptera, but differs most notably by distinctive head morphology. It includes 59 to 64 species in at least 19 genera and one genus-level parataxon. One species is known from the Early Cretaceous (*Congqingia rhora* Zhang), possibly three from the Paleocene, and the rest from the early Eocene through late Miocene. We describe new taxa from the Ypresian Okanagan Highlands of British Columbia, Canada and Washington, United States of America: 16 new species of *Dysagrionidae* of the existing genus *Dysagrion* (*D. pruettae*); the new genera *Okanagrion* (*O. threadgillae*, *O. hobani*, *O. beardi*, *O. lochmum*, *O. angustum*, *O. dorrellae*, *O. liquetoalatum*, *O. worleyae*, all new species); *Okanopteryx* (*O. jeppesenorum*, *O. fraseri*, *O. macabeensis*, all new species); *Stenodiafanus* (*S. westersidei*, new species); the new genus-level parataxon *Dysagrionites* (*D. delinei* new species, *D. sp. A*, *D. sp. B*, both new); and one new genus and species of the new family *Whetwhetaksidae* (*Whetwhetaksa millerae*)." (Authors)] Address: Archibald, S.B., Dept of Biological Sciences, Simon Fraser University, 8888 University Drive, Burnaby, British Columbia, V5A 1S6, Canada. 2. E-mail: sba48@sfu.ca

**17502.** Arumugam, S.; Athikesava, S. (2021): Diversity and distribution of aquatic insects in pond ecosystem in Cheyyar, Thiruvannamalai district of Tamil Nadu, India. *Uttar Pradesh Journal of Zoology* 42(9): 10-15. (in English) ["Aquatic insects are the most diverse group of organisms in freshwater bodies such as lakes, ponds, rivers, streams, reservoirs, etc. A pond ecosystem is a body of standing water and very important habitats for so many various types of animals

such as fishes, crustaceans, insects and amphibians. Aquatic insects are good bioindicators of water quality for assessment of pollution in short and long-term pollution events. The less or more aquatic insects are providing data to estimate the degree of environmental impact and its potential effects on other living organisms. In this study reveals diversity and distribution of aquatic insects from the pond ecosystem in the Kilpudupakkam, Cheyyar, Thiruvannamalai District for a period from August 2017 to January 2018. The aquatic insects were collected with the help of scoop net and hand nets. Later they were identified using of original literature. The insects identified for following 7 orders viz., Hemiptera, Coleoptera, Odonata, Ephemeroptera, Trichoptera, Diptera and Lepidoptera. Order Hemiptera (33.63%) is the largest population of pond ecosystem and compare with other orders and diversity indices were calculated. The order followed by Hemiptera were Coleoptera (27.21%), Odonata (14.98), Ephemeroptera (8.56%), Trichoptera (7.64%), Diptera (5.50%) and Lepidoptera (2.44%)." (Authors)] Address: Arumugam, S., P. G. and Research Dept Zool., Arignar Anna Govt. Arts College, Cheyyar, Tamil Nadu, India

**17503.** Arunima, J.; Nameer, P.O. (2021): A preliminary checklist of dragonflies and damselflies (Insecta: Odonata) of Vakkom Grama Panchayath, Thiruvanthapuram District, Kerala, India. *Journal of Threatened Taxa* 13(8): 19125-19136. (in English) ["A one-year study was conducted at Vakkom Grama Panchayath, Thiruvananthapuram district, Kerala, to assess the diversity of odonates. We report 49 species, which include 31 species of Anisoptera and 18 species of Zygoptera. Among dragonflies, Libellulidae dominated with 26 species, while Coenagrionidae with 10 species was the dominant family among the damselflies. The odonate diversity of Vakkom Grama Panchayath accounted for 28% of the odonates in Kerala and 25% of the odonates of the Western Ghats. Vakkom Grama Panchayath also recorded the presence of *Mortonagrion varralli* which is an uncommon species in Kerala. This study provides some important baseline information on the odonates of one of the grama panchayaths in Kerala, India. An updated checklist of 57 species of odonates of Thiruvananthapuram district, Kerala is also provided." (Authors)] Address: Arunima, J.; Centre Wildlife Stud., Coll. of Forestry, Kerala Agricult. Univ., Vellankkara, Thrissur, Kerala 680656, India. E-mail: arunima.bindhu@gmail.com

**17504.** Baile, E.L. (2021): The effects of urbanization on insect morphology: a meta-analysis. Honors thesis, University of Tennessee at Chattanooga: 22 pp. (in English) ["Urbanization has been shown to create a rapid change in the environment as you move from rural areas to urban areas. It can create a multitude of effects on the environment. Some examples include, land disturbance, pollution, increasing temperatures and a disturbance in vegetation and biodiversity. Insects are useful organisms that provide maintenance and upkeep for ecosystem functioning. The rapid development of urbanization and how it is changing the environment may impact insect morphology. Measuring morphological change in organisms have been used success-

fully as indicators of environmental and ecological disturbance. Changes that take place in an insect's morphology may indicate stress and environmental instability, which will help deepen the understanding of urbanizations impact on urban ecosystems. To evaluate the effect of urbanization on insect morphology, I conducted a meta-analysis of 23 published peer-reviewed studies focused on insect morphology within the context of urbanization. The resulting sample sizes and effect sizes given for changes in morphological traits were extracted and converted to effect size Pearson's ( $r$ ) for a more uniform measurement to analyze in the meta-analysis. I wanted to assess how urbanization impacted insect morphology and understand what may be the driving the effect of urbanization on insects. To identify possible sources of variation across studies, I analyzed five variables that focused on morphological traits, insect order, ecological level, environmental conditions and sex. The results indicated that although the overall effect size ( $r=0.19$ ) of all studies included showed a change or significant effect in the morphological traits of insects between urban and non-urban areas, only ~25% of those studies had an actual impact. The majority, ~75% of studies did not show urbanization to have a significant impact on insect morphology. The insect orders, Hymenoptera, Hemiptera, Odonata and Orthoptera showed a significant effect in morphological changes. Studies that focused on body size and a combination of multiple morphological traits showed a significant effect in morphological changes. In terms of ecological organizations, both population and community groups studied had a significant effect on insect morphology. Disturbance and temperature were the only environmental conditions that showed a significant effect. Studies that measured changes in insect morphology with combined male and female populations showed a significant effect in morphological changes versus studies that focused on a singular sex. These findings may suggest urbanization is causing morphological changes in insects by some capacity but it is not as impactful as one would presume." (Author)] Address: not stated

**17505.** Barling, N.T.; Heads, S.W.; Martill, D.M. (2021): ADDENDUM: Behavioural impacts on the taphonomy of dragonflies (Odonata) from the Lower Cretaceous Crato Formation, Brazil. *Palaeoentomology* 4(3): 203. (in English) ["In our recent paper discussing the impacts of dragonfly behaviour on their taphonomy from the Lower Cretaceous Crato Formation of Brazil (Barling et al., 2021), we figured eight specimens illustrating dragonflies in various states of preservation. In the caption to this figure we listed the temporary laboratory numbers assigned to these specimens during the study (identified with the prefix "UOP-PAL-") and not their permanent accession numbers. On completion of the study, all specimens were transferred to the Museu de Paleontologia Plácido Cidade Nuvens (MPPCD) at the Universidade Regional do Cariri in Crato, Brazil." **17506.** Baumann, K. (2021): Können intakte Gebirgsmoore in Zeiten des Klimawandels Refugien für seltene Libellenarten (Odonata) sein? Untersuchungen im Nationalpark Harz von 2017 bis 2020. *Libellula Supplement* 16: 35-66. (in German, with English summary) ["Can intact mountain bogs be refuges for rare dragonfly species (Odonata) in times of climate change? Investigations in the Harz National Park from 2017 to 2020 – The emergence abundance of *Aeshna juncea*, *A. subarctica*, *Somatochlora alpestris*, *S. arctica* and *Leucorrhinia dubia* was studied on permanent plots in two intact raised bogs of the Harz Mountains from 2017 to 2020. After the extremely dry summer of 2018, a supplementary exuviae search with a special focus on *S. alpestris* has been carried out in a further total of 19 raised bogs and slope located soligenous bogs. As a result of the drought in 2018, the small pools of the raised bogs were lost as reproductive waters for all species except *S. arctica*. This species endured the drought best, but still suffered significant population losses. *S. alpestris* was most affected by the drought, with probably only a maximum of 150 imagines emerging in the entire Harz Mountains in 2020, distributed among a few waters that had not dried up or had dried up only briefly in 2018. It became apparent that the intact mountain bogs of the Harz Mountains are massively exposed to the consequences of climate change. They can only serve as refuges for dragonflies to a very limited extent." (Author)] Address: Baumann, Kathrin, ALNUS GbR, Lärchenweg 15a, 38667 Bad Harzburg, Germany. E-mail: k.baumann@alnus.de

**17507.** Baumann, K.; Kastner, F.; Borkenstein, A.; Burkart, W.; Jödicke, R.; Quante, U. (2021): Rote Liste der in Niedersachsen und Bremen gefährdeten Libellen mit Gesamtartenverzeichnis. 3. Fassung – Stand 31.12.2020. Informationsdienst Naturschutz Niedersachsen 1/2021: 3-37. (in German, with English summary) ["The volunteer dragonfly working group of Lower Saxony and Bremen („Arbeitsgemeinschaft Libellen in Niedersachsen und Bremen“) has recently compiled a dragonfly atlas for the two federal states (Baumann et al. 2021a). For each species, the atlas includes a comprehensive analysis of the population situation and trend. It was therefore logical to compile a new Red List in this context. The atlas and the Red List are based on a comprehensive data set gathered by well over 1,000 volunteers. The dragonfly fauna of the study region is currently facing rapid changes, primarily caused by climate change. Direct negative effects of climate change have been identified for ten species with an affinity for bogs. In contrast, at least nine other species are profiting from this change, including those extending their range from the south. As a result, the number of species recorded from Lower Saxony and Bremen has increased to 73. Of these, 70 have been assessed in this Red List, 69 are established in the region, and one species is extinct since a long time. A total of 23 species (33 %) are ranked as Extinct or Endangered in the Red List. Almost half of these (11) are threatened with extinction, which is a significant deterioration from the previous Red List in 2007 (6). Overall, however, the number of Red List species has decreased, partly due to measures protecting streams, partly due to climate warming, and partly due to increased

knowledge as a result of improved data." (Authors)] Address: Jödicke, R., Am Liebfrauenbusch 3, 26655 Westerstede, Germany. E-mail: reinhard.joedicke@magenta.de

**17508.** Beck, S. (2021): Effects of *Microcystis aeruginosa* on New Jersey aquatic benthic macroinvertebrates. M.Sc. thesis, Montclair State University: 36 pp. (in English) ["As increases in anthropogenic eutrophication and climate change contribute to more severe and frequent cyanobacterial harmful algal blooms in freshwater ecosystems worldwide, understanding the effects and consequences cyanobacterial blooms have on aquatic organisms is crucial. *Microcystis aeruginosa* is one of the most common cyanobacteria taxa found in cyanobacterial blooms, producing a number of toxins including Microcystins. This study examined the effects of *Microcystis aeruginosa* on aquatic benthic macroinvertebrates, specifically the pollution intolerant taxa Ephemeroptera, the pollution moderately intolerant taxa Zygoptera, and the pollution tolerant taxa Chironomidae. In a controlled lab environment, macroinvertebrates were exposed to approximately 100,000 cells/ml of *Microcystis aeruginosa*. The survival percentage was lower for macroinvertebrates exposed to *Microcystis aeruginosa* in all three tolerance groups while corresponding with the pollution tolerance levels of the species. These findings support the notion that cyanobacterial blooms have deleterious effects on freshwater ecosystems and can affect aquatic food webs." (Author)] Address: not stated

**17509.** Belevich, O.; Yurchenko, Y.; Alekseev, A.; Kotina, O.; Odeyanko, V.; Tsentalovich, Y.; Yanshole, L.; Kryukov, V.; Danilov, V.; Glupov, V. (2021): Toxic effects of fine plant powder impregnated with avermectins on mosquito larvae and nontarget aquatic invertebrates. *Journal of Medical Entomology* 58(2): 773-780. (in English) ["The toxic effects of an avermectin-impregnated fine plant powder (AIFP) against larval *Aedes aegypti*, *Culex modestus*, and *Anopheles messeae*, as well as selected nontarget aquatic invertebrates, were studied under laboratory conditions. The possibility of trophic transfer of avermectins (AVMs) through the food chain and their toxic effects on predaceous species fed AIFP-treated mosquito larvae was also evaluated. Among mosquitoes, *Anopheles messeae* were the most sensitive to AIFP, while *Cx. modestus* exhibited the least sensitivity to this formulation. Among nontarget aquatic invertebrates, the greatest toxicity of AIFP was observed for benthic species (larval *Chironomus* sp.), whereas predators (dragonflies, water beetles, and water bugs) exhibited the lowest AIFP sensitivity. AIFP sensitivity of the clam shrimp *Lynceus brachyurus*, the phantom midge *Chaoborus crystallinus*, and the mayfly *Caenis robusta* Eaton was intermediate and similar to the sensitivity of the mosquito *Cx. modestus*. However, these nontarget species were more resistant than *An. messeae* and *Ae. aegypti*. Solid-phase extraction of mosquito larvae treated with AIFP and subsequent high-performance liquid chromatography (HPLC) analysis of the extracts revealed an AVM concentration of up to  $2.1 \pm 0.3 \mu\text{g/g}$ . Feeding the creeping water bug *Ilyocoris cimicoides* on the AIFP-treated mosquito larvae resulted in 51% mortality of the predaceous

species. But no toxicity was observed for *Aeshna mixta* larvae fed those mosquito larvae. The results of this work showed that this AVM formulation can be effective against mosquito larvae." (Authors)] Address: Belevich, Olga, Laboratory of Insect Pathology, Institute of Systematics and Ecology of Animals SB RAS, Novosibirsk, Russia

**17510.** Béthoux, O.; Norrad, R.E.; Stimson, M.R.; King, O.A.; Allen, L.F.; Deregnaucourt, I.; Hinds, S.J.; Lewis, J.H.; Schneider, J.W. (2021): A unique, large-sized stem Odonata (Insecta) found in the early Pennsylvanian of New Brunswick (Canada). *Fossil Record* 24: 207-221. (in English) ["A stem relative of dragon- and damselflies, *Brunellopteron norradi* Béthoux, Deregnaucourt and Norrad gen. et sp. nov., is documented based on a specimen found at Robertson Point (Grand Lake, New Brunswick, Canada; Sunbury Creek Formation; early Moscovian, Pennsylvanian) and preserving the basal half of a hindwing. A comparative analysis of the evolution of wing venation in early Odonates demonstrates that it belongs to a still poorly documented subset of species. Specifically, it displays a MPC+CuA fusion, a CuAC+CuP fusion, and a CuP+AA fusion, but it lacks the "extended" MP+Cu = CuA fusion and the "extended" (CuP / CuA+CuP) + AA fusion, the occurrence of which is typical of most Odonata, including *Meganeura*-like species. The occurrence of intercalary veins suggests that its closest relative might be *Gallotypus oudardi* Nel, Garrouste and Roques, 2008, from the Moscovian of northern France." (Authors)] Address: Béthoux, O., CR2P (Centre de Recherche en Paléontologie – Paris), MNHN – CNRS – Sorbonne Univ., 57 rue Cuvier, CP38, 75005, Paris, France. E-mail: obethoux@mnhn.fr

**17511.** Bhakare, S.D.; Nair, V.P.; Pawar, P.A.; Bhoite, S.H.; Sadasivan, K. (2021): Two new species of *Euphaea* Selys, 1840 (Odonata: Zygoptera: Euphaeidae) from northern Western Ghats, India. *Journal of Threatened Taxa* 13(5): 18200-18214. (in English) ["Two new species of the genus *Euphaea* are described from the Western Ghats of Satara District, Maharashtra, distinguished by their distinct morphology and coloration. *E. thosegharensis* Sadasivan & Bhakare sp. nov. is similar to *E. cardinalis* (Fraser, 1924), but is distinguished by the extensor and flexor surface of all femora black while all femora bright red in *E. cardinalis*; apical fourth of Hw black while apical half of Hw black in *E. cardinalis*; genae reddish-orange, black in *E. cardinalis*; a tuft of sparse stub black hair on either side of tergite of S9 while both S8 and S9 with tufts of long ventral hairs in *E. cardinalis*. Male genital vesicle mat black, with distal border rounded angles, while vesicle black and hexagonal in shape with rounded angles in *E. cardinalis* and S9 twice the length of S10, while S9 and S10 of equal length in *E. cardinalis*. *E. pseudodispar* Sadasivan & Bhakare sp. nov., is very close to *E. dispar* (Rambur, 1842), but is differentiated easily by the absence of yellow patch on legs as in *E. dispar*; only apical fifth of Hw black; genae being yellowish-white, while black in *E. dispar*; male genital vesicle brownish-black & rhomboid-shaped and with no transverse rugosities while black with distal border rounded and with fine transverse rugosities in *E. dispar*;

penis with single seta on each side while *E. dispar* has three pairs; sternite of S9 very prominently extending ventrally like a beak in comparison with *E. dispar*. We have identified additional morphological characters useful in taxonomy of *Euphaea* of the Western Ghats for example, tufts of ventral hairs on terminal abdominal segments genital vesicle, penile structure of males and sternite of S9 in the males, and vulvar scales of females. A taxonomic key to all known species of genus *Euphaea* of the Western Ghats is also provided." **17512.** Bhartiy, S.K.; Elangovan, V. (2021): Seasonal prey availability and diet composition of Lesser Asiatic Yellow House Bat *Scotophilus kuhlii* Leach, 1821. *Journal of Threatened Taxa* 13(8): 19002-19010. (in English) ["Diet is an important factor in understanding bat ecology and conservation. This study assessed seasonal prey availability and diet composition of *S. kuhlii* in various districts of Uttar Pradesh between January 2016 to December 2018. Fecal and insect samples were collected seasonally using sweep nets between 1800 and 1900 h. From each location 20 fecal pellets were selected for analysis and searched for taxonomically recognizable remnants. The analysis revealed that *S. kuhlii* fed on Coleoptera, Diptera, Hymenoptera, Isoptera, Orthoptera, Odonata, Blattellidae, Lepidoptera, and Hemiptera, identified from legs, antennae and wings/elytra in fecal pellets. Seasonal variation in the presence of isolated insect remnants and insect abundance at foraging grounds was observed. Thus *S. kuhlii* is a voracious feeder and plays an important role as a pest control agent." **17514.** Bobrek, R. (2020): *Cordulegaster bidentata* Selys, 1843 in fragmented landscape of the Wielickie Foothills: reassessment of the northern limit of species range in the Western Carpathians. *Fragmenta Faunistica* 63(2): 67-80. (in English) ["In 2018–2019, the occurrence of *C. bidentata* in the Wielickie Foothills, located between the Beskidy mountain ranges (in the south) and the Vistula river valley (in the north) was investigated. It was examined whether *C. bidentata* inhabits fragmented landscape, with forest pat-

ches of various sizes. Larvae of this dragonfly were searched in the forest streams, the bottom of which was visually scanned using binoculars. The presence of 49 larvae was confirmed on 17 stream sections out of 53 (32%). They were recorded in almost the entire geographical extent of the study area, from the southernmost to the northernmost forest patches. The neighboring occupied streams were separated by a maximum of 3.7 km, and breeding sites were found in forest patches of an area of 75–1280 ha. It was confirmed that *C. bidentata* occurs up to the orographic edge of the Western Carpathians. Its range is continuous between the northern edge of the Beskidy Mountains and the Vistula valley. New data shift the northern range limit of *C. bidentata* in the Western Carpathians by nearly 20 km. The field method used proved to be efficient in assessing the distribution of larvae in large areas, with relatively little field effort. Its wider use would allow a more complete recognition of distribution of *C. bidentata* in the Carpathian Foothills." (Authors)] Address: Bobrek, R., Polish Society for the Protection of Birds, Odrowaza 24, 05–270 Marki, Poland. E-mail: rafal.bobrek@gmail.com

**17515.** Bobrek, R. (2021): Post-mining ponds in the Sandomierz Forest (SE Poland) as an important site for the conservation of a species-rich odonate assemblage. *Acta zoologica cracoviensia* 64(1): 159-168. (in English) ["In this study, the species composition and diversity of dragonfly and damselfly assemblages of six post-mining ponds differing in habitat conditions, located within a single sand pit in the central part of the Sandomierz Forest (SE Poland) were assessed. In total, 42 species were recorded in 2019, including 35 species considered resident to the site. In the six studied ponds, a range of 8 to 30 species were recorded, including 5 to 26 resident species. In each pond, at least one unique species was found, and one-third of all species were confined to single ponds only. As a result, the qualitative (Jaccard) and quantitative (Bray-Curtis) similarity indices between the pairs of ponds were low, reaching 12-61% and 19-53%, respectively. Thus, despite a lack of distinct barriers and negligible distances between the ponds (max. 350 m), the structure of assemblages in adjacent water bodies differed considerably. This is probably largely due to the habitat selectivity of species. A redundancy analysis (RDA) showed, that factors such as area and plant diversity of the pond were shaping odonate assemblages, explaining 49.1% of the total variance in the dataset. Due to the high species richness and the identification of several species of special concern, the studied sand pit should be considered a valuable secondary habitat for odonates, which – after termination of exploitation – should be regarded as a good candidate for a site designated for the conservation of biodiversity." (Author)] Address: Bobrek, R., Polish Society for the Protection of Birds, Odrowaza 24, 05–270 Marki, Poland. E-mail: rafal.bobrek@gmail.com

**17516.** Borisov, S.N. (2021): Updates to the fauna of dragonflies (Odonata) of the Altaiskii Krai with new records of species for Siberia. *Eurasian Entomological Journal* 20(3): 136-141. (in English, with Russian summary) ["35 dragonfly

species were recorded during an expedition to the Altaiskii Krai, three of which, *Sympecma fusca*, *Anax imperator* and *Orthetrum brunneum*, are recorded for Siberia for the first time. New data on the occurrence of the rare and little-known species *Ischnura pumilio*, *A. parthenope* and *O. albistylum*, are provided. A new record of the migrant species *Sympetrum fonscolombii* in Siberia is also presented." **17517.** Bose, C.N.; Binoy, C.F.; Kakkassery, F.K. (2021): On the diversity and abundance of riparian odonate fauna (Insecta) of the midstream Chalakkudy River, Kerala, India. *Journal of Threatened Taxa*: 19053-19059. (in English) ["The riparian Odonate insect diversity of the midstream Chalakkudy River at six locations assessed from February 2018 to January 2019 has revealed the occurrence of 25 species of odonates. Among them, 10 species are dragonflies belonging to seven genera of the family Libellulidae and the remaining 15 species are damselflies belonging to six families and 11 genera. Five endemic damselfly species have been recorded. *Pseudagrion indicum* is endemic to the Western Ghats, while the remaining four species, *Vestalis apicalis*, *Libellago indica*, *Dysphaea ethela*, and *Heliocypha bisignata*, are endemic to India. Diversity indices of the odonates in all the six locations were analyzed and it showed less abundance at sites where tourist activities are more and with thin native riparian vegetation. Further, the study has unequivocally revealed that thick native riparian vegetation is essential for their perching and existence. By and large, the uncontrolled tourism activities and habitat alteration interfere with the density and diversity of these endemic species." **17518.** Boudot, J.-P.; Doucet, G.; Grand, D. (2021): Dragonflies and Damselflies of Britain and Western Europe: A Photographic Guide. Bloomsbury Publishing: 152 pp. (in English) ["Dragonflies and damselflies are some of the most beautiful, fragile and resilient insects found in the natural world. With their complex behaviours, astonishing aerobatic skills and preference for freshwater habitats, they are a very rewarding group of animals to observe in the field. Dragonflies and Damselflies of Britain and Western Europe features all 98 species found in the region. Packed with outstanding photography, this comprehensive book includes close-up illustrations to highlight key identification features, diagrams of wing venation, and detailed guides to dragonfly larvae and exuviae. Each species account includes an accurate distribution map and information on field characteristics, confusion species, habitat and ecology. An introduction to the life cycle of Odonata, guidance on when and where to look for them, and the best ways to observe and photograph dragonflies and damselflies in the field are also included. These sections, combined with the identification

guides, make this book the ultimate resource for any field naturalist or entomologist interested in these incredible insects." (Publisher)]

**17519.** Boudot, J.-P. (2021): Synchronism, sex ratio at emergence, and voltinism of *Epithea bimaculata* in Lorraine (North-East France) (Odonata: Corduliidae). *Libellula Supplement* 16: 67-78. (in English, with German summary) ["Population size in *E. bimaculata* varied considerably with time in northeastern France. However, emergences were always synchronised with an EM50 percentile ranging from four to eight days, irrespective of the population size. The sex ratio of all exuviae collected at one locality varied from ca 0.7 to ca 1.0, depending on the year. Larval development of a large part or of the totality of the population was demonstrated to be completed in one year only. These results compared to published data from other countries are discussed." (Author).] Address: Boudot, J.-P., Immeuble Orphée, Apt 703, 78 rue de la Justice, 54710 Ludres, France. **17520.** Brito, J.; Calvão, L.; Cunha, E.; Maioli, L.; Barbirato, M.; Rolim, S.; Juen, L. (2021): Environmental variables affect the diversity of adult damselflies (Odonata: Zygoptera) in western Amazonia. *International Journal of Odonatology* 24: 108-121. (in English) ["Our study evaluated the effects of environmental variables on the assemblages of the sub-order Zygoptera, and tested the hypothesis that environmental variables are more important determinants of the structure of these assemblages than limnological variables in streams. We sampled 17 streams in the Carajás National Forest and tested our hypothesis using a linear regression analysis, with the zygopteran species composition, richness, and abundance as the response variables. Our findings indicate that both limnological and physical variables influence, independently, the characteristics of the zygopteran assemblages. The riparian forest maintains the stability of the environment and provides dispersal corridors, along which the zygopterans can reach alternative, suitable environments. The small scale of this study also implies that the continuity of the vegetation is essential for the dispersal of the zygopterans among different landscapes. The high levels of abundance recorded in the better-preserved environments may reflect the maintenance of specific habitats and resource availability. Riparian forest is crucial to the ecological equilibrium of the stream systems, although further research at a broader spatial scale that focuses on a greater diversity of variables should provide more robust insights into the phenomenon." **17522.** Buczynski, P.; Bielak-Bielecki, P. (2021): Disjunct locality of *Sombre Goldenring Cordulegaster bidentata* Selys, 1843 (Odonata: Cordulegasteridae) in the Sandomierz Basin (SE Poland). *Odonatrix* 17\_5 (2021): 9 pp. (in Polish, with English summary) ["*C. bidentata* was found in the middle course of the Studzienica Stream on the north-eastern edge of the Sandomierz Basin in SE Poland (50.3889°N, 23.09-84°E, UTM: FA48, 219.5 m a.s.l.). One larva was caught on April 27, 2020 during studies conducted as part of the State Environmental Monitoring programme. The locality is described and data on the water parameters are provided. The locality is situated at least 5 km from human habitations in the vast Solska Forest, which consists mainly of moist mixed coniferous woodland. The strongly meandering stream bed is 1-3 m wide. The bottom sediments consist mainly of coarse-grained sand covered with CPOM and FPOM in lentic habitats. The water contains humic acids but its pH is neutral. Almost all the physical and chemical properties of the water meet the first-class quality criteria. The new locality, about 70 km from the Central Beskid Foothills, is the first one in Poland out-side the ranges of mountains and foothills. This discovery suggests that there may be more localities of *C. bidentata* here, forming a disjunct distribution area of this species. This may be a consequence of the relief of the borderland between the Roztocze Upland and the Sandomierz Basin. *C. bidentata* is the 69th odonate species recorded in Lublin Province; 93.4% of the Polish dragonfly fauna is present there." **17525.** Cervený, D.; Fick, J.; Klaminder, J.; McCallum, E.S.; Bertram, M.G.; Castillo, N.A.; Brodin, T. (2021): Water temperature affects the biotransformation and accumulation of a psychoactive pharmaceutical and its metabolite in aquatic organisms. *Environment International* 155 (2021) 106705: 8 pp. (in English) ["Pharmaceutically active compounds (PhACs) have been shown to accumulate in aquatic and riparian food-webs. Yet, our understanding of how temperature, a key environmental factor in nature, affects uptake, biotransformation, and the subsequent accumulation of PhACs in aquatic organisms is limited. In this study, we tested to what extent bioconcentration of an anxiolytic drugs (temazepam and oxazepam) is affected by two temperature regimes (10 and 20°C) and how the temperature affects the temazepam biotransformation and subsequent accumulation of its metabolite (oxazepam) in aquatic organisms. We used European perch (*Perca fluviatilis*) and dragonfly larvae (*Sympetrum* sp.), which represent predator and prey species of high ecological relevance in food chains of boreal and temperate aquatic ecosystems. Experimental organisms were exposed to target pharmaceuticals at a range of concentrations (0.2.6 µg L<sup>-1</sup>) to study concentration dependent differences in bioconcentration and biotransformation. We found that the bioconcentration of temazepam in perch was significantly reduced at higher temperatures. Also, temperature had a strong effect on temazepam biotransformation in the fish, with the production and subsequent accumulation of its metabolite (oxazepam) being two-fold higher at 20°C compared to 10°C. In contrast, we found no temperature dependency for temazepam bioconcentration in dragonfly larvae and no detectable biotransformation of the parent compound that would result in measurable concentrations of oxazepam in this organism. Our results highlight that while organisms may share the same aquatic ecosystem, their exposure to PhACs may change differently across temperature gradients in the environment." (Authors)] Address: Cervený, D., Dept of Wildlife, Fish & Environmental Studies, Swedish Univ. of Agricultural Sciences (SLU), Umeå, Sweden. E-mail: daniel.cervený@slu.se

**17526.** Cetinic, K.A.; Previšić, A.; Rožman, M. (2021): Holo- and hemimetabolism of aquatic insects: Implications for a differential cross-ecosystem flux of metals?. *Environmental Pollution* 277, 15 May 2021, 116798: 9 pp. (in English) ["Highlights: • Emerging aquatic insects facilitate cross-ecosystem transfer of metals. • Metamorphosis alters metal concentrations in aquatic insects. • Holometabolous aquatic

insects exhibit a two-step process in metal flux. • Greater rate of metal decline between larvae/pupae than pupae/adults in Trichoptera. • Bioamplification of toxic metals represents risk for terrestrial insectivores Abstract: Increased metal concentrations in aquatic habitats come as a result of both anthropogenic and natural sources. Emerging aquatic insects that play an indispensable role in these environments, transferring resources and energy to higher trophic levels in both aquatic and terrestrial habitats, may inadvertently also act as biovectors for metals and other contaminants. This study measured levels of 22 different metals detected in biofilm, aquatic and terrestrial life stages of Trichoptera and Odonata, as well as riparian spiders, to examine the uptake and transfer from freshwater to terrestrial ecosystems. We show that emerging insects transfer metals from aquatic to terrestrial ecosystems, however with large losses observed on the boundary of these two environments. Significantly lower concentrations of most metals in adult insects were observed in both hemimetabolous (Odonata) and holometabolous insect orders (Trichoptera). In holometabolous Trichoptera, however, this difference was greater between aquatic life stages (larvae to pupae) compared to that between pupae and adults. Trophic transfer may have also played a role in decreasing metal concentrations, as metal concentrations generally adhered to the following pattern: biofilm > aquatic insects > terrestrial invertebrates. Exceptions to this observation were detected with a handful of essential (Cu, Zn, Se) and non-essential metals (Cd, Ag), which measured higher concentrations in adult aquatic insects compared to their larval counterparts, as well as in aquatic and terrestrial predators compared to their prey. Overall, all metals were found to be bioavailable and biotransferred from contaminated waters to terrestrial invertebrates to some degree, suggesting that risks associated with metal-contaminated freshwaters could extend to terrestrial systems through the emergence of these potential invertebrate biovectors." **17531.** Chitsaz, N.; Siddiqui, K.; Marian, R.; Chahl, J. (2021): Numerical and experimental analysis of three-dimensional microcorrugated wing in gliding flight. *J. Fluids Eng.* Jan 2022, 144(1): 011205 : 11pp. (in English) ["In this study, computational fluid dynamics analysis was performed on a three-dimensional (3D) model of a Libellulidae wing to determine aerodynamic performance in gliding flight. The wing is comprised of various corrugated features alongside the spanwise and chordwise directions, as well as twist. The detailed features of real 3D dragonfly wing models, including all the corrugations through both span and chord, have not been considered in the past for a detailed aerodynamic analysis. The simulations were conducted by

solving the Navier–Stokes equations to demonstrate gliding performance over a range of angles of attack at low Reynolds numbers. The numerical model was validated against experimental data obtained from a fabricated corrugated wing model using particle image velocimetry. The numerical results demonstrate that bio-inspired wings with corrugations compared to flat profile wings generate more lift with lower drag, trapping the vortices in the valleys of wing corrugation leading to delayed flow separation and delayed stall. The experimental and numerical results demonstrate that the methodology presented in this study can be used to measure bio-inspired 3D wing flow characteristics, including the influence of complex corrugations on aerodynamic performance. These findings contribute to the advancement of knowledge required for designing an optimized bio-inspired micro-air vehicle." **17534.** Corral-Lopez, A.; Varg, J.E.; Cano-Cobos, Y.P.; Losada, R.; Realpe, E.; Outomuro, D. (2021): Field evidence for colour mimicry overshadowing morphological mimicry. *Journal of Animal Ecology* 90(3): 698-709. (in English) ["(1) Imperfect mimicry may be maintained when the various components of an aposematic signal have different salience for predators. Experimental laboratory studies provide robust evidence for this phenomenon. Yet, evidence from natural settings remains scarce. (2) We studied how natural bird predators assess multiple features in a multi-component aposematic signal in the Neotropical "clear wing complex" mimicry ring, dominated by glasswing butterflies. (3) We evaluated two components of the aposematic signal, wing colouration and wing morphology, in a predation experiment based on artificial replicas of glasswing butterflies (model) and Polythoridae damselflies (mimics) (*Euthore fasciata*) in their natural habitat. We also studied the extent of the colour aposematic signal in the local insect community. Finally, we inspected the nanostructures responsible for this convergent colour signal, expected to highly differ between these phylogenetically distinct species. (4) Our results provide direct evidence for a stronger salience of wing colouration than wing morphology, as well as stronger selection on imperfect than in perfect colour mimics. Additionally, investigations of how birds perceive wing colouration of the local insect community provides further evidence that a UV-reflective white colouration is being selected as the colour aposematic signal of the mimicry ring. Using electron microscopy, we also suggest that damselflies have convergently evolved the warning colouration through a pre-adaptation. (5) These findings provide a solid complement to previous experimental evidence suggesting a key influence of the cognitive assessment of predators driving the evolution of aposematic signals and mimicry rings." **17536.** De Knijf, G. (2021): *Forcipomyia paludis* as a parasite of Odonata in Belgium (Diptera: Ceratopogonidae; Odonata), with notes on its ecology and habitat. *Libellula Supplement* 16: 101-114. (in English, with German summary) ["The biting midge *F. paludis* is the only ceratopogonid species known to parasitise Odonata in Europe. This parasite is widely distributed in the Western Palaearctic, but has only once been formally cited for one damselfly species in Belgium. However, many photographs of parasitised Odonata are stored in the citizen science website [www.waarnemingen.be](http://www.waarnemingen.be) in Belgium. A thorough analysis of 2,300 photographs from four sites from 2019 and 2020 resulted in the finding of 100 photographs of 32 species of odonate being parasitised in Belgium. We also found two species, *Coenagrion scitulum* and *Sympetrum vulgatum* for the first time mentioned as hosts. Virtually all *F. paludis* (99%) were found at the sites Buitengoor and Hageven. Biting midges were found in at least 13% of the photographs from Buitengoor and 3% in Hageven. Most records date from the end of May to the end of July. The parasite prevalence was low: 87% of the individuals carried only one or two midges. They seemed to have a slight preference for the forewings over the hind wings (59% versus 41%), but no difference was found between the right and the left wings. The presence of biting midges on Odonata was correlated with the presence of *Cladium mariscus* vegetation. This vegetation type might be the larval habitat of *F. paludis*." **17537.** Deviche, P. (2021): Partial submergence: An undescribed behavioral adjustment for thermoregulation at high ambient temperature in Aeshnidae. *International Journal of Odonatology* 24: 71-81. (in English) ["Many insects including odonates thermoregulate using a combination of behavioral and physiological mechanisms. At high ambient temperature ( $T_a$ ), these mechanisms include decreased heat production and increased heat loss. Heat production can be reduced by decreasing activity. Heat loss can be enhanced by perching in a shaded microhabitat where temperature is cooler than in the surrounding environment. Aeshnids, which are intermittent endotherms, increase heat loss at high  $T_a$  also by increasing hemolymph circulation from the thorax, where most metabolic heat is produced, to the

abdomen, where it dissipates to the environment by convection. While studying two aeshnid species (*Anax junius* and *Rhionaeschna multicolor*) at a Sonoran Desert (Arizona, USA) stream, I observed partially submerged mature individuals of both sexes of these species. This heretofore undescribed behavior was seen only at  $T_a > 43$  °C and almost exclusively during the hottest part of the day (15:00–17:00 hr), when the daily difference between  $T_a$  and water temperature ( $T_w$ ) was, on average, largest. A cooling effect of partial submergence behavior on body temperature would, therefore, presumably be most effective also during this period. Several percher species of libellulids were present at the study site. These dragonflies are not known to use endothermy for thermoregulation or to increase hemolymph circulation to the abdomen to dissipate heat at high  $T_a$ , and none was ever observed to partially submerge. It is suggested in aeshnids that partial submergence at high  $T_a$  serves a thermoregulatory function by facilitating body heat dissipation from the abdomen." **17538.** Díaz-Martínez, C.; Cardo-Maeso, N.; Simarro-Tórtola, J.; Valero, A.G.; Conesa García, M.A. (2021): Ampliación de la distribución conocida y caracterización del hábitat de *Onychogomphus cazuma* Barona, Cardo & Díaz, 2020 (Odonata: Gomphidae) en España. *Boletín de la Sociedad Entomológica Aragonesa* 68: 368-382. (in Spanish, with English summary) ["Extension of the known distribution and habitat characterisation of *O. cazuma* in Spain Abstract: The previously recorded distribution of *O. cazuma* consisted of eight localities in the provinces of Valencia, Albacete and Murcia. This paper presents the results of the sampling carried out between 2019 and 2021, including six new localities in Cuenca, Albacete and Valencia, thus improving the knowledge of the distribution of this Iberian endemic and providing additional records in two of the known localities. The description of the localities where *O. cazuma* is present reinforces the hypothesis of a very specific larval habitat, associated to the existence of hot springs. However, the water temperature may not be a determining factor. The issue of its detectability and some conservation threats and opportunities are pointed out." (Authors)] Address: Díaz-Martínez, Cecilia, Sociedad Entomológica y Ambiental de Castilla-La Mancha, c/Londres, 7, 45003 Toledo, Spain. E-mail: cdiaz.cuenca@gmail.com

**17539.** Dolný, A.; Ožana, S.; Burda, M.; Harabiš, F. (2021): Effects of landscape patterns and their changes to species richness, species composition, and the conservation value of odonates (Insecta). *Insects* 12(6), 478: 14 pp. (in English) [oas 57: "Simple Summary: In this study, we aimed to evaluate the relationship between human transformations of land use/land cover and adult dragonfly diversity. Based on previous studies, we assumed that with increasing rates of environmental degradation and declining levels of naturalness, the representation of species with high conservation value would significantly decrease, which, however, would not affect the regional alpha diversity. Our results have

shown that species richness did not correspond to habitat naturalness, but the occurrence of endangered species was significantly positively correlated with increasing naturalness; thus, habitat degradation and/or the level of naturalness significantly affected species composition, while species richness remained unchanged. Based on our analyses, it is evident that most natural areas, and therefore the least affected areas, provide suitable conditions for the largest number of endangered species. This research extends our knowledge about the impact of human activities, especially the conversion and degradation of habitats, on the composition of odonates and freshwater animals at the regional scale. Abstract: Understanding the impact of the changing proportion of land-use patterns on species diversity is a critical issue in conservation biology, and odonates are good bioindicators of these environmental changes. Some freshwater ecosystems that have been modified due to human activities can serve as important secondary habitats for odonate assemblages; however, the majority of studies addressing the value of secondary habitats in industrial and urban areas for adult dragonfly diversity have been limited to the local scale, and the value of such habitats for gamma diversity is still unclear. The aim of this study was to determine the relationship between human transformations of land use/land cover and dragonfly diversity. We interpolated the information based on dragonfly occurrence per grid cell and land cover data, indicating naturalness and degradation in 677 grid cells in the Czech Republic. Species richness did not correspond to habitat naturalness, but the occurrence of endangered species was significantly positively correlated with increasing naturalness; thus, habitat degradation and/or the level of naturalness significantly affected species composition, while species richness remained unchanged. Threatened species that occur predominantly in natural areas and threatened species with a dominant occurrence in degraded squares were also separated, which indicated that the conservation of the latter should be prioritised." **17540.** Dow, R.A. (2021): An annotated checklist of the Odonata (Insecta) known from Sarawak with records to district level. *Sarawak Museum Journal* LXXX1, No. 101 (New Series); Special Issue 10: 313-422. (in English) ["The first checklist of the Odonata of the state of Sarawak in Malaysian Borneo is presented. 303 species are included in the list. Records are given to district level. For each species, a reference to the first record from each district in which it occurs is given, except where this paper represents the first published district record, in which case this is indicated. Additionally all references for the species containing original records from Sarawak, or significant discussion of material from or relevant to Sarawak, are given. Known taxonomic issues are discussed in notes. The number of records from each district and division is summarised." (Author)] Address: Dow, R.A., Naturalis Biodiversity Centre, P.O. Box 9517, 2300 RA Leiden, The Netherlands. Email: rory.dow-230@yahoo.co.uk

**17541.** Dow, R.A. (2021): Corrections, amendments and updates to "An annotated checklist of the Odonata (Insecta) known from Sarawak with records to district level". *Faunistic Studies in SE Asian and Pacific Island Odonata* 34: 1-6. (in English) ["Corrections, amendments and some updates to an annotated checklist of the Odonata of Sarawak (Dow 2021) published in a special edition of the Sarawak Museum Journal are listed. With one exception taxonomical updates given here are confined to those based on publications that appeared between the last revision of the manuscript (early April 2019) and its publication (February 2021). The exception is that a *Merogomphus* (?) species lumped under *M. femoralis* Laidlaw, 1931 in Dow (2021) is considered to be a separate species here. Unfortunately there are a number of problems with records at district level and the reader of Dow (2021) is advised to simply ignore the district level records and counts until a revised version of the checklist using an accurate characterisation of Sarawak's districts is produced. Additionally the number of species known from Sarawak is updated to reflect information published in Dow et al. (2021) and in this paper and now stands at 308." (Author)] Address: Dow, R.A., Naturalis Biodiversity Centre, P.O. Box 9517, 2300 RA Leiden, The Netherlands; Institute of Biodiversity and Environmental Conservation, Universiti Malaysia Sarawak, 94300 Kota Samarahan, Sarawak, Malaysia. **17543.** Dow, R.A.; Butler, S.G.; Ngiam, R.W.J.; Reels, G.T. (2021): Previously unpublished Odonata records from Sarawak, Borneo, part V: Odonata from the southwest of Sarawak, including the first records from the Bungo Range National Park. *International Dragonfly Fund - Report* 159: 1-77. (in English) ["Records of Odonata from three administrative divisions in the southwest of Sarawak (Kuching, Samarahan and Serian), mostly made during field work funded by the International Dragonfly Fund and the Sarawak Museum Campus Project, are presented. In the first part of the paper 176 species are listed, of which *Burmagomphus plagiatus* Lieftinck, 1964 was recorded from Sarawak for the first time during this study and one or possibly two unnamed

*Onychogomphus sensu lato* species were recorded from Borneo for the first time (one from a single female, the other from an exuvia). *Gynacantha maclachlani* is also recorded from Sarawak for the first time. The first records of Odonata from the Bungo Range National Park are included here. Other notable records include *Drepanosticta drusilla*, *D. kosterini*, *Podolestes chrysopus*, *Libellago stigmatizans*, *Rhinocypha aurofulgens* (recorded from southwest Sarawak for the first time), *Bornargiolestes reelsi*, *Amphicnemis madelenae*, *A. rigiketiti*, *Burmagomphus insularis*, *Gomphidia abbotti*, *Macrogomphus albardae*, *Macromia arachnomima*, *M. callisto* and *Nannophyopsis chalcosoma*. The importance of kampung (village) lands, still mostly farmed by traditional methods and presenting a mosaic of different habitat types in close proximity to each other, for conservation is discussed briefly, taking the Gomphidae as an example. In the second part of the paper some taxonomic issues are discussed and some molecular data is included. Bornean *Libellago stigmatizans* are shown to be indistinguishable from *L. stictica* (Selys, 1859) using COI based DNA barcoding, but the two are clearly separated in ITS. *Gomphidia caesarea* Lieftinck, 1929 is considered to be a junior synonym of *Gomphidia abbotti*, variation in *G. abbotti* is discussed and DNA barcoding data for *G. abbotti* and *G. maclachlani* is presented. The status of *Macrogomphus abnormis* Selys, 1884 is discussed and some COI data is presented to support the view that two species have been treated as *M. parallelogramma* in Borneo until now (an issue that will be dealt with in much more detail in a future paper). One of the *Onychogomphus sensu lato* species is discussed and illustrated from a female and illustrations of the female of "*Phaenandrogomphus*" *safei* are presented for the first time. A detailed list of previously unpublished specimens from the locations covered is given in an appendix and details of specimens used in the molecular analyses are given in a second appendix." (Authors)] Address: Dow, R.A., Naturalis Biodiversity Centre, P.O. Box 9517, 2300 RA Leiden, The Netherlands. E-mail: rory.dow230@yahoo.co.uk

**17544.** Dow, R.A.; Morris, J.R. (2021): The old Odonata (Insecta) Collection of the Sarawak Museum. *Sarawak Museum Journal* LXXX1, No. 101 (New Series); Special Issue 10: 261-311. (in English) ["The old Odonata collection of the Sarawak Museum has been examined and re-identified. An annotated list of the species and specimens present in the collection is given, along with remarks about the locations where they were collected. A total of 378 specimens are present in the collection, 356 of which are from or assumed to be from Sarawak, the remaining 22 specimens are from Sabah (all from Mount Kinabalu). In total, at least 89 species are represented in the collection, however the condition (or sex in some cases) of approximately 15% of the specimens precludes definite identification to species. The collection includes the holotype of *Orchithemis xanthosoma*, one of the syntypes of *Pseudagrionoptera diotima* and paratypes of *Podolestes harrissoni* and *Ictinogomphus acutus*. Other significant material includes the only specimen of *Euphaea ameeke* known from Limbang Division, the only specimen of *Gynacantha bayadera* from Sarawak and a series of

Chlorogomphus specimens." (Authors)] Address: Dow, R.A., Naturalis Biodiversity Centre, P.O. Box 9517, 2300 RA Leiden, The Netherlands; Institute of Biodiversity and Environmental Conservation, Universiti Malaysia Sarawak, 94300 Kota Samarahan, Sarawak, Malaysia. Email: rory.dow230@yahoo.co.uk

**17545.** El-Latief, M.E.A.; Elsayed, K.; Abdelrahman, M.M. (2021): Parametric study of a corrugated airfoil in a forward flight at ultra-low Reynolds number. SN Applied Sciences volume 3, Article number: 112 (2021): (in English) ["In the current study, the mid cross section of the dragonfly forewing was simulated at ultra-low Reynolds number. The study aims to understand better the contribution of corrugations found along the wing on the aerodynamic performance during a forward flight. Different flapping parameters were employed. FLUENT solver was used to solve unsteady, two-dimensional, laminar, incompressible Navier–Stokes equations. The results revealed that any stroke amplitude less than 1cm generated no thrust force. The stroke amplitude had to be increased to form the reversed Kármán vortices responsible for generating thrust force. The highest propulsive efficiency was found in the Strouhal number range  $0.2 < St < 0.4$  with a peak efficiency of 57% at  $St = 0.39$ . Changing the phase difference between pitching and plunging motions from advanced to synchronized caused lift force to drop 91% and thrust force to increase by 15%. On the other hand, changing the phase difference from synchronized to delayed caused lift and thrust forces to increase by 89% and 36%, respectively, and propulsive efficiency to deteriorate significantly. In all performed simulations, the airfoil was assumed to start motion from rest with no initial angle of attack. The increase in initial angle of attack generates a very high lift force with a fair loss for both thrust force and propulsive efficiency. The decomposition of flapping motion into its elementary motions revealed that the aerodynamic forces generated are a non-linear superposition from both pure pitching and pure plunging aerodynamic forces. This can be attributed to the non-linear interaction between unsteady vortices generated from these decomposed motions." **17546.** Eriksen, E.; Friberg, N.; Brittain, J.E.; Søli, G.; Ballot, A.; Årstein-Eriksen, E.; Blakseth, T.A.; Veiteberg Braaten, H.F. (2021): Ecological condition, biodiversity and major environmental challenges in a tropical river network in the Bago District in South-central Myanmar: First insights to the unknown. *Limnologica* 86 (2021) 125835: 12 pp. (in English) ["Freshwater ecosystems in the Indo-Burma biodiversity hotspot face immediate threats through habitat loss and species extinction. Systems to monitor ecological status and trends in biodiversity are therefore crucially needed. Myanmar is part of Indo-Burma but with no past experience of biomonitoring in freshwaters. In this study, we aimed to assess the ecological and biodiversity status of a lowland

river network in south-central Myanmar by identifying and quantifying pressures using macroinvertebrates as bioindicators. Novel data on water quality (nutrients, sediments and metals), hydromorphology (Morphological Quality Index; MQI), habitat quality (Litter-Siltation Index; LSI), land use, and macroinvertebrates were collected from 25 river sites. The dominant pressures on rivers were urban land use, inputs of untreated sewage, in-stream and riparian garbage littering, run-off from agricultural fields and plantations, as well as physical habitat degradation. Water chemistry data indicated inputs of sediments and nutrients to degraded streams, but no obvious metal pollution. The LSI and MQI indices indicated high perturbation in agricultural and urban areas, respectively. Ecological status was assessed using a first version of a modified Average Score per Taxon index (ASPT), while biodiversity was assessed by family richness within the orders Ephemeroptera, Plecoptera, Trichoptera, Coleoptera and Odonata (EPTCO), which was tested against the pressure gradient by principal component regressions. ASPT had high diagnostic capabilities ( $R^2 = 0.68$ ,  $p < 0.001$ ) and showed that the index can be used to evaluate ecological water quality in this region. Biodiversity, expressed as family richness, also declined along the gradient ( $R^2 = 0.59$ ,  $p = 0.041$ ), giving support to the fact that current land-use practices in this area are unsustainable." **17547.** Everling, S. (2021): The effect of temperature on the interaction between larvae of a native and a range expanding dragonfly species. MSc. thesis, Biology Education Centre and Department of Ecology and Genetics, Uppsala University: 26 pp. (in English) ["Climate change might affect the distribution of species; therefore, it is important to anticipate the imminent impact of climate change. Even though climate responses have the potential to affect species interactions, most models on the effect of climate change on species distribution assume that species respond to climate individually. Hence studies on competition effects are needed. In this study, I estimated growth, mortality, and behaviour (prey capture success, activity, exploration and boldness) at 20° C and 23° C at intra- and interspecific competition conditions in larvae of a native and a northward dispersing dragonfly. The results showed that the northward expanding *Sympetrum fonscolombii* had a higher growth and survival rate compared to the native *Sympetrum vulgatum* at interspecific conditions. At intraspecific conditions the results showed that temperature had no significant effect on the performance of *S. fonscolombii*, but *S. vulgatum* showed both a higher growth rate and a higher mortality at 23° C. A significant difference between temperatures within prey capture success rate was found in *S. vulgatum* only, during the second observation period. There was a correlation between activity and exploration in both species, between prey capture success rate and activity during the third observation round in *S. vulgatum*, and between prey capture success rate and boldness during the first observation round in *S. fonscolombii*. No other behaviours were correlated. Prey capture success rate was shown to be repeatable in both

species, while boldness was repeatable in *S. vulgatum* only. The behavioural results suggests that behavioural traits are relatively plastic over ontogeny in both species, possibly caused by behavioural variation within each instar. Additionally, boldness, but not activity and exploration, might aid *S. fonscolombii* in their northward expansion. The majority of these results were similar at both temperatures and indicate that *S. fonscolombii* has a higher capacity to tolerate climate change, and their presence might negatively impact the performance of *S. vulgatum*." (Authors)] Address: Everling, S., Uppsala Univ., Disciplinary Domain of Science & Technology, Biology, Biology Education Centre

**17548.** Faasen, T. (2021): *Inpabasis intermedia*, a new species of damselfly from Peru (Odonata: Coenagrionidae); with an illustrated key to all known *Inpabasis*-species. *International Journal of Odonatology* 24: 95-107. (in English) ["*Inpabasis intermedia* sp. n. (holotype ♂: Peru, Loreto Region) is described and illustrated. An illustrated key to both sexes is given for all members of the genus. Males of *I. intermedia* can be distinguished from its congeners by the angled division laterally between dark and light areas of the pterothorax, by the short unbranched paraprocts and rounded cerci which bear only a small apical tooth and by the genital ligula with two long apical processes ending in a flattened hook. Females can be distinguished by the dorso-posteriorly directed posterior prothoracic lobe with straight hind margin." **17549.** Fabian, J.M.; Wiederman, S.D. (2021): Spike bursting in a dragonfly target-detecting neuron. *Scientific Reports* 11( 4005) (2021): 6 pp. (in English) ["Dragonflies visually detect prey and conspecifics, rapidly pursuing these targets via acrobatic flights. Over many decades, studies have investigated the elaborate neuronal circuits proposed to underlie this rapid behaviour. A subset of dragonfly visual neurons exhibit exquisite tuning to small, moving targets even when presented in cluttered backgrounds. In prior work, these neuronal responses were quantified by computing the rate of spikes fired during an analysis window of interest. However, neuronal systems can utilize a variety of neuronal coding principles to signal information, so a spike train's information content is not necessarily encapsulated by spike rate alone. One example of this is burst coding, where neurons fire rapid bursts of spikes, followed by a period of inactivity. Here we show that the most studied target-detecting neuron in dragonflies, CSTMD1, responds to moving targets with a series of spike bursts. This spiking activity differs from those in other identified visual neurons in the dragonfly, indicative of different physiological mechanisms underlying CSTMD1's spike generation. Burst codes present several advantages and disadvantages compared to other coding approaches. We propose functional implications of CSTMD1's burst coding activity and show that spike bursts enhance the robustness of target-evoked responses." **17550.** Febriantim, N.A.; Murwitaningsih, S.; Sukandar, P.; Lestari, S. (2021): Dragonfly community in flowing and stagnating water in the Cibodas Botanical Garden Area. *IOP Conference Series: Earth and Environmental Science* 755: 7 pp. (in English) ["The diversity of dragonflies in Indonesia is quite high, namely about 750 species or 12.5% of the total in the world. This study aims to determine the dragonfly community ... in the Cibodas Botanical Garden Area. The research method used was a descriptive exploratory method, while the data collection technique used the Catch and Release technique (TLK). Data analysis in this study used descriptive analysis. Data collection was carried out in May-July 2018. The locations included in the flowing water group were Sakura Park and Ciismun Waterfall, while Air Mancur and Guest House were included in the stagnant water group. The results showed that there were 8 types of dragonflies identified, namely *Orthetrum pruinosum*, *O. sabina*, *O. glaucum*, *Pantala flavescens*, *Neurothemis fluctuans*, *N. terminata*, *Ischnura senegalensis*, *Coeliccia membranipes*. The most common species found was *P. flavescens* with 533 individuals, while the least species found was *Neurothemis terminata* with 4 individuals. Zygoptera was found only in 2 types in this study, namely the *C. membranipes* with the number of 101 individuals and *I. senegalensis* with the number of 19 individuals. The dominant types of dragonflies in flowing and stagnant water are *P. flavescens* and *O. pruinosum*. The *C. membranipes* dragonfly was only found in running water, namely at the location of the Ciismun waterfall and *Ischnura senegalensis* only found in stagnant water, namely at the location of the fountain." **17554.** Flöss, I. (2021): Individuelle Raumnutzung und Wiedersichtungsrate von *Somatochlora flavomaculata* in einer voralpinen Moorlandschaft (Odonata: Corduliidae). *Libellula Supplement* 16: 127-140. ["Individual spatial movements and resighting rates of *S. flavomaculata* in a prealpine mire landscape – In a part of a prealpine mire landscape near Wetzikon, Switzerland, a total of 292 mature males and seven females were individually marked either on their wings or legs in the summer of 1997. 85 males (30.5%) but no females were at least once resighted up to 49 days after marking. Of the wingmarked individuals 33.8% were resighted and 21.3% of the leg-marked ones. There was a

considerable difference between the resighting rates from the first half of the season and the second half due to a longer spell of bad weather in June and July. Multiple resightings within the same day showed that some males relocated their territories only slightly within several hours, whereas some males changed the sites up to 100 m distance. The great time intervals sometimes observed between resightings and, additionally, the resighting of five males up to 1.7 km outside the study area indicate that *S. flavomaculata* moves of a large scale within the mire landscape and thereby even overcomes dense forests." **17555.** Fraker, M.E.; Ludsin, S.A.; Luttbeg, B.; Denver, R.J. (2021): Stress hormone-mediated antipredator morphology improves escape performance in amphibian tadpoles. *Scientific Reports* 11(4427): 9 pp. (in English) ["Complete functional descriptions of the induction sequences of phenotypically plastic traits (perception to physiological regulation to response to outcome) should help us to clarify how plastic responses develop and operate. Rapid tadpoles express several plastic antipredator traits mediated by the stress hormone corticosterone, but how they influence outcomes remains uncertain. We investigated how predator-induced changes in the tail morphology of wood frog (*Rana sylvatica*) tadpoles influenced their escape performance over a sequence of time points when attacked by larval dragonflies (*Anax junius*). Tadpoles were raised with no predator exposure, chemical cues of dragonflies added once per day, or constant exposure to caged dragonflies crossed with no exogenous hormone added (vehicle control only), exogenous corticosterone, or metyrapone (a corticosteroid synthesis inhibitor). During predation trials, we detected no differences after four days, but after eight days, tadpoles exposed to larval dragonflies and exogenous corticosterone had developed deeper tail muscles and exhibited improved escape performance compared to controls. Treatment with metyrapone blocked the development of a deeper tail muscle and resulted in no difference in escape success. Our findings further link the predator-induced physiological stress response of rapid tadpoles to the development of an antipredator tail morphology that confers performance benefits." **17556.** Freienstein, F.M.; Fartmann, T.; Löffler, F. (2020): Libellengemeinschaften extensiv genutzter Karpfenteiche (Insecta: Odonata) - Schlüsselfaktoren für die Biodiversität und Empfehlungen für eine naturschutzgerechte Bewirtschaftung. *Berichte der Naturforschenden Gesellschaft der Oberlausitz* 28: 3-20. (in German, with English summary) ["Dragonfly communities of extensively managed carp ponds (Insecta: Odonata) - key factors for biodiversity and recommendations for management in accordance with nature conservation Owing to the drastic loss of natural freshwater habitats over recent decades, anthropogenic waterbodies are taking on an increased significance for the

conservation of biodiversity. The value of traditionally managed carp-pond complexes for biodiversity is well known. Nevertheless, the periodic draining of ponds for harvesting and high fish-stocking intensities are assumed to have negative effects on biodiversity. However, empirical studies of the impact of carp farming on pond biodiversity are still scarce. In this study, we analyzed the effects of habitat quality and pond management on odonate communities in an extensively managed carp-pond complex in Oberlausitz (Saxony, Germany). The study sites included farmed carp ponds characterized by various habitat structures and stocking intensities as well as abandoned carp ponds and new ponds created for species conservation. The carp-pond complex hosted a very high diversity of dragonflies, which can mainly be attributed to the small-scale coexistence of different management regimes and habitat structures. The most important factors for a high species diversity of odonates were a high structural diversity and a short duration of the drained period. The different pond types harbored distinct odonate assemblages. Owing to the sensitivity of several odonate species to drought, the existence of perennial conservation ponds had a substantial significance for preserving species richness in the study area. Nevertheless, even the ponds with the longest drainage phases hosted odonate species of high conservation concern. The results of this study underline that traditional carp farming can promote odonate diversity in Central European anthropogenic landscapes. Based on our results, we outline recommendations for pond management to maintain the biodiversity of carp ponds." **17564.** Gazzola, A.; Balestrieri, A.; Scribano, G.; Fontana, A.; Pellitteri-Rosa, D. (2021): Contextual behavioural plasticity in Italian agile frog (*Rana latastei*) tadpoles exposed to native and alien predator cues. *J. Exp. Biol.* 224(9) /jeb.240-465: 11 pp. (in English) ["Predation is a strong driver for the evolution of prey behaviour. To properly assess the actual risk of predation, anuran tadpoles mostly rely on water-borne chemical cues, and their ability to evaluate environmental information is even more crucial when potential predators consist of unknown alien species. Behavioural plasticity – that is, the capacity to express changes in behaviour in response to different environmental stimuli – is crucial to cope with predation risk. We explored the defensive behaviour of *R. latastei* tadpoles when exposed to the chemical cues of two predator species, one native (dragonfly larvae) and one alien (red swamp crayfish). Firstly, we observed whether a plastic life history trait (i.e. hatching time) might be affected by native predatory cues. Secondly, we recorded a suite of behavioural responses (activity level, lateralization and sinuosity) to each cue. For assessing lateralization and sinuosity, we developed a C++ code for the automatic analysis of digitally recorded tadpole tracks. Hatching time seemed not to be affected by the potential risk of predation, while both predator species and diet affected tadpoles' defensive behaviour. Tadpoles responded to a predator threat by two main defensive strategies: freezing and 'zig-

zagging'. While the first behaviour had previously been reported, the analysis of individual trajectories indicated that tadpoles can also increase path complexity, probably to prevent predators from anticipating their location. We also recorded a decrease in lateralization intensity, which suggests that under predation risk, tadpoles tend to scrutinize the surrounding environment equally on both sides." (Authors)] An invader prowls the ponds and rivers of Northern Italy, taking out locals and threatening entire species; can they fight back? This is not a Hollywood movie; it's happening right now in the gentle streams of Lombardy and the chief intruders are alien red swamp crayfish. 'This highly invasive and voracious predator ... can have dramatic impacts on freshwater fauna and alter aquatic ecosystems', says Daniele Pellitteri-Rosa from the University of Pavia, Italy. The crayfish have already devastated one local species: the Italian agile frog (*Rana latastei*). But hope for this threatened species could lie in the form of the next generation. If embryos in frogspawn can sense a lurking threat, they may be able to alter when they hatch to stand a better chance of survival. Alternatively, tadpoles might be able to improve their odds by taking evasive action when danger looms. Pellitteri-Rosa and colleagues decided to find out how Italian agile frog embryos and tadpoles respond to local predators – such as dragonfly larvae, which they always reside alongside – and the crayfish invaders that threaten their future. Collecting both predators from nearby waterways, Andrea Gazzola fed them on Italian agile frog tadpoles, to make sure that they reeked of danger; predators release the alarming aroma of their dismembered victims in their vicinity. Then, Pellitteri-Rosa retrieved freshly laid Italian agile frog frogspawn from ponds in three nearby areas, taking them to the lab to find out whether the stench of feasting dragonfly larvae would affect when the tiny frog embryos emerged from their eggs. But it did not. The tiny embryos were unable to alter when they hatched to evade danger. So, how would the youngsters fare in later life when faced with peril? Filming 15 day old tadpoles swimming in a cup, Gazzola then infused 2 ml of water carrying the odour either of unfed predators or of predators that had recently dined on tadpoles, while continuing to record the tadpoles' reactions. Sure enough, when Giovanni Scribano and Alessandro Balestrieri (University of Pavia) and Andrea Fontana (Istituto Nazionale di Fisica Nucleare, Italy) scrutinised the movies, they found the tadpoles were afraid of the fed dragonfly larvae, freezing ~80% of the time, while the fasted dragonfly larvae were almost as terrifying for the tadpoles. And when the youngsters did move after catching a whiff of their predator, they wove around more, in a bid to throw off the hunters, and switched course in all directions, to keep an eye out all around. However, the tadpoles were less savvy when Gazzola added eau de crayfish to their water. Only the tadpoles retrieved from a pond where crayfish reside showed any sign of toning down their activity to evade detection. The tadpoles from ponds with few or no crayfish didn't alter their behaviour much, as if they didn't have a care in the world. However, when Gazzola added a dash of water from the container of fed crayfish to the youngsters' home, the developing amphibians became more wary. Even the tadpoles that did not

share their home ponds with crayfish were slightly more cautious, but less so than the youngsters from ponds where crayfish had already taken up residence. It seems that Italian agile frog tadpoles can learn to evade alien predators, probably by learning to associate the scent of devoured tadpoles with the invader's aroma. But Pellitteri-Rosa and colleagues are anxious that time might be stacked against survival for species that are already teetering on the brink.] Address: Pellitteri-Rosa, D., Dipartimento di Scienze della Terra e dell'Ambiente, Università di Pavia, I-27100 Pavia, Italy. **17565.** Ge, Y.; Xia, C.; Wang, J.; Zhang, X.; Ma, X.; Zhou, Q. (2021): The efficacy of DNA barcoding in the classification, genetic differentiation, and biodiversity assessment of benthic macroinvertebrates. *Ecology and Evolution* 11(10): 5669-5681. (in English) ["Macroinvertebrates have been recognized as key ecological indicators of aquatic environment and are the most commonly used approaches for water quality assessment. However, species identification of macroinvertebrates (especially of aquatic insects) proves to be very difficult due to the lack of taxonomic expertise in some regions and can become time-consuming. In this study, we evaluated the feasibility of DNA barcoding for the classification of benthic macroinvertebrates and investigated the genetic differentiation in seven orders (Insecta: Ephemeroptera, Plecoptera, Trichoptera, Diptera, Hemiptera, Coleoptera, and Odonata) from four large transboundary rivers of northwest China and further explored its potential application to biodiversity assessment. A total of 1,144 COI sequences, belonging to 176 species, 112 genera, and 53 families were obtained and analyzed. The barcoding gap analysis showed that COI gene fragment yielded significant intra- and interspecific divergences and obvious barcoding gaps. NJ phylogenetic trees showed that all species group into monophyletic species clusters whether from the same population or not, except two species (*Polypedilum. laetum* and *Polypedilum. bullum*). The distance-based (ABGD) and tree-based (PTP and MPTP) methods were utilized for grouping specimens into Operational Taxonomic Units (OTUs) and delimiting species. The ABGD, PTP, and MPTP analysis were divided into 177 ( $p = .0599$ ), 197, and 195 OTUs, respectively. The BIN analysis generated 186 different BINs. Overall, our study showed that DNA barcoding offers an effective framework for macroinvertebrate species identification and sheds new light on the biodiversity assessment of local macroinvertebrates. Also, the construction of DNA barcode reference library of benthic macroinvertebrates in Eurasian transboundary rivers provides a solid backup for bioassessment studies of freshwater habitats using modern high-throughput technologies in the near future." **17566.** Geiger, M.; Koblmüller, S.; Assandri, G.; Chovanec, A.; Ekrem, T.; Fischer, I.; Galimberti, A.; Grabowski, M.; Haring, E.; Hausmann, A.; Hendrich, L.; Koch, S.; Mamos, T.; Rothe, U.; Rulik, B.; Rewicz, T.; Sittenthaler, M.; Stur, E.; Tonczyk, G.; Zangl, L.; Moriniere, J. (2021): Coverage and

quality of DNA barcode references for Central and Northern European Odonata. *PeerJ* 9:e11192 DOI 10.7717/peerj-11192: 31 pp. (in English) ["Background: Odonata are important components in biomonitoring due to their amphibiotic lifecycle and specific habitat requirements. They are charismatic and popular insects, but can be challenging to identify despite large size and often distinct coloration, especially the immature stages. DNA-based assessment tools rely on validated DNA barcode reference libraries evaluated in a supraregional context to minimize taxonomic incongruence and identification mismatches. Methods: This study reports on findings from the analysis of the most comprehensive DNA barcode dataset for Central European Odonata to date, with 103 out of 145 recorded European species included and publicly deposited in the Barcode of Life Data System (BOLD). The complete dataset includes 697 specimens (548 adults, 108 larvae) from 274 localities in 16 countries with a geographic emphasis on Central Europe. We used BOLD to generate sequence divergence metrics and to examine the taxonomic composition of the DNA barcode clusters within the dataset and in comparison with all data on BOLD. Results: Over 88% of the species included can be readily identified using their DNA barcodes and the reference dataset provided. Considering the complete European dataset, unambiguous identification is hampered in 12 species due to weak mitochondrial differentiation and partial haplotype sharing. However, considering the known species distributions only two groups of five species possibly co-occur, leading to an unambiguous identification of more than 95% of the analysed Odonata via DNA barcoding in real applications. The cases of small interspecific genetic distances and the observed deep intraspecific variation in *Cordulia aenea* are discussed in detail and the corresponding taxa in the public reference database are highlighted. They should be considered in future applications of DNA barcoding and metabarcoding and represent interesting evolutionary biological questions, which call for in depth analyses of the involved taxa throughout their distribution ranges." **17567.** González, R.C.; Jerkovic, M.; Arteaga, A.B. (2021): Insectos y arañas asociados a plantas ornamentales en David, Chiriquí, Panamá - Insects and spiders associated with ornamental plants in David, Chiriquí, Panama. *Aporte Santiaguino* 14(1): 9-20. (in Spanish, with English summary) ["The purpose of this work was to know the insects and spiders associated with ornamental plants in David, Chiriquí, Panama. For this, five random samplings were carried out in four locations, randomly selecting 35 plants which belong to 15 families and 20 species. The soil, branches and foliage levels were reviewed, manually collecting the arthropods found. The identification of the specimens was made by consulting specialized documentation and a photographic record was kept. The results obtained indicated that three species of spiders and 15 species of insects were associated with nine plant species. The predominant

spiders were *Argiope argentata* (Araneidae) and *Leucauge venusta* (Tetragnathidae). About defoliating insects, the Family Diapheromeridae (Phasmatodea) and *Oiketeticus kirbyi* (Lepidoptera: Psychidae), were found in *Arecaceae*; three species of Orthoptera associated with Toro grass, of which *Taeniopoda varipennis* (Romaleidae) stood out; Scarabaeidae and Chrysomelidae (Coleoptera) in *schefflera*. The biting-sucking species were represented by nymphs of *Blissus* sp. (Hemiptera: Blissidae) on Toro grass; *Aphis* sp. (Hemiptera: Aphididae) and *Coccus* sp. (Hemiptera: Coccidae), associated with ants (Hymenoptera: Formicidae); nymphs and adults of *Membracis mexicana* (Hemiptera: Membracidae), in *schefflera* shoots and damage by *Gynai-kothrips uzeli* (Thysanoptera: Phlaeothripidae) in *Ficus*. The predatory insects were represented by eggs and larvae of Chrysopidae (Neuroptera), found in *schefflera* and adults of *Orthemis ferruginea* (Odonata: Libellulidae), in water surfaces. The absence of parasitoids, pollinators and the low number of taxa found could be due to the use of synthetic pesticides, which breaks the trophic balance; although the surrounding wild vegetation can serve as a biological corridor for the species survival." (Authors)] Address: González, R.C., Univ. de Panamá. Facultad de Ciencias Agropecuarias, Chiriquí, Panamá. E-mail: rdcg31@hotmail.com

**17568.** González-Soriano, E.; Noguera, F.A.; Pérez-Hernández, C.X.; Zaragoza-Caballero, S.; González-Valencia, L. (2021): Patterns of richness, diversity and abundance of an odonate assemblage from a tropical dry forest in the Santiago Dominguillo Region, Oaxaca, México (Insecta: Odonata). *Biodiversity Data Journal* 9: e60980: 21 pp. (in English) ["A study on the patterns of richness, diversity and abundance of the Odonata from Santiago Dominguillo, Oaxaca is presented here. A total of 1601 specimens from six families, 26 genera and 50 species were obtained through monthly samplings of five days each. Libellulidae was the most diverse family (21 species), followed by Coenagrionidae (19), Gomphidae (4) and Calopterygidae (3). The Lestidae, Platystictidae and Aeshnidae families were the less diverse, with only one species each. *Argia* was the most speciose genus with 11 species, followed by *Enallagma*, *Hetaerina*, *Erythrodiplax* and *Macrothemis* with three species each and *Phyllogomphoides*, *Brechmorhoga*, *Dythemis*, *Erythemis* and *Orthemis* with two species each. The remaining 17 genera had one species each. *Argia pipila* Calvert, 1907 and *Leptobasis vacillans* Hagen in Selys, 1877 were recorded for the first time for the state of Oaxaca. We also analysed the temporal patterns of taxonomic and phylogenetic divergence for the Santiago Dominguillo Odonata assemblage: the Shannon diversity value throughout the year was 21.07 effective species, while the Simpson diversity was 13.17. In general, the monthly phylogenetic divergence was higher than expected for taxonomic distinctness, and lesser for average taxonomic distinctness. Monthly diversity, evenness and taxonomic divergence showed significant positive correlations (from moderate to strong) with monthly precipitation values. The analysis of our results, however, indicates that an increase in rainfall not only influences the temporal diversity of species, but

also the identity of supraspecific taxa that constitute those temporal assemblages, i.e. there is an increase in temporal phylogenetic divergence." (Authors)] Address: González-Soriano, E., Depto de Zoología, Instituto de Biología, UNAM, Ciudad de México, Mexico. E-mail: Enrique González-Soriano (esoriano@ib.unam.mx

**17569.** Günther, A.; Nicolai, B.; Petzold, F.; Waldhauser, M.; Lange, M. (2021): Aktueller Kenntnisstand zur Verbreitung von *Erythromma lindenii* in Ostdeutschland und der Tschechischen Republik (Odonata: Coenagrionidae). *Libellula* 40(1/2): 107-135. (in German, with English and Czech summaries) ["State of knowledge of the occurrence of *E. lindenii* in Eastern Germany and the Czech Republic – In the 20th century, *E. lindenii* was restricted in eastern Germany to a sharply defined, discontinuous enclave, which included parts of Berlin and Brandenburg and extended to western Poland. These isolated populations have been described as the subspecies *E. lindenii lacustre* (Beutler, 1985). The type form is spreading from southwestern Germany to the northeast at least since the 1970s. This expansion of the distribution area led to the first record in Thuringia in 1997, followed by the first record in Saxony-Anhalt from 2000. The first record in Saxony was made in the year 2002. In this case, however, a colonization from Brandenburg is more likely. The Czech Republic was probably colonized from Saxony (first recorded in 2009). The dispersal of the species accelerated considerably, especially in the years 2018 to 2020. In this study we present the current distribution of *E. lindenii* in East Germany and the Czech Republic. Large populations, becoming established in rivers like Saale (Thuringia), Mulde (Saxony) and Berounka (Bohemia), most probably have a key role in the very dynamic expansion of the species in the last few years. This colonization was obviously promoted by mild winters. Furthermore, we suspect positive effects to larval habitats in winter-green submerged vegetation through shorter and less deep freezing of the water bodies in the last years. We do not yet have any indications of direct contacts between the sub-populations of the isolated and the main range. However, this will undoubtedly take place in the next few years." (Authors)] Address: Günther, A., Naturschutzinstitut Freiberg, B.-Kellermann-Straße 20, 09599 Freiberg, Germany. E-mail: andre.guenther@extern.tu-freiberg.de

**17570.** Günther, A.; Lange, M.; Palfi, I. (2021): Erste Nachweise von *Coenagrion scitulum* in Ostdeutschland (Sachsen) deuten auf einen neuen Einwanderungsweg der Art hin (Odonata: Coenagrionidae). *Libellula* 40(1/2): 47-56. (in German, with English summary) ["First records of *C. scitulum* in Eastern Germany (Saxony) suggests a new migration route of the species – In the years 2019 and 2020 *C. scitulum* was recorded in Saxony and Eastern Germany for the first few times. On 06-vii-2019 a single male was photographically documented in the post-mining landscape of the former Berzdorf open-cast lignite mine south of Görlitz in SE Saxony (UTM: VS95). In 2020, at least four single individuals were discovered on a former military training area near Glauchau in SW Saxony (UTM: US23). It is unclear

whether these individuals immigrated in 2020 or were also due to an immigration in 2019 and subsequently successful reproduction. So far, no reproductive behaviour of the species has been observed in Saxony. The geographical location of the closest localities of the species suggests a new, southern migration route from the Czech Republic. This route could become important for the expansion in eastern Germany and western Poland in future years.] Address: Günther, A., Naturschutzzentrum Freiberg, B.-Kellermann-Str. 20, 09599 Freiberg, Germany. E-mail: andre.guenther@extern.tu-freiberg.de

**17571.** Guillermo-Ferreira, R.; Gorb, S.N. (2021): Heat-distribution in the body and wings of the morpho dragonfly *Zenithoptera lanei* (Anisoptera: Libellulidae) and a possible mechanism of thermoregulation. *Biological Journal of the Linnean Society* 133(1): 179-186. (in English) ["Animals that live in hot environments must deal with extreme temperatures and overcome the constraints imposed by overheating. Some species exhibit remarkable adaptations to control body temperature, usually in the form of structures that act as thermal windows to cool down the body by dissipating heat. Here, we describe the case of *Z. lanei*, which inhabits open areas in the Neotropical Savannah and the Amazon. Males have striking and unique adaptations on the wings, not known in any other insect. The wings are covered with wax nanocrystals that reflect ultraviolet light and infrared radiation. Furthermore, the wing membrane is permeated by an intricate system of tracheae, another unique trait in Insecta. We hypothesized that these adaptations might be important not only for intraspecific communication, but also for thermoregulation. We analysed male body and wing temperatures and compared them with another dragonfly with common translucent wings. The results suggest that the dorsal wing surface acts as a cooling system, whereas the ventral surface might serve to elevate body temperature. Therefore, we conclude that *Z. lanei* possesses adaptations that are unique in nature; a complex system of thermoregulation with the dual function of cooling down or elevating body temperature, depending on wing position." **17572.** Haberski, A.; Hagelin, J.C.; Barger, C.P.; Sikes, D.S.; DuBour, K.A. (2021): An efficient method for sampling aerial arthropods at nest sites of an insectivorous songbird in steep decline. *Avian Conservation and Ecology* 16(2):1: 10 pp. (in English, with French summary) ["The decline of aerial insectivorous birds has been hypothesized to stem, in part, from a decline in aerial arthropod prey, underscoring the need for long-term monitoring of both bird and arthropod populations. However, trapping arthropods can be time consuming and efficient methods are required. Our primary goal was to identify the optimal combination of insect traps to collect taxonomic orders of prey in the diet of a songbird in steep decline, the Olive-sided Flycatcher (*Contopus cooperi*). Our secondary goal was to sample the arthropod community as broadly as possible, and thereby monitor for

general changes in arthropod assemblages, which may affect multiple species of migratory insectivores. In the boreal forest of central Alaska, we compared captures of canopy Malaise traps and three types of near-ground pollinator traps (blue vane traps, yellow vane traps, and chemically baited wasp traps) at 22 breeding territories where adult flycatchers actively foraged and bred. Combined, traps collected 11,193 specimens from 12 arthropod orders, of which moths (Lepidoptera, 36%), flies (Diptera, 34%), and wasps (Hymenoptera, 18%) were the most abundant, and also known components of flycatcher diets. General linear mixed models determined that canopy Malaise traps collected the greatest overall ordinal richness (11 orders) with a significantly greater abundance of specimens from six orders, two of which are aquatic specialists linked to breeding success of Tree Swallows (*Tachycineta bicolor*), another declining aerial insectivore. The three types of near-ground pollinator traps overlapped in taxa collected, but blue vane traps captured the most flies, bees, and yellowjackets, all of which were not well represented in Malaise samples. All trap types failed to collect dragonflies, a known prey item of breeding *C. cooperi*. We therefore conclude that a combination of canopy Malaise traps and blue vane traps, plus hand-netting of dragonflies, is an efficient combination for quantifying prey abundance on *C. cooperi* territories, while simultaneously monitoring the broadest possible number of arthropod orders near flycatcher nests within the boreal forest." **17576.** Hart, I.S.; Utz, R.M.; Taylor, A.N.; Chess, M.; Porter, B.A.; Locy, D.D. (2021): High conservation value of the Odonata assemblage in the upper Ohio River mainstem: A large, regulated river in North America. *The American Midland Naturalist* 185(2): 175-186. (in English) ["Like many large rivers in modern industrialized regions, the Ohio River mainstem is a heavily modified riverine habitat comprised of various reservoir-dam series and shaped channels, rather than a free-flowing system. However, many odonate species in such habitats, even species of conservation concern, have been shown to prosper in degraded lotic habitats due to key life history attributes, such as rapid recolonization following large disturbances. In this study we characterize the assemblage of odonates in a Pennsylvania section of the Ohio River mainstem and determined if any species of conservation concern were present. We also tested hypotheses on distributions in the channel by testing if proximity to banks and channel depths helped predict odonate abundance. Samples were acquired as bycatch to benthic fish sampling conducted using electrified benthic trawling, a novel approach for collecting benthic macroinvertebrates in large freshwater rivers. We found seven odonate species, all of which were known to be species of conservation concern in one or more U.S. states. We also concluded that gradients of bank distance and river depth only weakly predicted odonate abundance, suggesting that the Ohio River species regularly use mid-channel habitat that is several meters deep. Life histories of most of the species collected are typical of those living in large lotic, and occasionally lentic, environments. Studies of other large, temperate rivers show that the ability to persist is not uncommon for odonates in these modified environments, and may be due to their ability to use mid-channel resources successfully. Despite the substantial differences between contemporary and historic conditions of habitats in the Ohio River basin, an odonate assemblage worth conserving continues to be present in the mainstem channel." **17578.** Hasanah, M.; Rohman, F.; Susanto, H. (2021): Environmental indicators based on Odonata diversity around the springs in Malang Raya, East Java. *AIP Conference Proceedings* 2353(1): 030035-1-030035-5. (in English) ["This research was designed to determine the environmental condition based on Odonata diversity found around the springs in Malang, East Java. The research was carried out around the springs, which focused on the species, the number of individuals of Odonata, habitat, and physical condition of the environment. Visual observation was used by the VES method, then counting the number of species and number of individuals within a radius of 200 m from the springs as a focal point of observation. Data collection was done at 4 springs, including Kendedes, Jenon, Taman, and Cangar. The results showed that there were 17 species of Odonata from 7 different families, with a total number of individuals found from 4 Springs as many as 245 individuals. The most common type was *Agriocnemis femina* and *Orthetrum sabina*. The analysis also portrayed a moderate Odonata diversity index and that there was a correlation between the physical condition of the environment and the species of Odonata found in a habitat. This condition can be used to describe the structure of the Odonata community in the area." **17580.** Husband, D.M.; McIntyre, N.E. (2021): Urban areas create refugia for odonates in a semi-arid region. *Insects* 2021, 12(5), 431: 15 pp. (in English) ["In western Texas, most wetlands are fed from precipitation runoff, making them sensitive to drought regimes, anthropogenic land-use activities in their surrounding watersheds, and the interactive effect between these two factors. We surveyed adult odonates in 133 wetlands (49 in grassland settings, 56 in cropland, and 28 in urban areas) in western Texas from 2003–2020; 33 species were recorded. Most species were widespread generalists, but urban wetlands had the highest species richness, as well as the most unique species of any of the three wetland types. Non-metric, multidimensional scaling ordination revealed that the odonate community in urban wetlands was distinctly different in composition than the odonates in non-urban wetlands. Urban wetlands were smaller in surface area than the other wetland types, but because they were fed from more consistently available urban runoff rather than seasonal precipitation, they had longer hydroperiods, particularly during a multi-year drought when wetlands in other land-cover contexts were dry. This anthropogenically enhanced water supply was associated with higher odonate richness despite presumably impaired water quality, indicating that consistent and prolonged presence of water in this semi-arid region was more important than the presence of native land cover within which the wetland existed. Compared to wetlands in the regional grassland landscape matrix, wetlands in agricultural and urban areas differed in hydroperiod, and presumably also in water quality; these effects translated to differences in the regional odonate assemblage by surrounding land-use type, with the highest richness at urban playas. Odonates in human environments may thus benefit through the creation of a more reliably available wetland habitat in an otherwise dry region." **17581.** Huynh, T.Q.; Oyabu, A.; Nomura, S.; Takashima, T.; Usio, N. (2021): Do agrochemical-free paddy fields serve as refuge habitats for Odonata? *Ecologies* 2(1): 15 pp. (in English) ["Agrochemical-free rice farming has attracted interest for restoring paddy field biodiversity and producing safe food. Odonata are commonly used as a biodiversity indicator in these low-input farms. However, the effect of agrochemical-free rice farming on odonate diversity has rarely been

assessed over the entire emergence period of these insects. We investigated whether different farming practices, such as conventional or natural (agrochemical-and fertilizer-free) cultivation, and associated water management strategies affect the emergence rates of Odonata in paddy field landscapes in central Japan. Weekly exuviae sampling in 2017 and 2019 suggested that odonate assemblages differed between conventional and natural paddy fields, with a higher number of taxa emerging from natural paddy fields. Contrary to expectations, conventional paddy fields had equivalent or higher emergence rates of all Odonata and two numerically dominant *Sympetrum* species. Peak emergence periods for numerically dominant taxa differed between the farming types, with the emergence of three *Sympetrum* species peaking in late June in conventional paddy fields and that of *S. frequens* peaking in early to mid-July in natural paddy fields. Our findings suggest that both conventional and natural paddy fields are important habitats for Odonata in Japan." (Authors)] Address: Takashima, T., JA Haku Head Office, Haku 925-8588, Japan

**17582.** Iamba, K.; Waldi, D.; Kumawayo, I.; Elias, M. (2021): A rapid assessment of insect communities in Balsa plantations of East New Britain Province, Papua New Guinea. *International Journal of Entomology Research* 6(2): 109-115. (in English) ["Insect communities were documented across six (6) commercial Balsa plantations in East New Britain Province of Papua New Guinea. Gilalum recorded mostly Coleopterans (50%) while very few Hymenopterans (16.7%), Lepidopterans (16.7%), Orthopterans (16.7%) and Odonata (16.7%). Lepidopterans were common in Kaingaski (55.6%) when compared to other taxa. There were more lepidopterans (58.8%) in Klinwata plantation than other taxa while 23.5% consisted of Orthopterans. Laup plantation had 35.7% lepidopterans, 21.4% hymenopterans, 21.4% odonatans, 14.3% coleopterans and 7.1% orthopterans. Putput had a good representation of lepidopterans (56.2%) followed by coleopterans (28.1%) and orthopterans (9.4%). Putput plantation was the most diverse site having a total of 32 species which were uniformly distributed ( $H=2.66$ ,  $E=0.77$ ). Tanao had the second highest diversity with species richness of 19 which were evenly distributed within the site ( $H=2.37$ ,  $E=0.81$ ). Laup plantation had the third highest diversity of 14 species with uniform distribution ( $H=1.93$ ,  $E=0.73$ ). Klinwata followed with total of 17 species that were less uniform in their distribution within the plantation ( $H=1.72$ ,  $E=0.61$ ). Gilalum recorded 6 species that were not uniformly distributed within the plantation ( $H=0.93$ ,  $E=0.52$ ). Kaingaski plantation had the lowest diversity with 9 species that were poorly distributed within the study site ( $H=0.79$ ,  $E=0.36$ ). From the aforementioned results, we concluded that a plantation with vegetation heterogeneity, complex undergrowth, low anthropogenic disturbances, long-standing trees, strict conservation guidelines and effective monitoring is paramount to enhance species richness of insects." **17583.** Jana, P.K.; Mallick, P.H.; Bhattacharya, T. (2021):

A study on the community structure of damselflies (Insecta: Odonata: Zygoptera) in Paschim Medinipur, West Bengal, India. *Journal of Threatened Taxa* 13(7): 18809-18816. (in English) ["For gauging suitability of zygopteran odonates as bioindicators of ecosystems, an attempt was made to record the seasonal diversity of damselflies from seven different types of habitats in Paschim Medinipur District, West Bengal covering 14 land use sites. The study revealed existence of 19 species of damselflies belonging to 10 genera under two families. While the riparian zone had maximum number of species (15), paddy field had the lowest number (six). *Ceriagrion coromandelianum* and *Agriocnemis pygmaea* were the most common species. *C. coromandelianum* was eudominant in grassland and wetland-forest interface, whereas *A. pygmaea* was eudominant in fish pond and paddy field. Six species, viz., *Paracerion calamorum*, *P. malayanum*, *Pseudagrion australasiae*, *P. decorum*, *P. spencei*, and *P. microcephalum* were confined only to the riparian zone. Maximum abundance of damselflies was found in the riparian zone and minimum in the paddy field. Damselflies exhibited a distinct peak in March–April and a lesser peak in September–October. Most of the land use patterns exhibited similar zygopteran faunal composition. Species diversity index was moderate (1.4–2.5) and evenness index was on the higher side (0.76–0.94). Dominance Index ranged from 26.2 to 64.6. Riparian zone appeared to be the least stressed and most equitable habitat with highest diversity and evenness index and lowest dominance index. Paddy field seemed to be the harshest habitat for damselflies with least diversity and highest dominance index. The present study suggests that community analysis of damselflies can be quite useful in the assessment of the quality of any ecosystem." (Authors)] Address: Jana, P.K., Dept Zool., Vidyasagar Univ., Midnapore, Paschim Medinipur, West Bengal 721102, India. E-mail: pathikjana@gmail.com,

**17584.** Janra, M.N.; Herwina, H. (2021): Parasitism on riparian dragonflies (Odonata) at biology education and research forest, Universitas Andalas. IOP Conf. Ser.: Earth Environ. Sci. 757 012083: 7 pp. (in English) ["Parasitism on dragonflies may become the least attention in most entomological studies in Indonesia, since it possesses much indirect effect to human being. The odonata parasitism is caused by the infestation of water mite larvae onto the body of adult dragonflies. In this paper we discuss the result of odonatological survey we did at two tributaries in Biology Education and Research Forest (BERF), Universitas Andalas. The survey had been conducted between August to November 2019. We recorded 17 dragonfly species bound to these tributaries, 12 Zygopterans and 5 Anispterans. Water mite infestation was observed to happen on four Zygopteran species and one Anisoptera. The highest prevalence was shown by *Orthetrum testaceum* (100%), followed by *Euphaea variegata* (16.67%), *Prodasineura verticalis* (14.29%), *Euphaea modigliani* (3.57%) and *Heliocypha angusta angusta* (0.85%). In overall, the prevalence on community level reached 3.29%. The parasitism case observed in the tributaries of BERF can be classified as low incident, each infested odonate only contained a single water mite except

for *O. testaceum* with two water mites. We presume that habitat condition may contribute to the rate of dragonfly parasitism, where a good habitat help lowering the parasitism incident." (Authors)] Address: Janra, M.N., Biology Dept, Fac. of Mathematics & Natural Sciences, Univ. Andalas, Padang, Indonesia. E-mail: mnjanra@sci.unand.ac.id

**17585.** Jiang, B.; Li, J.; Zhang, Y.; Sun, Y.; He, S.; Yu, G.; Lv, G.; Mikolajewski, D.J. (2021): Complete mitochondrial genomes of two damselfly species in coenagrionidae and phylogenetic implications. *Mitochondrial DNA Part B* 6(8): 2445-2448. (in English) ["*Agriocnemis femina* (Brauer, 1868) and *Ischnura senegalensis* (Rambur, 1842) are two damselflies inhabiting paddy lands. As an intermediate predator, they play an important role in controlling certain crop pest and mosquitoes. In this study, we sequenced complete mitogenomes of these two species. The total length of mitogenomes is 15,936 bp in *A. femina* and 15,762 bp in *I. senegalensis*. Both of mitogenomes consist of 13 protein-coding genes, 22 tRNA genes, two rRNA genes, and one control region. The close relationship between *I. senegalensis* and *I. elegans* was further proved by phylogenetic analysis. Our phylogenetic analysis indicated a clear two lineages in Coenagrionidae (Core and ridge-faced Coenagrionidae). Ridge-faced Coenagrionidae consisted of *Megaloprepus caerulatus* and *Ceriagrion fallax*. In core Coenagrionidae, *Ischnura* and *Enallagma* are most closely related; they formed one clade with *Agriocnemis* and then grouped together with *Paracerion*. Our study provides new genetic information for further study in phylogenetic analysis of Coenagrionidae." (Authors)] Address: Jiang, B., College of Life Science, Anhui Normal University, Wuhu, China. **17586.** Jödicke, R.; Borkenstein, A. (2021): Der lange Tag der *Leucorrhinia rubicunda* (Odonata: Libellulidae). *Libellula* 40(1/2): 77-92. (in German, with English summary) ["The long day of *L. rubicunda* – Amongst the Central European Libellulidae species *L. rubicunda* displays a particularly long diel activity. We studied the morning and evening activities of this species on hot and sunny days during its main flying season in 2018, both at the water and in its terrestrial habitat. Already three quarters of an hour after sunrise the first males flew from their roosting sites in the canopy of birch trees to sunlit trunks for warming up. About 20 minutes later they started to occupy their perches at the water, where females had already been ovipositing without having been harassed by males. During the whole course of the day typical perching of the males and occasional visits of females at the water with subsequent copulation took place. Oviposition was hardly possible when male abundance was high, because females were constantly disturbed by males. In the evening, as soon as the water was shaded, the behaviour of males switched from perching to permanent flying. Other individuals used this time for collective and sustained hunting in the air or basking on the last sunlit trunks of birch trees. Shortly before sunset the number of wheel formations increased, then the males rapidly

disappeared. Oviposition still regularly took place after sunset, defining *L. rubicunda* as a vespertine species." (Authors)] Address: Jödicke, R., Am Liebfrauenbusch 3, 26655 Westerstede, Germany. E-mail: reinhard.joedicke@magenta.de

**17587.** Johansson, F.; Watts, P.C.; Sniegula, S.; Berger, D. (2021): Natural selection mediated by seasonal time constraints increases the alignment between evolvability and developmental plasticity. *Evolution* 75(2): 464-475. (in English) ["Phenotypic plasticity can either hinder or promote adaptation to novel environments. Recent studies that have quantified alignments between plasticity, genetic variation and divergence propose that such alignments may reflect constraints that bias future evolutionary trajectories. Here, we emphasize that such alignments may themselves be a result of natural selection and do not necessarily indicate constraints on adaptation. We estimated developmental plasticity and broad sense genetic covariance matrices (G) among damselfly populations situated along a latitudinal gradient in Europe. Damselflies were reared at photoperiod treatments that simulated the seasonal time constraints experienced at northern (strong constraints) and southern (relaxed constraints) latitudes. This allowed us to partition the effects of (1) latitude, (2) photoperiod and (3) environmental novelty on G and its putative alignment with adaptive plasticity and divergence. Environmental novelty and latitude did not affect G, but photoperiod did. Photoperiod increased evolvability in the direction of observed adaptive divergence and developmental plasticity when G was assessed under strong seasonal time constraints at northern (relative to southern) photoperiod. Since selection and adaptation under time constraints is well understood in *Lestes* damselflies, our results suggest that natural selection can shape the alignment between divergence, plasticity and evolvability." **17591.** Ketenchiev, Kh.A.; Kozminov, S.G.; Paritov, A.Yu.; Sabanova, R.K.; Krapivina, E.A. (2021): Comparative study on the fauna composition of dragonflies (Insecta: Odonata) in the Armenian, Iranian and Asia Minor Highlands as part of the Asiatic Mediterranean (Mediterranean faunal subregion, Paleosubtropical region, Boreal kingdom. IOP Conference Series: Earth and Environmental Science, Volume 817, Ninth International Symposium "Steppes of Northern Eurasia" 7 - 11 June 2021, Orenburg, Russian: 9 pp. (in English) ["The paper presents the results of a comparative analysis of the taxonomic composition of the dragonfly faunas in the Armenian, Iranian and Asia Minor Highlands. Among all the regional faunas of the Mediterranean, the odonofauna of the Iranian and Asia Minor highlands is the richest, with 97 species each. The odonofauna of the Armenian Highlands includes 77 species. A specific feature of the Asia Minor odonofauna is the richness of rheophilic species. Among the representatives of the rheophilic fauna, the Gomphidae family in the Iranian Highlands includes 12 species, the genus *Anormogomphus* includes 1 species – *A. kiritschenkoi* Bartenef. There are 7 species in the Gomphidae family in the Armenian Highlands, and 10 species in the Asia Minor Highlands. In the suborder Zygoptera in the Iranian Highlands, the largest family is Coenagrionidae, in which the genus *Ischnura* is the richest in species. Specific

species characteristic of the compared highlands are given. The odonatofaunas of the uplands contain European and Eurasian boreal as well as endemic taxa, which gives the dragonfly fauna a distinctive appearance. Analysis of the odonatofauna of the Asia Minor Highlands shows its eclecticity and species richness. Unlike the dragonfly fauna of the Armenian Highlands, the presence of European species is noticeable in the fauna of the Asia Minor." **17592.** Khan, M. A.; Padhy, C. (2021): Aerodynamic characterization of bio-mimicked pleated dragonfly aerofoil. *International Journal of Aviation, Aeronautics, and Aerospace* 8(2): 24 pp. (in English) ["The work inspired by the dragonfly wing corrugation positioned at the front wing's radius section lying at 40% of the total wingspan of forewing from the root section. During gliding flight, dragonfly wings presumed to be an ultra-light aerofoil due to its well-defined cross-sectional corrugation. The aerodynamic simulation carried out to understand the aerodynamic performance of a bio-mimetic dragonfly corrugated airfoil at low Reynolds number range of 75000-150000 to explore the potential advantages of pleated airfoils at a varying angle of attack from 0° to 12°. CFD analysis accomplished by using ANSYS Fluent to understand the aerodynamic performance of the pleated aerofoil and its counterpart profiled aerofoil. The simulation result exhibits aerodynamic commission, i.e. the corrugated aerofoil's gliding ratio (CL/CD), is higher than that of a profiled aerofoil. The analysis demonstrates that the pleated corrugated aerofoil produces a comparable higher lift coefficient than that of profiled aerofoil NACA 0015 and reduces the separation bubble. The vortices trapped inside the valleys, which re-energize the flow and delay flow separation leads to an increment in lift coefficient (CL). These investigations amplify the demand of insect-inspired corrugated wing structure and make a possible application for improved design of pretended wings for micro air vehicles." **17593.** Khan, M.A.; Padhy, C. (2021): Influence of aerodynamic parameters on dragonfly inspired corrugated aerofoil. In: Rushi Kumar B., Sivaraj R., Prakash J. (eds) *Advances in Fluid Dynamics. Lecture Notes in Mechanical Engineering*. Springer, Singapore: 289-304. (in English) ["This work is focused on the variation of corrugation angle and peak height of 2-D corrugated aerofoil inspired from the forewing of 'Pantala Flavescens' or yellow dragonfly basal wing section. A computational analysis is done on a newly designed dragonfly corrugated aerofoil wing-A and wing-B at  $Re = 15.603 \times 10^3$  and the flow is considered as steady and density of the flow is constant. In this study, the aerodynamic performance of 2-D dragonfly corrugated aerofoil is performed at different angle of attack (AoA) with variation in corrugation angle and peak height. With the varying peak height and corrugation angle, there is low wake formation, reduced

drag, and increase in flight performance compared to streamlined aerofoil and flat plate. The computational fluid dynamic (CFD) analysis is performed using a high fidelity fluent solver. The CFD result shows that the aerodynamic performance, i.e., the gliding ratio (CL/CD) (CLCD) of wing-A is higher than wing-B and streamlined aerofoil. The vortex formed is trapped inside the valleys which re-energizes the flow and delays separation leads to an increment in lift coefficient (CL). This finding enhances the knowledge of insect-inspired corrugated wing structure and facilitate the application for improved design of artificial wings for MAVs and UAVs." **17594.** Khelifa, R.; Mahdjoub, H.; Baaloudj, A.; Cannings, R.A.; Samways, M.J. (2021): Effects of both climate change and human water demand on a highly threatened damselfly. *Scientific Reports* 11(7725): 11 pp. (in English) ["While climate change severely affects some aquatic ecosystems, it may also interact with anthropogenic factors and exacerbate their impact. In dry climates, dams can cause hydrological drought during dry periods following a great reduction in dam water discharge. However, impact of these severe hydrological droughts on lotic fauna is poorly documented, despite climate change expected to increase drought duration and intensity. We document here how dam water discharge was affected by climate variability during 2011–2018 in a highly modified watershed in northeastern Algeria, and how an endemic endangered lotic damselfly, *Calopteryx exul* Selys, 1853, responded to hydrological drought episodes. Analysis was based on a compilation of data on climate (temperature, precipitation, and drought index), water dam management (water depth and discharge volume and frequency), survey data on *C. exul* occurrence, and capture–mark–recapture (CMR) of adults. The study period was characterized by a severe drought between 2014 and 2017, which led to a lowering of dam water depth and reduction of discharge into the river, with associated changes in water chemistry, particularly during 2017 and 2018. These events could have led to the extirpation of several populations of *C. exul* in the Seybouse River (Algeria). CMR surveys showed that the species was sensitive to water depth fluctuations, avoiding low and high water levels (drought and flooding). The study shows that climate change interacts with human water requirements and affects river flow regimes, water chemistry and aquatic fauna. As drought events are likely to increase in the future, the current study highlights the need for urgent new management plans for lotic habitats to maintain this species and possible others." **17595.** Khelifa, R.; Mahdjoub, H.; M'Gonigle, L.; Kremen, C. (2021): Integrating high-speed videos in capture-mark-recapture studies of insects. *Ecology and Evolution* 11(11): 6033-6040. (in English) ["Capture–mark–recapture (CMR) studies have been used extensively in ecology and evolution. While it is feasible to apply CMR in some animals, it is

considerably more challenging in small fast-moving species such as insects. In these groups, low recapture rates can bias estimates of demographic parameters, thereby handicapping effective analysis and management of wild populations. Here, we use high-speed videos (HSV) to detect the mark of two large dragonfly species, *Anax junius* and *Rhionaeschna multicolor*, that rarely land and, thus, are particularly challenging for CMR studies. We test whether HSV, compared to conventional "eye" observations, increases the "resighting" rates and, consequently, improves estimates of both survival rates and the effects of demographic covariates on survival. We show that the use of HSV increases the number of resights by 64% in *A. junius* and 48% in *R. multicolor*. HSV improved our estimates of resighting and survival probability which were either under- or overestimated with the conventional observations. Including HSV improved credible intervals for resighting rate and survival probability by 190% and 130% in *A. junius* and *R. multicolor*, respectively. Hence, it has the potential to open the door to a wide range of research possibilities on species that are traditionally difficult to monitor with distance sampling, including within insects and birds." (Authors)] Address: Khelifa, R., Dept of Zoology and Biodiversity, Research Centre, University of British Columbia, Vancouver, BC, Canada

**17596.** Khelifa, R.; Mahdjoub, H.; Baaloudj, A.; Cannings, R.A.; Samways, M.J. (2021): Remarkable population resilience in a North African endemic damselfly in the face of rapid agricultural transformation. *Insects* 12(4), 353; <https://doi.org/10.3390/insects12040353>: (in English) ["There has been a rapid expansion of agricultural area worldwide, resulting in a substantial change in the physical structure, biodiversity, and ecosystem functioning of various natural habitats. In North Africa, many natural habitats have been transformed into agricultural lands, especially in the North, where biodiversity is the highest, to meet the food security and economic development of a rapidly growing population. We estimated the agricultural expansion in North African region between the 1990s and 2000s and found that the percentage of agriculture-free area within the species range declined from 79.5% to 26.2%. Knowing that agroecosystems near lotic environments simplify the structural complexity of habitats (from heterogeneous to homogenous ecological communities) of amphibiotic species such as odonates, we estimated the geographic range of an endemic damselfly and quantified the temporal change in the overlap between agriculture and species occurrence. Our results showed the overlap more than tripled between 1992 and 2005, suggesting that the species experienced a radical change in its terrestrial habitats. We conducted capture-mark-recapture to confirm that the species survives by frequently using croplands and grasslands. Abstract: Agriculture can be pervasive in its effect on wild nature, affecting various types of natural habitats, including lotic ecosystems. Here, we assess the extent of agricultural expansion on lotic systems in Northern Africa (Algeria, Tunisia, and Morocco) and document its overlap with the distribution of an endemic damselfly, *Platycnemis subdilatata* Selys, using species dis-

tribution modeling. We found that agricultural land cover increased by 321% in the region between 1992 and 2005, and, in particular, the main watercourses experienced an increase in agricultural land cover from 21.4% in 1992 to 78.1% in 2005, together with an increase in the intensity of 226% in agricultural practices. We used capture-mark-recapture (CMR) surveys in terrestrial habitats surrounding a stream bordered by grassland and cropland in northeastern Algeria to determine demographic parameters and population size, as well as cropland occupancy. CMR modeling showed that the recapture and survival probabilities had an average of 0.14 (95%CI: 0.14–0.17) and 0.86 (0.85–0.87), respectively. We estimated a relatively large population of *P. subdilatata* (~1750 individuals) in terrestrial habitats. The occupancy of terrestrial habitats by adults was spatially structured by age. Our data suggest that *P. subdilatata* has survived agricultural expansion and intensification better than other local odonate species, mainly because it can occupy transformed landscapes, such as croplands and grasslands." **17597.** Kietzka, G.J.; Pryke, J.S.; Gaigher, R.; Samways, M.J. (2021): Congruency between adult male dragonflies and their larvae in river systems is relative to spatial grain. *Ecological Indicators* 124: 14 pp. (in English) ["Highlights: • Dragonfly larvae and adults congruent for abundance and richness at larger scales. At all scales number of matches were never significantly greater than mismatches. The stages responded similarly to water temperature and agriculture. The stages responded differently to ten other variables. Larger scale assessments can use either adults or larvae, smaller scale use both. Abstract: Dragonflies are globally renowned bioindicators, with larvae, exuviae and/or adult life stages used in freshwater quality assessments. However, little is known about the extent to which conspecific adults and larvae occur within close proximity of each other, or how they comparably respond to biotic and abiotic factors. Firstly, we test the extent to which adult male dragonflies are congruent with their larvae at three independent sample unit scales (small 10 m × 3 m, medium 90 m × 3 m, and large 450 m × 3 m) along four rivers, along with a subset of 40 randomly selected small scale sites (small 40) to test for a possible effect of sampling design on the outcomes of the spatial scale analyses. Secondly, we test the extent to which adult males and larvae share similar responses to environmental variables. At medium and large spatial scales, larvae and adults were strongly congruent for abundance, species richness, and Dragonfly Biotic Index (DBI) scores. Despite this, at the small spatial scale, only 15% of observations matched (contained adults and conspecific larvae). This increased to 46% at the medium scale, and 60% at the large scale, neither of which were significantly different from the number of mismatches. Dragonfly species composition differed between larval and adult assemblages at the small, small 40, and medium scales but did not differ at the large scale. Water temperature was the only variable that generally elicited similar responses in both life stages, at all spatial scales. Exuviae here were so under-represented that

they provided no extra information. Assessments, where medium or large spatial scales are suitable for sampling, such as measuring the state of a river, can utilize either life stage. However, for comprehensive biodiversity surveys, both larvae and adults should be sampled." **17598.** Kladaric, L.; Cuk, R.; Dukic, I.; Popijac, A.; Marinovic Ruždjak, A. (2021): Can Ephemeroptera, Plecoptera, Trichoptera (EPT) assemblage reflect nitrogen and phosphorus load in the riverine ecosystem? *Natura Croatica* 30(1): 217-230. (in English, with Croatian summary) ["The aim of this paper is to make a comparative analysis of benthic macroinvertebrate compositions in streams and rivers in Croatia with relation to different physical-chemical factors, especially nutrients. Samples were collected according to the AQEM method. At all the sites, 20 taxa were recorded of which Turbellaria, Gastropoda, Bivalvia, Oligochaeta, Hirudinea, Crustacea, Ephemeroptera, Odonata, Plecoptera, Heteroptera, Trichoptera, Coleoptera and Diptera were included in the present study. Water temperature mostly affected the composition of benthic macroinvertebrates to which it was inversely proportional. Nutrient enrichment, i.e., higher concentrations of ammonium, nitrates, nitrites, total nitrogen, orthophosphates and total phosphorus mostly affected Ephemeroptera, Plecoptera, Trichoptera and Diptera, by decreasing their diversity." **17599.** Knoblauch, A.; Thoma, M.; Menz, M.H.M. (2021): Autumn southward migration of dragonflies along the Baltic coast and the influence of weather on flight behaviour. *Animal Behaviour* 176: 99-109. (in English) ["Highlights: • Evidence for dragonfly migration along the Baltic coast in Europe. *Aeshna mixta* and *Sympetrum vulgatum* show directed southward flight. Temperature, cloud cover and wind direction predict migration intensity. Migratory *Aeshna* and *Sympetrum* species respond differently to local weather. The migrant hawk *A. mixta* selects for favourable tail winds. Despite mass movements of insects being documented for decades, whether dragonflies migrate in Europe has not yet been experimentally tested. Similarly, little is known about the influence of weather on the movement decisions and intensity of dragonflies. Taking advantage of large movements of dragonflies along the Baltic Sea coast of Latvia, we investigated whether European dragonflies showed directed movements indicative of migratory behaviour and how weather influences their movements. First, we performed orientation tests with individual dragonflies of two commonly captured species, *A. mixta* and *S. vulgatum*, to determine whether dragonflies showed directed flight and whether flight direction differed from wind direction. Both *A. mixta* and *S. vulgatum* displayed a uniform mean southward orientation, which differed from the prevailing overhead wind direction, indicating migratory behaviour. Second, we investigated the influence of weather conditions on the abundance

of dragonflies captured. Differences in flight behaviour in relation to weather conditions were observed between *A. mixta* and the two smaller *Sympetrum* species (*S. vulgatum* and *S. sanguineum*). Generally, temperature, cloud cover and wind direction were the most important predictors for dragonfly abundance, with temperature positively, and cloud cover negatively, influencing abundance. *A. mixta* appeared to select favourable tail winds (northerlies), whereas abundance of *Sympetrum* increased with more easterly winds. Our results provide important information on the influence of local weather conditions on the flight behaviour of dragonflies, as well as evidence of dragonfly migration along the Baltic coast." (in German) ["Damselfly ditches in Swabia – management of ditches to conserve the ornate bluet and the southern damselfly: In Bavaria *Coenagrion mercuriale* and *C. ornatum* are endangered and threatened with extinction. Swabia is home to the main distribution of these species and therefore has an outstanding responsibility to preserve the populations of the two species. The project „Damselfly ditches in Swabia“ includes the recording investigation where the two species occur and the maintaining and development of their habitats. The project is successful because it cooperates with local actors and uses established sponsoring structures. The whole project is accompanied by intensive public relation. So the project goals can be ensured even beyond the project duration." (Publisher)] Address: Kling, Susanne, Landschaftspflegeverband Donautal-Aktiv e. V. E-mail: kling@donautal-aktiv.de

**17601.** Kohli, M.; Djernæs, M.; Sanchez Herrera, M.; Sahlen, G.; Pilgrim, E.; Simonsen, T.J.; Olsen, K.; Ware, J. (2021): Comparative phylogeography uncovers evolutionary past of Holarctic dragonflies. *PeerJ* 9:e11338 <https://doi.org/10.7717/peerj.11338>: 25 pp. (in English) ["Here, we investigate the evolutionary history of five northern dragonfly species to evaluate what role the last glaciation period may have played in their current distributions. We look at the population structure and estimate divergence times for populations of the following species: *Aeshna juncea*, *A. subarctica*, *Sympetrum danae*, *Libellula quadrimaculata* and *Somatochlora sahlbergi* across their Holarctic range. Our results suggest a common phylogeographic pattern across all species except for *S. sahlbergi*. First, we find that North American and European populations are genetically distinct and have perhaps been separated for more than 400,000 years. Second, our data suggests that, based on genetics, populations from the Greater Beringian region (Beringia, Japan and China) have haplotypes that cluster with North America or Europe depending on the species rather than having a shared geographic affinity. This is perhaps a result of fluctuating sea levels and ice sheet coverage during the Quaternary period that influenced dispersal routes and refugia. Indeed, glacial Beringia may have been as much a

transit zone as a refugia for dragonflies. *S. sahlbergi* shows no genetic variation across its range and therefore does not share the geographic patterns found in the other circumbo-real dragonflies studied here. Lastly, we discuss the taxonomic status of *Sympetrum danae*, which our results indicate is a species complex comprising two species, one found in Eurasia through Beringia, and the other in North America east and south of Beringia. Through this study we present a shared history among different species from different families of dragonflies, which are influenced by the climatic fluctuations of the past." (in German, with English summary) ["Colonisation of a newly created ditch in the canton Basel-City by *C. mercuriale* and other odonate species – A newly created section of a ditch in the canton Basel-City (Switzerland) was colonised by *C. mercuriale* after ten years. A sporadic monitoring of the Odonata fauna showed that prior to this date *Calopteryx splendens* and *C. virgo* had dominated and only few other species were present. *C. mercuriale* colonised only sectors with low density of vegetation. To colonise the new habitats, it had to disperse over more than 8 km. At the end of the flight period the density was four individuals per 100 m. Since *C. mercuriale* had never before been observed in this region, it is assumed that the species is currently in an initial stage of colonisation. Optimized measures will facilitate the development of a stable population." (Author)] Address: Küry, D., Life Science AG, Greifengasse 7, CH-4058 Basel, Switzerland. (2021): The damping and structural properties of dragonfly and damselfly wings during dynamic movement. *Communications Biology* 4( 737) (2021): 14 pp. (in English) ["For flying insects, stability is essential to maintain the orientation and direction of motion in flight. Flight instability is caused by a variety of factors, such as intended abrupt flight manoeuvres and unwanted environmental disturbances. Although wings play a key role in insect flight stability, little is known about their oscillatory behaviour. Here we present the first systematic study of insect wing damping. We show that different wing regions have almost identical damping properties. The mean damping ratio of fresh wings is noticeably higher than that previously thought. Flight muscles and

hemolymph have almost no 'direct' influence on the wing damping. In contrast, the involvement of the wing hinge can significantly increase damping. We also show that although desiccation reduces the wing damping ratio, rehydration leads to full recovery of damping properties after desiccation. Hence, we expect hemolymph to influence the wing damping indirectly, by continuously hydrating the wing system." **17614.** Liu, Z.; Zhou, T.; Cui, Y.; Li, Z.; Wang, W.; Chen, Y.; Xie, Z. (2021): Environmental filtering and spatial processes equally contributed to macroinvertebrate metacommunity dynamics in the highly urbanized river networks in Shenzhen, South China. *Ecological Processes* 10(23): 12 pp. (in English) [oas 57: "Background: Disentangling the relative roles of environmental filtering and spatial processes in structuring ecological communities is a central topic in metacommunity ecology. Metacommunity ecology in the temperate river ecosystems has been well developed, while less attention has been paid to subtropical urban river networks. Here, we examined the ecological factors and seasonal difference in structuring macroinvertebrates metacommunity assembly in the subtropical urban river networks in Shenzhen, South China. Results: Our results revealed that there was no significant distinction of macroinvertebrate community composition among seasons, with only the relative abundance of Mollusca and Odonata significantly differed in both wet and dry seasons. One possible explanation was that most macroinvertebrates are generally pollution-tolerant taxa characterized with nonseasonal life cycle. In addition, distance-based redundancy analysis and variation partitioning approach revealed that metacommunity was determined equally by the environmental and dispersal-related factors. Further, our results showed that, although a slight temporal variation of relative contribution, the identity and explanation power of ecological factors were different among seasons. Specifically, stronger environmental filtering structuring community dynamics was observed in the dry than wet seasons, which might be owing to higher environmental heterogeneity under a low water-flow condition. Moreover,

we detected that the influence of spatial processes was stronger in the wet than dry seasons, indicating an obvious dispersal processes due to high connectivity among sites. Conclusion: Overall, our results revealed that environmental and spatial factors equally explained variations of macroinvertebrate metacommunity, implying the necessity of considering dispersal-related processes structuring ecological communities in river bioassessment programs. Moreover, degraded habitat conditions and water quality were the predominant factors that affected macroinvertebrate communities, indicating the significance and feasibility of improving local abiotic conditions to sustain local biodiversity. Further, our findings revealed the importance of seasonal dynamics of these urban river networks in structuring macroinvertebrate metacommunity. Thereby, our study improves the understanding of ecological processes governing macroinvertebrate metacommunity and underlines the idea that community ecology studies should go beyond the single snapshot survey in river networks." **17615.** Lohr, M. (2021): *Selysiotthemis nigra* new for continental France (Odonata: Libellulidae). *Libellula Supplement* 16: 177-188. (in English, with French and German summaries) ["On 24-vii-2020 one adult male and two exuviae of *S. nigra* were found in the middle Durance Valley, southern France, in the North of the Var department, not far from the village of Vinon-sur-Verdon. These observations are the first records of the species in continental France. The exuviae were found on the shore of a former gravel pit, while the imago was photographed perching on a stem at a river bank near the Durance. The findings are discussed regarding the hitherto known range of the species, and possible immigration routes are described. The nearest sites where the species occurs are situated in northwestern Italy, northeastern Corsica and northeastern Spain, between 250 and 330 km from the Durance Valley. Most probably there is a migration of *S. nigra* along the shore of the Mediterranean Sea, either from the Southwest (Spain) or the Southeast (Corsica and Italy), before entering continental France and following the Durance Valley. The causes of an increase of records of *S. nigra* in an almost constant range, as well as the obvious spreading of other species like *Trithemis annulata* and *T. kirbyi*, are discussed. Climate change has clearly favoured the expansion of at least *T. annulata* and *T. kirbyi* during the last decades and years, respectively, and these species entered continental France coming from Spain. However, the increase of anthropogenic water bodies like man-made dams, irrigation basins, impoundments or gravel pits have also favoured this trend as recently stated for the highly ubiquitous *T. kirbyi*, for which both climate and habitat changes act in synergy. In the case of *S. nigra*, the increasing availability of such artificial, suitable habitats might be the main reason for the expansion as the species has been demonstrated to have recently established in areas where temperatures have decreased and rainfall increased since the turn of the millenium. Whether climatic factors also have a significant influence on the increase of observations and the small

range expansions of this species might be made clearer by future research." (Authors)] Address: Lohr, M., Technische Hochschule Ostwestfalen-Lippe, An der Wilhelmshöhe 44, 37671 Höxter, Germany. E-mail: mathias.lohr@th-owl.de

(2021): Odonata (Insecta) como indicador de la calidad ambiental en humedales de montaña neotropicales. *Acta Zoologica Mexicana* (N.S.) 37(1): 1-17. (in Spanish, with English summary) ["In order to evaluate the diversity of the Odonata order and relate it to environmental quality, in San Cristobal de Las Casas (Chiapas) four wetlands were chosen according to their accessibility and permissibility. For the environmental typology, among other characteristics, the visual quality was considered, estimated through the Index of the State of Conservation of Wetlands (IECH). Systematic monthly collections of adult odonates were carried out between July 2014 and June 2015. A total of 14 species, distributed in five families and 10 genera were found. The genus *Argia* was the richest, while *Ischnura denticollis* and *Enallagma rua* represented the dominant species. Las Cañadas, a wetland with suboptimal visual quality, presented the greatest diversity of dragonflies by integrating a lotic environment. As one of the parameters evaluated in the visual quality, the degree of alteration of the aquatic vegetation was very important in the differences found in the diversity and abundance of Odonata in the four wetlands. Maria Eugenia and La Kist classified as environments with optimal and regular visual quality, respectively, obtained the greatest similarity in their odonatofauna related to the different life forms of their aquatic vegetation and for the equivalent size of these two wetlands." **17617.** Lorenzo-Carballa, M.O.; Garrison, R.W.; Encalada, A.C.; Cordero-Rivera, A. (2021): Darwin returns to the Galapagos: Genetic and morphological analyses confirm the presence of *Tremea darwini* at the Archipelago (Odonata, Libellulidae). *Insects* 2021, 12, 21. <https://doi.org/10.3390/insects12010021>: 17 pp. (in English) ["The status of the *Tremea* species present in the Galapagos Islands (Odonata, Libellulidae) has been the subject of a long-standing debate among odonatologists. Here, we use molecular and morphological data to analyze a series of specimens from this genus collected in 2018 from the Islands of San Cristobal, Isabela, and Santa Cruz, with the aim of determining their relationship with *Tremea calverti* Muttkowski and with their currently considered senior synonym *T. cophysa* Hagen. We combined sequencing of mitochondrial and nuclear DNA with morphological examination of several specimens of *Tremea*, including representatives of continental *T. cophysa* and *T. calverti*. Our molecular analyses place the *Tremea* from Galapagos in the same clade as *T. calverti*, with *T. cophysa* as a closely related species. The morphological analyses found only one consistent difference bet-

ween *T. cophysa* and *T. calverti*: the presence of an accessory lobe in the male vesica spermalis of *T. cophysa* that is absent in *T. calverti* and in the *Tremea* from Galapagos. In agreement with our genetic results, the overall morphological differences documented by us indicate that the Galapagos material examined is conspecific with *T. calverti*. In light of this, and following the principle of priority in taxonomic nomenclature, *Tremea calverti* Muttkowski, 1910 should hereafter be considered a junior synonym of *Tremea darwini* Kirby, 1889." **17618.** Mafuwe, K.; Tambara, E.; Matutu, F.F.; Maforimbo, C.; Tsamba, J.; Mapendere, C.; Moyo, S. (2021): Community assembly of adult odonates in lacustrine systems of an understudied world heritage site of south-eastern Zimbabwe. *International Journal of Odonatology* 24: 122-138. (in English) ["Odonata are efficacious for management and conservation efforts in freshwaters. In recent times, increased effort has gone into enhancing awareness, data and information on dragonflies among scientists and policymakers. Here, we examined the Odonata community of dams within the Matobo National Park, a world heritage site in southern Zimbabwe. Specifically, we determined diversity of larval and adult odonate in five dams over one year. Several physico-chemical parameters were measured, including pH, total dissolved salts (TDS), electrical conductivity (EC). Further, we assessed how habitat types (i.e., detritus, sand, gravel, plant type) affect Odonata communities. In addition, surveys were conducted to identify critical threats to Odonata in the Matobo National Park and surrounding areas. Broadly, results showed that Odonata nymphs and volant adults did not change predictably across all sampling occasions. Further, pH was positively correlated with Libellulidae and Platycnemididae, whereas TDS and EC were positively correlated with Libellulidae, Platycnemididae and Macromiidae. Contrariwise, Gomphidae were found to be negatively correlated to TDS, EC and pH. The threat analyses identified natural system modifications, agricultural expansion and intensification, as well as human intrusions and disturbance as the major threats to Odonata and freshwater resources in Matobo National Park. Taken together, these data provide baseline data that will be useful for future monitoring of threats and subsequently conservation strategies in the Matobo National Park and other protected areas in Southern Africa." **17620.** Mallah, S.R.; Khan, M.H.; Agrawal, A. (2021): Dragonfly-inspired corrugated foil flight dynamics in heaving motion across various heaving frequencies. 5-6th Thermal and Fluids Engineering Conference (TFEC) 2021, 26–28 May : 71-79. ["The corrugated wing cross-section significantly affects flight dynamics of a dragonfly. Therefore, a heaving corrugated foil inspired from a dragonfly wing, is being numerically studied in this work. The objective is to understand the effect of heaving frequency on the lift and thrust coefficients of the bio-inspired corrugated foil, thereby unravelling the secret of dragonfly flight at various heaving frequencies of its wing. Two-dimensional numerical simulations are performed over a wide range of reduced frequencies,  $K = 0.09 - 2.63$ , covering the entire range of actual dragonfly wing's flapping frequency. The chord-based Reynolds number is 10,000 and a nondimensional heaving amplitude (normalized by the chord length) is 0.15. The results are compared against a smooth heaving NACA (National Advisory Committee for Aeronautics) 0012 foil. Over the studied heaving frequency range for the corrugated foil, at  $K = 0.09$  net drag on the corrugated foil is observed which transitions into a net thrust at  $K = 1.76$  and thereafter a monotonic increase in thrust is observed up to the largest studied reduced frequency. The drag to thrust transition is earlier for NACA0012 foil compared to corrugated foil because of lower leading-edge vortex strength and further at any studied  $K$ , NACA0012 foil is better in terms of thrust generation. The present study helps understand the influence of varying heaving frequency in the flight dynamics of dragonflies." (Authors)] Address: Mallah, S.R., Department of Mechanical Engineering, Indian Institute of Technology Bombay, Powai, Mumbai 400076, India

**17621.** Mallah, S.R.; Padinjattayil, S.; Agrawal, A.; Sharma, A. (2021): Investigating dragonfly flight dynamics at various heaving amplitudes of its wing. 5-6th Thermal and Fluids Engineering Conference (TFEC): 85-91. (in English) ["The dragonfly wing has a corrugated cross-section that significantly affects its flight dynamics. Therefore, inspired from a dragonfly wing, the corrugated foil performing heaving motion at various heaving amplitude, is being studied through numerical simulations. The objective is to understand the effect of heaving amplitude on the bioinspired corrugated foil, thereby unravelling the secret of dragonfly flight at various heaving amplitude of its wing. Two-dimensional numerical simulations are performed over a wide range of heaving amplitude (normalized by the chord length),  $H = 0.15 - 0.75$ . The chord-based Reynolds number is 10,000 and reduced frequency is 0.87. Further, to explore the effect of corrugations found in dragonfly wing, the results are compared with a smooth heaving NACA (National Advisory Committee for Aeronautics)0012 foil. Over the studied heaving amplitude range for the corrugated foil, at  $H = 0.15$

net drag on the corrugated foil is observed which transits into a net thrust at  $H = 0.3$ , however the time-averaged thrust is less than that for NACA0012 foil at all  $H$ . At any studied  $H$ , corrugated foil out-performs the NACA0012 foil in terms of time averaged lift generation. Therefore, corrugations found in dragonfly wings are for enhancement of lift rather than thrust. The present study helps understand the influence of corrugations of dragonfly wing in the enhanced lift generation mechanisms of dragonflies." (Authors)] Address: Mallah, S.R., Dept Mechanical Engineering, Indian Inst. Technology Bombay, Powai, Mumbai 400076, India

**17622.** Mancini, F.; De Giorgi, R.; Ludovisi, A.; Vizzini, S.; Mancinelli, G. (2021): Ontogenetic shift in the trophic role of the invasive killer shrimp *Dikerogammarus villosus*: a stable isotope study. *Biological Invasions* 23(6): 1803-1817. (in English) ["The introduction of the amphipod *Dikerogammarus villosus* in European fresh waters is to date recognized as a threat to the integrity of invaded communities. Predation by *D. villosus* on native benthic invertebrates is assumed as the key determinant of its ecological impact, yet available information describe the species as a primary consumer as well as a carnivore depending on local conditions. Here, we assessed the trophic position (TP) of *D. villosus* in Lake Trasimeno, a recently invaded lentic system in central Italy, using the CN isotopic signatures of individuals captured in winter spanning two orders of magnitude in body size. TP estimations were compared with those characterizing the native amphipod *Echinogammarus veneris* and other representative invertebrate predators. On average, *D. villosus* showed a trophic position higher than *E. veneris*, and comparable with that of odonate nymphs. An in-depth analysis revealed that large-sized individuals had a trophic position of 3.07, higher than odonates and close to that of the hirudinean predator *Erpobdella octoculata*, while small-sized specimens had a trophic position of 2.57, similar to that of *E. veneris* (2.41). These findings indicate that size-related ontogenetic shifts in dietary habits may per se vary the nature of the interaction between *Dikerogammarus villosus* and native invertebrates from competition to predation. Information collated from published isotopic studies corroborated the generality of our results. We conclude that intra-specific trophic flexibility may potentially amplify and make more multifaceted the impact of the species on other invertebrate species in invaded food webs." **17623.** Manger, R. (2021): Odonate wing vein preferences in haemolymph sucking *Forcipomyia paludis* (Diptera: Ceratopogonidae; Odonata). *Libellula Supplement* 16: 189-200. (in English, with German summary) ["In summer 2020, the Odonata fauna in the Weerribben-Wieden National Park was examined at various localities for the Odonata parasite *Forcipomyia paludis*. This park is currently one of the localities in the Netherlands where the species is found every year. Five localities in the area have been surveyed and many of the Odonata species were found to be infected by

biting midges. The parasites have been studied in more detail on photos of the Odonata species and an accurate overview was obtained on which wing veins they sucked. The highest numbers of biting midges were observed on the Cubitus vein. Furthermore, 91% of all observed midges sucked on the lower wing veins of the dragonflies and 9% on the upper ones. Biting midges were not observed in all of the sites surveyed in the park." (Author)] Address: Manger, R., Schukkingpad 17, 7971 BV Havelte, The Netherlands. E-mail: rene@mangereco.nl

**17624.** Martens, A.; Wildermuth, H. (2021): Gynandromorphism and intersexuality in Odonata: a review. *Odonatologica* 50(1/2): 65-80. ["Gynandromorphism is a rare phenomenon among insects, and as measured by the number of publications, particularly so in Odonata. The first case of gynandromorphism in the order was reported in 1866, the second in 1917. To date, 56 chimeric individuals have been described in 45 papers. Bilateral gynandromorphs account for about a third of all cases, the remainder consisting of phenotypical mosaics of male and female characters exhibited in wing patterns, genitalia, or other body parts. There are no patterns of gynandromorphism exclusive to Odonata. Here, as a basis for future work, we provide an overview as complete as possible of the known cases in the order of gynandromorphism in a broad sense, including intersexuality. This is the third review on this topic: the first dates from 1929 and the second from 1971, supplemented in 1975. In the last ten years, all new records have been based on photographic evidence rather than collected specimens, a practice which has its limitations and may skew the data by recording only the most obvious of cases. For future research it is recommended that specimens should not only be photographed in the field but also collected and preserved for detailed description and analysis in the laboratory. In addition, researchers should be alive to the possibility of finding gynandromorphs in final instar larvae and exuviae." **17626.** Matomela, N.H.; Chakona, A.; Kadye, W.T. (2021): Comparative assessment of macroinvertebrate communities within three Afrotropical headwater streams influenced by different land use patterns. *Ecological Indicators* 129 (2021) 107972: 11pp. (in English) ["Headwater streams in

Afrotropical ecoregions harbour locally adapted aquatic communities. However, across many regions in Africa, these ecosystems and their unique aquatic biodiversity have been severely impacted by unsustainable land use practices. We tested the hypothesis that land use disturbances were the primary drivers of community dynamics by comparing spatial and temporal dynamics together with trait-environment relationships of macroinvertebrate communities in three headwater streams influenced by different land use practices. The three headwater streams were distinguished based on high conductivity, total dissolved solids and alkaline pH in the agriculture-disturbed stream, and low temperature in a stream whose riparian zone was invaded by nonnative vegetation compared to a near-natural stream. Macroinvertebrate taxonomic diversity was, nevertheless, comparable among these three streams. Constrained canonical ordination revealed that seasonality was a major driver of macroinvertebrate dynamics that was reflected mostly by the abundances of six macroinvertebrate taxa (*Baetis*, *Dicentropetelum*, *Afronurus*, *Tricorythus*, *Simulium* and *Cheumatopsyche*), whereas land use contributed a small but significant difference. Trait-environment relationships reflected seasonal changes that included the importance of benthic substratum in winter, the occurrence of collector-gatherer invertebrates in spring and aerial breathing traits in summer. Land use-related traits were, nevertheless, reflected by gill respiration and grazer feeding traits represented by *Afronurus* in the near-natural stream, predator traits represented by *Aeshna* and *Lestes* in the invaded stream, and aerial respiration represented by *Enithares*, *Orectogyrus* and *Rhagovelia* in the agriculture-disturbed stream. Our results suggest that environmental variability associated with seasonality probably played a deterministic role within which land use disturbances operated. Overall, our study suggests that importance of using multiple metrics to unpack the patterns associated with land use disturbances in headwater streams." **17630.** Mikołajczuk, P. (2021): Habitat selection and population dynamics of *Nehalennia speciosa* (Charpentier, 1840) in Southern Podlasie and adjacent areas, Mideastern Poland. *Odonatrix* 17\_Suplement 1.IV, 81 pp, 51 pp suppl. (Polish, with English summary) ["The paper presents rich new data about 61 localities of *Nehalennia speciosa* discovered after 2009 in Mideastern Poland (tab. 1). Acidic Sphagnum mires formed greatest part of the species habitat spectrum there while acidic non-Sphagnum fens were slightly less frequent (fig. 5-l). Alkaline non-Sphagnum fens and water bodies in gravel pits were rarely inhabited by the species (fig. 5-l). The used by *N. speciosa* emergent plant formations were composed by many herbaceous species, but most frequently by – in descending order of frequency – *Carex rostrata*, *Juncus effusus*, *Carex lasiocarpa*, *Eriophorum vaginatum* and *Carex vesicaria* (fig. 6). The localities in the study area usually were only shallowly inundated and

lacked open, stable water bodies. This general feature was more pronounced in the eastern part of the study area, where almost no stable water bodies occurred, and it was less marked in the western part, where the stable water bodies occurred fairly often. Probably all the water bodies had anthropogenic (peat excavation) origin. Most of the recorded localities showed great habitat dynamics related to annual precipitation variability. The water level, being extremely risen in 2010-2011 and still high in further three years (tab. 3, fig. 7b), caused significant changes in the habitats, such as massive decline of forests and expansion of Sphagnum mosses and formations of Cyperaceae. During this time, at least 40–50% of the 37 monitored localities in the eastern part of study area became colonised by *Nehalennia speciosa* or at least attempts of colonisation occurred (tab. 4). The colonisations were really rapid, usually in the first two years of suitable conditions. In the next years, progressive drop in the water level caused drying up of the habitats and decline of the populations. Finally, probably only two of the 37 monitored populations were still existing in 2018, while the rest became extinct (tab. 4, fig. 7b). The main cause of the populations' extinction was, thus, absence of stable permanent water bodies, where *N. speciosa* might have survived the unfavourable dry years. Deep and relatively stable anthropogenic post-peat water bodies turned out, thus, to be very important for the species survival in the study area. The long-term precipitation data, historical maps and paleoecological data from upper peat deposits indicated that the localities in the eastern part of study area were hydrologically unstable also in the past, with a series of wet and dry phases during the 20th and 21st centuries (fig. 9). In many peat profiles, highly decomposed peat layers and botanical indicators of dry conditions, such as *Betula*, *Pinus*, *Carex canescens*, *Calamagrostis canescens* and *Lycopus europaeus*, were found in their 20th century's parts (fig. 8a-b). Some localities remained overgrown by forest for many decades, leaving relatively thick woody peat layers. The age of dying trees during extremely wet years 2010–2011 suggested that a previous similarly extremely wet period occurred here probably in the first half of the 20th century. However, the complex of wet episodes between the 1960s and 1980s was also significant. This situation suggest that occurrence of *N. speciosa* in the eastern part of study area was generally fluctuating not only in the 21st century, but at least since the first half of the 20th century. The paper also includes a synthesis of all published Polish data collected up to 2017 (fig.1, tab. 6) as well as comparison between the current (i.e. known in 2017) and older (2007) state of knowledge (tab. 7). Up to 2007, *N. speciosa* was described from 69 localities in Poland. These localities concentrated mainly in the northern part of the country, in areas covered by the last glaciation (lakelands), locally also in the east and south in old-glacial areas. The older data indicated that the species inhabited in Poland mainly small, natural dystrophic lakes surrounded by transition (Sphagnum) mires. Habitats of other types, such as peat excavation pools and transition mires without open water bodies were more rarely reported and located mainly in the old-glacial areas in the East. Almost all Polish localities known up to 2007 were situated in

forests. According to those data, the species was found most frequently in formations of *Carex lasiocarpa* and *C. limosa*, clearly more rarely in *Carex rostrata* and only exceptionally in other herbaceous plants' formations. Up to 2017, the number of known Polish localities rose to 168. Most of the newly reported localities were situated in old-glacial areas, mainly in the eastern part of country. The current data shows that the habitat spectrum in Poland is generally wider in comparison to older (2007) data and is different in last-glacial and old-glacial areas. In the former, the habitat spectrum was still based mostly on small, midforest dystrophic lakes surrounded by transition (*Sphagnum*) mires with a rim of *Carex limosa*/*Carex lasiocarpa* formations near the open water table, while in the latter the habitat spectrum was more diverse, comprising various types of nutrient-poor peatland (acidic *Sphagnum* mires, acidic and alkaline non-*Sphagnum* fens), in many cases without any open water bodies. Also broader spectrum of inhabited plant formations was recorded in the recently studied old-glacial areas, including e.g. *Carex rostrata*, *C. lasiocarpa*, *Juncus effusus*, *Eriophorum vaginatum*, *Carex vesicaria*, *C. elata*, and *Equisetum fluviatile*. The stable open water bodies inhabited in the old-glacial areas were often of anthropogenic origin. Some of the newly reported localities were also situated completely outside forests. Data from the study area and the recent water level oscillations recognisable on the photomaps indicated that the occurrence of *N. speciosa* in Poland is obviously fluctuating due to precipitation variability. This dynamics is regionally diversified: greater in the old-glacial areas and lesser in the last-glacial areas in the North. The terrestrialisation of natural water bodies is much more advanced in the old-glacial areas, because the lake depressions here are usually shallow and filled with sediments almost completely. For that reason, the habitats here are generally more sensitive to drying out in comparison with the last-glacial areas in the North, where stable, deep post-glacial lakes are still common. Except for mountains in the South of the country, also annual precipitation averages are higher in the last-glacial areas in the North, what is also followed by higher stability of the habitats in that zone. *N. speciosa* was considered as a low-mobile species due to its small size, delicate body build, poor flight activity, strong attachment to narrow-leaved vegetation in development places, very rare observations in unsuitable habitats (even very close, e.g. 100 meters from large populations) and occurrence mostly in stable, natural habitats. However, a) regularly reported colonisations of new habitats, including rapid colonisations of many localities recorded in the study area, b) the species genetics (low diversity, lack of phylogeographic structure) as well as c) its wide, trans-Palaearctic range do not support that conclusion. It seems, therefore, that long-distance relocation of imagines occurs more frequently. This relocation is hypothetically based on specific long-distance dispersal flights that comprise three main phases: 1) active rising into the air, possibly to considerable heights, 2) partly active flight driven and supported by air streams and observation of terrain from a height, 3) falling down into a suitable habitat. This suggested pattern of relocation was supported by data from the study area, where

active flights of imagines high into the air were observed. It might also explain rare observations of imagines in unsuitable habitats." (Author)] Address: Mikolajczuk, P., Sekcja Odonatologiczna Polskiego Towarzystwa Entomologicznego, Poland. E-mail: gugapm@wp.pl

**17633.** Monnerat, C.; Weiss, E.; Churko, G.; Fabian, Y. (2021): Die Libellengemeinschaft der Nassreisfelder in der Schweiz (Odonata). *Libellula Supplement* 16: 201-228. (in German, with English and French summaries) ["The dragonfly community in paddy fields in Switzerland (Odonata) – Odonata monitoring carried out in ten Swiss paddy fields in 2019 and 2020 revealed 42 species. Of these, 14 species developed in the fields, of which ten are bivoltine (*Ischnura elegans*, *I. pumilio*, *Anax ephippiger*, *A. imperator*, *A. parthenope*, *Crocothemis erythraea*, *Orthetrum albistylum*, *O. brunneum*, *O. cancellatum*, *Sympetrum fonscolombii*) and four univoltine (*Sympecma fusca*, *Sympetrum depressiusculum*, *S. striolatum*, *S. vulgatum*). The discovery of exuviae of *S. depressiusculum*, *S. striolatum*, and *S. vulgatum* in July 2020 documented their development and the survival of the eggs during the harvest in October and the preparation of the plots for sowing and planting in May. A mass emergence of a second generation of *A. ephippiger* and *S. fonscolombii* was observed in 2019. Population estimates for the Brugg site amounted to thousands or even tens of thousands of individuals, confirming the attractiveness of this habitat for the development of both migratory species in Central Europe. For *A. ephippiger*, the year 2019 corresponds to one of the largest known influxes in Switzerland and Europe over the last thirty years. The proven development of *S. depressiusculum* in the rice field of Ins suggests that rice fields have a

conservatory significance for this threatened species." (Authors)] Address: Monnerat, C., Info fauna, Bellevaux 51, 2000 Neuchâtel, Switzerland. E-mail: christian.monnerat@unine.ch

**17635.** Moore, M.P.; Hersch, K.; Sricharoen, C.; Leeb, S.; Reice, C.; Rice, P.; Kronick, S.; Medley, K.A.; Fowler-Finna, K.D. (2021): Sex-specific ornament evolution is a consistent feature of climatic adaptation across space and time in dragonflies. *PNAS* 2021 Vol. 118 No. 28 e2101458118. 7 pp. (in English) ["Adaptation to different climates fuels the origins and maintenance of biodiversity. Detailing how organisms optimize fitness for their local climates is therefore an essential goal in biology. Although we increasingly understand how survival-related traits evolve as organisms adapt to climatic conditions, it is unclear whether organisms also optimize traits that coordinate mating between the sexes. Here, we show that dragonflies consistently adapt to warmer climates across space and time by evolving less male melanin ornamentation—a mating-related trait that also absorbs solar radiation and heats individuals above ambient temperatures. Continent-wide macroevolutionary analyses reveal that species inhabiting warmer climates evolve less male ornamentation. Community science observations across 10 species indicate that populations adapt to warmer parts of species' ranges through microevolution of smaller male ornaments. Observations from 2005 to 2019 detail that contemporary selective pressures oppose male ornaments in warmer years; and our climate-warming projections predict further decreases by 2070. Conversely, our analyses show that female ornamentation responds idiosyncratically to temperature across space and time, indicating the sexes evolve in different ways to meet the demands of the local climate. Overall, these macro- and microevolutionary findings demonstrate that organisms predictably optimize their mating-related traits for the climate just as they do their survival-related traits." **17636.** Murwitaningsih, S.; Setyaningsih, M.; Sandajaja, D.P. (2021): Developing an Android-based guidebook to dragonflies and butterflies. *Advances in Social Science, Education and Humanities Research* 547: 227-231. (in English) ["Dragonflies (Odonata) and butterflies (Lepidoptera) play very important roles in the ecosystem and there are a great many of them. It is estimated that there are more than 5,000

types of dragonflies and 17,500 types of butterflies in the world, among them around 800-1,000 types of dragonflies and 2,200-3,000 types of butterflies can be found in Indonesia. A series of observations conducted in July 2018 at the Cibodas Botanical Garden in West Java found 8 species of dragonflies and 33 species of butterflies. The aim of this research is to develop an Android-based mobile guidebook application for dragonfly and butterfly observation that can be used at any time to easily identify dragonflies and butterflies. This research is a development research that refers to the 4D development model. In the Define stage, activities were carried out to collect initial information related to the diversity of dragonflies and butterflies. In the Design stage, activities were carried out to design books and Android applications. In the Develop stage, validation activities were carried out by dragonfly and butterfly experts, as well as media experts using questionnaires, interviews and discussions (FGD). In the Disseminate stage, activities were carried out to test an android application on students of the Biology Education Department at FKIP UHAMKA. The data obtained were analyzed using quantitative and qualitative descriptive techniques. The test results show that the guidebook was assessed as very good on the presentation aspect, very good for the material and good for the language, with a score of 88%, 85% and 82%, respectively. Thus, this mobile guidebook application, called ODOLEPI, is feasible for use in the observation of dragonflies and butterflies." **17639.** Nel, A. (2021): Maastrichtian representatives of the dragonfly family Aeschnidiidae question the entomofaunal turnover of the early Late Cretaceous. *Palaeoentomology* 4(3): 209-212. ["Gaps in the fossil record are the major challenge for estimations of impacts of crises of biodiversity of the various clades. They can lead to important misinterpretations in the effects of the different events on the fauna and flora. It is especially the case for the end-Cretaceous, which is 'near the midpoint of a 16-million-year gap in the insect fossil record' (Schachat & Labandeira, 2021: 111). All the important Cretaceous insect Konzentrat Lagerstätten are before the Turonian. The analysis of Schachat et al. (2019) has reconstructed a massive loss of family-level diversity for the insects at the boundary Cretaceous-Cenozoic, a possible artefact due to this gap. An alternative scenario was that a turnover in the entomofauna occurred during the early Late Cretaceous in relation to the floristic changes of the Albian–Cenomanian (Nel et al., 2018). This turnover would have also affected the aquatic insects through important changes in the freshwater environments (Sinitshenkova & Zherikhin, 1996; Ivanov & Sukatsheva, 2002). The current knowledge on the odonatan fossil record suggests a pronounced turnover with the last records of several major clades during the Cenomanian-Turonian and first records of several modern ones during the same period (Nel et al., 2015). The widespread and very diverse Jurassic–Cretaceous family Aeschnidiidae is among the best examples of such extinctions supposed to have occurred after the Cenomanian, because of the absence of any fossil in younger strata." **17640.** Nel, A.; Zhang, D. (2021): The recently proposed odonatan 'suborder' Cephalozygoptera: fact or fiction. *Palaeoentomology* 4(2): 165-170. (in English) ["The new 'suborder' Cephalozygoptera was recently proposed for three fossil families of damselfly-like Odonata, on the basis of three characters of the head. Here we show, thanks to counterexamples of the presence of these characters in compression fossils of genuine Zygoptera, that these 'characters' do not exist in reality but are due to deformations and compression of the heads, a very frequent phenomenon in the fossil record of the whole superorder Odonatoptera. Furthermore, these alleged characters would have to have been regarded as symplesiomorphies, insufficient to support a new clade. Consequently, we consider the Cephalozygoptera as unfounded, to be rejected in the current state of knowledge. A new phylogenetic analysis of the whole clade Panodonata would be welcome. We also discuss the position of some previously described fossils: the Paleocene genus *Valerea*

is restored in the Epallagidae (Euphaeidae), and the two Burmese amber genera *Electrodysagrion* and *Palaeodysagrion* are restored in the family *Dysagrionidae*." (Authors)] Address: Nel, A., Lab. Ent.. Mus. Natn. Hist. Nat., 45 rue Buffon, F-75005 Paris, France. E-mail: [anel@cimrs1.mnhn.fr](mailto:anel@cimrs1.mnhn.fr)

**17641.** Nemirini, T. (2021): Improving the performance of horizontal axial wind turbines using bioinspired airfoil shapes for its blades at low Reynolds numbers. PhD. thesis, Department of Electrical and Mining Engineering, University of South Africa. XII + 80pp.(in English) ["Small-scale wind turbines were not considered viable in the past due to their poor efficiencies, mainly because of their aerodynamic effects around the irfoil shape. Recently researchers have renewed interest in enhancing the aerodynamic performances of the blades' designs inspired by the aerodynamic pattern of biological characteristics of insects and marine mammals such as locusts, dragonflies, damselflies, Humpback Whales etc. Bioinspired wing designs have advantages compared to conventional smooth irfoil blades as they can counter the bending forces that the wings experience during flapping. Bio-inspired corrugated airfoil based on dragonfly wing geometries have been reported to perform well compared to conventional airfoil at low Reynolds numbers. Corrugated airfoils reduce flow separation and enhance aerodynamic performance by trapping vortices in the corrugations thus drawing flow towards the airfoil's surface. This results in the higher lift whilst incurring only marginally higher drag. Such airfoils also have an advantage when it comes to span-wise structural stiffness due to the corrugated cross-sections. Replacing conventional turbine blades by tubercles or corrugated blades could enhance turbine performance by reducing the pressure gradient along the leading edge; however, the aerodynamic effects at the leading edge will depend on the variations of wavelength and amplitude. In this study, two types of computational studies were investigated: Optimising a corrugated airfoil and investigating the aerodynamic effects of a sinusoidal shape at the leading edge of a blade. Previous studies used an idealized geometry based on the dragonfly wing cross-section profile but did not attempt to optimize the geometry. In the present study: a two-dimensional CFD model is constructed using ANSYS Fluent Workbench-Design Explorer to determine the optimal corrugated blade profile for four angles of attack (AOA) from 5° to 20° corresponding to typical AOA of small-scale wind turbine blades. Two modified blades with variations of wavelength and amplitude at the leading edge were studied to investigate the aerodynamic effects. Three-dimensional models were constructed using Qblade software and 3D points were exported to AutoCAD Inventor to generate the CAD model. The governing equations used are continuity and Navier-Stokes equations written in a frame reference rotating with the blade. The CFD package used is ANSYS FLUENT 19.0. The simulation was run under steady-state, using SST-k omega turbulence model. The modifications have improved the aerodynamic performance. The optimised corrugated blade produced a maximum increase of CL and L/D. Both modified blades (1 and 2) had their performances measured separately and compared to that of

baseline blade SG6042 (Conventional blade). Modified blade 1 had a lower wavelength and amplitude at the leading edge of 14.3 % and 4 % respectively of the chord. It was noted that the aerodynamic performance decreased by 6%. Modified model 2, on the other hand had a higher wavelength and amplitude at the leading edge. of 40.4 % and 11.9 % respectively of the chord. It was also noted the aerodynamic performance increased by 6%. From the empirical evidence highlighted above, it can be observed that there is a direct correlation between wavelength, amplitude, and aerodynamic performance of the blade." **17645.** Noorhidayah, M.; Arpah, A.; Norma-Rashid, Y. (2021): Classification and morphology of *Rhinocypha* spp. (Odonata): A comprehensive taxonomic study within the females. *Zoological Studies* 60: 39 pp. (in English) ["Studies on Odonata have gained worldwide attention as well as locally in Malaysia. Although there is a wealth of data available to be utilized for solving taxonomic problems but ecological and behavioural research areas are more favoured in contrast to taxonomy and systematics. Thus, there are existing confusions for correct identifications in closely related and sympatric species, especially in female odonates. One such example is in the genus of *Rhinocypha*. Consequently, the research is focused on taxonomic work, employing multi-approaches in the form of morphological (morphological diagnostics, Field Emission Scanning Electron Microscope and geometric morphometric analysis), with applying the molecular technique. 17 morphological characteristics were created to differentiate between the females of *Rhinocypha* spp. The FESEM on the female's ovipositor was done to focus on the anal appendages and sheathing valve (V3). Also, the phylogenetic patterns expressed by COI and 16S rRNA genes, and canonical variate analysis for the wing geometric morphometric revealed three clusters that supported the distinction of the *Rhinocypha* group. In summary, this study had effectively developed an integrated approach of classic morphological and trendy molecular, combined with microscopy techniques, FESEM, which provided corroborative evidence in resolving taxonomic uncertainties." **17648.** Novin, T.; Riyanto (2021): The abundance of Odonata insect in Lebak swamp, Bukit Baru, Palembang, Indonesia. *Jurnal Biologi Tropis* 21(1): 255-261. (in English) ["Lebak swamp in Bukit Baru has been largely degraded due to reclamation activity. Lebak swamp plays important role as land resource in Bukit Baru, Palembang. The aim of this study was to examine the composition of Odonata in lebak swamps in Bukit Baru, Palembang, Indonesia. The transect line (1 km) was used to collect odonata in the study area. This study recorded 8 species during the study period. The highest diversity of odonata was found in site A1. The highest abundance of odonata was recorded at site A2 and A4 and dominated by *Ceriatagris coromandelianum* and *Orthetrum sabina*. *Neurothemis ramburii* had the lowest abundance at site A1 and A2, but absent at site A3 and A4. The occurrence of odonate species are lower at site around anthropogenic activity suggests the need to protect the lebak swamp so that such uncommon species will not go into local extinction. *Neurothemis ramburii* can become potential species to evaluate the rate of disturbed environment." **17649.** Noviyana, W.; Triyanti, M.; Widiya, M. (2021): Inventory of dragonflies in the Curug Panjang Waterfall area, Muara Beliti District, Musi Rawas Regency. *Journal on Biology and Instruction* 1(1): 1-6. (in English, with Indonesian summary) ["There are many kinds of fauna in the waterfall Curug Panjang Muara Beliti, Musi Rawas Regency. One of the types of fauna found in this area is insects. Dragonflies is insects whose habitats live in water and in the air. This study aims to determine the types of dragonflies and abiotic factors carried out in the Curug Panjang waterfall area by using purposive sampling method. Data collection techniques are observation, documentation and identification. Sampling using insects net. The results of the study have been obtained by 2 sub-orders, 4 families and 12 different species namely *Diplacodes trivialis*, *Orthetrum pruinosum*, *O. sabina*, *O. pruinosum*, *Crocothemis servillia*, *Neurothemis ramburii*, *Trithemis aurora*, *Pantala flavescens*, *Tholymis tillarga*, *Ictinogomphus*, *Agriocnemis pygmaea*, and *Copera marginipes*. Abiotic factor measurement results are

with an average air temperature of 27,75°C, 76% air humidity and 396,5 lux light intensity." (Authors)] Address: Noviyana, Windy, Biology Education STKIP PGRI Lubuklinggau, Jl. Mayor Toha Kel. Air Kuti, Lubuklinggau, Indonesia. E-mail: windy.ny09@yahoo.com

**17650.** Nunes, L.; Casanueva, P.; Santamaría, T.; Hernández, M.A.; Campos, F. (2021): Useful biometric variables in Iberian exuviae of *Boyeria irene* (Fonscolombe, 1838) (Odonata: Aeshnidae). *International Journal of Odonatology* 24: 158-168. (in English) ["In species of similar shape and size, biometric analyses make it possible to establish differences. Within one species, biometrics can help researchers to detect differences between populations and analyze their adaptations to environmental conditions. Until now little was known about the biometrics of the Iberian populations of *B. irene*, a large species living mainly in southern Europe. Eight biometric variables were studied in male and female exuviae of *B. irene* collected in three rivers of the Iberian Peninsula, with the objective of ascertaining which are the most suitable populations of this species to study. An analysis of principal components (PCA) shows that lengths of the epiproct, paraproct and prementum are the most influential in each of the three populations. The other variables (head width, body length, length of the gonapophyses, maximum and minimum width of the prementum) proved not to be relevant in this context." **17652.** Odabasi, S. (2021): Assessment of habitat quality using macroinvertebrates and water quality parameters of a clay quarry wetland. *Journal of Advanced Research in Natural and Applied Sciences* 7(2): 274-281. (in English) ["In this study, it is aimed to determine the habitat quality of the Bozalan quarry wetland by using diversity and a compositional index of benthic macroinvertebrates and some of the water quality parameters. The field studies were conducted in the three sampling sites chosen in the wetland three times (March, April, and May) in 2018. The standard multi-habitat method was used for the benthos sampling. Besides, water sampling was performed for the parameters measured in-situ and analyzed in the laboratory to reveal the water quality status of the wetland. Some of the diversity index values of the benthic macroinvertebrates including Shannon Wiener (H'), Evenness Index (EI), and BMWP-e were calculated. The results showed that the sampling sites were categorized into higher classes (I and II) in general according to water quality criteria of the surface waters of Turkey. Fourteen taxa of benthic macroinvertebrates were identified. The most dominant taxa were *Coenagrion* sp. (42.31%), *Baetis rhodani* (15.38%), and *Physella acuta* (10%) in the study area. The highest number of individuals of macroinvertebrates was obtained in March (62 ind./m<sup>2</sup>), meanwhile the highest taxa number was determined in May (10 taxa). The H' index was reached its highest value in May (1.723), whereas the lowest value of the index was in March (1.054). The highest score of the BMWP-e was found in May (26), while the lowest score was found in April (16)."] (Authors)] Address: Odabasi, S., Vocational School of Marine Technologies, Çanakkale Onsekiz Mart University, Çanakkale, Turkey

**17653.** Okude, G.; Futahashi, R. (2021): Pigmentation and color pattern diversity in Odonata. *Current Opinion in Genetics and Development* 69: 14-20. (in English) ["The order Odonata (dragonflies and damselflies) comprises diurnal insects with well-developed vision, showing diverse colors in adult wings and bodies. It is one of the most ancestral winged insect groups. Because Odonata species use visual cues to recognize each other, color patterns have been investigated from ecological and evolutionary viewpoints. Here we review the recent progress on molecular mechanisms of pigmentation, especially focused on light-blue coloration. Results from histology and pigment analysis showed that ommochrome pigments on the proximal layer and pteridine pigments on the distal layer of the epidermis are essential for light-blue coloration. We also summarize genes involved in the biosynthesis of three major insect pigments conserved across insects and discuss that gene-functional analysis deserves future studies."] (Authors) Males of the following species are studied: *Calopteryx japonica*, *C. cornelia*, *Crocothemis servilia* (mature and immature), *Ceragrion melanurum*, *Paracercion hieroglyphicum*, *Lyriothemis pachygastra*, and *Orthetrum japonicum*.] Address: Okude, G., Department of Biological Sciences, Graduate School of Science, The University of Tokyo, Bunkyo-ku, Tokyo, 113-0033, Japan. **17655.** Orioli, V.; Gentili, R.; Bani, L.; Aguzzi, S. (2021): Microhabitat selection and population density of *Nehalennia speciosa* Charpentier, 1840 (Odonata: Coenagrionidae) in a peripheral microrefugium. *Wetlands* 41 (86). 14 pp. (in English) ["Peripheral populations of boreal tyrophilic animals and plants often occupy relict Alpine peatlands, which act as microrefugia. Ecological conditions within local peatlands can lead to uncommon adaptations, highly valuable for the long-term conservation of species and habitats. *N. speciosa* is an endangered Odonata distributed in Central and Eastern Europe with peripheral populations in the Alps. We investigated the microscale species-habitat association and the conservation status of one of these populations in a relict raised bog. We applied dynamic N-mixture models to assess population ecology and density, while disentangling predictors' effect on ecological and observation process. We counted *N. speciosa* individuals in spring 2018 along with vegetation, water, soil and weather conditions during surveys. Final model resulted reliable according to performance measures. Spatial variation in *N. speciosa* abundance was driven by vegetation type, with a strong selection for flooded hollows where *C. rostrata*, *R. alba* and *S. palustris* vegetation occupy acidic and oligotrophic shallow pools. Population density showed a peak in the first decade of June and increased with accumulation of superficial water. Detection probability was generally low and decreased further when wind blew. The reduced ecological plasticity of the species imperil the species to habitat and climate changes, which will be particularly threatening for its peripheral Alpine populations in the near future, causing water imbalance and rapid vegetation turnover within the peatlands' fragile microhabitat. The studied peat bog could thus be retained a key future microrefugium for the long-term conservation of tyrophilous wildlife and habitats."] (Authors)] Address: Orioli, V., Dept of Earth and Environmental Sciences, Univ. of Milano-Bicocca, Milan, Italy. **17656.** Pachomski, A.; McNulty, S.; Foss, C.; Cohen, J.; Farrell, S. (2021): Rusty Blackbird (*Euphagus carolinus*) foraging habitat and prey availability in New England: Implications for conservation of a declining boreal bird species. *Diversity* 2021, 13, 99.: 15 pp. (in English) ["*E. carolinus* is an imperiled migratory songbird that breeds in and near the boreal wetlands of North America. Our objective was to investigate factors associated with Rusty Blackbird wetland use, including aquatic invertebrate prey and landscape features, to better understand the birds' habitat use. Using single-season occupancy modeling, we assessed breeding Rusty Blackbird use of both active and inactive beaver-influenced wetlands in New Hampshire and Maine, USA. We

conducted timed, unlimited-radius point counts of Rusty Blackbirds at 60 sites from May to July 2014. Following each point count, we sampled aquatic invertebrates and surveyed habitat characteristics including percent mud cover, puddle presence/absence, and current beaver activity. We calculated wetland size using aerial imagery and calculated percent conifer cover within a 500 m buffer of each site using the National Land Cover Database 2011. Percent mud cover and invertebrate abundance best predicted Rusty Blackbird use of wetlands. Rusty Blackbirds were more likely to be found in sites with lower percent mud cover and higher aquatic invertebrate abundance. Sites with Rusty Blackbird detections had significantly higher abundances of known or likely prey items in the orders Amphipoda, Coleoptera, Diptera, Odonata, and Trichoptera. The probability of Rusty Blackbird detection was  $0.589 \pm 0.06$  SE. This study provides new information that will inform habitat conservation for this imperiled species in a beaver-influenced landscape." **17657.** Pachu, A.V.; Kumar, S.; Mohan, V.; Jeeva, V. (2021): Biomonitoring of water quality by the use of aquatic macroinvertebrates of the Mahan River in Singrauli, Madhya Pradesh, India. *Indian Forester* 147(4): 328-338. (in English) ["Aquatic macroinvertebrates in the perennial/seasonal streams of the River Mahan in the Mahan Reserved forest in Singrauli district, Madhya Pradesh were sampled semi-quantitatively with a view to ascertain biological water quality by employing the Macroinvertebrate Water Quality Index (MWQI). The study identified 747 individuals of macroinvertebrates comprising of 32 taxa belonging to 10 orders and 28 families with Ephemeroptera (57%) and Odonata (54%) as the dominant taxa respectively during monsoon and summer. Abundance and richness of macroinvertebrates were relatively high during summer than during the monsoons. Among the Biotic Indices of macroinvertebrates used for biomonitoring, the Taxa Tolerance Score (TTS) indicated 'good' with 'clean, but slightly impacted' water quality, that of the Average Score Per Taxon (ASPT) was 'moderate' and the Macroinvertebrate Water Quality Index (MWQI) indicated 'fair' water quality with 'significant pollution' respectively during both the sampling seasons. This study has improved the authors' knowledge about aquatic biodiversity of the water course and to improve the evaluation of water quality by employing biotic indices based on macroinvertebrates." Odonate taxa are treated at the family level. (Authors)] Address: Pachu, A.V., Institute of Forest Genetics and Tree Breeding, Coimbatore - 641002 India. E-mail: anishpachu@gmail.com

**17663.** de Paz, V.; Baños-Picón, L.; Rosas-Ramos, N.; Tobajas, E.; Tormos, J.; Asís, J.D. (2021): The role of artificial ponds in maintaining dragonfly populations in an intensified farmland landscape. A case of study in Zamora, Spain. *Journal of Natural History* 54(37-38): 2439- 2454. (in English) ["Freshwater ecosystems are exceptionally threatened habitats and suffer biodiversity losses that exceed those in any

other ecosystem. Small waterbodies have been typically neglected and excluded from conservation strategies, even though they are essential for maintaining freshwater biodiversity. Dragonflies are considered effective surrogates of the diversity of other taxa and bioindicators of the state of aquatic environments. This study compares, in an intensified farmland landscape of western Spain, the capacity of farm ponds to maintain dragonfly diversity by comparing the Odonata communities of the four type of aquatic systems (river, stream, reservoir and farm pond) present in this region, in which the extant of permanent water bodies is scarce. The results showed higher diversity and abundance values in farm ponds than in any other aquatic system, agreeing with previous studies. Also, farm ponds harbour species from every other aquatic system, thereby occupying an intermediate position in the MDS, which demonstrated their potential value to act as stepping stones. Nevertheless, investigation of the dragonfly community composition revealed a generally low degree of ecological integrity of the studied systems, which are negatively impacted by agricultural and livestock farming intensification. These findings support the role of farm ponds in the maintenance of dragonfly diversity in the study area and emphasise the need of a specific legislation to regulate and protect them." **17664.** Peng, L.; Zheng, M.; Pan, T.; Su, G.; Li, Q. (2021): Tandem-wing interactions on aerodynamic performance inspired by dragonfly hovering. *R. Soc. Open Sci.* 8: 202275. <https://doi.org/10.1098/rsos.202275>: 15 pp. (in English) ["Dragonflies possess two pairs of wings and the interactions between forewing (FW) and hindwing (HW) play an important role in dragonfly flight. The effects of tandem-wing (TW) interactions on the aerodynamic performance of dragonfly hovering have been investigated. Numerical simulations of single-wing hovering without interactions and TW hovering with interactions are conducted and compared. It is found that the TW interactions reduce the lift coefficient of FW and HW by 7.36% and 20.25% and also decrease the aerodynamic power and efficiency. The above effects are mainly caused by the interaction between the vortex structures of the FW and the HW, which makes the pressure of the wing surface and the flow field near the wings change. During the observations of dragonfly flight, it is found that the phase difference ( $\gamma$ ) is not fixed. To explore the influence of phase difference on aerodynamic performance, TW hovering with different phase differences is studied. The results show that at  $\gamma = 22.5^\circ$ , dragonflies produce the maximum lift which is more than 20% of the body weight with high efficiency; at  $\gamma = 180^\circ$ , dragonflies generate the same lift as the body weight." **17665.** Perron, M.A.C.; Richmond, I.C.; Pick, F.R. (2021): Plants, water quality and land cover as drivers of Odonata

assemblages in urban ponds. *Science of The Total Environment* 773, 15 June 2021, 145467: 12 pp. (in English) ["Highlights: • Dragonfly and damselfly assemblages were largely determined by local-scale factors. Plants and water quality were significant for both terrestrial and aquatic stages. Landscape factors explained less variation in Odonata community structure. Diverse native wetland plant communities benefit Odonata lifecycles. Abstract: As cities expand, urban ecosystems could either contribute to or impede conservation efforts. To maximize the potential for urban areas to support biodiversity, there is a need to understand how systems in an urban environment can sustain the natural history requirements of species. This study compared the relative importance of local-scale factors (plant communities and water quality) to landscape factors (surrounding land cover) in structuring assemblages of a group of well-known indicators of wetlands and aquatic ecotones. Odonata (dragonflies and damselflies), at both the adult and larval life stages, along with plant communities, pond water quality and surrounding land cover types were sampled at 51 ponds across a north temperate metropolitan area. Plant communities (particularly of wetland species) consistently explained the largest amount of variation in both dragonfly and damselfly community structure at all life stages. Pond water quality was of secondary importance for both aquatic and terrestrial life stages, with dragonflies more negatively affected by urban contaminants than damselflies. Overall, surrounding land cover types in pond catchments explained less variation in Odonata community structure, especially in the case of damselflies. However, the presence of adjacent ponds and wetlands had a measurable effect. Plant, water quality and land cover variables together explained as much as half of the variation in Odonata community structure at ponds. Urban ponds could potentially provide high quality habitat for species when designed and managed to promote native wetland plant communities and water quality is maintained." **17666.** Peryana, R.; Anggraito, Y.U.; Widiatningrum, T. (2021): Development of supplement book based on dragonfly diversity in Lusi watershed. *Journal of Biology Education* 10(1): 52-62. (in English) ["The Lusi River has local potential for abundant biodiversity, one of them is the diversity of dragonfly species. This local potential can be compiled into a teaching supplement to complement the student's teaching book. Data on the diversity of dragonflies in the Lusi watershed of Blora region was successfully obtained and compiled as a supplementary book of biodiversity chapters. However, the feasibility of the book needs to be assessed by material experts, media experts, teachers, and students. The purpose of this study was to analyze the feasibility and response of teachers and students to the supplement book developed. This study is designed as Research and Development (R&D) that is limited to the small-scale test stage. Eligibility data obtained by using media validation questionnaires and questionnaires made in accordance with BSNP 2014 standards, while teacher and student response data is obtained

by using teacher and student response questionnaires. The validation of material experts against teaching supplements got a score of 93.23% and media experts gave a score of 98.61%, both with very decent categories. However, there are suggestions from material and media validators for minor revisions. Teacher and student responses to teaching supplement received scores of 91.83% and 97.3% respectively with very decent categories. Based on the results of the study, it can be concluded that the teaching supplement of dragonfly diversity in Lusi River watershed is feasible for use in the study of biodiversity chapters." (2021): Niche partitioning at emergence of two syntopic dragonflies. *Ecologies* 2021, 2(1), <https://doi.org/10.3390/ecologies2010001>: 11pp. (in English) ["We investigated the ecological requirements in the emergence phase of two congeneric species of Aeshnidae, *Aeshna grandis* and *A. juncea*, occurring in syntopy at the southernmost limit of their range. We sampled the exuviae of the two species at the peak of their emergence in three lakes in NW Italy. In each lake we defined 30 to 50 sampling plots along the lake borders where we checked for the presence of exuviae and collected data on the microhabitat composition. By modeling the response of the exuviae presence and abundance against the environmental parameters, we could highlight a partial differentiation in the ecological requirements of the two species at emergence. In particular, *A. grandis* is more influenced by the structure of the aquatic vegetation than *A. juncea* and the niche space occupied by *A. grandis* is wider, almost totally encompassing the one of *A. juncea*. We argue that *A. grandis* exploits microhabitats rich in aquatic plants to avoid competition with *A. juncea*. We suggest the preservation of well-structured aquatic vegetation as a key management practice to preserve the three studied populations of *A. grandis*, a species which has been recognized as Vulnerable for Italy according to the IUCN criteria." **17670.** Pompilio, L.; Mosini, A. (2021): The Odonate fauna of Val Grande National Park (Insecta: Odonata). *Fragmenta entomologica* 53(1): 25-42. (in English) ["The results of a survey aimed at describing the Odonate fauna of Val Grande National Park are presented, which was carried out in the framework of the project "Animal Biodiversity Monitoring in Alpine Habitat". Relevant literature was examined and data collected intensively in summer 2016 and extensively in the period 2014-2019. Prior to this research specific knowledge on dragonfly and damselfly presence and distribution accounted for 6 species for the study area, which were recorded near the northern border but outside the park. The first Odonate checklist here provided is based on 188 records (1173 individuals), of which 137 are recent and unpublished. Comprehensively 25 species were recorded (14 breeding), which represent 26% of the Italian fauna, 36% of Piedmont and 58% of the province of Verbano Cusio Ossola, whereas three species were not confirmed; 10 species were found inside the park (4 breeding). Odonate diversity was remarkable, thanks to Val Grande geographical position between the Alps and the Insubric region and to high rainfall coupled with a complex orography. The study area hosts populations of the boreo-alpine species *Somatochlora alpestris* and *Sympetrum danae*, which are scattered and isolated in Italian Alps, and of the endemic European *Cordulegaster bidentata*; it hosts lotic taxa which are concentrated in SW Europe where they are under pressure because of droughts and exploitation of freshwater. Conservation and status issues of observed dragonflies and damselflies are discussed in the light of the growing interest gained by odonates as ecological indicators. The study proposes to use this knowledge to guide the future expansions of the protected area." (Authors)] Address: Pompilio, Lucia, Società di Scienze Naturali del Verbano Cusio Ossola, Natural

**17671.** Pound, K.L.; Larson, C.A.; Passy, S.I. (2021): Current distributions and future climate-driven changes in diatoms, insects and fish in U.S. streams. *Global Ecology & Biogeography* 30(1): 63-78. (in English) ["Aim Biodiversity on Earth is threatened by climate change. Despite the vulnerability of freshwater habitats to human impacts, most climate change projections have focused on terrestrial systems. Here, we examined how the current distributions and biodiversity of stream taxa might change under mitigated, stabilizing and increasing greenhouse gas emissions. Location Conterminous USA. Time period Present day to 2070. Major taxa studied Stream diatoms, insects and fish. Methods We developed species distribution models for 336 freshwater taxa from 1,227 distinct stream localities using water chemistry, watershed and climatic variables. Models based only on climate were used to project changes in the distributions and biodiversity of cold- versus warm-water taxa under representative concentration pathways (RCPs) ranging from 2.6 to 8.5 W/m<sup>2</sup>. Results In all three organismal groups, climate emerged as the strongest predictor of species distributions, providing comparable explanatory power to water chemistry and watershed variables combined. The RCP-based projections suggested a widespread expansion of warm-water taxa, outpacing the decline of cold-water taxa. Consequently, overall species richness would increase, but beta diversity would decrease drastically with the severity of climate change. A closer look at individual taxa and functional guilds revealed that vulnerable cold-water taxa included: (a) diatom guilds forming the base and bulk of the biofilm; (b) environmentally sensitive insects, characteristic of unpolluted streams; and (c) ecologically and recreationally important salmonids, which were forecast to diminish dramatically in source habitats. Warm-water fish projected to increase their distributions include bait bucket release minnows and dominant predators. Main conclusions Our results suggest potentially devastating impacts of climate change on stream ecosystems, with the restructuring of diatom, insect and fish communities, diminished distributions of functionally important taxa and widespread expansion of warm-water taxa, giving rise to biotic homogenization. Given that the magnitude of these biotic shifts depends on the severity of climate change, appropriate current policy decisions are necessary to preserve freshwater ecosystems." **17673.** Preston, D.L.; Layden, T.J.; Segui, L.M.; Falke, L.P.; Brant, S.V.; Novak, M. (2021): Trematode parasites exceed aquatic insect biomass in Oregon stream food webs. *Journal of Animal Ecology* 90(3): 766-775. (in English) ["1. Although parasites are increasingly recognized for their ecosystem roles, it is often assumed that free-living organisms dominate animal biomass in most ecosystems and therefore provide the primary pathways for energy transfer. 2. To examine the contributions of parasites to ecosystem energetics in freshwater streams, we quantified the standing biomass of trematodes and free-living organisms at nine sites in three streams in western Oregon, USA. We then compared the rates of biomass flow from snails *Juga plicifera* into trematode parasites relative to aquatic vertebrate predators (sculpin, cutthroat trout and Pacific giant salamanders). 3. The trematode parasite community had the fifth highest dry biomass density among stream organisms (0.40 g/m<sup>2</sup>) and exceeded the combined biomass of aquatic insects. Only host snails (3.88 g/m<sup>2</sup>), sculpin (1.11 g/m<sup>2</sup>), trout (0.73 g/m<sup>2</sup>) and crayfish (0.43 g/m<sup>2</sup>) had a greater biomass. The parasite 'extended phenotype', consisting of trematode plus castrated host biomass, exceeded the individual biomass of every taxonomic group other than snails. The substantial parasite biomass stemmed from the high snail density and infection prevalence, and the large proportional mass of infected hosts that consisted of trematode tissue (M = 31% per snail). 4. Estimates of yearly biomass transfer from snails into trematodes were slightly higher than the combined estimate of snail biomass transfer into the three vertebrate predators. Pacific giant salamanders accounted for 90% of the snail biomass consumed by predators. 5. These results demonstrate that trematode parasites play underappreciated roles in the ecosystem energetics of some freshwater streams." **17675.** Quanz, M.E.; Walker, T.R.; Oakes, K.; Willis, R. (2021): Contaminant characterization in wetland media surrounding a pulp mill industrial effluent treatment facility. *Wetlands Ecol. Manage.* 29: 209-229. (in English) ["Three media (sediment, surface water, and dragonfly larvae tissue) were collected from wetlands surrounding an industrial effluent treatment facility prior to closure. Samples were analyzed for metals, total mercury, and polychlorinated dibenzo-p-dioxins/polychlorinated dibenzofurans (PCDD/PCDF) concentrations. Sediment and surface water concentrations were compared to provincial and federal guidelines, as well as reference wetland concentrations. Exceedances of arsenic, cadmium, chromium, copper, zinc, and PCDD/PCDF guidelines were found in deeper areas of wetlands historically contaminated from effluent, as well as wetlands exposed to current effluent inputs. Composite Libellulidae samples were collected from wetlands, and comparisons were made to reference tissue concentrations ? 20%. Elevated As, Cu and Pb tissue concentrations were measured at two site wetlands, but total mercury (THg) and PCDD/PCDF reference tissue concentrations were higher than wetlands near the effluent treatment facility. Spearman rho tests identified a significant correlation between sediment and tissue Pb concentrations and between surface water and sediment THg concentrations. Results suggest relatively low ecological risk to macroinvertebrates within wetlands near the effluent treatment facility from current effluent inputs, and highlight strengths and weaknesses of federal and provincial guidelines." **17677.** Rasaily, B.; Kalkman, V.J.; Katel, O.; Suberi, B. (2021): The distribution, phenology and altitudinal range of

dragonflies and damselflies in Bhutan. International Dragonfly Fund - Report 160: 21-74. (in English) ["Odonata are attractive and relatively well studied insects that can serve to monitor the conservation status of freshwater habitats. Their effective use as conservation tools necessitates some basic requirements. It should be possible to identify adults and preferably also larvae with relative ease, and basic data on distribution and habitat preferences needs to be available. Freshwater habitats in Bhutan are relatively well preserved but are nonetheless threatened by both climate change and the construction of hydroelectric installations. Biological monitoring of freshwater biodiversity in Bhutan is therefore urgently needed and should include data on dragonflies and damselflies. In order to establish a framework for effective monitoring we constructed a database of all published records and use these to present information on the distribution, the altitudinal range and phenology of all species thus far recorded from Bhutan." **17684.** Rychla, A. (2021): Persistence of exuviae in natural conditions: Results of monitoring of selected dragonfly species (Odonata: Anisoptera) at the lake Plaw in western Poland. *Odonatrix* 172 (2021): 9 pp. (in Polish, with English summary) ["Exuviae of Odonata are valuable sampling material in faunistic, phenological, and monitoring research. However, one of the downsides of this method is impermanence of exuviae in natural conditions, which still makes the designation of sampling frequencies difficult. In this study, the effort has been made to investigate persistence time of exuviae of five selected Anisoptera. The experiment revealed that the average durability of the exuvial material was 4 (median) to 7 (arithmetic mean) days, without any significant differences between species. However, there was considerable variation within the collected material, with minimal and maximal values lying between 1 and 35 days of persistence for individual exuviae. The results indicate, that investigations of rare species may require sampling frequencies at least at weekly scale whereas biweekly sampling should be sufficient to obtain the representative species richness." **17687.** Santangelo, J.M.; Vanschoenwinkel, B.; Trekels, H. (2021): Habitat isolation and the cues of three remote predators differentially modulate prey colonization dynamics in pond landscapes. *Oecologia* 196: 1027- 1038. (in English) ["Recent evidence suggests predators may change colonization rates of prey in nearby predator-free patches as an example of context-dependent habitat selection. Such remote predator effects can be positive when colonizers are redirected to nearby patches (habitat compression), or negative when nearby patches are avoided (risk contagion). However, it is unknown to what extent such responses are predator- and prey-specific and change with increasing distance from predator patches. We evaluated how cues of fish, backswimmers and dragonfly larvae affect habitat selection in replicated pond landscapes with predator-free patches located at increasing distances from a predator patch. We found evidence for risk contagion and compression, but spatial colonization patterns were both predator- and prey-specific. The mosquito *Culex pipiens* and water beetle *Hydraena testacea* avoided patches next to patches with dragonfly larvae (i.e. risk contagion). Predator-free patches next to patches with backswimmers were avoided only by mosquitoes. Mosquitoes preferentially colonized patches at some distance from a fish or backswimmer patch (i.e. habitat compression). Colonization patterns of beetles also suggested habitat compression, although reward contagion could not be fully excluded as an alternative explanation. Water beetles preferred the most isolated patches regardless of whether predators were present in the landscape, showing that patch position in a landscape alone affects colonization. We conclude that habitat selection can be a complex product of patch isolation and the combined effects of different local and remote cues complicate current attempts to predict the distribution of mobile organisms in landscapes." **17690.** Santana, M.S.; Bezerra dos Santos, C.; Mitsuka, P.M. (2021): Composição de macroinvertebrados associados a macrófitas aquáticas como parâmetro para avaliação da qualidade da água de um reservatório no semiárido baiano. *Biotemas* 34(3): 1-14. (Portuguese, with English summary) ["Composition of macroinvertebrates associated with aquatic macrophytes as a parameter for assessing water quality in a reservoir in the semiarid region of Bahia. Macroinvertebrates associated with aquatic macrophytes have become more abundant since the plant's morphological characteristics contribute to an increase in colonization, diversity and environmental quality assessment. This study

presents a survey of the composition and richness of macroinvertebrates (Insecta Class) associated with different species of aquatic macrophytes and evaluates the water quality of the Tanque de Aroeiras reservoir, Caetité, Bahia. Macroinvertebrates were collected from macrophyte banks of different biotypes (*Nymphaea* L.; *Ludwigia* L.; *Polygonum ferugineum* Wedd.) and identified at the family taxonomic level. The Biological Monitoring Working Party System (BMWP) and Average Score per Rate (BMWP-ASPT) indices were determined. A total of 7,120 specimens were recorded, with a richness of 27 families, distributed in the following orders: Coleoptera, Diptera, Ephemeroptera, Hemiptera, Odonata (Aeshnidae, Coenagrionidae, Libellulidae, Protoneuridae) and Trichoptera. Coleoptera showed greater richness, while dipterans showed greater dominance, with Chironomidae being more abundant. This fact may be associated with a variety of aquatic life habits that contribute to a greater availability of food resources. The results of the BMWP-ASPT classified the water in this reservoir as likely to be moderately polluted. All things considered, this study highlights the importance of new research for added knowledge regarding the macroinvertebrate community and its application in evaluating the water quality of this reservoir." **17691.** Santos, J.P.; Lopes, G.N.; Gonzaga, K.S.; Abreu, K.G.; Souza Muniz, L.E.; Cartaxo, P.H. (2021): Insetos como bioindicador de qualidade ambiental em ambientes aquáticos - Insects as a bioindicator of environmental quality in aquatic environments. *Revista Thema* 19(2): 356-366. (Portuguese, with English summary) ["Strategies for monitoring the environmental quality of the most diverse ecosystems have been developed, especially for the aquatic environments, spaces severely affected by anthropic actions. Among the techniques developed, the use of bioindicators, species that show sensitivity to changes in the environment and respond to these anthropogenic stimuli are highlighted. In this sense, the present study aimed to analyze in the scientific literature the advances in the use of these organisms, with emphasis to the class Insecta and its applicability of use for the monitoring of the ecological health of aquatic ecosystems. The main orders of insects reported for use in bioindication of the environmental quality of water bodies are Diptera and Odonata. Chironomidae (Diptera) is often applied in studies of heavy metal contamination, and the development of larvae is considered for bioindication, as they develop in contact with the sediment, an important compartment of accumulation of contaminants in the aquatic body. Odonata insects can be used in the larval or adult phase for bioindication whose families may respond to changes in the environment, some being more sensitive than others to environmental changes. The use of these organisms may represent an efficient strategy for monitoring these environments, facilitating the interpretation of the effects of anthropogenic impacts on these ecosystems and their ecological relationships." **17697.** Schultz, B.; Koprivnikar, J. (2021): The contributions of a trematode parasite infectious stage to carbon cycling in a model freshwater system. *Parasitology Research* 120(5): 1743-1754. (in English) ["Parasites remain understudied members of most ecosystems, especially free-living infectious stages, such as the aquatic cercariae of trematodes (flatworms). Recent studies are shedding more light on their roles, particularly as prey for a diverse array of aquatic predators, but the possible fates of cercariae remain unclear. While this is critical to elucidate because cercariae represent a large potential source of energy and nutrients, determining the fate of cercariae-derived organic matter involves many logistical challenges. Previous studies utilized elemental and stable isotope analysis when examining host-parasite interactions, but none has used such approaches to track the movement of cercariae biomass within food webs. Here we report that *Plagiorchis* sp. cercariae were effectively labelled with  $^{13}\text{C}$  by introducing this compound in the food of their snail host. We then added  $^{13}\text{C}$ -labelled cercariae as a potential food source to experimental mesocosms containing a simplified model freshwater food web represented by diving beetles (*Dytiscidae* sp.), dragonfly larvae (*Leucorrhinia intacta*), oligochaete worms (*Lumbriculus variegatus*), and a zooplankton community dominated by *Daphnia pulex*. The oligochaetes had the highest ratio of  $^{13}\text{C}$  to  $^{12}\text{C}$ , suggesting benthic detritivores are substantial, but previously unrecognized, consumers of cercariae biomass. In an experiment where *L. variegatus* were fed mass

equivalents of dead *D. pulex* or cercariae, growth was greater with the latter diet, supporting the importance of cercariae as food source for benthic organisms. Given the substantial cercariae biomass possible in natural settings, understanding their contributions to energy flow and nutrient cycling is important, along with developing methods to do so." **17698.** Schwantes, D.; Gonçalves Junior, A.C.; Manfrin, J.; Campagnolo, M.A.; Zimmermann, J.; Conradi Junior, E.; Bertoldo, D.C. (2021): Distribution of heavy metals in sediments and their bioaccumulation on benthic macroinvertebrates in a tropical Brazilian watershed. *Ecological Engineering* 163, 1 May 2021, 106194: 10 pp. (in English) ["The objectives of this study were (i) to evaluate the quality of the Ouro River, a tropical Brazilian river, assessing the concentration of the metals in surface waters, sediments, and benthic macroinvertebrates; (ii) to investigate the possible sources of pollution in Ouro River basin through field research and spatial analysis (G.I.S.); (iii) to evaluate the possible occurrence of metals bioaccumulation in the trophic chain, by comparing the concentration of the metals in water, sediments (total and bioavailable) and in benthic macroinvertebrates; and (iv), to assess the biological metrics of benthic macroinvertebrates that inhabit the Ouro River, and the possible relation regarding its distribution (richness, abundance, dominance) with the human occupancy. Water, sediment, and macroinvertebrates samples were assessed in five sample sites for 9 months. The macroinvertebrates were arranged, identified, and analyzed taxonomically. The concentrations of Cu, Zn, Fe, Mn, Cd, Pb, and Cr in waters and sediments (total and Mehlich-1) were determined, the obtained results were compared to Brazilian and international standards indexes (Igeo and E.F.). According to our findings, the quality of Ouro River is directly affected by the human activities carried out in the watershed, and despite that the vast majority of the assessed metals in water was found below the legislation maximum levels, these accumulate in sediments, with extremely high enrichment of Cd, and moderately to heavily contamination of Cd, Mn, and Cu. Also, Zn and Pb high bioaccumulation in macroinvertebrates was observed, in which concentrations were 172% and 92% higher than the mean total concentration in sediment. The fit's goodness indicates that Mehlich-1 could be used as an extractant solution for the correlation of Pb in sediments and B.M.I. On average, Pb levels in the benthic are 14.94x higher than the bioavailable fraction in sediments (Mehlich-1). Mainly for Decapoda, Bivalve, and Gastropoda, results indicate high adsorption rates of Pb and Zn. The probable metal contamination in the Ouro River basin is from diffuse sources such as agriculture erosion (fertilizers and fertilizers with heavy and toxic heavy metals)." **17700.** Sganzerla, C.; Schmidt Dalzochio, M.; Prass, G.; Périco, E. (2021): Effects of urbanization on the fauna of Odonata on the coast of southern Brazil. *Biota Neotropica* 21(1): 10 pp. (in English, with Portuguese summary) ["Urbanization significantly increases the rates of environmental disturbance, being one of the main causes of habitat loss and biodiversity. The growing trend of converting the natural landscape into areas for real estate speculation in the coastal region of the southernmost part of Brazil is a current concern, as the region is home to unique ecosystems, such as dunes, wetlands and large brackish lagoons. As they are organisms sensitive to environmental changes, variations in the structure of Odonata communities are used as indicators of habitat quality reflecting the human impact on the environment. Here we assessed how the Odonata community is affected by the growing urbanization around natural ponds on the coast of the state of Rio Grande do Sul, testing the hypothesis that the increase in the percentage of urbanization negatively influences the Odonata community, following the same pattern found for other groups of invertebrates. The collections took place in 28 coastal ponds, which were classified as urbanized and non-urbanized based on the surrounding ground cover. Anisoptera's richness, abundance and composition were influenced by urbanization, but the same was not found for Zygoptera. The analysis of indicator species specifies three species associated with non-urbanized areas: *Erythrodiplax* sp.1, *Erythemis credula* and *Telebasis corallina*. Our study highlights the importance of Odonata as organisms that indicate environmental integrity and reinforces the need for urban planning strategies that favor the conservation and maintenance of the environments affected by urbanization." **17701.** Shao, H.; Li, Q.; Liu, Y. (2021): The complete mitochondrial genome of *Ceriagrion fallax* (Odonata: Zygoptera: Coenagrionidae) and phylogenetic analysis. *Mitochondrial DNA Part B*, 6:2: 491-492. (in English) [*C. fallax* is ubiquitous in south China and is particularly easy to be found in some rice fields. In this study, we sequenced and analyzed the complete mitochondrial genome (mitogenome) of *C. fallax*. This mitogenome was 15,350 bp long and encoded 13 protein-coding genes (PCGs), 22 transfer RNA genes (tRNAs) and two ribosomal RNA unit genes (rRNAs). The nucleotide composition of the mitogenome was biased toward A and T, with 74.0% of A+T content (A 42.1%, T 31.9%, C 14.6%, G 11.4%). Gene order was conserved and identical to most other previously sequenced Zygoptera dragonflies. Most PCGs of *C. fallax* have the conventional start codons ATN (seven ATG, two ATT, and two ATC), with the exception of *nad3* and *nad1* (TTG). Except for four PCGs (*cox1*, *cox2*, *cox3*, and *nad5*) end with the incomplete stop codon T—, all other PCGs terminated with the stop codon TAA. Phylogenetic analysis showed that *C. fallax* got together with the same family species (*Agriocnemis femina*, *Enallagma cyathigerum*, *Ischnura elegans*, *I. pumilio*) with high support value. The relationships (Megapodagrionidae + ((Calopterygidae + (Euphaeidae + Pseudolestidae)) + (Coenagrionidae + Platynemididae))) were supported within Zygoptera." (Authors)] Address: Yunxiang Liu, Y. **17703.** Silva, G.G.; Poulin, R.; Guillermo-Ferreira, R. (2021): Do latitudinal and bioclimatic gradients drive parasitism in Odonata?. *International Journal for Parasitology* 51(6): 463-470. (in English) ["Highlights: • Prevalence of parasites in odonates is driven by latitudinal and bioclimatic gradients. Latitudinal variation affects ecto-, but not endoparasites. Prevalence of water mites is positively associated with latitude. Gregarines are not affected by bioclimatic gradients. Abstract: Prevalence of parasites in wild animals may follow ecogeographic patterns, under the influence of climatic factors and macroecological features. One of the largest scale biological patterns on Earth is the latitudinal diversity gradient; however, latitudinal gradients may also exist regarding the frequency of interspecific interactions such as the prevalence of parasitism in host populations. Odonata are hosts

of a wide range of ecto- and endoparasites, interactions that can be affected by environmental factors that shape their occurrence and distribution, such as climatic variation, ultraviolet radiation and vegetation structure. Here, we retrieved data from the literature on parasites of Odonata, represented by 90 populations infected by ectoparasites (water mites) and 117 populations infected by endoparasites (intestinal gregarines). To test whether there is a latitudinal and bioclimatic gradient in the prevalence of water mites and gregarines parasitizing Odonata, we applied Bayesian phylogenetic comparative models. We found that prevalence of ectoparasites was partially associated with latitude, showing the opposite pattern from our expectations – prevalence was reduced at lower latitudes. Prevalence of endoparasites was not affected by latitude. While prevalence of water mites was also positively associated with vegetation biomass and climatic stability, we found no evidence of the effect of bioclimatic variables on the prevalence of gregarines. Our study suggests that infection by ectoparasites of dragonflies and damselflies is driven by latitudinal and bioclimatic variables. We add evidence of the role of global-scale biological patterns in shaping biodiversity, suggesting that parasitic organisms may prove reliable sources of information about climate change and its impact on ecological interactions." **17704.** Silva-Filho, E.S.; Guimarães de Araújo-Piovezan, T.; Dantasa, J.O.; Silvestre, M.; Alves, E.E.; Ribeiro, G.T. (2021): Controle de Larvas de *Aedes aegypti* por Ninfas de libélula (Odonata) sob Condições Laboratoriais - *Aedes aegypti* Larvae Control by Dragonflies (Odonata) under laboratory conditions. *Ensaio e Ciência* 25(2): 239-242. (in Portuguese, with English summary) ["Studies of *A. aegypti* control are especially important for reducing the incidence of Dengue, Zika and Chikungunya cases that are responsible for thousands of human deaths in the world. This study hypothesizes that Odonata nymphs influence the *A. aegypti* larvae control with different efficacy among their families, due to their chewing apparatus morphology and to their diverse behavior in nature. The objective was to evaluate the efficiency of seven families of Odonata nymphs as predators of the *A. aegypti* larvae under laboratory conditions. Odonata nymphs of seven families were collected with a net trap at Poxim Açu River. Each nymph was placed in a 20-cm diameter plastic recipient containing river water at room temperature. In order to verify the Odonata nymphs predation on the *A. aegypti* larvae, the predation rate of 30 mosquito larvae was verified on each recipient per day. The Odonata nymphs presented an average predation rate of 6.08 mosquito larvae per day. The families Aeshnidae (9,28) and Libellulidae (8,37) obtained the greatest average predation rate per day. All the Odonata families predated from 25 to 30 larvae in at least one day, except Cordulidae. Therefore, the Aeshnidae and Libellulidae predators were highly effective on the *A. aegypti* control. Thus, they represent a low-cost alternative for *Aedes* control in cisterns and water tanks at home sites, which have similar conditions to the ones

found in this experiment." (Authors)] Address: Guimarães de Araújo-Piovezan, Talita, Instituto Federal de Sergipe. SE, Brasil. E-mail: talit\_a@hotmail.com

**17707.** Sniegula, S.; Raczynski, M.; Golab, M.J.; Johansson, F. (2020): Effects of predator cues carry over from egg and larval stage to adult life-history traits in a damselfly. *Freshwater Science* 39(4): 804-811. (in English) ["Non-consumptive predator effects experienced in early life stages of prey may result in life-history costs in later life stages. Such effects can, for example, alter the growth rate during the juvenile stage, which may carry over to size at maturity. However, we have limited knowledge of the carry-over effects starting from the egg stage through the larval stage to the adult stage. Here, we present results from a laboratory experiment in which we exposed *Ischnura elegans* to chemical cues originating from a fish predator, perch. We used a 2 × 2-full-factorial design in which the damselflies were exposed to predator cues during either the immobile egg or the mobile larval stage. The presence of predator cues, i.e., non-consumptive predator effects, during the egg stage caused decreased survival, but only until 2 wk after larval hatching. Predator cues during the larval stage caused de-

creased survival until emergence and an increase in development time until emergence. However, mass at emergence was not affected by predator cues. When fish cues were present in the egg or larval stage, there was a lower growth rate until final-instar larvae than in larvae that did not receive fish cues. Our results add to the growing number of studies showing that predation-risk cues in the egg stage can carry over to the adult stage, which ultimately could have consequences for adult life-history traits, such as survival and fecundity." **17709.** Son, S.-h.; Choi, J.-y. (2021): Influence of environmental characteristics on the community structure of benthic macroinvertebrates in stream-type waterways constructed at upper reaches of Geum River. *Korean Journal of Ecology and Environment* 54(1): 24-38. (in English) ["Microhabitat in the upper stream is created by various environment variables such as the bottom substrate and the physicochemical factors, and may influence the distribution of benthic macroinvertebrates. We investigated the bottom substrate and environmental variables influencing the distribution of benthic macroinvertebrate in 26 stream-type waterways established at upper reaches of Geum River. During study period, total 85 families, 160 species, 9305 individuals of benthic macroinvertebrates were recorded [Odonata: 10 families with 26 species (16,4%); no further details are given]. The stream-type waterways, where the bottom substrates consist mainly of pebble (16~64 mm) and cobble (64~256 mm) or with rapid water velocity (more than 0.2 m/s) and high dissolved oxygen (more than 120%), were supported by high species diversity of benthic macroinvertebrate. Hierarchical cluster analysis and the nonparametric multidimensional scale (NMDS) divided 26 stream-type waterways into a total of three clusters. In Cluster 1, the invertebrate species, such as *Branchiura sowerbyi*, *Cloeon dipterum*, *Ischnura asiatica*, *Paracercion calamorum*, and *Radix auricularia*, closely related to aquatic macrophytes, and *Chironomidae* spp., *Limnodrilus gotoi*, and *Tanytopodinae* sp. were abundant in waterways, with high coverage of silt and clay as well as high turbidity and total nitrogen. The benthic macroinvertebrate species (*Cheumatopsyche brevilineata*, *Drunella ishiyamana*, *Dugesia japonica*, *Ephemera orientalis*, *Gumaga KUa*, *Macrostemum radiatum*, *Potamanthus formosus*, *Semisulcospira libertine*, *Stenelmis*

vulgaris, and Teloganopsis punctisetae) included in Cluster 2 were dominated in sites with high cover rates of pebble and gravel. Cluster 3 was predominantly covered by the Cobbles, was supported by Simulium sp. Such a clear distinction in the study sites means that each stream-type waterways is governed by a clear habitat environment. In the case of some sites with low species diversity, improvement measures are required to restore nature, such as improving the function of inflows and outflows, creating meandering channel, and inducing the settlement of littoral vegetation." **17710.** Souza, A.G.M. de; Lameira Neto, V. de J.; Pereira Junior, A. (2021): A. Integrative review on biology, water quality and the order Odonata. Research, Society and Development 10(9), p. e24910917605, 2021. DOI: 10.33448/rsd-v10i9.17605: 18 pp. (in Portuguese, with English and Spanish summaries) ["Sciences such as biology generate information about ecosystems, such as aquatic ecosystems, and promote integration with ethnic knowledge associated with botany. The objective of this work was to carry out an integrative review about the interrelationship of biology with various environmental areas, under two aspects, conservation, and balance, to investigate the relationship between biology and research on water quality and the use of the order Odonata as bioindicator of the environmental quality of water bodies. The research method was deductively associated with a quantitative and qualitative approach of a basic nature. The data obtained and analyzed indicated that the biological terms are present in most of the selected literature (n = 46.2%); regarding water quality, there was a small reduction (n = 30.8%); the use of the order Odonata as bioindicators of water quality is still scarce (n = 22.9%). As for the use of descriptors in the analyzed research, the following citations were identified: "Biological terms and water quality" (n = 65.8%); "Odonata and water quality" (n = 21.1%); "Biological terms and Odonata" (n = 13.2%). The order Odonata, as a bioindicator, is evolving (Amount = 33.3%) and with high frequency (fr > 50%) when compared to the application of Biological Terms and Water Quality. So, the application of biology is already effective in environmental areas such as water quality analysis. However, the use of Odonata as bioindicators of water quality is not used very often yet. Thus, it is recommended that there is a greater appreciation by researchers of this relationship, which can contribute to the qualification and monitoring of this natural resource more comprehensively and effectively." **17711.** Späth, J.; Brodin, T.; Cervený, D.; Lindberg, R.; Fick, J.; Nording, M.L. (2021): Oxylinins at intermediate larval stages of damselfly *Coenagrion hastulatum* as biochemical biomarkers for anthropogenic pollution. Environmental Science and Pollution Research 28: 27629-27638. (in

English) ["Aquatic pollution resulting from anthropogenic activities requires adequate environmental monitoring strategies in sentinel organisms. Thus, biochemical biomarkers have been used as early-warning tools of biological effects in aquatic organisms. However, before using these markers for environmental monitoring, knowledge about their developmental variation is vital. In this study, we assessed baseline levels and developmental variations of a group of potential biomarkers, oxylinins, during the lifespan of *C. hastulatum* using liquid chromatography-tandem mass spectrometry. Effects of wastewater exposure on baseline levels were studied in a subset of damselflies to investigate the responsiveness due to anthropogenic pollution. Thirty-eight oxylinins deriving from four polyunsaturated fatty acids via two enzymatic pathways were detected in damselflies at three larval stages and in the adult form. Overall, oxylinin baseline levels showed developmental variation, which was lowest in the intermediate larval stages. Effects of exposure to wastewater effluent on oxylinin baseline levels were dependent on the life stage and were greatest in the early and intermediate larval stages. The study provides first insights into oxylinin profiles of damselflies at different stages of development and their developmental variation. Based on our results, we propose further strategies for incorporating oxylinins in damselfly larvae as biochemical markers for anthropogenic pollution." **17712.** Stunkle, C.R.; Davidson, A.T.; Shuart, W.J.; McCoy, M.W.; Vonesh, J.R. (2021): Taxa-specific responses to flooding shape patterns of abundance in river rock pools. Freshwater Science 40(2): 397-406. (in English) ["Connectivity and patch size are important landscape characteristics that drive patterns of abundance and diversity across scales. However, responses to connectivity and patch size are dependent on species traits. Riverine landscapes are highly dynamic both spatially and temporally, with hydrologic connectivity being a major driver of abundance and diversity. Here we modeled the densities of 2 taxa that differ in life history and dispersal ability, the Virginia River Snail (*Eliemia virginica*) and skimmer dragonfly larvae (*Pantala* spp.), as a function of flooding, patch area, and season in >300 riverine rock pools. We found key differences in how each taxon responded to these predictors. Specifically, increasing pool flood height had a strong negative effect on snail densities, whereas dragonfly nymph densities increased as pools became isolated from the river channel for longer durations of time. Increasing pool surface area had a positive effect on snail densities, whereas dragonfly nymph densities showed no such relationship. Dragonfly nymph densities were greater in summer and autumn than in spring, but snails showed no difference in their temporal distribution across seasons. Our study highlights how differential responses to landscape characteristics are dependent on organism traits. These findings give insight into patterns of abundance and diversity across spatiotemporal scales." (Authors)] Address: Stunkle, C.R., Center Environmental Studies, Virginia Com-

monwealth Univ., 1000 West Cary Street, Suite 105, Richmond, Virginia 23284 USA. E-mail: crstunkle@vcu.edu

**17713.** Sumanapala, A.P. (2021): *Macromia weerakooni* sp. nov. (Odonata: Anisoptera: Macromiidae), a new dragonfly species from Sri Lanka. *International Journal of Odonatology* 24: 169-177. (in English) ["The genus *Macromia* is represented in Sri Lanka by two endemic species. In this paper a third presumed endemic species is described based on a single male specimen collected at Kirikitta, Weliveriya, Western Province in the low country wet zone of the country. *Macromia weerakooni* sp. nov. differs from its congeners in Sri Lanka by having turquoise blue eyes, an entirely black labrum, a short yellow ante-humeral stripe, an interrupted yellow stripe on the anterior margin of metepisternum and differences in the secondary genitalia and anal appendages. As this is the only record of the species knowledge of its natural history and distribution is limited. This discovery highlights the need for further systematic surveys of Odonata in Sri Lanka using sampling methods suitable for the detection of elusive species." **17717.** Tang, D.H.Y.; Visconti, P. (2021): Biases of Odonata in Habitats Directive: Trends, trend drivers, and conservation status of European threatened Odonata. *Insect Conservation and Diversity* 14(1): 1-14. (in English) ["1. Odonata, are important ecological indicators with widely recognised conservation value. They are generally better researched and protected than other invertebrates, yet, they have received limited protection from the European Union (EU)'s Habitats Directive, which serves as the major legislative tool for species conservation in Europe. 2. We reviewed the conservation status and trends, legal protection status, and knowledge gaps of Odonates within the EU. Among the 22 threatened and 27 endemic species in EU, respectively 19 and 11 of them are not protected by the Directive. Out of the 35 species which are threatened and/or listed on the Annexes, 61.5% of them are declining. 3. Nevertheless, threatened non-Annex species are more likely to have a decreasing population trend than Annex species. There are also 26% of threatened non-Annex species with unknown trends. Inaccuracies in evaluating Odonata trends are also revealed due to the lack of standardised methodology and incomplete surveys. 4. Moreover, most conservation research focuses on climate change's effects on range shift, therefore knowledge gaps exist in understating how water and habitat qualities, the most important Odonate trend drivers, shape Odonata conservation status. 5. There is an urgent need to revise the legal protection status of Odonata in Europe, for instance by revising the EU Habitats Directive Annexes to include threatened damselflies and dragonflies. 6. There is also an urgent need for systematic, standardised, and regular survey to be able to investigate trends and drivers of change to identify priority conservation actions." **17720.** Thakuria, D.; Kalita, J. (2021): Diversity and distribution of odonates in Rani Reserve Forest, Assam, India. *Journal of Threatened Taxa* 13(1): 17487-17503. (in English) ["Odonata are the bioindicators of freshwater ecosystem health and is recognised as an excellent 'flagship' group among insects. Baseline knowledge on the diversity and distribution of odonates over spatiotemporal scale is the key to biodiversity conservation. Rani Reserve Forest of Assam is a mosaic of all the habitat types suitable for odonates. The present work aims at studying the diversity and distribution of Odonates in Rani Reserve Forest. The study was carried out from December 2014 to November 2017 by categorising the study area into three major habitat types: 1. lentic system, 2. lotic system and 3. terrestrial woodland. A total of 67 species belonging to 44 genera, representing 11 families were recorded. First published records of three species, *Onychothemis testacea*, *Philoganga montana* and *Indocnemis orang* from the state are also provided herewith. Species richness was the highest in lentic system whereas recorded the lowest in running waters of larger forested streams. Shannon diversity index also indicated that the lentic system is relatively diverse (2.95) and smaller streams of the lotic system showed the highest species evenness (0.87). Libellulidae (43%) was found to be the most dominant family belonging to suborder Anisoptera followed by Coenagrionidae (22%) of suborder Zygoptera. Philogangidae (1%) recorded the lowest number of species. Taxonomically related species showed distinct ecological segregation within these different habitat types occupying different microhabitats therein." **17721.** Theischinger, G.; Miller, J.; Tang, C.; Huxley, M.; Jacobs, S. (2021): What will happen to them? Notes on some dragonfly (Odonata) species that are susceptible to the impacts of global warming-induced climate change. *The Victorian Naturalist* 138(3): 68-77. (in English) ["Many aquatic macroinvertebrates that require specific habitat niches are expected to relocate in response to global warming-induced climate change. For some species, relocation will not be possible because of geographic constraints or complete loss of the required habitat. Data compiled by Theischinger et al. (2018) was used to identify some species of Odonata at risk of extinction due to loss of habitat caused by climate change. While numerous species are at risk, this paper details only examples of habitats most likely to be impacted. Twelve species requiring these habitats are discussed. Species most at risk are those requiring alpine, sub-alpine and montane habitats. The combined effects of reduced rainfall and increased temperatures have been identified as the factors most likely to degrade these habitats catastrophically. Australia has limited alpine, sub-alpine and montane regions, and little or no alternative habitat for these species. Also, species requiring spring-fed streams are at risk due to reduced renewal of groundwater, while those that inhabit large slow-flowing rivers, particularly in the Murray Darling Basin, are likely to be impacted by algal blooms." (Authors)] Address: Jacobs, S., 55 Lindley Avenue, Narrabeen, NSW 2101, Australia. E-mail: janrob02@gmail.com

**17722.** Thongprem, P.; Davison, H.R.; Thompson, D.J.; Lorenzo-Carballe, M.O.; Hurst, G.D.D. (2021): Incidence and diversity of *Torix Rickettsia*-Odonata symbioses. *Microbial Ecology* 81: 203-212. (in English) ["Heritable microbes are an important component of invertebrate biology, acting both as beneficial symbionts and reproductive parasites. Whilst most previous research has focussed on the 'Wolbachia pandemic', recent work has emphasised the importance of other microbial symbionts. In this study, we present a survey of odonates (dragonflies and damselflies) for *torix* group *Rickettsia*, following previous research indicating that this clade can be common in other aquatic insect groups. PCR assays were used to screen a broad range of odonates from two continents and revealed 8 of 76 species tested were infected with *Rickettsia*. We then conducted further deeper screening of UK representatives of the Coenagrionidae damselfly family, revealing 6 of 8 UK coenagrionid species to be positive for *torix Rickettsia*. Analysis of *Rickettsia* gene sequences supported multiple establishments of symbiosis in the group. Some strains were shared between UK coenagrionid species that shared mtDNA barcodes, indicating a likely route for mitochondrial introgression between sister species. There was also evidence of coinfecting *Rickettsia* strains in two species. FISH analysis indicated *Rickettsia* were observed in the ovarioles, consistent with heritable symbiosis. We conclude that *torix Rickettsia* represent an important associate of odonates, being found in a broad range of species from both Europe and South America. There is evidence that coinfection can occur, vertical transmission is likely, and that symbiont move-

ment following hybridisation may underpin the lack of 'bar-coding gap' between well-established species pairs in the genus. Future work should establish the biological significance of the symbioses observed." (Authors)] Address: Hurst, G.D.D., Institute of Infection, Veterinary and Ecological Sciences, University of Liverpool, Liverpool L69 7ZB, UK. E-mail: g.hurst@liverpool.ac.uk

**17723.** Tüzün, N.; Savasçi, B.B.; Stoks, R. (2021): Seasonal time constraints shape life history, physiology and behaviour independently, and decouple a behavioural syndrome in a damselfly. *Oikos* 130(2): 274-286. (in English) ["The integration of traits into 'syndromes' has been suggested as a useful framework to advance insights in trait responses to environmental stressors. Yet, how stressors shape the consistency ('repeatability') of traits and their covariation at the individual level remains debated. We studied how seasonal time constraints shape trait repeatability and integration of life-history, behavioural, and physiological traits along a fast-slow continuum, using the 'pace-of-life syndrome' as a framework. We manipulated the photoperiod during the larval development of the damselfly *Ischnura elegans*, generating a time-relaxed early, a control, and a time-constrained late group. The photoperiod treatment did not seem to affect the voltinism of the larvae. As predicted, late-period larvae accelerated development and growth, yet this acceleration was no longer detectable for growth and metabolic rate during the final instar, possibly due to costs of the initial life-history acceleration. This warrants caution when inferring a species' pace-of-life based on a specific developmental stage. The late-period larvae were as predicted more active (only during the later stages of the final instar) and bolder than the control larvae, but not different from the early-period larvae. Most studies on time constraints only compared late and control animals, thereby potentially wrongly concluding adaptive responses to time constraints. Activity, boldness, and body mass were repeatable, while growth and metabolic rates were not. Notably, repeatabilities did not change under time constraints. There was no support for an overall trait integration in a pace-of-life syndrome, yet activity and boldness covaried positively as expected. Importantly, this 'behavioural syndrome' was decoupled in the late-period larvae, which might be adaptive to enhance energy acquisition to fuel the accelerated development rate. Our results suggest that besides the predicted plastic acceleration of life-history, plastic changes in behavioural trait integration may also be an important but overlooked adaptive aspect of responding to time constraints." **17724.** Twardochleb, L.; Hiltner, E.; Pyne, M.; Zametske, P. (2021): Freshwater insects CONUS: A database of freshwater insect occurrences and traits for the contiguous United States. *Global Ecology & Biogeography* 2021: 16 pp. (in English) ["Freshwater insects comprise 60% of freshwater animal diversity; they are widely used to assess water qua-

lity, and they provide prey for numerous freshwater and terrestrial taxa. Our knowledge of the distribution of freshwater insect diversity in the USA is incomplete because we lack comprehensive, standardized data on their distributions and functional traits at the scale of the contiguous United States (CONUS). We fill this knowledge gap by presenting Freshwater insects CONUS: A database of freshwater insect occurrences and traits for the contiguous United States. This database includes 2.05 million occurrence records for 932 genera in the major freshwater insect orders, at 51,044 stream locations sampled between 2001 and 2018 by federal and state biological monitoring programmes. Compared with existing open-access databases, we tripled the number of occurrence records and locations and added records for 118 genera. We also present life-history, dispersal, morphological and ecological traits and trait affinities (analogous to fuzzy-coded traits) for 1,007 stream insect genera, assembled from existing databases, reference books and the primary literature. We nearly doubled the number of traits for 11 trait groups and added traits for 180 genera that were not available from open-access databases. Our database, Freshwater insects CONUS, facilitates the mapping of freshwater insect taxonomic and functional diversity and, when paired with environmental data, will provide a powerful resource for quantifying how the environment shapes stream insect diversity and taxon-specific distributions." (2020): Dragonflies of Dragon's Blood Island: Atlas of the Odonata of the Socotra Archipelago (Yemen). *Rendiconti Lincei. Scienze Fisiche e Naturali* 31: 571-605. (in English) ["Odonata are important bioindicators of aquatic ecosystem health. We discuss the distribution and richness of the 22 odonate species known from the Socotra Archipelago UNESCO World Heritage Site (Yemen) in the western Indian Ocean. We compiled 841 records from literature, field data and museum collections, covering a surveying period of 123 years (1896–2019). Distribution of the only endemic, *Azuragrion granti* (McLachlan, 1903), an indicator of pristine lotic waters, is updated. Relatively higher dragonfly species richness occurs in eastern Socotra where suitable aquatic habitats are present all year. We observed a significant drop of the number of taxa over several decades in areas in the Hadiboh Plain where human development impacts are strongest. We discuss the indigenous people's perception of dragonflies to assess the potential of these invertebrates as local flagships for aquatic biodiversity conservation. Our knowledge of the Socotran Odonata remains incomplete, yet they are now among the best studied animal groups in the archipelago. A new record of an Oriental *Anax* indicates that the island's dragonfly fauna may yet harbour surprises. Our compilation of odonate records is the first for Socotra and serves as a baseline for future monitoring of the archipelago's vital aquatic habitats. We converted all records into a geodatabase which we uploaded to an online, freely available web mapping server and mobile application to facilitate research and conservation of the Socotran dragonflies ([www.dragonfliesofsocotra.com](http://www.dragonfliesofsocotra.com))."] (Authors)] Address: Van Damme, K., Senckenberg Res. **17731.** Vilenica, M.; Kerovec, M.; Pozojevic, I.; Mihaljevic, Z. (2021): Odonata assemblages in anthropogenically impacted lotic habitats. *Journal of Limnology* 80(1): 10 pp. (in

English) ["Increasing human pressures have a negative impact on freshwater habitats and their biota worldwide. To protect habitats and the species contained within them, ecological assessments over a gradient of near natural to degraded freshwater habitats are essential. Odonata assemblages were investigated at 46 study sites in Croatia encompassing slightly to heavily modified lowland rivers and streams. Nymphs were sampled between April and September 2016 using a benthos hand net. A total of 19 species was recorded, and *Ischnura elegans* and *Platycnemis pennipes* were most frequently recorded. RDA analysis indicated that water pollution (i.e. levels of chemical oxygen demand and total organic carbon), water temperature and oxygen concentration had the highest influence in the formation of Odonata assemblages at a specific habitat, reflecting their widely recognized bioindicator properties. This study showed that degraded lowland rivers can provide habitat for a relatively low number of species with broad ecological tolerance, while rare and specialist species are generally not able to reproduce there. These results contribute to our knowledge of Odonata occurrence in anthropogenically impacted habitats, and their relationships with such degraded environment." **17732.** Wade, A. (2021): Role of vegetated buffer zones for mitigating wetland pesticide contamination and protecting aquatic invertebrate communities in northern prairie wetlands. M.Sc. thesis, Toxicology Centre, University of Saskatchewan. XIII, 151 pp. (in English) ["Prairie Pothole Region (PPR) wetlands are unique resources that provide a number of ecosystem services. However, the majority of these wetlands have been drained or otherwise degraded due to agricultural activities. Wetlands in the PPR are frequently contaminated by agrochemicals from surrounding agriculture, which has been previously demonstrated to have negative impacts on wetland ecology. Vegetation buffers have been proven to be effective in mitigating pesticide and nutrient contamination of water bodies, but have yet to be fully researched in their efficacy in protecting PPR wetlands. Here I examined how multiple agricultural stressors impact PPR wetland health, and whether natural wetland vegetation or producer-implemented perennial plantings are effective buffers, able to mitigate some of the negative effects of agriculture to wetlands. Measurements of pesticides, nutrients, other water quality parameters, in addition to aquatic invertebrate community endpoints were used to comprehensively evaluate the health of PPR wetlands. Pesticide contamination was widespread, with 59 of the 60 wetlands sampled in 2018 and 2019 containing one or more pesticides in a single growing season. Natural wetland vegetation and the degree of its disturbance from agricultural activities did not have a significant effect on pesticide concentrations in wetlands, although this disturbance did influence the aquatic invertebrate community. Wider and less disturbed wetland vegetation zones were associated with greater macroinvertebrate richness ( $p = 0.031$ ) and greater abundance of Odonata ( $p = 0.001$ ). Aspects of water quality

were significant predictors of multiple aquatic invertebrate community indices. The occurrence of cyanobacteria blooms as well as increased total nitrogen (TN) were associated with declines in Shannon's diversity (Cyanobacteria:  $p = 0.001$  and TN:  $p = 0.016$ ) and Shannon's Evenness (Cyanobacteria:  $p = 0.002$  and TN:  $p = 0.001$ ) as well as increases in Berger-Parker Dominance (Cyanobacteria:  $p = 0.004$  and TN:  $p = 0.001$ ). The Pesticide Toxicity Index (PTIs) calculated for each wetland was associated with changes to the aquatic invertebrate community including a decline in total and relative insect abundance ( $p = 0.016$  and  $p < 0.001$ ) and an increase in relative snail abundance ( $p = 0.005$ ). Higher PTIs were also associated with a shift in relative abundance of different functional feeding groups ( $p = 0.017$ ). This PTI associated shift in taxa and functional feeding groups likely has greater implications for ecosystem function including the many wildlife species that depend on aquatic insects for food. Perennial buffers are considered an important management tool to reduce the negative impacts of agriculture on surface waters. Perennial vegetated buffers recently planted under conservation incentive programs were evaluated for their efficacy in mitigating pesticide and nutrient runoff and protecting wetland health. Wetlands that were fully surrounded by perennial buffers and/or other natural vegetation contained significantly lower concentrations of pesticides ( $p = 0.001$ ), lower PTIs ( $p < 0.001$ ), and total phosphorus ( $p = 0.005$ ). However, the presence of perennial buffers alone did not have a significant effect on pesticide or nutrient detections, and even those wetlands that were fully surrounded by perennial buffers or additional natural vegetation all contained some detectable pesticide contamination. The presence of perennial buffers was significantly associated with greater abundances of macroinvertebrates ( $p = 0.001$ ), zooplankton ( $p = 0.005$ ), and insects ( $p = 0.039$ ) which may benefit the many wildlife species that depend on wetland invertebrate productivity for food. This study establishes a framework for using wetland invertebrate communities as an integrative biomonitoring tool for assessing effects of complex agricultural stressors to PPR wetlands. The results from this study demonstrate negative effects of multiple agricultural stressors on wetland health, as measured by changes in the aquatic invertebrate community. Findings here suggest that leaving or planting wetland vegetation around PPR wetlands could increase community richness and abundance of beneficial insects, but is not sufficient for protecting wetlands from pesticide contamination. However, surrounding wetlands with perennial vegetation plantings in addition to other natural vegetation could be an effective method for reducing pesticide and nutrient contamination of wetlands and increasing the abundance and diversity of aquatic invertebrates, which are an important food source for many wildlife species. These findings may help guide producers and land managers motivated to improve wetland health and ecosystem services in prairie agricultural landscapes." (Author)] Address: not stated

**17738.** Wang, Z.; Li, B.; Luo, Q.-q.; Zhao, W. (2021): Effect of wall roughness by the bionic structure of dragonfly wing on microfluid flow and heat transfer characteristics. *International Journal of Heat and Mass Transfer* 173 July 2021, 121201: (in English) ["Highlights: • A novel of bionic rectangular microchannel (BRM) with a hydraulic diameter of 1000  $\mu$ m was designed based on the bionic wall roughness (BWR)

of dragonfly wings structure. Using k-w (SST) model on the calculation of turbulence in the microchannel are effectiveness and reliability. The existence of BWR can effectively increase the temperature and velocity fluctuation range of the fluid, and enhance the fluid disturbance and velocity, and generate a large number of regular vortex flow in a wide scope. The effects of the bionic rectangular microchannel (BRM) on flow and heat transfer is significantly better than that of the smooth rectangular microchannel (SRM), and an enhancement of 218% in heat transfer was achieved compared to a SRM, and the thermal enhancement factor is 1.34. Transition occurs when the re number range of flow in BRM is 933–1166. Abstract: In order to strengthen flow and heat transfer performance of the smooth rectangular microchannel (SRM), a novel of bionic rectangular microchannel (BRM) with a hydraulic diameter of 1000  $\mu\text{m}$  was designed based on the bionic wall roughness(BWR) of dragonfly wings structure. The effect of BWR and different microchannel lengths, and BWR with different tiny structures on flow and heat transfer was investigated, and the optimal of BWR's parameter, arrangement, combination and Re number range were studied. The results indicated that the influence of BWR on the flow and heat transfer performance is significantly better than that of SRM. When the Re is 5830, the heat transfer performance of the BRM model is 2.08 times that of SRM, and the heat enhancement factor is 1.233. Moreover, the optimal BRM's maximum velocity of the fluid is 19.6 m/s, which is 3.1 times of that of SRM, and the maximum temperature is 14.3 K lower than that of SRM, and an enhancement of 218% in heat transfer was achieved compared to a SRM, and the thermal enhancement factor is 1.34. Compared with BWR effect, the influence of the entry effect on heat transfer can be ignored, and the existence of BWR increases the number and scope of fluid disturbance and brings a large number and a wide range of high speed vortex flow appears in BRM, and they are regularly distributed after each group of BWR and the central of the microchannel, which further increases the flow velocity and disturbance, and reduces the range of low-speed and high-temperature region near the wall, and finally enhances flow and heat transfer performance." **17739.** Wendel, E. (2021): Effects of pH and conductivity on the condition and abundance of dragonfly larvae. BSc. thesis, Halmstad University, School of Business, Innovation and Sustainability: 17 pp. (in English) ["Acidification in lentic ecosystems can generate significant negative impacts for freshwater organisms. Prior research has shown that most dragonfly (Odonata) species are more tolerant against low pH than other aquatic invertebrates; however, detailed knowledge regarding autecology and physiological burdens of pH and conductivity is still scarce. In this thesis, the effects of two environmental factors on the condition (mass per unit head width) and abundance of dragonfly were researched in a series of 18 lakes in SW Sweden. Regressionary analy-

sis revealed that the larva condition of *Libellula quadrimaculata* is significantly dependent upon pH and presumably also conductivity, while no such relationship was indicated for *Cordulia aenea*. The inferior condition of *L. quadrimaculata* in acidic lakes is presumably an evolutionary adaption, whereas part of its tolerance mechanism utilises more fats and carbohydrates than protein. The data also supports the proposal that the abundance of *L. quadrimaculata* increases at lower pH, although further examination is required to conclude the suspected trend." **17741.** Abe, K.; Takahashi, D.; Hayakawa, K. (2019): Habitat use by the near-endangered dragonfly *Aeshna mixta soneharai* in reservoir ponds in Ueda, Nagano Prefecture, Japan. *Japanese Journal of Conservation Ecology* 24(2): 201-208. (in Japanese, with English summary) ["*A. mixta soneharai* mainly inhabits artificial reservoir ponds and is a natural monument protected by the regulations of Ueda, Nagano Prefecture, Japan. The habitat use of this species was investigated on the Shioda Plain, where there are many reservoir ponds. The percentage of shoreline covered by emergent water plants was higher in ponds with the dragonfly than in those without the dragonfly. In the generalised linear model, forest and apple orchard areas around the ponds positively contributed to the occurrence of this dragonfly, in addition to shoreline emergent plants. A route census at an orchard showed that *A. m. soneharai* used the orchard as habitat. These results are consistent with the reproductive ecology of the species, which uses emergent water plants as spawning sites. *A. m. soneharai* use forest habitat for sub-adult maturation. Similar to forest, sub-adult *A. m. soneharai* are likely to use orchards. This study suggests that restoration near reservoir ponds would be effective for the conservation of *A. m. soneharai*. When it is difficult to restore forest around ponds, apple orchards with economic potential might serve as an alternative habitat." **17742.** Adu, B.W.; Amusan, B.O.; Oke, T.O. (2019): Assessment of the water quality and Odonata assemblages in three waterbodies in Ilara-Mokin, south-western Nigeria. *International Journal of Odonatology* 22(2): 101-114. (in English) [„This study investigated the biological water quality and Odonata assemblages in three waterbodies in Ilara-Mokin, with the aim of determining the ecological integrity of the ecosystems. Sampling of Odonata specimens was carried out over April–August, 2017 between 9.00am and 4.00 pm under favourable conditions. Some physico-chemical

parameters of the water such as dissolved oxygen, electrical conductivity, temperature, flow rate, pH, and water depth were also investigated. A total of 41 odonate species were recorded in this study and this was represented by 29 dragonfly and 12 damselfly species. These species are contained in seven families (Macromiidae, Gomphidae, Libellulidae, Calopterygidae, Coenagrionidae, Chlorocyphidae and Platycnemididae). The seven families were recorded at Aponmu River while Omifunfun River and Isokun River accounted for six and four families respectively. However, the highest number of individuals was collected at Isokun River. Libellulidae was the dominant family. Diversity indices revealed that Aponmu river was the richest in terms of species richness, diversity and taxa distribution (Shannon: 3.18, Simpson D: 0.95, Margalef: 7.38, evenness: 7.38, equitability: 0.93). Dragonfly Biotic Index (DBI) analysis indicated that Omifunfun River represented the best habitat condition in the study area while Isokun River was considered the most perturbed sampled site in the study area. Conservative efforts should be intensified to protect Omifunfun River in order to preserve all extant aquatic biota and other available resources therein." **17743.** Agboola, O.A.; Downs, C.T.; O'Brien, G. (2019): Macroinvertebrates as indicators of ecological conditions in the rivers of KwaZulu-Natal, South Africa. *Ecological Indicators* 106, November 2019, 105465: 10 pp. (in English) ["Highlights: • Macroinvertebrate multimetric assessment of ecological health was conducted. • 38 rivers in KwaZulu-Natal (KZN) Province, South Africa were assessed. • 9 of the selected metrics had strong correlations with environmental variables. • Increasing chemical deterioration along longitudinal gradients of rivers was found. • Macroinvertebrate community metrics could detect pollution and habitat degradation Abstract: This study examined the effectiveness of macroinvertebrate community-based multimetrics to assess the ecological health of 38 rivers in KwaZulu-Natal (KZN) Province, South Africa. The study area comprised of headwater to lowland rivers determined by their hydro-morphology. Of the 40 tested metrics, only 11 core metrics were

finally selected because of their ability to distinguish between reference and impaired sites, correlation strength with environmental variables and their reliability. Nine out of the selected metrics had strong correlations with environmental variables and these were total number of taxa, total number of Diptera taxa, total number of Plecoptera individuals, percentage of Ephemeroptera Plecoptera and Trichoptera taxa, percentage of Odonata taxa, total number of Trichoptera individuals, total number of Gastropoda individuals, total number of Oligochaeta individuals and total number of Coleoptera individuals. This study showed increasing chemical deterioration along longitudinal gradients of the rivers in KZN. We found that macroinvertebrate community metrics could detect nutrient pollution, organic pollution and physical habitat degradation in the rivers of KZN. We recommend more studies and validation of macroinvertebrate community-based metrics in the assessment of rivers in KZN, because they are relatively cheap and easy to use. The use of macroinvertebrate community metrics could be an effective alternative assessment method in the case of the lowland rivers where the lack of quality data often has negative impacts on the use of the biotic indices (South African Scoring System (SASS), Average Score Per Taxon (ASPT) and Macroinvertebrate Response Assessment Index (MIRAI))." **17745.** Allgeier, S.; Friedrich, A.; Brühl, C.A. (2019): Mosquito

control based on *Bacillus thuringiensis israelensis* (Bti) interrupts artificial wetland food chains. Science of The Total Environment 686: 1173-1184. (in English) ["Highlights: • Chironomidae are the non-target aquatic invertebrates most affected by Bti. • Development of newt larvae was indirectly affected in Bti treated food chains. • *Aeshna cyanea* decreased newt survival by 27% when Bti was applied. • Larval chironomids are a key component in the diet of aquatic predators. Abstract: The biocide *Bacillus thuringiensis israelensis* (Bti) has become the most commonly used larvicide to control mosquitoes in seasonal wetlands. Although Bti is considered non-toxic to most aquatic organisms, the non-biting chironomids show high susceptibilities towards Bti. As chironomids are a key element in wetland food webs, major declines in their abundance could lead to indirect effects that may be passed through aquatic and terrestrial food chains. We conducted two mesocosm experiments to address this hypothesis by assessing direct and indirect effects of Bti-modified availability of macroinvertebrate and zooplankton food resources on the predatory larvae of palmate and smooth newts (*Lissotriton helveticus*, *Lissotriton vulgaris*). We examined newt survival rates and dietary composition by means of stable isotope ( $\delta^{15}\text{N}$  and  $\delta^{13}\text{C}$ ) analysis in the presence of Bti treatment and a predator (*A. cyanea*). We assessed palmate newts' body size at and time to metamorphosis while developing in Bti treated mesocosms. Chironomid larvae were the most severely affected aquatic invertebrates in all Bti treated food chains and experienced abundance reductions by 50 to 87%. Moreover, stable isotope analysis revealed that chironomids were preferred over other invertebrates and comprised the major part in newts' diet (56%) regardless of their availability. The dragonfly *A. cyanea* decreased survival of newt larvae by 27% in Bti treated mesocosms showing affected chironomid abundances. Increasing intraguild predation is most likely favored by the Bti-induced reduction of alternative prey such as chironomid larvae. The decreased food availability after Bti treatment led to slightly smaller *L. helveticus* metamorphs while their developmental time was not affected. Our findings highlight the crucial role of chironomids in the food webs of freshwater ecosystems. We are also emphasizing the importance of reconsidering human-induced indirect effects of mosquito control on valuable wetland ecosystems particularly in the context of worldwide amphibian and insect declines." **17746.** Aydin, D.D. (2019): Diyarbakir ili Odonata faunasi. MSc thesis, Dicle Üniversitesi, Fen Bilimleri Enstitüsü: 50 pp. (in Turkish, with English summary) ["In this study, 261 Odonata samples were collected in May, June, July and August 2017 surveys in Diyarbakir (Baglar, Kayapinar, Sur and Yenisehir). Among these samples, it was determined that they belong to 3 families, 5 genera and 7 species group taxa. The species and distribution areas of the Odonata order were investigated. The study was conducted in 2017 in

Diyarbakir. In the spring and summer, field studies were carried out once a week. As a result of the study, 7 species belonging to 3 families belonging to Odonata order were identified. *Brachythemis fuscopalliata*, *Crocothemis erythraea*, *Orthetrum albistylum*, *O. brunneum*, *O. coerulescens*, *Platynemis dealbata* and *Ischnura elegans*. These species identified in the study are the first records for the Diyarbakir insect fauna." (Author)] Address: not stated

**17747.** Barmiento, S.H.; Vriend, L.M.; van Grunsven, R.H. A.; Vijver, M.G. (2019): Environmental levels of neonicotinoids reduce prey consumption, mobility and emergence of the damselfly *Ischnura elegans*. *Journal of Applied Ecology* 56: 2034-2044. (in English) ["1. Freshwaters are among the most endangered ecosystems in the world as a result of anthropogenic interference such as pollution. Pollution in the form of neonicotinoids has been intensively studied, but data thus far is often conflicted by contrasting responses between laboratory and field experiments. In addition, toxicity data are scarce and contradictory for insects such as odonates and a potential risk to them may therefore be overlooked. 2. We investigate the potential risk of neonicotinoids to odonates by exposing nymphs of *I. elegans* to environmentally relevant concentrations of the neonicotinoid thiacloprid. We consider *I. elegans* as an indicator species for other Odonates as it is an abundant, widespread and eurytopic species. We analyse the effects of thiacloprid on multiple endpoints (survival, consumption, growth, molting, mobility and emergence), using cage-experiments as well as controlled field observations in naturally colonized experimental ditches. In addition, we assess sensitivity by either feeding the damselfly nymphs with lab-cultured prey or by letting them feed freely on natural aquatic invertebrates. 3. All sublethal endpoints of *I. elegans* are affected to some degree, and strongly depend on the food offered; free-feeding nymphs are more sensitive than culturefed nymphs. Environmental relevant concentrations of thiacloprid strongly reduce the emergence of *I. elegans* and this effect is more substantial in the natural populations compared to the caged damselflies. This is likely explained by exclusion of additional biotic pressures such as predation in the caged experiment. 4. Policy implications. Literature reports that one out of seven Odonates is threatened and 24% of the species have declining populations. Our observations show that current risks of neonicotinoids to Odonates are underestimated in laboratory experiments as the toxicity is governed by multiple biotic factors such as food quantity/quality and predation. Given the widespread abundance of *I. elegans*, the observed sensitivity to neonicotinoids and current population trends of this species, these results indicate neonicotinoids play a central role in the Odonate decline in general .... Conclusions: Clear effects of environmentally relevant concentrations of the neonicotinoid thiacloprid on the life cycle of *I. elegans* were shown. While no direct effects on mortality were observed at environmental relevant concentrations, all sublethal endpoints tested were affected. Our results strongly depended on the food offered, which indicates that current laboratory assessments performed at ad libitum food underestimate neonicotinoid toxicity in the actual environment. In addition,

it appears that even our realistic exposure scenario using caged individuals in experimental ditches also underestimate toxicity as the emergence of natural populations was more strongly affected. This is likely because biotic pressures such as predation add to toxicity and these pressures are not included within the caged experiment nor the common laboratory approaches. Finally, our observed reduced fitness during the nymph stage and the strong decline in natural emergence can be indicative for neonicotinoids adding to the ongoing *I. elegans* decline." **17748.** Basha, M. (2019): Microbial communities associated with dragonfly nymphs raised in varying concentrations of Amoxicillin. Undergraduate thesis, under the direction of Colin Jackson from Biological Sciences, The University of Mississippi: 27 pp. (in English) ["The bacteria on and within an organism make up that organism's microbiome. Given interest in the use of antibiotics in agriculture and the effect of microbes on human health, more studies are needed on the microbial community composition of different organisms and how it responds to antibiotic use. This study investigated changes in the amount of antibiotic resistant bacteria present in [the not identified] dragonfly nymphs exposed to differing concentrations of amoxicillin. Next generation sequencing of the 16S rRNA gene was used to identify cultures of these antibiotic resistant bacteria. Increasing the concentration of antibiotics the dragonfly nymphs were exposed to resulted in greater numbers of antibiotic resistant bacteria. From both amoxicillin + TSA and TSA-only plates, Proteobacteria was the most abundant phyla detected. Bacteroidetes was the major phyla detected in nymphs raised in 0% amoxicillin and plated on amoxicillin + TSA plates. There was a high relative proportion of members of the phylum Firmicutes in all samples plated on TSA plates. In the nymphs raised in 0% amoxicillin plated on TSA plates, members of Firmicutes made up the majority of their microbiome. This study demonstrates that the bacterial communities associated with dragonfly nymphs are affected by changes in the environment, and that exposure to antibiotic pollution likely increases the number of antibiotic resistant bacteria within aquatic insects." **17749.** Bechly, G. (2019): New fossil Odonata from the Upper Jurassic of Bavaria with a new fossil calibration point for Zygoptera. *Palaeoentomology* 2(6): 618-632. (in English) ["Three new taxa of odonates are described from the Upper Jurassic Solnhofen limestone from Eichstätt and Painten in Bavaria (Germany), including the first two genuine Zygoptera (*Andrephlebia buergeri* gen. et sp. nov. in fam. inc. sed. and *Jurahemiphlebia haeckeli* gen. et sp. nov. in Hemiphlebiidae) and a new taxon of Stenophlebiptera (*Reschiostenophlebia koschnyi* gen. et sp. nov. in Stenophlebiidae). With an age of about 152 million years, the holotype of *Jurahemiphlebia* from the Painten locality represents the oldest fossil record and thus a new calibration point for crown group Zygoptera, Lestoidea, and Hemiphlebiidae, and the oldest record for any living odonate family. Furthermore, the first relatively complete

specimen of the dragonfly *Prohemeroscopus kuehnapefeli* (Prohemeroscopidae) is described, which was previously known only from a pair of isolated hind wings. A revised diagnosis is provided for the species and genus." (Author)] Address: Bechly, G., Biol. Inst., 16310 NE 80th Street, Redmond, WA 98052, USA. E-mail: gbechly@biologicinstitute.org

**17750.** Black, K.L.; Fudge, D.; Jarvis, W.M.C.; Robinson, B.W. (2019): Functional plasticity in lamellar autotomy by larval damselflies in response to predatory larval dragonfly cues. *Evolutionary Ecology* 33(2): 257-272. (in English) ["Adaptive autotomy is the self-amputation of an appendage in response to external stimuli that benefits survival. Variation in the ease of appendage removal among populations suggests that autotomy performance is under selection, evolves, or is phenotypically plastic, although the latter has never been experimentally tested. We model an autotomy threshold that optimally balances how the benefits of surviving predator attack versus the costs of losing an appendage vary with predator presence. We test for functional plasticity in autotomy threshold in the caudal lamellae of *Enallagma damselfly* larvae [*E. ebrium* / *E. hageni* species-pair] by experimentally manipulating non-lethal cues from predatory dragonfly larvae. Predator cues lead to functional plastic responses in the form of smaller lamellar joints that required lower peak breaking force. This is the first experimental demonstration of functional plasticity in autotomy to cues from a grasping predator, a novel form of indirect predator effects on prey, realized through plasticity in morphological traits that govern the autotomy threshold. This supports the model of optimized autotomy performance and provides a novel explanation for variation in performance among populations under different predator conditions. Plastic autotomy responses that mitigate costs in the face of variation in mortality risks might be a form of inducible defense." **17754.** Brown, T.A.; Fraker, M.E.; Ludsin, S.A. (2019): Space use of predatory larval dragonflies and tadpole prey in response to chemical cues of predation. *The American Midland Naturalist* 181(1): 53-63. (in English) ["Chemical cues are frequently a key source of information to aquatic organisms. Both predators (kairomones digestive metabolites) and prey (alarm and damage-released cues) may generate chemical cues during their interactions, and different cue types can have different informational values. How predators and prey use the information from chemical cues to make spatial movement decisions influences both their direct interaction rates and their interactions with other species. We measured the spatial response of predatory larval *Anax junius* and predator-naive green frog (*Lithobates clamitans*) tadpoles exposed to several types of chemical cues using experimental mesocosms. We found tadpoles only responded with spatial avoidance when exposed to both *Anax* kairomones and conspecific alarm cues together, whereas *Anax* did not exhibit consistent spatial responses to any cue type. Our results suggest tadpole prey selectively respond

to environmental information from chemical cues (possibly to minimize costly antipredator behavior due to responding to insufficient information or reflecting a need for associative learning). They also show predatory dragonflies may use non-chemical information to make space use decisions (possibly due to inability to detect the same chemical cues as tadpoles)." **17756.** Buczynski, P.; Kusal, K.; Tonczyk, G.; Mikołajczuk, P.; Bobrek, M.; Bobrek, R.; Czechowski, P.; Długosz, I.; Długosz, M.; Dubicka, A.; Dumnicka, E.; Goc, M.; Golab, M.J.; Goral, N.; Hadwiczak, M.; Holnicki-Szulc, F.; Jedro, G.; Jirak-Leszczynska, A.; Kusal, B.; Milaczewska, E.; Miszta, A.; Morawski, M.; Raczynski, M.; Snigula, S.; Switala, M.; Tarkowski, A.; Sylwia Woniak, S. (2019): Dragonflies (Odonata) recorded in the Niepolomice Forest and in the valley of the River Raba during the 16th Symposium of the Odonatological Section of the Polish Entomological Society (June 20-23, 2019). *Odonatrix* 15\_8 (2019): 16 pp. (Polish, with English summary) ["The Niepolomice Forest is the largest forest complex in the vicinity of Kraków. However, knowledge of its fauna is very incomplete and very out of date. This area was visited in late June 2019 during field sessions of the 16th National Odonatological Symposium of the Polish Entomological Society. 39 odonate spp. were recorded, including *Leucorrhinia albifrons* for the first time in the Province of Małopolska. This species richness is a function mainly of the natural and semi-natural habitats in the river valleys at the edge of the forest and of the anthropogenic water bodies in its interior (mainly fire protection ponds). Considering the location of the Niepolomice Forest and the diversity of its habitats, one can expect at least 50 spp. to occur here. Although these results are preliminary, they do permit an assessment of the condition of the habitats. The most valuable of the sites researched were the dystrophic Czarny Staw (Black Pond) in the centre of the

forest and the adjacent peat bog. The tyrphophiles *Leucorrhinia pectoralis* and *L. rubicunda* were not found, although historical data indicate that they were present in the Niepolomice Forest 90-100 years ago; their non-discovery in 2019 may have been due to this research period being quite short and too late in the season. A short reconnaissance in the nearby valley of the River Raba yielded 18 species. Comparison of these data with data from the 1970s indicates that its fauna has changed: thermophilic spp. have appeared while some spp. typical of small permanent water bodies have probably disappeared." **17757.** Byrne, A. (2019): Constructing the global Irish woman traveller: Cynthia Longfield's scientific researches in South America, 1921-27. *ABEI Journal - The Brazilian Journal of Irish Studies* 21(2): 27-36. (in English) ["Irish-born Cynthia Longfield (1896-1991) became a leading entomologist after participating in three expeditions to South America in the 1920s. Working unpaid in the British Museum for 30 years, she catalogued Odonata (dragonflies and damselflies) from all over the world, published scientific papers, and collaborated with British, Irish and international scientists. While she made several other collecting expeditions to Africa and South-East Asia in the 1920s and 1930s, her early experiences of South American natural history are a crucial aspect of her formation as an internationally renowned scientist, and are an interesting chapter in the long history of Irish connections with the region. She was a migrant, a traveller, and a scientist, and was a person at once privileged by her class and denied basic equalities due to her gender. This article firstly considers her scientific career in the context of Irish women's migration in the first half of the twentieth century, before focusing on her three voyages to South America in 1921-7 and, finally, examining the ways in which her participation in the St George expedition— as one of just three women aboard ship – was reported in the Anglophone press." **17758.** Chelli, A.M.; Moulai, R. (2019): Diversity and ecological diagnosis of dragonflies of high-mountain temporary ponds in the Akfadou massif forest (Algeria). *Zoology and Ecology* 29(1). 10 pp. (in English) ["An Odonata study was carried out during six successive months at five high-mountain temporary ponds located in the Akfadou massif forest, northeast Algeria. These wetlands are virtually unexplored; some of these places are unknown to the general public. However, some of them appear to face numerous threats. The results obtained by this study gave us an idea of the odonatological settlement in this area. With 18 species of Odonata, this territory contains about 1/3 of the Algerian Odonata fauna, of which nine species reproduce in this forest massif. These study stations share in common three species, namely: *Ischnura graellsii*, *Anax imperator*, and *Orthetrum cancellatum*. These three species are omnipresent in more than 75% of the surveys and are distributed in a consistent way in various biotopes. The first species (*I. graellsii*)

together with *Lestes virens* and *Chalcolestes viridis* dominate in numbers, accounting for more than half of the total numbers recorded. The Shannon-Weaver index and Equitability index applied to odonatological fauna reveal that Agoulmime Ikher (AI) and Agoulmime Tala Guizane (AT) ponds are the best-structured and most stable in terms of stands in this massif." **17760.** Córdoba-Aguilar, A.; Rocha-Ortega, M. (2019): Damselfly (Odonata: Calopterygidae) population decline in an urbanizing watershed. *Journal of Insect Science* 19(3), 30. 6 pp. (In English) ["Reduction of terrestrial vegetation and degradation of water quality are among the factors driving insect population decline in growing cities. In this study, we investigated the extent of habitat deterioration, behavioral and physiological responses, and fitness of a *Hetaerina americana* population in a semitropical region in central Mexico. The study population was located in a riverine area that crosses a small urban area (Tehuixtla city). We related two habitat variables (tree/shrub covered area and numbers of wastewater outlets) to presumable damselfly responses (larval and adult abundance, duration of adults exposed directly to sunlight, lipid content and muscle mass, and egg survival) over the years 2002 and 2016. We detected a reduction in terrestrial vegetation cover, an increase in wastewater outlets, and a decrease in larval and adult abundance. Adults were more exposed to sunlight in 2016 than in 2002 and showed a reduced lipid content and muscle mass in 2016. Egg survival also decreased. Although correlative,

these results suggest impairment of damselfly condition (via lipid and muscle reduction) and fitness as urbanization increases." **17761.** Corso, A. (2019): Morphological variability of *Cordulegaster trinacriae* in Italy (Odonata: Cordulegasteridae). *Odonatologica* 48(3/4): 175-201. (in English) ["This paper describes the most helpful features for field identification of *C. trinacriae* and the relevant morphological variability encountered. In *C. trinacriae* the yellow frons was without a dark horizontal marking in about 70 % of the sample or showed a barely patterned frons, while the remaining 30 % showed a more or less defined dark smudge, though always narrower and less bold than in *C. boltonii*. The percentage of unmarked versus marked frons was similar throughout the distributional range of *C. trinacriae* except in Sicily, where the unmarked yellow frons was much more common (87 %) and in Campania, where individuals with a dark mark on the frons were slightly more common than unmarked ones. In *C. trinacriae* the occipital triangle was almost always yellow with no or almost no dark markings, cleaner, and purer yellow than in *C. boltonii* from central Italy. The appendages of *C. trinacriae* always showed the characteristic form except for a few individuals, which might be hybrids. In *C. boltonii* they were found to be rather variable, especially on individuals from the southern part of its distributional range in central Italy, where intermediates and hybrids occur. Here, the appendages were sometimes similar (but not identical) to *C. trinacriae*, and therefore, this character is considered of limited use in the field. Individuals of *C. trinacriae* can be distinguished in areas of sympatry from intermediate *C. boltonii* and from hybrids when they show the following characters: i) unmarked yellow frons; ii) bright yellow, almost unmarked occipital triangle; ii) typical deeply notched lower appendages and long, sinuous upper appendages." (2019): Seasonal changes in relative contribution of environmental control and spatial structuring on different dispersal groups of stream macroinvertebrates. *Hydrobiologia* 828: 101-115. (in English) ["The role of environmental control and spatial structuring may vary depending on dispersal mode within a metacommunity in stream systems. However, as a result of high seasonal variation in environment conditions and phenological features, there might be considerable seasonal changes in the relative importance of structuring factors. The objective of this study was (i) to determine the relative role of structuring factors for aquatic macroinvertebrates with different dispersal mode groups which have seasonal variation in their dispersal capacity and (ii) to disentangle seasonal changes in metacommunity structuring. We sampled 50

stream sites of the Middle Danube Basin (Hungary) in spring and summer. We compared Distance–Decay Relationships between communities of different dispersal groups (including Odonata) and distance measures, and then we used variation partitioning analysis and Moran's eigenvector maps based on overland and watercourse distances to reveal structuring processes in both seasons. We found that metacommunities of all dispersal groups were influenced in both seasons mainly by environmental factors with additional impacts of the spatial components. Our findings suggest that metacommunities of taxa with temporally stable dispersal capacity have seasonally stable structuring processes, while the relative importance of structuring factors can vary seasonally in groups with seasonally changing dispersal capacity." **17765.** Deacon, C.; Samways, M.J.; Pryke, J.S. (2019): Aquatic insects decline in abundance and occupy low-quality artificial habitats to survive hydrological droughts. *Freshwater Biology* 64(9): 1643-1654. (in English) ["1. Hydrological extremes have negative impacts on natural, agricultural, and urban landscapes and place substantial ecological pressure on freshwater habitats. However, the role of artificial freshwater habitats during hydrological drought is poorly understood. Insects make up much of total aquatic fauna (including Odonata) and lend themselves to understanding how drought impacts freshwater ecosystems. 2. Using the Greater Cape Floristic Region as an example of a drought-prone area, we determined the effects of a severe drought on a subset of insects occupying lentic habitats in terms of their species richness, diversity, and assemblage composition. Here, we: (1) calculated the percentage change in average precipitation between a record dry season and the last consistently wet decade; (2) identified the environmental variables driving aquatic insect species richness, diversity and composition; (3) identified the environmental differences between natural ponds and artificial reservoirs; (4) determined whether artificial reservoirs act as suitable habitats for focal taxa during drought; and (5) compared these results to other, pre-drought studies. 3. Environmental variables related to water chemistry and physical characteristics were drivers of species richness, diversity, and composition, yet vegetation cover remained a major driver. In terms of marginal vegetation cover, most artificial reservoirs did not resemble natural ponds, yet overall 38.4% of sampled aquatic insect species were shared between natural ponds and artificial reservoirs. We found some rare endemic species in artificial reservoirs that had never before been recorded in this habitat during wet years. When our drought findings were compared to earlier, wet years, species richness did not change significantly, although abundance was much lower during the drought year. 4. We postulate that historically, these aquatic insects, which have been through many ecological filters such as drought, must have sought low-quality habitats to survive water stress periods. Artificial reservoirs, being novel landscape features, cannot fully replace natural ponds, but enable some aquatic insects to survive drought. Artificial reservoirs can be attractive habitats to aquatic insects when they resemble natural ponds, with specific reference to their marginal vegetation characteristics." **17766.** Dehane, H. (2019): Contribution à l'étude de l'inventaire des Odonates à Oued Djedi (Biskra). Mém. de Master, Univ. de Biskra: 53 pp. (in French, with Arabian and English summaries) ["The study of the number and distribution of Odonate gives us an important idea of the health and vitality of its environmental system. In this work we studied the dragonflies in Oued Djedi which passed from Sidi Khaled to the State of Biskra for a period of 9 months (from September 2018 to May 2019). We collected 7 species of dragonflies, including 7 Anisoptera. We have also studied the phenology of these species with a comparison with the model of Samraoui and Corbet (2000). And we did a study on their ecology (life cycle, flight period and reproduction). A comparison of our results with other studies carried out in different regions with different climates (different bioclimatic stages: humid, semihumid, semi-arid, arid and Saharan) shows the influence of climate on the distribution of Odonata species (low specific richness in our region of study)."] (Author) *Anax ephippiger*, *A. imperator*, *Orthetrum chrysostigma*, *Crocothemis erythraea*, *Sympetrum fonscolombii*, *Trithemis annulata*, *T. kirbyi*] Address: not stated

**17767.** Delnat, V.; Tran, T.T.; Janssens, L.; Stoks, R. (2019): Daily temperature variation magnifies the toxicity of a mixture consisting of a chemical pesticide and a biopesticide in a vector mosquito? *Science of The Total Environment* 659: 33-40. (in English) ["Highlights: •The influence of temperature on the toxicity of mixtures has largely been ignored. •Mosquitoes were exposed to two pesticides under daily temperature variation (DTV). •DTV did not increase the toxicity of the single pesticides. •DTV increased the toxicity of the pesticide mixture. •DTV is omnipresent in nature, hence important for risk assessment of mixtures. Abstract: While many studies on the toxicity of pesticides looked at the effects of a higher mean temperature, effects of the realistic scenario of daily temperature variation are understudied. Moreover, despite the increasing interest for the toxicity of pesticide mixtures how this is influenced by temperature has been largely ignored. We tested whether daily temperature variation (DTV) magnifies the toxicity of two pesticides with a different mode of action, the organophosphate pesticide chlorpyrifos (CPF) and the biopesticide *Bacillus thuringiensis* var. *israelensis* (Bti), and of their mixture in the vector mosquito *Culex pipiens*. Single exposure to CPF and Bti increased mortality and reduced female development time, and exposure to CPF also increased female wing length. DTV was not lethal and did not change the toxicity of the individual pesticides. Yet, a key novel finding was that high DTV increased the mortality of the mixture by changing the interaction between both pesticides from additive to synergistic. Given that in nature daily temperature variation is omnipresent, this is important both for vector control and for ecological risk assessment. The higher toxicity of the mixture at high DTV compared to the typically used constant test temperatures in the laboratory urges caution when evaluating the environmental impact of pesticide mixtures."] (Authors)] Address: Stoks, R., Lab. voor Aquatische Ecol., K.U.Leuven, De Beriotstraat 32, 3000 Leuven, Belgium. **17768.** Delpon, G.; Vogt-Schilb, H.; Munoz, F.; Richard, F.; Schatz, B. (2019): Diachronic variations in the distribution of butterflies and dragonflies linked to recent habitat changes in Western Europe. *Insect Conservation and Diversity* 12(1): 49-68. (in English) ["1. In the context of ongoing global changes, it is crucial to characterise and understand the species distribution dynamics. Despite increasing emphasis on insects' conservation issues, evidence of distribution changes in insects over a wide range of bioclimatic conditions remains scarce in Western Europe. 2. We examined distribution changes in butterflies and dragonflies in three European countries over 34 years, determined the influence of environmental changes, especially land cover, and assessed how of species ecology related to distinct responses. We analysed the diachronic variations by compiling occurrence data in France, Belgium, and Luxembourg for 240 butterfly and 95 dragonfly taxa. 3. We found contrasting patterns of diachronic variation in butterfly and dragonfly distributions, i.e. a strong gradient of disappearance for butterflies (from northwest to southeast with significantly higher rate of disappearance in urbanised and intensive agriculture areas of north-western France), whereas dragonflies showed lower and heterogeneous variation in occurrences, mainly related to alteration and regression of aquatic habitats. 4. Species responses appeared closely linked to their ecological preferences, with greater decline in habitat specialist species. Butterfly and dragonfly species are constrained by their dependence to host plant species and to aquatic habitats, respectively, and proved to convey complementary insights on the influence of environmental changes in biodiversity dynamics. 5. Conservation priorities were identified across species and administrative units, revealing that almost 80% of the declining taxa were not listed on the current protection lists. Our results support the need to update current French policies in terms of insect conservation."] (Authors)] Address: Schatz, B., Centre d'Ecol. Un site urbain enclavé d'une richesse odonatologique exceptionnelle, 1-22. *Les Naturalistes belges* 100(3): 1-22. (in French, with English summary) ["The site of the former Schaerbeek-Josaphat railway station, locally referred to as friche Josaphat, is a post-industrial wasteland enclosed within the urban fabric of north-eastern Brussels. The inventories that have been conducted there for the last seven years reveal the exceptional richness of its dragonfly fauna. The factors of this richness are the juxtaposition of extensive feeding grounds harbouring a very diverse flora and entomofauna, and small aquatic environments particularly favourable to reproduction, as well as the location of the site in a plain which historically represented a migration and dispersal route for many organisms. Alteration of the site, and in particular a reduction in the area and the continuity of the feeding grounds, would make it lose its high biological, recreational and educational value. Preserved, the site has an

exceptional capacity to fulfill a number of complementary functions, essential for the promotion of the natural heritage in the city of tomorrow, haven of biodiversity, support of leisure activities, teaching and research facility." (2019): Ecological factors and the distribution of adult Odonata in Puerto Rico. *Life: The Excitement of Biology* 7(3): 115-147. (in English) ["Puerto Rico's dragonfly and damselfly (Odonata) fauna, while abundant and diverse, is not well known, with the most recent surveys being over 80 years old. This work reports on sampling conducted on the island between late 2015 and early 2017. A total of 1,754 specimens in 19 genera and 30 species were collected, representing 61.2% of the species reported for the island. The number of individuals, number of genera, and number of species were higher on sites with a mean annual precipitation between 1300 mm and 1900 mm and a mean maximum annual temperature between 28.51°C and 32.50°C. Similarly, the number of individuals, number of genera, and number of species were higher on the woodland and shrubland cover types than on any of the other cover types. While some inferences can be made from our data, an increased collection effort in less sampled areas is necessary." **17771.** Do, Y.; Choi, M.B. (2019): Identifying adult dragonfly prey items using DNA barcoding and stable isotope analysis. *Entomological Research* 49(4): 165-171. (in English) ["Using DNA barcoding and stable isotope analysis, we identified adult dragonfly prey items from the fecal pellets of five dragonfly species — *Nannophya pygmaea*, *Ischnura asiatica*, *Sympetrum eroticum*, *Orthetrum albistylum*, and *Anax parthenope* — collected from a mountain bog located in south-eastern South Korea. Twelve operational taxonomic units (OTUs) belonging to four orders, Coleoptera, Diptera, Hemiptera, and Lepidoptera, were identified as prey items of adult dragonflies using DNA barcoding. Among prey items, Dipterans were the most common, comprising seven of the 10 OTUs. Based on stable isotope analysis, adult dragonflies and their nymphs were among the most numerous predators in both aquatic and terrestrial habitats. Additionally, dragonfly species with smaller adult sizes had different isotopic compositions to those reaching larger adult sizes. Both  $\delta^{15}\text{N}$  and  $\delta^{13}\text{C}$  values were significantly lower in smaller species than in larger species, indicating differences in their trophic levels and carbon sources." **17772.** Drury, J.P.; Anderson, C.N.; Cabezas Castillo, M.B.; Fisher, J.; McEachin, S.; Grether, G.F. (2019): A general explanation for the persistence of reproductive interference.

*The American Naturalist* 194(2): 268-275. (in English) ["Reproductive interference is widespread, despite the theoretical expectation that it should be eliminated by reproductive character displacement (RCD). A possible explanation is that females of sympatric species are too similar phenotypically for males to distinguish between them, resulting in a type of evolutionary dilemma or catch-22 in which reproductive interference persists because male mate recognition (MR) cannot evolve until female phenotypes diverge further, and vice versa. Here we illustrate and test this hypothesis with data on *Hetaerina* spp.. First, reproductive isolation owing to male MR breaks down with increasing interspecific similarity in female phenotypes. Second, comparing allopatric and sympatric populations yielded no evidence for RCD, suggesting that parallel divergence in female coloration and male MR in allopatry determines the level of reproductive isolation on secondary contact. Whenever reproductive isolation depends on male MR and females of sympatric species are phenotypically similar, the evolutionary catch-22 hypothesis offers an explanation for the persistence of reproductive interference." **17773.** Encinias, M. (2019): Reproductive character displacement in *Calopteryx aequabilis* and *C. maculata*: Improving species recognition through the divergence of male mating preferences. MSc. thesis, Department of Biology, James Madison University. VI + 25 pp. (in English) ["An ongoing evolutionary question is how co-occurring species maintain reproductive barriers when they are morphologically, behaviorally, and ecologically similar. Without geographic isolation, traits involved in species recognition may be under selection to enhance reproductive barriers. Exaggerated trait differences between species in sympatric populations may reflect selection to reduce misdirected mating between species, or reproductive character displacement. While this phenomenon is widely recognized as an important stage in the speciation process, there is little direct evidence of this process in nature. In two North American damselfly species, *Calopteryx aequabilis* and *C. maculata*, wing pigmentation is sexually dimorphic and also shows exaggerated differences in sympatric populations, particularly in female wings. When these species occur together, they occupy the same mating territories and the potential for misdirected mating is high. I hypothesize that female wing pigmentation is under selection for species recognition. In this study, I conducted male mate choice experiments in which I altered female wings by switching them within and between species. I measured male mating preference of both species in allopatric and sympatric populations by giving males a choice of two female types in a natural setting. Results supported the hypothesis that male preferences in sympatry diverge corresponding to female wing pigmentation. Sympatric *C. aequabilis* males preferred lighter-winged females, which significantly differed from the dark wing preferences of *C. maculata* males and allopatric *C. aequabilis* males. By manipulating the female wing pigmentation directly, I identified that this is the specific trait under selection. These findings

indicate that male mating preferences and female wing pigmentation diverged in sympatry to reduce misdirected mating of two closely related species." (Author)] Address: not stated

**17774.** Favret, C.; Normandin, E.; Cloutier, L. (2019): The Ouellet-Robert Entomological Collection: new electronic resources and perspectives. *The Canadian Entomologist* 151(4): 423-431. ["The Ouellet-Robert Entomological Collection (Université de Montréal, Montréal, Québec, Canada) is one of the largest and most important university collections in Canada. Although officially dedicated in 1984, much of the material in the collection dates to the 1930s and 1940s work of the Clerics of Saint Viator, Joseph Ouellet and Adrien Robert. In order to establish curatorial priorities, a collection profile was conducted grading eight criteria on a scale of 1–4, the most important being the conservation status of the specimens. A taxonomic inventory of the collection was also conducted, including the number of pinned specimens and alcohol vials, as well as a brief geographic description: whether or not at least one specimen of each species was collected in Québec or in North America. Finally, the specimen metadata for Odonata, Ephemeroptera, and Trichoptera were digitised. The inventory and specimen data can be downloaded at [Canadensys.net](http://Canadensys.net). The collection houses approximately 1.5 million specimens, of which one-third are pinned, representing 20 000 species. Half of those species are recorded from Québec. The inventory and profile will be updated and the specimen database grown as portions of the collection are re-curated by personnel and volunteers, including the student-run organisation, "Club QMOR"."] (Authors)] Address: Favret, C.: E-mail: [ColinFavret@AphidNet.org](mailto:ColinFavret@AphidNet.org)

**17775.** Feindt, W. (2019): Conservation genomics: speciation of the Neotropical damselfly species *Megaloprepus caerulatus* – as a model for insect speciation in tropical rainforests. PhD thesis, Naturwissenschaftliche Fakultät der Gottfried Wilhelm Leibniz Universität Hannover: 270 pp. (in English, with German summary) ["The Neotropics are the most diverse ecoregion on earth. This remarkable biological diversity is associated with a great variety of speciation events through a complex geological history and habitat structure. Unfortunately, current changes to climate and habitat are erasing species at shocking rates. Consequently, modern evolutionary and ecological research must combine basic scientific research with state-of-the-art conservation genetics. In evolutionary biology, the study of speciation processes and how phenotypic novelties arise is of central interest. To approach this task in flying insects, the world's largest living odonate species, *Megaloprepus caerulatus* (Odonata: Zygoptera, Pseudostigmatidae) is an excellent model organism. *Megaloprepus caerulatus*, which is the only representative of its genus, has a wide distributional range, from Mexico to Peru, but a narrow and conserved ecological niche. As a forest specialist *Megaloprepus* is dependent on intact old growth rain forests and water filled tree holes to maintain stable but small population sizes. In the last 150 years' speciation processes in this genus were often under

discussion. Because of small but regionally restricted morphological differences, the narrow ecological niche and the continuous conversion of the Neotropical ecoregion over time, speciation seems probable. The central focus of this thesis is to study the effects of paleogeography and ecological changes over time on speciation and phenotypic changes in *Megaloprepus*. Therefore, the population genetic structures and species boundaries are studied, and new insights into RNA-Sequencing (RNA-Seq) are presented as a foundation for large-scale comparative studies. A first study uses two mitochondrial sequence markers and a panel of microsatellites to investigate the population genetic structure of four *Megaloprepus* populations ranging from Mexico to Panama. The results showed relatively low genetic diversity within populations, but a strong differentiation among populations, supporting a speciation hypothesis. A comprehensive biogeographic study followed to falsify or verify this hypothesis. Samples from 11 museum collections and newly collected material across 14 populations from Mexico to Peru were analyzed simultaneously by applying phylogenetics, population genetics, species distribution models, niche comparisons and morphometrics. The results unambiguously proved the speciation hypothesis and revealed that the genus *Megaloprepus* consists of four species. Hereby the estimated diversification times suggest that the species splits were associated with the Andean uplift (10-8 Mya) and migration events following the closure of the Isthmus of Panama (3-2 Mya). The current distribution ranges of the four *Megaloprepus* species are restricted and can be explained by Pleistocene climatic variations as well as by today habitat structure. Even more interesting is the underlying mode of speciation. A strong niche similarity indicates phylogenetic niche conservatism and consequently sets the speciation mode to 'non-adaptive'. However, currently observable divergence in wing patterns is an evolutionary novelty, which are most likely related to the environment but now under sexual selection. The final species description covers all four species, including wing coloration patterns, and variation of shape in the male secondary sexual organs and the prothorax. In a first attempt to approach the great variety of speciation patterns among odonates and to reveal the significantly different radiation patterns of the two sister genera *Megaloprepus* (4 species) and *Mecistogaster* (8 species), three mitochondrial genomes were generated as a valuable resource for future speciation and phylogenetic studies. Hereby, the focus will be on the genes involved oxidative phosphorylation. These results are a solid prerequisite to study speciation, the evolution of taxonomic/genomic key characters and radiation patterns within the family of the Pseudostigmatidae in detail. RNA-Seq is the method of choice for studying ecologically important organisms that lack genomic resources. Consequently, the transcriptome of a single larval thorax is presented. This transcriptome has a high level of completeness (93%) and provides the first reported wing gene sequences for odonates and supplies a valuable resource for future studies on wing coloration and wing development. Furthermore, because RNA-Seq is a frequently used method and for publication it is obligatory to upload raw reads to a public database, a submission guideline for

this process was developed. This guideline includes two all-inclusive protocols explaining all necessary steps to upload data to the National Center for Biotechnology Information (NCBI). RNA-Seq has already revolutionized the understanding of adaptation, speciation, phenotypic variability and population structures, and will continue to contribute to the understanding of evolution. Novel transcript identification and differential expression analyses (also in dependence of environmental conditions) are the most promising approaches. In a race against extinction, flying insects own a significant role for studying speciation and the genomic patterns of diversity." Beiträge zur Entomofaunistik 20: 161-176. (in German, with English summary) ["Assessment of the ecological status of the retention basins at Wienfluss and Mauerbach. – In the present study the ecological status of seven retention basins at Wienfluss and Mauerbach (Austria, Vienna) has been assessed by an investigation of the dragonfly fauna. The assessment is based on a comparison of the rivertype-specific reference species with the status quo, considering the Rhithron-Potamon-Concept. For metarhithron waterbodies, such as the investigated water sections of Wienfluss and Mauerbach, three first-degree indicator species (*Calopteryx virgo*, *Onychogomphus forcipatus* and *Cordulegaster heros*) and four second-degree indicator species (*Pyrrhosoma nymphula*, *Ophiogomphus cecilia*, *Orthetrum brunneum* and *O. coerulescens*) have been defined. The investigations revealed 24 dragonfly species, 21 of them autochthonous, including species of the reference fauna and species characteristic of epipotamon waterbodies. Thus, the species inventory indicates a transitional zone between rhithron and potamon. Due to the autochthonous occurrence of first- and second-degree species, the retention basins have been classified as a "high" and "good ecological status". **17779.** Flint, P. (2019): Observations of dragonflies (Odonata) from northern Cyprus. *Libellula* 38(1/2): 1-28. (in English, with German summary) ["During observations by two resident observers in northern Cyprus from June 2003 to September 2004 21 species of dragonfly were recorded. These included nine species not previously recorded from the north of the island, two of which, *Erythromma viridulum* and *Trithemis arteriosa*, were not previously mentioned in the island's literature; the former being a new species for the island. These observations were the first long-term observations on the island and were made during a period of rapid climate and habitat change; the results for *Diplacodes lefebvrii*, *Anax parthenope*, *Orthetrum chrysostigma*, *O. sabina*, *Selysiothemis nigra*, *T. annulata*, and *T. arteriosa* appear to reflect these environmental changes. Other significant records include: *Lestes macrostigma* (early records and migration/dispersal), *Sympecma fusca* (early records), *Erythromma lindenii* (recorded in only one previous year), *A. ephippiger* (mass migration) and *Sympetrum striolatum* (winter mating and ovipositing). Thirty two of the wetlands/water bodies we monitored were not mentioned in the earlier literature. The composition of the island's dragonfly fauna is discussed in relation to island biogeography, climate, and habitat diversity. It is suggested that the low species richness and the narrow species range are due to island biogeographical factors, particularly (in the case of the latter) to the island's poor habitat diversity; and that the surprising absence of endemics may be due to the island's aridity and recurrent drought year clusters. From this it is further suggested that the fauna may be relatively high in species which are quick to colonise and which have generalist habitat preferences." **17781.** Gallesi, M.M.; Sacchi, R. (2019): Voltinism and larval population structure of *Calopteryx splendens* (Odonata: Calopterygidae) in the Po Valley. *International Journal of Odonatology* 22(1): 21-30. (in English) ["Adaptation of life-history traits is an important factor for the success of insects. Voltinism is a feature that descends from several life-history traits and, given that the latter depend on the specific environment of growth, voltinism can vary between populations across latitudes or habitats. In addition, some insects, like many odonates, have developed different patterns of voltinism within the same population, due to mechanisms of cohort splitting. *C. splendens* is a widespread damselfly in Europe that has been extensively studied regarding its evolutionary ecology, but detailed studies about its voltinism are relatively scarce and confined to the central and northern areas of Europe. So we investigated the voltinism and larval development of a population of *C. splendens* both by captive rearing and in the field in Northern Italy, the southernmost area in which its voltinism has been studied so far. We found an earlier start of larval growth, with respect to previous studies. Additionally, the head-width of larvae of the same instar decreased with the cohort ageing. Finally, the results are consistent with a two-groups emerging pattern that may support partial semivoltinism or partial bivoltinism of *C. splendens* in Northern Italy." (2019): Tree Swallow (*Tachycineta bicolor*) nest success and nestling growth near oilsands mining operations in Northeastern Alberta. *Journal of Zoology* 97(6): 547-557. (in English) ["Industrial development and contaminant exposure may affect reproductive success and food quality for birds. Tree swallows (*Tachycineta bicolor* (Vieillot, 1808)) nesting near oilsands development in northern Alberta potentially experience elevated environmental stressors that could influence reproduction. We measured reproductive and growth endpoints in tree swallows, predicting reduced reproductive success and nestling growth near oilsands operations compared to reference sites. We also identified

the invertebrate prey in the stomach contents of nestlings to understand variability in the diet and its potential effect on growth and survival of nestlings. From 2012 to 2015, clutch initiation varied among years but was not influenced by proximity to oilsands operations. Hatching and fledging success decreased in response to increased precipitation, regardless of location. Measurements of nestling growth reflected the variation associated with nestling sex and possibly asynchronous hatching. The composition of the nestling diet was significantly different; birds near oil sands development consumed Odonata, while birds at reference sites consumed Ephemeroptera. Nestlings from all sites consumed relatively high quantities of terrestrial insects. Our results demonstrate that factors such as weather conditions, diet, hatching order, and nestling sex are important when interpreting the potential effects of oilsands development on nest success and nestling growth." **17786.** Goertzen, D.; Suhling, F. (2019): Urbanization versus other land use: Diverging effects on dragonfly communities in Germany. *Biodiversity and Distributions* 25: 38-47. (in English) ["Aim: Land use change, such as urbanization and intensification of agricultural practices, poses major threats for biodiversity. We examined whether the composition of freshwater species differs between landscapes dominated by urban, agricultural or more natural structures in a region with a long history of landscape transformation. We determined the differences and characteristics of the dragonfly fauna in relation to major land use categories. We particularly focused on urban land use, as it generally induces a high level of landscape transformation. Location: Germany. Methods: We used distribution data of dragonflies derived from a citizen science database, which was compiled for the German distribution atlas. To analyse whether different land use categories are associated with distinct species compositions, we performed the classification method random forest. Results: Based on dragonfly abundance per grid cell, we identified distinct land use-related assemblages that were separated by two gradients, that is, the level of transformation and a gradient from open land to forest. In particular, urban landscapes possessed a distinct species composition with specific species, all of which were opportunistic and supported by warm climate. They also comprised significantly higher  $\alpha$ -diversity than intensive agricultural landscapes. Similar values of  $\beta$ -diversity over all land use categories implied a countrywide homogenized dragonfly fauna, which is probably caused by historic land use. Main conclusions: Our results indicate that land use is a relevant driver for the composition of freshwater species at the landscape scale. Urban landscapes maintain species diversity better than agricultural landscapes, but they modify the species composition. Additional research on the effects of land use change is required to understand species responses and predict future distributions in a changing world in order to plan sustainable conservation strategies." **17787.** Gomes Pereira, D.F.; Barbosa de Oliveira Junior, J.M.; Juen, L. (2019): Environmental changes promote larger species of Odonata (Insecta) in Amazonian streams. *Ecological Indicators* 98: 179-192. (in English) ["Highlights: • The relationship between environmental factors and functional characters of Odonata is tested. • Type of oviposition and thorax width are the most affected functional characters. • The more impactful environmental factors for the Odonata were habitat integrity and macrophytes cover. Abstract: Species occurrence can be affected by the availability of environments that fit within the limits of variation of its niche and by interaction with other species. Modifications in the environment, especially those caused by mankind, are considered the leading cause for species extinction. Such a response from the species is not random, with patterns that can follow functionality and/or morphology of each taxa. In this context, the objective of this study was to assess how environmental factors affect adult Odonata species, testing the hypotheses: a) that the environment acts as a filter upon the species by means of facilitating or excluding specific characteristics and b) that because of the order's requirements for thermoregulation and reproduction, thorax width and oviposition type are the variables most affected in the group. A total of 97 streams were sampled in eastern Amazonia, distributed along a gradient of different states of preservation, from completely preserved to heavily impacted by plantations and livestock. Six functional characteristics and seven environmental descriptors were selected, and to assess their relationships, a combination of Fourth Corner and RLQ analysis was used. The Habitat Integrity Index was the descriptor with the biggest impact on the Odonata community, presenting a negative correlation with wing width, thorax width and exophytic oviposition, and a positive correlation with endophytic oviposition. Macrophyte cover was the next most relevant environmental descriptor, showing a negative correlation with abdomen length, and positive correlation with thorax width and exophytic oviposition. The results show that poorly preserved environments favour the occurrence of organisms with a wider thorax and the substitution of endophytic oviposition with the exophytic type. Since changes to the environment do not usually alter Odonata richness but rather the composition, these results show a favouritism for groups with mentioned characteristics, such as Libellulidae, to the detriment of other groups (especially Zygoptera), which can result in community homogeneity and both biodiversity and functional loss. The maintenance of well-preserved environments is therefore indispensable in assuring Odonata biodiversity, as well as the best way to preserve the different behavioural and eco-physiological groups in the order. The Odonata community's response, directed through its morphological and behavioural characteristics, sheds light on ecological patterns, and thus the addition of oviposition habits in conservation measures aimed at preserving the order can render them more adequate, as this is a critical aspect of population maintenance and colonization of new sites." **17788.** Graham, S.R. (2019): Do *Enallagma exsulans* from streams and lakes show patterns of divergence? M.Sc. thesis, University of Arkansas. 53 pp. (in English) ["Divergent selection across heterogenous environments could lead to adaptive divergence in populations resulting in potential local adaption. These populations have phenotypic differences that are fitness related and make native individuals more fit than non-native individuals. My research focuses on a species of damselfly, *Enallagma exsulans*, to explore local adaptation and morphological differences as a result of divergent selection or plasticity. My first study explored potential local adaptation of wild caught stream and lake *E. exsulans* using a reciprocal transplant design, a classic approach for this objective. The stream and lake sites chosen were on a small spatial scale allowing for potential gene flow among populations, a process that could hinder local adaptation. In the second part of my research, I reared stream and lake *E. exsulans* in a common garden and transplanted them into stream and lake environments. I expected to find that native individuals had higher fitness, measured as growth rates, than non-native individuals indicating local adaptation. Unfortunately, I was unable to collect any results due to a storm damaging my experimental set-up. There are still important questions about local adaptation occurring at small spatial scales with potential for gene flow, and if plasticity is another mechanism for coping with changing environments. In the next part of my study, I used individuals raised in a common garden environment for a small scale mesocosm reciprocal transplant replicating the field study. All larvae lost body mass, no matter the origin of the individual or the condition under which it was tested. I also completed geometric morphometric analyses of wild caught individuals from both stream and lake environments and common garden reared individuals to determine if morphological differences are the result of divergent selection between populations. In wild-caught individuals, I found significant differences in body and lamellae shape between lake and stream populations suggesting divergent selection. In common garden individuals, I did not detect significant differences, suggesting morphological divergence is not genetically based. Last, I completed behavioral assays with common garden individuals placing larvae into stream and lake conditions and scoring behavior, but no results were significant between lake and stream populations." **17789.** Haak, N. (2019): Identification of individual dragonflies. *Brachytron* 20(1): 3-17. (in Dutch, with English summary) ["Individual dragonflies can be identified from a large number of individuals using a picture of their wing venation, similar to identification of humans based on fingerprints or facial recognition. This offers interesting opportunities for dragonfly research although lack of suitable identification software can still be a challenge. In a small city park in the middle of Middelburg (Zeeland, the Netherlands), every

summer a relatively large group of *Aeshna mixta* can be seen that hunt or rest in the park but do not originate there. Using photographs of wing patterns, I registered which individuals were present in the park from day to day. During the research period from July to October 2018, 1008 different Migrant hawkers were identified of which the large majority visited the park just once and left within one day after arrival. Only 9.4% of identified individuals were seen on more than one (two or three) days and just 1.9% visited the park on days that were more than one week apart. The observations suggest that *A. mixta* that visit the park are part of a migratory stream or at least show directional swarming." **17790.** Haase, P.; Pilotto, F.; Li, F.; Sundermann, A.; Lorenz, A.W.; Tonkin, J.D.; Stoll, S. (2019): Moderate warming over the past 25 years has already reorganized stream invertebrate communities. *Science of The Total Environment* 658: 1531-1538. (in English) ["Highlights: •We studied stream invertebrate communities over 25 years in central Europe. •Temperature increased by 0.5°C. Total abundance and richness increased. •Cold-adapted species declined while warmer-adapted species increased. •Community temperature index increased at a similar pace as physical temperature. •Results raise conservation concerns in view of the stronger future warming. Climate warming often results in species range shifts, biodiversity loss and accumulated climatic debts of biota (i.e. slower changes in biota than in temperature). Here, we analyzed the changes in community composition and temperature signature of stream invertebrate communities over 25 years (1990–2014), based on a large set of samples (n = 3782) over large elevation, latitudinal and longitudinal gradients in central Europe. Although warming was moderate (average 0.5°C), we found a strong reorganization of stream invertebrate communities. Total abundance (+35.9%) and richness (+39.2%) significantly increased. The share of abundance (TA) and taxonomic richness (TR) of warm-dwelling taxa (TA: +73.2%; TR: +60.2%) and medium-temperature-dwelling taxa (TA: +0.4%; TR: +5.8%) increased too, while cold-dwelling taxa declined (TA: -61.5%; TR: -47.3%). The community temperature index, representing the temperature signature of stream invertebrate communities, increased at a similar pace to physical temperature, indicating a thermophilization of the communities and, for the first time, no climatic debt. The strongest changes occurred along the altitudinal gradient, suggesting that stream invertebrates use the spatial configuration of river networks to track their temperature niche uphill. Yet, this may soon come to an end due to the summit trap effect. Our results indicate an ongoing process of replacement of cold-adapted species by thermophilic species at only 0.5°C warming, which is particularly alarming in the light of the more drastic climate warming projected for coming decades." (Authors) The paper includes a passing reference to Odonata.] Address: Pilotto, Francesca, Department of River Ecology and Conservation, Senckenberg Research Institute and Natural History Museum Frankfurt, Gelnhausen, Germany. **17791.** Haley, S. (2019): How does aquatic invertebrate community structure and abundance relate to brook trout (*Salvelinus fontinalis*) habitat quality? Honours Bachelor of Environmental Management, Natural Resources Management: (in English) ["67 streams located south-west of Lake Nipigon, Ontario, were sampled for brook trout and macroinvertebrate orders. Sixteen orders were used to determine if their community structure significantly changed in different brook trout habitat and different brook trout densities (no brook trout, one to fifteen brook trout or more than 15 brook trout). Though the orders Odonata, Oligochaeta, Trichoptera, Chironomidae, Nematoda, Simuliidae, Gastropoda and Plecypoda varied in response to brook trout habitat quality and abundance, the community structures did not change significantly. Pollutant sensitive orders, Trichoptera, Ephemeroptera, and Plecoptera that are used as indicators and share similar habitat to brook trout did not significantly change in response to brook trout densities. Future direction may involve identifying macroinvertebrates to family or genus level to detect community changes, or analyzing further data such as invertebrate biomass, diversity or richness in these streams." **17792.** Hashimoto, K.; Eguchi, Y.; Oishi, H.; Tazunoki, Y.; Tokuda, M. Sánchez-Bayo, F.; Goka, K.; Hayasaka, D. (2019): Effects of a herbicide on paddy predatory insects depend on their microhabitat use and an insecticide application. *Ecological Applications* 29(6), 2019, e01945. 11pp. (in English) [ "Indirect effects of agrochemicals on organisms via biotic interactions are less studied than direct chemical toxicity despite their potential relevance in agricultural landscapes. In particular, the role of species traits in characterizing indirect effects of pesticides has been largely overlooked. Moreover, it is still unclear whether such indirect effects on organisms are prevalent even when the organisms are exposed to direct toxicity. We conducted a mesocosm experiment to examine indirect effects of an herbicide (pentoxazone) on aquatic predatory insects of rice paddies. Because the herbicide selectively controls photosynthetic organisms, we assumed that the effects of the herbicide on predatory insects would be indirect. We hypothesized that phytophilous predators such as some Odonata larvae, which cling to aquatic macrophytes, would be more subject to negative indirect effects of the herbicide through a decrease in abundance of aquatic macrophytes than benthic, nektonic, and neustonic predators. Also, we cross-applied an insecticide (fipronil) with herbicide application to examine whether the indirect effects of the herbicide on the assembling predators act additively with direct adverse effects of the insecticide. The herbicide application did not decrease the abundance of phytoplankton constitutively, and there were no clear negative impacts of the herbicide on zooplankton and prey insects (detritivores and herbivores). However, the abundance of aquatic macrophytes was significantly decreased by the herbicide application. Although indirect effects of the herbicide were not so strong on most predators, their magnitude and sign differed markedly among predator species. In particular, the abundance of phytophilous predators was more likely to decrease than

that of benthic, nektonic, and neustonic predators when the herbicide was applied. However, these indirect effects of the herbicide could not be detected when the insecticide was also applied, seemingly due to fipronil's high lethal toxicity. Our study highlights the importance of species traits such as microhabitat use, which characterize biotic interactions, for predicting indirect effects of agrochemicals. Given that indirect effects of the chemicals vary in response to species traits and direct toxicity of other chemicals, efforts to explain this variation are needed to predict the realistic risks of indirect effects of agrochemicals in nature." **17793.** Hefler, C. (2019): Inherent aspects of root flapping tandem wing arrangements in nature: forewing - hindwing interactions in dragonfly flight. Ph.D. thesis, Mechanical and Aerospace Engineering, Hong Kong University of Science and Technology: xxi, 164 pp.- (in English) ["Micro air vehicles (MAVs) are operate in the size region under the same environmental conditions as natural flyers. Insects are a prime target for bioinspired designs of MAVs, as their wing-root fixed musculature is simpler than the flight muscles of birds and bats. Dragonflies are highly aerobatic insects having high aspect ratio wings in tandem; they control individual wings to utilize wake elements of the forewings by their hindwings. This thesis contains my effort to characterize the unique interactions between the wings of dragonflies. I use a spanwise resolved approach to address the gradual change of wing geometric relations in the root fixed flapping wing system. With the use of in-vivo flow measurements two characteristic regions with distinct flow features, and two transient regions delimiting these, were identified. The dimensionless arc length was introduced to describe the effect of interaction in the wings spanwise direction. This parameter includes not only the phasing relations of the wings, but the ventral or dorsal shift in a wing's flapping, thus it is more generally applicable. Additionally, the flight direction was found to affect the inter-wing interactions. Secondly, a multilayer wing is proposed that generates lift with simple flapping motion. The wing takes up a different shape during the downstroke and during the upstroke; that mimics the asymmetric wing pitching of dragonflies. The wing generates an additional trailing edge vortex between its layers during upstroke that can boost thrust. The characteristic parameter defining the performance of the double layer wing is the difference between the dynamic shape deformation during the upstroke and the downstroke. It relates to the ratio of the chord length of the wing's layers. A chord ratio of 0.5 resulted in the best performance. I hope that my work will inspire further scientific research on dragonflies as well as MAV engineering." (Author)] Address: not stated

**17794.** Henze, M.J.; Lind, O.; Kohler, M.; Kelber, A. (2019): Seeing and (not) being seen: Sensory ecology of the blue-

tailed damselfly *Ischnura elegans*. *Frontiers in Physiology*. Conference Abstract: International Conference on Invertebrate Vision. doi: 10.3389/conf.fphys.2013.25.00068: 2 pp. (in English) ["Adult *I. elegans* are colourful insects. Males turn bright green after emergence and become blue over the days. Females show a red or purple colouration first and, when sexually mature, either mimic the blue colour of the males or are camouflaged by an inconspicuous olive-green or brown. In the past, the mating system and the underlying genetics and population ecology of *I. elegans* have been studied intensively. However, the sensory basis of their colour polymorphism for (1) intraspecific and (2) predator-prey interactions have not been explored. We quantified backgrounds in the natural habitat and the body colouration of the damselflies by spectral reflectance measurements, including time series documenting the animals' colour change. (1) To understand the function of the colours for mate and rival detection, we determined the angular, spectral and polarization sensitivity of photoreceptors in the compound eyes of males. Four spectral types of receptors maximally sensitive in the UV (370 nm), blue (440 nm), green (540 nm) and red (600 nm) region of the spectrum were found by intracellular recordings (Fig. 1). The sensitivity curve of the red receptor is narrower than an opsin template indicating spectral filtering, likely by the green receptor. Combining spectral reflectance and spectral sensitivity data in a model enables us to reconstruct the saliency of the different colour morphs to conspecific males searching for mates or trying to chase off rivals. (2) The functions of the colours for predator avoidance are also largely unknown. In similar models, we therefore incorporate known spectral sensitivities of passerines, potential predators on *I. elegans*. This allows us to judge which colour morphs are best camouflaged for the birds. Our goal is a physiologically based understanding of the reasons for colour polymorphism, a common phenomenon in damselflies." (Authors)] Address: not stated

**17795.** Hunger, H.; Benken, T.; Watts, P. (2019): Untersuchungen zur Auswirkung der Habitatfragmentierung auf *Coenagrion mercuriale* mit genetischen Methoden und GIS-Modellen. *Mercuriale* 18/19: 59-95. (in German, with English summary) ["Studies on the impact of habitat fragmentation on *Coenagrion mercuriale* using genetic methods by microsatellite analysis and GIS models in Baden-Württemberg – Microsatellites are highly variable non-coding genomic regions that are inherited like alleles and therefore can be used for population studies. Genomic DNA, taken from 32 occurrences of the species, was isolated from leg samples of *C. mercuriale* and amplified by the polymerase chain reaction (PCR). Thirteen microsatellite loci were synthesized by use of specific primers flanking these microsatellite regions according to a standard protocol. These amplification products were separated by length by capillary electrophoresis and assigned to discrete „alleles“. The variability of these DNA sections at the investigated occurrences forms the basis for the statistical evaluations. A range from 0.425 to 0.591 was determined for the expected heterozygosity (He) as a degree for genetic diversity in the study area. The allele number per locus (Na) fluctuated between 2.71 and

4.86. The values within the core zone (patch 2) were relatively constant (He = 0.482-0.541; Na = 4.0-4.8), whereas larger fluctuations were measured in the isolated patches. There was no clear evidence of a bottleneck. The genetic differentiation (calculated as  $F_{ST}/1-F_{ST}$ ) is small overall in the study area but increases with distance (isolation by distance; IBD). Values from 0.002 to 0.071 were determined for populations less than five km, and values between 0.006 and 0.205 over 20 km apart. The proportion of migrants was estimated using the MCMC algorithm. Based on the genetic studies, the gene flow between the populations was calculated and potential migration routes were described. Dispersal models supplied by the Cost-Distance extension in ArcView Spatial Analyst were calculated for a 54.2 km<sup>2</sup> area in the "Freiburger Bucht", comprising nine genetics sampling sites. First, Euclidean distances were calculated. Following this, three cost matrices were created for the study area: "historic land use" – based on a historic map from the 1850s – "generalised recent land use" – based on ATKIS land use data scaled down to the historic land use map – and "recent land use", a more sophisticated model. All three models were combined with topographic surface data. The "Isolation by Distance Web Service" was then used to quantify the level of correlation between genetic distances and Euclidean respectively cost distances. The level of correlation rose in the order given above, with only the "recent land use" cost matrix yielding cost distances that were correlated with genetic distances on a significant level." **17796.** Iannella, M.; D'Alessandro, P.; Biondi, M. (2019): Entomological knowledge in Madagascar by GBIF datasets: estimates on the coverage and possible biases (*Insecta*). *Fragmenta Entomologica* 51(1): 1-10. (in English) ["Although Madagascar is one of the world's most important biodiversity hotspots, the knowledge of its faunistic diversity is still incomplete, notwithstanding many field campaigns were organized since the 17th century until nowadays, leading to a huge number of vertebrate and invertebrate records. In this contribution, taking into consideration the geographic distribution by a GBIF dataset including 286,764 records referred to nine insect orders (Coleoptera, Diptera, Hemiptera, Hymenoptera, Lepidoptera, Neuroptera, Odonata, Orthoptera, Trichoptera), we tried to supply some observations on the spatial distribution and to point out some possible biases in the entomological knowledge of Madagascar. Hymenoptera, Coleoptera and Diptera were the most represented orders in the dataset, respectively. Some orders show many "coupled" sampling, with peaks of shared sampled localities between Diptera with Hymenoptera (98.07%) and Hemiptera with Coleoptera (64.21%). Considering the geographic location and the extension of the vegetation macrogroups in Madagascar, the entomological data result unevenly distributed. Current Protected Areas' (PAs) network covers about the 70% of the total of the collecting localities for the nine insect orders considered, even though some, such as Trichoptera, Odonata, and Neuroptera

seem significantly less protected than others. However, the possible new PAs planned for Madagascar could greatly increase in the future the protection level for all 9 insect orders analyzed, especially for Neuroptera, Odonata and Lepidoptera. A percentage of 82.3% of the whole sampling localities falls inside the PAs themselves or within 1000 m from their borders. A similar pattern is observed for the road network: the 62.9% of the localities fall at least at 1000 m from a road, with no sampling localities observed further than 10 km from a road; statistically significant clusters were observed in evaluating these biases, coinciding with major towns or PAs." **17800.** Kemabonta, K.A.; Adu, B.W.; Nwabueze, O.F.; Ogbogu, S.S.; Ohadiwe, A. (2019): The diversity and distribution of dragonflies and damselflies (Odonata) in University of Lagos, Akoka, Lagos, south-west Nigeria. *The Zoologist* 17: 1-5. (in English) ["The presence of Odonata may be taken as an indication of good ecosystem quality. The greatest numbers of species are found at sites that offer a wide variety of microhabitats. A survey of Odonata fauna inhabiting the University of Lagos, Akoka Lagos, south-west Nigeria was carried out between July and December 2014, with a view of determining its diversity and distribution. Four study sites used were Distance Learning Institute (DLI), Lagoon, Faculty of Science, and High Rise Area. Data collected were subjected to inferential statistics and analysis of variance (ANOVA). Diversity indices were used to compare the odonate species in the study sites. Seven hundred and fifty (750) individuals representing 39 species in 22 genera and four families (Aeshnidae – 3%, Coenagrionidae – 13%, Libellulidae – 81% and Calopterygidae – 3%) were recorded. *Orthetrum* (18%) was the most dominant genus, followed by *Ceragrion* (10%) while *Palpopleura* and *Trithemis* (8%) were the least dominant genera. The site with most diverse Odonata fauna ( $H' = 2.70$ ,  $E = 0.27$ ), was High Rise Area while the least was the Lagoon Area ( $H' = 1.97$ ,  $E = 0.27$ ). Odonata in High Rise Area were significantly lower ( $p > 0.0128$ ) than those in DLI and Science Area which were not significantly different from each other (0.00039 and 0.00368 respectively). The paucity of species with narrow range of adaptation at the university especially at Lagoon Area where they were expected to occur is an indication that the forested part of the campus is under considerable human disturbance. Urgent measures are needed to preserve the natural the natural habitats of these Odonata species." **17802.** Khelifa, R. (2019): Sensitivity of biodiversity indices to life history stage, habitat type and landscape in Odonata community. *Biological Conservation* 237: 63-69. (in English) ["Highlights: • Improving our understanding of species distribution is key for effective management. • The distribution

of odonates in Northeast Algeria based on adult, oviposition, larvae and exuviae was analyzed. • Combining different life history stages improves the accuracy of species distribution. • The diversity of odonates was influenced by habitat and landscape configuration. Abstract: Assessing biodiversity and prioritizing the conservation of sites requires a robust methodology that minimizes the estimation errors of biodiversity indices and thus maximizes management efficiency. In aquatic insects, while there is still a debate about the use of different life history stages to increase the reliability of the biodiversity estimates, little is known about the effect of habitat and landscape characteristics. Here, odonates are used to assess the sensitivity of important biodiversity indices to the use of different life history stages (adult, oviposition, exuvia, and larva) and the influence of habitat type (lotic vs. lentic) and freshwater landscape complexity (proximity to a diversity of wetlands). Unlike exuvia and larvae, the use of adults gave inaccurate estimates of species richness, Relative Taxonomic Distinctness (RTD), Conservation Priority Index (CPI), but was quite reliable for Dragonfly Biotic Index (DBI). Interestingly, recording the mating state (oviposition) of the adult improved the accuracy of RTD and CPI by ~40 and 60%, respectively. The estimation bias was higher in lotic than in lentic habitat and it increased with the freshwater landscape complexity. Our study shows that applying a multi-life stage approach in biodiversity indices reveals site connectivity at the landscape level." (Authors)] Address: Khelifa, R., Dept Zoology & Biodiversity, Research Centre, Univ.y of British Columbia, Vancouver, BC, Canada

**17803.** Kietzka, G.J. (2019): Dragonflies as bioindicators and biodiversity surrogates for freshwater ecosystems. Dissertation, Doctor of Philosophy (Conservation Ecology) at Stellenbosch University, Department of Conservation Ecology and Entomology, Faculty of AgriSciences: 191 pp. (in English) ["Biological indicators (bioindicators) are useful for rapid and cost-effective ecosystem assessments. Dragonflies are valued for their potential as bioindicators in freshwater ecosystems. My dissertation aims to assess and expand on their use as bioindicators in transformed landscapes and as surrogates for other aquatic biodiversity. Of the three bioindicator categories (environmental, ecological and biodiversity), biodiversity indicators and their application are poorly understood. The umbrella species concept is a biodiversity surrogacy method that aims to conserve a large number of species in an ecosystem by focusing on a select group of co-occurring species. I used the umbrella index, which quantitatively identified a group of seven dragonfly species and a group of eight Ephemeroptera, Plecoptera and Trichoptera (EPT) species, any of which could be used as biodiversity surrogates (Chapter 2). Adult dragonflies can only be surveyed on warm, windless days during summer, but are easily identifiable. On the other hand, their larvae can be sampled under any weather conditions and are also sensitive bioindicators. I showed that the interchangeability of the life stages for assessments was dependent on landscape spatial scale, coupled with the specific question asked (Chapter 3). Comprehensive biodiversity surveys at fine ecological scales should sample both adults

and larvae. However, at larger spatial scales with coarser ecological questions, either adults or larvae can be used. To mitigate the detrimental effects caused by forestry, ecological networks (ENs) are integrated into plantation landscapes. These comprise grassland corridors connected to protected areas (PAs), which often include rivers. They aim to conserve biodiversity by creating habitats or facilitating dispersal of grassland species. I showed that water quality and adult dragonfly diversity did not differ between EN corridors and PAs (Chapter 4). Therefore, the EN approach is an effective method for conserving dragonfly diversity and river ecosystem integrity in plantation landscapes. In the Pietermaritzburg Botanical Gardens, an insect conservation pond was built along a degraded stream. Dragonfly species richness and abundance significantly increased, as both lentic and lotic species were able to colonize the area. Over time, the pond became overgrown and siltation reverted it back to a stream, which negatively affected dragonfly diversity. Shortly after extensive restoration efforts, the dragonfly assemblage had almost completely recovered and closely resembled that of the original pond. This was linked to alien plant removal, decreased vegetation cover and the inclusion of a range of microhabitats. This indicates that conservation ponds need to be actively maintained to keep their function as biodiversity reservoirs. This highlights the value of dragonflies as indicators of habitat quality in aquatic restoration projects. Throughout the thesis, adult dragonflies continuously demonstrated their success as bioindicators. The umbrella index validated the use of dragonflies as biodiversity indicators and surrogates for some of the most sensitive aquatic taxa (the EPT). Although dragonfly larvae and adults are both indicators of water quality, they are not always interchangeable, in terms of sampling at the species level. Their interchangeability depends on the specific question asked and the scale used. I also successfully monitored dragonfly assemblage responses in agricultural lotic and urban lentic environments, which highlighted their benefits for good aquatic conservation planning in transformed landscapes." **17804.** Kosterin, O.E. (2019): Amendments and updates to F.C. Fraser's key to Indian *Lestes* spp. (Odonata: Lestidae) to resolve confusion of *L. patricia* Fraser, 1924 and *L. nigriceps* Fraser, 1924, with notes on *L. nodalis* Selys 1891 and *L. garoensis* Lahiri, 1987. *Zootaxa* 4671(2): 297-300. (in English) ["Last year I reported the rediscovery in Cambodia of *Lestes nigriceps* Fraser, 1924, described from Pusa, India (Fraser 1924a) but never reported since that time from India (Kosterin 2018). In my paper I presumed non-conspicuity of the male and females of the type series and made critical comments on Fraser's appendage drawing (Fraser 1924a: plate IX: 6) and verbal descriptions (Fraser 1924a; 1933) of this species but did not consider his key for *Lestes* Leach, 1815 in the 1st volume of "Fauna of British India including Ceylon and Burma. Odonata" (Fraser 1933). Later I found a considerable corruption in this key, which could lead

to misidentifications. (It is noteworthy to stress that Fraser explicitly provided keys for males only)." (Author)] Address: Kosterin, O.E., Institute of Cytology & Genetics SB RAS, Acad. Lavrentyev Ave. 10, Novosibirsk, 630090, Russia. E-mail: kosterin@bionet.nsc.ru

**17805.** Kosterin, O.E. (2019): Description of a female and variation of *Microgomphus alani* Kosterin, 2016 (Odonata: Gomphidae) in Cambodia, with a note on sexual dimorphism in *Microgomphus* spp.. *Zootaxa* 4701(3): 276-290. (in English) ["*M. alani* was described from two teneral males from the Cardamom Mts. in SW Cambodia; it turned out that the description was based on the holotype with the anal appendages not fully expanded. Further specimens of *M. alani* (all mature) are reported: a male and two females from the Phnom Kulen Mts, NW Cambodia and five males and one female from Mondulkiri Province, E Cambodia. The appendage shape in mature males is illustrated and discussed and the female is described for the first time. The specimens from E Cambodia are ca 15-20% larger than those from SW and NW Cambodia and exhibit some differences in the shapes of the male epiproct and anterior hamulus and face maculation, however evaluated as insufficient to erect a new taxon. A hitherto neglected manifestation of sexual dimorphism in probably most *Microgomphus* spp. and at least some *Heliogomphus* spp. is pointed out. It concerns the mid- and metafemur, in males armed with numerous, dense and small spinulets but with two rows of long, sparse spines in females. An earlier report of *Microgomphus jurzitzai* Karube, 2000 for Cambodia was based on a misidentified *M. alani* specimen and is cancelled. A female specimen earlier identified and described from Thailand as *Heliogomphus selysi* Fraser, 1925 most probably was *M. alani* as well." **17806.** Kumar, A.; Kumar, N.; Das, R.; Lakhani, P.; Bhushan, B. (2019): In vivo structural dynamic analysis of the dragonfly wing: the effect of stigma as its modulator. *Philosophica Transactions of the Royal Society A. Mathematical, Physical and Engineering Sciences* 377(2150): 14 pp. (in English) ["The flapping of the dragonfly (*Lyrithemis elegatissima*) forewing under in vivo condition has been analysed by image correlation technique to get an insight of its structural dynamics. The modal parameters such as flapping frequency, natural frequencies, mode shapes and modal strain have been obtained that will facilitate the biomimetic design of wings for micro air vehicles. The stigma, which is a pigmented spot at the leading edge of the wing near the tip having heavier mass, takes an active role in the real-time flapping by shaping its trajectory as eight-shaped, which enhances the drag coefficient and stroke efficiency. The extra mass on it and its removal transformed the trajectory into two different elliptical and oval shapes, respectively, which reduced the drag coefficient and stroke efficiency of the flapping wing by altering the flapping kinematics." **17808.** LeNaour, A.; Baeta, R.; Sansault, E.; Deville, M.; Pincebourde, S. (2019): Telemetry reveals the habitat selected by immature dragonflies: implications for conservation of the threatened dragonfly *Leucorrhinia caudalis* (Odonata: Anisoptera). *Journal of Insect Conservation* 23(1): 147-155. (in English) ["Determining how species use different habitats during critical phases of their development is one of the crucial challenges that conservation biology meets. However, habitat requirements remain unknown for most species, in particular for the rarest and most threatened which by definition are difficult to study. Here, we used animal-borne telemetry to identify the habitat of the sexually immature adults in the threatened dragonfly *Leucorrhinia caudalis*. We used an harmonic radar with customized tags fixed on the back of the abdomen of flying immature dragonflies to monitor their position within an area composed of various types of habitats including open areas, forest and water bodies. From 62 tagged individuals, we obtained 23 detections, all within a quite restricted area around the pond of emergence. About 75% of the detections happened in the forest canopy and the individuals were likely positioned at the top of the trees. The relatively low detection rate was probably due to high predation within the study area during the maturation phase in this dragonfly but long-range dispersal cannot be excluded. The use of forest canopy as a maturation habitat is an important knowledge for planning conservation strategies in this endangered species, especially for populations living in areas without any protection status. Although technological constraints are still limiting its efficiency, animal-borne telemetry appears to be useful to determine precisely habitat selection by rare species." **17809.** Lohmann, A. C., Corcoran, A. J. and Hedrick, T. L. (2019): Dragonflies use underdamped pursuit to chase conspecifics. *J. Exp. Biol.* 222, jeb190884. <http://jeb.biologists.org/content/222/11/jeb190884>: 8 pp. (in English) ["Pursuit is

a common behavior exhibited by animals chasing prey, competitors and potential mates. Because of their speed and maneuverability, dragonflies are frequently studied as a model system for biological pursuit. Most quantitative studies have focused on prey pursuits in captive environments. To determine whether a different pursuit strategy is used when chasing conspecifics of nearly equal speed and agility, we recorded 3D flight trajectories from nine territorial chases between male *Erythemis simplicicollis* dragonflies in natural field conditions. During chases, dragonflies used an interception strategy with an unusually high-magnitude gain ( $k = -10.03 \text{ s}^{-1}$  horizontal;  $-8.86 \text{ s}^{-1}$  vertical) and short time delay ( $t = 50 \text{ ms}$ ). The product  $kt$  determines how aggressively a pursuer corrects course to achieve interception. Previous studies of prey pursuit have found  $kt$  values close to  $-1/e$  ( $-0.37$ ), the time-optimal value for achieving pursuit without overshooting. However, we found that dragonflies chasing conspecifics use more negative  $kt$  ( $-0.50$  horizontal;  $-0.44$  vertical), resulting in pursuits with a high degree of overshooting (i.e. moving past the target and alternating position from side to side). We confirmed via simulation that the observed gain and delay produce overshooting. We propose that overshooting is an adaptive feature of conspecific chases that can be achieved with only slight modification of the strategy used for intercepting prey. Overshooting might help avoid potentially damaging collisions while exhibiting the pursuing animal's flight performance and competitive ability. Repeated close approaches might also evoke evasive responses from the other dragonfly, effectively herding the competitor out of the territory." (Authors)] Address: Lohmann, Amanda, Dept Biol., Univ. North Carolina, Chapel Hill, NC 27514, USA. E-mail: amanda.lohmann@duke.edu

**17810.** Lu, K.; Wu, H.; Xue, Z.; Lu, X.; Batzer, D.P. (2019): Development of a multi-metric index based on aquatic invertebrates to assess floodplain wetland condition. *Hydrobiologia* 827: 141-153. (in English) ["The construction of levees breaks the connection of floodplains with river channels. Few assessments have examined the impacts on aquatic ecosystems. We developed a multi-metric index (MMI) based on aquatic invertebrates (including Odonata and treated at the family level) to assess floodplain wetland condition in the Wusuli River, northeastern China. We sampled the aquatic invertebrate communities in 18 floodplain wetlands along the Wusuli River including wetlands from headwater, middle river, and downstream reaches. Each site included paired wetlands with a wetland connected to the river floodplain and a wetland isolated from the floodplain by levees. Metrics related to the aquatic invertebrate community were selected as candidate metrics for the MMI. Then, a range test, discrimination analysis, and correlation analytics were used to select the candidate metrics based on their ability to distinguish reference and isolated wetlands. Four core indicators were selected to build the MMI: total number of taxa, %Gastropoda, Pielou's index, and %Collector-Gatherers. Four ordinal rating categories were defined: poor, fair, good, and excellent condition. The results showed 88.9% of the levee isolated wetlands, which were identified as being in poor or fair condition. Levee construction

has a consistent negative impact on floodplain wetland condition. Our MMI provides a biomonitoring way to determine the success of restoration strategies." (Authors)] Address: Batzer, D.P., Dept of Entomology, Univ. Georgia, Athens, GA 30602, USA. E-mail: dbatzer@uga.edu

**17817.** Martín, R.; Maynou, X. (2019): The Odonata community of a Mediterranean stream in the Catalan Pre-Coastal mountain range, NE Iberian Peninsula. *Boletín de la Sociedad Entomológica Aragonesa (S.E.A.)* 65: 195-206. (in English, with Spanish summary) ["We describe the composition, structure and seasonal variation of the adult Odonata

community of a Mediterranean stream in the Catalan Pre-Coastal mountain range (NE Iberian Peninsula) and assess the stream's conservation value using a multimetric approach based on measurements of species richness, diversity and abundance, presence of bioindicator species and taxa deserving protection status. The species assemblage was comparatively rich –26 species recorded as adults, 22 of them with breeding confirmed– and composed mainly of generalist univoltine taxa typical of slow-flowing and standing waters adapted to a riffle-pool sequence in a seasonal environment. Western Mediterranean, Ibero-Maghrebine and Holomediterranean elements were dominant with 17 species (65%). Analysis of community structure revealed small differences between pools and riffles but the seasonal variation was more pronounced, with diversity and abundance values being maximum in June and July. The most widely represented families were Coenagrionidae and Libellulidae, together including 54% of the species detected. The riverine habitat health indicator species *Boyeria irene* and *Cordulegaster boltonii* had a limited occurrence at the studied stream because the seasonal hydrological fluctuations reduce habitat suitability for these rheophilous taxa. Although we did not find any species categorized as vulnerable or threatened at a regional level, one of the stream inhabitants, *Coenagrion mercuriale*, enjoys protected status under the Habitats Directive (92/43/EEC), which entails the legal obligation to develop and implement appropriate measures for its conservation. The ISOI index, which assesses habitat ecological integrity based on the analysis of the dragonfly community, achieved a score of 18 out of 20, indicating that the environmental quality of the sampled stretch was excellent. Our results show that this type of mid-mountain stream offers an interesting combination of habitats for aquatic invertebrates and is worth protecting from human-caused alterations. Management should focus on the preservation of suitable conditions for running water specialists, since it is their habitats that are becoming increasingly threatened." **17819.** Maynou, X.; Martín, R. (2019): Phenology of the Odonata assemblage in a Mediterranean stream in the north-eastern Iberian Peninsula. *Odonatologica* 48(1/2): 27-48. (in English) ["We investigated the Odonata species composition of larvae, final instar (F-0) exuviae, and adults occurring in a sequence of two different mesohabitats - pool and riffle - in a short stretch of a Mediterranean stream running down the Catalan Pre-Coastal Range (north-eastern Iberian Peninsula). We sampled them during the period 2017–2018 and recorded adults of 26 taxa and confirmed by the presence of final instar exuviae that at least 21 were breeding successfully in that environment. We describe, for the first time for this region and habitat type, larval growth patterns, timings of adult emergence, and flight periods of the most abundant species and characterize the life cycles of some of them. These life cycles can be classified into three types: i) univoltine with overwintering in the larval stage and emergence taking place in spring or summer of the following year (*Coenagrion mercuriale*, *C. puella*, *Ceragrion tenellum*, and *Pyrrhosoma nymphula*); ii) predominantly univoltine of the previous type with a small fraction of the population being semivoltine (*Anax imperator* and *Orthetrum coerulescens*, tentative conclusion); and iii) univoltine with overwintering in the egg stage, a short larval growth period in the following spring, emergence in early summer, a long maturation period, and reproduction postponed until late summer or early autumn (*Chalcolestes viridis* and *Sympetrum striolatum*). Our results may contribute to fill in gaps in the knowledge of voltinism and phenology of the life cycles of Odonata in correlation with latitude, geographical area, and habitat type." **17820.** Meland, S.; Gomes, T.; Petersen, K.; Håll, J.; Lund, E.; Kringstad, A.; Grung, M. (2019): Road related pollutants induced DNA damage in dragonfly nymphs (Odonata, Anisoptera) living in highway sedimentation ponds. *Scientific Reports* 9, Article number: 16002 (2019). doi:10.1038/s41598-019-52207-4: 15 + 12 pp. (in English) ["Nowadays, stormwater sedimentation ponds are popular in stormwater management because of their ability to mitigate flooding and treat polluted runoff from e.g. roads. In addition, they may provide other ecosystem services such as biodiversity. These man-made habitats will inevitably be polluted and the organisms living therein may be negatively affected by the chemical cocktail present in both the water and sediment compartments. The present study explored DNA damage in dragonfly nymphs (Odonata, Anisoptera) living in highway sedimentation ponds in comparison with natural ponds. The concentrations of Polycyclic aromatic hydrocarbons (PAHs), alkylated PAHs and metals were also determined in sediment samples from the different ponds. The results showed that DNA damage was significantly higher in dragonfly nymphs living in sedimentation ponds compared to nymphs

living in natural ponds. DNA damage was also highly and significantly correlated with the pollution levels in the sediment, i.e., PAH and Zinc. Finally, we report the concentrations of various alkylated PAHs which appeared to be very dominant in the sedimentation ponds. Our results show that there may be a conflict between the sedimentation ponds' primary function of protecting natural water bodies from polluted runoff and their secondary function as habitats for organisms. Overall, we suggest that this must be considered when planning and designing stormwater measures." (2019): Low cross-taxon congruence among aquatic organisms in artificial tropical ponds: implications for biomonitoring. *Annales de Limnologie - International Journal of Limnology* 55(21): 9 pp. (in English) ["The use of biodiversity surrogates is often suggested to increase the cost-effectiveness of biomonitoring programs, as this demands less time and taxonomic expertise. In addition, the detection of multi-taxon associations is a first step toward a better understanding of how organisms interact with each other. Such a multi-taxon association is termed a congruence, and can be detected through measuring the similarity in the distributional patterns shown by different biological groups. To assess the ability of different taxa to serve as surrogates for others, we carried out a Procrustes analysis on the beta diversity patterns of seven biological groups (aquatic birds, Amphibians, Macrophytes, Coleoptera, Odonata, Heteroptera and phytoplankton) in 35 ponds of the Cerrado biome. We found that: (i) the values of congruence in the studied ponds were weak; (ii) among all the biological groups compared, the highest congruence was found between amphibians and macrophytes; (iii) amphibians were congruent with the Coleoptera, Heteroptera, and macrophytes; (iv) the different taxa studied had different responses to environmental conditions; and (v) although they showed relatively weak congruence with the other taxa in each pond environment, amphibian communities were the most strongly influenced by environment variables. Almost all the communities observed in these systems showed unique pattern and thus should be studied and monitored in their entirety.] Address: Melo, Fernanda, Laboratório de Ficologia, Campus Goiânia-Laranjeiras, Universidade Estadual de Goiás, Goiânia, Brasil. **17825.** Nagy, H.B.; László, Z.; Szabó, F.; Szocs, L.; Dévai, G.; Tóthmérész, B. (2019): Landscape-scale terrestrial factors are also vital in shaping Odonata assemblages of watercourses. *Scientific Reports* volume 9, Article number: 18196 (2019): 8 pp. (in English) ["Habitat loss and fragmentation causes a decline in insect populations. Odonata are especially threatened by the destruction of both aquatic and terrestrial environment. Moreover, effects of large-scale habitat heterogeneity on Odonata assemblages are poorly studied. In a two years study along East-European lowland

watercourses both aquatic and terrestrial environment were studied to reveal the importance of local (e.g. water depth, macrovegetation cover, etc.) and landscape-scale (e.g. farmland patch size, forest patch proportion, etc.) variables to Odonata (as well as to dragonflies and damselflies separately) through increasing spatial sampling scales. The specimens were sampled using 500m long transects from May to September. Results, both on local and landscape scales emphasized the importance of terrestrial environment on Odonata. Local variables influence damselflies, while dragonflies are more sensitive to landscape variables. Damselfly's diversity decreased with increasing macrovegetation cover, while dragonfly's diversity decreased with the increasing degree of land use intensification, but increased with the length of watercourses. It is thus vital to stress the importance of partial watercourse clearing, and moderate maintenance of traditional farm management based on small parcel farming near watercourses to maintain diverse and healthy Odonata assemblages.] Address: László, Z., Hungarian Dept Biol. & Ecology, Babes-Bolyai Univ., str. Clinicilor nr. 5–7, 400006, Cluj-Napoca, Romania. E-mail: laszlozoltan@gmail.com

**17828.** Oliveira-Junior, J.M.B.; Dias-Silva, K.; Teodósio, M.A.; Juen, L. (2019): The response of Neotropical dragonflies (Insecta: Odonata) to local and regional abiotic factors in small streams of the Amazon. *Insects* 10, 446: 19 pp. (in English) ["Since the relative role of local and regional abiotic factors on the Odonata diversity in rainforest streams is still poorly understood, we evaluated the effects of these factors on adult Odonata from preserved and altered streams in the Amazonian region. Adult Odonata were sampled in 98 streams in the Eastern Amazon, Pará, Brazil. Six variables were used to measure local environmental factors: habitat integrity index; mean canopy over the channel; and four physical and chemical descriptors of the water. To measure regional environmental factors, six variables were also used: altitude gradient, three bioclimatic variables and two percentage forest variables. In partial redundancy analysis, both abiotic factors (local and regional) were important to explain the variation in the Odonata community. The Odonata community can be influenced by regional and local factors. The relationship between Odonata and the local (e.g., integrity, canopy cover, and physical and chemical descriptors of the water) and regional (e.g., bioclimatic and forest cover variables) environmental variables recorded in this study has important implications for the use of these organisms to monitor small streams of the Eastern Amazon. The scale at which habitat is measured is an important issue in community structuring studies considering the rapid environmental changes. It is of great importance to consider the different scales in studies assessing community structure, once an adequate habitat must meet the ecological needs of all stages of the life of the Odonata."(Authors)] Address: Oliveira-Junior, J.M.B., Programa de Pós-Graduação em Zoologia (PPGZOOL), Programa de Pós-Graduação em Ecologia (PPGECO), Lab. de Ecologia e Conservação (LABECO), Universidade Federal do Pará (UFPA), Rua Augusto Correia, N.1, Bairro Guamá, Belém 66075-110, Pará, Brazil

**17829.** Ortega Salas, H. (2019): Sistemática y distribución del género *Paraphlebia* Sélys in Hagen, 1861 (Odonata: Thaumateuridae) en México y Centroamérica. M.Sc. thesis, Universidad Nacional Autónoma de México, Posgrado en Ciencias Biológicas, Instituto de Biología Sistemática: VI + 108, 2 app. (in Spanish, with English summary) ["For over a century, the genus *Paraphlebia* has remained one of the least known in Mexico and Central America. The use of alar coloration and the relative position of the RP3 vein, have so far been the only diagnostic characters available to separate

the species of this genus. This work provides a taxonomic revision of the genus including the characterization of *P. zoe*, *P. hyalina*, *P. fifth* and *P. duodecima*; the synonymy of *P. abrogata* with *P. quinta*; as well as the description of 10 new species distributed in Mexico, Guatemala, Honduras and Nicaragua. New diagnostic characters and a dichotomous key are proposed for the identification of all males of the species known for this genus. We present maps with the known distributions of all species and finally, the first phylogenetic hypothesis for the genus derived from the 12S, 16S, 28S and CO1 genes, where we differentiate two clades, which are found to be congruent with cerci morphology." **17830.** Petrulevicius, J.F. (2019): A new *Frenguelliidae* (Insecta: Odonata) from the Eocene of Arroyo Chacay, Patagonia, Argentina. *Palaeoentomology* 2(6): 591-595. (in English) ["The family *Frenguelliidae* Petrulevicius & Nel, 2003 was hitherto known from two genera and three species: *Frenguella patagonica* Petrulevicius & Nel, 2003, *F. iglesiasi* Petrulevicius & Nel, 2013 and *Treintamilun vuelvenlucha* Petrulevicius, 2017. *Frenguelliidae* is a very interesting group, controversially considered either an *Epiproctophora*, basal to *Euepiproctophora* by Petrulevicius & Nel (2003, 2007, 2013) and Petrulevicius et al. (2011), or a *Zygoptera* by Nel & Arillo (2006), Nel et al. (2008), Lak et al. (2009) and Bechly & Poinar (2013). Only the *epiproctophoran* hypothesis was discussed and based principally in a putative character of the group, the curved CuP (Petrulevicius & Nel, 2003, 2007, 2013). The *zygopteran* hypothesis could be reasonably adopted due to the presence in *Frenguelliidae* of a character which is absent in the basal *Epiproctophora*: the IR2 aligned with the subnodus (Petrulevicius, 2017). Other characters shared by *Frenguelliidae* and other *Zygoptera* are homoplastic and are also present in some *Epiproctophora*, i.e., *arculus* nearer to Ax2 than to Ax1 in *Cyclothemistidae*: *Triassoneura* (Fujiyama, 1991) and *Epiophlebiidae*: *Mesoepiophlebia* (Nel & Jarzembowski, 1996); the lack of pterostigmal brace in *Campterothlebiidae*: *Ctenogampsothlebia* (Petrulevicius et al., 2011); absence of secondary antenodals could also occur in *Triassoneura*. The morphology of the new species does not contradict the hypothesis postulated by Petrulevicius & Nel (2003, 2007, 2013) about the phyletic position of the group which remains uncertain and its resolution exceeds the possibility of the present work but is a nice topic for future research." **17832.** Pinkert, S. (2019): Physiological and historical determinants of the distribution and abundance of insects. Dissertation, Philipps-Universität Marburg: 285 pp. (in English) ["Understanding the consequences of past and future climatic changes on biodiversity has become one of the most important challenges of current ecological research. Due to the fundamental importance of climate for determining the distribution and abundance of species, climatic changes have led to strong shifts of species' ranges to higher altitudes and latitudes as well as to local changes in the phenology and abundance of species during the last decades. Nevertheless, most organisms are incapable of rapid responses to such changes as they are constrained by, for instance, phylogenetic conservatism in thermal adaptations and dispersal limitations. Therefore, a mechanistic understanding of the variation in functional traits of species is crucial for predicting biological responses to climate change. However, so far, most trait-based inferences focused on endotherm taxa, whereas the physiological processes shaping the diversity patterns of ectothermic organisms, particularly of insects, remain poorly understood. The overall objective of this PhD thesis is to investigate the importance of interactions between environmental factors and species' functional traits across regions, scales and taxa, to improve forecasts of the ecological consequences of climate change as well as our understanding of the ecological and evolutionary processes that determine biogeographical patterns, the range size and the abundance of insects. Insects, like 99.9 % of the species on our planet, are ectothermic organisms that in contrast to endothermic organisms, mainly depend on thermal energy from their environment for their activity and for maintaining vital physiological processes. Ectotherms therefore evolved adaptations to the temperature regime in which they live. From a physiological perspective, strong arguments exist that biophysical principles link variation in species' colour lightness and body size to heat gain and loss in endothermic animals. Larger species retain body heat more efficiently than smaller species owing to their lower surface-area-to-volume ratio, and darker coloured species heat up faster than lighter coloured species because they absorb more solar radiation. Other functions include enhanced immunocompetence of larger species and enhanced pathogen resistance (Gloger's rule) as well as UV protection of darker species. Mechanistic links between these two morphological traits, species' physiology and climate are hence probably important determinants of variation in the distribution and abundance of ectotherm organisms, but the limited availability of distributional and morphological data has so

far hampered a large-scale perspective on the physiological processes that shape biogeographical patterns in insects. Constraints to the evolution of species' morphological traits and dispersal abilities can limit the colonization of regions characterized by new climates or habitats and thereby influence geographical patterns in the phylogenetic diversity or geographical rarity of taxa. On the one hand, spatial concentrations of rare species are important conservation targets, because they indicate the distribution of species that are both particularly vulnerable to extinction in the future and unique elements of biodiversity. On the other hand, overall patterns of these facets of diversity provide information about past dispersal events and the ecological processes that shaped contemporary patterns of biodiversity. In six chapters of my thesis I investigate whether biogeographical patterns of insect assemblages are driven by variation in the colour lightness and the body size. I show that melanin-based thermoregulation, pathogen resistance and UV protection are important mechanisms that influence the distribution of dragonflies, butterflies and moths at both local and continental scales. In all studies, species assemblages in cooler climates are on average darker coloured than assemblages in warmer climates. Furthermore, in line with the prediction that darker colouration is advantageous in regions with high humidity and in regions with high solar radiation due to the protective functions of melanin, colour lightness generally decreases with increasing precipitation and insolation. Body size clines are less strong and differ considerably among the considered taxa. In addition, I demonstrate that contrasting effects of the benefits and the energetic costs of an investment into body size and melanization on the range size and abundance of butterfly species can offset each other when their interactions with components of the energy budget are not taken into account. Thus, larger and darker butterfly species only have wider distributions and are more abundant if they compensate the costs of an investment into body size and melanization by reducing mobility costs or increasing energy uptake. In three additional chapters, I investigate whether evolutionary constraints on species' thermal adaptations and dispersal ability influence the composition of insect assemblages and I assess the extent to which diversity patterns of insects are shaped by the contemporary climate and historical climatic changes. Using European dragonflies, I show that both phylogenetic conservatism of thermal adaptations and dispersal limitations constrain the recolonization of previously glaciated areas of Europe, resulting in a decrease of the endemism and phylogenetic diversity of assemblages with decreasing temperature and the increasing proportion of species with a high dispersal ability. In addition, I demonstrate that the climatic changes since the Last Glacial Maximum are consistently major drivers of the endemism and species richness of mammals, birds, amphibians and dragonflies across Africa. However, the results of this study also indicate that the signatures of species' responses to historical climatic changes differ considerably between the considered taxa and are currently less effectively protected. Finally, using a group of flightless orthopterans endemic to Africa, I exemplify that the diversity of this group, and probably most of the insect

diversity today found in the Eastern Arc Mountain biodiversity hotspot, has been generated by the interplay of humid periods that allowed the spread of forest-bound lineages across Africa with aridity-driven fragmentations of forests and their associated faunas. In conclusion, I demonstrate that both body size and colour lightness are major determinants of distribution and abundance of insects, across taxa, regions and scales. Despite the significant contributions of other functions of colour lightness, such as pathogen resistance and UV protection, as well as of the thermoregulatory function of body size, melanin-based thermoregulation is the most important and a strikingly general mechanism that shapes biogeographical patterns of insect. To understand and predict the effects of body size and colour lightness on ecological dynamics of insect species it is, however, crucial to account for their interactions with components of the energy budget, because the contrasting effects of an investment into body size, wing size and melanization on the range size and abundance of species can partly offset each other. Purely correlative approaches that predict spatio-temporal variation in the distribution and abundance of insect species based on easily measured morphological traits are therefore prone to false mechanistic conclusions and likely underestimate the functional importance of morphological traits. Furthermore, phylogenetic conservatism of thermal adaptations and dispersal limitations affect trait-environment relationships and species' responses to historical climatic changes. Together these results highlight the potential of models that integrate morphological, climatic and phylogenetic data for improving predictions of species' responses to climate change as well as our understanding of the processes that generated and maintain the remarkable diversity of insects on Earth." **17834.** Pokorný, J.; Waldhauser, M. (2019): Mapping the distribution of reophilic dragonflies, damselflies and water beetles in the Czech Republic in the years 2012–2015. *Průroda*, Praha 39: 95-112. (in Czech, with English summary) ["Mapping the distribution of reophilic dragonflies and water beetles was carried out in the Czech Republic in the years 2012–2015. The investigations were focussed on sites with current or potential occurrence of the species of European Community importance, *Ophiogomphus cecilia*, *Stylurus flavipes* and the genus *Cordulegaster*. The mapping ran under the scheme "Monitoring and Widescale Mapping of the EC Species of Importance as a Ground for the Completing the Natura 2000 Network in the Czech Republic". Mapping took place in 444 quadrates of grid mapping, i.e. covering two thirds of the area of the country. Five species are on the Red List (Hejda et al. 2017). Twelve obligatory or facultative reophilic species were found: *Calopteryx splendens*, *C. virgo*, *Ischnura elegans*, *Platycnemis pennipes*, *Stylurus flavipes*, *Gomphus vulgatissimus*, *Ophiogomphus cecilia*, *Onychogomphus forcipatus*, *Cordulegaster boltonii*, *C. bidentata*, *C. heros* and *Somatochlora metallica*. The results improved our knowledge on the distribution of most of the Goldenring and Clubtail species. Significant new data on their distribution, not only in new quadrates, but also in new extensive areas were gathered. These new findings can be mostly considered as filling in the gaps in our knowledge rather than the species spreading to new areas. A total of 2,167 specimens of water beetles belonging to 115 species were found. ..." (Authors)] Address: Pokorný, J., Hrusice 33, CZ-251 66 Hrusice. E-mail: aegolius.j@seznam.cz

**17835.** Porst, G.; Brauns, M.; Irvine, K.; Solimini, A.; Sandin, L.; Pusch, M.; Miler, O. (2019): Effects of shoreline alteration and habitat heterogeneity on macroinvertebrate community composition across European lakes. *Ecological Indicators* 98: 285-296. (in English) ["Human lake shore alterations often result in a substantial decrease of littoral and riparian habitat diversity and physical complexity, but the intensity at which shore alterations affect biodiversity may differ among European geographical regions. We tested if the response of littoral macroinvertebrate communities to human shoreline alterations is consistent among geographical regions. We compared community composition and diversity of human altered with those of unmodified littoral zones from 51 lakes across seven European countries in four geographical regions based on pooled composite as well as habitat-specific macroinvertebrate samples. Taxon richness and community composition differed among shore types and different habitats in all geographic regions, with morphological alteration having an overall negative effect on macroinvertebrate taxon richness. In addition, habitat heterogeneity also had a strong effect on littoral communities, with highest taxon richness found in the structurally complex macrophyte habitats in all regions. Average proportional densities of Diptera and Oligochaeta taxa generally increa-

sed in morphologically altered shores in all geographical regions, while Bivalvia, Crustacea, Ephemeroptera, Gastropoda and Trichoptera showed comparatively lower numbers in many anthropogenically altered sites. Furthermore, taxon richness was positively correlated with habitat diversity. We were able to relate changes in littoral communities to anthropogenic shoreline alterations, and linked the effect to the loss of habitats and habitat complexity. The results of our study demonstrate that littoral macroinvertebrates respond consistently negative to the influence of morphological alterations across European geographical regions in terms of biodiversity. While macroinvertebrates have previously been identified to be useful descriptors of morphological change in single countries/regions, we can now validate that they can be used to assess the ecological status of lakes in terms of morphological alterations across European regions. Our results can be used to further improve already existing WFD-compliant multimetric indices, for example by including taxa groups, which show a strong reaction to shoreline alterations. This could be supported by the inclusion of a suit of indicator taxa reflecting the loss of complex habitats such as macrophytes in the lake littoral. ... Odonata taxa showed a general decrease from macrophyte to sand and stone habitats in all, but the Northern European lakes". **17839.** Razkallah, Z.; Houhamdi, M. (2019): Community structure of the odonatofauna of an important Maghreb watershed: the Seybouse (Northeast Algeria). *Zoology and Ecology* 28(4): 395-402. (in English) ["Odonata of the Maghreb have been shown to be particularly diverse and rich in endemic species. Although studies have peaked during the last decade, especially in the Seybouse watershed (Northeast Algeria), a few have used larvae to assess the community structure and ecology of odonates. Here, we present a larva-based investigation of the odonate of the Seybouse watershed conducted during 2015–2016 in a dozen of sites using community ecology quantitative approaches and multivariate analysis to determine the checklist, species richness, abundance, and environmental characteristics of communities. We found 17 species (7 zygopteran and 10 anisopteran), of which *Calopteryx exul*, *Coenagrion mercuriale*, *Gomphus lucasii* were locally and/or globally of conservation concern. There was a strong correlation between the frequency occurrence (distribution) and abundance, meaning that the cosmopolitan species were also the most abundant in the community. The multivariate analysis showed that the communities were structured by substrate type and abiotic factors such as conductivity, dissolved oxygen, and

water flow. Our study also confirms the extinction of some populations of the endangered endemic *C. exul*, and thus rings the alarm for an urgent conservation plan that should manage the extensive water pumping and pollution in the region." **17840.** Rocha-Ortega, M.; Rodríguez, E.P.; Córdoba-Aguilar, A. (2019): Spatial and temporal effects of land use change as potential drivers of odonate community composition but not species richness. *Biodiversity and Conservation* 28: 451-466. (in English) ["Land-use changes and land cover change are drivers of diversity. The effects of such drivers over the temporal trend in species richness and composition, particularly on invertebrate diversity in megadiverse countries, is controversial. One key animal group to clarify this controversy is that of odonate insects (dragonflies and damselflies), given their combined close water-land requirements. We have investigated whether changes in land use impact species richness and composition of odonates from 1980 to 1993 (period I) to 1994–2010 (period II) in Mexico. The effect of land use changes and land cover changes on species richness was analyzed using multiple diversity measures and at different spatial scales. In period II, an area reduction in original vegetation and increase in land use occurred. Responses to land use varied among spatial scales and measures of diversity but, overall, species richness in the transformed area was higher than in the original vegetation. However, species composition indicated a high species turnover inside hydrologic regions (watersheds) and across land uses classes, particularly between original and secondary vegetation. Our interpretation is that despite high land use conversion in Mexico, adult odonates seem resilient to land use change in terms of species richness, but not in species composition, which is in partial agreement with the intermediate disturbance hypothesis. Finally, we suggest that hydrologic region scale and use of entropy maximization (HCDT entropy), could provide a reliable biodiversity estimation of species loss associated with land use change." **17841.** Rodríguez, J.S.; Molineri, C. (2019): The larva of *Neoneura confundens* Wasscher and van't Bosch, 2013 (Odonata, Coenagrionidae) and key to the larvae of genus. *Anais da Academia Brasileira de Ciências* 91(4): 10 pp. (in English) ["The beautifully colored damselflies included in *Neoneura* Selys are divided in 28 species known from North, Central and South America. Larval stage is little known, only seven species were described at this stage. We describe and illustrate the final instar larva of *Neoneura confundens* for the first time. Adults associated to this larva correspond to the blue form of the species and are also discussed and illustrated. The larva of *N. confundens* is similar to other *Neoneura* larvae, showing 1 premental seta and a

well-marked nodus in caudal lamellae, but it can be differentiated by having fringed posterior margin in all tibiae and in middle and hind tarsi, among other characters. A key to known larvae of *Neoneura* and new records extending the species range in the southern cone are provided." **17842.** Rodríguez-Escobar, F.E.; Carrillo-Muñoz, A.I.; Serrano-Meneses, M.A. (2019): Seasonal variation in the allometry of wing pigmentation in adult males of the territorial damselfly *Hetaerina vulnerata* (Insecta Odonata). *Ethology Ecology & Evolution* 32(2): 148-161. (in English) ["Several sexually selected traits exhibit positive allometry. One of the explanations for this pattern suggests that positive allometry should be expected only for "pure" threat male signals, whilst isometry and negative allometry should occur in "pure" courtship signals. Wing pigmentation (WP) is a sexually selected trait exhibited by the males of several Zygoptera taxa, which has been the focus of a number of studies of allometry. Whilst WP tends to exhibit positive allometry in many taxa, the pattern is not general. Previous studies have shown that in *Hetaerina vulnerata*, a territorial species in which WP is used as a "pure" threat signal, positive allometry is common. However, little attention has been paid to the seasonal variation in the allometry of WP in this species. To address this research gap, we collected data from a full reproductive season, from a natural population of *H. vulnerata* located in Central Mexico. Our results suggest that, first, male WP and body size generally increase throughout the season. Second, WP increases as the end of the season approaches, independently of body size. Finally, WP tends to be either not related to body size, or to exhibit isometry during the first half of the season (April–June), and positive allometry during the second half of the season (July–October). We suggest that our results may be explained by (i) the availability of resources critical to the development of larvae, as well as the duration of development, and (ii) an increase in the number or larger males towards the end of the season, which may favour the exaggeration of WP. Furthermore, the opportunity for sexual selection may vary, so that WP may be more relevant to male mating success towards the end of the reproductive season." **17843.** Ryan, S.C.; Belby, C.S.; King-Heiden, T.C.; Haro, R.J.; Ogorek, J.; Gerrish, G.A. (2019): The role of macroinvertebrates in the distribution of lead (Pb) within an urban marsh ecosystem. *Hydrobiologia* 827: 337-352. (in English) ["Environmental risk from contaminated aquatic sediments requires an understanding of its spatial distribution, bio-availability and rate of transfer to resident aquatic and terrestrial biota. We hypothesized that macroinvertebrates play a role in the sequestration, distribution, and dispersal

of lead from lead shot contaminated sediments. To assess this, we sampled the predominant aquatic macroinvertebrate, *Leptocerus americanus*, from sites within the La Crosse River Marsh (La Crosse, WI) identified to contain high levels of lead contamination. We measured lead content in larval cases, larval tissues and emergent adult tissues. Lead concentrations within whole larvae correlated with levels of lead within sediments, and lead was differentially partitioned between larval tissue and their silk cases. Over 90% of the lead was retained in larval cases, while the rest was distributed to the body tissue, which was largely conserved during the process of metamorphosis. Our models support that *L. americanus* emerging from the marsh in the contaminated area transfer as much as 160 mgPb out of the aquatic habitat each year. Our work demonstrates that macroinvertebrates affect the mobilization and dispersal of contaminants within aquatic sediments, and this role should be evaluated when making management decisions regarding contaminated ecosystems." The paper includes only a passing note to Odonata (Authors)] Address: Gerrish, Gretchen, The River Studies Center, Univ. of Wisconsin – La Crosse, La Crosse, WI 54601, USA. **17844.** Ryazanova, G.I. (2019): Odonata and anthropogenic salinization of inland waters. *Moscow University Biological Sciences Bulletin* 74: 33-39. (in English) [Original publication in *Vestnik Moskovskogo universiteta. Seriya 16. Biologiya* 74(1):42-49. (In Russ.) "Anthropogenic salinization of inland waters and its impact on freshwater biota are topical environmental problems. Such salinization leads to changes in the natural environment, which is undesirable from the point of view of environmental protection and is not indifferent to humans. One of the three most important factors of anthropogenic salinization of fresh water in temperate and cold climates, along with agricultural and mining activities, has been the widespread use of chemical reagents in the fight against road icing. Today, the main components of these reagents are Na and Ca chlorides - cheap and easily accessible natural materials. Their blend of sand and sand, used in de-icing practices, is usually stored in bulk at special outdoor sites all year round. Exposure to precipitation makes it a source of salinization of surrounding soils and waters. In 2015, 2016 and 2018, the salinity of inland water bodies was recorded near the long-term open storage of anti-ice reagents in the Kaluga region. The anthropogenic nature of salinization of the surveyed reservoirs was determined. The main components of water body salinization in the study area are Na and Ca chlorides. Maximum salinization level in the studied conditions is 4‰, the degree of salinization depends on the distance of the reservoir from the road salt storage. The influence of anthropogenic salinity on dragonflies, mainly of the *Coenagrion puella* L. species, was considered. It was found that the influence of increased water salinity is manifested only in slowing down the development of individuals with a high level of fluctuating asymmetry, it does not affect their number in the population. The high salinity of the water only leads to changes in the timing of migration of individuals with high levels of FA. It is assumed that dragonflies, as one of the

mass objects of freshwater biota, obviously, are not subject to significant influence of anthropogenic salinization. Translated with [www.DeepL.com/Translator](http://www.DeepL.com/Translator) Russian Text © The Author(s), 2019, published in *Vestnik Moskovskogo Universiteta, Seriya 16: Biologiya*, 2019, Vol. 74, No. 1, pp. 42–49.] Address: Ryazanova, G.I., Dept of Biology, Moscow State University, Moscow, Russia. **17845.** Rychla, A. (2019): Besiedlung künstlicher Kleingewässer durch Großlibellen (Odonata: Anisoptera) – eine 4-jährige Studie aus der Niederschlesischen Heide (SW Polen). *International Dragonfly Fund Report* 140: 1-18. (in German, with English summary) ["Dragonflies frequently colonise newly created pools. However, little is known about the long-term establishment of populations, especially of rare and endangered species. The aim of this study was to investigate the colonization process at small artificial waters by dragonflies with special focus on typical peat bog species. From 2015 to 2018, exuviae of Anisoptera were collected quantitatively at six man-made pools, three new and three old ones, in the Lower Silesian Forest. The colonization success by Zygoptera was investigated qualitatively and served as an additional information on the biodiversity of these waters. In total, 26 Odonata species (9 Zygoptera and 17 Anisoptera) with successful reproduction were found. However, species diversity varied significantly both between the pools and the years of study. There were no significant differences between new and old pools. There were four peat bog species (*Aeshna juncea*, *Leucorrhinia dubia*, *L. albifrons*, *L. pectoralis*) among the autochthonous species, Long-term development could only be confirmed for *A. juncea* and *L. dubia* in particular pools. *Leucorrhinia albifrons* occurred only sporadically and was not found in the last study year (2018). By contrast, *L. pectoralis* did complete its development in the years 2017 and 2018. Generally, these species preferred waters with moderately or well developed vegetation. The results confirm that a wide range of species can reproduce in artificial pools. However, permanent reproduction could be recorded for just a few dragonfly species. Consequently, man-made pools in the Lower Silesian Forest should not be considered as long-term surrogate habitats but rather as temporary sub-population patches of the regional dragonfly fauna." **17846.** Sackville, M.; Brauner, C.J.; Matthews, P.G.D. (2019): Complete larval development of the dragonfly, *Rhionaeschna multicolor*, at 20°C under natural photoperiod (Odonata: Aeshnidae). *Notulae odonatologicae* 9(3): 103-108. (in English) ["*Rhionaeschna multicolor* was reared from hatch to emergence in a controlled laboratory setting for the first time. Complete development at 20°C under natural photoperiod consisted of 13 stadia over 428 ± 3 days. Molt timing and total exuvia length tightly followed semi-log ( $R^2 = 0.993$ ,  $Sy.x = 0.349$ ) and exponential growth curves ( $R^2 = 0.984$ ,  $Sy.x = 1.301$ ), respectively, yielding a mean growth ratio of 1.26 ± 0.026. Winter diapause may persist through spring and summer photoperiods for late stadia nymphs in

these conditions, potentially delaying adult emergence relative to nymphs reared in the wild." (Authors)] Address: Sackville, M., Department of Zoology, University of British Columbia, Vancouver, British Columbia, Canada V6T 1Z4. E-mail: mikesack@zoology.ubc.ca

**17847.** Sánchez-Rosario, A. (2019): Distribución de la riqueza de especies de los odonatos (Insecta: Odonata) de la República Dominicana: una actualización a partir de especímenes de colección. Distribution of species richness of the odonates (Insecta: Odonata) of the Dominican Republic: An update from collection specimens. *Actualidades Biológicas* 41 (111): 72-80. (in Spanish, with English summary) ["Scientific collections are important biodiversity records, as is the one from the Instituto de Investigaciones Botánicas y Zoológicas (IIBZ) from the Universidad Autónoma de Santo Domingo in Dominican Republic. They provide a partial but useful view of the common occurrence localities and information gaps of specific groups of organisms. Presented in this paper are a list of species and an occurrence map of adult odonate specimens represented in the collection from the IIBZ; a comparison of them with reports from previous works was performed. Of the 67 species currently reported in the Dominican Republic, 63 were found in the collection. Regarding previous works, species richness increased in some provinces, such was the case in Distrito Nacional, where it increased from 44 to 51. A correlation analysis examined the association between numeric richness and the drainage density, annual precipitation and surface area of the province; none of the correlations yielded significant results. Additionally, linear mixed effect models were generated, using the mentioned variables as fixed effect and a qualitative variable related to accessibility and population density as random effect. All the models found that a substantial percentage of the variance of the numeric richness is explained by the random effect variable, which means the accessibility conditions the species' occurrence, suggesting a sampling bias exists. From this arises the need of collecting specimens in regions with few records to better comprehend the distribution of odonates in the country." **17849.** Sanubar Guliyeva A. (2019): Species composition and quantitative distribution of the larvae of dragonflies (Odonata) in the new ecological conditions of the lake Mehman. Economic and Social Development. 37th International Scientific Conference on Economic and Social Development – "Socio Economic Problems of Sustainable Development" Book of Proceedings. Editors: Muslim Ibrahimov, Ana Aleksic, Darko Dukic, Baku: 985-988. (in English) ["The paper presents new data on species composition, number and distribution of the larvae of Odonata in new environmental conditions of the different habitats of in the lake Mehman. Field works conducted in 2015 - 2017 in the lake Mehman resulted in the rearings of 25 species and forms of dragonfly larvae. Seven of these *L. nympha*, *S. fusca*, *E. viridulum*, *I. pumilio*, *O. cancellatum*, *L. depressa*, *L. quadrimaculata*, *Cordulia* sp. are new to the lake. Species *Lestes virens*, and *I. elegans*, were found in winter, spring and autumn of 2015 and winter and autumn of 2017; *C. scitulum* in winter and autumn of 2015; *C. hastulatum* - winter, spring and autumn of 2017; *E. fatime* in winter and autumn of 2015 - 2017; in winter and spring of 2015 - 2017. Species *C. mercuriale* [sic!], *C. scitulum*, *L. virens*, *I. elegans*, *C. puella*, *E. najas*, *O. albistylum* are observed in the lake in all seasons and are dominated by widespread. It should be noted that the decrease in the number of larvae of dragonflies in the summer, especially at depths of up to 0.5 m is due to their intensive consumption by fish and water birds and emergence of adult dragonflies which leave the lake. On the other hand, in summer period, the volume of oxygen in shallow water of the lake Mehman greatly reduced, and as a result of evaporation of water, the amount of salts in water is increased. In such circumstances, the probability of occurrence of freshwater organisms in the benthos is naturally decreased. The study of the distribution of larvae of dragonflies on specific habitats of the lake revealed their maximum development on plant and silty habitats, and the minimum - on black silty sand. Changes in biomass of benthic organisms as well as larvae of dragonflies, which developed very poor is analyzed. Poor development of dragonfly larvae in the lake Mehman characterized, on the one hand with their intensive consumption by fish and water birds and on the other hand - the steady worsening of the environmental conditions of the lake." **17850.** Schilder, R.J.; Stewart, H. (2019): Parasitic gut infection causes functional and molecular resemblance of *Libellula pulchella* dragonfly flight muscle to skeletal muscle

of obese vertebrates. *Journal of Experimental Biology* 222(5): jeb188508. doi: 10.1242/jeb.188508: 10 pp. (in English) ["We previously demonstrated the existence of a naturally occurring, metabolic disease phenotype in *Libellula pulchella* dragonflies, that shows high similarity to vertebrate obesity and type II diabetes, and is caused by a protozoan gut parasite. To further mechanistic understanding of how this metabolic disease phenotype affects male *L. pulchella* fitness in vivo, we examined infection effects on in situ muscle performance- and molecular traits relevant to *L. pulchella* flight performance in nature. Importantly, these traits were previously shown to be affected in obese vertebrates. Similar to obesity effects in rat skeletal muscle, dragonfly gut infection caused a disruption of relationships between body mass, flight muscle power output and alternative pre-mRNA splicing of troponin T, a trait known to affect muscle calcium sensitivity and performance in insects and vertebrates. In addition, when simulated in situ to contract at cycle frequencies ranging from 20-45Hz, infected individuals' flight muscles displayed a left-shift in the power-cycle frequency curves, i.e., their optimal cycle frequency was significantly reduced. Interestingly, this left-shift resulted in power-cycle frequency curves that were similar to those produced by flight muscles of non-infected, teneral (i.e., physiologically immature) adult *L. pulchella* males. Overall, our results indicate that effects of metabolic disease on skeletal muscle physiology in natural insect systems are similar to those observed in vertebrates maintained in laboratory settings. More generally, they indicate that study of natural, host-parasite interactions can contribute important insight into how environmental factors other than diet and exercise may contribute to the development of metabolic disease phenotypes." **17851.** Schilling, E.G.; Lawrenz, R.; Kundel, H. (2019): An assessment of the geographic distribution and status of a rare dragonfly, *Rhionaeschna mutata*, at the northwestern edge of its range. *Northeastern Naturalist* 26(3): 523-536. (in English) ["*R. mutata* is a rare North American dragonfly, most widely distributed in the eastern US. In 2009, a reproductive population was found in 2 ponds in eastern Minnesota, establishing a substantial northwestern range expansion. We assessed the geographic distribution of the Spatterdock Darter in the region to inform conservation planning for this species. Using previously defined habitat criteria, we identified potential reproductive ponds in the ecoregion with GIS. In 2015 and 2016, we used multiple methods to survey 25 ponds for Spatterdock Darter nymphs, adults, and exuviae. We found no Spatterdock Darters in the region, despite intensive survey efforts targeted at ponds that met the habitat criteria. The Spatterdock Darter may be present in this water-rich region, but was undetected by our efforts, or a local extirpation may have occurred, possibly linked to recent fish colonization in one of the original reproductive ponds." **17855.** Song, N.; Li, X.; Yin, X.; Li, X.; Yin, J.; Pan, P. (2019): The mitochondrial genomes of palaeopteran insects and insights into the early insect relationships. *Scientific Reports* | (2019) 9:17765 | <https://doi.org/10.1038/s41598-019-54391-9>: 11 pp. (in English) ["Phylogenetic relationships of basal insects remain a matter of discussion. In particular, the relationships among Ephemeroptera, Odonata and Neoptera are the focus of debate. In this study, we used a next-generation sequencing approach to reconstruct new mitochondrial genomes (mitogenomes) from 18 species of basal insects, including six representatives of Ephemeroptera and 11 of Odonata, plus one species belonging to Zygentoma. We then compared the structures of the newly sequenced mitogenomes. A tRNA gene cluster of IMQM was found in three ephemeropteran species, which may serve as a potential synapomorphy for the family Heptageniidae. Combined with published insect mitogenome sequences, we constructed a data matrix with all 37 mitochondrial genes of 85 taxa, which had a sampling concentrating on the palaeopteran lineages. Phylogenetic analyses were performed based on various data coding schemes, using maximum likelihood and Bayesian inferences under different models of sequence evolution. Our results generally recovered Zygentoma as a monophyletic group, which formed a sister group to Pterygota. This confirmed the relatively primitive position of Zygentoma to Ephemeroptera, Odonata and Neoptera. Analyses using site-heterogeneous CAT-GTR model strongly supported the Palaeoptera clade, with the monophyletic Ephemeroptera being sister to the monophyletic Odonata. In addition, a sister group relationship between Palaeoptera and Neoptera was supported by the current mitogenomic data." (Authors)] Address: Song, N., College of Plant Protection, Henan Agri. **17857.** Strobl, K.; Moning, C.; Kollmann, J. (2019): Positive trends in plant, dragonfly and butterfly diversity of rewetted montane peatlands. *Restoration Ecology* doi: 10.1111/rec.-12957. 11 pp, 7 pp suppl. mat. (in English) ["Drainage and afforestation of peatlands cause extensive habitat degradation and species losses. Restoration supports peatland biodiversity by creating suitable habitat conditions, including stable high water tables. However, colonization by characteristic species can take decades or even fail. Peatland recovery is monitored shortly after restoration, but initial trends may not continue, and results might differ among taxonomic groups. This study analyzes trends in plant, dragonfly, and butterfly diversity within 18 years after rewetting of montane peatlands in central Germany. We compared diversity and species composition of 19 restored sites with three drained peatlands and one near-natural reference site. Restoration resulted in improved habitat conditions and benefited species diversity, but there were marked differences among taxonomic groups. Dragonflies rapidly colonized small water bodies but their diversity did not further increase in older restoration sites. Characteristic peatland vegetation recovered slowly, since it depended on a high water holding capacity that was only reached after peat started accumulating. Generally, plant diversity developed towards reference conditions albeit incompletely, even 18 years after restoration. Butterflies responded less to peatland restoration; generalists increased only temporarily and specialists could not establish. In conclusion, peatland restoration improves habitat conditions and biodiversity, while trajectories of recovery are nonlinear and incomplete after two decades. This highlights the need of long-term monitoring and a strategic selection of indicator species for evaluation of restoration success." (Authors)] Address: Strobl, Katharina, Chair of Restoration Ecology, Technical University of Munich, Emil-Ramann-Str. 6, 85354 Freising, Germany. E-mail: katharina.strobl@tum.de

**17858.** Sugiman, U.; Romdhoni, H.; Putera, A.K.A.; Robo, R.J.; Oktavia, F.; Raffudin, R. (2019): Oviposition behaviour and oviposition site selection in *Pseudagrion pruinsum* (Burmeister) (Odonata: Coenagrionidae). *Jurnal Entomologi Indonesia* 16(1): 29-40. (in Indonesian, with English summary) ["*Pseudagrion pruinsum* (Burmeister) is a common damselfly that is widely distributed in Southeast Asia. However, information related to the oviposition behavior and habitat is still limited. This study was aimed to determine the behavior of *P. pruinsum* when laying eggs and characterized the oviposition habitat. This research used focal sampling method to observe oviposition behavior and measure habitat parameters on egg-laying location. Results

showed, there was mate guarding when *P. pruinatum* females lay eggs. The male forms a tandem formation (contact mate guarding), then released the female and keep a guarding behavior around the female (non-contact mate guarding). Eggs were placed by the female on plant tissue with the technique of positioning the body to remain on the surface and then submerged. There is no tendency of *P. pruinatum* behavior towards one type or technique. Based on the results of principal component analysis, 75.8% of habitat components can be described for egg-laying habitat. Air temperature, pH, light intensity, and heterogeneity of vegetation positively correlated with the occurrence of egg-laying while TDS, humidity, water depth, and water temperature were negatively correlated. The results of this study concluded that the characteristics of egg-laying techniques included, i.e contact and non-contact mate guarding by the males and females putting eggs on the surface then submerged into water." Doctoral thesis, Department of Physiology, Development, and Neuroscience, University of Cambridge: 198 pp. (in English) ["The control of behaviour in all animals requires efficient transformation of sensory signals into the task-specific activation of muscles. Predation offers an advantageous model behaviour to study the computational organisation underlying sensorimotor control. Predators are optimised through diverse evolutionary arms races to outperform their prey in terms of sensorimotor coordination, leading to highly specialised anatomical adaptations and hunting behaviours, which are often innate and highly stereotyped. Predatory flying insects present an extreme example, performing complex visually-guided pursuits of small, often fast flying prey over extremely small timescales. Furthermore, this behaviour is controlled by a tiny nervous system, leading to pressure on neuronal organisation to be optimised for coding efficiency. In dragonflies, a population of eight pairs of bilaterally symmetric Target Selective Descending Neurons (TSDNs) relay visual information about small moving objects from the brain to the thoracic motor centres. These neurons encode the movement of small moving objects across the dorsal fovea region of the eye which is fixated on prey during predatory pursuit, and are thought to constitute the commands necessary for actuating an interception flight path. TSDNs are characterised by their receptive fields, with responses of each TSDN type spatially confined to a specific portion of the dorsal fovea visual field and tuned to a specific direction of object motion. To date, little is known about the descending representations mediating target tracking in other insects. This dissertation presents a comparative report of descending neurons in a variety of flying insects. The results are organised into three chapters: Chapter 3 identifies TSDNs in damselflies and compares their response properties to those previously described in dragon-

flies. Demoiselle TSDNs are also found to integrate binocular information, which is further elaborated with prism and eyepatch experiments. Chapter 4 describes TSDNs in two dipteran species, the robberfly *Holcocephala fusca* and the killerfly *Coenosia attenuata*. Chapter 5 describes an interaction between small- and wide-field visual features in TSDNs of both predatory and nonpredatory dipterans, finding functional similarity of these neurons for prey capture and conspecific pursuit. Dipteran TSDN responses are repressed by background motion in a direction dependent manner, suggesting a control architecture in which target tracking and optomotor stabilization pathways operate in parallel during pursuit." **17860.** Svensson, E.I. (2019): Eco-evolutionary dynamics of sexual selection and sexual conflict. *Functional Ecology* 33: 60-72. (in English) ["1. The research framework of eco-evolutionary dynamics is increasing in popularity, as revealed by a steady stream of review articles and a recent and influential book, but primary empirical research is lagging behind. Moreover, the few empirical case studies demonstrating eco-evolutionary dynamics might not be entirely representative. 2. Much current research on eco-evolutionary dynamics is focused on how ecological interactions lead to natural selection on phenotypic traits ("eco-evo"), and in turn how the evolutionary change in such traits feed back on ecological dynamics ("evo-eco"). A key feature of eco-evolutionary dynamics is thus a feedback loop between ecology (e.g., population dynamics) and evolution (i.e., genetic change). 3. In contrast to previous research on eco-evolutionary dynamics driven by natural selection, the role of eco-evolutionary feedbacks in sexual selection and sexual conflict is largely unknown. Here, I review theory and the limited empirical evidence in this area and identify some promising future lines of research. 4. I update a past review on contemporary evolution of secondary sexual traits in natural populations and formulate six explicit and rigorous criteria for contemporary evolution of secondary sexual traits by natural or sexual selection or sexual conflict. I then discuss the other key prediction of eco-evolutionary dynamics (i.e., evolution by sexual selection or sexual conflict shapes ecological dynamics). My overview reveals that our current knowledge in this area is limited and mainly come from theoretical models and laboratory experiments. 5. A major challenge in eco-evolutionary dynamics is therefore to link ecological and population dynamics with sexual selection and sexual conflict. This is not an easy task but might be possible with carefully chosen study systems and methods." References to *Ischnura elegans* are made. **17861.** Takahashi, Y.; Noriyuki, S. (2019): Colour polymorphism influences species' range and extinction risk. *Biology letters* 15(7): 5 pp. (in English) ["Polymorphisms in a population are expected to increase the growth rate and the sta-

bility of the population, leading to the expansion of geographical distribution and mitigation of extinction risk of a species. However, the generality of such ecological consequences of colour polymorphism remains uncertain. Here, via a comparative approach, we assessed whether colour polymorphisms influence climatic niche breadth and extinction risk in some groups of damselflies, butterflies and vertebrates. The climatic niche breadth was greater, and extinction risk was lower in polymorphic species than in monomorphic species in all taxa analysed. The results suggest that colour polymorphism facilitates range expansion and species persistence." (Authors)] Address: Takahashi, Y., Graduate School of Science, Chiba University, Chiba, Japan. E-mail: takahashi.yum@gmail.com

**17862.** Thompson, A. (2019): The life history of *Anax junius* (Drury) in Minnesota: Determining instars, growth development pathways, emergence phenology, and the effect of temperature on development (Odonata: Aeshnidae). Ph.D. thesis, University of Minnesota: 135 pp. (in English) ["... the study of dragonflies and damselflies, is presently at a delightful stage of maturity. The basics of odonate life history are well understood but the details of how different species express variations in their development and reproduction, in response to different evolutionary drivers, is ripe for exploration. These variations can only be discovered through field observations executed with thoughtful experimental design and then the observational data collected must be interpreted with appropriate statistical and analytical tools. For a naturalist with a patient and inquisitive mind this kind of research is exceptionally rewarding. Chapters 1, 2, and 3 focus on these goals. Observational data on *A. junius* growth and emergence were collected over a period of two years at Crow-Hassan Park Reserve, near Minneapolis, Minnesota. Severe winter conditions are the largest constraint influencing dragonfly life histories in Minnesota. Odonata must both survive the winter, and time their emergence and reproduction so that they occur during the short growing season. This research was designed to explore how northern *A. junius* have adapted to survive winter. Chapter 1 demonstrates the application of a statistical tool that identifies the number of instars in a field-collected sample of nymphs: a need for interpreting observed growth and development data. This mixed distribution analysis has been used in other fields of entomology, but this is the first time (to the author's knowledge) that it has been applied to dragonflies. Chapter 2 maps nymph growth over time and identifies different *A. junius* growth pathways that are associated with two different overwintering strategies. Chapter 3 summarizes observations of *A. junius* emergence phenology via exhaustive exuviae collection, and reveals that cold temperatures and stochastic events are the greatest constraints on emergence duration. Northern ectoderms, like dragonflies, with life histories that are constrained by severe winters are impacted by climate change. The implications of the changing climate on dragonfly natural history are of increasing conservation interest. Rare and threatened niche species of Odonata could be at risk of extinction if their habitat conditions are altered beyond to what they can adapt to.

However, *A. junius* is a common and abundant dragonfly and is of conservation interest for different reasons. Extremely common species are the skeletons of ecosystems; they make up most of the biomass and provide structure and support for all the other components. A change in the geography or abundance of *A. junius* could have wide-ranging and cascading effects. Models based on known temperature thresholds are required to predict ectoderm response to the changing climate. Chapter 4 describes an experiment that defined these threshold temperatures for the northern winter growth pathway of *A. junius*. Development duration and rate were measured for nymphs reared in different temperature-controlled chambers, and the base and optimum growth temperatures were calculated for the last two nymph development stages. These values can now be used in models to predict the impact of climate change on the phenology of *A. junius* development and emergence. Note: Some materials and methods descriptions, figures, and tables are repeated in this dissertation because each chapter was written with the intent to be published individually." **17863.** Toussaint, E.F.A.; Bybee, S.M.; Erickson, R.J.; Condamine, F.L. (2019): Forest giants on different evolutionary branches: Ecomorphological convergence in helicopter damselflies. *Evolution* 73(5): 1045-1054. (in English) ["The convergent evolution of analogous features is an evolutionary process occurring independently across the tree of life. From the evolution of echolocation, prehensile tail, viviparity, or winged flight, environmental factors often drive this astonishing phenomenon. However, convergent evolution is not always conspicuous or easily identified. Giant damselflies count among the largest flying insects on Earth, and have astonishing ecologies including orb-web spider plucking and oviposition in phytotelmata. One species occurs in the Afrotropics and 18 species are found in the Neotropics. Convergent evolution was historically hypothesized based on the ecological and morphological affinities of these two geographically distant lineages but was not supported by earlier phylogenetic inferences supporting their monophyly. Using a molecular supermatrix approach and a large selection of outgroups, we revisit and reject the monophyly of Afrotropical and Neotropical giant damselflies that is otherwise supported by a morphological phylogeny. Molecular divergence time estimation suggests an origin of Afrotropical giant damselflies in the late Paleogene, and of Neotropical ones at the Cretaceous/Paleogene boundary, thereby rejecting a long-standing West Gondwana vicariance hypothesis. The strong ecological and morphological resemblances between these two independent lineages represents an astonishing case of Amphi-Atlantic tropical convergent evolution." **17864.** Veras, D.S.; Castro, E.R.; Lustosa, G.S.; de Azevêdo, C.A.S.; Juen, L. (2019): Evaluating the habitat integrity index as a potential surrogate for monitoring the water quality of streams in the cerrado-caatinga ecotone in

northern Brazil. *Environ. Monit. Assess.* 191:562: 9 pp. (in English) ["Human activities have long been altering the natural conditions of streams, including the quality of their water, throughout most of Brazil. This problem is even worse in regions with low rainfall levels, such as the Brazilian Northeast, where water quality needs to be monitored more carefully. In this context, the present study investigated the effects of environmental integrity on the physicochemical characteristics of the streams of the basin of the Itapecuru River in northeastern Brazil. We tested the hypothesis that streams with lower habitat integrity would have higher conductivity, pH, and temperature, due to the reduced input of allochthonous organic matter and the greater washout of sediments to the stream bed. A total of 15 streams, of a sedimentary basin, were evaluated in the municipality of Caxias, in the Brazilian state of Maranhão, between June 2015, and July 2016; each stream was sampled once a month during the drought period in the region, where physicochemical measurements were taken to determine the environmental integrity of the stream through the application of a habitat integrity index. Streams with greater habitat integrity had lower conductivity, pH, and temperature and had higher discharge rates. The index proved to be not an effective tool for the evaluation of water quality, but was found to be important for the management of hydrographic basins by indicating important changes in environmental variables. In this case, the index can be used primarily for the management of hydrographic basins, given that it can be applied straightforwardly, it can be interpreted easily by decision-makers, and it can quantify alterations to the structure of the system with precision." **17865.** Verheyen, J.; Delnat, V.; Stoks, R. (2019): Increased daily temperature fluctuations overrule the ability of gradual thermal evolution to offset the increased pesticide toxicity under global warming. *Environ. Sci. Technol.* 53(8): 4600-4608. (in English) ["The widespread evidence that global warming can increase species sensitivities to chemical toxicants, and vice versa, and the recent insight that thermal evolution may mitigate these effects is crucial to predict the future impact of toxicants in a warming world. Nevertheless, a major component of global warming, the predicted increase in daily temperature fluctuations (DTFs), has been ignored at the interface of evolutionary ecotoxicology and global change biology. We studied whether a 4 °C warming and a 5 °C DTF increase (to 10 °C DTF) magnified the negative impact of the insecticide chlorpyrifos (CPF) in larvae of low- and high-latitude populations of the damselfly *Ischnura elegans*. While 4 °C warming only increased CPF-induced mortality in high-latitude larvae, the high (10 °C) DTF increased CPF-induced larval mortality at both latitudes. CPF reduced the heat tolerance; however, this was buffered by latitude-specific thermal adaptation to both mean temperature and DTF. Integrating our results in a space-for-time substitution indicated that gradual thermal evolution in high-latitude larvae may offset the negative effects of CPF on heat tolerance under warming, unless the

expected DTF increase is taken into account. Our results highlight the crucial importance of jointly integrating DTFs and thermal evolution to improve risk assessment of toxicants under global warming." **17866.** Verheyen, J.; Stoks, R. (2019): Current and future daily temperature fluctuations make a pesticide more toxic: Contrasting effects on life history and physiology? *Environmental Pollution* 248: 209-218. (in English) ["Highlights: • Daily temperature fluctuations (DTFs) increased chlorpyrifos toxicity. • Chlorpyrifos only induced mortality and reduced growth rate in the presence of DTFs. • Chlorpyrifos did not affect life history when the temperature was kept constant. • Current and future DTF increased toxicity to the same extent. Abstract: There is increasing concern that climate change may make organisms more sensitive to chemical pollution. Many pesticides are indeed more toxic at higher mean temperatures. Yet, we know next to nothing about the effect of another key component of climate change, the increase of daily temperature fluctuations (DTFs), on pesticide toxicity. Therefore, we tested the effect of the pesticide chlorpyrifos under different levels of DTF (constant=0°C, low=5°C (current maximum level) and high=10°C (predicted maximum level under global warming)) around the same mean temperature on key life history and physiological traits of *Ischnura elegans* damselfly larvae in a common-garden experiment. At all levels of DTF, chlorpyrifos exposure was stressful: it reduced energy storage (fat content) and the activity of its target enzyme acetylcholinesterase, while it increased the activity of the detoxification enzyme cytochrome P450 monooxygenase. Notably, chlorpyrifos did not cause mortality or reduced growth rate at the constant temperature (0°C DTF), yet increased mortality 6x and reduced growth rate with ca. 115% in the presence of DTF. This indicates that daily short-term exposures to higher temperatures can increase pesticide toxicity. Our data suggest that when 5°C DTF will become more common in the studied high-latitude populations, this will increase the toxicity of CPF, and that a further increase from 5° DTF to 10°C DTF may not result in a further increase of pesticide toxicity. Our results highlight the biological importance of including daily temperature fluctuations in ecological risk assessment of pesticides and as an extra dimension in the climate-induced toxicant sensitivity concept." **17867.** Verheyen, J.; Stoks, R. (2019): Shrinking body size and physiology contribute to geographic variation and the higher toxicity of pesticides in a warming world. *Environ. Sci. Technol.* 53, 19: 11515-11523. (in English) ["To improve current and future risk assessment of pesticides under global warming, mechanistic insights and consideration of daily temperature fluctuations (DTFs) are needed. One overlooked mechanism how both higher mean temperatures and DTFs

may increase toxicity is by reducing body size (temperature-size-rule). We studied whether a higher mean temperature and DTF magnified chlorpyrifos toxicity in *Ischnura elegans* damselfly larvae, and whether this was mediated by temperature-induced reductions in body size and/or physiological changes. The lethal effects of chlorpyrifos were magnified at the high mean temperature (up to ~15 %) and under DTF (up to ~33 %), and especially at their combination (up to ~46 %) indicating synergisms. This highlights that not only considering DTFs, but also their interaction with higher mean temperatures is pivotal for realistic predictions of pesticide toxicity. Both higher temperatures and DTFs resulted in smaller larvae, which were more sensitive to chlorpyrifos. Notably, the DTF-induced smaller body sizes, as well as the higher oxidative damage to lipids, contributed to the higher chlorpyrifos toxicity under DTF. By integrating the temperature-size rule and size-pesticide sensitivity pattern we provide proof-of-principle for a novel, likely general mechanism contributing to geographic variation and the higher toxicity of pesticides in a warming world." **17869.** Walia, G.K.; Dhillon, G.K. (2019): Mitochondrial COI gene barcoding four species of genus *Ischnura* (Odonata: Coenagrionidae) from India. J. Adv. Zool. 40(1): 69-77. (in English) ["Taxonomically, identification of complex taxa based on external morphological characters may leads to wrong identification of unknown organism at species level because these characters may also be altered due to geographical and seasonal variations. To overcome this molecular taxonomy has been emerged. In India, out of 9 morphologically described species of genus *Ischnura* (Odonata: Coenagrionidae), *Ischnura senegalensis* is the only species, which has been barcoded on the basis of COI gene. During the present study, mitochondrial COI gene has been barcoded for four species of genus *Ischnura* (*I. aurora*, *I. forcipata*, *I. rufostigma* and *I. senegalensis*), collected from fresh water bodies from the states of Punjab and Himachal Pradesh (India). Across the final alignment of COI sequences of 352bp, there are 282 conserved sites (80.1%), which represents that COI gene is highly conserved. Conspecific species show <1% divergence range (0% to 0.6%) and interspecific divergence ranges from 7.5% to 15.6%. COI gene sequences of all the species shows 95 – 100% similarity with the sequences of conspecific species deposited in GeneBank. Mitochondrial COI gene based DNA barcoding has been done for *I. aurora*, *I. forcipata* and *I. rufostigma* for the

first time from India and for *I. forcipata* throughout the world." (Authors)] Address: Walia, G.K., Dept of Zoology and Environmental sciences, Punjabi University, Patiala-147 002, Punjab, India. Email: gurinderkaur\_walia@yahoo.co.in

**17872.** Willink, B.; Duryea, M.C.; Svensson, E.I. (2019): Macroevolutionary origin and adaptive function of a polymorphic female signal involved in sexual conflict. The American Naturalist 194(5): 707-724. (in English) ["Intersexual signals that reveal developmental or mating status in females have evolved repeatedly in many animal lineages. Such signals have functions in sexual conflict over mating and can therefore influence sexually antagonistic coevolution.

However, we know little about how female signal development modifies male mating harassment and thereby sexual conflict. Here, we combine phylogenetic comparative analyses of a color polymorphic damselfly genus (*Ischnura*) with behavioral experiments in one target species to investigate the evolutionary origin and current adaptive function of a developmental female color signal. Many *Ischnura* species have multiple female color morphs, which include a male-colored morph (male mimics) and one or two female morphs that differ markedly from males (heterochrome females). In *Ischnura elegans*, males and male-mimicking females express a blue abdominal patch throughout post-mergence life. Using phenotypic manipulations, we show that the developmental expression of this signaling trait in heterochrome females reduces pre-mating harassment prior to sexual maturity. Across species this signal evolved repeatedly, but in heterochrome females its origin is contingent on the signal expressed by co-occurring male-mimicking females. Our results suggest that the co-option of a male-like trait to a novel female antiharassment function plays a key role in sexual conflict driven by pre-mating interactions." **17874.** Xue, J.; Zhang, H.; Ning, X.; Bu, W.; Yu, X. (2019): Evolutionary history of a beautiful damselfly, *Matrona basilaris*, revealed by phylogeographic analyses: the first study of an odonate species in mainland China. *Heredity* 122: 570–581. (in English) [„*M. basilaris* is distributed mainly in mainland China. A total of 423 individuals from 48 populations covering almost the entire range were sampled to explore the genetic diversity, phylogeographic structure, and demographic dynamics of the species using sequences of three mitochondrial genes (COI, COII, and ND1) and a nuclear (ITS1 + 5.8 S + ITS2) gene. Phylogenetic tree, median-joining network, and BAPS analyses indicated a four-group division of the entire population, and the divergence

event was estimated to have occurred in the middle Pleistocene. The diverse terrain of mainland China as well as past climatic oscillations were assumed to have shaped the current phylogeographic pattern of *M. basilaris*. Multiple lines of evidence supported population expansion in Group 1 and Group 2 but not in Group 3 or Group 4. The expansion times corresponded to the transition phase from the LIG (~0.14–0.12 Mya) to the LGM (~0.021–0.018 Mya). The pre-LGM expansion model reflected a different pattern affecting the historical dynamics of the population of East Asian species caused by Pleistocene climatic changes. Interestingly, Group 2 exhibited a disjunctive distribution pattern. The possible reasons were introgression caused by female-biased dispersal or human phoresy during construction of the Forbidden City during the Ming Dynasty of China." **17878.** Lu, S.; Qiu, R.; Hu, J.; Li, X.; Chen, Y.; Zhang, X.; Cao, C.; Shi, H.; Xie, B.; Wu, W.-M.; He, D. (2020): Prevalence of microplastics in animal-based traditional medicinal materials: Widespread pollution in terrestrial environments. *Science of The Total Environment* 709, 20 March 2020, 136214: 9 pp. (in English) ["Highlights: • 20 types of animal medicinal materials and 10 types of fresh animals were collected in China. • Microplastics (MPs) were found in all medicinal materials with average incidence rate of 94.67%. • The abundance of MPs was in the range of  $1.80 \pm 0.38$  to  $7.80 \pm 0.83$  items/individual. • Major MPs were microfibers (84.68%), or PET (40.45%), Rayon (30.64%) and PE (10.11%). • MPs show similar characteristics between medicinal materials and fresh animals. Abstract: Microplastics (MPs) pollution is an emerging environmental and health concern. MPs have been extensively observed in the aquatic environment, yet rarely investigated in the terrestrial ecosystem, especially in relation to health risks. To evaluate potential MPs pollution in land-dwelling animal medicine materials, we collected 20 types of small animal-based medicinal materials and 10 types of available fresh terrestrial animals from eight different regions in China. MPs were found in all medicinal materials with an average incidence rate of 94.67%. The abundance of MPs was in the range of  $1.80 \pm 0.38$  to  $7.80 \pm 0.83$  items/individual or  $1.59 \pm 0.33$  to  $43.56 \pm 9.22$  items/g (dry weight), with polymer distribution by polyethylene terephthalate (40.45%), rayon (30.64%), polyethylene (10.11%), nylon (7.35%), polypropylene (5.93%), and polyvinyl chloride (5.52%). The majority of MPs were microfibers (84.68%), with 15.32% of fragments. Moreover, MPs were directly observed in the intestine, detected in all ten types of fresh medicinal animals with the abundance of  $0.83 \pm 0.35$  to  $3.42 \pm 0.46$  items/individual. Furthermore, significant positive correlations ( $R: 0.32-0.99$ ,  $p < 0.05$ ) of MPs characteristics were found between medicinal materials and fresh animals, including shape, size, color, and polymer distribution of MPs. The results support that MPs in the medicinal materials were likely derived from living animals. This study demonstrates the prevalence of MPs in animal-based, traditional medicinal materials, and also suggests widespread MPs pollution in terrestrial environments and latent health risks." **17879.** Lupiyaningdyah, P. (2020): The past, present and future of dragonfly research in Indonesia. *BIO Web Conf.* 19(00024): 4 pp. (in English) ["Up to present, Indonesia has 900 described species of dragonflies with around 70% are endemic; among them, the most diverse is in Papua. This data is collected based on 356 publications from scientific journals, bulletins, magazines, books, theses, and proceedings from 1773 to 2019. There is still a lack of information about what is the most and least popular topics and where is the most explored regions in Indonesia for Odonata research. I categorized the topics into biodiversity, taxonomy and systematics, biogeography, conservation, ecology, education, ethnozoology, history, and molecular. The result shows that the most popular topic is biodiversity by 139 publications and the least are history and molecular by only one publication. Most popular group to be observed is dragonflies in general (both suborders) by 200 publications and the least observed is Anisoptera by only 71 publications. Java is the most explored island for about 160 publications in 250 years." (in German, with English summary) ["Dragonfly records in the city of Braunschweig between 1980 and 2018 were evaluated to provide an overview of the distribution and changes in the population of dragonfly species that are particularly protected by the Habitats Directive (FFH-species). Five FFH-species occurred: *Coenagrion mercuriale*, *Leucorrhinia albifrons*, *L. caudalis*, *L. pectoralis*, and *Ophiogomphus cecilia*. Two of these, *L. pectoralis* and *O. cecilia*, were recorded since the late 1980s and early 1990s, respectively, and have native populations. In the case of *O. cecilia*, there was a significant increase in grid cells occupied during the investigation period. In recent years, *C. mercuriale* and *L. caudalis* were observed. *Leucorrhinia albifrons* was observed only once in 2007. The four established or possibly established species are characteristic for four different types of freshwater habitats and thus possible target species for nature conservation. In this work, we report on the development of the occurrences over a period of four decades and we provide information on possible actions to protect and promote these populations." (2020): Diet of *Glossogobius callidus* (Teleostei: Gobiidae) in freshwater impoundments in the Sundays River Valley of the Eastern Cape, South Africa. *African Journal of Aquatic Science* 44(4): 415-420. (in English) ["Despite the high abundance of the gobiid fish *Glossogobius callidus* in many freshwater ecosystems in South Africa, very few studies have assessed the biology and ecology of the species. Here, we investigated the diet of *G. callidus* populations sourced from Sundays River irrigation ponds. A total of 571 fish grouped into two size classes (TL, range  $\pm$  SD: juveniles of 20–60  $\pm$  45 mm; adults of 61–140  $\pm$  85 mm) were sampled by seine netting; prey items were removed from the guts and identified and sorted to obtain dietary information for each prey group. Of the examined guts, 97% contained prey comprising 17 taxa within 10 taxonomic groups. Teleosts were identified to species level, whereas most dietary components were identified to a broad taxonomic group. Aquatic invertebrates were the most important

component of the diet of *G. callidus*, but the index of relative importance (%IRI) of dominant invertebrate taxa varied according to ontogenetic stage of *G. callidus* and season. Prey taxa included: Diptera, Hemiptera, Trichoptera, Odonata, Cladocera, Copepoda, Hydracarina, Amphipoda, Mollusca and Teleostei. Dipteran prey taxa were consistently encountered in both size classes and across all seasons. *G. callidus* can therefore be regarded as a generalist invertivore." **17887.** Nicolai, B. (2020): Libellen am Leth (Nordharzvorland, Sachsen-Anhalt) im Klimawandel Hotspot der Odonatenfauna und sein schnelles Ende. *Abh. Ber. Mus. Heineanum* 12: 91-115. (in German, with English summary) ["The Leth is a small isolated subsurface lake in the arable landscape of the north-eastern Harz foreland. From 2016 to 2020, the Odonatenfauna was recorded there over 33 days and a total of 31 dragonfly species (12 Zygoptera, 19 Anisoptera) were detected. For 20 species there were indications of reproduction at the lake. Seven species were identified

as once only guests. A number of heat-loving, southern species are to be highlighted. These species include *Lestes barbarus*, *Aeshna affinis*, *Crocothemis erythraea* and *Sympetrum meridionale*, which were down-to-earth during the observation period at the Leth. Two species (*Lestes sponsa*, *Coenagrion lunulatum*), which Handtke (1966, 1968) identified at this location, could not be detected. The hot summers and lack of rainfall in recent years led to the very shallow lake completely drying out in 2020. Due to the general climate development, no temporary water surface is expected in the near future. The Leth thus seems to be lost as a dragonfly hotspot in the northern Harz foreland for an unforeseeable time." (Author)] Address: Nicolai, B., Herbingstr. 20, 38820 Halberstadt, Germany. **17888.** Nidup, T.; Tamang, D.T.; Tobgay, S.; Bajgai, R.C.; Wangmo, S.; Dorji, T.; Wangchuk, K. (2020): Abundance and distribution of threatened *Epiophlebia laidlawi* Tillyard, 1921 (Odonata: Epiophlebiidae) in eastern Bhutan. *Sherub Doenme: The Research Journal of Sherubtse College* 13(1): 79-89. (in English) ["With series of macro-invertebrate studies, *Epiophlebia laidlawi* Tillyard, 1921 is recorded from Trashigang (Gomchu stream) and Trashi Yangtse (Gellingchu, Mangchi and Chuthakang), districts in eastern Bhutan. Its abundance is higher in post-monsoon season. The pH of the water from Gom-chu stream ranged from 6.63-7.50, electrical conductivity from 18.02-241  $\mu\text{S}/\text{cm}$ , total dissolved solids from 11.21-121.66 mg/l, turbidity from 0-2 NTU and water temperature from 8.5-16.3°C. The abundance of the *E. laidlawi* is negatively correlated to water temperature ( $r=-0.650$ ,  $p=0.058$ ) and positively correlated to altitude ( $r=0.496$ ,  $p=0.174$ ) and turbidity ( $r=0.381$ ,  $p=0.312$ ). Six stages of nymphs are measured and reported. The nymph of Gomphidae is the only Odonata nymph found associated with the habitat of *E. laidlawi*. The fish species, *Creteuchiloglanis bumdelingensis* Thoni & Gurung, 2018 is reported from the habitat of *E. laidlawi* and is the additional new locality for the fish in Bhutan. As *E. laidlawi* is Near Threatened, it deserves to be protected through policies and laws of Bhutan. Due to anthropogenic pressure its habitats are disturbed and thus, intervention is required from the policy makers on the conservation of the habitats." **17898.** Osuala, F.I.; Abiodun, O.A.; Oyeleke, B.G.; Humphrey, O.F. (2020): Biodiversity of fauna and heavy metal assessment in selected areas of University of Lagos Akoka Campus, Lagos, Nigeria. *Ife Journal of Science* 22(2): 159-173. (in English) ["The biodiversity of terrestrial fauna and assessment of some heavy metals - cadmium (Cd), chromium (Cr), cobalt (Co), lead (Pb), nickel (Ni) and manganese

(Mn) concentrations in soil samples were investigated in selected areas of the University of Lagos Akoka campus. Atomic Absorption Spectrophotometer (AAS) was used for heavy metals analysis and biodiversity index was calculated with Margalef, Shannon-Weiner and Simpson index. On the basis of the Shannon-Weiner index, Zoological garden had the highest species richness (2.75) while High-Rise (1.71) had the lowest species diversity. On the basis of the Simpson index (1-D), Faculty of Science had the highest species diversity (0.95) while High-Rise had the lowest diversity (0.75). Formicidae (21.60%), Gecarcinidae (13.77%) and Libellulidae (13.51%) were the families with the highest relative abundance in the University of Lagos while Cercopithecidae (0.26%), Elapidae (0.34%) and Gryllidae (0.34%) were the families with least relative abundance. The result of the soil texture (particle size) of the various sampled zones indicated that sand is the dominant component with a mix of loam. Heavy metal mean concentrations of the soil samples from the University of Lagos indicated the presence of Pb (0.17 - 29.67 mg/kg), Ni (0.59 - 6.63 mg/kg), Mn (72.72 - 398.63 mg/kg), Cr (0.01 - 16.23 mg/kg), Cd (0.20 - 0.87 mg/kg) and Co (0.17 - 6.52 mg/kg). All heavy metals detected were below Federal Ministry of Environment (FMEnv) and European Union (EU) permissible limit for heavy metals in soils except Mn. Though, Mn is biologically important with low toxicity, there is need for consistent monitoring of the heavy metals so as not to pose a threat to the biodiversity of the study area." (Authors)] Address: Osuala, F.I., Dept of Zoology, Fac. of Science, University of Lagos, P.M.B. 101017, Lagos, Nigeria. E-mail: fphilosu@yahoo.com

**17901.** Pattanayak, A., Kumari, M., Pahari, P.R., & Deen, S.N.P.Y. (2020): Aquatic insects (Odonata) diversity in floating and emergent macrophytes in Saheed Matangini Block (Tamluk), West Bengal (India). Uttar Pradesh Journal of Zoology 41(13): 27-33. (in English) ["Geographical zone-wise biodiversity study of different species is of paramount importance to monitor and conserve the species diversity in an ecosystem. The objective of present study was to make a diversity database of macrophyte associated aquatic insects in Purba Medinipur, West Bengal, India. The aquatic insects were collected from aquatic macrophytes, Ipomoea aquatica, Eichhornia crassipes and Nelumbo nucifera grown in 6 water bodies of Sahid Matangigi Block (Tamluk, 22.3°N 87.92°E), Purba Medinipur, West Bengal, India. The results revealed that occurrences of 6 aquatic insect orders (Coleoptera, Hemiptera, Odonata, Diptera, Ephemeroptera and Trichoptera) in Ipomoea aquatica with maximum abundance of 3 odonate families (Libellulidae, Coenagrionidae and Platynemididae). The present biodiversity study of aquatic insects indicate that Odonata especially prefer floating macrophyte as a favourable habitat and therefore higher species diversity therein. Further study is needed considering other aquatic macrophytes in this concern to develop a valid species specific database essential for biodiversity conservation in the rapidly changing present environment." (Authors)] Address: Department of Zoology, Magadh University, Bodh-Gaya, Gaya-824234, Bihar, India

**17902.** Pavithran, S.; Chitra, N.; Arulprakash, R.; Sugumaran, M.P. (2020): Diversity of Odonata in the rice fields of Tamil Nadu. Journal of Entomology and Zoology Studies 8(5): 2115-2118. (in English) ["Odonata is one of the most predominant natural enemy of the rice ecosystems and their diversity in rice fields from different parts of Tamil Nadu viz., Coimbatore, Aduthurai, Pudukkottai, Ramanathapuram, Bhavanisagar and Gudalur was studied. The Odonata assemblage comprised 21 species under 19 genera under 4 families. Anisoptera were dominant with 15 species and 14 genera over Zygoptera (6 species, 5 genera). Libellulidae was the most speciose family with 14 species followed by Coenagrionidae with 5 species. Diversity analysis of Odonata from rice fields of Tamil Nadu revealed that the order of Simpson Diversity index (SID) of diversity was Coimbatore (0.89) > Bhavanisagar (0.88) > Aduthurai (0.87) > Ramanathapuram (0.87) > Gudalur (0.84) > Pudukkottai (0.82). Margalef index ( $\hat{a}$ ) of species richness were high in Coimbatore (2.33) and least in Gudalur (1.55). Evenness of species within the region (Pielou's evenness index, E1) was the highest for Bhavanisagar (0.94) and the lowest for Aduthurai (0.84). Among the different regions, Odonata in rice fields of the Coimbatore and Aduthurai were found to have a maximum similarity." (2020): Target species affects the duration of competitive interactions in the Neotropical dragonfly, *Micrathyrina atra* (Odonata: Libellulidae). Notulae odonatologicae 9(5): 173-177. (in English) ["Dragonflies often engage in aggressive interactions over access to mates, food, or other resources. We should expect species to have behavioral adaptations for minimizing such interactions with other species because they are not competing with them for mates and often require different resources. We conducted observational trials in natural water pools that provide new evidence for one such adaptation in the Neotropical *Micrathyrina atra*-males in this species have shorter interactions with

individuals of other species than with conspecifics." (Authors)] Address: Peniston, J.H., Dept of Biology, University of Florida, Gainesville, FL, USA. E-mail: jimmpen@ufl.edu

**17907.** Perez, E.S.N.; Bautista, M.G. (2020): Dragonflies in the City: Diversity of Odonates in Urban Davao, Philippines. *Journal of Agricultural Science and Technology A* 10: 12-19. (in English) ["Dragonflies are well-known group of insects because of their biological and ecological importance in a community, that is, they indicate the environmental health of an ecosystem. However, in an urban ecosystem, there are many threats that can affect the assemblages of dragonfly species such as the intensification of urbanization which contributes biodiversity loss of most dragonfly species. This study aimed to identify dragonfly species and determine the species richness, relative abundance, species diversity, evenness and effective number of dragonflies in selected areas in Davao City. Opportunistic sampling using sweep net and photo documentation were used during the study. The sampling lasted for three months from June 2017 to August 2017. A total of 962 individuals of dragonflies were observed and recorded comprising of six species of dragonflies from six different genera of one family. *Orthetrum sabina* was the most abundant among the six species recorded in all sampling sites. The species richness was six. Low species diversity was obtained in all sampling which shows that the sites were not evenly distributed and indicating that the study sites were not diverse in terms of the number of species and highly disturbed." **17908.** Perron, M.A.C.; Pick, F.R. (2020): Stormwater ponds as habitat for Odonata in urban areas: the importance of obligate wetland plant species. *Biodiversity and Conservation* 29: 913-931. (in English) [Urbanization significantly alters hydrological regimes in cities by reducing infiltration rates and increasing runoff. Stormwater ponds have been constructed in North American cities to mitigate the effects of increased urban runoff by dampening floods and filtering out contaminants. However, these ponds may also provide habitat for wetland species in cities. This study aimed at determining the significance of stormwater ponds as attractive habitats for the adult stages of Odonata, widely considered bioindicators of aquatic and wetland ecosystem health. A total of 41 urban stormwater ponds and ten rural natural ponds were sampled across the National Capital Region of Canada. On average, stormwater ponds had fewer species and lower abundance of dragonflies but, in contrast, more species of damselflies. Stormwater ponds had a higher total plant species richness because of a higher number of non-native species. However, some stormwater ponds had similar odonate and plant species assemblages to natural ponds. The variation in odonate abundance and species composition was largely explained by plant community composition and significantly linked to the presence of specific obligate wetland plant species. Overall, this study highlights the importance of wetland features in cities and points to design

elements of stormwater ponds that could be implemented to enhance biodiversity and ecosystem services." (Authors)] Address: Perron, Mary Ann C., Department of Biology, University of Ottawa, 20 Marie Curie Private, Ottawa, ON K1N 6N5, Canada. E-mail: mperr058@uottawa.ca

**17915.** Phuge, S.; Shetye, K.; Pandit, R. (2020): Effect of water level on insect-tadpole predator-prey interactions. *Acta Oecologica* Volume 108, October 2020, 103649. (in English) ["Highlights: • High water level increases survival of neustonic prey. • Low water level reduces predation pressure on benthic prey. • The presence of mesopredator in the water column increases the survival of prey tadpoles. Abstract: Predator-prey interactions are affected by environmental conditions. We examined the effect of changes in water level on the predator-prey interactions in a food web comprising of a top predator (dragonfly naiad), one mesopredator (backswimmer), and prey tadpoles of species that differ in microhabitat occupancy (neustonic and benthic). The results revealed that under high water level conditions (HWL), predators took longer to attack the neustonic tadpoles (*Microhyla nilphamariensis*) relative to the low-water-level condition (LWL). Dragonfly larvae mostly attacked the benthic tadpoles (*Euphylyctis cyanophlyctis*) when the water level was high. Nevertheless, under LWL, dragonfly larvae

equally attacked both benthic and neustonic tadpoles. Interestingly, dragonfly larvae frequently attacked mesopredators (i.e., backswimmers) when they were presented together with neustonic tadpoles. These results demonstrated that changes in water level influence predator-prey interactions in the pond ecosystem where neustonic tadpoles faced lower risk under HWL. The reduction of water level favored the survival of benthic prey tadpoles. The presence of mesopredator (backswimmers) reduced the predation risk of neustonic tadpoles. These results help to understand how the differences in predation risks shape anti-predator responses in these prey tadpoles." **17918.** Qin, J.; Xie, S.; Cheng, F. (2020): Broad diet composition and seasonal feeding variation facilitate successful invasion of the Shimofuri Goby (*Tridentiger bifasciatus*) in a water transfer system. *Water* 12(12), 3411; <https://doi.org/10.3390/w12123411>: 9 pp. (in English) ["The diet composition of an invasive population of Shimofuri goby (*Tridentiger bifasciatus*) was investigated bimonthly during the period from September 2015 through August 2016 in Nansi Lake, a storage lake of the East Route of the South-to-North Water Transfer Project, China. The diet consists of a broad spectrum of prey items, including mollusca (*Bellamya* sp.

and *Physa* sp.), aquatic insects (Odonata sp., Chironomidae sp., and Cirolanidae sp.), other macroinvertebrates (Nematoda sp. and Rhynchobdellida sp.), shrimp (*Palaemon modestus* and *Gammarus* sp.), fish (*Rhinogobius giurinus* and *Tridentiger bifasciatus*), fish eggs, and detritus. Dominant diets shifted from Rhynchobdellida sp. and unidentified digested food in July to *P. modestus* during September and November, and then shifted to both *P. modestus* and *R. giurinus*. Additionally, cannibalism was observed in March before spawning season of the goby, during which large males (SL > 70.0 mm) preyed on small-sized ones. We suggest that broad spectrum of prey items and apparent seasonal shifting of dominant diets in the invasive goby fish, which might be an important mechanism favoring its successful invasion in water transfer system." **17919.** Ramírez, A.; Maldonado-Benítez, N.; Mariani-Ríos, A.; Figueroa-Santiago, J. (2020): Dragonflies and damselflies (Odonata) from Puerto Rico: a checklist with notes on distribution and habitat. *PeerJ* 8:e9711 <https://doi.org/10.7717/peerj.9711>: 18 pp. (in English) ["Background: Conservation of tropical freshwater fauna requires a solid understanding of species biodiversity patterns. We provide an up to date annotated list of Odonata of Puerto Rico, which is based on current reports. The list is complemented with notes on the geographic and altitudinal distribution of this order on the island. We also compare current composition relative to early reports conducted when Puerto Rico was mostly an agricultural region. Methods: We surveyed adult Odonata all over Puerto Rico with the aid of undergraduate students. Students were trained on capturing, preserving, and data basing specimens. All material was centralized, identified by the lead author, and deposited in the Zoology Museum at the University of Puerto Rico (MZUPR), Río Piedras campus. Surveys were complemented with focal collections by the authors and a literature review of published records for Puerto Rico and the Caribbean. We requested records from specialists to obtain the most complete list of species for the island. Results: An annotated list of Odonata from Puerto Rico is presented, reporting 49 species distributed in two suborders and four families. We provide information on species distribution among municipalities and elevations around Puerto Rico. A historic list of species was developed for the 1930s-1940s, when agriculture covered most of Puerto Rico, based on literature and museum specimens. Both current and historic records are similar and suggest that the Odonata fauna is dominated by generalist species and has changed little since the agricultural period. Our list provides a point of reference to understand biodiversity patterns in Puerto Rico and the Caribbean and for assessing the effects of land use change on aquatic insect diversity." (Authors)] Address: Ramírez, A., Dept of Applied Ecology, North Carolina State Univ., Raleigh, NC, USA. E-mail: alonso.ramirez@ncsu.edu

**17921.** Ranjan, K.S.; Pawar, A.A.; Roy, A.; Saha, S. (2020): Trans-continental migration of dragonfly *Pantala flavescens* between India and Africa: Energetics and Role of wind. *Bulletin of the American Physical Society*; 73rd Annual Meeting of the APS Division of Fluid Dynamics; Sunday–Tuesday, November 22–24, 2020; Virtual, CT (Chicago time). Session X02: Biological Fluid Dynamics: Flying (10:45am - 11:30am). 10:45 AM, Tuesday, November 24, 2020: (in English) [Verbatim: *P. flavescens* migrates between India and Africa, covering a distance of around 14000-18000 km, crossing the Indian ocean twice, which is very extraordinary for a dragonfly or any flier. The route followed in this migration is India-Maldives-Seychelles-Africa-India, comprising of four legs. For such a migration, flight energetics and role of wind are most important factors. Computation models were developed for energetics, optimal time and route estimation. Energetics estimation shows, a *P. flavescens* can fly for 90hrs, covering a distance of 1400km; without wind, time required for the completion of migration is more than 90hrs for all the legs. Our results show that with wind assistance, the time taken is well within 90hrs for all the legs. Also, *P. flavescens* detour from the virtual direct line connecting the two points of a leg in the sense of geodesic, and it follows the wind, which is expected based on the wind compensation capability of dragonflies. The results clearly show that wind assistance is vital if *P. flavescens* has to complete the migration. *Pantala flavescens* is able to achieve this great feat with the help of winds and stand in league of birds as far as migration flight is concerned.] Address: Indian Inst. Technology Kharagpur

**17922.** Reels, G.T. (2020): A ranking of key dragonfly sites in Hong Kong using a species conservation value assessment metric. *Faunistic Studies in Southeast Asian and Pacific Island Odonata* 31: 1-50. (in English) ["Dragonflies were surveyed at 33 sites across the territory of Hong Kong Special Administrative Region over the period 2016-2017. Surveys included identification of larvae, exuviae and adults, and involved 92 separate site visits. The chosen sites covered the whole spectrum of dragonfly habitats in Hong Kong, with the exception of actively managed fish ponds and reservoirs. Twenty-two of the study locations had been identified as "key dragonfly sites" by Wilson (1997a); eight of these are found to no longer merit such status. Two of the "key dragonfly sites" are here retained and expanded to include adjacent dragonfly-rich areas, and four new key dragonfly

sites are proposed. Sites are evaluated by species richness, number of species of conservation importance (Reels 2019), and by means of a species conservation value metric (Reels 2019) applied to the entire dragonfly species assemblage present at each site. By all such measures, Sha Lo Tung / Hok Tau is determined to be Hong Kong's premier dragonfly site." (Author)] Address: Reels, G.T., 31 St Anne's Close, Winchester, SO22 4LQ, UK. **17928.** Rohman, A.; Faradisa, N. (2020): Dragonfly diversity (Insect: Odonata) in Asem Binatur River, Pekalongan, Indonesia. *Borneo Journal of Resource Science and Technology* 10(1): 79-84. (in English) ["This research was conducted in the Asem Binatur River, Pekalongan, Indonesia, from November 2018 to April 2019. The purpose of this study was to determine species diversity, the index value of the Pekalongan River dragonfly diversity by using the point count method. Long hand high net, wrapping paper/papilot and camera were used to catch and observe the dragonflies. The Shannon-Wiener species diversity index was calculated. Seven species of dragonflies were recorded from Asem River. There were *Diplacodes trivalis*, *Neurothemis ramburii*, *N. stigmatizans*, *Crocothemis servilia*, *Pantala flavescens*, *Orthetrum sabina* and *O. chrysis*. The Shannon-Wiener diversity index analysis was ranged from 0 to 0.31, indicating low diversity. Abiotic parameter measurements showed the humidity was 67.17%, the soil pH was 7.11, the light intensity was 46310 lux and the temperature was 30 °C. The analysis of the dragonfly diversity index was correlated with the poor water quality status in Asem Binatur River, Pekalongan." **17930.** Román-Heracleo, J.; Springer, M. (2020): First record of *Elga leptostyla* Ris, 1911 (Odonata, Libellulidae) from Costa Rica. *Check List* 16(4): 911-914. (in English) ["During research in the Tirimbina Biological Reserve, on the Caribbean slope of Costa Rica, we captured adult specimens and reared larvae of *Elga leptostyla* Ris, 1911 (Libellulidae). This species was previously reported only from southern Panama to northern South America. Therefore, this is the first record of the species and genus from Costa Rica, increasing the number of Libellulidae species recorded in the country to 95. This species' known distribution is northwards." (Authors)] Address: Román-Heracleo, J., Sistema de Estudios de Posgrado en Biología, Univ. de Costa Rica, San Pedro Montes de Oca, 11501-2060 San José, Costa Rica. E-mail: romanjareth@gmail.com

**17931.** Rusconi, J.M.; Di Battista, C.; Balcazar, D.; Rosales, M.; Achinelly, M.F. (2020): *Amphimermis enzoni* n. sp. (Nematoda: Mermithidae) parasitizing damselflies and dragonflies in Argentina. *Journal of Nematology* 52: 1-9. (in English) ["A mermithid nematode was found parasitizing nymphs of Odonata. The host specimens were collected from the stream Cajaravilla, Magdalena, Buenos Aires state, Argentina. In this work, we described *Amphimermis enzoni* n. sp., a nematode new to science. Nematodes were identified through morphological and molecular methods. The combination of the following characters separates *A. enzoni* n. sp. from other members of the genus *Amphimermis* Steiner: long and S-shaped vagina, twisted spicules for proximal 34% of their length, untwisted for 12%, again twisted for 30%, and untwisted for the last 24%; genital papillae arranged in three rows, medial row marginally longer than sub-medial rows; medial row bifurcated immediately anterior and posterior to cloaca, with 111 genital papillae (73 pre-anals and 38 post-anals). The sequences of 18S rDNA regions from *A. enzoni* formed a well-supported monophyletic clade with two GenBank sequences of *Amphimermis* spp. (EF617354 and EF617355) with 0.63 to 1.26% divergence and two Mermithidae spp. (LC512371 and LC512370) with 0.63 to 1.1% divergence, respectively. To our knowledge, this is the first example of mermithid infection in nymphs of dragonflies and damselflies for South America." **17934.** Schädel, M.; Müller, P.; Haug, J.T. (2020): Two remarkable fossil insect larvae from Burmese amber suggest the presence of a terminal filum in the direct stem lineage of dragonflies and damselflies (Odonata). *Rivista Italiana di Paleontologia e Stratigrafia* 126(1): 13-35. (in English) ["The fossil record of dragonfly relatives (Odonoptera) dates back to the Carboniferous, yet knowledge about these extinct animals is meagre. For most of the species little is known except for the characteristics of the wing venation. As a result, it is difficult to include fossil larvae in a (wing character based) phylogenetic tree as the wing venation is not visible in most of the larval instars. Two larval specimens from Cretaceous Burmese amber are in the focus of this study. The two specimens likely represent two subsequent early stage larval instars of the same individual. Not only is this an exceptional case to study ontogenetic processes in fossils – the larval instars are morphologically completely different from all known larvae of Odonata with respect to the posterior abdominal region. Therefore, besides the difficulties regarding the phylogenetic interpretation and though all Burmese amber odonatans are known from adults only, a new species – *Arcanodraco filicauda* n. sp. – is formally described. Aside from likely representing a new species, the morphology of the posterior abdominal region is highly informative for reconstructing the character evolution within the lineage towards modern dragonflies and damselflies. A long median process in both of the fossils meets all criteria to be interpreted as a terminal filum (structure or derivative of tergite of abdominal segment 11, annulated in one of the specimens). Although the exact phylogenetic affinity of *Arcanodraco filicauda* n. sp. remains enigmatic, the presence of a larval terminal filum can be reconstructed for the ground

pattern of Odonoptera (including its direct stem lineage)." (Authors)] Address: Schädel, M., Dept of Biology, Ludwig-Maximilians-Univ. München, Großhaderner Str. 2, 82152 Planegg-Martinsried, Germany. E-mail: mario.schaedel@palaeo-evo-devo.info

**17935.** Schneider, T.; Sar, K.D.; Schneider, J. (2020): Odonata from N-Myanmar during dry season – the Putao-Region. *Entomologische Zeitschrift*, Schwanfeld 130(4): 213-216. (in German, with English summary) ["There is a lack of knowledge about the Odonata fauna of Myanmar, because little field work was done there in the last decades. We undertook a first approach to study the Odonata fauna of the Putao-Region (N-Myanmar) during dry season 2019. Thirty-six species were observed during a five day fieldtrip. Most of the species were widely distributed in the deforested surrounding of Putao and belong to common dragonflies of South-East Asia. Other more rare species were restricted to brooks in the natural forests adjacent to the deforested area, like: *Matrona nigripictus*, *Aristocypha fenestrella*, *Euphaea sanguinea*, *Indocnemis orang*, and *Coeliccia svihleri*." (2020): First records of *Aeshna isoceles* and the rediscovery of *Lestes barbarus* on Cyprus (Odonata: Lestidae, Aeshnidae). *Notulae odonatologicae* 9(5): 185-195. (in English) ["In this paper we report the presence of *A. isoceles* for the first time from Cyprus. Five males were observed and photographically documented in May 2012 in a small valley below Rizokarpaso on the Karpasia peninsula. This was, however, not followed up at that time. The species was rediscovered by members of the CDSG in the same valley in April 2019. Reproductive behaviour (copula and oviposition) was observed and a population is assumed to be present. It seems possible that the species has been present on the island for some time but overlooked, due to the remoteness of the site. Furthermore, members of the CDSG also photographically documented a male *L. barbarus* at an agricultural tank near Agridia in August 2019. The last published sighting of this species on Cyprus was of four specimens dating back to 1948 that are stored in the collection of the British Museum of Natural History. We further report on two unpublished sightings of this species at Fasouri marsh in 1997 and on the Gialias river near Kotsiatis in 2002. The records of *Aeshna isoceles* increase the Odonata checklist for Cyprus to 38 species." (Authors)] Address: Sparrow, D.J., Cyprus Dragonfly Study Group (CDSG), P.O. **17951.** Supple, J.A.; Pinto-Benito, D.; Khoo, C.; Wardill, T.J.; Fabian, S.T.; Liu, M.; Pusdekar, S.; Galeano, D.; Pan, J.; Jiang, S.; Wang, Y.; Liu, L.; Peng, H.; Olberg, R.M.; Gonzalez-Bellido, P.T. (2020): Binocular encoding in the damselfly pre-motor target tracking system. *Current Biology* 30(4): 645-656. (in English) ["Highlights: • Demoiselles align their prey frontally during predatory flights • Target-selective descending neurons are homologous in dragonflies and damselflies • TSDN reference frame is binocular-fused in damselflies but sagittal in dragonflies • Summation to threshold explains binocular responses of demoiselle TSDNs. Summary: Akin to all damselflies, *Calopteryx*... possess dichoptic (separated) eyes with overlapping visual fields of view. In contrast, many dragonfly species possess holoptic (dorsally fused) eyes with limited binocular overlap. We have here compared the neuronal correlates of target tracking between damselfly and dragonfly sister lineages and linked these changes in visual overlap to pre-motor neural adaptations. Although dragonflies attack prey dorsally, we show that demoiselles attack prey frontally. We identify demoiselle target-selective descending neurons (TSDNs) with matching frontal visual receptive fields, anatomically and functionally homologous to the dorsally positioned dragonfly TSDNs. By manipulating visual input using eyepatches and prisms, we show that moving target information at the pre-motor level depends on

binocular summation in demoiselles. Consequently, demoiselles encode directional information in a binocularly fused frame of reference such that information of a target moving toward the midline in the left eye is fused with information of the target moving away from the midline in the right eye. This contrasts with dragonfly TSDNs, where receptive fields possess a sharp midline boundary, confining responses to a single visual hemifield in a sagittal frame of reference (i.e., relative to the midline). Our results indicate that, although TSDNs are conserved across Odonata, their neural inputs, and thus the upstream organization of the target tracking system, differ significantly and match divergence in eye design and predatory strategies." (2020): Inventarisasi Jenis Capung (Anisoptera) Dan Capung Jarum (Zygoptera) di Sumber Clangap dan Sumber Mangli Kabupaten Kediri. *Seminar Nasional Biologi 5 tahun 2020 - Jurusan Biologi Fakultas Sains dan Teknologi, UIN Sunan Gunung Djati Bandung*: 113-119. (in Indonesian, with English summary) ["Sumber Clangap and Mangli are springs that are located at Puncu Village, Puncu District, Kediri Regency. These two springs are commonly used by local residents as their water resources. Both locations have a good water quality that makes them suitable habitats for dragonflies. This research was aimed to make an inventory of odonate species in Sumber Clangap and Mangli. The method used in this research was belt transect and visual day flying to obtain data on the type and number of dragonflies. The data obtained were then analyzed using the Shannon-Wiener Heterogeneity Index and the percentage of relative abundance. The results showed that the Odonata taken from Sumber Clangap comprised 13 species from 6 families, while in Sumber Mangli there were 10 species from 7 families. Sumber Clangap had a higher value of diversity ( $H' = 1.99$ ) compared to Sumber Mangli ( $H' = 1.79$ ). The percentage of relative abundance analysis showed that *Euphaea variegata* was the most dominant species in both locations with a value of 27.30%." **17954.** Suzuki, K.; Watanabe, Y.; Tojo, K. (2020): Embryogenesis of the damselfly *Euphaea yayeyamana* Oguma (Insecta: Odonata: Euphaeidae), with special reference to the

formation of their larval abdominal "gill-like" appendages. *Entomological Science* 23: 280-293. (in English) ["The acquisition of wings in insects is the most significant subject in considering the diversification and adaptive radiation of insects, that is, the "macro-evolution" of insects. In the discussion of the origin of insect wings, Palaeoptera has attracted particular attention in phylogenetic and evolutionary studies. In particular, Ephemeroptera have segmental gill-structures on their abdominal segments during their nymphal stage, and these have been noted in discussions regarding their homology and/or serial homology between wings, gills and appendages. Although Odonata has received little attention in the course of these discussions, there are cases of segmental gill-like structures on their abdomen in the two families, Euphaeidae and Polythoridae. Under such circumstances, in this study, the embryological developmental process in *Euphaea yayeyamana* of Euphaeidae was observed, focusing on the formation process of the gill-like structures. As a result, it was revealed that four of the seven pairs of gill-like projection structures started their visible formation within the middle stages of embryonic development, and the remaining three pairs developed during the early stages of post-embryogenesis. Some joint-like structures existed in all of the gill-like projections. It was revealed that muscle tissue was interposed within these protrusions and that all of the projections themselves fully articulated, and that the nervous system was extended into the protrusions. All of the gill-like projections strongly suggested their homology with the cephalic and thoracic appendages, when we considered them with regard to their serial homology based on the topology of their formation position." (Authors)] Address: Suzuki, K., Department of Biology, Faculty of Science, Shinshu University, Matsumoto, Japan,

**17955.** Taguchi, M. (2020): Variation and blackening of the white pruinosity on the dorsal abdomen in a mature male of the white-tailed skimmer *Orthetrum albistylum* Selys, 1848 (Anisoptera: Libellulidae) in coastal, Yokohama. *Tombo* 62: 91-103. (in English, with Japanese summary) ["The pruinosity, consisting of wax, of *O. albistylum* is considered to play an advantageous role in territorial behavior and communication between individuals, by strongly reflecting ultra violet light (UV). In 2018, in Keihin district, Yokohama City, a blacked male specimen with pruinosity on only half of the abdomen was discovered. As a result of this, we researched variation in this species in five localities; three in the city, one in the northern part of the prefecture (Kenhoku), and one south of Tama district. We found there was a broad spectrum on the dorsum of the 6th abdominal segment of mature male specimens, as divided into five stages, from lacking pruinosity to completely pruinose. In addition, it was revealed that the pruinosity area does not change once maturity is reached. In the coastal region, although UV and radiant heat are strong, the blackish variant was more frequent compared to other regions. This variant is considered to be weaker in its sexual appeal, but the sex ratio in the coastal region was biased to female, and male competition was not so strong. On the other hand, the sex ratio at Kenhoku was most biased to male, and there male

competition appeared to be strongest. The results from Kenhoku showed that the individuals with most developed pruinosity were dominant, and the ratio of this variant was negatively correlated with the ratio of female/male. When immature, the adults of Odonata need to develop the muscle of the thorax, moreover, males of this species have to secrete the wax for pruinosity. Because small worms are not abundant for food in the coastal region, it is speculated that to reduce the burden of producing wax the colour change is an adaptation, creating situation with less male competition. However, a bottleneck effect cannot be excluded in such phenomenon, and actually, multi factors may induce the frequency of blackened variants of the male in the coastal region." **17958.** Tierney, A.; Deregnacourt, I.; Anderson, J.M.; Tierney, P.; Wappler, T.; Béthoux, O. (2020): The Triassic Mesophlebiidae, a little closer to the crown of the Odonata (Insecta) than other 'triasolestids'. *Alcheringa: An Australasian Journal of Palaeontology* 44(2): 279-285. (in English) ["Two new, subcomplete forewings belonging to the 'triasolestid assemblage', a group of Triassic stem-relatives of dragon- and damselflies (Odonata), are described. One, re-

covered from Australia (Aranbanga Volcanic Group), belongs to *Mesophlebia antinodalis* Tillyard, 1916, previously documented on the basis of two very incomplete wings. The other, recovered from South Africa (Molteno Formation), is assigned to a new species, *Mesophlebia elegans* sp. nov. The new data allow a reconsideration of the diagnosis of the genus *Mesophlebia* Tillyard, 1916 and a re-instatement of the family Mesophlebiidae Tillyard, 1916. Notably, the new specimens possess, near the wing base, a posterior lobe absent in most 'triassolestid' genera, but present in crown-Odonata and a number of their stem-relatives. *Lobodonata* tax. nov. is erected to accommodate odonates possessing this lobe. The nature of the 'vein-like' element anteriorly delimiting this lobe is discussed. We submit that it might have been initially composed of an invagination of the posterior wing-margin ('fibula'), which was later captured by AA, imposing its course on CuP." **17962.** Tsaryk, Y.; Reshetylo, O.; Nazaruk, K.; Lesnik, V. (2020): Species diversity of invertebrates (Invertebrata) on the routes of student zoology practice in the Western Chornohora (the Ukrainian Carpathians). *Studia Biologica* 14(2): 137-150. (in Ukrainian, with English summary) ["Since the second half of the 19th century invertebrate fauna of the Carpathians has been studied in detail by numerous scientists. The western branches of the Chornohora massif of the Ukrainian Carpathians has been attractive for the researchers of different groups of invertebrates. However, there is no possibility to evaluate their diversity dynamics in this area due to the lack of generalized comparative long-term data. With regard to that and considering the advantageous localization of the high-mountain biological station of Ivan Franko National University of Lviv as a convenient place for such investigation, the aim of our study was to describe the species diversity of invertebrates in the Western Chornohora for the initiation of stationary research of its dynamics. The material was collected by students according to the standard zoological methods during their field practice trips in July 2015–2019 on seven radial routes in various coenotic conditions and on different sites of the Western Chornohora. 149 species of invertebrate animals from 9 classes were identified in total. Insects considerably predominate among them by the species composition (about 80 %). The most common species of the 14 registered orders of Insecta represent Coleoptera (about 40 %), Hymenoptera and Lepidoptera (15 % each). ... The study revealed seven species listed in the Red Data Book of Ukraine (... *Cordulegaster bidentata*, ...." **17963.** Tunon, M. (2020): Time constraint and genetic (phenotypic) variation in wing shape in a damselfly along a latitudinal gradient. MSc. thesis, Biology Education Centre and Animal Ecology, Uppsala University: 25 pp. (in English) ["This degree project examined the effect of time constraint on wing shape and phenotypic variation in wing shape along a latitudinal gradient in the damselfly species *Lestes sponsa*. Fore and hind wings from individuals originating from three different latitudes: North (66°N), Central (59°N) and South (54°N) Europe were treated with their native temperature and photoperiod. In addition, the north and south populations were treated with south and north conditions respectively, resulting in five groups in total. Morphometric analyses of the wings revealed a positive correlation between body mass and wing centroid size, along with a difference in wing shape between the groups. Forewings and hindwings from the northern group were broader and rounder than wings from the central and southern groups. Additionally, the wings from

the transplant groups resembled those of the native group of their treatment, indicating a phenotypic plasticity in wing shape. Lastly, statistical tests of phenotypic variation revealed that variation was highest in relative warp 2 in the forewings and hindwings, and this warp represents the curvature of the wing both upwards/downwards or towards the inside/outside of the wing. These results on phenotypic variation indicate that even in a new or changing environment, *L. sponsa* could be capable of adapting to varying temperatures and environmental conditions. This study builds our understanding of how this damselfly species, and potentially insects, will be affected by current and future potential climate change." (Author)] Address: not stated

**17964.** Vega-Sanchez, Y.M.; Mendoza-Cuenca, L.F.; Gonzalez Rodriguez, A. (2020): *Hetaerina calverti* (Odonata: Zygoptera: Calopterygidae) sp. nov., a new cryptic species of the American Rubyspot complex. *Zootaxa* 4766(3): 485-497. (in English) ["*Hetaerina americana* Fabricius, 1798 has a long and irresolute taxonomic history. Several synonyms have been suggested (*H. californica* Hagen in Selys-Longchamps, 1859, *H. basalis* Hagen in Selys-Longchamps, 1859, *H. texana* Walsh, 1863, *H. scelerata* Walsh, 1863, etc.), related to the variation in the size of the wing spots as well as to the morphology of the male cerci. However, Calvert (1901) suggested that *H. americana* represents one variable species. Nevertheless, Vega-Sánchez et al. (2019) through a genetic and morphological analysis presented evidence to propose that *H. americana* represents a species complex. In the present work, we describe a new species that belongs to this complex: *H. calverti* sp. nov. The morphological characteristics by which males and females of *H. calverti* differ from *H. americana* are highlighted. The most important character for the differentiation of males is the shape of the cerci and the size of the individuals (when the two species are in sympatry). In females, the main differences are in the shape of the intersternites and the medio-dorsal carina of the last segment of the abdomen. Some generalities about the biology of the species are presented, including geographical distribution patterns and genetic divergence data." **17970.** Wakhid; Rauf, A.; Krisanti, M.; Sumertajaya, I.M.; Maryana, N. (2020): Aquatic insect assemblages in four urban lakes of Bogor, West Java, Indonesia. *Biodiversitas* 21(7): 3047-3056. (in English) ["Urban lakes represent important habitats for some freshwater organisms and support a high diversity of insect fauna. Study was conducted with the objectives to determine and compare aquatic insect assemblages in four urban lakes of Bogor, West Java, Indonesia. Insects were collected in the littoral zone using D-net at a certain interval along the perimeter of each lake. Sampling was carried out monthly during March, April, and May 2017. A total of 6,686 individuals representing 82 species / morphospecies, 28 families, and seven orders were recorded. Estimation of species richness by Chao1 suggested that sampling completeness for Situ Babakan, Situ Burung, Situ Gede, and Situ Tonjong were 88.71%, 75.86%, 82.17%, and 95.23%, respectively. Rarefaction curves indicated that more sampling would record a higher species richness. The least species richness and diversity of aquatic insect assemblages occurred in Situ Babakan characterized by high organic pollution due to fish farming. Canonical correspondence analysis showed that certain environmental factors were related to some species. ... Odonates such as *Pseudagrion* sp.1, *Rhinocypha* sp., *Acisoma panorpoides*, *Orthetrum sabina* and *Crocothemis servilla* were associated with conditions of a high density of macrophytes. Our study provides baseline data for future monitoring and conservation management of these lakes." (Authors)] Address: Wakhid, Program of Entomology, Graduate School, Institut Pertanian Bogor. Jl. Meranti, Kampus IPB Darmaga, Bogor 16680, Indonesia

**17971.** Wakhid; Rauf, A.; Krisanti, M.; Sumertajaya, I.M.; Maryana, N. (2020): Species richness and diversity of aquatic insects inhabiting rice fields in Bogor, West Java, Indonesia. *Biodiversitas* 21: 34-42. (in English) ["Rice fields occupy the largest cultivated area in agricultural landscape in Indonesia and support a variety of living organisms, including aquatic insects. This study was conducted with the objective to determine the species richness and diversity of aquatic insects inhabiting rice fields. Sampling was made in March, May, and July 2017 in rice fields at Situgede, Pandansari, and Kawungluwuk (Bogor region, West Java, Indonesia), and carried out by dragging dip net on the bottom along the edge of the rice plots. A total of 3,306 individuals representing 45 species of aquatic insects belonging to 30 genera, 20 families, and seven orders were recorded. Order Hemiptera was the most abundance comprising 28.89% of the total insects collected, followed by Diptera (24.80%), Coleoptera (24.41%), and Odonata (21.42%). Functional feeding group analysis showed that collectors-gatherers had the highest proportion (40 - 46%), followed by predators (23-44%) and scrapers (10-35%). Rank-abundance curve showed low species evenness with the four most abundant species were *Micronecta siva* (Kirkaldy) (Hemiptera: Micronectidae), *Chironomus* sp. (Diptera: Chironomidae), *Orthetrum sabina*, and *Helochaeres* sp. (Coleoptera: Hydrophilidae). The Shannon-Wiener index showed the lowest value ( $H' = 1.84$ ) at Situgede and the highest ( $H' = 2.05$ ) at Pandansari. Richness

estimate and individual-based rarefaction curve revealed that rice fields at Pandansari have more species richness than the other two sites. This study provides some insights into the aquatic insect community of the human-made ecosystem and suggests that the ecological approach to pest management is necessary for maintaining ecosystem health and promoting biodiversity." (Authors)] Address: Wakhid, Program of Entomology, Graduate School, Institut Pertanian Bogor. Jl. Lingkar Akademik, Kampus Dramaga, Bogor 16680, West Java, Indonesia

**17972.** Wakimura, K.; Takemon, Y.; Ishiwata, S.; Tanida, K.; Abbas, E.M.; Inai, K.; Taira, A.; Tanaka, A.; Kato, M. (2020): A reference collection of Japanese aquatic macroinvertebrates. *Ecological Genetics and Genomics* 17 (2020) 100065: 6 pp. (in English) ["Properly identified specimen databases that include DNA sequences are mandatory for studies on species identification by DNA barcodes, metabarcoding of biota, and environmental DNA (eDNA) analyses. In addition, high-resolution digital images of well-characterized specimens are useful for morphology-based taxonomy studies. We have isolated the genomic DNA of physical collections (specimens) of Japanese aquatic macroinvertebrates that were stored at the authors' laboratory and determined partial coding regions for 18S rRNA, histone H3, and mitochondrial cytochrome c oxidase subunit I (COI) genes. Through this work, digital data (photographs and DNA sequences) on aquatic macroinvertebrates inhabiting Japan, along with their collection data, have been made available on the J-amir website ([http://www.b.s.osakafu-u.ac.jp/~mkato/J-amir\\_home.htm](http://www.b.s.osakafu-u.ac.jp/~mkato/J-amir_home.htm)). As of March 2020, our collections included 75 taxa of Ephemeroptera (out of 152 species known to inhabit Japan), 30 taxa of Odonata (out of 211 species), 11 taxa of Plecoptera (out of 203 species), and 33 taxa of Trichoptera (out of 484 species), in addition to data of other orders. The website will be continuously updated with new data. Our collection offers a reference for species identification by DNA barcodes, quick image matching of aquatic macroinvertebrates, and evaluating the molecular phylogeny of aquatic insects." **17973.** Walker, J.; Mahoney, M.; Templeton, A.R.; McKenzie, P.; Vogt, T.E.; Cashatt, E.D.; Smentowski, J.; Day, R.; Gillespie, R.; Henry, B.; Wiker, J.; Braude, S.; Landwer, B. (2020): Contrasting Ozark and Great Lakes populations in the endangered Hines emerald dragonfly (*Somatochlora hineana*) using ecological, genetic, and phylogeographic analyses. *Conservation Science and Practice*. 2020:e162: 15 pp. (in English) ["The federally endangered *S. hineana* is found in fens surrounding the Great Lakes region and in a small portion of the Missouri Ozarks. Most previous work has focused on the populations in the Great Lakes region. We present mark/recapture studies and genetic surveys to address the status of the Ozark populations. The densities and genetic diversity tend to be higher in the Ozarks than in the Great Lakes region. A phylogeographic analysis indicates

that the Ozarks, with its unglaciated fens, is the likely source for the populations currently inhabiting the formerly glaciated Great Lakes region, and genetic diversity decreases with increasing distance from the Ozarks. This work illustrates the inadequacy of using geography alone to identify a population as marginal and of less conservation concern. We also reanalyzed genetic data on the Great Lakes populations, where several populations have been extirpated over the last several decades. We show that the populations in the Great Lakes region have already lost more than 30% of their genetic diversity over just several decades, and the phylogeographic analysis indicates that increased fragmentation is a possibility in this region due to local extirpations. Ecologically and genetically, the Ozark populations should have a high priority in management plans, and the high rate of loss of genetic diversity and potential fragmentation indicates that continued monitoring and management is needed in the Great Lakes region for this highly endangered dragonfly." **17974.** Wang, C.; Zhang, R.; Zhou, C.; Sun, Z. (2020): Numerical investigation on flapping aerodynamic performance of dragonfly wings in crosswind. *International Journal of Aerospace Engineering*, Volume 2020 |Article ID 7325154: 14 pp. (in English) ["Numerical simulations are performed to investigate the influence of crosswind on the aerodynamic characteristics of rigid dragonfly-like flapping wings through the solution of the three-dimensional unsteady Navier-Stokes equations. The aerodynamic forces, the moments, and the flow structures of four dragonfly wings are examined when the sideslip angle between the crosswind and the flight direction varied from 0° to 90°. The stability of the dragonfly model in crosswind is analyzed. The results show that the sideslip angle has a little effect on the total time-average lift force but significant influence on the total time-average thrust force, lateral force, and three-direction torques. An increase in the sideslip angle gives rise to a larger total time-average lateral force and yaw moment. These may accelerate the lateral skewing of the dragonfly, and the increased rolling and pitching moments will further aggravate the instability of the dragonfly model. The vorticities and reattached flow on the wings move laterally to one side due to the crosswind, and the pressure on wing surfaces is no longer symmetrical and hence, the balance between the aerodynamic forces of the wings on two sides is broken. The effects of the sideslip angle on each dragonfly wing are different, e.g., has a greater effect on the aerodynamic forces of the hind wings than those of the fore wings. When sensing a crosswind, it is optimal to control the two hind wings of the bionic dragonfly-like micro aerial vehicles." (Authors)] Address: Wang, C., School of Mech. Engineer., Dongguan Univ. Tech., Dongguan 523000, China

**17975.** Wildermuth, H.; Schneider, B. (2020): Froschattacken auf schlüpfende Kleinlibellen. *Libellula* 39(1/2): 91-104. (in German, with English summary) ["Frog attacks on emerging damselflies – Besides birds and spiders, frogs are among the most important predators of dragonflies. While

ovipositing females and tandems may successfully avoid being preyed on by frogs, pharate larvae as well as emerging and freshly emerged imagines seem to be helplessly exposed to their predators. However, this is not principally the case. By means of video films from a gravel pit by the river Rhine at the Swiss/German border we demonstrate by several examples that damselflies during emergence may react on approaching green frogs and avoid predation by different tactics. Pharate larvae and emerging imagines either remained motionless and were no longer noticed by the predator or the larvae suddenly disengaged from the substrate and dropped with flipping movements back into the water. Frog attacks occurred at the water line, from floating platforms or by stalking their prey under the water surface. Prey-catching leap and tongue projection were released by movements of the prey, occasionally occurring with some delay. Frog attacks on emerging damselflies were only sometimes successful. Thus, damselflies are able to actively avoid predation even during emergence." (Authors)] Address: Schneider, B., Wolfbühlstrasse 34A, 8408 Winterthur, beatsch@bluewin.ch

**17976.** Wildermuth, H. (2020): Arthropoden im Nahrungsspektrum des Eisvogels *Alcedo atthis*. *Ornithologischer Beobachter* 117: 296-311. (in German, with English summary) ["The food of the Kingfisher mainly comprises small fish, rarely other aquatic vertebrates and occasionally also invertebrates, largely arthropods. While the diversity and the preferred size of fish prey has extensively been studied, comparatively little is known about the arthropod prey spectrum. The aim of this study was to learn more about the crustacean and insect prey, its origin and behaviour in respect to the Kingfisher as predator. Study site was the river Töss near Winterthur (canton of Zürich), a tributary of the river Rhine in the Swiss Plateau. Some of the captured prey was identified on photos and video films. More detailed information was obtained by the analysis of 160 regurgitated pellets that were collected outside the breeding burrow in springtime between 2010 and 2019. Altogether 1415 fragments of 442 prey items could be identified to species or genus level, in some cases only to family level yet. Almost half of the prey were water bugs, predominantly Backswimmers *Notonecta* sp., and one third consisted of dragonfly larvae comprising ten species, most of them *Anax* *Imperator* and *Orthetrum* *cancellatum*. The remaining 18 % were composed of two crustacean Orders, mainly amphipods, and six insect Orders, mayflies and stoneflies among them. The prey originated partly from the river and partly from ponds, depending on the breeding localities and the accessible hunting grounds. Based on direct observation and indirect inferences from pellet analyses the Kingfisher catches its prey usually by plunging into the water but he can also capture it from the water surface or the bottom. Terrestrial prey may be taken from Vegetation, wet mud or dry sand and even from midair. This diurnal bird can also detect primarily nocturnal prey such as the larvae of *Cordulegaster* *boltonii* when they are not completely burrowed in soft ground or occasionally move by day." **17978.** Willink, B.; Duryea, M.C.; Wheat, C.; Svensson, E.I. (2020): Changes in gene expression during female reproductive development in a color polymorphic insect. *Evolution* 74(6): 1063-1081. (in English) ["Pleiotropy (multiple phenotypic effects of single genes) and epistasis (gene interaction) have key roles in the development of complex phenotypes, especially in polymorphic taxa. The development of discrete and heritable phenotypic polymorphisms often emerges from major-effect genes that interact with other loci and have pleiotropic effects on multiple traits. We quantified gene expression changes during ontogenetic color development in a polymorphic insect (*Ischnura elegans*), with three heritable female morphs, one being a male mimic. This female color polymorphism is maintained by male mating harassment and sexual conflict. Using transcriptome sequencing and de novo assembly, we demonstrate that all three morphs downregulate gene expression during early color development. The morphs become increasingly differentiated during sexual maturation and when developing adult coloration. These different ontogenetic trajectories arise because the male-mimic shows accelerated (heterochronic) development, compared to the other female morphs. Many loci with regulatory functions in reproductive development are differentially regulated in the male-mimic, including upstream and downstream regulators of ecdysone signaling and transcription factors potentially influencing sexual differentiation. Our results suggest that long-term sexual conflict does not only maintain this polymorphism, but has also modulated the evolution of gene expression profiles during color development of these sympatric female morphs." **17980.** Wolterink, K.K. (2020): Verklaring versnelde afname van venlibellen in Nederland. *Afstudeerwerkstuk, Aeres Hogeschool Almere*. 40 pp. (Dutch, with English summary) ["Insect populations are suffering a very severe global decline. A lot of publications focus on pollinators, because of their financial merits. A different group of species that are suffering from a severe decline, are acid water dragonflies. There are several well-known reasons for the decline of dragonflies. The reason why acid water dragonflies show a faster decline than other dragonflies however, is not as well researched or described. *Coenagrion lunulatum*, *C. hastulatum* and *Aeshna juncea* are 3 rare species that are showing a rapid decline in the Netherlands. The rapid decline of these 3 species is researched in this report, using a collection of available literature. Reasons known to cause a decline in dragonfly populations were researched. These reasons were then looked at, to see whether they impact acid water dragonflies more severely than other species, causing the faster decline. The influence of species characteristics, invasive species, drought, accumulation of sludge, acidification, a lack of balance in water chemistry, conductivity, habitat fragmentation and lack of proper nature conservation were researched. Afterwards the impact of each effect was weighted according to relevant literature, to check which effects had the largest impact on acid water dragonflies compared to other species of dragonfly. The results showed multiple effects have a more negative effect on acid water dragonflies than on other species. Drought has the biggest impact on dragonflies in general, and an even larger impact on acid water dragonflies. The pressure of invasive species has a large effect on acid water dragonflies in the form of sunfish. Moorland pools are sensitive to acidification, and severe acidification can lead to local extinction of dragonflies. The species characteristics of acid water dragonflies also influence them negatively. Some of the researched effects have been inadequately researched, making it difficult to make an accurate measurement of their effect. To make these measurements more reliable, specific research into these effects has to be done in pools where the 3 researched species occur. In conclusion, it is not possible to name a single reason for the rapid decline of acid water dragonflies. The faster decline is mostly caused by the increased sensitivity to well-known reasons for the decline of dragonflies. Droughts cause the most issues, but invasive species, negative species characteristics and acidification

also contribute to the rapid decline." (Author)] Address: not stated

**17981.** Wonglersak, R.; Fenberg, P.B.; Langdon, P.G. (2020): Temperature-body size responses in insects: a case study of British Odonata. *Ecological Entomology* 45(4): 795-805. (in English) "1. Body size is highly correlated with physiological traits, fitness, and trophic interactions. These traits are subject to change if there are widespread reductions of body size with warming temperatures, which is suggested as one of the 'universal' ecological responses to climate change. However, general patterns of body size response to temperature in insects have not yet emerged. 2. To address this knowledge gap, we paired the wing length (as a proxy for body size) of 5331 museum specimens of 14 species of British Odonata with historical temperature data. Three sets of analyses were performed: (i) a regression analysis to test for a relationship between wing length and mean seasonal temperature within species and subsequent comparisons across species and suborders; (ii) an investigation of whether the body size of species has an effect on sensitivity to warming temperature; and (iii) a linear-mixed effects model to investigate factors that potentially affect temperature-size response. 3. The regression analysis indicated that wing length is negatively correlated with mean seasonal temperatures for Zygoptera, whereas Anisoptera showed no significant correlation with temperature. 4. There is a significant decline in wing length of all Zygoptera (but not Anisoptera) with collection date, suggesting that individuals emerging later in the season are smaller. 5. Life-cycle type was not important for predicting wing length-temperature responses, whereas sex, species, and suborder were indicated as important factors affecting the magnitude of temperature-size responses in Odonata. 6. Overall, wing lengths of Zygoptera are more sensitive to temperature and collection date than Anisoptera." (2020): Development of a camera trap for perching dragonflies: a new tool for freshwater environmental assessment. *PeerJ* 8:e9681 <https://doi.org/10.7717/peerj.9681>. 21 pp. (in English) ["Although dragonflies are excellent environmental indicators for monitoring terrestrial water ecosystems, automatic monitoring techniques using digital tools are limited. We designed a novel camera trapping system with an original dragonfly detector based on the hypothesis that perching dragonflies can be automatically detected using inexpensive and energy-saving photosensors built in a perch-like structure. A trial version of the camera trap was developed and evaluated in a case study targeting red dragonflies (*Sympetrum* spp.) in Japan. During an approximately 2-month period, the detector successfully detected *Sympetrum* dragonflies while using extremely low power consumption (less than 5 mW). Furthermore, a short-term field experiment using time-lapse

cameras for validation at three locations indicated that the detection accuracy was sufficient for practical applications. The frequency of false positive detection ranged from 17 to 51 over an approximately 2-day period. The detection sensitivities were 0.67 and 1.0 at two locations, where a time-lapse camera confirmed that *Sympetrum* dragonflies perched on the trap more than once. However, the correspondence between the detection frequency by the camera trap and the abundance of *Sympetrum* dragonflies determined by field observations conducted in parallel was low when the dragonfly density was relatively high. Despite the potential for improvements in our camera trap and its application to the quantitative monitoring of dragonflies, the low cost and low power consumption of the detector make it a promising tool." **17994.** Khelifa, R.; Mahdjoub, H. (2021): EcoDragons: A game for environmental education and public outreach. *Insects* 2021, 12, 776. 14 pp. (in English) ["Simple Summary: We face serious ecological and societal issues that require a rethinking of our approaches to involving the public in problem-solving and decision-making. Researchers need help from community scientists to gather data and generate fruitful discussions to tackle planetary problems. However, the establishment and maintenance of strong links between scientists and society require innovative ways of communication outside conventional educational institutions. Here, we propose a game that teaches the players the basics of ecological thinking when approaching environmental issues and biodiversity conservation. The game is called EcoDragons and it uses dragonflies as the main biological entity to colonize, establish and maintain biodiversity in an empty landscape that regularly faces climatic and anthropogenic disturbances. While the current EcoDragons was based on European dragonflies, the concept is highly adaptable to dragonflies of other regions (changing the species names), or even to other taxonomic groups. Besides the various pedagogical benefits, the game has the potential to foster public engagement in biodiversity conservation and community science. Abstract: Environmental education is crucial to tackling the pressing ecological and societal issues on our planet. Although there are various ways to approach environmental education and raise public awareness, games are potentially an effective vehicle of knowledge and engagement because they vulgarize the scientific information in a universal

'language' and bring people together. Here, we designed a game, EcoDragons, that integrates principles of ecology, biological conservation, life history, and taxonomy. The protagonists of the game are dragonflies and damselflies. The aim of the game is to colonize habitats with different species and use ecological processes (e.g., predation, competition, and mutualism) and conservation measures (e.g., restoration and reintroduction) to face random environmental disturbances (e.g., climate warming, drought, pollution, and biological invasion). The version of the game presented in this paper was based on European species. The game includes 50 species (25 dragonflies and 25 damselflies). The winner of the game is the one who occupies more habitats, establishes and maintains the largest number of species, and solves more anthropogenic disturbances. EcoDragons has a global outreach potential to educate the public about ecology, conservation, and organismic life history, and will probably engage people in environmental advocacy." **17996.** Yang, L.-J.; Kapri, N. ; Waikhom, R.; Unnam, N.K. (2021): Fabrication, aerodynamic measurement and performance evaluation of corrugated flapping wings. *Journal of Aeronautics, Astronautics and Aviation* 53(1): 83-93. (in English) ["This paper deals with the fabrication, aerodynamic measurement, and performance evaluation of the corrugated wing patterns on a flapping wing micro air vehicle (FWMAV). The corrugated wing pattern is generally seen in insects. Insect wings with their corrugated topological features give themselves high load-bearing capacity during flapping and hovering. It is believed that appropriate corrugated structures on insect wings enhance aerodynamic performance. A new fabrication process using polydimethylsiloxane (PDMS)-molding and parylene coating was proposed and implemented for a 24 cm-span FWMAV, which is composed of corrugated wing inspired by the dragonfly wing. The fabrication includes the master wing template made by three-dimensional (3D) printing, the PDMS molding process for wing template duplication, and the final parylene coating to obtain corrugated wings. The parylene-C thickness was selected as 40 µm. For comparing the aerodynamic performance, two types of flapping wings were implemented on the FWMAVs: first with a pair of parylene corrugated wings and the other with polyethylene terephthalate (PET) flat membrane (without corrugation) wings. The lift signal was

then measured by the load cell in a wind tunnel. Regarding the aerodynamic performance of flapping wings, a systematic performance estimation of finding the cruising conditions and the cruising lift for FWMAVs was investigated through the massive wind tunnel data. The parylene flapping wings with corrugation attained lift coefficients of 7.8-8.0, which the PET flat membrane wing cannot achieve so far." **17997.** Ye, Y.; Hu, C.; Jiang, Y.; Davison, G.W.H.; Ding, C. (2021): Three-dimensional niche partitioning between two colonially nesting ardeid species in central China. *Avian Research* volume 12, Article number: 33 (2021): 8 pp. (in English) ["Background: Interspecific competition is known to be strongest between those species that are both closely related and sympatric. Egrets are colonially nesting wetland birds that often overlap and can therefore be expected to compete in roosting and nesting habitat as well as in diet. According to the niche partitioning hypothesis, it is to be expected that these similar species would show differentiation in at least one of the main niche dimensions to reduce competition. We tested niche partitioning between the colonially nesting Little Egret (*Egretta garzetta*) and Cattle Egret (*Bubulcus ibis*) in temporal, spatial and trophic dimensions. Methods: Field study was conducted in three mixed egret colonies in Yangxian County, southwest Shaanxi Province, central China. For each nest colony we recorded its spatial location, the height of nesting trees and of nests, the height of roosting trees and of roosting individuals within the trees. We determined the first egg-laying and first hatching dates of the two species. Craw dissection of storm-killed egret nestlings was used to measure the diet. Six transects were surveyed to study foraging habitat selection. Results: We found that hatching time of Little Egrets peaked earlier (by about 1 month) than that of Cattle Egrets. Cattle Egrets nested and roosted higher than Little Egrets. The foraging habitats used by Little Egrets were dominated by river banks (73.49%), followed by paddy fields (13.25%) and reservoirs (10.84%), whereas Cattle Egret foraging sites were characterized by grasslands (44.44%), paddy fields (33.33%) and river banks (22.22%). Little Egrets consumed more fishes (65.66%) and Odonata larvae (13.69%) than Cattle Egrets, while Cattle Egrets were found feeding mainly on Coleoptera (29.69%) and Orthoptera (23.29%). Little Egrets preyed on larger mean biomasses of food items than Cattle Egrets. Conclusions: Our results confirm the niche partitioning hypothesis as a mechanism for coexistence among ecologically similar species. In two coexisting egret species, niche partitioning is multidimensional, such that the two coexistent species occupy differing ecological space based on all three temporal, spatial and trophic niche dimensions." **17998.** Yu, D.-N.; Yu, P.; Zhang, L.; Storey, K.B.; Gao, X.; Zhang, J. (2021): Increasing 28 mitogenomes of Ephemeroptera, Odonata and Plecoptera support the Chiasmomyaria

hypothesis with three different outgroup combinations. *PeerJ* 9:e11402 <https://doi.org/10.7717/peerj.11402>: 25 pp. (in English) ["Background: The phylogenetic relationships of Odonata (dragonflies and damselflies) and Ephemeroptera (mayflies) remain unresolved. Different researchers have supported one of three hypotheses (Palaeoptera, Chiasmomyaria or Metapterygota) based on data from different morphological characters and molecular markers, sometimes even re-assessing the same transcriptomes or mitochondrial genomes. The appropriate choice of outgroups and more taxon sampling is thought to eliminate artificial phylogenetic relationships and obtain an accurate phylogeny. Hence, in the current study, we sequenced 28 mt genomes from Ephemeroptera, Odonata and Plecoptera to further investigate phylogenetic relationships, the probability of each of the three hypotheses, and to examine mt gene arrangements in these species. We selected three different combinations of outgroups to analyze how outgroup choice affected the phylogenetic relationships of Odonata and Ephemeroptera. Methods: Mitochondrial genomes from 28 species of mayflies, dragonflies, damselflies and stoneflies were sequenced. We used Bayesian inference (BI) and Maximum likelihood (ML) analyses for each dataset to reconstruct an accurate phylogeny of these winged insect orders. The effect of outgroup choice was assessed by separate analyses using three outgroups combinations: (a) four bristletails and three silverfish as outgroups, (b) five bristletails and three silverfish as outgroups, or (c) five dip-lurans as outgroups. Results: Among these sequenced mitogenomes we found the gene arrangement IMQM in Heptageniidae (Ephemeroptera), and an inverted and translocated tRNA-Ile between the 12S RNA gene and the control region in Ephemereillidae (Ephemeroptera). The IMQM gene arrangement in Heptageniidae (Ephemeroptera) can be explained via the tandem-duplication and random loss model, and the transposition and inversion of tRNA-Ile genes in Ephemereillidae can be explained through the recombination and tandem duplication-random loss (TDRL) model. Our phylogenetic analysis strongly supported the Chiasmomyaria hypothesis in three different outgroup combinations in BI analyses. The results also show that suitable outgroups are very important to determining phylogenetic relationships in the rapid evolution of insects especially among Ephemeroptera and Odonata. The mt genome is a suitable marker to investigate the phylogeny of inter-order and inter-family relationships of insects but outgroup choice is very important for deriving these relationships among winged insects. Hence, we must carefully choose the correct outgroup in order to discuss the relationships of Ephemeroptera and Odonata." **17999.** Brockhaus, T. (2012): Wie kam *Somatochlora alpestris* (Selys) in die zentraleuropäischen Gebirge? Der Lebensraumwechsel einer stenothermen transpaläarktisch verbreiteten Kaltzeitart am Beispiel des Erzgebirges (Sachsen) (Odonata, Anisoptera, Corduliidae). *Entomologische Nachrichten und Berichte* 56(1): 17-28. (in German, with English summary) ["How arrived *S. alpestris* in the mountains of Central Europe? The habitat change of a stenothermal ice-age species. The case of the Erzgebirge Mts. (Saxony) as an example. – *S. alpestris* is a cold-stenothermal species exhibiting recent transpalaeartic boreo-montane disjunction. The north of the area extends into the subarctic permafrost region of North Eurasia, while mountains in Eurasia were colonised into the Alpine regions. By comparing recent ecological conditions in the northern Permafrost regions of Scandinavia with the conditions during the coldest period of the Weichselian, 21.000 years BP. it is shown that *S. alpestris* may have inhabited an enormous transpalaeartic area during the last cold time. It included the periglacial areas of Central Europe between the northern ice core and the ice cores of the European mountains. At the end of the last cold time the species inhabited those boreal areas which became ice-free, or it withdrew into the Eurasian mountains, respectively. From pollen analyses much is known about the genesis of the bogs in the Erzgebirge. On the basis of this example it is outlined, how the habitat change from the periglacial cold-time tundra into the recent bogs took place during a time interval of approximately 14.000 years." **18001.** Buczynski, P. (2012): Materials to the knowledge of dragonflies (Odonata) of Lublin region. Part IV. The collection of Yuri Mikhailovich Kolosov. *Odonatrix* 8(1): 23-27. (in Polish, with English summary) [The author discusses one of the oldest well preserved collection of dragonflies from Poland, collected in the years 1899–1915. Kolosov (1892–1943) was a Russian entomologist connected with the School of Agriculture and Forestry in Puławy. He published the description of migration of *Libellula quadrimaculata* through Puławy, mentioning incidentally 18 other species (Kolosov 1915). His collection is preserved in the Museum and Institute of Zoology of Polish Academy of Sciences. It consists of 102 specimens, belonging to 34 species. The collection is incomplete, as evidenced by the lack of many common species: the fauna of the studied area had at least over 40 species and the material was mainly collected in the valley of the central River Vistula in the vicinities of Puławy (51°25'N, 21°58'E). The collection of Kolosow is a unique record of the old composition of the valley of the River Vistula, with the great share of non-recorded contemporary tyrphophilous dragonflies as well as lacustrine species associated with moderately eutrophic oxbows (e.g. *Nehalennia speciosa*, *Aeshna juncea*, *Epitheca bimaculata*, *Leucorrhinia* spp.). The record of *Orthetrum albistylum* is also valuable – then it was the northernmost site in the whole range of this species.] Address: Buczynski, P., Dept of Zool., Maria Curie-Skłodowska University, Akademicka 19, PL-20-033 Lublin, Poland. **18003.** Dossena, M.; Yvon-Durocher, G.; Grey, J.; Montoya, J.M.; Perkins, D.M.; Trimmer, M.; Woodward, G. (2012): Warming alters community size structure and ecosystem functioning. *Proc. R. Soc. B.* 279: 3011-3019. (in English) ["Global warming can affect all levels of biological complexity, though we currently understand least about its potential impact on communities and ecosystems. At the ecosystem level, warming has the capacity to alter the structure of communities and the rates of key ecosystem processes they mediate. Here we assessed the effects of a 48C rise in temperature on the size structure and taxonomic composition of benthic communities in aquatic mesocosms, and the rates of detrital decomposition they mediated. Warming had no effect on biodiversity, but altered community size structure in two ways. In spring, warmer systems exhibited steeper size spectra driven by declines in total community biomass and the proportion of large organisms. By contrast, in autumn, warmer systems had shallower size spectra driven by elevated total community biomass and a greater proportion of large organisms. Community-level shifts were mirrored by changes in decomposition rates. Temperature-corrected microbial and macrofaunal decomposition rates reflected the shifts in community structure and were strongly correlated with biomass across mesocosms. Our study demonstrates that the 4°C rise in temperature expected by the end of the century has the potential to alter the structure and functioning of aquatic ecosystems profoundly, as well as the intimate linkages between these levels of ecological organization." *Ischnura elegans*, *Libellula quadrimaculata*, *Orthetrum cancellatum* (Authors)] Address: Dossena, M., School of Biological and Chemical Sciences, Queen Mary University of London, London E1 4NS, UK

**18004.** Ishizawa, N. (2012): Observation of an annular solar eclipse. *Newsletter from Kunugiyama Forest* 18: 1-4. (in English) [rice paddies at Bodaigi, Tokorozawa City, Saitama Prefecture, Japan (35°46'14" N, 139°25'26" E). "*Orthetrum albistylum speciosum* were flying around at an extremely low light intensity at the partial solar eclipse (Ta ca. 22°C),

therefore, the reason why the delayed appearance of them seemed to be due to low Ta; the time when Ta exceeded 20°C was 8:20 a.m. The light intensity at the magnitude maximum of the former partial solar eclipse was 771 lx (Ta: 22.3°C), the perching posture of *O.a. speciosum* male was changed from the normal posture with its body axis parallel to the horizon (Photo 3A) to near the upright position (Photo 3B Ishizawa, 2011) e.g. the posture of sleeping. Such behaviours at the solar eclipse were also observed by Katatani (2010) at Nara Prefecture. It is assumed that dragonflies may adopt sleeping posture when the light intensity lowers ca. less than 1,000 lx. Even when the light intensity exceeds 2,000 lx like this time, dragonflies might not be active at lower Ta. The factor of Ta influenced on them more than the annular solar eclipse. *O. a. speciosum* and *O. japonica* are said to be the perchers and ectothermic insects that depend their thermoregulation on the solar power. At the annular solar eclipse the light intensity doesn't seem to influence on the behaviour of animals." (Author)] Address: Ishizawa, N., 1644-15, Yamaguchi, Tokorozawa City, Saitama Pref., Japan. **18006.** Klein, B.A. (2012): The curious connection between insects and dreams. *Insects* 2012, 3, 1-17; doi:10.3390/insects3010001: 17 pp. ["A majority of humans spend their waking hours surrounded by insects, so it should be no surprise that insects also appear in humans' dreams as we sleep. Dreaming about insects has a peculiar history, marked by our desire to explain a dream's significance and by the tactic of evoking emotions by injecting insects in dream-related works of art, film, music, and literature. I surveyed a scattered literature for examples of insects in dreams, first from the practices of dream interpretation, psychiatry, and

scientific study, then from fictional writings and popular culture, and finally in the etymology of entomology by highlighting insects with dream-inspired Latinate names. A wealth of insects in dreams, as documented clinically and culturally, attests to the perceived relevance of dreams and to the ubiquity of insects in our lives... One common contextual category for dream interpretation is the killing of annoying insects. To kill lice on your body signifies a release from anxiety and sorrow, and to clean lice from your body signifies hope for the release of evils [37]. For Europeans, to kill a wasp denotes the dreamer's ability to stand up fearlessly against opponents [34], and to eat a dragonfly means that you are consumed by passion at the risk of hurting others' feelings [35]. Interpretations exist for dreams about most of the insect orders, of which the parasitic, biting, and stinging insects are well represented." **18009.** Mikołajczuk, P.; Milaczevska, E. (2012): New localities of the Sedgling *Nehalennia speciosa* (Charpentier, 1840) (Odonata: Coenagrionidae) in the eastern part of Masovia and in the northern part of the Lublin District. *Odonatrix* 8(1): 1-10. (in Polish, with English summary) ["The authors give 17 new sites of *N. speciosa* discovered in the years 2010–2011 in central–eastern Poland. This data is essential due to poor level of studying of this area and the species itself: stenotopic, under protection and very strongly

threatened in Poland (EN category on the Red list of dragonflies of Poland). Species co-occurring with Sedgling were also given, indicating autochthonous species (marked with \* symbol) and probably autochthonous (#). Among new sites 7 ones have situated in the eastern part of Masovia and 10 in the northern part of the Lublin District. They fill the gap between sites in northern Poland and the Łęczyńsko-Włodawskie Lake District and the areas of Koźienice. Therefore the state of maintenance of the species in the central-eastern part of the country is much better than it was suggested earlier (Bernard et al. 2009). Other discoveries in eastern Poland also confirm this fact ... The localities of Sedgling known before and new ones probably do not form the isolated range island but they belong to the extension of its compact main part situated in northern Poland. This is even more likely that at least in eastern Masovia there are numerous peat bogs located in forests similar to those described in this paper. This suggests the existence of a large number of yet unknown sites of *N. speciosa* which can form compact concentrations on which the analysis of satellite maps and geological maps of the Quaternary seem to indicate. In Poland *N. speciosa* inhabits: I. narrow zone of floating and waterlogged mats of vegetation on the boundary of open water table of lakes and small water bodies, and II. at least partially flooded parts of *Sphagnum* peat bogs and fens, usually at their small depression. Habitats of the first type are dominating (Bernard, Buczyński 2008). Among the localities we studied, we observed two types of environments, however, the rarer second type was more often (Bernard, Buczyński 2008). The preferences of imagines of *N. speciosa* towards *Carex* sp., *C. rostrata*, *C. lasiocarpa* and *Eriophorum vaginatum* were observed. New data shows that the number of localities in potential gaps of the range of *N. speciosa* can be large. Therefore taking a look for this species in other areas where such studies have not been conducted is needed." (Authors)] Address: Mikołajczuk, P., ul. Partyzantów 59c/26, 21-560 Międzyrzec Podlaski, Poland. E-mail: gugapm@wp.pl

**18011.** Perkin, J.S.; Shattuck, Z.R.; Bonner, T.H. (2012): Life history aspects of a relict Ironcolor Shiner *Notropis chalybaeus* population in a novel spring environment. *The American Midland Naturalist* 167(1): 111-126. (in English) [*N. chalybaeus* (Cyprinidae) "is generally absent from groundwater-dominated systems throughout its range; however, a relict disjunct population occurs within the spring-fed upper reaches of the San Marcos River in central Texas. We conducted monthly seine collections within the restricted 2.2

km headwater range of the species to assess food habits and reproductive life history within a unique spring-run environment. Prey items were dominated by aquatic insects including Diptera (16% by weight), Ephemeroptera (13%), and Odonata (5%), as well as terrestrial insects (9%). The population consisted of four age groups with a maximum life span of 2.5 y. Reproductive ecology showed a protracted spawning season ranging Mar.–Dec. during which multiple clutches were produced. Reproductive maturity was reached at approximately 1 y (36 mm SL), mean mature oocyte diameter was 0.8 mm, and number of mature oocytes per clutch ranged 46–326. Comparisons between ironcolor shiner populations in the San Marcos River and thermally dynamic Marshalls Creek of Pennsylvania revealed mature female size was larger ( $T_{38} = 10.48$ ,  $P < 0.01$ ) and mature oocyte diameter smaller ( $T_{38} = 16.87$ ,  $P < 0.01$ ) in the upper San Marcos River. Literature accounts regarding ironcolor shiner reproductive ecology suggest a latitudinal trade-off between reproductive season length and oocyte size. Our findings provide further evidence for the roles of photoperiod and water temperature in structuring the reproductive seasonality of spring-dwelling fishes, specifically the lack or delay of terminating cues in stenothermal waters. In this manner, aquifer depletion and alteration of thermal regimes threaten spring-dwelling fishes by disrupting naturally occurring reproductive cues." **18013.** Thomsen, P.F.; Kielgast, J.; Iversen, L.; Wiuf, C.; Rasmussen, M.; Gilbert, M.T.P.; Orlando, L.; Willerslev, E. (2012): Monitoring endangered freshwater biodiversity using environmental DNA. *Molecular ecology* 21(11): 2565-2573. (in English) ["Freshwater ecosystems are among the most endangered habitats on Earth, with thousands of animal species known to be threatened or already extinct. Reliable monitoring of threatened organisms is crucial for data-driven conservation actions but remains a challenge owing to nonstandardized methods that depend on practical and taxonomic expertise, which is rapidly declining. Here, we show that a diversity of rare and threatened freshwater animals—representing amphibians, fish, mammals, insects and crustaceans—can be detected and quantified based on DNA obtained directly from small water samples of lakes, ponds and streams. We successfully validate our findings in a controlled mesocosm experiment and show that DNA becomes undetectable within 2 weeks after removal of animals, indicating that DNA traces are near contemporary with presence of the species. We further demonstrate that entire faunas of amphibians and fish can be detected by high-throughput sequencing of DNA extracted from pond water. Our findings underpin the ubiquitous nature of DNA traces in the environment and establish environmental DNA as a tool for monitoring rare and threatened species across a wide range of taxonomic groups. ... We specifically surveyed six animal species representing different taxonomic groups: the amphibians common spadefoot toad (*Pelobates fuscus*) and great crested newt (*Triturus cristatus*), the fish European weather loach (*Misgurnus fossilis*), the mammal Eurasian otter (*Lutra lutra*), the dragonfly large white-faced darter (*Leucorrhinia pectoralis*) and the crustacean tadpole shrimp (*Lepidurus apus*). ... The success rate of the DNA-based species detection by qPCR in ponds with known occurrence of the targeted species was 100% for the fish, 91–100% for the amphibian species, 82% for the dragonfly and 100% for the tadpole shrimp .... the system for *L. pectoralis* was tested negative for *L. dubia*, *L. rubicunda*, *Anax imperator* and *Cordulia aenea*." (Authors);] Address: Willerslev, E., Centre for GeoGenetics, Natural History Museum of Denmark, Univ. Copenhagen, Øster Voldgade 5-7, DK-1350 Copenhagen, Denmark. E-mail: ewillerslev@snm.ku.dk

**18015.** Debecker, S.; Sanmartín-Villar, I.; Guinea-Luengo, M.; Cordero-Rivera, A.; Stoks, R. (2016): Integrating the pace-of-life syndrome across species, sexes and individuals: covariation of life history and personality under pesticide exposure. *Journal of Animal Ecology* 85(3): 726-738. (in English) ["(1.) The pace-of-life syndrome (POLS) hypothesis integrates covariation of life-history traits along a fast-slow continuum and covariation of behavioural traits along a proactive-reactive personality continuum. Few studies have investigated these predicted life-history/personality associations among species and between sexes. Furthermore, whether and how contaminants interfere with POLS patterns remains unexplored. (2.) We tested for covariation patterns in life history and in behaviour, and for life-history / personality covariation among species, among individuals within species and between sexes. Moreover, we investigated whether pesticide exposure affects covariation between life history and behaviour and whether species and sexes with a faster POLS strategy have a higher sensitivity to pesticides. (3.) We reared larvae of four species of *Ischnura* damselflies (*I. elegans*, *I. genei*, *I. graellsii* and *I. pumilio*) in a common garden experiment with an insecticide treatment (chlorpyrifos absent/present) in the final instar. We measured four life-history traits (larval growth rate during the pesticide treatment and development time; adult mass and lifespan) and two behavioural traits (larval feeding activity and boldness, each before and after the pesticide treatment). (4.) At the individual level, life-history traits and behavioural traits aligned along a fast-slow and a proactive-reactive continuum, respectively. Species-specific differences in life history, with fast-lived species having a faster larval growth and development, a lower mass at emergence and a shorter lifespan, suggested that time constraints in the larval stage were predictably driving life-history evolution both in the larval stage and across metamorphosis in the adult stage. Across species, females were consistently more slow-lived than males, reflecting that a large body size and a long lifespan are generally more important for females. In contrast to the POLS hypothesis, there was only little evidence for the expected positive coupling between life-history pace and proactivity.

Pesticide exposure decreased larval growth rate and affected life-history/personality covariation in the most fast-lived species. (5.) Our study supports the existence of life-history and behavioural continua with limited support for life-history/personality covariation. Variation in digestive physiology may explain this decoupling of life history and behaviour and provide valuable mechanistic insights to understand and predict the occurrence of life-history/personality covariation patterns." **18016.** Agus, M.; Pujiastuti, Y.; Windusari, Y. (2017): The Diversity of the dragonfly (Odonata) as an indication of water quality. *Science & Technology Indonesia* 2(4): 80-84. (in English) ["Information on the diversity of dragonfly in the University area is still not much. Reduced areas that support the growth and development of dragonfly species are thought to have an impact on the decline of the population and the diversity of these species. The purpose of this study identified and analyzed the diversity of dragonfly species. Dragonfly are collected through direct capture and using sticky traps, then visual observations are made for identification. Environmental conditions in the area of Sriwijaya University Campus is still good, with the visibility of environmental parameters in the form of DO, BOD and COD still meet environmental quality standards so that dragonflies are still able to lay eggs to keep their generation. Sriwijaya University campus found 19 species of Odonata belonging to 5 families and 2 sub-ordo, with the value of species diversity index of 2.05 and moderate." **18021.** Angradi, T.R.; Bartsch, W.M.; Trebitz, A.S.; Brady, V.J.; Launspach, J.J. (2017): A depth-adjusted ambient distribution approach for setting numeric removal targets for a Great Lakes Area of Concern beneficial use impairment: Degraded benthos. *Journal of Great Lakes Research* 43(1): 108-120. (in English) ["We compiled macroinvertebrate data collected from 1995 to 2014 from the St. Louis River Area of Concern (AOC) of Lake Superior. Our objective was to define depth-adjusted cutoff values for benthos condition classes to provide an analytical tool for quantifying progress toward achieving removal targets for the degraded benthos beneficial use impairment. We used quantile regression to model the limiting effect of depth on selected benthos metrics, including taxa richness, percent non-oligochaete individuals, combined percent Ephemeroptera, Trichoptera, and Odonata individuals, and density of ephemeropterid mayfly nymphs (Hexagenia). We created a scaled trimetric index from the first three metrics. Metric values above the 75th percentile quantile regression model prediction were defined as being in relatively excellent condition in the context of the degraded beneficial use impairment for that depth. We set the cutoff between good and fair condition as the 50th percentile model prediction, and we set the cutoff between fair and poor condition as the 25th percentile model prediction. We examined sampler type, geographic zone, and substrate type for confounding effects. Based on these analyses we combined data across sampler types and created separate models for each of three geographic zones. We used the resulting condition-class cutoff values to determine the relative benthic condition for three adjacent habitat restoration project areas. The depth-limited pattern of ephemeropterid abundance we observed in the St. Louis River AOC also occurred elsewhere in the Great Lakes. We provide tabulated model predictions for application of our depth-adjusted condition class cutoff values to new sample data." **18022.** Ansari, N.A. (2017): Diversity of odonate fauna in Surajpur Lake: An urban wetland of Upper Gangetic Plain, Northern India. *Journal of Ecology and Environmental Sciences* 43(2): 73-79. (in English) ["Surajpur Lake is a prominent urban wetland site in Upper Gangetic Plain, Northern India known for its rich avifaunal and other aquatic biodiversity. Present study was carried out to assess the odonate diversity from March 2010 to February 2013 by applying standard survey techniques. During the study period, a total of 36 species belonging to 29 genera and 5 families of odonate fauna were recorded. Anisoptera were represented by 25 species and Zygoptera by 11 species. Libellulidae was the dominant family among the dragonflies and Coenagrionidae among the damselflies. The relative abundance of odonates includes 14 species as common, 11 as very common,

7 were occasional, 3 were rare and one was very rare out of 36 species. The diversity of odonate fauna discussed in the light of results hitherto unreported." (Authors)] Address: unknown

**18023.** Arambourou, H.; Sanmartín-Villar, I.; Stoks, R. (2017): Wing shape-mediated carry-over effects of a heat wave during the larval stage on post-metamorphic locomotor ability. *Oecologia* 184(1): 279-291. (in English) ["Two key insights to better assess the ecological impact of global warming have been poorly investigated to date: global warming effects on the integrated life cycle and effects of heat waves. We tested the effect of a simulated mild (25 °C) and severe (30 °C) heat wave experienced during the larval stage on the flight ability of the damselfly *Ischnura elegans*. To get a mechanistic understanding of how heat stress may translate into reduced post-metamorphic flight ability, we evaluated the hypothesized mediatory role of adult size-related traits, and also tested alternative pathways operating through changes in wing shape and two flight-related traits (both relative fat and flight muscle contents). Exposure to a heat wave, and particularly the severe one, shortened the larval stage, reduced adult size-related traits and modified the wing shape but did not significantly affect emergence success, relative fat content and relative flight muscle mass. Notably, the heat wave negatively affected all components of flight ability. Unexpectedly, the heat wave did not reduce flight ability through reducing size. Instead, we identified a novel size-independent mechanism bridging metamorphosis to link larval environment and adult flight ability in males: through affecting wing shape. The present study advances mechanistic insights in the still poorly understood coupling of life stages across metamorphosis. Additionally, our results underscore the need for integrative studies across life stages to understand the impact of global warming." **18024.** Arjangay, A.; Darvizeh, A.; Tooski, M.Y.; Ansari, R. (2017): An experimental and numerical investigation on low velocity impact response of a composite structure inspired by dragonfly wing configuration. *Composite Structures* 184: 327-336. (in English) ["The low velocity impact response of a novel foam-based composite structure inspired by microstructural features of dragonfly wings is investigated through the use of FE model and experiments. A nonlinear progressive damage model of the composite skins is incorporated into the FE code by VUMAT subroutine. Inter-laminar damage is reproduced using interface cohesive elements and the foam core is modeled as a crushable foam material. The numerical results are compared with experimental data acquired by impact testing on bio-inspired structures consisting of E-glass/epoxy skins filled by polyurethane foam, where a good agreement is achieved. To assess the contribution of the sandwich vein on the impact behavior of the structure, a comparison is made between different veiny structures and monolithic laminates with the same materials under low velocity impact. It is concluded that the sandwich vein can limit the damage propagation and makes the rest

of the structure remain intact." (Authors)] Address: Arjangay, A., Dept Mechanical Engineering, Univ. of Guilan, P.O. Box 3756, Rasht, Iran. E-mail: azadeh.arjangpay@gmail.com

**18025.** Babořová, M.; Noskovic, J.; Ivanic Porhajařová, J. (2017): Dragonflies (Odonata) of the Nature Reserve Torozlín and water area Štrkáren gravel-pit in the southwestern part of the Slovak Republic. *Acta fytotechn zootech* 20(3): 49-53. (in English) ["Over the period of the years 2014 and 2015 in the locality of nature reserve Torozlín and water area Štrkáren gravel-pit being located at the village Komjatice, lying in the southwestern part of the Podunajská pahorkatina upland was evaluated the species of dragonflies. 179 individuals of dragonflies were collected during the monitoring period, of which 13 species were determined as belonging to eight families. On the locality of the Torozlín Nature Reserve, the dominant species were *Ischnura elegans* (37.50%), *Platycnemis pennipes* (28.85 %), *Sympetrum vulgatum* (10.58 %), *S. sanguineum* (5.76 %) and *Platycnemis pennipes* (54.67 % *Ischnura elegans* (37.33 %) and *Libellula depressa* (5.34 %). Based on the fact that the Torozlín site has a marshy character, the species composition was more varied. Protection and vulnerability were assessed by the Red List of IUCN, the European Red List of dragonflies and the Red List of dragonflies of the Slovak Republic. Evaluation of protection was carried out under the Decree of the Ministry of Environment of the Slovak Republic No. 492/2006 Collection of Laws. For individual species found also their dominance was calculated." **18027.** Bakare, S.S.; Verma, P.R.; Andrew, R.J. (2017): Ultrastructure of spermatozoa of *Anax guttatus* (Odonata: Aeshnidae). *Odonatologica* 46(3/4): 241-254. (in English) ["In *A. guttatus* the mitochondria accumulate at the base of the nucleus to form a single nebenkern during spermiogenesis. An electron dense matrix 'centriole adjunct' is formed at the base of the nucleus surrounding the nebenkern. The acrosomal

vesicle migrates to the anterior end of the nucleus. The ultrastructure of the spermatozoa reveals that its elongated head lodges an apical inverted 'T' shaped, double-layered acrosome and a long, electron-dense nucleus, while the tail is composed of the axoneme, a pair of identical mitochondria derivatives, and the lateral/osmophilic bodies. The nucleus is displaced on one side by the axoneme. The axoneme consists of microtubules, and these are arranged into nine outer peripheral inter-singlets, nine peripheral doublets, and two central tubules (9+9+2 type). The mitochondrial derivatives and lateral bodies surround the axoneme at the tail region of the spermatozoon. A large number of cristae are evident in the longitudinal section of the derivatives. The spermatozoon of *A. guttatus* is therefore characterized by several unique features, such as the absence of a centriole, a spiked double layered acrosome, and a long nucleus with a sub-central axoneme running all along its length. The mitochondria derivative runs parallel to the axoneme, while a pair of lateral bodies is located parallel to the mitochondrial derivatives." (Authors)] Address: Andrew, R.J., P. G. (2017): Effects of human disturbance and riparian conditions on Odonata (Insecta) assemblages in eastern Amazon basin streams. *Limnologia* 66: 31-39. (in English) ["Riparian vegetation is an important determinant of the physical, chemical, and biological condition of streams, and odonates are useful indicators of

riparian condition. To identify environmental factors that structure Odonata assemblages in tropical forest streams, we collected adult odonate specimens and habitat data from 50 stream sites located in the Brazilian municipality of Paragominas (Pará state). We collected 1769 specimens representing 11 families, 41 genera, and 97 species. Of these species, 56 were Zygoptera, and 41 were Anisoptera. Improved environmental condition was reflected in increased Zygoptera species richness and reduced Anisoptera species richness. Channel shading was strongly and positively related to Zygoptera richness, and negatively to Anisoptera richness. Zygoptera species richness, but not Anisoptera species richness, was related positively to bank angle, quantity of wood in the stream bed, electrical conductivity, and decreased water temperature. Altered riparian vegetation structure was the principal determinant of odonate assemblage structure. Our results indicate that maintaining intact riparian vegetation is fundamental for conserving or re-establishing aquatic odonate assemblage structure." (Authors)] Address: Barbosa de Oliveira-Junior, J.M. **18030.** Barden, P.; Ware, J.L. (2017): Relevant relicts: The impact of fossil distributions on biogeographic reconstruction?. *Insect Systematics and Diversity* 1(1): 73-80. (in English) ["Localized extinction can play a significant role in obscuring reconstructions of historical biogeography. Insects, one of the most diverse clades in the tree of life, have complex patterns of local endemism, patterns of relictual distributions, and clades which are rather widespread and cosmopolitan. At the same time, insects have a rich fossil record that can contribute to the inference of ancestral geographical distributions, in light of present ranges. Here, we review current and ancestral insect distributions to explore the impact of fossil ranges on ancestral area reconstruction. Known examples of relictual distributions within Phasmatodea and termites are discussed, while we test the impact of fossil inclusion on biogeographic reconstruction within ants and dragonflies. The inclusion of fossil distributions increases the breadth of ancestral ranges across several nodes in ant and dragonfly phylogenies, which has implications for biogeographically based interpretations of past evolutionary ecology for these groups. More broadly, the incorporation of fossil data into estimates of ancestral distributions will not only improve the accuracy of those estimates but also provide additional temporal context." **18031.** Barnard, A.A.; Fincke, O.M.; McPeck, M.A.; Masly, J.P. (2017): Mechanical and tactile incompatibilities cause reproductive isolation between two young damselfly species. *Evolution* 71(10): 2410-2427. (in English) ["External male reproductive structures have received considerable attention as a cause of reproductive isolation (RI), because the morphology of these structures often evolves rapidly

between populations. This rapid evolution presents the potential for mechanical incompatibilities with heterospecific female structures during mating and could thus prevent interbreeding between nascent species. Although such mechanical incompatibilities have received little empirical support as a common cause of RI, the potential for mismatch of reproductive structures to cause RI due to incompatible species-specific tactile cues has not been tested. We tested the importance of mechanical and tactile incompatibilities in RI between *Enallagma anna* and *E. carunculatum*, two damselfly species that diverged within the past ~250,000 years and currently hybridize in a sympatric region. We quantified 19 prezygotic and postzygotic RI barriers using both naturally occurring and lab-reared damselflies. We found incomplete mechanical isolation between the two pure species and between hybrid males and pure species females. Interestingly, in species pairs for which mechanical isolation was incomplete, females showed greater resistance and refusal to mate with hybrid or heterospecific males compared to conspecific males. This observation suggests that tactile incompatibilities involving male reproductive structures can influence female mating decisions and form a strong barrier to gene flow in early stages of speciation." **18033.** Bastos dos Santos, T.; Cardoso Peixoto, P.E. (2017): Agonistic interactions in the dragonfly *Micrathyrina unguolata*: does male fighting investment come from an innate ability or an indomitable will? *Behavioral Ecology and Sociobiology* 71(7), Article number: 104: (in English) ["In fights between males for access to mating territories, the winner may be the rival with the highest fighting capacity or that places the highest value on the disputed site. However, it is also

possible that both factors simultaneously affect dispute settlement. Therefore, a better understanding of contest resolution rules may be achieved by simultaneously investigating how winning chances depend on individual motivation linked to resource value and on individual traits linked to fighting capacity. In this study, we used males of *Micrathyrina unguolata* to evaluate whether individual fighting ability, individual motivation, or the interaction between both factors determine the individual investment in territorial contests. For this, we simulated the approach of an intruder to trigger a territorial defense response by either resident (marked males present in the territory for at least 1 day before the experiment) or substitute males (marked males that occupied the territories after we removed the residents). Resident males fought longer against the potential intruder than their substitute counterparts. However, traits related to fighting ability had a marginal effect on the time invested in fights. These results indicate that resident males are more willing to invest in fights regardless of their physical or physiological attributes. Distinct motivational levels among individuals should increase the variation in mean contest duration among rival pairs. If this effect is widespread, it may have important implications for studies that investigate contest rules by relating fighting duration and individual traits. Significance statement: In many species, the winner of territorial fights is the individual with higher fighting ability or the one that values more the disputed resource and consequently is more motivated to fight. However, because these two factors may interact to determine the winner, investigations should benefit by simultaneously evaluating the effect of fighting ability and motivation on contest resolution. Here, we induced fights between focal males against artificially introduced rivals to test if male investment in fights is affected by an interaction between traits linked to fighting ability and motivational status. We showed that the prior occupation of a territory was the main determinant of the time spent fighting. We conclude that the previous occupation of a territory may increase individual motivation to fight due to higher valuation of the resource and eventually may surpass the effect of fighting ability to determine the winner." **18034.** Beatty, C.D.; Sánchez Herrera, M.; Skevington, J.H.; Rashed, A.; Van Gossum, H.; Kelso, S.; Sherratt, T.N. (2017): Biogeography and systematics of endemic island damselflies: The Nesobasis and Melanesobasis (Odonata: Zygoptera) of Fiji. *Ecology & Evolution* 7(17): 7117-7129. (in English) ["The study of island fauna has greatly informed our understanding of the evolution of diversity. We here examine the phylogenetics, biogeography, and diversification of the damselfly genera *Nesobasis* and *Melanesobasis*, endemic to the Fiji Islands, to explore mechanisms of speciation in these highly speciose groups. Using mitochondrial (COI, 12S) and nuclear (ITS) replicons, we recovered Garli-part maximum likelihood and MrBayes Bayesian phylogenetic hypotheses for 26 species of *Nesobasis* and eight species/subspecies of *Melanesobasis*. Biogeographical patterns were

explored using Lagrange and Bayes-Lagrange and interpreted through beast relaxed clock dating analyses. We found that *Nesobasis* and *Melanesobasis* have radiated throughout Fiji, but are not sister groups. For *Nesobasis*, while the two largest islands of the archipelago—Viti Levu and Vanua Levu—currently host two distinct species assemblages, they do not represent phylogenetic clades; of the three major groupings each contains some Viti Levu and some Vanua Levu species, suggesting independent colonization events across the archipelago. Our Beast analysis suggests a high level of species diversification around 2–6 Ma. Our ancestral area reconstruction (Rasp-Lagrange) suggests that both dispersal and vicariance events contributed to the evolution of diversity. We thus conclude that the evolutionary history of *Nesobasis* and *Melanesobasis* is complex; while inter-island dispersal followed by speciation (i.e., peripatry) has contributed to diversity, speciation within islands appears to have taken place a number of times as well. This speciation has taken place relatively recently and appears to be driven more by reproductive isolation than by ecological differentiation: while species in *Nesobasis* are morphologically distinct from one another, they are ecologically very similar, and currently are found to exist sympatrically throughout the islands on which they are distributed. We consider the potential for allopatric speciation within islands, as well as the influence of parasitic endosymbionts, to explain the high rates of speciation in these damselflies." **18035.** Bhusnar, A.R.; Sathe, T.V. (2017): Biology of a dragonfly *Crocothemis servilia servilia* Drury (Odonata: Libellulidae), a predator of paddy pests in Kolhapur. *IOSR Journal of Pharmacy and Biological Sciences* 12(3): 18-21. (in English) ["*C. servilia* is biocontrol agent of paddy pests in Kolhapur region of Maharashtra. It predates on paddy jassid *Nilaparvata* sp., Paddy borer *Chilo suppressalis* (Walker) and Jowar stem borer *Chilo partellus* (Swin). Therefore, biology of *C. servilia servilia* has been studied under laboratory conditions (24±°C, 70 - 75% RH and 12 hr Photo period). It completes its life cycle within 3 months, egg stage lasts for 18 days and nymphal period is 72 days. There are 12 instars, each has about 7 ;V 10 days duration. During nymphal period they feed on paramoecium, daphnia, redworms and mosquito larvae. Adult survives for 4 days without food. Mated female can lay about 140-150 eggs in water body/water trough. A single mated female, an average can produce 142 adults under laboratory conditions." (Authors)] Address: Bhusnar, A.R., Dept Zoology, Yashwantrao Chavan Warana Mahavidyalaya Warananagar, India

**18036.** Blades, D.C.A.; Copley, C.; Lee, K. (2017): An efficient storage system for adult Odonata specimens, with application for other museum collections. *Collection Forum* 31(1-2): 15-22. (in English) ["A new system of storing adult Odonata (damselfly and dragonfly) specimens is described and compared to existing storage systems. The major design innovation is the use of tongue and groove ("zipper lock") resealable polyethylene envelopes manufactured to fit the

standard index card and specimen arrangement currently used in major collections. Other design improvements include low-cost, adhesive-free specimen trays and glass-top drawers built to fit in standard-dimension Cornell insect cabinets. Comparisons of materials and designs with other available systems are presented and discussed. Finally, examples are presented of this new system's applicability to other collections such as Lepidoptera and Archeology." (2017): Cross-realm assessment of climate change impacts on species' abundance trends. *Nature Ecology & Evolution* 1(67): (in English) ["Climate change, land-use change, pollution and exploitation are among the main drivers of species' population trends; however, their relative importance is much debated. We used a unique collection of over 1,000 local population time series in 22 communities across terrestrial, freshwater and marine realms within central Europe to compare the impacts of long-term temperature change and other environmental drivers from 1980 onwards. To disentangle different drivers, we related species' population trends to species- and driver-specific attributes, such as temperature and habitat preference or pollution tolerance. We found a consistent impact of temperature change on the local abundances of terrestrial species. Populations of warm-dwelling species increased more than those of cold-dwelling species. In contrast, impacts of temperature change on aquatic species' abundances were variable. Effects of temperature preference were more consistent in terrestrial communities than effects of habitat preference, suggesting that the impacts of temperature change have become widespread for recent changes in abundance within many terrestrial communities of central Europe." The data set includes Odonata. (Authors)] Address: Bowler, Diana, Senckenberg Biodiv. & Climate Res. Centre, 60325 Frankfurt/M., Germany. E-mail: diana.e.bowler@gmail.com

**18041.** Brasil, L.S.; Da Silva G., Nubia F.; Batista, J.D.; De Resende, B.O.; Cabette, H.; Soares, R. (2017): Aquatic insects in organic and inorganic habitats in the streams on the Central Brazilian savanna. *Revista Colombiana de Entomología* 43(2): 286-291. (in English, with Spanish summary) ["A major part of the mechanisms that affects species distribution is related to environmental conditions. Within a stream channel

the accumulation of substrates like litter, roots, stones, gravel and sand create habitats that act as shelter and/or food source to aquatic communities, in this way supporting, or not, the establishment of different species. Based on this fact we verified the structure of aquatic insect communities in organic and inorganic habitats within Cerrado streams. Tested for differences on genera richness (i), individual abundance (ii) and genera composition (iii), and also (iv) verified if there are any indicator genera, which are faithful and specific to organic or inorganic habitats. Sampled organic (litter) and inorganic (sand and gravel) substrates in five sections of three streams and collected individuals of the orders Ephemeroptera, Plecoptera, Trichoptera, Odonata and Heteroptera (EPTOH). Community composition differed between habitats, with organic ones having higher richness and abundance, besides being the only habitat that presented faithful and specific genera (six). It is argued that this difference may be caused due to shelter and food supply provided by organic substrates." (Authors)] Address: Brasil, L.S., Av. Perimetral, 1901/1907, Museu Paraense Emílio Goeldi, Campus de Pesquisa Coordenação de Zoologia - Terra Firme Belém, Pará, Brasil - CEP 66017-970, Caixa Postal 399. E-mail: brasil\_biologia@hotmail.

**18042.** Breviglieri, C.P.B.; Oliveira, P.S.; Romero, G.Q. (2017): Fear mediates trophic cascades: Nonconsumptive effects of predators drive aquatic ecosystem function. *The American Naturalist* 189(5): 490-500. (in English) ["Predators control prey populations and influence communities and the functioning of ecosystems through a combination of consumptive and nonconsumptive effects. These effects can be locally confined to one ecosystem but can also be extended to neighboring ecosystems. In this study, we investigated the nonconsumptive effects of terrestrial avian predators on the communities of aquatic invertebrates inhabiting bromeliads and on the functioning of these natural ecosystems. Bromeliads with stuffed birds placed nearby showed a decrease in aquatic damselfly larvae abundance and biomass, and we can infer that these changes were caused by antipredator responses. These larvae, which are top predators in bromeliad ecosystems, changed the composition of the entire aquatic invertebrate community. While total species richness, mesopredator richness, and shredder abundance increased in the presence of birds, scraper biomass decreased, possibly as a consequence of the increase in mesopredator richness. High scraper biomass in the absence of birds may have accelerated detrital decomposition, making more nutrients available for bromeliads, which grew more. These results show that nonconsumptive effects triggered by terrestrial predators can cascade down to lower trophic levels and dramatically affect the functioning of aquatic ecosystems, which can in turn alter nutrient provision to terrestrial ecosystems." **18043.** Buczynski, P.; Szlauer-Lukaszewska, A.; Tonczyk, G.; Buczynska, E. (2017): Groyne: a factor modifying the

occurrence of dragonfly larvae (Odonata) on a large low-land river. *Marine and Freshwater Research* 68: 1653-1663. (in English) ["The regulation of rivers and their valleys has had a strong, negative influence on the maintenance of their original biota. Nevertheless, some hydro-engineering works conducted along already regulated rivers may be beneficial, creating habitats for endangered species and assemblages. Such works include the construction of groynes. We analysed this effect on the occurrence of dragonfly larvae along middle and lower stretches of the Oder, where groynes were built over a distance of 306 km, creating an area of uniform habitat. We demonstrated that the presence of groynes increased not only the abundance of dragonfly larvae, but also the species richness and diversity of these insects. Habitats were recreated for assemblages typical of a river with highly diverse habitat conditions, from typically riverine assemblages to those occurring in oxbow lakes, also endangered by regulations. The fauna along the stretches with groynes was richer and more valuable than that along the stretches without groynes, achieving values approaching those obtained from modelled unregulated rivers. This can be put down to greater habitat heterogeneity and groyne-reduced levels of waves produced by ships. The presence of groynes provides the key to the restoration or stabilisation of the populations of certain species and to renaturalisation processes." **18044.** Büsse, S.; Bybee, S.M. (2017): Larva, nymph and naiad – a response to the replies to Bybee et al. (2015) and the results of a survey within the entomological community. *Systematic Entomology* 42: 11-14. (in English) ["Conclusions: The goal of this survey was not to seek an outcome based on the idea that 'winner takes all' or 'might is right'; the most prevalent opinion is not necessarily the most scientifically 'correct' one. However, we felt it was important to explore the current usage across the entomological community regarding the terminology for immature insects. Our goal is to foster the most complete understanding possible regarding the usage of these terms and the terminology of the immature stage of insects. It is important to be aware that there are different terminologies and opinions in order to make a conscious decision as to which terminology to choose, as specialized terminology is useful for facilitating efficient and accurate communication across discipline boundaries (as well as insect groups). The scientific world is fraught with different opinions and ideas. The way that we discuss, frame, test and refute these opinions and ideas is central to the scientific process. The need for efficient and accurate communication among scientists is paramount. Simply being aware of the opinions that exist regarding how terminology is applied, the history of that terminology and its actual usage is a step forward." (Authors)] Address: Büsse, S., Dept Funct. **18045.** Buxton, V.L.; Sperry, J.H. (2017): Reproductive decisions in anurans: A review of how predation and competition affects the deposition of eggs and tadpoles. *BioScience*

667(1): 26-38. (in English) ["The selection of breeding habitat has broadscale implications for species distributions and community structure and smaller-scale ramifications for offspring survival and parental fitness. In anurans, offspring deposition is a decisionmaking process that involves the assessment of multiple factors at a breeding site, including the presence of predators and competitors. Evolutionary theory predicts that adult anurans should seek to minimize the risk of predation to offspring, reduce the pressure of competition, and maximize offspring survival. Many experimental studies have demonstrated the ability of anurans to assess deposition sites for predation and competition and to choose accordingly, but our understanding of the various ecological factors involved in site choice and the broader consequences of choice is still limited. Here, we review and synthesize the literature on the influence of predators [including Odonata] and competitors on anuran deposition behaviour. We highlight current gaps in our understanding of this topic and outline future avenues of research." **18047.** Castaños, C.E.; Córdoba-Aguilar, A.; Munguía-Steeyer, R. (2017): Physiological condition and wing pigmentation expression in a damselfly with seasonal polyphenism. *Physiological Entomology* 42(4): 346-354. (in English) ["Secondary sexual traits can be indicators of individual condition that may present seasonal polyphenism as a result of the differential costs of expression along the season. Wing spots in male damselflies of the Calopterygidae family are secondary sexual traits associated with intrasexual competition and mate choice. *Hetaerina titia* Drury is a calopterygid damselfly where males show red and black wing spots, contrasting with other

species of the genus whose males only express a red wing spot. In the present study, we evaluate the seasonal variation of the expression of male's red and black wing spots and their allometric patterns. Additionally, we measure male condition in the form of proteins, lipids, soluble carbohydrates and glycogen in early and late seasons. Black wing spots present higher variation than red wing spots and males of the late season are more pigmented. Allometry is positive for wing red spot in the early season and for black spot in the late season. Males of the late season present a higher concentration of proteins, soluble carbohydrates and glycogen, although there is no variation in the lipid content. The results of the present study suggest that, in *H. titia* males, black pigmentation replaces the function of the red pigmentation to signal condition. Both traits, however, may be heavily affected by environmental situations (e.g. food availability)." (Authors)] Address: Córdoba-Aguilar, A., Depto Ecología Evol., Inst. de Ecología, Univ. **18048.** Chari, L.D.; Moyo, S.; Richoux, N.B.; (2017): Trophic ecology of adult male Odonata. I. Dietary niche metrics by foraging guild, species, body size, and location. *Ecological Entomology* 43: 1-14. (in English) ["1. Information on the dietary niches of adult odonates is sparse, as they are highly mobile and evasive animals, which makes them difficult to observe in their natural habitat. Moreover, there is a lack of knowledge on how varying behavioural traits of odonates relate to phenomena like niche partitioning. 2. This study investigated niche partitioning amongst odonate species, foraging guilds and size classes in a riverine system in the Eastern Cape province of South Africa. A combination of stable isotope and fatty acid-based niches was used to infer odonate feeding. 3. Both fatty acid and stable isotope-based niches showed that there was niche separation amongst odonates that forage in flight (fliers) and those that forage from a perch (perchers), amongst odonates of different size classes (damselflies, medium- and large-sized dragonflies), and amongst species, although varying levels of niche overlap were observed in each case. 4. Niche sizes of odonates varied between an upstream and a downstream site. Generally greater niche overlap was recorded at the narrow upstream site (associated with low insect emergence rates) than the wider downstream site (associated with high insect emergence rates), indicating that a greater degree of resource sharing occurred at the upstream site where aquatic food was less abundant. 5. The findings of this study suggest that dietary niches of odonates can be influenced by foraging guild, body size, and/or environmental conditions, and additional study in a variety of regions is recommended to determine the greater applicability of these findings." (2017): Spätsommeraspekt der Libellenfauna (Odonata) ausgewählter Standorte an Bodensee und Dornbirnerach (Vorarlberg). *inatura – Forschung online* 45: 10 pp. (in German, with English summary) ["This paper deals with the late summer aspect of the dragonfly fauna at selected sites of the Austrian shore of Lake Constance and at the Dornbirnerach. Investigations carried out by the end of July / beginning of August 2017 revealed a species inventory of 19 spp., 17 at the Lake Constance, 5 at the Dornbirnerach. Particular highlights are the records of the autochthonous population of *Sympetrum depressiusculum*, («critically endangered» according to the Austrian Red List and «vulnerable» according to the European Red List) and of *Somatochlora flavomaculata*, («endangered» according to the Austrian Red List). Both species were found at the Lake Constance. *Boyeria irene*, already sighted at the Constance Rhine (Suisse) and at the Lake Constance in Germany but not detected for Austria at all, was not found." (Author)] Address: Chovanec, A., Umweltbundesamt, Spittelauer Lände 5, 1090 Wien, Austria. E-Mail: [andreas.chovanec@bmlfuw.gv.at](mailto:andreas.chovanec@bmlfuw.gv.at)

**18052.** Chovanec, A. (2017): Auswirkungen von Restrukturierungsmaßnahmen am Rußbach (Niederösterreich, Weinviertel) auf die Libellenfauna (Insecta: Odonata). *Wiss. Mitt. Niederösterr. Landesmuseum* 27: 69-96. (in German, with

English summary) ["The ecological status (with a special focus on hydro-morphology) of two rehabilitated sections of the Rußbach in Lower Austria was assessed by an odonotological study. Dragonfly surveys were carried out in 2015, which was one year after the finishing of the hydraulic engineering at the section Unterolberndorf (UO) and about ten years after the creation of the near-natural retention area Schleinbach (SB). Key element of the assessment procedure, which is in compliance with the Austrian Water Act and the EU Water Framework Directive, is a comparison between the current situation and the river type-specific reference conditions. Due to the size of the catchment areas the two sections belong to different river types. This is the reason why different reference communities were used in the assessment procedure, which was carried out on the basis of the Dragonfly Association Index (DAI). The DAI has been developed in order to evaluate the ecological status of lowland rivers of the bioregion Eastern Ridges and Lowlands. A total of 23 dragonfly species was recorded, which nearly corresponds to 30 % of the Austrian inventory of Odonate species; twenty species were autochthonous at least at one of the two river sections. Twelve of the 23 species were found at both sections. Five species are "threatened" Red List species, one of them, *Coenagrion ornatum*, which was autochthonous at both sections, is listed in the Appendix II of the Fauna-Flora-Habitat Directive. At the section UO a total of 15 species were recorded, with 12 species of them being classified as autochthonous. At the section SB 20 species were found, with 17 of them being autochthonous. The abundances of most species at the section SB were remarkably low, owing to shadowing by riparian woods, encroachment of dense reed and drying out of the standing water body in the retention area. Both river sections were ranked as class II ("good ecological status"), therewith representing the second best class and quality target in the 5-tiered classification scheme. Management measures in order to save the status are proposed." (Author)] Address: Chovanec, A., Krotenbachgasse 68, 2345 Brunn am Gebirge, Austria. e-mail: andreas.chovanec@bmlfuw.gv.at

(2017): Recovery of aquatic insect-mediated methylmercury flux from ponds following drying disturbance. *Environmental Toxicology and Chemistry* 36(8): 1986-1990. (in English) ["Small ponds exist across a permanence gradient and pond permanence is hypothesized to be a primary determinant of insect community structure and insect-mediated methylmercury (MeHg) flux from ponds to the surrounding terrestrial landscape. Here we present the first experiment examining the recovery of insect-mediated MeHg flux following a drying disturbance that converted permanent ponds with insectivorous fish to semi-permanent ponds without fish. We used floating emergence traps to collect emergent insects for 10 weeks in the spring and summer from five ponds with fish (permanent) and five ponds that were drained to remove fish, dried and refilled with water (semi-permanent). During the 73 day period after semi-permanent ponds were refilled, total MeHg flux from semi-permanent

ponds was not significantly different than total MeHg flux from permanent ponds, indicating that insect-mediated MeHg flux had rapidly recovered in semi-permanent ponds following the drying disturbance. Methylmercury fluxes from Anisoptera and phantom midges (Diptera: Chaoboridae) were significantly greater from newly refilled semi-permanent ponds than permanent ponds but the MeHg fluxes from other eight emergent insect taxa did not differ between treatments. The present study demonstrates the impact of drying disturbance and the effect of community structure on the cross-system transport of contaminants from aquatic to terrestrial ecosystems. This article is protected by copyright." (Authors)] Address: Chumchal, M.M., Department of Biology, Texas Christian University, Fort Worth, Texas, USA. E-mail: m.m.chumchal@tcu.edu

**18054.** Ciolan, E.; Cicort-Lucaciu, A.-S.; Sas-Kovács, I.; Ferenti, S.; Covaciu-Marcov, S.-D. (2017): Wooded area, forest road-killed animals: Intensity and seasonal differences of road mortality on a small, newly upgraded road in western Romania. *Transportation Research Part D: Transport and Environment* 55: 12-20. (in English) ["Highlights: •On a recently modernized road from Romania numerous invertebrates and vertebrates were killed. •Animals related with forests and watercourses had the highest road mortality. •The surrounding forests had existed before the road, which affects the native fauna of the region. •The seasonality of road mortality is due to the victims' life cycle and meteorological conditions. The roads are one of the most obvious expressions of modern society, being considered vital for economical growth. Nevertheless, roads have a very strong negative impact upon environment, manifested, among others, by road mortality. In Romania numerous minor roads are currently upgraded and asphalted. In the year 2016, on a road of this kind, in a wooded mountain area, we recorded 1628 road killed animals belonging to 48 taxons. The majority were forest and wet areas animals (earthworms, snails, amphibians, etc), characteristic for the road's vicinity. Flying or dry areas animals were fewer. The road crosses the forest and the wet areas animals' habitats. Now, they are certain victims on the road, because its recent upgrade had increased the cars' speed. Road mortality differed between periods and according to the road surroundings aspect. The highest road mortality intensity was registered at the end of the spring. It has dropped in the summer and then rose again in the autumn, but just moderately. The animals were affected according to their life cycle and ecological demands. On this minor road surrounded by relatively uniform wooded habitats, the road mortality differences were determined in the first place by the demandings and life cycle of the victims, which were affected by meteorological conditions. This studied road is a proof of how forest native animals are exposed once their habitat is crossed by a road." **18056.** Cook, P. (2017): Female color variation and male harassment in the polymorphic damselfly *Megalagrion calliphya*. MSc. thesis, Department of Biology, James Madison University: VI, 25 pp. (in English) ["Female dimorphism is commonly hypothesized to be a result of adaptations to male harassment. I tested whether polymorphic female coloration in the Hawaiian damselfly *M. calliphya* is under selection from male sexual harassment via two possible forms of negative frequency-dependent selection: the male mimicry and the learned mate recognition hypotheses. I measured male behavior toward tethered females at mating sites under naturally occurring conditions and found no evidence for either hypothesis. Harassment rates did not significantly differ between female morphs. One measure of morph frequency did predict harassment of all individuals, but this relationship was driven by a single population. I found no evidence that negative frequency-dependent selection contributes to the maintenance of polymorphism in this species. Future studies of female polymorphism should test other selective pressures which may act on polymorphism." (Author)] Address: not stated

**18057.** Cordero-Rivera, A. (2017): Sexual conflict and the evolution of genitalia: male damselflies remove more sperm when mating with a heterospecific female. *Sci Rep.* 2017 Aug 10;7(1):7844. doi: 10.1038/s41598-017-08390-3. (in English) ["In *Calopteryx* damselflies, males remove rivals' sperm stored by the female, thereby reducing sperm competition. This behaviour may create a sexual conflict, because females could lose the sperm stored in the spermatheca, used for long-term storage. Comparative evidence suggested antagonistic coevolution between sexes, which might prompt the evolution of narrow spermathecal ducts, or longer spermathecae, hindering sperm removal. *Calopteryx haemorrhoidalis* and *C. splendens* coexist and sometimes hybridize. Therefore, here I predicted that if females

coevolve with conspecific males, heterospecific males should have an advantage when interspecific matings occur because females will show less resistance to them than to conspecific males. By hand-pairing females to males of both species, I found that in intraspecific and interspecific matings, sperm was almost completely removed from the bursa (97-100%), but only partially from the spermathecae, with more spermathecal removal in interspecific (63-71%) than intraspecific matings (14-33%). This suggests that heterospecific males are more efficient in sperm removal as predicted by a sexually-antagonistic coevolutionary scenario. Furthermore, in most cases, only the left spermatheca was emptied, suggesting that the evolution of more than one spermatheca might also be a female counter-adaptation to regain control over fertilization." **18058.** Cordero-Rivera, A. (2017): Phenotypic variability in *Hemiphlebia mirabilis* (Odonata: Hemiphlebiidae): insights into the origin of the discoidal cell in odonates. *Austral Entomology* 56(4): 433-438. (in English) ["This paper reports on the studies of two populations of the locally distributed damselfly *Hemiphlebia mirabilis* Selys in south-eastern Australia to determine the length of the maturation period, describe age-related changes in colouration, and quantify phenotypic variability in body size and wing venation. Modern odonates have a closed discoidal cell, which likely increases flight efficiency, but *H. mirabilis* was thought to always have an open discoidal cell in the fore wings. The study of 82 specimens documents variability in the discoidal cell character of wings as open or closed, with a minority of specimens showing all four discoidal cells closed, and others having one hind wing cell also open. Males are larger than females and body size decreases over the short flight season. Recapture histories of marked animals suggest that males emerge earlier than females and that sexual maturation takes 4-5 days. They become progressively darker, from metallic green to bronze, and their wings less flexible with age. The colour of pterostigma is sexually dimorphic. Male paraprocts and female anal valves are bright white, but in some specimens show a sky bluish tint when observed in direct daylight. Given that recent molecular studies suggest that *H. mirabilis* has evolved from an ancestral lineage, body colouration and wing venation may be plesiomorphic characters for this taxon." **18059.** Cordero-Rivera, A. (2017): Behavioral diversity (Ethodiversity): A neglected level in the study of biodiversity. *Frontiers in Ecology and Evolution* 5(7): 8 pp. (in English) ["The concept of biodiversity embraces a multifaceted and hierarchical analysis of the complexity of life, with implications in many areas of science, philosophy, ethics, politics, and even religion. Three levels are included in the commonly accepted definitions: genetical, species, and ecosystem diversity,

going from the intraspecific level to the landscape. Here, I argue that a fourth level, never included in biodiversity studies, is of prominent relevance: ethological diversity or "ethodiversity." There is a growing number of studies describing alternative behaviors, behavioral plasticity, learning, and even personality, as characteristics of animal populations or individuals. Ethodiversity is also relevant in unraveling cryptic biodiversity, such as species that differ in their behavior but are otherwise undistinguishable. Maintaining ethodiversity is therefore essential in conservation, and cannot be achieved simply by focusing on genetic diversity. Behavior has profound ecological consequences, particularly in species interactions, and is a crucial element in the adaptability of animals to new environments. Ethodiversity is important at the intraspecific, inter-population, and species level and has practical relevance in several fields, like captive breeding, eco-novelty, and popular science. Finally, I expect ethodiversity to show a latitudinal cline, with more diverse and elaborate behaviors per species in the tropical regions, given the increase in interactions near the equator." **18060.** Coughlan, N.E.; Stevens, A.L.; Kelly, T.C.; Dick, J.T.A.; Jansen, M.A.K. (2017): Zoochorous dispersal of freshwater bivalves: an overlooked vector in biological invasions? *Knowl. Manag. Aquat. Ecosyst.* 2017, 418, 42: 8 pp. (in English, with French summary) ["Vectors that underpin the natural dispersal of invasive alien species are frequently unknown. In particular, the passive dispersal (zoochory) of one organism (or propagule) by another, usually more mobile animal, remains poorly understood. Field observations of the adherence of invasive freshwater bivalves to other organisms have prompted us to assess the importance of zoochory in the spread of three prolific invaders: zebra mussel *Dreissena polymorpha*; quagga mussel *Dreissena bugensis*; and Asian clam *Corbicula fluminea*. An extensive, systematic search of the literature was conducted across multiple online scientific databases using various search terms and associated synonyms. In total, only five publications fully satisfied the search criteria. It appears that some fish species can internally transport viable adult *D. polymorpha* and *C. fluminea* specimens. Additionally, literature indicates that veligers and juvenile *D. polymorpha* can adhere to the external surfaces of waterbirds. Overall, literature suggests that zoochorous dispersal of invasive bivalves is possible, but likely a rare occurrence. However, even the establishment of a few individuals (or a single self-fertilising *C. fluminea* specimen) can, over-time, result in a substantial population. Here, we highlight knowledge gaps, identify realistic opportunities for data collection, and suggest management protocols to mitigate the spread of invasive alien species. ... Two adult zebra mussels *Dreissena polymorpha* attached to the dorsal carapace of an odonata nymph *Epicordulia* sp. (*Corduliidae*) larva. The nymph was collected on Lake Mendota, Madison, WI (43°04'38.800N 89°24'10.600W) on 24th October 2016 via a minnow trap in 2m of water"]

**18062.** Cuevas-Yáñez, K.; Benítez, M.; Rocha, M.; Córdoba-Aguilar, A. (2017): Large-scale human environmental intervention is related to a richness reduction in Mexican odonates. *Revista Mexicana de Biodiversidad* 88: 664-673. (in English, with Spanish summary) ["It is unclear how land use change, reduction in tree cover and human footprint impact species occurrence and co-occurrence especially at a large regional scale. This is particularly prevalent for species with complex life cycles, for example odonates (dragonflies and damselflies). We evaluated richness of odonates in Mexico in terms of land use, tree cover and human footprint. We also analyzed how odonate species co-occur to interpret our richness analysis using a community perspective. We used odonate collecting records from year 2000 to 2014. Odonate geographical records were more abundant in forest and agricultural areas, and decreased in areas without vegetation. Although our results may suffer of incomplete samplings, there was a positive relationship between species richness and tree cover, and a quadratic relationship with human footprint was observed. These results indicate that some degree of forest disturbance may still sustain relatively high odonate richness levels. Finally, species tend to co-occur in particular ensembles with some species being key in their ecological communities. Further studies should detail the role these key species play in their environments to provide community stability." **18063.** de Souza, M.M.; Pires, E.P.; Brunismann, A.G.; Milani, L.R.; Pinto, A.P. (2017): Dragonflies and damselflies (Odonata) from the wetland of the Rio Pandeiros, northern region of Minas Gerais State, Brazil, with a description of the male of *Archaeogomphus vanbrinkii* Machado (Anisoptera: Gomphidae). *International Journal of Odonatology* 20(1):

13-26. (in English) ["The Odonata from the Refúgio Estadual da Vida Silvestre do Rio Pandeiros (RVSP), located in the Cerrado domain, Minas Gerais State, Brazil, were rapidly surveyed. Sampling efforts were undertaken along the Rio Pandeiros margins during four sampling periods between the rainy (spring–summer) and dry seasons (autumn–winter) from July 2014 to April 2015. We sampled 97 adult specimens of 48 species from seven families, and there were 21 species of Zygoptera, and 27 species of Anisoptera. The dry season yielded a greater species richness and abundance, with Libellulidae dominant along the overall sampling period. A comparison with other biotas in Minas Gerais bringing together a total list of 204 species is provided. RVSP represents an ecotone between the Cerrado and Caatinga domains at the São Francisco river basin and its assemblage exhibited higher similarity index with other Cerrado areas in that state. Our sampling included rare species, many hitherto known only from their type series, and seven new state records were detected for *Hetaerina proxima*, *Enallagma novaehispaniae*, *Oxyagrion fernandoi*, *Telebasis griffinii*, *Telebasis obsoleta*, and *Erythrodiplax leticia*. In addition, the first known male of *Archaeogomphus vanbrinki* is described and taxonomic notes presented. The nomenclature status of the specific name "vanbrinki" is revised, and as a consequence all subsequent spellings other than the original are considered unjustified emendations in light of the International Code of Zoological Nomenclature." **18064.** Deacon, C.; Samways, M.J. (2017): Conservation planning for the extraordinary and Endangered *Spesbona damselfly*. *Journal of Insect Conservation* 21(1): 121-128. (in English) ["*S. angusta* is one of the world's rarest insects, is Red Listed as Endangered, and occurs today at only one known locality in the Cape Floristic Region (CFR), South Africa. It has some unusual characteristics, including rapid and reversible colour change in both sexes, and a larva with frilled lamellae that lives in a micro-habitat free of competitors and large anisopteran enemies. We define here the characteristics of its habitat and record some other unusual behavioural traits, including the adult male's ability to sail on the water surface, very strong site selection for oviposition, and female approach to males, all in the context of its conservation. We used satellite imagery to determine the location of habitats within its locality. We further used infrared imagery to identify warmer and cooler habitats within the area. Details of its occurrence were mapped, based on observational data acquired throughout the flight season. From this, we were able to establish that its population moves around its locality, and we also establish its environmental requirements for conservation. We also indicate its umbrella value for representing two other threatened odonate species, Endangered *Proischnura polychromatica* and Vulnerable *Syncordulia legator*, as well as some other CFR endemic odonates. Conservation of this species requires continual monitoring and removal of invasive alien trees as a priority. Translocation should also be considered as various risks to

this one locality are high. A potential site is identified." (Authors)] Address: Deacon, C., Department of Conservation Ecology and Entomology, Stellenbosch University, Matieland, South Africa. E-mail: charldeacon@sun.ac.za

**18065.** Delnat, V.; Debecker, S.; Stoks, R. (2017): Integrating trait multidimensionality, predation and autotomy to explain the maintenance of boldness. *Animal Behaviour* 130: 97-105. (in English) ["Highlights: •Mechanisms maintaining bolder animals within populations are not fully understood. •We scored boldness traits and linked these to autotomy and mortality by predation. •Boldness-related traits did not frequently covary, indicating multidimensionality. •Bold individuals were not killed more by predators. •Bold larvae relied more on autotomy to compensate increased risk-taking behaviour. There is an ongoing debate on how personality types are maintained within populations. We tested, for the first time, the potential of trait multidimensionality and trait compensation, where prey compensate for the costs of one trait by relying more on another one, in maintaining variation in boldness within a population. We studied how four boldness-related traits and swimming escape performance covary and shape the probability of survival and autotomy of *Ischnura pumilio* damselfly larvae in an experiment with predatory dragonfly larvae. Our results did not support the common belief that bold individuals are selected against in terms of survival selection by predation. Instead, we found survival selection favouring individuals combining being bold for two boldness-related traits. The four boldness-related traits did not covary frequently, supporting the multidimensionality of boldness. Moreover, animals bolder for one trait (activity in the presence of predator cues) were shyer for another trait (response to predator cues), which indicated trait compensation. However, the support for trait compensation was limited. The only other case of trait compensation was that bold larvae compensated for their increased risk-taking behaviour in the presence of a predator with a higher probability of autotomy. These patterns may contribute to maintaining variation in boldness in damselfly populations. Just as boldness-related traits are multidimensional, the mechanisms underlying their persistence in natural populations are also likely to be multifaceted." (Authors)] Address: Stoks, R., Lab. Aquatische Ecologie, K.U.Leuven, De Beriotstraat 32, 3000 Leuven, Belgium. E-mail: robby.stoks@bio.kuleuven.ac.be

**18066.** Dronzikova, M.V. (2017): Influence of river pollution on the biodiversity of dragonflies (Odonata) in the Tom' River Basin. *Bulletin of Kemerovo State University. Series: Biological, Engineering and Earth Sciences* 3 (2017): 4-10. (in Russian, with English summary) ["Some species are so sensitive to environmental changes that may serve as indicators, which defines their significance for a complex evaluation of ecosystem condition on the territory under study. The current research shows that separate species of dragon-flies (and the reophile species in particular) are very sensitive to pollution and can serve as the indicators of environment. The research was conducted mainly in the area around the cities of Novokuznetsk, Mezhdurechensk, Osynniky, Kiselevsk,

Prokopyevsk and Tashtagol, where the Tom-river is contaminated with pollutants from industrial sewage. The authors made an attempt to analyze the odonatocomplexes of the water sources of the Tom' River basin (the Tom, the Kondoma, the Aba, The Mrass-su) and register the chemical structure of the water. The results showed that the general odonatocomplex of the Tom' River basin consists of 6 kinds of rheophils. However, downstream from large industrial centers, there is a sharp decline in the number of species, almost to the point of complete disappearance at some rivers, which clearly correlates with the degree of water pollution." (Author)] Address: Dronzikova, Marina, Kemerovo State University (Novokuznetsk branch), 23, Tsiolkovsky St., Novokuznetsk, Russia, 654041. E-mail: m\_dronzikova@mail.ru

**18067.** Dubcova, D. (2017): Reprodukční chování samcu páskovce kroužkovaného (*Cordulegaster boltonii*). Diplomová práce. Univerzita Karlova, Přírodovědecká fakulta, Katedra ekologie, Raha: 65 pp. (in Czech, with English summary) [Communication among animals often relies on visible signals and the ability to compatibly perceive them. Correct signal perception is especially important for animals with male sexual selection. In my master's thesis, I am addressing the issue of how does a male golden-ringed dragonfly (*C. boltonii*) recognize a female of the same kind and therefore, what is the main trigger of copulation behavior. Dragonflies display a wide variety of colors and possess very big eyes. These characteristics already suggest that they are very liable on color vision (Futahashi, 2015). Their sight is perfectly developed within the insect class and plays the most important role in the imagines in comparison to other senses. The ability to orient themselves using sight is not just important for orientation in space, nonetheless it is important for reproduction. Since golden-ringed dragonflies do not demonstrate visible color dimorphism, previous as well as my research suggests that the key role for female reconnaissance is primarily their typical movement above water surface during oviposition. In my research, I presented variable types of lure - females to male *C. boltonii* and I observed what is the foremost trigger of reproduction behavior in the males. Besides the above mentioned female movement I achieved to demonstrate that the males perceive also the markings respectively the black striping of their counterpart. Moreover, I confirmed my hypotheses that if a male performs the same movements as a female, the other males do consider him a female. *C. boltonii* do not display color sexual dimorphism therefore the movement is the key signal which allows the male to recognize the sex of another dragonfly. I further examined if the males would react positively to an artificial substitute and how much would their reactions differ from the reactions to a proper female dragonfly. Since recently several studies addressed also the ability of ultraviolet light perception within sexually dimorphic kinds of dragonflies, I at-tempted to determine if golden-ringed dragonflies possess and perceive UV markings as well. It turned out that *C. boltonii* reflect UV markings among each other and even with more significantly stronger stimuli by which a male recognizes a female, the absence of UV markings significantly lowers their reactivity." **18068.** Dwivedi, Y.D.; Ho, W.H.; Donepudi Jagadish; Rao, P.M.V. (2017): Spanwise flow analysis of gliding bio-inspired corrugated wing. *Jour. of Adv. Research in Dynamical & Control Systems*, 12-Special Issue: 313-322. (in English) ["Most of the artificially flying machines have profiled smooth wing section, however the natural low Reynolds number flyers like insects specifically the dragonfly, do not have such types of profiled wings instead have corrugated wings with well-defined pattern. This paper presents an experimental flow visualisation and boundary layers measurements of a bio-inspired corrugated wing and compared with a flat plate at low to moderate chord Reynolds numbers ranging from  $1.5 \times 10^5$  to  $3.75 \times 10^5$  by varying the angle of attack from 00 to + 120 by using low speed subsonic open wind tunnel. The boundary layer measurements were done at a fixed chord location ( $0.7 x/c$ ) and different semispan locations (30%, 60% and 90% of the wing's semispan) from the longitudinal axis of the wing. Flow visualisation was done by using coloured tufts, placed in different span locations. The flow reversal was observed at particular Reynolds numbers and angles of attack only. The boundary layer measurements showed that there is a clear distinction on the velocity gradient profile in all the three tested semispan locations on both the types of the wings. The corrugated wing showed delayed stall and flow separation compared with the flat plate. The visualization of flow in both wings showed that there exists a spanwise flow moving from wing tip to root, indicating that there exist a three dimensional fluid flows." **18069.** Eda, S. (2017): Unusual connections in copulation, and oviposition behaviour in dragonflies. *Tombo* 59: 29-45. (in Japanese, with English summary) ["Unusual connections and oviposition behaviour, including abnormal patterns, of Odonata are reviewed. Unusual connections are divided into male-male tandem in the same and different species, male-female tandem in the different species with and without copulation or oviposition, and triple connections of the same and different species. The triple connections are classified into A, B, AB, O, MMM types (cf. Fig. 2) and Y and X types are newly proposed. The quartets were also observed in 4 cases. Oviposition (ovi.) behaviour can be divided into the following 9 types (cf. Fig. 3). A: Sitting ovi. into plant, B: sitting ovi. into mud, C: Sitting ovi. into water, D: Flying ovi. into mud, E: Flying ovi. into water, F: Sitting ovi. onto plant surface, G: Flying ovi. onto plant surface, H: Sitting ovi. above water, I: Flying ovi. above water. Among Japanese species, F and H types are unusual." (Author)] Address: Eda, S., 3-4-25 Sawamura, Matsumoto, Nagano 390-0877, Japan. E-mail: SND02767@nifty.com

**18070.** Fan, X.-L.; Lin, Z.-H. (2017): Vulnerability and behavioral responses of South Chinese anuran tadpoles to native dragonfly (*Pantala flavescens*) naiads and introduced western mosquitofish (*Gambusia affinis*). *Journal of Freshwater Ecology* 32(1): 529-539 . (in English) ["Anti-predator behavior is an important fitness component in most animals. Alien predator species are a serious threat to amphibian populations. We studied the vulnerability and behavioral defenses

of tadpoles of six Chinese anurans in response to the introduced, active foraging predator *Gambusia affinis* (western mosquitofish) and compared them with the responses to the native ambush predator *Pantala flavescens* (naiad stage) in laboratory experiments. The tadpoles were *Bufo gargarizans*, *Duttaphrynus* (formerly *Bufo*) *melanostictus*, *Rana zhenhaiensis*, *Fejervarya multistriata*, *Microhyla onata*, and *Hoplobatrachus chinensis* from Lishui, Zhejiang, South China. Our data showed that both native *P. flavescens* and introduced *G. affinis* could prey on the six tadpole species to different degrees and that the two toad tadpoles (*B. gargarizans* and *D. melanostictus*) were significantly less vulnerable to predation than the frog ones. The reduced vulnerability of toad tadpoles to predation may be attributed to their unpalatability and their continuous swimming ability, traits that are adaptive in more permanent habitats. Compared with the ambush predator *P. flavescens*, tadpoles reduced their activity level and used spatial avoidance measures when encountering *G. affinis*. Overall, our results suggest that some of the tadpoles in the study area are likely to recognize and respond to the predation threats of *G. affinis*." **18072.** Futahashi, R. (2017): Molecular mechanisms underlying color vision and color formation in dragonflies. In: Toshio Sekimura & H. Frederik Nijhout (editors): *Diversity and evolution of butterfly wing patterns. An integrative approach.* Springer Nature. ISBN 978-981-10-4955-2: 303-320. (in English) ["Dragonflies are colorful diurnal insects with large compound eyes. Because they visually recognize conspecific and heterospecific individuals, their body color plays essential roles in ecology and reproductive biology. Here I introduce the recent topics of molecular mechanisms underlying color vision and color formation in dragonflies. Complex wing color polymorphism is recognized among the two closely related Japanese *Mnais* species, presumably due to stepwise character displacement to avoid interspecific mating. We discovered an extraordinary large number of visual opsin genes by RNA sequencing of 12 dragonfly species. Manual correction after de novo assembly was crucial for determining the exact number and sequence of opsin genes. Each opsin gene was differentially expressed between the adult and larva, as well as between dorsal and ventral regions of adult compound eyes, highlighting the behavior, ecology, and adaptation of aquatic larva to terrestrial adult. The repertoire of opsin genes differed among dragonfly species, plausibly involved in the diversity of the habitat and

behavior of each species. We also found that sex-specific yellow-red color transition in red dragonflies is regulated by redox changes in ommochrome pigments, which unveils a previously unknown molecular mechanism underlying body color change in animals. Establishment of the methods of gene functional analyses in dragonflies is desired for future studies." **18073.** Gabel, F.; Lorenz, S.; Stoll, S. (2017): Effects of ship-induced waves on aquatic ecosystems. *Science of the Total Environment* 601–602: 926-939. (in English) ["Highlights: • Effects of ship-induced waves are reviewed. • Abiotic: increase of erosion, resuspension of sediments and chemicals and turbidity. • Biotic: effects on dislocation, growth, reproduction and diversity on all trophic levels. • Effects on ecosystem services and management options are discussed. Most larger water bodies worldwide are used for navigation, and the intensity of commercial and recreational navigation is expected to further increase. Navigation profoundly affects aquatic ecosystems. To facilitate navigation, rivers are trained and developed, and the direct effects of navigation include chemical and biological impacts (e.g., inputs of toxic substances and dispersal of non-native species, respectively). Furthermore, propagating ships create hydrodynamic alterations, often simply summarized as waves. Although ship-induced waves are recognized as influential stressors, knowledge on their effects is poorly synthesized. We present here a review on the effects of ship-induced waves on the structure, function and services of aquatic ecosystems based on more than 200 peer reviewed publications and technical reports. Ship-induced waves act at multiple organizational levels and different spatial and temporal scales. All the abiotic and biotic components of aquatic ecosystems are affected, from the sediment and nutrient budget to the planktonic, benthic and fish communities. We highlight how the effects of ship-induced waves cascade through ecosystems and how different effects interact and feed back into the ecosystem finally leading to altered ecosystem services and human health effects. Based on this synthesis of wave effects, we discuss strategies for mitigation. This may help to develop scientifically based and target-oriented management plans for navigational waters that optimize abiotic and biotic integrity and their ecosystem services and uses." **18074.** Gabryszuk, M. (2017): Photogrammetric reconstruction of tandem-wing kinematics for free-flying dragonflies undergoing a range of flight maneuvers. M.Sc. Thesis, Faculty of the Graduate School of the University of Maryland, College Park: VIII, 111pp. (in English) ["Photogrammetric methods are used to reconstruct the body and wing kinematics of free-flying dragonflies. A novel experimental setup was designed and constructed to allow for repeated untethered flights in a constrained flight arena. Kinematic data are presented for twelve individual flights and a total of 23 complete

wing strokes, including unaccelerating, accelerating, climbing, and turning flight. High variability is observed in the wing motions employed by individual dragonflies, particularly in terms of stroke amplitude, pitch angle, and wingbeat frequency. Forewing and hindwing flapping is found to be neither in phase nor fully out of phase across all cases, with the forewings lagging the hindwings by an average of 90 degrees. Downstroke durations are observed to be shorter than upstroke durations except in highly accelerating flights. Migratory dragonflies are found to exhibit notably different wing kinematics than non-migratory species." *Erythemis simplicicollis*, *Pachydiplax longipennis*, *Pantala hymenaea* (Author)] Address: not stated

**18075.** Gainzarain, J.A.; Lasa, J.M. (2017): Presencia de *Brachytron pratense* (Müller, 1764) (Odonata, Aeshnidae) en una localidad montana de la provincia de Álava (norte de España). *Boletín de la Sociedad Entomológica Aragonesa* 61: 231-232. (in Spanish, with English summary) ["Presence of *B. pratense* at a montane locality in the province of Álava (northern Spain). "The Iberian distribution of the species appears to be very limited by altitude, and is restricted to coastal or very altitude, and is restricted to coastal localities or those very close to the coast. the coast, so the discovery of a population in Álava at 1000 m a.s.l. is noteworthy. of a population in Álava at 1000 m a.s.l. is noteworthy. On 26 June 2016 two males were observed at the Iturbaz reservoir, in the Entzia mountain range (30TWN56). Entzia (30TWN5640), one of which was photographed (Fig. 1). Two males were found again on 4 July at the same place, where, as on the same date where, as on the previous date, they flew constantly over a very specific area at over the water in a very specific area of the banks. In 2017, repeated visits to this repeated visits to this locality, and the species was observed again on three occasions on three occasions: 25 May (two, maybe three, ♂), 2 June (two ♂), 2 June (two ♂), 2 June (two ♂), 2 June (two ♂) and 2 June (two ♂). June (two ♂), and 7 June (one ♂), in all cases showing the same behaviour as in 2016. showing the same behaviour as in 2016. On subsequent visits, on 13 and 21 June no individuals were detected. As no juveniles or females have been observed, but the continued presence of males in two consecutive of males in two consecutive years in a locality very distant from other far away from other sites occupied by the species clearly points to the existence of an established to the existence of an established population in this pond." **18076.** García-García, P.L.; Vázquez, G.; Novelo-Gutiérrez, R.; Favila, M.E. (2017): Effects of land use on larval Odonata assemblages in cloud forest streams in central Veracruz, Mexico. *Hydrobiologia* 785: 19-33. (in English) ["This study analyzes the effect of stream water quality and its relationship with habitat characteristics on larval Odonata assemblages in streams found in tropical montane cloud forests, pastures, and coffee plantations in the upper La Antigua River

watershed. The main factors that influenced larval Odonata assemblages in forest streams were low temperatures and high oxygen levels in water, coupled with a high diversity of the substrate and riparian vegetation; in pasture streams and coffee plantation streams, sedimentation strongly affected the composition of larval Odonata assemblages. In all the streams, species richness (0 D) was higher during the dry season. The highest Shannon a diversity (1 D) values were found in forest streams during the rainy season; however, in pasture and coffee plantation streams, 1 D values were higher during the dry season. The low species turnover in forest streams suggests that these streams provide highly stable conditions for Odonata assemblages; however, in pasture and coffee plantation streams, the higher turnover was related to the more variable water and habitat conditions. Thus, the persistence of Odonata assemblages in the upper La Antigua River watershed is closely related to the conservation status of the tropical montane cloud forests." **18077.** Gerner, N.V.; Kone, M.; Ross, M.S.; Pereira, A., Ulrich, A.C.; Martin, J.W.; Liess, M. (2017): Stream invertebrate community structure at Canadian oil sands development is linked to concentration of bitumen-derived contaminants. *Science of the Total Environment* 575: 1005-1013. (in English) ["Highlight: • Aquatic exposure and effects were examined in Northern Alberta (Canada). • Effects on invertebrate community structure were monitored. • Effects at concentrations 100 times below the acute sensitivity of *Daphnia magna* • A biological indicator system, SPEARoil, was designed. • SPEARoil is applicable for future routine monitoring of oil sands related effects. In Canada, the Athabasca oil sands deposits are a source of bitumen-derived contaminants, reaching the aquatic environment via various natural and anthropogenic pathways. The ecological effects of these contaminants are under debate. To quantify the effects of bitumen-derived contaminants we monitored the aquatic exposure of polycyclic aromatic hydrocarbons (PAHs), metals, and naphthenic acids as well as the invertebrate community in the Athabasca River and its tributaries. PAH concentrations over 3 consecutive years were related to discharge and were highest in the year with high autumn rainfall. In the year with the highest PAH concentrations, these were linked with adverse effects on the aquatic invertebrate communities. We observed relative effects of the composition and concentration of contaminants on the invertebrate fauna. This is reflected by the composition and abundance of invertebrate species via the use of the species' traits "physiological sensitivity" and "generation time". Applying the SPEAR approach we observed alterations of community structure in terms of an increased physiological sensitivity and a decrease of generation time for the average species. These effects were apparent at concentrations 100 times below the acute sensitivity of the standard test organism *Daphnia magna*. To rapidly identify oil sands related effects in the field we designed a biological indicator system, SPEARoil,

applicable for future routine monitoring.] Address: Gerner, Nadine, UFZ, Helmholtz Centre for Environmental Research, Department System-Ecotoxicology, Permoserstr. 15, 04318 Leipzig, Germany

IT1110033 "Stazioni di *Myricaria germanica*" (Insecta: Odonata; Orthoptera; Lepidoptera: Rhopalocera). *Rivista piemontese di Storia naturale* 38: 207-224. (in Italian, with English summary) ["This paper presents the results of a one-year monitoring project on insect fauna carried out in the SCI IT1110033 "Stazioni di *Myricaria germanica*". Dragonflies, grasshoppers and butterflies were chosen as target taxa in this research, providing an overview of the diversity status of these groups in the study area. Overall, 15 dragonfly, 30 grasshopper and 51 butterfly species were found, enhancing and updating the information about the presence and the distribution of these insects in the SCI. While dragonflies are strictly relied on small wetlands and ditches within the Pellice's river ecosystem, grasshopper and butterfly diversity depends mainly on habitat heterogeneity. The relatively high quality of the river ecosystem, together with the extensive management of meadows, produce a number of habitats (e.g. dry grasslands, gravel beds, bushes, hay meadows, etc.) essential for hosting species with a wide range of ecological requirements. Therefore, the conservation of the river ecosystem quality and the maintenance of an extensive meadows management are critical measures to preserve the entomological diversity in the SCI." **18079.** Gleason, J.E.; Rooney, R.C. (2017): Aquatic macroinvertebrates are poor indicators of agricultural activity in northern prairie pothole wetlands. *Ecological Indicators* 81: 333-339. (in English) ["The Northern Prairie Pothole Region (NPPR) of Alberta, Canada, contains numerous shallow marshes that serve as important habitat for wildlife and provide essential ecosystem services. Many of these wetlands have been destroyed or degraded by human activity and the majority of remaining wetlands occur in landscapes affected by crop and cattle production. Alberta has implemented a conservation policy which requires the creation of wetland assessment tools. Aquatic macroinvertebrates are frequently used as indicators of environmental condition in rivers, but their effectiveness as indicators in prairie pothole wetlands is not clear. To evaluate the capacity of aquatic macroinvertebrates identified to family-level resolution to serve as regional bioindicators of agricultural disturbance in NPPR wetlands, we sampled macroinvertebrates at 64 fishless wetlands. The wetlands spanned a gradient in the extent of agriculture from 0 to 100% cover within a 500 m buffer around each wetland. We discovered that, contrary to our predictions, macroinvertebrate family richness and community composition could not predict agricultural disturbance (cropping or cattle grazing). We conclude that efforts to develop bioindicators for NPPR wetlands should be redirected to other taxa that are less costly to identify to species and that exhibit sensitivity to agricultural disturbance. ... We were particularly

optimistic about chironomids and odonates, but we could discern no relationship between these taxa and land use. For Odonata, these results are contrary to both our predictions and previous research from Alberta's NPPR (e.g., Hornung and Rice, 2003; Silver and Vamosi, 2012). One explanation for this discrepancy may be that these studies identified larval odonates to genus, but as mentioned this was beyond the scope of our limited study." **18080.** Golab, M.J.; Golab, P.A.; Contreras-Garduño, J.; Zajac, T.; Sniegula, S. (2017): The effects of habitat deterioration and social status on patrolling behavior in the territorial damselfly *Calopteryx splendens*. *Polish Journal of Ecology* 65(1): 122-131. (in English) ["Patrolling behaviour plays an important role in resource defense and in shaping social interactions in territorial species. However, it is not clear whether and how resource deterioration affects patrolling and interactions between territorial males. We addressed this issue by studying the territorial patrolling of *C. splendens* males, which use riverine vegetation patches composed of floating rafts of *Potamogeton natans* as territories. Males can hold single territories established on one vegetation patch (solitary residents) or hold adjacent territories established on shared vegetation patch (contiguous residents). The study predicted that solitary males engage more in patrolling than contiguous residents and that patrolling intensity is proportional to patch quality. Two types of semi-natural vegetation patches were sunk: of high and low quality measured on the basis of the patch size (range 2–5 m<sup>2</sup>) and its attractiveness to damselflies (measured as number of residents, non-territorial males and contests observed at a given patch). Changes in number of patrolling flights were monitored for solitary and two contiguous residents: first which hold territory situated closer to the patch centre and secondary holding territory nearer to the edge of a patch. Results indicated that solitary residents patrolled more often than either of the two contiguous residents. Habitat deterioration significantly reduced the patrolling intensity of both single and first contiguous resident, however, their patrolling activity was not resumed at the same intensity after the original patch had been restored. The secondary resident of a contiguous pair did not respond to habitat deterioration, but increased its patrolling activity following restoration. Patch quality was found to have no impact on patrolling, which implies that social context can be more important in predicting changes in patrolling behaviour in response to resource deterioration." (2017): Efecto de las descargas domésticas y de beneficio de café sobre la calidad del agua y la diversidad de larvas de Odonata (Insecta) en un arroyo de bosque mesófilo de montaña en Veracruz, México. *Revista Mexicana de Biodiversidad* 88: 372-380. (in Spanish, with English summary) ["Effect of domestic and coffee mill discharges on the

water quality and the Odonata larval diversity in a mountain cloud forest stream in Veracruz, Mexico: Two contrasting sites along Huehueyapan River (Veracruz, Mexico), one relatively conserved and the other one impacted by domestic and coffee mill discharges, were compared based on water quality data, and the structure of the Odonata larval assemblages. Riparian vegetation of both sites was differentially modified or replaced. Physical and chemical parameters and Odonata larvae were gathered from January to November 2001. A Hotelling-T test was used to compare the physico-chemical parameters while rank/abundance graphs and Renyi diversity profiles were constructed using Odonata larvae data. A total of 2,212 larvae of 13 species in 7 genera were collected. The sites were very similar in number of species and Odonata larval assemblage structure, however, some of the most abundant species at both sites showed significant differences in abundance. The observed differences between the 2 sites are mainly explained by differences in the structure of riparian vegetation and the availability of substrates for odonates and, secondarily, by physical and chemical changes in the water. An abundance ratio was established based on the most abundant species for monitoring future impairment or recovery changes." **18082.** Grof-Tisza, P.; LoPresti, E.; Heath, S.K.; Karban, R. (2017): Plant structural complexity and mechanical defenses mediate predator-prey interactions in an odonate-bird system. *Ecology and Evolution* 7(5): 1650-1659. (in English) ["Habitat-forming species provide refuges for a variety of associating species; these refuges may mediate interactions between species differently depending on the functional traits of the habitat-forming species. We investigated refuge provisioning by plants with different functional traits for Odonata nymphs emerging from water bodies to molt into their adult stage. During this period, nymphs experience high levels of predation by birds. On the shores of a small pond, plants with mechanical defenses (e.g., thorns and prickles) and high structural complexity had higher abundances of odonate exuviae than nearby plants which lacked mechanical defenses and exhibited low structural complexity. To disentangle the relative effects of these two potentially important functional traits on nymph emergence-site preference and survival, we conducted two fully crossed factorial field experiments using artificial plants. Nymphs showed a strong preference for artificial plants with high structural complexity and to a lesser extent, mechanical defenses. Both functional traits increased nymph survival but through different mechanisms. We suggest that future investigations attempt to experimentally separate the elements contributing to structural complexity to elucidate the mechanistic underpinnings of refuge provisioning." **18083.** Groover, R.S. (2017): Temporal and Spatial Aspects of the Colonization and Re-Colonization of Dragonflies in

Lentic Habitats. Dissertation, George Mason University, Fairfax, VA: xii, 147 pp. (in English) ["This dissertation describes dragonfly species of Hanover County, Virginia, which species are most likely to be first colonizers of a new or reconstructed impoundment, which species are never found as first colonizers, and which species are the dominant species three years after the impoundment fills with water. In this Piedmont region of Virginia, *Erythemis simplicicollis*, *Libellula incesta*, *Libellula luctuosa*, and *Perithemis tenera* were the first to colonize all sites researched. *Celithemis eponina* and *Pachydiplax longipennis* did appear as first colonizers, but not at all sites. Proximity to a source site appears to be a determinate for these six species, not any size or behavioral characteristics. Seventeen species, no matter what the proximity of a source site, never were first colonizer species for a new impoundment. During this research three species not previously noted on published species lists from government or organizations for this county were collected: *Anax junius*; *Libellula pulchella*; and *Pantala hymenaea*. Seven species found during this study are new additions for the Commonwealth of Virginia official species list for Hanover County: *A. junius*; *A. longipes*; *Celithemis eponina*; *C. fasciata*; *Libellula vibrans*; *Pantala flavescens*; and *Tramea lacerata*. Investigations regarding dominance after three years indicated that dominance did not change; whatever species arrived first, maintained dominance. Additional community structure in the lentic habitat was observed. This dissertation investigated the impact of wind on dispersal direction. In a manipulated mark and observation experiment, findings indicate that wind velocity in excess of 5 km/hr. resulted in the dragonfly's dispersal downwind. Less than 5 km/hr. results in varied direction of flight. Wind direction and velocity may impact direction of dispersal for adult dragonflies. Larval dragonflies were reared in an outdoor vivarium, the first of its kind, with documented survival of 74%, or greater, of the tenebrals." (Author)] Address: not stated

**18084.** Gwiazda, R.; Ledwon, M.; Neubauer, G. (2017): Sex-specific foraging behaviour of adult Whiskered Terns *Chlidonias hybrida* in response to body mass and offspring age. *Acta Ornithologica* 52(1): 81-92. (in English) ["Understanding foraging strategies remains a central question in behavioural ecology, but studies investigating how foraging of sexes is affected by other individual characteristics, like body size, are still scarce. We investigated how foraging behaviour during chick rearing varies in males and females with brood size, offspring age and individual body mass of parents, in a sexually size-dimorphic waterbird, the Whiskered Tern *Chlidonias hybrida*. Our study took place at the carp fish ponds in southern Poland, where both invertebrates (dragonflies, a typical prey of females — caught by picking) and small vertebrates (fish, tadpoles, frogs, males typical prey — caught by plunge-diving) are plentiful and available for both sexes during chick-rearing period. In total, 1680 attacks of 29 uniquely marked birds (16 males and 13 females) were observed during chick-rearing period. Foraging techniques were affected by sex of the parent and offspring age, interacting with body mass, and brood size. Males foraged mainly by plunge diving, but avoided this foraging technique

if their broods were small and when offspring were young, probably because the chicks were too small to consume vertebrate prey caught by diving. In contrast, females foraged mostly by picking prey from the air, water surface or floating leaves, for most of chick-rearing period, but increased frequency of plunge diving as offspring age increased. A significant interaction between body mass and offspring age suggests that birds differing in body mass foraged differently as their offspring grew. We conclude that despite sex-specific differences in foraging behaviour (and prey type delivered to the chicks), both sexes in the Whiskered Tern alter foraging behaviour in response to both brood and individual birds' attributes." **18088.** Hashim, N.A.; Aziz, M.A.; Basari, N.; Saad, K.; Jasmi, A.H.; Hamid, S.A. (2017): Diversity and guild structure of insects during rice flowering stage at a selected rice field in Penang, Malaysia. *Malays. Appl. Biol.* 46(3): 161-169. (in English) ["A study on diversity of insects in rice field was conducted at Kg Terus, Guar Perahu in Penang. This study aims to determine the diurnality and guild structure of insect in rice field specifically during the flowering stage of rice. Insects were collected using sweep net method and light trap method. Overall, a total of 1936 insect specimens representing 28 species, 19 families and seven orders were collected. Twenty five species from 19 families were caught during day time while 17 species from 13 families were trapped at night. Coleopterans were the dominant insect captured during day time sampling with *Micraspis crocea* from family Coccinellidae captured in highest number (223). In contrast, Hemipterans was dominant during night time with *Nilaparvata lugens* from family Delphacidae found in highest number (258). The Odonata recorded the highest diversity index ( $H' = 1.2587$ ) while Coleoptera recorded the highest richness index ( $Imargalef = 5.8390$ ) values for diurnal insect. For nocturnal insect, Hemiptera recorded the highest values for both diversity index ( $H' = 1.2655$ ) and richness index ( $Imargalef = 5.8390$ ). In term of guild structure, the rice pest was the most dominant insect found in rice field for both diurnal and nocturnal group. This followed by predator, others (visitor/pollinator) and parasitoid groups. Result of this study will identify the classification of insect present during the flowering stage of rice allowing farmers to forecast pest population build up to assist in the pesticides selection that will be generally applied at the end of flowering stage. This consequently will help to conserve beneficial insects and lower the pest management cost." (Authors)] Address: Hashim, N.A., School of Food Science & Technology, Univ. **18090.** Higashikawa, W.; Yoshimura, M.; Yagi, T.; Maeto, K. (2017): Short and flat grass preferred by adults of the endangered dragonfly *Sympetrum pedemontanum elatum* (Odonata: Libellulidae). *Applied Entomology and Zoology* 52: 605-613. (in English) ["*S. pedemontanum* (Müller in Allioni) is widely distributed across the Eurasian continent and its neighboring islands. However, the populations of its subspecies *S. pedemontanum elatum* (Selys) in Japan have been rapidly decreasing with the loss of habitats in rural and suburban areas since the 1970s. For the conservation of this subspecies, which is now listed as endangered in many prefectures, it is important to understand the habitat preferences of the adults. Previous studies indicate that adult males of this species tend to fly on the flat surface of rice paddy fields. Thus, we hypothesized that they preferred short and flat grass. Field experiments in the Sakasegawa River, Hyogo Prefecture, Japan, showed that adult *S. p. elatum* significantly preferred the trimmed grass of *Phragmites japonicus* to untreated shaggy grass, regardless of sex. Our results indicate the importance of grass management for the conservation of this species, not only in and around paddy fields but also in fluvial habitats, which are abundant in Japan." **18091.** Hill, M.J.; Biggs, J.; Thornhill, I.; Briers, R.A.; Gledhill, D.G.; White, J.C.; Wood, P.J.; Hassall, C. (2017): Urban ponds as an aquatic biodiversity resource in modified landscapes. *Global Change Biology* 23: 986-999. (in English) ["Urbanization is a global process contributing to the loss and fragmentation of natural habitats. Many studies have focused on the biological response of terrestrial taxa and habitats to urbanization. However, little is known regarding the consequences of urbanization on freshwater habitats, especially small lentic systems. In this study, we examined aquatic macro-invertebrate diversity (family and species level) and variation in community composition between 240 urban and 782 nonurban ponds distributed across the United Kingdom. Contrary to predictions, urban ponds supported similar numbers of invertebrate species and families compared to nonurban ponds. Similar gamma diversity was found between the two groups at both family and species taxonomic levels. The biological communities of urban ponds were markedly different to those of nonurban ponds, and the variability in urban pond community composition was greater than that in nonurban ponds, contrary to previous work showing homogenization of communities in urban areas. Positive spatial autocorrelation was recorded for urban and nonurban ponds at 0–50 km (distance between pond study sites) and negative spatial autocorrelation was observed at

100–150 km and was stronger in urban ponds in both cases. Ponds do not follow the same ecological patterns as terrestrial and lotic habitats (reduced taxonomic richness) in urban environments; in contrast, they support high taxonomic richness and contribute significantly to regional faunal diversity. Individual cities are complex structural mosaics which evolve over long periods of time and are managed in diverse ways. This facilitates the development of a wide range of environmental conditions and habitat niches in urban ponds which can promote greater heterogeneity between pond communities at larger scales. Ponds provide an opportunity for managers and environmental regulators to conserve and enhance freshwater biodiversity in urbanized landscapes whilst also facilitating key ecosystem services including storm water storage and water treatment." **18092.** Hoeymans, B. (2017): The dragonfly fauna of the Merkske valley. *Brachytron* 19(2): 55-70. (in Dutch, with English summary) ["A total of 50 species of damselflies and dragonflies has been observed in the Merkske valley. Thirty-eight of them have populations in the study area and probably three more species are also reproducing. Seven species are only known to occur erratically. Most of these have rather a Mediterranean or southeastern origin. Colonisation of the area by *Gomphus vulgatissimus* is expected in the near future. Two species, *Aeshna subarctica* and *Sympetrum flaveolum* no longer occur in the area. The impressive list of species illustrates the regional importance of Het Merkske for the dragonfly population." (Author)] Address: Hoeymans, B.: E-mail: bart.hoeymans@vlaanderen.be

**18093.** Holzweber, H.; Waringer, J.; Chovanec, A. (2017): Ökologie von Hochmoorlibellen (Insecta: Odonata) im Freiwald und Weinsbergerwald (Ober- und Niederösterreich). *Acta ZooBot Austria* 154: 75-88. (in German, with English summary) ["The ecological status of mires is mostly evaluated by vegetation; however, dragonflies (Odonata) are reliable and valuable indicators for the hydrological and morphological status of mires. Based on the occurrence of autochthonic Odonata, the Dragonfly Association Index (DAI) thereby gives information about the ecological situation of mires. For this investigation the ecology of dragonflies in mires was observed between April and September 2015. Study sites were situated in seven bogs in the Freiwald and Weinsbergerwald area in the Austrian Bohemian Massif, with 27 sampling sites in total. Overall, 14 different dragonfly species were found, and 11 species are autochthonic. *Coenagrion hastulatum*, *Aeshna juncea*, *Leucorrhinia dubia*, *Somatochlora alpestris* and *Somatochlora arctica* are autochthonic dragonflies which are dependent on mires. Additionally, the sampling sites were divided into different quality classes, based on vegetation, and were assessed via a DAI developed specifically for this region, which is also applicable to other limnological ecosystems. For the development of this DAI, 53 potentially occurring dragonfly species were classified by their ecological requirements via cluster analysis. As a result, we defined nine associations which correlate with mire-specific

characteristics. In the mires of this region three fundamental associations were extracted: association in mires with open water, association in mires without open water and association in marshy waters with emerged vegetation. The results show that three sampling sites are in a very good condition, three are in a good and 21 sampling sites are in a bad condition. Most of the mires in this region are anthropogenically affected, and the reproduction sites for specific dragonflies depending on mires continually decrease. Via individual preservation and renaturation these sites could persist, recover and even increase, thereby providing habitats for rare mire plants and animals." **18094.** Horgan, F.G.; Ramal, A.F.; Villegas, J.M.; Jamorlin, A.; Bernal, C.C.; Perez, M.O.; Pasang, J.M.; Naredo, A.I.; Almazan, M.L.P. (2017): Effects of bund crops and insecticide treatments on arthropod diversity and herbivore regulation in tropical rice fields. *Journal of Applied Entomology* 141(8): 587-599. (in English) ["Ecological engineering using vegetable or flower strips is promoted as a potential pest management strategy in irrigated rice. Farmers in the Philippines often plant rice levees (bunds) with vegetables, particularly string beans (*Vigna unguiculata* [L.] Walpers) to supplement income, but without considering the potential for pest management. This study examines the effects of planted bunds on rice herbivores and their natural enemies. We compared arthropods in (a) rice fields that had string beans planted on bunds, (b) fields without string beans and without any insecticide applications and (c) fields without string beans but with insecticide treatments (standard practice). Rice yield was similar across all treatments; however, the vegetation strips produced an extra 3.6 kg of fresh string bean pods per metre of bund. There were no apparent increases in major natural enemy groups in fields with string beans compared to fields with conventional bunds. Fields with insecticide treatments had higher damage from leafhoppers (Lepidoptera: Pyralidae). The sprayed fields also had lower parasitism of planthopper eggs and fewer predatory Odonata. Furthermore, the mortality of planthopper (Delphacidae: Hemiptera) and stemborer (Pyralidae) eggs by parasitoids and predators was density dependent only in the unsprayed fields (with and without string beans). Our results demonstrate that planting string beans on rice bunds improves the productivity of rice farms, but our ecological engineering system did not appreciably affect natural enemy or herbivore abundance; however, chemical insecticides adversely affected pest regulatory ecosystem functions leading to higher pest damage." **18096.** Ichikawa, Y.; Yokoi, T.; Watanabe, M. (2017): Thermal factors affecting egg development in the wandering glider dragonfly, *Pantala flavescens* (Odonata: Libellulidae). *Applied Entomology and Zoology* 52(1): 89-95. (in English) ["*P. flavescens* arrives in Japan from tropical regions every spring. The offspring colonize areas throughout Japan, with rapid increases in populations in the autumn, but all individuals die in the winter, suggesting low tolerance to low temperatures. However, few quantitative data on egg development and water temperature have been reported for this species. Females at the reproductive stage were collected from fields throughout the flying season and their eggs released using an artificial oviposition technique. Almost all of the eggs were fertilized. Egg size was stable throughout the seasons. Most eggs hatched within a period of 5 days at high water temperatures (35 and 30 °C), which were recorded in the shallow ponds and rice paddy fields from summer to early autumn. However, the egg-stage duration increased with declining water temperature. All eggs in water at 15 °C had failed to hatch by 90 days. The calculated critical temperature of water was determined to be approximately 14.3 °C; the total effective temperature for the egg stage was about 80 degree-days. Thus, low water temperatures in winter may prevent *P. flavescens* overwintering in Japan." (Authors)] Address: Yokoi, T., Graduate School of Life and Environmental Sciences, University of Tsukuba. **18098.** Ivanova, E.P.; Song Ha Nguyen, S.H.; Guo, Y.; Baulin, V.A.; Webb, H.K.; Truong, V.K.; Wandiyanto, J.V.; Garvey, C.J.; Mahon, P.J.; Mainwaring, D.E.; Crawford, R.J. (2017): Bactericidal activity of self-assembled palmitic and

stearic fatty acid crystals on highly ordered pyrolytic graphite. *Acta Biomaterialia* 59: 148-157. (in English) ["The wings of insects such as cicadas and dragonflies have been found to possess nanostructure arrays that are assembled from fatty acids. These arrays can physically interact with the bacterial cell membranes, leading to the death of the cell. Such mechanobactericidal surfaces are of significant interest, as they can kill bacteria without the need for anti-bacterial chemicals. Here, we report on the bactericidal effect of two of the main lipid components of the insect wing epicuticle, palmitic (C<sup>16</sup>) and stearic (C<sup>18</sup>) fatty acids. Films of these fatty acids were re-crystallised on the surface of highly ordered pyrolytic graphite. It appeared that the presence of two additional CH<sub>2</sub> groups in the alkyl chain resulted in the formation of different surface structures. Scanning electron microscopy and atomic force microscopy showed that the palmitic acid microcrystallites were more asymmetric than those of the stearic acid, where the palmitic acid microcrystallites were observed to be an angular abutment in the scanning electron micrographs. The principal differences between the two types of long-chain saturated fatty acid crystallites were the larger density of peaks in the upper contact plane of the palmitic acid crystallites, as well as their greater proportion of asymmetrical shapes, in comparison to that of the stearic acid film. These two parameters might contribute to higher bactericidal activity on surfaces derived from palmitic acid. Both the palmitic and stearic acid crystallite surfaces displayed activity against Gram-negative, rod-shaped *Pseudomonas aeruginosa* and Gram-positive, spherical *Staphylococcus aureus* cells. These microcrystallite interfaces might be a useful tool in the fabrication of effective bactericidal nanocoatings. Statement of Significance: Nanostructured cicada and dragonfly wing surfaces have been discovered to be able physically kill bacterial cells. Here, we report on the successful fabrication of bactericidal three-dimensional structures of two main lipid components of the epicuticle of insect wings, palmitic (C<sup>16</sup>) and stearic (C<sup>18</sup>) acids. After crystallisation onto highly ordered pyrolytic graphite, both the palmitic and stearic acid films displayed bactericidal activity against both Gram-negative *Pseudomonas aeruginosa* and Gram-positive *Staphylococcus aureus* cells. The simplicity of the production of these microcrystallite interfaces suggests that a fabrication technique, based on solution deposition, could be an effective technique for the application of bactericidal nanocoatings." (2017): Examination of the link between life stages uncovered the mechanisms by which habitat characteristics affect odonates. *Ecosphere* 8(9): e01930. 10.1002/ecs2.1930: 7 pp. (in English) ["The larval and adult stages of amphibious animals are affected by both aquatic and terrestrial habitat characteristics, and each stage also affects the other. However, this link between life stages has been largely overlooked in previous studies. We examined the effect of aquatic and terrestrial habitat characteristics on

the diversity of larval and adult odonates, taking into account the link between the two life stages. Species diversity of adult and larval odonates and aquatic plants, as well as patterns of land use, was investigated in 63 irrigation ponds. We created structural equation models, with paths from land use and aquatic plants characteristics to larval and adult stages of odonates, as well as between the two stages, and chose the best model based on the lowest Akaike information criterion. Adult odonates, but not larvae, were affected by aquatic and terrestrial habitat characteristics, suggesting that the former is the key stage for odonate communities. We observed a positive relationship between the diversity of aquatic plants and larval odonates, but this was in fact due to the effects of aquatic plants on adults, which carried over to the larval stage. Our study showed that a consideration of the link between life stages is crucial for a complete understanding of the relationship between habitat characteristics and amphibious animal populations." **18101.** Janssens, L.; Stokks, R. (2017): Stronger effects of Roundup than its active ingredient glyphosate in damselfly larvae. *Aquatic Toxicology* 193: 210-216. (in English) ["Highlights: •Commercial pesticide formulations can be more toxic than their active ingredient. •We compared the effects of Roundup and its active ingredient glyphosate. •Roundup was more toxic than glyphosate in terms of survival, behaviour and physiology. •Glyphosate itself reduced growth rate, escape swimming speed and fat content. •Sublethal effects matter when comparing commercial products and active ingredients. Abstract: Pesticides are causing strong decreases in aquatic biodiversity at concentrations assumed safe by legislation. One reason for the failing risk assessment may be strong differences in the toxicity of the active ingredient of pesticides and their commercial formulations. Sublethal effects, especially those on behaviour, have been

largely ignored in this context, yet can be equally important as lethal effects at the population and ecosystem levels. Here, we compared the toxicity of the herbicide Roundup and its active ingredient glyphosate on survival, but also on ecologically relevant sublethal traits (life history, behaviour and physiology) in damselfly larvae. Roundup was more toxic than glyphosate with negative effects on survival, behaviour and most of the physiological traits being present at lower concentrations (food intake, escape swimming speed) or even only present (survival, sugar and total energy content and muscle mass) following Roundup exposure. This confirms the toxicity of the surfactant POEA. Notably, also glyphosate was not harmless: a realistic concentration of 2 mg/l resulted in reduced growth rate, escape swimming speed and fat content. Our results therefore indicate that the toxicity of Roundup cannot be fully attributed to its surfactant, thereby suggesting that also the new generation of glyphosate-based herbicides with other mixtures of surfactants likely will have adverse effects on non-target aquatic organisms. Ecotoxicological studies comparing the toxicity of active ingredients and their commercial formulations typically ignore behaviour while the here observed differential effects on behaviour likely will negatively impact damselfly populations. Our data highlight that risk assessment of pesticides ignoring sublethal effects may contribute to the negative effects of pesticides on aquatic biodiversity." **18102.** Jiang, Y.; He, Z.; Zhao, M.; Wang, C.; Sun, L.; Feng, Y. (2017): Oil content and fatty acid composition of six kinds of common edible dragonfly naiads. *China Oils and Fats* 42(3): 135-139. (in Chinese, with English summary) ["In order to evaluate the nutritional value of common edible dragonfly naiads in Yunnan and Guizhou provinces, the oil content and fatty acid composition of *Epophthalmia elegans*, *Anax parthenope julius*, *Ictinogomphus rapax*, *Partiala flavescens*, *Sinictinogomphus clavatus* and *Orthetrum pruinatum neglectum* were analyzed by Soxhlet extraction method and GC-MS. The results showed that the oil contents of six kinds of dragonfly naiads were 5.72% -11.90%. The oil contents of *Sinictinogomphus clavatus* and *Orthetrum pruinatum neglectum* were the highest and the lowest respectively. 18-29 kinds of fatty acids were identified, including odd-number carbon fatty acids, EPA and DHA, which had special functions. The unsaturated fatty acids (UFA) accounted for 61.50% -65.22% of total fatty acids and the polyunsaturated fatty acids (PUFA) accounted for 29.57% -50.00% of total UFA. The contents of hexadecanoic acid were the highest, which were 17.57% -24.61%. The ratios of n-6 PUFA to n-3 PUFA were 0.68 -1.30, which were similar to the freshwater fish oils. The ratios of saturated fatty acid to monounsaturated fatty acid to PUFA in *Pantala flavescens* and *Orthetrum pruinatum neglectum* were 1.17:1.2:1 and 1.3:1.18:1, which were close to the ratios recommended by the North Atlantic Treaty Organization and the American Heart Association (1:1.5:1 and (0.8 - 1) :1.5:1)." **18103.** Jiang, Y.; Zhao, M.; Me, Z.; Wang, C.; Sun, L.; Feng, Y. (2017): Nutrition composition and evaluation of six edible dragonfly naiads. *Biotic Resources* 39(5): 352-359. (in Chinese, with English summary) ["To utilize the resource of edible dragonflies scientifically, we analyzed and valued the nutritional composition of six common edible dragonfly naiads collected in Yunnan and Guizhou provinces of China. The contents of protein, oil, carbohydrate, moisture, ash, amino acid, mineral element and fat soluble vitamin were analyzed by Kjeldahl method, Soxhlet extraction method, anthrone colorimetry method, auto analysis of free amino acid method, atomic absorption method, inductively coupled plasma mass spectrometry method (ICP-MS) and high performance liquid chromatography (HPLC). The results showed that the average content of moisture of six common edible dragonfly naiads were 81.17%, the average contents of protein, oil, carbohydrate and ash were 65.62%, 9.80%, 3.01% and 5.47% respectively from dry basis. Their amino acid composition fits the ideal protein pattern established by WHO/FAO, and the limiting amino acids were Met + Cys and Trp. The closeness degrees of protein of six common edible dragonfly naiads to egg protein were 0.59~0.66. They were rich in mineral elements, especially Calcium and Selenium, and as high as 0.252~3.859 mg · kg<sup>-1</sup> or tocopherol was detected in six specimens. Edible dragonflies have prospects of development and utilization, but it should be noted that some heavy metal elements in some species exceed the standard." **18105.** Johansson, F.; Halvarsson, P.; Mikolajewski, D.J.; Höglund, J. (2017): Phylogeography and larval spine length of the dragonfly *Leucorrhinia dubia* In Europe. *PLoS ONE*

12(9): e0184596. <https://doi.org/10.1371/journal.pone.0184596>: 9 pp. (in English) ["Presence or absence of predators selects for different kind of morphologies. Hence, we expect variation in traits that protect against predators to vary over geographical areas where predators vary in past and present abundance. Abdominal larval spines in dragonfly larvae provide protection against fish predators. We studied geographical variation in larval spine length of the dragonfly *Leucorrhinia dubia* across Western Europe using a phylogenetic approach. Larvae were raised in a common garden laboratory experiment in the absence of fish predators. Results show that larvae from northern Europe (Sweden and Finland) had significantly longer larval spines compared to larvae from western and central Europe. A phylogeny based on SNP data suggests that short larval spines is the ancestral stage in the localities sampled in this study, and that long spines have evolved in the Fenno-Scandian clade. The role of predators in shaping the morphological differences among the sampled localities is discussed." **18106.** Jones, D.K.; Hintz, W.D.; Schuler, M.S.; Yates, E.K.; Mattes, B.M.; Relyea, R.A. (2017): Inducible tolerance to agrochemicals was paved by evolutionary responses to predators. *Environ. Sci. Technol.* 51(23): 13913-13919. (in English) ["Recent research has reported increased tolerance to agrochemicals in target and nontarget organisms following acute physiological changes induced through phenotypic plasticity. Moreover, the most inducible populations are those from more pristine locations, far from agrochemical use. We asked why do populations with no known history of pesticide exposure have the ability to induce adaptive responses to novel agrochemicals? We hypothesized that increased pesticide tolerance results from a generalized stressor response in organisms, and would be induced following sublethal exposure to natural and anthropogenic stressors. We exposed larval wood frogs (*Lithobates sylvaticus*) to one of seven natural or anthropogenic stressors (predator cue (*Anax* spp.), 0.5 or 1.0 mg carbaryl/L, road salt (200 or 1000 mg Cl<sup>-</sup>/L), ethanol-vehicle control, or no-stressor control) and subsequently tested their tolerance to a lethal carbaryl concentration using time-to-death assays. We observed induced carbaryl tolerance in tadpoles exposed to 0.5 mg/L carbaryl and also in tadpoles exposed to predator cues. Our results suggest that the ability to induce pesticide tolerance likely arose through evolved antipredator responses. Given that antipredator responses are widespread among species, many animals might possess inducible pesticide tolerance, buffering them from agrochemical exposure." **18109.** Jung, S.W.; Cho, Y.C.; Lee, H.-G. (2017): Community characteristics and biological quality assessment on benthic macroinvertebrates of Bongseonsa stream in Gwangneung Forest, South Korea. *Korean J. Environ. Ecol.* 31(6): 508-519. (in Korean, with English summary) ["There have been many studies on monitoring of biodiversity changes and preservation of Gwangneung Forest Biosphere Reserve (GFBR) in South Korea in recognition of the rare ecosystem that has been preserved for a long period. However, there are few studies on diversity and community characteristics of benthic macroinvertebrates as an indicator of stream health of GFBR. The purpose of this study was to assess the water quality of Bongseonsa Stream that penetrated through Gwangneung Forest and the nearby torrents by analyzing the benthic macroinvertebrates community during April to September 2016. The investigation collected a total of 114 species of benthic macroinvertebrates belonging to 56 families, 17 orders, 8 classes, and 5 phyla from the Bongseonsa Stream and Kwangneung Stream. Ephemeroptera and Trichoptera were the largest groups in species diversity with 30 species (32.3%) and 16 species (17.2%), respectively, and Tubificidae sp., *Baetis fuscatus*, *Antocha* KUa, and *Cheumatopsyche brevilineata*, which usually habit in contaminated streams, appeared frequently. Among the feeding function groups, the gatherers and hunters appeared relatively frequently, and the shredders and scrapers appeared frequently in the torrents. Among the habitat oriented groups, the clingers and burrower appeared more frequently and represented the microhabitats in the shallow areas. The result of the analysis of benthic macroinvertebrates community showed that the dominant index was 0.48±0.10 in average while it was lowest with 0.33 in GS 8 of the Gwangneung Forest torrent

and highest in BS 1 of Bongseonsa Stream. The diversity and richness indices were inversely proportional to the dominant index and were 2.53 and 4.22, respectively, in GS 8 where the dominant index was low. The result of the analysis of community stability showed that area I, which had high resistance and restoration, was high in Bongseonsa Stream while the area III, which had low resistance and restoration, was high in Gwangneung Forest, indicating that the water system in Gwangneung Forest had a wider distribution of species sensitive to agitation. The biological water quality assessment showed ESB of  $50.88 \pm 17.69$ , KSI of  $1.11 \pm 0.57$ , and BMI of  $78.55 \pm 11.05$  GS 8 of Gwangneung Forest torrent was judged to be the highest priority protective water area with the best water environment and I class water quality with ESB of 63, KSI of 0.55, and BMI of 89.9. On the contrary, BS 1 of Bongseonsa Stream was judged to be the high priority improvement area that had the lowest water quality rating of III with ESB of 25, KSI of 2.13, and BMI of 62.7. Although the diversity of water beetle was higher in the water system of nearby Bongseonsa Stream than the water system inside the Gwangneung Forest, the annual community structure appeared to have distinct differences." **18111.** Karlsson, E. (2017): Temperature acclimation in dragonfly larvae: which species are more vulnerable to global warming? M.Sc. thesis, Biology Education Centre and Department of ecology and genetics/Animal ecology, Uppsala University: 33pp. (in English) ["Climate change is affecting all known habitats on earth. Increased temperatures in aquatic habitats will not only heat the waters but will also cause larger variation in temperature fluctuation. Many animals in aquatic systems are adapted to specific habitats in these waters and may face disadvantages if temperatures changes too much. In my project, I have used larvae of dragonflies and damselflies to examine how they might be affected by changes in water temperature caused by climate change. I sampled damselfly and dragonfly larvae in three lakes around Uppsala at two water depths, in order to examine whether these species differed in their depth distribution. Larvae exposed to thermal fluctuations should be better at adapting to the increase in temperature from global warming. In a laboratory experiment I tested the ability to acclimate to three temperatures (18, 21 and 24 °C) in three

species of damselfly larvae (*Ischnura elegans*, *Coenagrion pulchellum*, and *Erythromma najas*), over four different time intervals (1, 2, 12 and 24 hours) for *E. najas* and two time intervals for *I. elegans* and *C. pulchellum*. To measure acclimation, I introduced prey items in a laboratory experiment, and counted how many strikes and captures the larvae managed to do during a 10 min interval after being acclimated to the four different time intervals. The results of the field sampling in the lakes showed species specific depth distribution differences in dragonfly and damselfly larvae, with the majority of species preferring the surface over the bottom. The results from the temperature acclimation experiments showed that species changed then strikes and capture success on prey over the different time intervals, and especially *E. najas* showed a clear trend that suggest adaptation to temperate changes. Species differed in prey capture behaviour, with *E. najas* having the highest and *C. pulchellum* the lowest number of strikes and capture success. Results also suggested that *E. najas* is able to acclimate to the temperatures over the time period tested. This species also had a wide depth distribution in the lakes, which might explain its faster acclimation, even though a similar depth distribution was found in the non acclimating *C. pulchellum*. The other two species (besides *E. najas*) showed less clear patterns with regard to acclimation and it was difficult to tell if they were able to acclimate to the tested temperatures. My results suggest that damselfly larvae species are able to acclimate in prey capture behaviour over relatively short time periods in response to temperature fluctuations, and they might therefore be able to adapt to increasing temperature fluctuations in the future." **18112.** Kaunisto, K.M.; Roslin, T.; Sääksjärvi, I.E.; Vesterinen, E.J. (2017): Pellets of proof: First glimpse of the dietary composition of adult odonates as revealed by metabarcoding of feces. *Ecology and Evolution*. 2017;7. <https://doi.org/10.1002/ece3.3404>: 8588-8598. (in English) ["Recent advances in molecular techniques allow us to resolve the diet of unstudied taxa. Odonates are potentially important top-down regulators of many insects. Yet, to date, our knowledge of odonate prey use is based mainly on limited observations of odonates catching or eating their prey. In this study, we examine the potential use of metabarcoding in establishing the diet of three adult odonate species (*Lestes sponsa*, *Enallagma cyathigerum*, and *Sympetrum danae*) at a site in southwestern Finland. To this purpose, we compared three different methods for extracting DNA from fecal samples: the Mache-rey-Nagel Nucleospin XS kit, a traditional salt extraction, and the Zymo Research Fecal Microprep kit. From these extracts, we amplified group-specific mitochondrial markers (COI and 16S rRNA) from altogether 72 odonate individuals, and compared them to comprehensive reference libraries. The three odonate species show major overlap in diet, with no significant differences between individuals of different size and/or gender, reflecting opportunistic foraging of adult odonates. Of a total of 41 different prey species detected, the most frequently consumed ones were Diptera, with additional records of six other orders. Based on our data, the best DNA

extraction method is the traditional salt extraction, as it provides the most information on prey content while also being the most economical. To our knowledge, this is the first study to resolve the species-level diet of adult odonates. Armed with the appropriate methodological caveats, we are ready to examine the ecological role of odonates in both terrestrial and aquatic food webs, and in transferring subsidies between these two realms." **18114.** Khandakera, M.S.K.; Dudek, D.M.; Beers, E.P.; Dillard, D.A. (2017): Expression, crosslinking, and developing modulus master curves of recombinant resilin. *Journal of the Mechanical Behavior of Biomedical Materials* 69: 385-394. (in English) ["Highlights: • Recombinant resilin comprising exons 1 & 2 crosslinked for mechanical testing. • DMA tests conducted as function of temperature, frequency, & ethanol concentration. • Storage modulus increases observed spanning three orders of magnitude. • Glass transition, H-bonding, or structural reorganization likely responsible for effect. • Properties of recombinant resilin are in fair agreement with actual insect resilin. Abstract: Resilin is a disordered elastomeric protein found in specialized regions of insect cuticles, where low stiffness and high resilience are required. Having a wide range of functions that vary among insect species, resilin operates across a wide frequency range, from 5 Hz for locomotion to 13 kHz for sound production. We synthesize and crosslink a recombinant resilin from clone-1 (exon-1 + exon-2) of the gene, and determine the water content (approximately 80 wt%) and dynamic mechanical properties, along with estimating surface energies relevant for adhesion. Dynamic moduli master curves have been developed, by applying the time-temperature superposition principle (TTSP) and time-temperature concentration superposition principle (TTCSP), and compared with reported master curves for natural resilin from locusts, dragonflies, and cockroaches. To our knowledge, this is the first time dynamic moduli master curves have been developed to explore the dynamic mechanical properties of recombinant resilin and compare with resilin behavior. The resulting master curves show that the synthetic resilin undergoes a pronounced transition with increasing ethanol concentrations, with the storage modulus increasing by approximately three orders of magnitude. Although possibly a glass transition, alternate

explanations include the formation of intramolecular hydrogen bonds or that the chitin binding domain (ChBD) in exon-2 might change the secondary structure of the normally disordered exon-1 into more ordered conformations that limit deformation." **18115.** Khelifa, R. (2017): Spatiotemporal pattern of phenology across geographic gradients in insects. 2017. University of Zürich, Faculty of Science: 141 pp. (in English, with German summary) ["Phenology – the timing of recurrent biological events – influences nearly all aspects of ecology and evolution. Phenological shifts have been recorded in a wide range of animals and plants worldwide during the past few decades. Although the phenological responses differ between taxa, they may also vary geographically, especially along gradients such as latitude or elevation. Since changes in phenology have been shown to affect ecology, evolution, human health and the economy, understanding phenological shifts has become a priority. Although phenological shifts have been associated with changes in temperature, there is still little comprehension of the phenology-temperature relationship, particularly the mechanisms influencing its strength and the extent to which it varies geographically. Such questions would ideally be addressed by combining controlled laboratory experiments on thermal response with long-term observational datasets and historical temperature records. Here, I used odonates (dragonflies and damselflies) and Sepsid scavenger flies to unravel how temperature affects development and phenology at different latitudes and elevations. The main purpose of this thesis is to provide essential knowledge on the factors driving the spatiotemporal phenological dynamics by (1) investigating how phenology changed in time and space across latitude and elevation in northcentral Europe during the past three decades, (2) assessing potential temporal changes in thermal sensitivity of phenology and (3) describing the geographic pattern and usefulness of thermal performance curves in predicting natural responses. Additionally, this thesis presents (4) a new behavior in odonates and (5) a commemoration of the 100th anniversary of a noteworthy book in odonatology. In Chapter I, the phenological shift of adult odonates across latitude and elevation was examined with long-term observation data of 54 species in six European countries, historical temperature records and experimental studies on species-specific thermal performance curves. Geographic variation in phenological shifts is expected since the magnitude of recent climate warming varies across both space (latitude and elevation) and time (seasons). However, little information exists on whether the average temperature, fluctuation of temperature or physiological response to such temperature fluctuations is the best predictor of phenology. First, phenology has shifted across both latitude and elevation, but to a different extent (magnitude), increasing with latitude and decreasing with elevation. Although average temperature explained some of the variation in spatiotemporal pattern of phenology, the physiological response (development) to temperature fluctuations provi-

ded better predictions. These results indicate that while researchers rely mostly on temperature data to explain phenological shifts, understanding the non-linear relationship between temperature and development would permit more robust predictions. Chapter II investigates the temporal changes in sensitivity of phenology to temperature (ST) using the same data as chapter one. Here, I tested the hypothesis that the phenology of species has become less sensitive to temperature over time, and that this pattern may vary geographically. There was an overall decline in ST between 1980 and 2013, but geographically this decline was observed along latitudinal but not elevational gradients. To explain this geographic pattern of ST, I tested three non-mutually exclusive hypotheses: (1) the position of the environmental temperature within the thermal performance curve determines the strength of the response of species to warming, (2) photoperiod has declined after phenological advancements and caused the decline in the thermal response of species, and (3) reduced chilling by winter warming has affected the response of species to spring temperature. I found the strongest support for hypotheses 2 (photoperiod limitation) and 3 (winter warming). These findings reveal that interactions between environmental cues may change the response of species to warming, thereby rendering long-term predictions very challenging. Chapter III focuses on the use of the thermal performance curve (TPC) for predicting larval development under laboratory and field conditions. Although the average temperature has been used extensively to assess the effect of warming, recent studies have highlighted the relevance of temperature fluctuations in shaping thermal responses. More importantly, there is missing knowledge on the usefulness of TPC in predicting development under natural conditions. I therefore combined laboratory and field experiments in five species of Sepsis flies (Diptera: Sepsidae), using distant populations from the temperate region (Europe, Africa and North America), to compare observed development data with theoretical estimates derived from TPC. The predictability of development under fluctuating temperature was better in the laboratory than in the field. Interestingly, accounting for temperatures that fall below a critical minimum improves the predictability of development such that flies not encountering cold conditions show predictable development times whereas flies encountering cold conditions tend to emerge earlier than expected. This study reveals the importance of cold temperatures in shaping thermal reaction norms, thus providing new insights to improve predictions of the responses of ectotherms to future climate change. Chapter IV provides the first description of sexual death feigning in a dragonfly species. Death feigning (playing dead) is a widespread behavior in animals, being recorded in mammals, birds, fish, reptiles, amphibians and insects. However, sexual death feigning, with one sex playing dead to avoid the opposite sex, is particularly rare. To date, the only four cases recorded include a species of spider, two species of robber flies and a species of mantis. Although death feigning has been documented in odonates, this thesis is the first record of sexual death feigning in *Aeshna juncea*. I suggest that sexual conflict has been the primary driver of the evolution of this behavior due to high levels of male harassment in this species.

Since the moorland hawkler is widespread in Europe where dragonflies have been studied extensively, it is likely that other cases of sexual death feigning remain undiscovered. Chapter V presents a commemoration of an important book in odonatology – *The Biology of Dragonflies* by Tillyard (1917) – and discusses the influence of this book on the field of odonatology, the contributions of the author to the understanding of dragonfly biology and systematics and the scientific advances over the last century. Tillyard has set the foundation for the study of the biology of dragonflies by providing the basic knowledge on their morphology, anatomy and embryology that is still in use today. I divide the history of odonatology into four major periods: Selys era, Tillyard era, Corbet era and the blossoming era (contemporary odonatology). This thesis, as well as many other studies on dragonflies, would not have seen the light of day without Tillyard's (1917) '*The Biology of Dragonflies*'; I therefore dedicate a chapter of my thesis to its 100th anniversary. The results shown in this thesis are particularly important because, unlike plants, ectotherms (cold-blooded animals) have received very little attention in the study of geographic and temporal patterns of phenology. Even though this group of animals encompasses most of the global biodiversity, its members share similar thermal adaptations (thermal performance curve). Consequently, understanding the mechanisms affecting their spatiotemporal pattern of phenology would help us predict their future response and adjust management plans accordingly." **18116.** Kietzka, G.J.; Pryke, J.S.; Samways, M.J. (2017): Aerial adult dragonflies are highly sensitive to in-water conditions across an ancient landscape. *Diversity and Distributions* 23(1): 14-26. (in English) ["Aim: Adult dragonflies are renowned for being good bioindicators of anthropogenic change, but their response to the heterogeneity of undisturbed river systems has received little investigation. The Cape Floristic Region (CFR) has had a long lineage of natural selection which has honed life stages to the fine grain of the river systems. This leads to the intriguing question: How sensitive are the aerial adults to the in-water conditions? Location: Rivers of the CFR, in the Western Cape Province, South Africa, are naturally heterogeneous and complex ecosystems running across a geologically ancient landscape. The CFR is a significant centre of local endemism for many taxa, including dragonflies. Methods: We investigated dragonfly assemblages and 20 environmental variables along untransformed reaches of three CFR rivers. Results: We found that each river has its own particular 'signature' dragonfly assemblage. We also found that certain in-water parameters were the most important factors driving adult dragonfly assemblages, and not variables associated with substrate or riparian vegetation under these historic, natural conditions. This responsiveness to a heterogeneous range of in-water variables was similar from one river to the next, and also was independent of species turnover among the different dragonfly assemblages. Main conclusions: From a conservation perspective, the natural variation in certain water parameters, particularly in-water conditions, is essential for supporting

the full suite of adult dragonfly species. Challenging but important for conservation planning is that each river has its own biotic merit. Addressing this challenge also means that maintenance and restoration of historic, heterogeneous, in-water conditions in addition to the removal of alien invasive trees which are already known to be highly detrimental to this largely irreplaceable dragonfly fauna. Prioritizing which rivers to conserve can be achieved through using indices involving dragonflies." **18117.** Kobashi, K.; Harada, T.; Adachi, Y.; Mori, M.; Ihara, M.; Hayasaka, D. (2017): Comparative ecotoxicity of imidacloprid and dinotefuran to aquatic insects in rice mesocosms. *Ecotoxicology and Environmental Safety* 138: 122-129. (in English) ["Highlights: • Effects of imidacloprid and dinotefuran on paddy aquatic invertebrates were compared. • While applied at the same dose, residues of imidacloprid in both water and soil were higher than those of dinotefuran. • The number of species affected by imidacloprid exposures was higher than dinotefuran. • Dragonflies and chironomids are susceptible to neonicotinoids. • Mesocosms are key tools for assessing ecological risks of pesticides. Abstract: There are growing concerns about the impacts of neonicotinoid insecticides on ecosystems worldwide, and yet ecotoxicity of many of these chemicals at community or ecosystem levels have not been evaluated under realistic conditions. In this study, effects of two neonicotinoid insecticides, imidacloprid and dinotefuran, on aquatic insect assemblages were evaluated in experimental rice mesocosms. During the 5-month period of the rice-growing season, residual concentrations of imidacloprid were 5–10 times higher than those of dinotefuran in both soil and water. Imidacloprid treatment (10 kg/ha) reduced significantly the populations of, *Crocothemis servilia mariannae* and *Lyriothemis pachygastra* nymphs, whereas those of *Orthetrum albistylum speciosum* increased slightly throughout the experimental period. However, *Notonecta triggutata*, which numbers were high from the start, later declined, indicating possible delayed chronic toxicity, while *Guignotus japonicus* disappeared. In contrast, dinotefuran (10 kg/ha) did not decrease the populations of any species, but rather increased the abundance of some insects, particularly Chironominae spp. larvae and *C. servilia mariannae* nymphs, with the latter being 1.7x higher than those of controls. This was an indirect effect resulting from increased prey (e.g., chironomid larvae) and lack of competition with other dragonfly species. The susceptibilities of dragonfly nymphs to neonicotinoids, particularly imidacloprid, were consistent with those reported elsewhere. In general, imidacloprid had higher impacts on aquatic insects compared to dinotefuran." **18118.** Kobayashi, T.; Ralph, T.J.; Lobb, J.; Miller, J.; Theischinger, G.; Hunter, S.J.; Jacobs, S.J. (2017): Dunphy Lake in Warrumbungle National Park, NSW: aquatic animal community after

the Wambelong fire in 2013. *Australian Zoologist* 39(3): 469-479. (in English) ["Fires are a common occurrence in Australian terrestrial ecosystems. A large fire occurred in January 2013 within and adjacent to the Warrumbungle National Park, near Coonabarabran in NSW, burning over 560 km<sup>2</sup> of the park and surrounding region (the Wambelong fire). The Wambelong fire affected Dunphy Lake, the only lake in the park. In this study, we assessed the post-fire aquatic animal community of the lake in March and September 2014. At the times of sampling the lake was largely dry and had only small isolated pools. We found 53 invertebrate taxa including the larvae of *Austrogynacantha heterogena* and one vertebrate species (larvae of the frog *Litoria rubella*) in the pool-water samples. Artificial inundation of the lake sediment samples under laboratory conditions led to the emergence of 31 taxa, totalling 62 taxa in the lake overall. Most taxa found in the lake are opportunistic and characteristic of those in still-water bodies. Dunphy Lake seems to be highly resilient in sustaining diverse aquatic animals. We highlight the importance of complementary pre- and post-fire data for improved assessments and interpretations of fire impacts to guide monitoring of post-fire recovery." **18119.** Koprivnikar, J.; Urichuk, T.M.Y.; Szuroczi, D. (2017): Influences of habitat and arthropod density on parasitism in two co-occurring host taxa. *Canadian Journal of Zoology* 95(8): 589-597. (in English) ["Habitat attributes are known to influence infectious diseases such as those caused by parasites, but most studies have only considered single host and/or parasite taxa, making it difficult to assess which features may be of general importance and to predict how alterations could affect disease dynamics. We examined infection with trematode (flatworm) parasites in two commonly co-occurring host taxa, larval amphibians and larval odonates to investigate links with landscape-level features, including agricultural activity. We also assessed pond community composition with respect to the abundance and richness of aquatic arthropods known to prey upon tadpoles and/or free-swimming trematode infectious stages. Larval amphibians from agricultural sites were most likely to be parasitized but had lower infection intensities, and infected hosts were positively associated with increasing distance to the nearest forest habitat, but negatively with road distance. The opposite was observed for larval odonate infection status; however, probability and intensity of parasitism in both host taxa was negatively associated with greater predatory arthropod abundance, consistent with the "dilution effect" of biodiversity on infectious diseases. Our approach demonstrates the importance of considering multiple host taxa when studying habitat links to diseases, and future studies incorporating even greater diversity will be needed." F.; Lorenz-Lemke, A.P.; Kvist, S. (2017): DNA barcoding of odonates from the Upper Plata basin: Database creation and genetic diversity estimation. *PLoS ONE* 12(8): e0182283.: 14 pp. (in English) ["We present a DNA barcoding study of Neotropical odonates from the Upper Plata basin, Brazil. A total of 38 species were collected in a transition region of "Cerrado" and Atlantic Forest, both regarded as biological hotspots, and 130 cytochrome c oxidase subunit I (COI) barcodes were generated for the collected specimens. The distinct gap between intraspecific (0–2%) and interspecific variation (15% and above) in COI, and resulting separation of Barcode Index Numbers (BIN), allowed for successful identification of specimens in 94% of cases. The 6% fail rate was due to a shared BIN between two separate nominal species. DNA barcoding, based on COI, thus seems to be a reliable and efficient tool for identifying Neotropical odonate specimens down to the species level. These results underscore the utility of DNA barcoding to aid specimen identification in diverse biological hotspots, areas that require urgent action regarding taxonomic surveys and biodiversity conservation." **18123.** Kumara, H.I.G.C.; Samarawikrama, V.A.M.P.K. (2017): Diversity of dragonfly species in the Hakkinda Islands of Mahaweli River in the Gatabe area. Project Report. A Research Grant in the Faculty of Humanities and Social Sciences University of Ruhuna: 19 pp. (in English) ["Hakkinda Islands surrounded by the Mahaweli River, close to the Kandy-Gatambe area is a bio-geographical hotspot in Sri Lanka, however, bio-geographical importance of these islands has been overlooked during the last few decades as a result of development projects and varied human activities. Considering that, the President of Sri Lanka has made an order declaring the Waratenna-Hakkinda area as a protected environmental area. According to the rudimentary survey, this protected area can be identified a special habitat to dragonfly species... Since the knowledge about diversity of dragonfly species is limited, this research's main objective is to bridge that gap in prevalent knowledge. This research is guided by Quantitative-Deductive research methodology. Under this methodology, line transects and quadrat sampling methods have been used in primary data collection process. According to research findings, a total of 16 dragonfly species from 8 families are identified and both riverine forest and river islands have rich diversity compared with home gardens in the area. Among the available species, 37.5% are identified to be endemic to the country. *Neurobasis chinensis*, *Vestalis apicalis* and *Libellago finalis* are identified to be vulnerable species. This research concludes that even if there are a high diversity of dragonfly species in the river islands and riverine forest areas, human activities and their irresponsible behaviour have directly / indirectly negatively influenced on dragonfly habitats and their breeding colonies. The research, thus, identifies an immediate requirement for a mechanism and regulations to protect a biologically important breeding colony of dragonfly species and their habitats to protect their diversity." **18124.** Lambret, P.; Boudot, J.-P.; Chelmick, D.; De Knijf, G.; Durand, E.; Judas, J.; Stoquet, A. (2017): Odonata surveys 2010–2016 in the United Arab Emirates and the Sultanate of Oman, with emphasis on some regional heritage species. *Odonatologica* 46(3/4): 153-205. (in English) [oas 55: "Six field trips were carried out in the United Arab Emirates (UAE) and the Sultanate of Oman in autumn 2010, late winter 2013, spring 2014, autumn 2014, spring 2015 and spring 2016. We recorded 37 species at 87 localities, including new localities for some species of regional interest. Information on all observed Odonata species was recorded including their life stage, behaviour, habitat and water characteristics. Exuviae were also systematically collected. *Urothemis thomasi* was discovered at several new sites in the Hajar Mountains, the Dhofar and the Al Wusta regions, filling in the gap between the Dhofar and the Muscat area. In addition, new localities for two Arabian endemics:

Arabicnemis caerulea and Arabineura khalidi were found, with their occurrence in the Dhofar region extending their known area and demonstrating that A. khalidi cannot be regarded as a strict Hajar endemic. Important differences were noticed in the species composition of formerly surveyed localities, which may be ascribed to habitat degradation through management directed towards human recreation. Lastly, the well-known and diverse zoogeographical influences of Omani and the Emirati odonatofauna are confirmed with a large set of species of African origin in the Dhofar and a smaller set of species of Indomalayan origin visiting both the Dhofar and the northeast of the region during migrations and establishing, at least temporary, reproductive localities." (in English) ["Although a full life cycle approach is optimally needed to make conservation decisions, the egg stage is often neglected for insect species of special conservation interest. Water management and related abiotic factors are relevant factors to consider in aquatic species. *Lestes macrostigma* is a threatened damselfly restricted to temporary brackish waters. Here we provide detailed information on its hatching success and phenology in two natural field populations. Shoots containing fresh egg clutches of *L. macrostigma* were sampled in late June, just after the oviposition period. In the fall, shoots were separately placed in plastic boxes in two ponds in southern France. Examination of eggs indicated *L. macrostigma* overwinters at an early embryonic stage. The following spring we monitored hatching in detail. Hatching began on 15 March in both ponds and ended on 27 April. Hatching was synchronized, with half of the eggs hatching within five days in the first pond and 14 days in the second pond. Lower water temperatures decreased hatching success and likely also delayed hatching. Embedment of shoots in ice increased egg mortality. Based on our data, wildlife managers are encouraged to maintain water levels high during winter to reduce the risk of freezing of *L. macrostigma* eggs." **18126.** Lamelas-López, L.; Florencio, M.; Borges, P.A.V.; Cordero-Rivera, A. (2017): Larval development and growth ratios of Odonata of the Azores. *Limnology* 18(1): 71-83. (in English) ["To fully understand odonate life cycles, it is vital to analyse the patterns of larval growth, which are tightly associated with variations in environmental factors. However, the identification of larval instars is often difficult, especially for early development stages. We hypothesise that pond hydroperiod influences odonate larval growth, and test this idea with novel information about the environmental characteristics of 12 study ponds in Terceira Island (Azores). This study, which represents the first analysis of larval

development of Odonata in the Azores, involved determining the instars of development and growth ratios. We measured the morphological characteristics of 898 Odonata larvae, and found that they significantly differed between temporary and permanent ponds. To estimate the larval instars, we used two methods: frequency distribution methods and correlation diagrams between body characteristics. The first method was the most effective, allowing the estimation of 17 instars for *Anax imperator*, 13 for *Sympetrum fonscolombii* and 10 for *Ischnura hastata*, as well as growth ratios between instars for head width, total length, abdomen length, wings and antenna length. Our results also suggest that a combination of the two methods is the most appropriate strategy for estimating the number of instars and growth ratios during larval development." **18127.** Lancaster, L.T.; Dudaniec, R.Y.; Hansson, B.; Svensson, E.I. (2017): Do group dynamics affect colour morph clines during a range shift? *Journal of Evolutionary Biology* 30(4): 728-737. (in English) ["Species exhibiting colour-polymorphism are thought to have an ecological advantage at the landscape scale, because spatial segregation of alternatively-adapted ecotypes into diverse habitats can increase the total species' niche breadth and thus confer greater geographic range size. However, morph frequencies are also influenced by intra-populational processes such as frequency- or density-dependent social interactions. To identify how social feedback may affect clinal variation in morph frequencies, we investigated reciprocal interactions between morph-specific thermal tolerance, local climatic conditions, and social environments, in the context of a colour-morph frequency cline associated with a recent range expansion in *Ischnura elegans* in Sweden. Cold tolerances of gynochromes (female-like female morph) were positively correlated with local gynochrome frequencies, suggesting a positive frequency-dependent fitness benefit of being common. In contrast, androchrome (male-mimic female morph) cold tolerances were improved following recent exposure to cold weather, suggesting a beneficial environmental acclimation effect. Thus according to an environment-matching hypothesis for clinal variation, androchrome frequencies should therefore increase towards the (cooler) range limit. In contrast to this prediction, gynochrome frequencies increased at the expanding range limit, consistent with a positive frequency-dependent social feedback when invading novel climates. Our results suggest that when phenotypes or fitnesses are affected by interactions with conspecifics, beneficial social effects on environmental tolerances may i) facilitate range shifts and ii) reverse or counteract typical patterns of intraspecific interactions and environment-matching clines observed in stable populations observed over broader geographic scales." **18128.** Lancaster, L.T.; Morrison, G.; Fitt, R.N. (2017): Life history trade-offs, the intensity of competition, and coexistence in novel and evolving communities under climate change. *Phil. Trans. R. Soc. B* 372: 20160046: 10 pp. (in English) ["The consequences of climate change for local biodiversity are little understood in process or mechanism, but these changes are likely to reflect both changing regional species pools and changing competitive interactions. Previous empirical work largely supports the idea that competition will intensify under climate change, promoting competitive exclusions and local extinctions, while theory and conceptual work indicate that relaxed competition may in fact buffer communities from biodiversity losses that are typically witnessed at broader spatial scales. In this review, we apply life history theory to understand the conditions under which these alternative scenarios may play out in the context of a range-shifting biota undergoing rapid evolutionary and environmental change, and at both leading- edge and trailing-edge communities. We conclude that, in general, warming temperatures are likely to reduce life history variation among competitors, intensifying competition in both established and novel communities. However, longer growing seasons, severe environmental stress and increased climatic variability associated with climate change may buffer these communities against intensified competition. The role of life history plasticity and evolution has been previously underappreciated in community ecology, but may hold the key to understanding changing species interactions and local biodiversity under changing climates. This article is part of the themed issue 'Human influences on evolution, and the ecological and societal consequences'." The paper includes many references to Odonata. (2017): Context-dependent local movements of the blue-tailed damselfly, *Ischnura elegans*: effects of pond characteristics and the landscape matrix. *Journal of Insect Conservation* 21(2): 243-256. (in English) ["The loss of ponds and the fragmentation of their surrounding landscape negatively impacts the biodiversity of wetlands, such as damselflies. They are short-distance dispersers and can be influenced by the quality of suitable habitats and the landscape matrix. The aim of this study was to test the effect of the environmental context (i.e. pond characteristics and the surrounding landscape) on movements and survival probability in a damselfly species, *Ischnura elegans*. Three approaches (i.e. capture-mark-recapture, individual tracking and translocation studies) were performed in Northwestern France. The characteristics of ponds did not influence damselfly survival. However, the landscape context affected movements within ponds, and between ponds. Individuals from open-field ponds moved over longer distances than individuals from urban ponds. Moreover, in cases of disturbances, such as a pond drying up, movements from one pond to another were observed only in the open-field context. The ecological quality of the pond did not appear to affect survival of individuals, probably because *I. elegans* has a high tolerance to changes in ecological factors. However, higher local movements depend on the degree of openness of the

landscape. Landscape context is hence a key issue in damselfly conservation planning and in maintaining ecological continuities, such as along greenways and blueways, and specifically the degree of landscape openness during pond creation." **18130.** Leandro, C.; Jay-Robert, P.; Vergnes, A. (2017): Bias and perspectives in insect conservation: A European scale analysis. *Biological Conservation* 215: 213-224. (in English) ["Insects are among the most diverse and abundant organisms on Earth, and they play a major role in ecosystem functioning. To protect them from decline, some conservation measures have been put in place, based primarily on threatened species lists. This is the case in Europe, where 123 of the 105,000 known European insect species are currently protected. Yet how were these few species selected? Are those species representative of the European entomofauna? Is it possible for a conservation policy based on the protection of only 0.12% of described species to be effective? In this study, we aimed to measure bias in the selection of species for conservation by comparing protected and unprotected species in Europe. To this end, we considered 15 characteristics divided into five main categories: 'Taxonomy', 'Morphology', 'Diet', 'Knowledge' and 'Distribution'. We investigated bias in species selection and found that protected species were significantly larger, better known, more widespread and more multicoloured than a randomly selected set of unprotected species. Moreover, butterflies, dragonflies and grasshoppers were overrepresented, as were nectarivorous and saproxylophagous species. In contrast, Hymenoptera and Diptera, together representing >40% of European entomofauna, do not appear on the current list of protected species. To address this bias, we propose recommendations to improve the protection of insects at the European scale, including making lists more 'dynamic', introducing new criteria, and a paradigm shift towards conserving assemblages and ecological function. Existing technical and societal means could be used to achieve an integrative conservation approach for insects." (Authors)] Address: Leandro, Camilla, Univ. Paul Valéry Montpellier 3, Univ Montpellier, EPHE, CNRS, IRD, CEFE UMR 5175, F-34000, Montpellier, France. E-mail: camilla.leandro@cefe.cnrs.fr

(in English) ["*Leptagrion lencionineto* sp. nov. is described from two males, the holotype and a paratype, collected in Brazil: São Paulo, Campos do Jordão, Condomínio Paradise, alt. 1 796m a.s.l., 16-x-2005, F. Lencioni Neto leg., both deposited in the author's collection. The new species differs from all congeners by the elevated and bifurcated hind lobe of prothorax." (Authors)] Address: Lencioni, F.A.A., Rua Aníbal, 216 – Jardim Coleginho – BR-12310-780, Jacareí, S.P., Brazil. E-mail: odonata@zygoptera.bio.br

**18132.** Lesch, V.; Bouwman, H.; Kinoshita, A.; Shibata, Y. (2017): First report of perfluoroalkyl substances in South African Odonata. *Chemosphere* 175: 153-160. (in English) ["Highlights: • Dragonfly samples collected in South Africa analysed at NIES for PFASs. • PFOS was quantifiable in all individuals. • Quantifiable concentrations differ between southern and northern sites. • Agricultural areas in the northern sites had low concentrations. • Industrial areas in the southern sites had significantly higher concentrations. Abstract: Perfluorinated substances are global and ubiquitous pollutants. However, very little is known about these substances in invertebrates, and even less in terrestrial invertebrates in particular. We analysed adult male dragonflies from six sites in South Africa for perfluoroalkyl substances (PFASs), including perfluorooctanesulfonic acid (PFOS), perfluorooctanoic acid (PFOA), perfluorononanoic acid (PFNA), perfluorodecanoic acid (PFDA), perfluoro-*n*-undecanoic acid (PFUnA), perfluoro-*n*-dodecanoic acid (PFDoA), perfluorohexanoic acid (PFHxA), and perfluorohexane sulfonic acid (PFHxS). PFOS was detected in all individuals, with less quantifiable occurrences of the other substances. The dragonflies from the three northern sites located in farming areas had significantly lower SPFAAs concentrations than the southern sites located closer to industrial areas (median SPFAAs of 0.32 ng/g wm (wet mass) for North, and 9.3 ng/g wm for South). All substances except PFOS occurred at similar concentrations at all six sites when quantifiable, but PFOS dominated in the Southern sites. The highest median concentration was from Bloemhof Dam (SPFAAs = 21 ng/g wm), which is known to be polluted by PFOS. Perfluorinated substances are not known to be manufactured in South Africa, therefore the residues detected are likely to have been derived from imported products. Odonata play a significant role in freshwater ecology. Any impacts on these aquatic and aerial predators are likely to have effects on aquatic and associated ecosystems. Further studies are required over a much larger geographic region and to investigate sources." (Authors)] Address: Lesch, Velesia, Research Unit for Environmental Sciences and Management, North-West University, Potchefstroom, South Africa. E-mail: velesialesch1@gmail.com

**18133.** López, J. A. (2017): Diversidad de libélulas (Insecta: Odonata) en los humedales de montaña de San Cristóbal de Las Casas, Chiapas, México. Tesis, Instituto de Ciencias Biológicas, Universidad de Ciencias y Artes de Chiapas: IV, 91 pp. (in Spanish) ["The aim of this study was to assess the diversity of the order Odonata (Insecta) in the mountain wetlands of San Cristóbal de Las Casas. Four sampling sites were chosen according to their accessibility and permissibility, corresponding to three lentic and one lotic environment. All sites were characterised and a Wetland Conservation Status Index (WCSI) was constructed. Systematic monthly sampling was carried out at each site during the period July 2014-June 2015. A one-kilometre transect close to the water bodies was walked and the sampling effort consisted of six hours of collecting adult odonates with an aerial entomological net/person. The type of sampling was with and without replacement. As a result, 14 odonate species were obtained, distributed in five families and 10 genera. *Ischnura*

*denticollis* and *Enallagma rua* were the most dominant species. The quality of the sampling was reliable and representative. Although the Kruskal-Wallis analysis of variance did not determine significant differences between odonate richness, Las Cañadas obtained the highest number of species due to its high heterogeneity of microhabitats as a lotic environment. On the other hand, the ANOVA test did elucidate significant differences between the abundance of odonates in the different sampling sites, largely due to the anthropogenic impact on aquatic macrophytes in Las Cañadas and Cinco de Marzo, which in turn allowed these wetlands to be the most diverse, unlike María Eugenia and La Kisst, which maintain a better state of conservation of this type of vegetation. These results are in line with the intermediate disturbance hypothesis, and therefore, Hutcheson's paired analysis determined significant differences between the diversity of most of the wetlands. On the other hand, nested assemblages were found in all wetlands, which could indicate local colonisation and extinction of species. Likewise, Jaccard's coefficient estimated the highest species similarity among the lentic wetlands, while the highest complementarity was between Las Cañadas and La Kisst. Because of these characteristics, the similarity dendrogram separated the odonatofauna by type of environment (lentic-lotic) and by the conservation status found in the wetlands. Finally, the frequency of occurrence of odonates in relation to mean monthly temperature and precipitation determined a clear difference between the seasonality and voltinism of the different odonate species in San Cristóbal." **18134.** Lu, Y.-H.; Jin, L.-P.; Kong, L.-C.; Zhang, Y.-L. (2017): Phytotoxic, antifungal and immunosuppressive metabolites from *Aspergillus terreus* QT122 isolated from the gut of dragonfly. *Current Microbiology* 74(1): 84-89. (in English) ["Insect gut microbes have been considered as a resource for bioactive metabolites. The aim of this study was to characterize the compounds of a fungus *Aspergillus terreus* QT122 associated with the gut of dragonfly. Five main phytotoxic, antifungal, and immunosuppressive substances were isolated from the fungus QT122. The structures of such compounds were identified as emodin (1), 1-methyl emodin (2), terrein (3), methyl 6-acetyl-4-methoxy-7,8-dihydroxynaphthalene-2-carboxylate (4), and dihydrogeodin (5) on the basis of spectroscopic analysis and by comparison of the corresponding data to those reported in the literature previously. The compound 3 exhibited the best phytotoxic activity against the radicle growth of *A. retroflexus* L. and *E. crusgalli* L. with their IC<sub>50</sub> values of 11.2 and 3.1 µg/mL, which were comparable to that of the positive control of 2,4-dichlorophenoxyacetic acid (2,4-D) with the IC<sub>50</sub> values of 8.1 and 1.6 µg/mL, respectively. The compounds 2-3 showed potent antifungal activity in the growth of *Alternaria solani* with the IC<sub>50</sub> value of less than 0.1 µg/mL and the compound 2 also had great inhibitory effect against the growth of *Fusarium oxysporum* f. sp. *cucumerinum* (IC<sub>50</sub> < 0.1 µg/mL), which was comparable to that of referenced cycloheximide with IC<sub>50</sub> value of below 0.1 µg/mL. The compounds 3-5 exhibited strong immunosuppressive activities against the T cell viability with the inhibition rates

of more than 99%, which were comparable to positive cyclosporin A under the concentration of 20 µM. These results suggest that the compounds 2–5 have the potential to be used as bio-control agents in agriculture or immunosuppressive agents." **18135.** Luke, S.H.; Dow, R.A.; Butler, S.; Khen, C.V.; Aldridge, D.C.; Foster, W.A., Turner, E.C. (2017): The impacts of habitat disturbance on adult and larval dragonflies (Odonata) in rainforest streams in Sabah, Malaysian Borneo. *Freshwater Biology* 62: 491-506. (in English) ["1. Dragonfly assemblages ... in Southeast Asian rainforests are extremely diverse but increasingly threatened by habitat disturbance, including logging and conversion of forest to oil palm plantations. 2. Land-use change can affect dragonfly larval stages by altering within-stream environmental conditions, and adults by loss of perches, shade and hunting habitat. However, the extent to which dragonflies are affected by land-use change is not well known, and strategies for conservation are poorly developed. 3. We surveyed dragonfly adults and larvae, forest quality and stream environmental conditions across 16 streams in Sabah, Malaysia. Habitat surrounding the streams included pristine forest, selectively logged forest, oil palm with forested riparian buffer strips and oil palm without buffers. 4. Overall abundance and species richness of adult dragonflies stayed constant with habitat disturbance, but larval abundance and richness decreased with higher habitat disturbance, and larvae were largely absent from oil palm streams. There was also a clear shift in community composition of both adult and larval dragonflies. Anisoptera adults were more species rich and abundant, but Zygoptera adults were less species rich in more disturbed sites. 5. The presence of riparian buffers in oil palm plantations offered some protection for forest-associated dragonfly species, and streams with wider riparian buffers supported adult assemblages more similar to those found in logged forest. However, oil palm streams with riparian buffers still contained a depauperate larval assemblage compared to logged forest areas, and dragonfly assemblages in narrow riparian buffer streams were similar to those found in streams surrounded by continuous oil palm. 6. Our results provide clear evidence of the effect of land-use change on dragonflies. Conservation efforts to conserve forest communities should target the preservation of existing forest areas, but management within oil palm plantation landscapes to preserve riparian buffers can still have a marked beneficial effect on dragonfly communities." **18138.** Mahmood, T.; Adil, A. (2017): Diet composition of small Indian mongoose (*Herpestes javanicus*) varies seasonally in its native range. *Animal Biology* 67(1): 69-80. (in English) ["Feeding habits of mammals are very important to investigate in any ecosystem and are a central topic in ecology and population biology. The current study aimed at investigating diet composition of *H. javanicus* in an agro-ecosystem of Sialkot District using a faecal analysis method. Results revealed a diverse diet of the species, comprising both animal and plant matter. Animals were consumed more heavily (58%) than plants (8%). The predominant prey species were insects, while rodents, birds, seeds and plant leaves comprised a smaller portion of the diet. The insects prey species belonged to five different orders: Odonata, Orthoptera, Coleoptera (ground beetles), Dermaptera and Hymenoptera (family Formicidae; ants). The consumption of insects was higher during the summer season. Mammalian prey included five different rodent species: *Bendicota bengalensis* (lesser bandicoot rat), *Nesokia indica* (short-tailed mole rat), *Suncus murinus* (Asian musk shrew), *Tatera indica* (Indian gerbil) and *Mus musculus* (house mouse). Prey species richness was higher in the summer as was the diversity index, while the evenness index showed slightly higher values in spring and autumn compared to summer and winter. We conclude that small mammals are important prey species of the mongoose while insects are eaten regularly and in reasonably large numbers in its native range." **18140.** Manenti, R.; Zanetti, N.; Pennati, R.; Scari, G. (2017): Factors driving semi-aquatic predator occurrence in traditional cattle drinking. *J. Limnol.* 76(1): 34-40. (in English) ["In several cases, human impact on water bodies and on their freshwater communities is detrimental, but in some cases the human activity may favour and enhance the biodiversity of small water bodies, as traditional cattle drinking pools. Despite their small size, small water bodies may constitute hot spot of biodiversity often representing the only lentic aquatic biotope in landscapes where superficial water lacks or flows in lotic environments like creeks and streams. Predators are good indicators of biodiversity in ponds and give information of food chain web complexity. In particular, semi-aquatic predators like amphibians and dragonflies may account for a substantial percentage of energy flow between aquatic and terrestrial ecosystems. In this study, we evaluated the conservation value of traditional cattle drinking pools building by assessing the factors determining the occurrence and distribution of the semiaquatic predators. From April to August 2015, we investigated 30 distinct pools recording several abiotic and biotic environmental variables. We detected 4 semi-aquatic predators: *Salamandra salamandra* larvae, *Triturus carnifex*, *Aeshna* sp. larvae and *Libellula* sp. larvae. Abiotic features played a major role in shaping the predator community that resulted linked to stable, with no dryness period, and large drinking pools. Invertebrate prey biomass was not particularly important, while vegetation cover and occurrence of unpalatable tadpoles were the most important biotic features of the pools. Our study provides novel evidence on the importance of cattle drinking pools management to preserve biodiversity especially in areas where traditional pastoral activity is disappearing." (Authors)] Address: Manenti, R., Dipartimento di Bioscienze, Università degli Studi di Milano, Via Celoria 26, 20133 Milano, Italy. E-mail: raoulmanenti@gmail.com

**18141.** Manger, R.; Moorlag, H.A. (2017): An emerging Blue hawker (*Aeshna cyanea*) at the end of October in the Netherlands. *Brachytron* 19(2): 114-116. (in Dutch, with English summary) ["On the 24th of October 2017, a male *A. cyanea* emerged at a garden pond in Hoogeveen and flew away two days later. For the time being, this is the latest observation of an emerged *A. cyanea* in the Netherlands. The place of emergence was near a rather shallow garden pond in a sheltered garden. The year 2017 was one of the warmest years in the Netherlands since meteorological data were first recorded. It is suspected that the dragonfly had a one-year larval development, and therefore could emerge so late in the season." (Authors)] Address: Manger, R., Stoepveldsingel 55, 9403 SM Assen. **18143.** Martin, J.M.; Saaristo, M.; Bertram, M.G.; Lewis, P.J.; Coggan, T.L.; Bradley O. Clarke, B.O.; Wong, B.B.M. (2017): The psychoactive pollutant fluoxetine compromises antipredator behaviour in fish. *Environmental Pollution* 222: 592-599. (in English) ["Highlights: •Mosquitofish (*G. holbrooki*) exposed to fluoxetine (FLX) at two realistic levels. •FLX at the lower level increased activity in the presence or absence of a predator. •FLX at both levels reduced latency to enter predator strike zone. •FLX caused sex-dependent reduction in 'freezing' after a simulated predator strike. •Exposure to FLX can have detrimental sub-lethal impacts on antipredator behaviour. Abstract: Pharmaceuticals are increasingly being detected in aquatic ecosystems worldwide. Particularly concerning are pharmaceutical pollutants

that can adversely impact exposed wildlife, even at extremely low concentrations. One such contaminant is the widely prescribed antidepressant fluoxetine, which can disrupt neurotransmission and behavioural pathways in wildlife. Despite this, relatively limited research has addressed the behavioural impacts of fluoxetine at ecologically realistic exposure concentrations. Here, we show that 28-day fluoxetine exposure at two ecologically relevant dosages—one representing low surface water concentrations and another representing high effluent flow concentrations—alters antipredator behaviour in Eastern mosquitofish (*Gambusia holbrooki*). We found that fluoxetine exposure at the lower dosage resulted in increased activity levels irrespective of the presence or absence of a predatory dragonfly nymph (*Hemianax papuensis*). Additionally, irrespective of exposure concentration, fluoxetine-exposed fish entered the predator 'strike zone' more rapidly. In a separate experiment, fluoxetine exposure reduced mosquitofish freezing behaviour—a common antipredator strategy—following a simulated predator strike, although, in females, this reduction in behaviour was seen only at the lower dosage. Together, our findings suggest that fluoxetine can cause both non-monotonic and sex-dependent shifts in behaviour. Further, they demonstrate that exposure to fluoxetine at environmentally realistic concentrations can alter antipredator behaviour, with important repercussions for organismal fitness." **18145.** Martins, R.T.; Couceiro, S.R.M.; Melo, A.S.; Moreira, M.P.; Hamada, N. (2017): Effects of urbanization on stream benthic invertebrate communities in Central Amazon. *Ecological Indicators* 73: 480-491. (in English) ["Urbanization and its physical and chemical effects on aquatic environments influence invertebrate communities negatively. Yet, it is not clear how urbanization affects inter-annual variation of invertebrate assemblages in streams. We 1) evaluated urbanization effects on the ecological conditions (biotic and abiotic) of streams in Manaus and 2) analyzed invertebrate community variation over time (between 2003 and 2010). Data on abiotic variables and invertebrates from 2003 were obtained from a previous study. In 2010 we sampled abiotic variables and invertebrate communities in the same low-order urban streams sampled in 2003 (n = 40). We recorded high values of total nitrogen, total phosphorous, deforestation, total impervious area (TIA), water temperature, pH, and electrical conductivity in the most urbanized streams, as compared to the least-impacted ones. In contrast, the least-impacted streams had high dissolved oxygen concentrations. Water quality was poorer in 2010 than in 2003: oxygen concentration was lower and total nitrogen, total phosphorous, deforestation, and TIA significantly higher in 2010. We recorded higher inter-annual variation of abiotic variables in the most-impacted streams as compared to the least-impacted streams. EPT (% of Ephemeroptera, Plecoptera, and Trichoptera) and richness metrics decreased with urbanization. On the other hand, % OP (percent of Oligochaeta and Psychodidae) increased with urbanization. Observed and EPT richness and % OP increased between 2003 and 2010. On the other hand, rarefied richness decreased between years. Increases of observed and EPT richness between 2003 and 2010 were related to low inter-annual variability in streams conditions; however, differences of % OP and rarefied richness were not related to inter-annual variability in environmental conditions. The degree of urbanization did not explain the magnitude of the within-stream difference of invertebrate communities between 2003 and 2010. The increased effects of urbanization represented by the abiotic variables sampled and the reduction of invertebrate richness and increased dominance of tolerant taxa indicate that public policy is not enough to protect or mitigate human impacts on the urban water systems under study." **18146.** Masahiro, S.; Hirai, N.; Ishii, M. (2017): Early community assembly of aquatic insects in experimental ponds established across the forest margin of a Satoyama coppice. *Jpn. J. Environ. Entomol. Zool.* 28(3): 133-142. (in English, with Japanese summary) ["We investigated early community assembly of aquatic insects across the forest margin in Satoyama, the traditional rural landscape in Japan. In April 2011, we established six experimental ponds using plastic tanks (220 L, 20 cm in depth) filled with tap water, with two each outside (Plot A), at the margin (Plot B) and inside (Plot C) a Satoyama coppice in Osaka Prefecture. We surveyed aquatic

insects twice monthly between May and December and canopy openness as the indicator of environmental factors related to coppice forest seasonally. A total of 72,324 individuals belonging to 25 insect taxa were recorded in this study with 14,076, 5,699, 4,098, 14,079, 19,935 and 14,437 individuals from 17, 5, 10, 12, 13 and 12 taxa recorded at Ponds A1, A2, B1, B2, C1 and C2, respectively. In all ponds, taxa richness gradually increased until July or August and thereafter gradually decreased or remained constant. Abundance of each abundant family except Libellulidae differed significantly among the three plots or in time–plot interactions. The most dominant taxa changed from Chironomidae to Notonectidae (*Notonecta triguttata*) and then to Baetidae (*Cloeon* spp.) in Ponds A1 and A2, from Chironomidae to Libellulidae (*Orthetrum melania*) and again to Chironomidae in Pond B1 and from Chironomidae to Baetidae in Pond B2. Only Chironomidae was dominant in Ponds C1 and C2. Non-metric multidimensional scaling showed that community assembly differed among plot locations across the forest margin, although canopy openness was similar at Plots B and C. Our results show that aquatic insect communities developed rapidly in newly created habitats in Satoyama and the environmental gradient across the forest margin generated taxonomic diversity. With regard to the functional characteristics of aquatic insects, predatory plankton, herbivorous neuston and detritivores colonized abundantly inside the forest, and predatory divers and herbivorous benthos colonized abundantly outside the forest. Our results demonstrate that creation of aquatic habitats across a forest margin would be effective for conserving taxonomic and functional diversity of aquatic insect communities in Satoyama, one of the biodiversity hotspot habitats in Japan." **18147.** Mason, N.A. (2017): Effects of wind, ambient temperature and sun position on damselfly flight activity and perch orientation. *Animal Behaviour* 124: 175-181. (in English) ["Highlights: •I examined effects of abiotic factors on damselfly flight and perching behaviour. •Activity increased at low wind speeds but was uncorrelated with ambient temperature. •Perched damselflies tended to face the wind (showed rheotaxis) during high winds. •Sun position was uncorrelated with perching orientation. •At higher temperatures, however, resting damselflies tended to face the sun. Many animals rely on movement for survival and reproduction. Directed movements incur metabolic costs, however, and animals adjust their behaviour to optimize energy expenditures in different abiotic conditions. Physical flows and solar radiation vary over time and space and influence animal behaviour at multiple spatiotemporal scales. Here, I quantify the effects of wind speed, wind direction, ambient temperature and sun position on the fine-scale movement ecology and perch orientation of a widespread damselfly, *Enallagma doubledayi*. Through field observations, I found that damselflies fly, forage and engage competitors in territorial interactions more often in calm rather than windy conditions. Furthermore, perched damselflies exhibit rheotaxis, in which individuals typically face into the wind,

presumably to minimize biomechanical costs associated with drag and possibly to detect inbound prey on the water surface and in the air column. In contrast, ambient temperature and the position of the sun were largely unassociated with activity levels and damselfly orientation. At higher ambient temperatures, however, perched odonates faced the sun with increasing consistency, perhaps to thermoregulate by minimizing exposure to solar radiation. Taken together, these findings suggest that damselflies preferentially fly when the ratio of animal speed to wind speed is high and adjust their perch orientation to minimize energy loss. These findings strengthen conceptual links between activity budgets and perch orientation strategies among animals in variable abiotic conditions." **18148.** May, M.L.; Gregoire, J.A.; Gregoire, S.M.; Lubertazzi, M.A.; Matthews, J.H. (2017): Emergence phenology, uncertainty, and the evolution of migratory behavior in *Anax junius* (Odonata: Aeshnidae). *PLoS ONE* 12(9): e0183508. <https://doi.org/10.1371/journal.pone.0183508>: 27 pp. (in English) ["Mass migrations by Odonata, although less studied than those of Monarch butterflies and plague locusts, have provoked comment and study for many years. Relatively recently, increasing interest in dragonflies, supported by new technologies, has resulted in more detailed knowledge of the species involved, behavioral mechanisms, and geographic extent. In this paper we examine, in four independent but complementary studies, how larval habitat and emergence phenology interact with climate to shape the evolution of migratory strategy in *Anax junius*, a common species throughout much of the eastern United States and southern Canada. In brief, we argue that fish predation on larvae, coupled with the need for ample emergent vegetation for oviposition and adult eclosion, dictates that larval development and survival is optimal in ponds that are neither permanent nor extremely ephemeral. Coupled with annual variation in regional weather and winters in much of their range too cold for adult survival, conditions facing newly emerged *A. junius* may unpredictably favor either local reproduction or long-distance movement to more favorable areas. Both temperature and hydroperiod tend to favor local reproduction early in the adult activity period and migration later, so late emerging adults are more likely to migrate. No single pond is always predictably suitable or unsuitable, however, so ovipositing females also may spread the risk to their offspring by ovipositing at multiple sites that, for migrants, may be distributed over very long distances." **18149.** May, M.L. (2017): Body temperature regulation in the dragonfly, *Arigomphus villosipes* (Odonata: Anisoptera: Gomphidae). *International Journal of Odonatology* 20(3/4): 151-163. (in English) ["Regulation of thoracic muscle temperature has been investigated in a number of dragonfly species but is poorly known in the large and diverse family, Gomphidae. Moreover, temperatures of other body regions

have been recorded in very few ectothermic insects. In addition, correlations among multiple components of thermoregulatory behavior have rarely been examined quantitatively. Here I examine thermoregulation in *Arigomphus villosipes*, a medium-sized gomphid common at the shores of lakes and ponds in the northeastern USA. Measurements of the temperatures of the thorax (Tth), head (Th) and abdomen (Tab), using standard "grab and jab" techniques, indicate that both Tth and Th are relatively independent of air temperature (Ta). It is not clear whether Tth and Th are independently regulated, although some data suggest that they might be. *Arigomphus villosipes* can warm its thoracic musculature endothermally to maintain high Tth during cool Ta in conditions of low solar radiation intensity. However, regulation is principally behavioral, involving variation in body and wing postures and perhaps in perch substrate choice. Certain of these behaviors are closely associated to form suites of behavior that together are adapted to enhance or inhibit heating, while others are constrained by trade-offs with other functional demands. The former have a significant demonstrable effect on Tth. These combinations of behaviors results in a well-developed capacity for thermoregulation, allowing the insects to expand their activity periods and choice of perches, and probably improving male performance during competitive chases of females prior to mating." **18150.** Maynou X.; Martín, R.; Aranda, D. (2017): The role of small secondary biotopes in a highly fragmented landscape as habitat and connectivity providers for dragonflies (Insecta: Odonata). *Journal of Insect Conservation* 21: 517-530. (in English) ["Habitat loss and degradation are considered major threats to freshwater biodiversity and to invertebrates in particular. These often irreversible processes may lead to local and regional extinctions of species, most notably of stenotopic taxa. In spite of this, a number of studies have shown that small habitat patches can sustain rich and abundant communities. The present work assesses the relevance of a group of four small man-made (secondary) wildlife ponds to Odonata species diversity and abundance. Results obtained on pond recruiting capacity, species richness, abundance and habitat use by means of exuviae collection and monitoring of adults using a capture-mark-recapture (CMR) method indicate the potential suitability of these small aquatic biotopes and the surrounding landscape as habitat providers and stepping stone connectors in the Vallès lowlands (Catalonia, Spain). This region, close to the metropolitan area of Barcelona, has severely degraded natural habitats and high landscape fragmentation due to infrastructure, urban and industrial expansion. A comparison among a greater number of sites (ponds and sections of streams and rivers) distributed across the region showed that adequately managed small waterbodies harbour richer Odonata communities than others that are unmanaged or managed specifically for other types of fauna or uses. Appropriate care of these small biotopes avoids disturbance and keeps them free from vertebrates like fish and waterfowl which, under certain conditions, may have a strong influence on the invertebrate communities because,

apart from feeding on larvae, they may have a negative impact on macrophyte development and water quality. While rivers and streams, the only natural aquatic habitats in the area, may be both expensive and technically challenging to restore and manage successfully, the creation and/or restoration of small ponds and short river sections in suitable locations can be a cost-effective method for enhancing freshwater vegetation and invertebrate diversity in this impacted landscape. ... Adults of a total of 24 species were recorded between 2015 and 2016 in the Vallès lowlands. Of these, 15 were anisopterans. In and around the Gallecs study ponds the number of taxa recorded was 18, 12 of them belonging to Anisoptera. Six taxa, *Lestes virens virens*, *Ischnura pumilio*, *Pyrrosoma nymphula*, *Platynemis latipes*, *Onychogomphus forcipatus unguiculatus* and *Sympetrum meridionale*, were considered accidentals. Excluding them, the number of species per sampling site in the region ranged from 1 to 13 (Online Resource 2). The average species richness was 7.58 ( $\pm$  SE = 0.68) with 12 sites (50%) hosting 7–9 species. The most widespread taxon was *Ischnura graellsii* (present at 22 sites), followed by *Anax imperator* Leach, 1815 and *Orthetrum cancellatum* (18) and *Crocothemis erythraea* and *Sympetrum fonscolombii* (17). Other fairly well distributed taxa were *Chalcolestes viridis*, *Anax parthenope* and *Sympetrum striolatum* (13) and *Aeshna mixta* and *Trithemis annulata* (11). The rest had a more restricted distribution (1–7 sites)" (Authors)] Address: Maynou X., Catalan Odonata Study Group, Institució Catalana d'Història Natural, Barcelona, Spain

**18151.** McMullen, L.E.; De Leenheer, P.; Tonkin, J.D.; Lytle, D.A. (2017): High mortality and enhanced recovery: modelling the countervailing effects of disturbance on population dynamics. *Ecology Letters* 20(12): 1566-1575. (in English) ["Disturbances cause high mortality in populations while simultaneously enhancing population growth by improving habitats. These countervailing effects make it difficult to predict population dynamics following disturbance events. To address this challenge, we derived a novel form of the logistic growth equation that permits time-varying carrying capacity and growth rate. We combined this equation with concepts drawn from disturbance ecology to create a general model for population dynamics in disturbance-prone systems. A river flooding example using three insect species (a fast life-cycle mayfly, a slow life-cycle dragonfly and an ostracod) found optimal tradeoffs between disturbance frequency vs. magnitude and a close fit to empirical data in 62% of cases. A savanna fire analysis identified fire frequencies of 3–4 years that maximised population size of a perennial grass. The model shows promise for predicting population dynamics after multiple disturbance events and for management of river flows and fire regimes." **18152.** Meadows, A.J.; Owen, J.P.; Snyder, W.E. (2017): Keystone nonconsumptive effects within a diverse predator community. *Ecology and Evolution* 7(23):10315- 10315 (in English) ["The number of prey killed by diverse predator communities is determined by complementarity and interference

among predators, and by traits of particular predator species. However, it is less clear how predators' nonconsumptive effects (NCEs) scale with increasing predator biodiversity. We examined NCEs exerted on *Culex* mosquitoes by a diverse community of aquatic predators. In the field, mosquito larvae co-occurred with differing densities and species compositions of mesopredator insects; top predator dragonfly naiads were present in roughly half of surveyed water bodies. We reproduced these predator community features in artificial ponds, exposing mosquito larvae to predator cues and measuring resulting effects on mosquito traits throughout development. Nonconsumptive effects of various combinations of mesopredator species reduced the survival of mosquito larvae to pupation, and reduced the size and longevity of adult mosquitoes that later emerged from the water. Intriguingly, adding single dragonfly naiads to ponds restored survivorship of larval mosquitoes to levels seen in the absence of predators, and further decreased adult mosquito longevity compared with mosquitoes emerging from mesopredator treatments. Behavioral observations revealed that mosquito larvae regularly deployed "diving" escape behavior in the presence of the mesopredators, but not when a dragonfly naiad was also present. This suggests that dragonflies may have relaxed NCEs of the mesopredators by causing mosquitoes to abandon energetically costly diving. Our study demonstrates that adding one individual of a functionally unique species can substantially alter community-wide NCEs of predators on prey. For pathogen vectors like mosquitoes, this could in turn influence disease dynamics." (Authors)] Address: Meadows, Amanda, Entomology, Washington State Univ., Pullman, WA, USA. **18154.** Mendes, F.; Kiffer Jr., W.P.; Moretti, M.S. (2017): Structural and functional composition of invertebrate communities associated with leaf patches in forest streams: a comparison between mesohabitats and catchments. *Hydrobiologia* 800: 115-127. (in English) ["We evaluated the influence of mesohabitats and catchments on the structural and functional composition of invertebrate communities [including 'Odonata'] associated with leaf patches in Atlantic Forest streams. We hypothesized that invertebrate communities would be more influenced by inter-habitat than inter-catchment variation, i.e., invertebrate taxonomic and trophic composition would differ more between pools and riffles than among catchments. Invertebrate richness differed among catchments only, while values of total abundance and biomass were higher in pools. The influence of mesohabitats on the structure of invertebrate communities was high, and most taxa had specificities with one mesohabitat. Among insect shredders, *Gryopterigidae* (Plecoptera) and *Blattodea* occurred more in riffles; *Phylloicus*, *Nectopsyche*, and *Triplectides* (Trichoptera) occurred more in pools. The biomass of omnivorous macroconsumers (*Trichodactylus fluviatilis* and *Macrobrachium potiuna*) was higher in pools and also differed among catchments. Except gathering-collectors, the taxonomic composition of functional feeding groups differed between pools and riffles. The obtained results corroborated the hypothesis that the structural and functional composition of invertebrate communities is more influenced by inter-habitat than by inter-catchment variation, and reinforced the importance of maintaining the biological and geomorphological characteristics of streams to allow the accumulation of leaves in different mesohabitats and preserve the aquatic biodiversity." **18155.** Miguel, T.B.; Calvão, L.B.; Carneiro Vital, M.V.; Juen, L. (2017): A scientometric study of the order Odonata with special attention to Brazil. *International Journal of Odonatology* 20(1): 27-42. (in English) ["The insects of the order Odonata have an aquatic larval stage and land-dwelling adults. These insects play an important role in aquatic ecosystems and are excellent bioindicators. The present study was based on a scientometric analysis of the research available on the Odonata, which aimed to identify the principal trends and gaps in the database on these organisms, compiled online from databases of the Institute for Scientific Information – ISI, Scielo and journals *Odonatologica* and *International Journal of Odonatology*. A total of 2317 papers were analyzed, permitting the detection of the following tendencies: a gradual increase in the number of papers occurred over time, most of the papers had an ecological perspective, most focused primarily on the adult stage and species level, and 49 studies focused on bio-indication by examining variation in the composition of the community, fluctuating asymmetry, bioaccumulation, species richness and abundance, and odonate habitat index (OHI). The increase in the ecological studies of odonates may reflect the dynamic characteristics of this order, and its relatively well-defined systematics,

principally in the case of the adults. Despite the increase in the number of publications, there are still many gaps, such as biogeography, parasitism, competition within and among species, evolutionary and phylogenetic relationships, as well as studies of the larval stages of these organisms. Given the sensitivity of the members of this order to environmental variables, they may be used for the evaluation of aquatic systems, given their roles as detectors, exploiters or accumulators, depending on the type of response to environmental modifications." **18156.** Mikl, L.; Adámek, Z.; Všeticková, L.; Janác, M.; Roche, K.; Šlapanský, L.; Jurajda, P. (2017): Response of benthic macroinvertebrate assemblages to round (*Neogobius melanostomus*, Pallas 1814) and tubenose (*Proterorhinus semilunaris*, Heckel 1837) goby predation pressure. *Hydrobiologia* 785: 219-232. (in English) ["One of the main assumed impacts of invasive gobies is predation on benthic macroinvertebrates. Despite numerous dietary studies, however, quantitative evaluations of impact in European river systems are scarce. Here, we investigate the impact of tubenose (*Proterorhinus semilunaris*, Heckel 1837) and round (*Neogobius melanostomus*, Pallas 1814) gobies on macroinvertebrates in a lowland river (River Dyje, Czech Republic) by allowing and preventing gobiid access to rip-rap substrate naturally colonised by invertebrates at two sites (Site 1—tubenose goby only, Site 2—tubenose and round gobies). Gobies had a negative impact on invertebrates at both sites, with overall invertebrate density reduced by 15% (ca. 17.9 g m<sup>-2</sup> per year) at Site 1 and 36% (ca. 23.6 g m<sup>-2</sup> per year) at Site 2. Both species showed increased impact in summer and ingested larger invertebrates preferentially, resulting in an overall reduction in invertebrate body size. Tubenose gobies had a significant impact on Annelida, Gastropoda, Crustacea and Ephemeroptera nymphs, while tubenose and round goby together impacted Anoptera nymphs, Odonata nymphs and Chironomidae larvae. Our results confirm that round and tubenose gobies can have a significant negative impact on aquatic invertebrate density and community composition." (Authors)] Address: Mikl, L., Inst. Vertebrate Biology, Acad. Sciences Republic, Kvetná 8, 603 65 Brno, Czech Republic. E-mail: libor.mikl@seznam.cz

**18157.** Mitamura, T. (2017): The impacts of the Great East Japan Earthquake and tsunami to individual number of Odonata on coastal area of Fukushima Prefecture, north eastern Honshu, Japan. *Tombo* 59: 23-28. (in Japanese, with English summary) ["On 11-III-2011, the coastal area of Fukushima prefecture was inundated by the Great East Japan Earthquake and tsunami. The disaster damaged many human lives and biodiversity. Since the habitat of organism was exposed to radiation by the accident of Fukushima No.1 nuclear power plant, investigation of natural environment is not progressing in the coastline area of Fukushima Prefecture. The number of Odonata decreased after the tsunami. *Mortonagrion hirosei* and *Platycnemis foliacea sasakii* have disappeared in Fukusnima pref. The number of Aeshnidae species

decreased to 7 from 12 in Matsukawa-ura, Soma." (Authors)] Address: Mitamura, T., 7-4 Sekiai, Koori-mächi, Date-gun, Fukushima pre f., 969-16, Japan

**18158.** Mozhui, L.; Kakati, L.N.; Changkija, S. (2017): A study on the use of insects as food in seven tribal communities in Nagaland, Northeast India. *Journal of Human Ecology* 60(1): 42-53. (in English) ["This paper documents the use of insect as food among seven tribal communities of Nagaland. Information was obtained through personal field interviews with 240 informants with the help of semi-structured questionnaires. It was found that 82 species of insects belonging to 9 orders (Odonata, Orthoptera, Mantodea, Isoptera, Hemiptera, Coleoptera, Hymenoptera, Lepidoptera and Diptera) are an important traditional food item principally consumed by the tribal people. Insects are preferred as eggs, larvae, nymphs, pupa or adult which are cooked, roasted or consumed raw. Documentation was done by calculating the "use value" (UV) of each species. It is evident from the study that insects can enhance nutritional deficiencies and can also improve the livelihood of the rural poor in the region. Hence, an inventory of food insects covering as many tribes is necessary so as to get benefit from their natural diversity before the existing traditional information is lost." **18161.** Nasirian, H.; Irvine, K.N. (2017): Odonata larvae as a bioindicator of metal contamination in aquatic environments: application to ecologically important wetlands in Iran. *Environmental Monitoring and Assessment* 189(9) 436: 18 pp. (in English) ["The objectives of this study were twofold: (i) assess the bioaccumulation characteristics of a suite of metals associated with several different species of Odonata and (ii) examine Odonata species richness as a reflection of ecosystem health in two ecologically important wetlands of southwestern Iran, the Shadegan and Hawr Al Azim wetlands. Levels of arsenic (As), cadmium (Cd), cobalt (Co), chromium (Cr), copper (Cu), iron (Fe), mercury (Hg), manganese (Mn), lead (Pb), and zinc (Zn) were determined using inductively coupled plasma optical emission spectrometry (ICP-OES) in nine different Odonata larva species. Based on these data, biota-sediment accumulation factors (BSAFs) were calculated and generally, it was found that Cr, Cu, Mn, and Zn were being taken up by the Odonata (BSAFs >1). Because of its prevalence in the wetland and its observed ability to take up metals, it is suggested that *Ischnura ramburii* is an appropriate indicator of ecosystem health for these wetlands with respect to metal contamination. Odonata species richness across all sites was 49, while for the individual sites, the greatest species richness was 26 and the lowest species richness was 13. The species richness value across all sites is quite healthy, given the arid climate of the region." **18162.** Nel, A.; Weis, R. (2017): A new Early Jurassic damselfly from the Grand Duchy of Luxembourg (Odonata: Campterophlebiidae). *Alcheringa* 41(3): 1-5. (in English) ["*Gallodorsettia kronzi* gen. et sp. nov., the first representative of the damselfly family Campterophlebiidae from the Toarcian of Grand Duchy of Luxembourg, is described herein. Its closest relative is the genus *Dorsettia*, known from the early Lower Jurassic of UK and China. The Campterophlebiidae seem to be rare in the Early Jurassic of Western Europe,

despite being one of the most diverse odonatan families at that time, especially in Asia." (Authors)] Address: Weis, R., Musée national d'histoire naturelle, Luxembourg, Section Paléontologie, 25, rue Münster L-2160 Luxembourg, Grand-Duché de Luxembourg. E-mail: rweis@mnhn.lu

**18163.** Ngiam, R.W.J.; Lim, W.L.; Collins, C.M. (2017): A balancing act in urban social-ecology: human appreciation, ponds and dragonflies. *Urban Ecosystems* 20(4): 743-758. (in English) ["Green spaces in cities provide cultural ecosystem services (CES) such as nature connection, wildlife interaction and aesthetic appreciation which can improve aspects of human well-being. Recognising these benefits, researchers are now examining the complex relationship between humans and nature in urban social-ecology. Most studies investigate people's appreciation and valuation of different green space features and their contribution to urban biodiversity. Recommendations arising from such studies are best practices to achieve a balance between landscape aesthetic and ecological objectives, but many knowledge gaps still exist. In a social-ecological project in Greater London, appreciation of ponds and dragonflies in urban green spaces, and the environmental factors determining dragonfly diversity were investigated. We found ponds and their appearance were valued by people as enhancing their green space experience. The preference for wild-looking ponds was moderate. Dragonflies were enjoyed for their colour and high visibility, especially by those who had basic dragonfly knowledge. Species richness of dragonflies was positively associated with habitat heterogeneity in and around a pond. However, people were unable to relate a heterogeneous pond to more dragonfly species. For the first time, some factors that influence the human appreciation-ponds-dragonflies (HPD) relationship in an urban context are revealed. To fully realise the CES potential of ponds and dragonflies in Greater London, a HPD framework is proposed. The framework underpins strategies that foster cultural sustainability for ponds and dragonfly conservation." **18164.** Nilsson-Örtman, V.; Johansson, F. (2017): The rate of seasonal changes in temperature alters acclimation of performance under climate change. *The American Naturalist* 190 (6): 743-761. (in English) ["How the ability to acclimate will impact individual performance and ecological interactions under climate change remains poorly understood. Theory predicts that the benefit an organism can gain from acclimating depends on the rate at which temperatures change relative to the time it takes to induce beneficial acclimation. Here, we present a conceptual model showing how slower seasonal changes under climate change can alter species' relative performance when they differ in acclimation rate and magnitude. To test predictions from theory, we performed a microcosm experiment where we reared a mid- and a high-latitude damselfly species alone or together under the rapid seasonality currently experienced at 62°N and the slower seasonality predicted for this latitude under climate change and measured larval growth and survival. To separate acclimation

effects from fixed thermal responses, we simulated growth trajectories based on species' growth rates at constant temperatures and quantified how much and how fast species needed to acclimate to match the observed growth trajectories. Consistent with our predictions, the results showed that the midlatitude species had a greater capacity for acclimation than the high-latitude species. Furthermore, since acclimation occurred at a slower rate than seasonal temperature changes, the midlatitude species had a small growth advantage over the high-latitude species under the current seasonality but a greater growth advantage under the slower seasonality predicted for this latitude under climate change. In addition, the two species did not differ in survival under the current seasonality, but the midlatitude species had higher survival under the predicted climate change scenario, possibly because rates of cannibalism were lower when smaller heterospecifics were present. These findings highlight the need to incorporate acclimation rates in ecological models." **18165.** Nixon, M.R.; Orr, O.G.; Vukusic, P. (2017): Covert linear polarization signatures from brilliant white two-dimensional disordered wing structures of the phoenix damselfly. *J. R. Soc. Interface* 2017 14 20170036: 8 pp. (in English) ["Pseudolestes mirabilis reflects brilliant white on the ventral side of its hindwings and a copper-gold colour on the dorsal side. Unlike many previous investigations of odonate wings, in which colour appearances arise either from multilayer interference or from wing-membrane pigmentation, the whiteness on the wings of *P. mirabilis* results from light scattered by a specialized arrangement of flattened waxy fibres and the copper-gold colour is produced by pigment-based filtering of this light scatter. The waxy fibres responsible for this optical signature effectively form a structure that is disordered in two dimensions and this also gives rise to distinct optical linear polarization. It is a structure that provides a mechanism enabling *P. mirabilis* to display its bright wing colours efficiently for territorial signalling, both passively while perched, in which the sunlit copper-gold upperside is presented against a highly contrasting background of foliage, and actively in territorial contests in which the white underside is also presented. It also offers a template for biomimetic high-intensity broadband reflectors that have a pronounced polarization signature." (2017): Electroporation-mediated RNA interference reveals a role of the multicopper oxidase 2 gene in dragonfly cuticular pigmentation. *Applied Entomology and Zoology* 52(3): 379-387. (in English) ["Dragonflies are colorful insects, and recent RNA sequencing studies have identified a number of candidate genes potentially involved in their color pattern formation and color vision. However, functional aspects of such genes have not

been assessed due to the lack of molecular genetic tools applicable to dragonflies. We established an electroporation-mediated RNA interference (RNAi) procedure using the tiny dragonfly *Nannophya pygmaea* Rambur, 1842 that targets the multicopper oxidase 2 gene (MCO2; also known as lac-case2 gene) responsible for cuticular pigmentation in many insects. RNA sequencing of *N. pygmaea* and genomic survey of the dragonfly *Ladona fulva* identified four multicopper oxidase family genes: MCO1, MCO2, MCO3 and multicopper oxidase-related protein gene (MCORP). In *N. pygmaea*, MCO2 was specifically expressed around the cuticular pigmentation period, whereas MCO1 was constantly expressed. MCORP was expressed at adult stages, and MCO3 was scarcely expressed. When we applied *in vivo* electroporation, final instar larvae injected with MCO2 small interfering RNA became adults with patchy unpigmented regions. RNAi without *in vivo* electroporation did not affect cuticular pigmentation, suggesting that dragonflies do not show a systemic RNAi response. These results indicate that MCO2 is required for cuticular pigmentation across diverse insects, and highlight the usefulness of the electroporation-mediated RNAi method in dragonflies." **18168.** Oliveira-Junior, J.M.B.; Ligeiro, R.; Juen, L. (2017): Odonata (Insecta) as a tool for the biomonitoring of environmental quality. *Ecological Indicators* 81: 555-566. (in English) ["Highlights: •Different assemblage characteristics can potentially be used to assess loss of environmental integrity. •Species composition was the characteristic that best evaluated ecological integrity. •Taxonomic diversity and taxonomic distinction also achieved good results. •Species richness and abundance/biomass relationships did not provide good responses. •Deconstructing Odonata assemblages and choosing the right indicators are mandatory for efficient ecological assessments. Abstract: Despite the fundamental dependence of human populations on water resources, a range of anthropogenic impacts, in particular the removal of riparian vegetation, threaten freshwater environments. One of the most effective means of evaluating the effects of anthropogenic disturbance in aquatic ecosystems is the use of bioindicators, and the insects of the order Odonata are

among the most efficient indicators, due to their enormous sensitivity to environmental changes. In this context, the present study aimed to verify which parameters of the odonate community (species richness, abundance/biomass, composition, taxonomic diversity and taxonomic/phylogenetic distinctness) are most effective for the evaluation of the loss of environmental integrity. The study focused on 50 streams in the northeast of the Brazilian state of Pará. The streams were sampled during the dry season, between June and August 2011. The physical characteristics of each stream were evaluated using a Habitat Integrity Index (HII). The species composition provided the best parameter for the evaluation of ecological integrity, providing a relatively accurate assessment at a lower mean research cost than other parameters. Taxonomic diversity and distinctness also provided relatively reliable results, contributed additional information on the evolutionary relationships among the odonate taxa, and also provided a low-cost approach. Deconstructing communities is necessary to detect impacts, considering the considerable variation in the environmental requirements of the different species. Overall, the parameter that best responded to gradients of disturbance was species composition, followed by diversity and taxonomic distinctness. Given these findings, odonate-based biomonitoring should focus on these parameters to guarantee the optimal detection and evaluation of habitat alterations." (2017): Feeding ecology of the Sicilian pond turtle *Emys trinacris* (Testudines, Emydidae) influenced by seasons and invasive aliens species. *Ecological Research* 32(1): 71-80. (in English) ["Feeding ecology of a species is

the result of its evolutionary history, biology, physiology and local constraints, such as prey availability, intra- and inter-specific interactions and environmental characteristics. In this study we investigated the still unknown diet of the Sicilian pond turtle, with special emphasis to the relationships with recently introduced alien species in the "Lake Preola and Gorghi Tondi" Nature Reserve (Sicily, Italy). A total of 83 faecal samples were collected in three different periods. *E. trinacris* seems an opportunistic and generalist species. The main prey taxa were aquatic invertebrates [including Odonata], including the invasive *Procambarus clarkii*, while non-aquatic preys are found sporadically. Plant matter, mainly leaves and roots of aquatic forms, was also found in high frequency with a high occurrence of fruits and seeds in spring. We did not find a significant difference in diet composition within sex and age, while an evident divergence was found between periods and sites. In particular, we noticed a decrease in prey abundance and in food-niche breadth from pre-reproductive period to post-reproductive period. Moreover a very clear difference was found between a site with allochthonous fishes and a site fish-free, with a more abundant and wide diet spectrum in the last one, as a result of the increased availability of prey. We highlighted the importance to take any possible actions to avoid the spread of fishes in other basins and to study the indirect impact of *Procambarus clarkii*, as possible vector of harmful trace element." The climate of the state divided into the tropical, temperate and alpine Zones. The State is endowed with rich floral and faunal diversity. However, Odonata fauna of Sikkim has been far less explored. With the addition of the new records

of *Caliphaea confusa*, *Zygonyx iris* and validation of the occurrence of *Rhinocypha unimaculata* for the State Sikkim, Odonata diversity counts now 77. However, further surveys will identify more species of Odonates from Sikkim.] Address: Payra, A., Dept of Wildlife and Biodiversity Conservation, North Orissa University, Odisha - 757003, India

**18176.** Pestic, V.; Gligorovic, B.; Savic, A.; Buczyński, P. (2017): Ecological patterns of Odonata assemblages in karst springs in central Montenegro. *Knowl. Manag. Aquat. Ecosyst.* 2017, 418, 3: 20 pp. (in English, with French summary) ["Karstic springs are important habitats for maintaining freshwater biodiversity. However, little is known about Odonata larvae assemblages in karstic springs, and studies about the ecological factors that determine species distribution in these habitats are still lacking. In this study the composition of Odonata larvae communities from 91 springs located in the central part of Montenegro was investigated. The richest fauna was found in sublacustrine springs, followed by limnocrenes, while that of the rheocrenes was less rich. The results obtained confirm the main research hypothesis that Odonata larvae assemblages in the karstic springs in the central part of Montenegro were comparably influenced by the environmental parameters acting on the level of individual springs as well as the factors acting at the landscape level. Odonata larvae assemblages divided springs into four groups. On the other hand, the springs could be divided into three groups based on habitat and landscape characteristics. CCA indicates that disturbance factors such as the permanence and directness of human influence on springs for use as drinking water sources are foremost in determining Odonata assemblages at the level of individual springs. The habitat scale considered several factors that influence Odonate assemblages, including altitude and riparian vegetation. This study proves that further odonatological studies in springs should include both types of factors and their interactions." **18177.** Phillips, I.D.; Prestie, K.S. (2017): Evidence for substrate influence on artificial substrate invertebrate communities. *Environmental Entomology* 46(4): 926-930. (in English) ["Cobble baskets are frequently used as a tool to measure differences in benthic macroinvertebrate communities between waterbodies; however, underlying differences in substrate type may influence the resultant colonization of baskets, misrepresenting communities. This study tests the hypothesis that cobble basket placement influences the resulting benthic macroinvertebrate community. Cobble basket arrays (n = 4) were deployed in Dog Lake, Saskatchewan, in 2011 (97 d) and 2012 (95 d) on cobble habitats and soft or sandy substrates ~100 m apart. Baskets placed on cobble substrate had significantly higher Shannon–Weaver diversity relative to those placed on soft substrate in both years, and higher % EPT (Ephemeroptera Plecoptera Trichoptera) in 2011, but total density was not significantly different. Non-metric multidimensional scaling revealed that the community was different between both treatments, characterized

by higher densities of *Gammarus lacustris* Sars in baskets placed on soft sediment in both years, higher densities of *Aeshna* sp. and *Mystacides* sp. on cobble substrate in 2011, and higher densities of *Helobdella stagnalis* (L.) and *Glossophinia complanata* (L.) on cobble substrate in 2012. The results were consistent with the hypothesis that baskets placed on cobble substrate versus soft substrate will result in differing community colonization. The resulting recommendation for monitoring and assessment using cobble baskets in lakes is that baskets be placed on comparable substrate type when comparing between lakes, and that cobble beds be chosen as a more appropriate substrate for deployment, as the added habitat complexity of baskets on soft sediment may act as an attractant and not reflect the true community composition of that habitat." **18178.** Phillips, N.; Knowles, K.; Bomphrey, R.J. (2017): Petiolate wings: effects on the leading-edge vortex in flapping flight. *Interface Focus* 7: 20160084: 13 pp. (in English) ["The wings of many insect species including crane flies and damselflies are petiolate (on stalks), with the wing planform beginning some distance away from the wing hinge, rather than at the hinge. The aerodynamic impact of flapping petiolate wings is relatively unknown, particularly on the formation of the lift-augmenting leading-edge vortex (LEV): a key flow structure exploited by many insects, birds and bats to enhance their lift coefficient. We investigated the aerodynamic implications of petiolation  $P$  using particle image velocimetry flow field measurements on an array of rectangular wings of aspect ratio 3 and petiolation values of  $P \frac{1}{4}$  1–3. The wings were driven using a mechanical device, the 'Flapperatus', to produce highly repeatable insect-like kinematics. The wings maintained a constant Reynolds number of 1400 and dimensionless stroke amplitude  $L^*$  (number of chords traversed by the wingtip) of 6.5 across all test cases. Our results showed that for more petiolate wings the LEV is generally larger, stronger in circulation, and covers a greater area of the wing surface, particularly at the mid-span and inboard locations early in the wing stroke cycle. In each case, the LEV was initially arch-like in form with its outboard end terminating in a focus-sink on the wing surface, before transitioning to become continuous with the tip vortex thereafter. In the second half of the wing stroke, more petiolate wings exhibit a more detached LEV, with detachment initiating at approximately 70% and 50% span for  $P \frac{1}{4}$  1 and 3, respectively. As a consequence, lift coefficients based on the LEV are higher in the first half of the wing stroke for petiolate wings, but more comparable in the second half. Time-averaged LEV lift coefficients show a general rise with petiolation over the range tested." (Authors)] Address: Bomphrey, R.J.; E-mail: rbomphrey@rvc.ac.uk

**18179.** Piano, E.; Isaia, M.; Falasco, E.; La Morgia, V.; Soldato, G.; Bona, F. (2017): Local versus landscape spatial influence on biodiversity: a case study across five European

industrialized areas. *Environmental Monitoring and Assessment* 189:126: 12 pp. (in English) ["Land use change — mostly habitat loss and fragmentation — has been recognized as one of the major drivers of biodiversity loss worldwide. According to the habitat amount hypothesis, these phenomena are mostly driven by the habitat area effect. As a result, species richness is a function of both the extent of suitable habitats and their availability in the surrounding landscape, irrespective of the dimension and isolation of patches of suitable habitat. In this context, we tested how the extent of natural areas, selected as proxies of suitable habitats for biodiversity, influences species richness in highly anthropogenic landscapes. We defined five circular sampling areas of 5 km radius, including both natural reserves and anthropogenic land uses, centred in five major industrial sites in France, Italy and Germany. We monitored different biodiversity indicators for both terrestrial and aquatic ecosystems, including breeding birds, diurnal butterflies, grassland vegetation, Odonata, amphibians, aquatic plants and benthic diatoms. We studied the response of the different indicators to the extent of natural land uses in the sampling area (local effect) and in the surrounding landscape (landscape effect), identified as a peripheral ring encircling the sampling area. Results showed a positive response of five out of seven biodiversity indicators, with aquatic plants and Odonata responding positively to the local effect, while birds, vegetation and diatoms showed a positive response to the landscape effect. Diatoms also showed a significant combined response to both effects. We conclude that surrounding landscapes act as important biodiversity sources, increasing the local biodiversity in highly anthropogenic contexts." (Authors)] Address: Isaia, M., Dept of Life Sciences & Systems Biology, Univ. of Turin, Turin, Italy

**18180.** Pires, M.M.; Stenert, C.; Maltchik, L. (2017): Partitioning beta-diversity through different pond hydroperiod lengths reveals predominance of nestedness in assemblages of immature odonates. *Entomological Science* 20(1): 318-326. (in English) ["Patterns of freshwater invertebrate assemblage structure in the transition from permanent to non-permanent lentic habitats are well described in the literature. However, the effects of small changes in the hydroperiod of non-permanent ponds on invertebrate assemblage structure remain less studied, especially on  $\beta$ -diversity. Thus, we tested the effects of different pond hydroperiod lengths on the assemblage structure of immature odonates, in terms of both  $\alpha$ - and  $\beta$ -diversity. Small high-altitude ponds with different hydroperiod lengths (assigned to 'short', 'medium' and 'long' hydroperiods) were sampled in southern Brazil between 2013 and 2014. Based on the hypothesis that shorter hydroperiods filter constituents of lentic fauna, i.e. that long-living species cannot inhabit shorter-hydroperiod ponds, we expected to find higher  $\alpha$ - and  $\beta$ -diversity in longer hydroperiods, as well as predominance of the nestedness component in  $\beta$ -diversity. Restricted occurrence of some genera and higher  $\alpha$ -diversity of immature odonate assemblages was detected in long-hydroperiod ponds. Within-hydroperiod  $\beta$ -diversity values did not vary among hydroperiods, because the occasional occurrence of some genera with high dispersal  $\alpha$ -

bility of adults in short-hydroperiod ponds yielded similar values of the  $\beta$ -diversity among hydroperiods. Partitioning of  $\beta$ -diversity among hydroperiods revealed a significant higher contribution of the nestedness component rather than turnover. This pattern is explained by the occurrence of some generalist genera across the whole gradient of hydroperiod, as a subset of fauna in longer-hydroperiod ponds. Thus, our results suggest that reduction in hydroperiod length, if occurring in the future climate change, would favour habitat-generalist taxa in lentic ecosystems." **18181.** Popova, O.N.; Haritonov, A.Y.; Sushchik, N.N.; Makhutova, O.N.; Kalachova, G.S.; Kolmakova, A.A.; Gladyshev, M.I. (2017): Export of aquatic productivity, including highly unsaturated fatty acids, to terrestrial ecosystems via Odonata. *Science of The Total Environment* 581–582: 40-48. (in English) ["Highlights: •We measured abundance and emergence of odonates in forest-steppe during 31 years. •Odonates bring organic carbon to the land, which is equal to land insect production. •Highly unsaturated fatty acids (HUFA) were measured in biomass of odonates. •Odonates subsidize essential HUFAs in land as many as all other amphibiotic insects. Abstract: Based on 31-year field study of the abundance and biomass of 18 species of odonates in the Barabinsk Forest–Steppe (Western Siberia, Russia), we quantified the contribution of odonates to the export of aquatic productivity to surrounding terrestrial landscape. Emergence varied from 0.8 to 4.9 g of wet biomass per m<sup>2</sup> of land area per year. Average export of organic carbon was estimated to be 0.30 g·m<sup>-2</sup>·year<sup>-1</sup>, which is comparable with the average production of herbivorous terrestrial insects in temperate grasslands. Moreover, in contrast to terrestrial insects, emerging odonates contained high quantities of highly unsaturated fatty acids (HUFA), namely eicosapentaenoic acid (20:5n<sup>-3</sup>, EPA), and docosahexaenoic acid (22:6n-3, DHA), which are known to be essential for many terrestrial animals, especially for birds. The export of EPA + DHA by odonates was found to be 1.92–11.76 mg·m<sup>-2</sup>·year<sup>-1</sup>, which is equal to an average general estimation of the export of HUFA by emerging aquatic insects. Therefore, odonates appeared to be a quantitatively and qualitatively important conduit of aquatic productivity to forest-steppe ecosystem." **18182.** Preston, T.M.; Ray, A.M. (2017): Effects of energy development on wetland plants and macroinvertebrate communities in Prairie Pothole Region wetlands. *Journal of Freshwater Ecology* 32(1): 29-34. (in English) ["Energy production in the Williston Basin, USA, results in the coproduction of highly saline, sodium chloride-dominated water (brine). The Prairie Pothole Region (PPR) overlies the northeastern portion of the Williston Basin. Although PPR wetlands span a range of salinity, the dominant salt is sodium sulfate, and salinities are much lower than brine. Introduction of brine to wetlands can result in pronounced water-quality changes; however, the ecological effects of such contamination are

poorly understood. We examined the effects of brine contamination on primary productivity, emergent macrophyte tissue chemistry, and invertebrate communities [including Odonata] from 10 wetlands in the PPR. Based on a recognized Contamination Index (CI) used to identify brine contamination in the PPR water-quality samples indicated that six wetlands were uncontaminated while four were contaminated. Across this gradient, we observed a significant decrease in above-ground biomass and a significant increase in tissue chloride concentrations of hardstem bulrush (*Schoenoplectus acutus*) with increased CI values. Additionally, a significant decrease in macroinvertebrate taxonomic richness with increased CI values was observed. These findings provide needed insight on the biological effects of brine contamination on PPR wetlands." **18184.** Pujol-Buxó, E.; García-Guerrero, C.; Llorente, G.A. (2017): Alien versus predators: effective induced defenses of an invasive frog in response to native predators. *Journal of Zoology* 301(3): 227-234. (in English) ["Inducible defenses enhance fitness of prey living in environments with unpredictable predation risk, but these plastic reactions depend on the detection of the threat by the prey. To anuran larvae confronted with unknown predators, only prey-borne cues are noticeable, generally triggering either an incomplete set of reactions or no response at all. Thus, we should expect a certain disadvantage for establishing invasive anurans if tadpoles are unable to recognize local predators. Here, we test the presence and effectiveness of inducible defenses in tadpoles of the invasive frog *Discoglossus pictus* confronting two native predators. Using both lab and mesocosm experiments, we also evaluate the effects these predators may exert on the invasive frog populations. Interestingly, although *D. pictus* has been introduced from another continent,

its native (African) and invasive (European) ranges are included in the same ecoregion (Mediterranean Basin), sharing several genera and species of aquatic predators. In both experiments and using both invertebrates, tadpoles responded to the native predators, and our results match those usually reported in similar predator-prey systems using combinations of native species. Moreover, these reactions seem clearly effective in reducing mortality and injury rates of *D. pictus* tadpoles. We believe that the introduced frog is highly benefiting from a previous knowledge of populations of these or similar predator species. Therefore, even though native and invasive ranges of *D. pictus* are in different continents, the similarity of predator communities of both areas may be advantageous for its establishment and expansion." **18185.** Quintana, A.T.; Tur, B.R. (2017): Emergence patterns of Odonata (Insecta) from a lotic habitat in Eastern Cuba. *Revista de Biología Tropical/International Journal of Tropical Biology and Conservation* 65(2): 807-818. (in Spanish, with English summary) ["The emergence patterns of tropical odonates (dragonflies and damselflies) are scarcely known. We studied the emergence patterns of odonates in a freshwater lotic system in Giro, Northern Santiago de Cuba, between January and December 2008. We visited the locality between 09:00 and 14:00, on a weekly basis, and collected exuviae from a fixed section (8 x 1 m<sup>2</sup>) offshore, along the riparian vegetation. We collected data on species composition and, for each species, abundance, relative biomass and emergence pattern. We collected 443 exuviae belonging to 22 species: seven Zygoptera and 15 Anisoptera. Half of the annual Odonata emergence took place in the dry season (December to March) with the highest value in February (25%). For species for which we found seven or more exuviae per month, *Enallagma coecum* and *Macrothemis celeno* tended to be a synchronal emergence. We also found temporal segregation of the emergence pattern between *M. celeno* and *Protoneura capillaris*, *Neoneura maria*, *Progomphus integer* and *Scapania frontalis*. These differences were probably related to the highest annual fluctuations of temperature, relative humidity and number of rainy days per month. We concluded that there is an asynchrony and heterogeneity in Odonata emergence times in the studied freshwater lotic system." **18186.** Rajabi, H.; Schroeter, V.; Eshghi, S.; Gorb, S.N. (2017): The probability of the wing damage in the dragonfly *Sympetrum vulgatum* (Anisoptera: Libellulidae): a field study. *Biology Open* 6(9): 1290-1293. (in English) ["Dragonfly wings resist millions of cycles of dynamic loading in their lifespan. During their operation, the wings are subjected to relatively high mechanical stresses. They further experience accidental collisions which result from the insects' daily activities, such as foraging, mating and fighting with other individuals. All these factors may lead to irreversible wing damage.

Here, for the first time, we collected qualitative and quantitative data to systematically investigate the occurrence of damage in dragonfly wings in nature. The results obtained from the analysis of 119 wings of more than 30 individuals of *S. vulgatum*, collected at the second half of their flight period, indicate a high risk of damage in both fore- and hindwings. Statistical analyses show no significant difference between the extents of damage neither in fore- and hindwings nor in male and female dragonflies. However, we observe a considerable difference in the probability of damage in different wing regions. The wing damage is found to be mainly due to two failure modes: wear and fracture." **18187.** Ramos-Merchante, A.; Prenda, J. (2017): Macroinvertebrate taxa richness uncertainty and kick sampling in the establishment of Mediterranean rivers ecological status. *Ecological Indicators* 72: 1-12. (in English) ["Freshwater macroinvertebrates have been extensively used as environmental indicators and are the most prevalent biological group used in aquatic bioassessment in the European Water Framework Directive (WFD 2000/60/EEC), usually through several popular indices, as the Biological Monitoring Working Party (BMWP). Many of these indices are based on taxa richness, i.e. the number of taxa present in a given area, as the simplest and most common measure of biodiversity. Given the importance to the WFD of the ecological status assessment by macroinvertebrates and the consequences thereof, sampling requires careful consideration and evaluation of the associated uncertainty. In this work, carried out in a Mediterranean river, we show that after 20 sample "kicks" it was possible to estimate the true taxa richness using Clench nonlinear asymptotic models (CM). However, cumulative curves of taxa extracted with kick sampling underestimated the true number of theoretical taxa (A). In order to achieve an acceptable error a very large sample size was required, always >20 kicks. According to these criteria, sampling was clearly inefficient in most localities. The minimum effort required to achieve a significant and acceptable level of taxa richness, for 90% of A, should be between 25 and 71 kicks and for 95% of A, 52–150 kicks. Both satisfactory percentages represent a mean difference of 2 (range 0–6) and 3 (range 1–8) taxa actually not being captured from the total predicted for each locality, for 90 and 95% of the CM asymptote, respectively. This study shows that by using the 20 kicks methodology it is possible to achieve reliable true macroinvertebrate richness estimates, but the establishment of the community composition, i.e. the full taxa making up any index score, will be inaccurate to an unknown degree." Odonata are treated at the family level (Authors)] Address: Prenda, J., Dept Integrated Sciences, Univ. of Huelva, Campus Universitario El Carmen, Avda, Andalucía s/n, 21071, Huelva, Spain. **18188.** Rana, J.S.; Semalty, B.; Singh, P.; Swami, N.; Dewan, S.; Singh, J.; Gusain, M.P.; Gusain, O.P. (2017): Checklist of benthic macroinvertebrate taxa along different riparian land use types in Alaknanda River catchment of the Central

Himalaya, Uttarakhand (India). Proceedings of the Zoological Society 72(2): 130-153. (in English) ["A checklist of benthic macroinvertebrates recorded at 08 different riparian land use (RLU) types in Alaknanda river catchment (ARC) in the Central Himalaya (India) is provided here. Among 77 taxa recorded, 73 insect genera belonged to 9 orders and 52 families at different RLU types. Majorities were nymphs and larvae of Ephemeroptera, Plecoptera, Trichoptera, Coleoptera, Lepidoptera, Odonata [including obviously wrong identifications], Hemiptera, Megaloptera and Diptera. The highest number of insect taxa (50) was recorded from Dense Mixed Forest; whereas, the lowest (27) was recorded from barren site i.e., Montane Barren. Also, the forested site had most number of common taxa (25). Benthic macroinvertebrates at Chir Pine Forest serves as a link between Dense Mixed Forest and Open Mixed Forest. Agricultural sites had 36 taxa in common. Interestingly the agricultural sites share 24 taxa with the forested sites. Overall 13 benthic insect taxa were ubiquitous in ARC, while 15 were rare, confined to a single site." **18189.** Rapacciuolo, G.; Ball-Damerow, J.E.; Zeilinger, A.R.; Resh, V.H. (2017): Detecting long-term occupancy changes in Californian odonates from natural history and citizen science records. *Biodiversity and Conservation* 26(12): 2933-2949. (in English) ["In a world of rapid environmental change, effective biodiversity conservation and management relies on our ability to detect changes in species occurrence. While long-term, standardized monitoring is ideal for detecting change, such monitoring is costly and rare. An alternative approach is to use historical records from natural history collections as a baseline to compare with recent observations. Here, we combine natural history collection data with citizen science observations within a hierarchical Bayesian occupancy modeling framework to identify changes in the occupancy of Californian Odonata over the past century. We model changes in the probability of occupancy of 34 odonate species across years and as a function of climate, after correcting for likely variation in detection probability using proxies for recorder effort and seasonal variation. We then examine whether biological traits can help explain variation in temporal trends. Models built using only opportunistic records identify significant changes in occupancy across years for 14 species, with eight of those showing significant declines and six showing significant increases in occupancy in the period 1900–2013. These changes are consistent with estimates obtained using more standardized resurvey data, regardless of whether resurvey data are used individually or in conjunction with the opportunistic dataset. We find that species increasing in occupancy over time are also those whose occupancy tends to increase with higher minimum temperatures, which suggests that these species may be benefiting from increasing temperatures across California. Furthermore, these species are also mostly habitat generalists, whilst a number of habitat specialists display some of the largest declines in occupancy across years. Our approach enables more ro-

bust estimates of temporal trends from opportunistic specimen and observation data, thus facilitating the use of these data in biodiversity conservation and management." **18190.** Renner, S.; Périco, E.; Ely, G.; Sahlén, G. (2017): Preliminary dragonfly (Odonata) species list from the Pampa biome in Rio Grande do Sul, Brazil, with ecological notes for 19 new records for the State. *Biota Neotropica* 17(4) e20170374: 8 pp. (in English) ["An inventory of Odonata was carried out in the southern half of the state of Rio Grande do Sul, Brazil, in the Pampa biome. Originally, this biogeographical region was covered mostly by open fields and grassland, with sections of higher vegetation surrounding water bodies and rocky hills. Today the landscape is fragmented due to agricultural activities, mainly cattle farming, rice crops and forest plantations. Our survey was conducted in three municipalities from this region, between March 2015 and April 2016. Aiming at a general overview of the species composition, our sampling sites were selected on a wide basis, including lakes, bogs, temporary water bodies, small streams and river sections. 82 species of Odonata were collected comprising 40 genera and seven families. The dominant families were Libellulidae (56,1%), Coenagrionidae (24,5%) and Aeshnidae (7,3%). We found a diverse odonate assemblage, adding 19 new species records for the state of Rio Grande do Sul." (Authors)] The following species are detailed: *Mnesarete lencionii* Garrison, 2006, *Argia lilacina* Selys, 1865, *Minagrion waltheri* Selys, 1876, *Oxyagrion rubidum* (Rambur, 1842), *Archaeogomphus densus* Belle, 1982, *Brechmorhoga nubecula* Rambur, 1842, *Dasythemis venosa* Burmeister, 1839, *Diastatops obscura* (Fabricius, 1775), *Dythemis nigra* Martin, 1897, *Erythemis vesiculosa* Fabricius, 1775, *Erythrodiplax lygaea* Ris, 1911, *Gynothemis venipunctata* Calvert, 1909, *Idiataphe longipes* Hagen, 1861, *Macrothemis heteronycha* Calvert in Ris, 1909, *Macrothemis lutea* Calvert, 1909, *Micrathyria spuria* Selys, 1900, *Orthemis aequilibris* Calvert, 1909, *Orthemis attenuata* Erichson, 1848, *Tholymis citrina* Hagen, 1867] Address: Renner, S., Universidade do Vale do Taquari, Laboratório de Ecologia e Evolução, Rua Avelino Talini, 171, Bairro Universitário, 95900-000 Lajeado, RS, Brazil

**18191.** Roberts, D. (2017): Mosquito larvae can detect water vibration patterns from a nearby predator. *Bulletin of Entomological Research* 107(4): 499-505. (in English) ["Mosquito larvae have been shown to respond to water-borne kairomones from nearby predators by reducing their activity, and thus visibility. If they can identify the predator, they can then alter their response depending upon the associated predation risk. No studies have shown that mosquito larva may also detect water-borne vibrations from the predator. Final instar larvae of three mosquitoes: *Culiseta longiareolata*, *Culex perexiguus* and *C. quinquefasciatus*, were exposed to recorded vibrations from feeding dragonfly nymphs, to dragonfly kairomones and the combined effect of both. Predator vibrations caused *C. longiareolata* to significantly re-

duce bottom feeding and instead increased the more passive surface filter feeding. The larvae also significantly increased escape swimming activity. These behavioural changes were not significantly different from the effect of dragonfly kairomones, and there was no synergistic or additional effect of the two. *C. perexiguus* gave a smaller (but still significant) response to both dragonfly vibrations and to kairomones, probably due to a different feeding behaviour: when lying on the bottom, it was an inactive filter feeder. *C. quinquefasciatus* did not respond to either vibrations or kairomones and during these experiments was entirely an inactive surface filter feeder. Both *C. longiareolata* and *C. perexiguus* were thus able to detect and identify vibrations from feeding dragonfly nymphs as an anti-predator strategy. The lack of response in *C. quinquefasciatus* is probably a result of living in water that is highly polluted with organic material, where few predators can survive." (2017): Idiosyncratic responses of aquatic and terrestrial insects to different levels of environmental integrity in riparian zones in a karst tropical dry forest region. *Austral Entomology* 556(4): 459-465. (in English) ["Decisions about biodiversity conservation depend on how different taxonomic groups respond to human-influenced environmental change. Here, we ask whether richness and composition of terrestrial (frugivorous butterflies and dung beetles) and aquatic insects (Plecoptera, Trichoptera, Ephemeroptera, Odonata and Coleoptera) change in a congruent manner across a gradient of riparian habitat degradation in a karst tropical dry forest region of Brazil, the Bodoquena Plateau. Our results showed incongruent ordination patterns based on the different taxa analysed. We found no correlation between richness and composition of the groups and environmental integrity. Incongruent responses among the taxonomic groups may be a consequence of high variability in ecological requirements among different taxa. Additionally, the effect of human disturbance on these taxonomic groups can be masked by the predominant presence of generalist species in tropical dry forests and by historical factors related to the adaptability of several species to changing ecosystems." **18193.** Sahito, H.A.; Bhutto, S.R.; Kousar, T.; Jatoti F.A.; Mangrio, W.M.; Ghumro, B.D.; Shah, Z.H. (2017): Morphotaxonomic characteristics of dragonfly, Lesser Emperor, *Anax parthenope* (Selys, 1839) (Odonata: Aeshnidae) at region Sukkur, Sindh. *J. of Advanced Botany and Zoology* 5(2): 1-6. (in English) ["Odonates are ecologically important as both predators and prey. Their larvae constitute a natural biological control over mosquito larvae and thus help to control several epidemic diseases like malaria, dengue, filaria etc. *A. parthenope* has been identified for the first time at region

Sukkur, Sindh - Pakistan. The study was mainly emphasized on morphological differences between male and female specimen. Both male and female specimens were having some same but mostly different characteristics. Like both male and female had large green compound eyes touching dorsally, head was found hypognathous, thorax dark green with visible thoracic segments, male had slightly larger than female wings, bigger in size and more colorful. Which was very rare in insects, fore and hind wings were not similar, forewing narrow and elongated whereas; the hind wings were broad basally, distal part of the wing was yellowish, abdomen was black dorsally and ventrally but found greenish from lateral side. It was concluded that there was a lot of potential to explore Odonata fauna of this region. The climate and topography of this area along with lot of natural pastures and aquatic bodies support dragonflies' life and biology. However, due to rapid increase in urbanization, suitable habitats of Odonata were disappearing at an alarming rate. Thus, only single specie was found. Further surveys and necessary conservation measures were also adopted, therefore, suggested as need of the day to utilize it, in right direction after knowing its species complex." **18196.** Satpathi, C.R. (2017): A treatise on dragonflies (Order: Odonata, Class: Insecta) of rice ecosystems in eastern India. *World Scientific News* 86(2): 67-133. (in English) ["This study highlights the 75 species of dragonfly fauna associated with rice ecosystems in eastern India out of which 15 species were regular and rest were sporadic. From the general

taxonomic point of view all the species were grouped under 5 families of under order Odonata. Comparing different body parts the double branching keys were prepared for easy identification of 15 common dragonfly species recorded in rice ecosystems of West Bengal. Each key begins with a couplet (a pair of alternative) and each of which leads to another couplet. Finally the reader reaches the specific identity of species. Free hand drawing of wings of the 50 dragonflies were also used for separate identification of these insect species. In addition to this, different studies were made on courtship and mating, egg laying habitats, nymphal development, longevity, flight capacity of dragonfly to make the study more interesting to the reader. The population build up of dragonfly, favors to certain altitude as well as availability of water which is reverse to the other group of insects. Three different localities were selected at 9.75 m (Chakdaha), 200 m (Cooch Behar) and 1250 m (Kalimpong) of which former two represent an unique physiographic ecological system in Eastern India characterized by extreme diversities of dragonfly inhabiting there. The studies on natural enemies of dragonfly along with their major threats indicated that about 2, 4 and 4 species were critically endangered, endangered and vulnerable in rice ecosystem of West Bengal. Dragonflies are very sensitive to changes in landscape and are reliable indicators of wetland health. Therefore the effective conservation of dragonfly depends entirely on conservation of their habitats. Different studies were made to estimate the role of dragonfly in integrated pest management of rice crop in West Bengal. An investigation was also carried out to find out the crop stage wise diversification of individual predator and found that dragonfly was more diverse during flowering to ripening stages of crop respectively. The values Simpson and Shannon diversity index showed that dragonflies are specific flowering to ripening stage of crop. Subsequently the value of Margalef index and Menhinick index also indicated that the aforesaid predators were more diverse in flowering stage of crop whereas it was least in vegetative stage of crop. From the Hill's diversity the number of abundant and most abundant species was calculated where maximum and minimum were obtained from dragonfly and staphylinid respectively. The studies on colonization and succession of major dragonfly taxa in the rice field indicated that it followed a uniform pattern in relation to growth stages as well different phases in the rice field. The studies on relative abundance of dragonfly in different ecosystems reflected that their population in fields could be conserved and enhanced through maintenance of rice weed flora on bund or allowing ratoon rice after the rice crop during fallow period. The fallow land has limited effect on incidence of insect predator in rice crop. The relative ranking chart of 50 important predators in rice ecosystem of West Bengal indicates that the insect belonging to Coleopteran (17) were top of the list whereas dragonfly was third (10). The validity of chart may increase over time and they will need to be updated periodically." (Author)] Address: Satpathi, C.R., Dept of Agri. Entomology, Fac. **18197.** Siepielski, A.M.; Beaulieu, J.M. (2017): Adaptive

evolution to novel predators facilitates the evolution of damselfly species range shifts. *Evolution* 71(4): 974-984. (in English) ["Most species have evolved adaptations to reduce the chances of predation. In many cases adaptations to coexist with one predator generate tradeoffs in the ability to live with other predators. Consequently, the ability to live with one predator may limit the geographic distributions of species, such that adaptive evolution to coexist with novel predators may facilitate range shifts. In a case study with *Enallagma* damselflies, we used a comparative phylogenetic approach to test the hypothesis that adaptive evolution to live with a novel predator facilitates range size shifts. Our results suggest that the evolution of *Enallagma* shifting from living in ancestral lakes with fish as top predators, to living in lakes with dragonflies as predators, may have facilitated an increase in their range sizes. This increased range size likely arose because lakes with dragonflies were widespread, but unavailable as a habitat throughout much of the evolutionary history of *Enallagma* because they were historically maladapted to coexist with dragonfly predators. Additionally, the traits that have evolved as defenses against dragonflies also likely enhanced damselfly dispersal abilities. While many factors underlie the evolutionary history of species ranges, these results suggest a role for the evolution of predator-prey interactions." **18198.** Simon, S.; Sagasser, S.; Saccenti, E.; Brugler, M.R.; Schranz, M.E.; Hadrys, H.; Amato, G.; DeSalle, R. (2017): Comparative transcriptomics reveal developmental turning points during embryogenesis of a hemimetabolous insect, the damselfly *Ischnura elegans*. *Sci Rep.* 2017 Oct 19;7(1):13547. doi: 10.1038/s41598-017-13176-8.: 14 pp. (in English) ["Identifying transcriptional changes during embryogenesis is of crucial importance for unravelling evolutionary, molecular and cellular mechanisms that underpin patterning and morphogenesis. However, comparative studies focusing on early/embryonic stages during insect development are limited to a few taxa. *Drosophila melanogaster* is the paradigm for insect development, whereas comparative transcriptomic studies of embryonic stages of hemimetabolous insects are completely lacking. We reconstructed the first comparative transcriptome covering the daily embryonic developmental progression of *I. elegans*, an ancient hemimetabolous representative. We identified a "core" set of 6,794 transcripts - shared by all embryonic stages - which are mainly involved in anatomical structure development and cellular nitrogen compound metabolic processes. We further used weighted gene co-expression network analysis to identify transcriptional changes during Odonata embryogenesis. Based on these analyses distinct clusters of transcriptional active sequences could be revealed, indicating that embryos at different development stages have their own transcriptomic profile according to the developmental events and leading to sequential reprogramming of metabolic and developmental genes. Interestingly, a major change in transcriptionally active sequences is correlated with katabolism (revolution) during mid-embryogenesis, a 180° rotation of the embryo within the

egg and specific to hemimetabolous insects." (Authors)] Address: Simon, Sabrina., Biosystematics Group, Wageningen Univ. & Research, Droevendaalsesteeg 1, 6708 PB, Wageningen, The Netherlands. E-mail: sabrina.simon@wur.nl.

**18201.** Sniegula, S.; Janssens, L.; Stoks, R. (2017): Integrating multiple stressors across life stages and latitudes: Combined and delayed effects of an egg heat wave and larval pesticide exposure in a damselfly. *Aquatic Toxicology* 186: 113-122. (in English) ["Highlights: •Exposure of eggs to an heat wave was followed by exposure of larvae to a pesticide. •Heat exposure of the eggs had delayed costs in adult damselflies. •Larval pesticide exposure reduced fitness traits in larval and adult stage. •Both stressors were mainly additive and never synergistic. •Multistressor studies should integrate across life stages to capture total costs. Abstract: To understand the effects of pollutants in a changing world we need multistressor studies that combine pollutants with other stressors associated with global change such as heat waves. We tested for the delayed and combined impact of a heat wave during the egg stage and subsequent sublethal exposure to the pesticide esfenvalerate during the larval stage on life history and physiology in the larval and adult stage of the damselfly *Lestes sponsa*. We studied this in a common garden experiment with replicated central- and high latitude po-

pulations to explore potential effects of local thermal adaptation and differences in life history shaping the multistressor responses. Exposure of eggs to the heat wave had no effect on larval traits, yet had delayed costs (lower fat and flight muscle mass) in the adult stage thereby crossing two life history transitions. These delayed costs were only present in central-latitude populations potentially indicating their lower heat tolerance. Exposure of larvae to the pesticide reduced larval growth rate and prolonged development time, and across metamorphosis reduced the adult fat content and the flight muscle mass, yet did not affect the adult heat tolerance. The pesticide-induced delayed emergence was only present in the slower growing central-latitude larvae, possibly reflecting stronger selection to keep development fast in the more time-constrained high-latitude populations. We observed no synergistic interactions between the egg heat wave and the larval pesticide exposure. Instead the pesticide-induced reduction in fat content was only present in animals that were not exposed to the egg heat wave. Our results based on laboratory conditions highlight that multistressor studies should integrate across life stages to fully capture cumulative effects of pollutants with other stressors related to global change." **18202.** Sniegula, S.; Golab, M.J.; Johansson, F. (2017): Cannibalism and activity rate in larval damselflies increase along a latitudinal gradient as a consequence of time constraints. *BMC Evolutionary Biology* 17, Article number: 167: 9 pp. (in English) ["Background: Predation is ubiquitous in nature. One form of predation is cannibalism, which is affected by many factors such as size structure and resource density. However, cannibalism may also be influenced by abiotic factors such as seasonal time constraints. Since time constraints are greater at high latitudes, cannibalism could be stronger at such latitudes, but we know next to nothing about latitudinal variation in cannibalism. In this study, we examined cannibalism and activity in larvae of the damselfly *Lestes sponsa* along a latitudinal gradient across Europe. We did this by raising larvae from the egg stage at different temperatures and photoperiods corresponding to different latitudes. Results: We found that the more seasonally time-constrained populations in northern latitudes and individuals subjected to greater seasonal time constraints exhibited a higher level of cannibalism. We also found that activity was higher at north latitude conditions, and thus correlated with cannibalism, suggesting that this behaviour mediates higher levels of cannibalism in time-constrained animals. Conclusions: Our results go counter to the classical latitude-predation pattern which predicts higher predation at lower latitudes, since we found that predation was stronger at higher latitudes. The differences in cannibalism might have implications for population dynamics along the latitudinal gradients, but further experiments are needed to explore this." (2017): Do males with higher mating success invest more in armaments? An across-populations study in damselflies. *Ecological Entomology* 42(4): 526-530. (in English) ["1. Males with higher mating success would be expected to invest more in traits that facilitate mating, leading to steeper allometry of those traits with respect to body size. Across-population studies following latitudinal variation in male mating success are an excellent study system to address this question. 2. Males of the damselfly *Lestes sponsa* were used to investigate whether the allometric patterns of the length and width of the anal appendages, used for grasping the female prior to mating, corresponded to male mating success. Across a large latitudinal gradient, it was hypothesised that there is a larger investment in the grasping apparatus, i.e. a steeper allometric slope, following higher mating success. 3. Behavioural observations in field enclosures showed the highest mating success at high latitude, while there were no significant differences in mating success between the central and low latitudes. Positive allometry was found for the length of the anal appendages in high-latitude males, while central- and low-latitude males showed no significant regressions of the traits on body size. 4. These results partially support the hypothesis, as high-latitude, more successful males invested more in the length (but not the width) of the grasping apparatus than did central- and low-latitude males. Therefore, higher mating success might be facilitated by larger investment in armaments. Intraspecific studies on allometric patterns of traits that participate in mating success might offer new insights into the role of those traits in the reproductive behaviour of a species." **18204.** Start, D.; Gilbert, B. (2017): Predator personality structures prey communities and trophic cascades. *Ecology Letters* 20(3): 366-374. (in English) ["Intraspecific variation is central to our understanding of evolution and population ecology, yet its consequences for community ecology are poorly understood. Animal personality – consistent individual differences in suites of behaviours – may be particularly important for trophic dynamics, where predator personality can determine activity rates and patterns of attack. We used mesocosms with aquatic food webs in which the top predator (dragonfly nymphs) varied in activity and subsequent attack rates on zooplankton, and tested the effects of predator personality. We found support for four hypotheses: (1) active predators disproportionately reduce the abundance of prey, (2) active predators select for predator-resistant prey species, (3) active predators strengthen trophic cascades (increase phytoplankton abundance) and (4) active predators are more likely to cannibalise one another, weakening all other trends when at high densities. These results suggest that intraspecific variation in predator personality is an important determinant of prey abundance, community composition and trophic cascades." **18205.** Suhling, F.; Martens, A.; Suhling, I. (2017): Long-distance dispersal in Odonata: Examples from arid Namibia. *Austral Ecology* 42(5): 544-552. (in English) ["We report cases of long-distance dispersal in Odonata, some of which were directly observed by identifying single individuals of riverine species in unsuitable habitat, mostly desert, far distant from reproduction habitats. The shortest possible linear distances of the observation points to reproduction habitats were measured. Furthermore, established populations of riverine species were recorded in artificial lakes in central and southern Namibia far distant from the next regular reproduction sites. Our records demonstrate that single individuals of riverine species were probably covering distances of several hundred kilometres over arid landscape without any intervening possible reproduction habitat. Although it is likely that only small numbers of individuals of the river populations may disperse long distances, relatively recent colonizations of artificial habitats suggest that a few, or even single, dispersing individuals may lead to large-scale-range expansions." **18207.** Swaegers, J.; Strobbe, F.; McPeck, M.A.; Stoks, R. (2017): Selection on escape performance during ecological speciation driven by predation. *Animal Behaviour* 124: 153-159. (in English) ["Highlights: •We reconstructed selection on escape traits during habitat shifts in damselflies. •Fish predation selected for decreased swimming propensity but did not affect speed. •Dragonfly predation selected for increased speed but did not affect propensity. •Quantitative genetic rearing showed both escape traits to be heritable. •Phenotypic evolution of antipredator traits may occur at an ecological time-scale. Despite the many study systems in which predation has played a major role in phenotypic diversification and speciation, the underlying selective regimes imposed by different predator assemblages have rarely been quantified. We did so for the damselfly genus *Enallagma* which strongly diverged in antipredator traits when the ancestral species occupying lakes containing fish (hereafter fish lakes) repeatedly

invaded fishless lakes with dragonfly larvae as top predators (hereafter dragonfly lakes). In two selection experiments in field enclosures we quantified the selection on two key escape traits of two fish-lake *Enallagma* species associated with survival selection by fish in the ancestral fish lakes and by dragonfly predators in the invaded fishless, dragonfly lakes. In accordance with the different hunting modes, fish imposed selection for a decreased swimming propensity while dragonfly larvae imposed selection for increased swimming speed in one of the two species. In two complementary quantitative genetic rearing experiments, we found relatively low but significant broad-sense heritabilities for both escape traits. Integrating these estimates for the selection coefficients and the heritabilities suggests that the evolutionary increase in swimming speed associated with the habitat shift may have occurred rapidly. Our study suggests that the phenotypic evolution of ecologically important traits related to habitat shifts may occur at an ecological timescale." (Authors)] Address: Swaegers, J., Dept Biology, Lab. **18214.** Tüzün, N.; Op de Beeck, L.; Stoks, R. (2017): Sexual selection reinforces a higher flight endurance in urban damselflies. *Evolutionary Applications* 10(7): 694-703. (in English) ["Urbanisation is among the most important and globally rapidly increasing anthropogenic processes, and is known to drive rapid evolution. Habitats in urbanised areas typically consist of small, fragmented and isolated patches, which is expected to select for a better locomotor performance, along with its underlying morphological traits. This, in turn, is expected to cause differentiation in selection regimes, as populations with different frequency distributions for a given trait will span different parts of the species' fitness function. Yet, very few studies considered differentiation in phenotypic traits associated with patterns in habitat fragmentation and isolation along urbanisation gradients, and none considered differentiation in sexual selection regimes. We investigated differentiation in flight performance and flight-related traits, and sexual selection on these traits across replicated urban and rural populations of *Coenagrion puella*. To disentangle direct and indirect paths going from phenotypic traits over performance to mating success, we applied a path analysis approach. We report for the first time direct evidence for the expected better locomotor performance in urban compared to rural populations. This matches a scenario of spatial sorting, whereby only the individuals with the best locomotor abilities colonise the isolated urban populations. The covariation patterns and causal relationships among the phenotypic traits, performance and mating success strongly depended on the urbanisation level. Notably, we detected sexual selection for a higher flight endurance only in urban populations, indicating that the higher flight performance of

urban males was reinforced by sexual selection. Taken together, our results provide a unique proof of the interplay between sexual selection and adaptation to human-altered environments." **18216.** Uiterwaal, S.F.; Mares, C.; DeLong J.P. (2017): Body size, body size ratio, and prey type influence the functional response of damselfly nymphs. *Oecologia* 185(3): 339-346. (in English) ["Predator-prey interactions play a crucial role in structuring food webs, and the functional response is one way to measure the strength of this interaction. Here, we examine how predator and prey body size affects the functional response of a generalist predator—damselfly [mostly *Ischnura verticalis* and *Enallagma civile*] nymphs—feeding on three prey types: copepods, *Daphnia*, and *Chydorus*. Our results suggest that consumption of copepods is independent of predator body size, while increased predator body size is associated with an increased space clearance rate for *Daphnia* and a reduced space clearance rate for *Chydorus*. When considered together, foraging rates on *Daphnia* and *Chydorus* (both cladocerans) are consistent with a hump-shaped functional response, with peak foraging rates occurring at an intermediate predator-prey size ratio. Thus, although most food web theory assumes allometric predator-prey links or peaked functional responses at intermediate predator-prey size ratios, our results suggest that both relationships may occur in food webs, in addition to size-independent functional responses." **18217.** Usio, N.; Nakagawa, M.; Aoki, T.; Higuchi, S.; Kadono, Y.; Akasaka, M.; Takamura, N. (2017): Effects of land use on trophic states and multi-taxonomic diversity in Japanese farm ponds. *Agriculture, Ecosystems & Environment* 247(1): 205-215. (in English) ["Highlights: •Farm ponds are among the most biodiverse anthropogenic freshwater habitats. •Land use and fish abundance were among the significant factors affecting the trophic states of ponds. •Multi-taxonomic richness patterns changed along the gradient of trophic states. •A clear-water state was associated with diverse aquatic plants, macroinvertebrates, and adult Odonata. •A turbid

state was associated with diverse phytoplankton and fish. Abstract: Farm ponds are among the most biodiverse anthropogenic freshwater habitats because of their small size, shallow water depth, and aquatic vegetation. Land-use changes, such as converting riparian vegetation to human use or changing the management practices of farm ponds, are assumed to be major factors that change such ecosystems from a clear-water state to a turbid state, leading to deterioration of water quality and biodiversity in such ponds. Using the database of a large-scale pond survey, we evaluated the effects of surrounding land use (landscape factors and modern pond management practices), fish abundance, and other environmental variables on total phosphorus concentration and taxonomic richness patterns of six biological indicators associated with changes in the trophic state. Local- and landscape-level vegetation structure associated with land use and total fish abundance were among the factors influencing the total phosphorus concentration of farm ponds, a main driver of trophic state changes. In addition, a transition from a clear-water state to a turbid state was associated with lower taxonomic richness of aquatic plants, macroinvertebrates, and adult Odonata, and a higher taxonomic richness of phytoplankton and fish. Based on these results, we discuss potential land-use and pond management strategies for conserving and/or restoring the water quality and biodiversity of farm ponds through maintenance of a clear-water state." **18218.** Van Allen, B.G.; Rasmussen, C.J.; Dibble, C.J.; Clay, P.A.; Rudolf, V.H.W. (2017): Top predators determine how biodiversity is partitioned across time and space. *Ecology letters* 20: 1004-1013. (in English) ["Natural ecosystems are shaped along two fundamental axes, space and time, but how biodiversity is partitioned along both axes is not well understood. Here, we show that the relationship between temporal and spatial biodiversity patterns can vary predictably according to habitat characteristics. By quantifying seasonal and annual changes in larval dragonfly communities across a natural predation gradient we demonstrate that variation in the identity of top predator species is associated with systematic differences in spatio-temporal  $\beta$ -diversity patterns, leading to consistent differences in relative partitioning of biodiversity between time and space across habitats. As the size of top predators increased (from invertebrates to fish) habitats showed lower species turnover across sites and years, but relatively larger seasonal turnover within a site, which ultimately shifted the relative partitioning of biodiversity across time and space. These results extend community assembly theory by identifying common mechanisms that link spatial and temporal patterns of  $\beta$ -diversity." **18219.** Van Dievel, M.; Stoks, R.; Janssens, L. (2017): Beneficial effects of a heat wave: higher growth and immune components driven by a higher food intake. *Journal of Experimental Biology* 220: 3908-3915. (in English) ["While heat

waves will become more frequent and intense under global warming, the ability of species to deal with extreme weather events is poorly understood. We investigated how a heat wave influenced growth rate and investment in two immune components (phenoloxidase activity and melanin content) in larvae of *Ischnura elegans* and *Enallagma cyathigerum*. Late instar larvae were kept at 18°C (i.e. their average natural water temperatures) or at a simulated long heat wave at 30°C. To explain the heat wave effects, we quantified traits related to energy uptake (food intake and growth efficiency), energy expenditure (metabolic rate measured as activity of the electron transport system, ETS) and investment in energy storage (fat content). The two species differed in life strategy with *I. elegans* having a higher growth rate, growth efficiency, ETS activity, and fat content. In line with its preference for cooler water bodies, the heat wave was only lethal for *E. cyathigerum*. Yet, both species benefited from the heat wave by increasing growth rate, which can be explained by the higher increase in food intake than metabolic rate. This may also have contributed to the increased investments in energy storage and immune components under the heat wave. This mediatory role of food intake indicates the critical role of food availability and behaviour in shaping the impact of heat waves. Our results highlight the importance of including behavioural and physiological variables to unravel and predict the impact of extreme climate events on organisms." **18223.** Villalobos Jiménez, G. (2017): The impacts of urbanisation on the ecology and evolution of dragonflies and damselflies (Insecta: Odonata). Ph.D. thesis, The University of Leeds School of Biology: XV, 234 pp. (in English) ["Urbanisation is one of the main drivers of ecosystem change. The impacts of urban land use on biodiversity have been investigated, but other aspects of ecology have been overlooked, as well as the effects of urban stressors. Understanding the effects of specific urban stressors is crucial in order to appropriately manage urban areas and conserve their biodiversity. Odonata are a suitable taxon for evaluating the impacts of urbanisation on both terrestrial and aquatic ecosystems. Here, using a combination of field and laboratory data, I study the ecological impacts of urban stressors on odonates. I found that the urban heat island has negligible impacts on the phenology of odonates compared to climate change. Moreover, noise disturbance reduces significantly the feeding rate of the damselfly *Ischnura elegans*, although anthropogenic noise has no significant impact. Regarding the impacts of polarised light pollution (PLP), the strength of polarotaxis increased significantly with age in laboratory-reared specimens, but there was no significant differentiation between

urban and rural populations. However, field-caught urban specimens showed less preference to polarised light compared to rural populations, suggesting strong selective pressures are acting upon urban populations, but no adaptation has occurred. Flight-related traits showed no significant differentiation among urban and rural populations of *I. elegans*. Lastly, biodiversity patterns did not differ among urban and rural areas, although aquatic vegetation and presence of fish were the main drivers of community composition. These results show odonates can tolerate a wide range of urban stressors, notably *I. elegans*. However, PLP, fish, and absence of aquatic vegetation in urban ponds can have a negative impact on odonate biodiversity, which has important implications on conservation and management of urban areas. Urban ecosystems are complex, thus an integrative approach is necessary in order to understand in depth the impacts of urbanisation on biodiversity." **18225.** Vivas-Santeliz, J.; De Marmels, J. (2017): Current knowledge of Odonata in Venezuela: diversity and distribution of endemic taxa. *Odonatologica* 46(1/2): 35-54. (in English) ["So far, 525 species and 14 subspecies of odonates are known to occur in Venezuela. These are distributed in 124 genera and 13 families, with an undescribed species of the genus *Ypirangathemis* and *Paracordulia*. Despite Venezuela being one of the countries of Latin America with a very high diversity of described species, research on odonates is stagnant, mainly due to the small number of odonatologists and even more because of the political, economic and

social situation in this country, rendering field trips to collect odonates almost impossible. The country harbours a significant number of endemics, including six endemic genera and a total of 78 endemic species. The Pantepui region, as well as the Andean and Coastal Cordilleras all have high levels of endemism. A majority of endemic species is found within protected areas. However, threats to their survival have increased over the years, since there are no conservation plans for them or their habitats. Just seven species have so far been evaluated and catalogued in the Red Data Book of Venezuelan fauna, among them *Phyllogomphoides brunneus*, which is the only species of Odonata included in this Red Data Book that is not endemic to the country. The present paper aims to identify the distributions and diversity of endemic species in Venezuela, which can be used as a base to others investigations, including conservation studies in which they are assessed for inclusion in the Red List." **18226.** Walia, G.K.; Katnoria, N. (2017): Linear characterization of chromosomes in two species of family Euphaeidae (Odonata: Zygoptera). *International Journal of Entomology Research* 2(4): 75-78. (in English) ["Chromosome complement and meiotic behavior of chromosomes in two species of family Euphaeidae have been described by conventional staining, C- banding, silver nitrate staining and sequence specific staining. *Anisopleura lestoides* reveals two complements n=12 (without m chromosomes) and n=13 (with m chromosome), while *Bayadera indica* possess n=13m. In *Anisopleura lestoides* all the autosomal bivalents including m bivalent are showing terminal C-bands and NOR bands. Whereas in *Bayadera indica*, terminal C-bands on both ends in 9 autosomal bivalents and C-bands on one side in 3 bivalents, whereas terminal NOR bands are present in 10 autosomal bivalents, 1 NOR band on one side in 1 bivalent, m bivalent is C-negative and NOR-negative. X chromosome is C-positive and NOR rich in both the species. In the sequence specific staining, two autosomal bivalents show both CMA3 and DAPI bright signals and remaining bivalents including m bivalent and X chromosome possess CMA3 bright and DAPI dull regions in *Anisopleura lestoides*, while all the chromosomes show both DAPI and CMA3 bright signals in *Bayadera indica*." **18227.** Waller, J.T.; Svensson, E.I. (2017): Body size evolution in an old insect order: No evidence for Cope's Rule in spite of fitness benefits of large size. *Evolution* 71(9): 2178-2193. (in English) ["We integrate field data and phylogenetic comparative analyses to investigate causes of body size evolution and stasis in an old insect order: odonates ("dragonflies and damselflies"). Fossil evidence for "Cope's Rule" in odonates is weak or non-existent since the last major extinction event 65 million years ago, yet selection studies show consistent positive selection for increased body

size among adults. In particular, we find that large males in natural populations of the banded demoiselle (*Calopteryx splendens*) over several generations have consistent fitness benefits both in terms of survival and mating success. Additionally, there was no evidence for stabilizing or conflicting selection between fitness components within the adult life-stage. This lack of stabilizing selection during the adult life-stage was independently supported by a literature survey on different male and female fitness components from several odonate species. We did detect several significant body size shifts among extant taxa using comparative methods and a large new molecular phylogeny for odonates. We suggest that the lack of Cope's rule in odonates results from conflicting selection between fitness advantages of large adult size and costs of long larval development. We also discuss competing explanations for body size stasis in this insect group." **18228.** Wang, A.R.; Kim, M.J.; Kim, S.S.; Kim, I. (2017): Additional mitochondrial DNA sequences from the dragonfly, *Nannophya pygmaea* (Odonata: Libellulidae), which is endangered in South Korea. *International Journal of Industrial Entomology* 35(1): 51-57. (in English) ["The tiny dragonfly, *Nannophya pygmaea* (Odonata: Libellulidae), is an endangered insect in South Korea. Previously, a partial mitochondrial DNA sequence that corresponded to a DNA barcoding region has been used to infer genetic diversity and gene flow. In this study, we additionally sequenced the barcoding region from *N. pygmaea* that had been collected from three previously sampled populations (40 individuals) and these sequences were combined with the preexisting data. We also selected and sequenced an additional mitochondrial gene (ND5) to find further variable gene regions in the mitochondrial genome. DNA barcoding sequences of 108 individuals from five South Korean localities showed that genetic diversity was highest in Gangjin, Jeollanam-do Province. Muuido, which was previously occupied by a single haplotype, was also found to have an identical haplotype, which confirmed the low genetic diversity on this islet. Gene flow among populations is highly limited, and no clear distance- or region-based geographic partitioning was observed. Phylogenetic relationships among haplotypes showed that there were no discernable haplotypes in South Korea. ND5 provided slightly more haplotypes compared to the barcoding region in 40 individuals (14 vs. 10 haplotypes in the COI gene). It also had a slightly higher within-locality diversity estimate, which suggested that ND5 had potential as mitochondrial DNA-based marker for population genetic analysis." **18229.** Batista, J.D. (2010): Sazonalidade, impacto ambiental e o padrão de diversidade beta de Odonata em riachos tropicais no Brasil Central. Vicososa, Minas Gerais, Brazil. Federal University of Viçosa.: X, 98 pp. (in Portuguese, with English summary) ["Seasonality, environmental impact and pattern of beta diversity of Odonata in tropical streams of Central Brazil: In this study, I investigated how seasonality and environmental impacts affect the composition and structure of Odonata communities, testing the following hypotheses: 1) the potential species distribution modeling can be useful as a tool to predict environmental changes; 2) changes in the landscape deriving from anthropization affect the distribution and pattern of beta diversity of Odonata; 3) seasonality causes effect in the distribution and richness pattern of Odonata. The study was carried out in streams of river Pindaíba basin, Mato Grosso, with samplings in the dry and rainy seasons, between 2005 and 2009. Sampling of Odonata was done by fixed-areas scan method. Results showed that 1) the distribution model predicted a greater quantity of families and species at all sites in relation to validation data. This result was attributed to habit and species activity hour constraints and sampling effort. However, the use of models can be an important strategy for biodiversity analyses in systems with few historic information about biogeographic distribution; 2) the turnover pattern was dominant for Anisoptera and for Zygoptera, even in areas with smaller integrity. Increase of nestedness in Anisoptera, and the inverse pattern in Zygoptera, can be the result of different levels of specialisation of these groups, producing an unbalanced pattern of unique species in the two systems; 3) the greater richness of Odonata was found in the rainy season, which is an inverse pattern in relation to previous studies in Atlantic Forest, suggesting that Odonata in Cerrado rivers were less controlled by temperature constraints. Finally, it was showed that variation in water temperature acts as a stressing factor in community dynamics, decreasing the number of species that are not adapted to severe environmental conditions, favouring the synchrony of the remaining species due to ecological similarity." **18230.** Fulan, J.A.; Raimundo, R.; Figueiredo, D.; Correia, M. (2010): Abundance and diversity of dragonflies four years after the construction of a reservoir. *Limnetica* 29(2): 279-286. (English, with Portuguese summary) ["Few studies have investigated the impacts of river impoundments on reservoir constructions. Reservoir construction deeply changes dragonflies' habitat structures, especially in relation to shoreline vegetation. This study investigated the effects of the impoundment of the Guadiana River and its tributaries on dragonflies four years after the construction of a reservoir. A total of 17 dragonfly species (11 Zygoptera and ten Anisoptera), representing six families, were recorded in 21 sites in the years 1999 and 2003. *Aeshna mixta*, *Coenagrion caerule-scens*, *C. scitulum*, *Sympetrum fonscolombii*, *S. meridionale* and *S. striolatum* were sampled just before the impoundment took place, and *Anax parthenope*, *Onychogomphus forcipatus*, *Orthetrum coerulescens*, *Trithemis annulata*, *Platycnemis acutipennis* and *P. latipes* were recorded only after the construction of the reservoir. We concluded that the construction of the Alqueva Reservoir four years earlier did not change the dragonfly species richness, possibly because of species overlap, but that the species composition was modified. Changes in marginal vegetation may have been important to new species compositions." (Authors)] Address: Fulan, J.A., Federal University of Amazonas, Brazil, Campus of Humaitá, Brazil. **18231.** Grand, D. (2010): Deux siècles d'étude des libellules en Rhône-Alpes (Insecta, Odonata). *Bulletin mensuel de la Société linnéenne de Lyon hors-série n°2* 2010: 23-29. (French, with English summary) ["Two centuries of regional odonatology: A general presentation of the order Odonata (systematics, biology) is proposed first of all, followed by information on these insects in Rhone-Alpes, a region situated at the crossroads of Alpine, Atlantic and Mediterranean climates. Then, a synthesis summarizes more than two centuries of regional odonatology, where the local status of 7 species is discussed and specified. Finally, the study leads to the report of an improvement of the biodiversity of the regional dragonflies, especially owed these last 50 years to a much better knowledge of their current distribution

and, additionally, to the effects of the global warming." (Author)] Address: deceased

**18232.** Kovacs, T.; Ambrus, A. (2010): Faunistical Studies on the Odonata of the Szigetköz, NW Hungary. In: Gubányi, A. & Mészáros, F. (eds.): *A Szigetköz állattani értékei. Magyar Természettudományi Múzeum, Budapest: 39-48.* (Hungarian, with English summary) ["Odonata populations have been studied for the longest period of time in the Szigetköz area of Hungary. A total of 51 species were found in the Szigetköz (3196 data) at six permanent sampling sites and some 70 sampling sites examined at varying intervals. With the 52 species found in the imago form the presence of a total of 53 Odonata species were proven in this area. The diversion of the course of the river Danube has led to the disappearance of 2 species- *Coenagrion ornatum* and *Aeshna viridis*— from Szigetköz. The diversion of the river did not cause detectable changes in the faunas of the following habitat types: flood plain and the shallow and deep gravel pit lakes beyond the embankments, the eastern moor of the riverside forest Parti-erdo and the Mosoni Danube. But the water replenishment of the area has significantly changed the character of some of the typical, stagnant, slowly flowing water bodies, which harboured rich vegetation. The number of valuable elements of the rich fauna, which is a characteristic feature of stagnant waters, has decreased. The number of riverine species, as well as those tolerant of a wide range of conditions, along with the population size of such species, has increased. In some cases this process has led to the decrease of the total number of species. This trend is a result of decreasing habitat diversity." **18234.** Mogren, C.L.; Trumble, J.T. (2010): The impacts of metals and metalloids on insect behavior. *Entomologia Experimentalis et Applicata* 135(1): 1-17. (in English) ["In toxicology studies, the use of death as an endpoint often fails

to capture the effects a pollutant has on disruptions of ecosystem services by changing an animal's behavior. Many toxicants can cause population extinctions of insect species at concentrations well below the EC25, EC50, or EC90 concentrations traditionally reported from short-term bioassays. A surprising number of species cannot detect metal and metalloid contamination, and do not always avoid food with significant metal concentrations. This frequently leads to modified ingestion, locomotor, and reproductive behaviors. For example, some species show a tendency to increase locomotor behaviors to escape from locations with elevated metal pollution, whereas other insects greatly decrease all movements unrelated to feeding. Still others exhibit behaviors resulting in increased susceptibility to predation, including a positive phototaxis causing immatures to move to exposed positions. For purposes of reproduction, the inability to avoid even moderately polluted sites when ovipositing can lead to egg loss and reduced fitness of offspring. Ultimately, impaired behaviors result in a general reduction in population sizes and species diversity at contaminated sites, the exceptions being those species tolerating contamination that become dominant. Regardless, ecosystem services, such as herbivory, detritus reduction, or food production for higher trophic levels, are disrupted. This review evaluates the effects of metal and metalloid pollution on insect behaviors in both terrestrial and aquatic systems reported in a diverse literature scattered across many scientific disciplines. Behaviors are grouped by ingestion, taxis, and oviposition. We conclude that understanding how insect behavior is modified is necessary to assess the full scope and importance of metal and metalloid contamination." (Authors) The paper includes a reference to *Sympetrum corruptum*.] Address: Mogren, Christina, Dept Entom., Univ. California, 900 University Avenue, Riverside, CA 92521, USA. **18235.** Norma-Rashid, Y. (2010): Odonata of Fraser's hill, montane ecozones with conservation implications. Proceedings of National Biodiversity Seminar 2008, ISBN 978-967-5557-05-7: 49-59. (in English, with Malaysian summary) ["In this study, the fauna, habitat preference and ecological features of the dragonflies occurring in the montane forests of Fraser's Hill were investigated with vernacular names also mentioned. To date, 26 species from eight family groups have been documented from current and previous works. The available habitats in the ecozone are listed together with the distinctive associated species. Species diversity in higher latitudes is known to be not as diverse but what has been highlighted in the paper is the degree of endemism reaching 23%. Evident from the findings are existence of taxonomically isolated species such as *Devadatta argyroides* (Selys, 1859), *Onychothemis coccinea* (Lieftinck, 1953) and *O. testacea* (Laidlaw, 1902). The Action Plan proposed by Moore (1997), regarded these dragonflies as priority species from the Oriental region apt for further study and conservation action. Implications for potentially endangered, threatened or vulnerable species status within the study area are also evaluated. The paper concluded that among other suggestions there should be an initiative to create odonate refuges

as these creatures resembled natural flagships for raising public awareness of the importance of conserving forests, aquatic habitats and biodiversity." **18238.** Simon, A. (2010): Synthèse des connaissances préalable à la déclinaison régionale du Plan National d'Action Odonates en Haute-Normandie. Première partie: Etat des lieux des connaissances. Direction Régionale de l'Environnement, de l'Aménagement et du Logement: 78 pp. (in French) ["As part of its strategy to combat the erosion of biodiversity, the Ministry of Ecology, Energy, Sustainable Development and the Sea (MEEDDM) has developed National Action Plans (NAP). One of these plans concerns Odonata. In order to better take into account the specific characteristics of the different territories, this NAP must be adapted to the regions. In order to anticipate this regional adaptation, the DREAL of Haute-Normandie commissioned the Conservatoire des Sites Naturels de Haute-Normandie to produce a preliminary summary, gathering the available information on the subject. This preliminary summary presents: - The state of knowledge available on the Odonata of Upper Normandy. - The results of additional field surveys carried out for the preparation of this synthesis. - The inventory of regional actors likely to be concerned by the implementation of the Odonata Action Plan. On the basis of available knowledge and the recently drawn up Red List of Odonates in Haute-Normandie, a list of 17 species of odonates threatened in Haute-Normandie was validated by the CSRPN to be included in the regional version of the action plan. This document also presents the updated lists of ZNIEFF determining species

and regional rarity indices." (DeepL)] Address: Conservatoire des Sites Naturels de Haute-Normandie, Rue Pierre de Coubertin, B.P. 424, 76 805 Saint-Etienne-du-Rouvray, France. <http://www.cren-haute-normandie.com>

**18242.** Afrane, Y.A.; Lawson, B.W.; Brenya, R.; Kruppa, T.; Yan, G. (2012): The ecology of mosquitoes in an irrigated vegetable farm in Kumasi, Ghana: abundance, productivity and survivorship. Parasites & Vectors 2012, 5:233: 7 pp. (in English) ["Background: Irrigated vegetable farms within the city of Kumasi, Ghana, create hotspots for the breeding of malaria vectors, which could lead to high transmission of malaria. This study investigated the abundance and productivity of mosquitoes in an irrigated vegetable farm in Kumasi, Ghana. Methods: Adult mosquito productivity was estimated five days in a week in different irrigated scheme types

(dug-out wells, furrows and footprints) for 12 weeks using emergence traps. Larval sampling was done five days a week to estimate the abundance of larvae from the different irrigated schemes types. Results: Mosquito breeding in the irrigated vegetable field was confined to dug-out wells, furrows and human footprints. Mosquito productivity ( $m^2$ /week) was highest in the dugout wells followed by the human footprints and the least was in the furrows (11.23, 5.07 and 4.34 *An. gambiae*/ $m^2$ /week). Larval abundance for the late instars (3rd, 4th and pupae) also followed the same trend, with the dug-out wells having the highest larval abundance followed by the human footprints and then the furrows (13.24, 6.81, 5.87 larvae/week). Mosquito productivity and abundance was negatively correlated with rainfall ( $R^2=0.209$ ;  $P < 0.01$ ). Conclusion: This study showed that adult and larval mosquito abundance and larval survival were high in the irrigated fields in the irrigated vegetable farm. This therefore, contributed significantly to adult mosquito populations and hence malaria transmission in the city." (Authors) The paper includes a passing reference to Odonata.] Address: Yaw AAfrane, Y.A., School Health Sci., Bondo Univ. College, Bondo, Kenya. E-mail: yaw\_afrane@yahoo.com

**18243.** Baeta, R.; Sansault, E.; Pincebourde, S. (2012): Déclinaison régionale du Plan National d'Actions en faveur des Odonates en région Centre 2013-2017. Association Naturaliste d'Étude et de Protection des Écosystèmes « Caudalis » / Institut de Recherche sur la Biologie de l'Insecte / Direction Régionale de l'Environnement, de l'Aménagement et du Logement Centre: 112 pp. (in French, with English summary) ["Conservation of Odonata species contributes to the maintenance of biodiversity and to the functioning of natural ecosystems. They are particularly sensitive to environmental changes as they are potentially exposed to threats in both aquatic and terrestrial medium. A national plan for the conservation of Odonata species was launched in 2010 in France, with the aim to assess the population level of 18 species that were declared under threat. This national plan is downscaled here at the level of the region Centre. This regional plan reviews our knowledge on population level of several Odonata species, and suggests action plans for the period 2013-2017 in terms of increasing knowledge, conservation management and communication at several levels. This approach aims at stabilizing these threaten species in the region Centre by networking all actors in the conservation of Odonata species. The review shows that the sampling effort has increased substantially since 2000s, although it remains heterogeneous over the region Centre territory. The region Centre hosts 8 species targeted by the national plan (priority 1). In addition, the regional plan targets 13 species of priority level 2 and 9 of priority level 3. The regional plan proposes 9 actions to increase our knowledge. As specified in the national plan, the species *Leucorrhinia caudalis* is among the main targets of this plan. The Loire Valley is also of concern as 2 species of priority level 1, *Gomphus flavipes* and *Ophiogomphus cecilia*, are associated to this particular freshwater system. Finally, 5 actions for conservation management / administration, and 3 actions for communication and training are proposed with the aim to protect

these Odonata species and their habitats." (Authors)] Address: Sansault, E., Association Naturaliste d'Étude et de Protection des Écosystèmes (ANEPE) « Caudalis », 118 rue de l'Ermitage, F-37100 Tours, France. E-mail: anepe.caudalis@gmail.com

**18244.** Bhat, S.U.; Dar, G.A.; Sofi, A.H.; Dar, N.A.; Pandit, A.K. (2012): Macroinvertebrate community associations on three different macrophytic species in Manasbal Lake. Research Journal of environmental Sciences 6(2): 62-76. (in English) ["Three macrophytic species namely *Ceratophyllum demersum*, *Hydrilla verticillata* and *Potamogeton lucens* were investigated for the macroinvertebrate association [including "Odonata"] in Manasbal Lake. A total of 15 macroinvertebrate taxa were reported from these macrophytic species belonging to three phyla including Annelida, Mollusca and Arthropoda. Arthropoda was the dominant phyla comprising of class Insecta, Crustacea and Arachnida. Annelida was the second dominant phyla represented by two classes Hirudinea and Oligochaeta. Mollusca were only represented by families, Lymnaeidae and Planorbidae. All the three phyla showed dominance pattern with respect to macrophytic species in the order of *Ceratophyllum demersum* followed by *H. verticillata* and then *P. lucens*. The results of study also showed that, the *C. demersum* comparatively harboured large density of macroinvertebrates than the other two macrophytic species, despite the fact that the total number of macroinvertebrate taxa remained the same on all the three macrophytic species thereby reflecting homogeneity of habitats. Among the insects, Chironomidae was dominant taxa on *C. demersum* followed by *H. verticillata* and then *P. lucens*." (Authors)] Address: Ullah Bhat, S., P.G. **18248.** Carrère, V.; Blanchon, Y. (2012): Découverte de *Gomphus flavipes* (Charpentier, 1825) en Languedoc-Roussillon (Odonata, Anisoptera: Gomphidae). *Martinia* 28(1): 55- (in French) [Verbatim: "On 20 July 2010, an imago of *G. flavipes* was observed on the Gard bank of the Rhône, in the commune of Codolet (Y. Blanchon, pers. obs.). This is the first record of this species in the Languedoc-Roussillon region. This observation is to be put in relation with the rediscovery of this gomphid in the Rhône-Alpes region in the Rhône valley (GRAND et al., 2011. *Gomphus flavipes* (Charpentier, 1825) rediscovered in the Rhône river basin (Anisoptera: Gomphidae). *Martinia*, 27 (1): 9-26), then in Provence-Alpes-Côte d'Azur (BLANCHON et al., 2011. Rediscovery of *Gomphus flavipes* (Charpentier, 1825) in Provence-Alpes-Côte d'Azur (Odonata, Anisoptera: Gomphidae). *Martinia*, 27 (2): 121-122). Almost a year later, on 19 May 2011, and about 150 km from the nearest known breeding areas (on the Rhône at Arles), an exuvia of *G. flavipes* was found on the Aude, in the commune of Cuxac-d'Aude. On 10 June 2011, a second exuvia was found in the same sector (L. Spanneut, pers. comm.), then a third on 20 June 2011. This series of observations constitutes the first evidence of reproduction of this gomphid in Languedoc-Roussillon. On each occasion, a single exuvia of *G. flavipes* was recorded, while no imago was observed. The species was found in the company of exuviae of *Gomphus simillimus* Selys, 1840, *G. pulchellus* Selys, 1840, *G. vulgatissimus* (Linnaeus, 1758), *Onychogomphus forcipatus unguiculatus* (Vander Linden, 1823) and *Oxygastra curtisii* (Dale, 1834). The dominant species was *G. simillimus* on 19 May and *G. vulgatissimus* on 20 June. On 10 June, *G. flavipes* was the only exuvia recorded. In this sector, the Aude has a minor bed about 30 metres wide. Its banks are sandy and occupied by riparian vegetation. Numerous roots are visible on the banks above and in the water; branches of dead wood also emerge from the river. One exuvia was found on roots at the level of the banks, another on the trunk of a shrub, a few tens of centimetres above the water. It should be noted that at the beginning of 2011, the Aude was subjected to a major flood, which was likely to modify the habitats and populations of dragonflies present. As a result, exuviae were rare and localised on the river banks during the 2011 surveys. These findings suggest that the species could very probably reproduce in other localities in Languedoc-Roussillon, in particular on the banks of the Rhône in Gard." pp. (in English) ["3.4.3 Preliminary results: We captured a total of 314 individuals (3436 when *U. imbuta* and *U. fastigiata* are included) representing 53 species, belonging to 29 genera and 9 families (7 Anisoptera, 2 Zygoptera, see Appendix 1). Two species could not be identified to genus level and are classified as Unknown species A and B. A total of 39 species were recorded during the surveys and an additional 14 were found on other occasions. Two families stand out for having both the most genera and species: Libellulidae and Coenagrionidae. The two families combined comprise ~ 73% of the species found in the area. 8.0 Appendix 1. **18250.** Chen, K.; Xiao, N.; Wang, B.; Li, J. (2012): The effects of petroleum exploitation on water quality bio-assessment and benthic macro-invertebrate communities in the Yellow River Delta wetland, Dongying. *Acta Ecologica Sinica* 32(6): 1970-1978. (in Chinese, with English summary) ["The major environmental risks associated with petroleum extraction (e. g. oil spills and leaks) are well known. There is a lot of information on the impacts of petroleum exploration on benthic communities in foreign studies. In this study, we probed the effects of petroleum exploration on macro-invertebrate assemblages, which are important components of benthic communities in this wetland ecosystem. The object of the investigation was to provide scientific data to guide the management, ecological restoration, conservation of biodiversity, and sustainable development of aquatic ecosystems. Physicochemical variables were measured at 34 sites in the Yellow River Delta wetland, Dongying, China, in October 2009, and benthic macro-invertebrate assemblages were collected using a D-frame net and a Peterson grab. The water body in the study area was oligohaline, its salinity ranging between 0.05 and 5 ppt. A total of 84 macro-invertebrate taxa, belonging to 70 genera, 41 families, 12 orders, 6 classes, and 3 phyla, were collected. Insecta comprised 52.4% of all benthic invertebrate taxa, of which Odonata and Diptera accounted for 23% and 24%, respectively. The structure and diversity of macro-invertebrate assemblages were expressed using the Shannon-Wiener index, the Margalef index and the dominance index. Water quality was assessed by the Shannon-Wiener index and the biotic index. The dominant species at most of the sites were either *Chironomus* spp. or *Glyptotendipes* spp. with overall dominance indices of 0.0315 and 0.0522, respectively. Pearson correlation analysis showed that the Shannon-Wiener index was negatively correlated with total nitrogen (TN) ( $r = -0.446$ ,  $P = 0.02$ ) but was not correlated with any of the other physicochemical variables measured. The biotic index was not correlated with any of the physicochemical variables. The numbers of molluscan taxa were negatively correlated with salinity ( $r = -0.422$ ,  $P = 0.028$ ) and positively correlated with pH ( $r = 0.435$ ,  $P = 0.023$ ). Likewise, the percentages of individual Mollusca at the sites were negatively correlated with salinity ( $r = -0.395$ ,  $P = 0.041$ ) and positively correlated with pH ( $r = 0.565$ ,  $P = 0.002$ ). The numbers of oligochaete taxa were significantly positively correlated with TN ( $r =$

0.524,  $P = 0.005$ ). The petroleum content of the water was not correlated with any of the biological indices and was not considered to be a major stressor. Canonical correspondence ordination analysis (CCA) showed that TN, pH, and salinity were the major contributors to the macro-invertebrate community structure, with 12.18% of species variation explained by these three variables. The substrate and hydrophytes also had effects on the structure of the macro-invertebrate communities. Cluster analysis and MDS ordination of sampling sites showed that all sites could be divided into 11 separate groups at the similarity level of 30%. Oligochaeta and Mollusca were the two main taxa responsive to environmental variables. The bio-assessment indicated that the Shannon-Wiener diversity index was a better indicator of water quality than the biotic index. Bio-assessment using the Shannon-Wiener index showed that the water quality of the Yihong River tributary, the Guangli River upstream, the Tiao River upstream, and the Dongzhang reservoir were clean, that nine sites were slightly polluted, and that the remaining sites were moderately to heavily polluted. We proposed that a comprehensive evaluation of water quality should ideally combine the Shannon-Wiener index, the biotic index, and physicochemical measurements. Additionally, other evaluation methods could be developed based on the biological indices for this region, taking into account the special characteristics of this native ecological environment."
