- 19319.** Buczynski, P.; Bielak-Bielec, P. (2019): Materials to the knowledge of dragonflies (Odonata) of rivers and lakes in Central Eastern Poland. *Notatki Entomologiczne* 4(2): 1-10. (in Polish, with English summary) ["The authors present and discuss a collection of dragonfly larvae from the years 2015–2018, obtained in central-eastern Poland (21°47'–24°08'E, 50°38'–51°43'N) in the rivers (28 sites) and lakes (three sites). Data from rivers, except for one site in the stagnant river's mouth section, is typical of species-poor assemblages characteristic for middle and lower reaches of rivers. Noteworthy are the occurrence sites of two species protected by law: *Gomphus flavipes* and *Ophiogomphus cecilia*. At the same time, a small number of records of *O. cecilia* may show a still insufficient water quality in a large part of the studied rivers. In the material from lakes, the most interesting is the presence of thermophilous *Orthetrum albistylum* and *Crocothemis erythraea*, which indicates the increasing water temperature in the lake littoral in the area of research and the associated change in the composition of the fauna of this habitat. The collection of the exuvia of *Erythromma viridulum* in the aquarium at the pet shop in Lublin is separately discussed: in most cases the material obtained in this way represents introduced exotic species. This is a valuable tip that native species can colonize aquariums in shops and that the identification of such individuals in aquariums should begin by checking whether it is not such a case." (Authors)] Address: Buczynski, P., Dept of Zool., Maria Curie-Skłodowska University, Akademicka 19, PL-20-033 Lublin, Poland. E-mail: pawbucz@gmail.com
- 19320.** Cao, L.; Hou, W.; Hu, C. (2019): The complete mitochondrial genome sequence of *Acisoma panorpoides* Rambur, 1842 (Odonate: Libellulidae). *Mitochondrial DNA Part B* 4(2): 3644-3645. (in English) ["The phylogenetic relationships of dragonflies have received great attention all the time. For a better understanding the phylogenies among

odonate insects, the paper presented the complete mitochondrial genome of *Acisoma panorpoides* based on next generation sequencing data of total genomic DNA. The total length comprised 15,249 bp and the 37 genes (2 rRNA genes, 13 protein coding genes and 22 tRNA genes). Gene content and gene arrangement were identical to other odonate mitogenomes. Phylogenetic analyses using the whole sequences of the mitochondrial genome placed *A. panorpoides* as a sister species to *Hydrobasileus croceus* in Libellulidae." **19322.** Chelli, A.; Moulai, R. (2019): Ecological characterization of the odonatafauna in lotic and lentic waters of northeast Algeria. *Annales de la Société entomologique de France* (N.S.) 55(5): 430-445. (in English, with French summary) ["The purpose of this paper is to determine the Odonata fauna structure and composition in Bejaia's wetlands, which have been poorly sampled until now. This paper is a report of a pioneer study of dragonflies in the Bejaia area in northeastern Algeria, with the aim to improve the knowledge of the Odonata taxa present in this vast territory, which covers 3268 km<sup>2</sup>. This region is of major importance, and contains Wadi Soummam which is classified by the Ramsar Convention as of international importance. In addition, Lake Mezaia is included in the Gouraya National Park, and the area also contains high mountain forest ponds, which are unknown to both the general public and the scientific community due to their remote location and poor accessibility. Despite the anthropogenic pressures on these wetlands, this study recorded 33 Odonata species, which represented 52% of the species known in Algeria. None were new to the country. The recorded species included two Maghrebian endemic taxa, namely *Platycnemis subdilatata* and *Enallagma*

*deserti*." (Authors)] Address: Chelli, A., Laboratoire de Zoologie Appliquée et d'Écophysiologie Animale, Faculté des Sciences de la Nature et de la Vie, Université de Bejaia, Bejaia, Algeria

**19323.** Chovanec, A. (2019): Libellenkundliche Bewertung des restrukturierten Mündungsabschnitts der Mattig (Oberösterreich). im Auftrag des Amtes der Oberösterreichischen Landesregierung, Abt. Wasserwirtschaft: 37 pp. (in German) ["The lowest river kilometre of the Mattig in Braunau (Upper Austria) was the subject of a dragonfly study in 2019. Its aim was to evaluate the measures carried out in 2005-2007 for the ecological upgrading of this hyporhithral stretch of water. The restructuring measures favoured the colonisation of the river by dragonfly species specific to the water body type (especially *Calopteryx virgo*, *Gomphus vulgatissimus*, *Onychogomphus forcipatus*), which is expressed in the assessment "very good dragonfly ecological status". However, the low numbers of individuals, especially of sediment-bound species from the family Gomphidae, show that the supply of corresponding larval habitats in the studied section is rather low. Widening and the creation of flow-calming and flow-free zones promoted the abundance of individuals of *Calopteryx splendens*, a species with its longitudinal zonal focus in the Potamal, and of limnophilic species. This indicates potamalisation effects. The different characteristics of the five mapped study stretches in terms of water morphology, flow and bedload conditions as well as vegetation are reflected in differences in the dragonfly fauna." (Author/DeepL)] Address: Chovanec, A., Krottenbachgasse 68, 2345 Brunn am Gebirge, Austria. E-mail: andreas.chovanec@bmnat.gv.at

**19324.** Chovanec, A. (2019): Restrukturierungsmaßnahmen an der Krems im Bereich Ansfelden / Oberaudorf (Oberösterreich): Bewertung aus libellenkundlicher Sicht im Jahr 2019. Im Auftrag des Amtes der Oberösterreichischen Landesregierung, Abt. Wasserwirtschaft: 59 pp. (in German) ["In the years 2006 - 2008, hydraulic engineering interventions were carried out on the approximately 1.5 km long section of the Krems in Ansfelden / Oberaudorf in order to increase flood safety and ecologically enhance the watercourse. Corrections were carried out in 2018. The aim of the present study, which was carried out in 2019, was to examine the ecological effectiveness of the measures in terms of dragonflies. At each of the six study stretches mapped six times, 28 dragonfly species were detected, of which 22 were classified as certain, probable or possibly native (reproducing). 21 species - 18 of them certainly, probably or possibly native - belong to the reference species spectrum specific to the water body type (indicator and accompanying species). In this area, the Krems is assigned to the transitional region Hyporhithral / Epipotamal of the bio-region Bavarian-Austrian Alpine Foothills. Four leading species (*Calopteryx splendens*, *Calopteryx virgo*, *Gomphus vulgatissimus* and *Onychogomphus forcipatus*) were certainly ground-dwelling, which could be confirmed by the finding of exuviae and newly hatched individuals. The high individual densities should be emphasised: 17 of the 22 ground-

dwelling species occurred frequently, very frequently or en masse in at least one study section. Based on the findings, the dragonfly ecological status of the entire watercourse section can be classified as "very good". The different water typological characteristics of sections in the study area are reflected in the dragonfly fauna: The free-flowing section of the Krems (study sections A and B) had a high structural diversity (gravel banks, helophytes, flow-calm zones with submerged macrophytes in the flow shadow of groynes) and was colonised in particular by the rheophilic and rheobiont (flow-loving) reference species. The dragonfly ecological condition of this section was assessed as "very good". As a result of the hydraulic engineering corrections carried out in 2018, the left-bank side channel connected on both sides (sections D and E) was doped and flowed through from the main channel of the Krems throughout 2019, which had a positive effect on the dragonfly fauna specific to the water body type. This section was also the habitat of rheophilic and rheobiont reference species in particular. The dragonfly ecological status of this section was classified as "good". (2019): Shale Barren mapping and threatened and endangered species surveys for Raystown Lake, PA: U.S. Army Corps of Engineers, Baltimore District. Technical Report. Project 122148: 192 pp. (in English) ["This study mapped and surveyed shale barren plant communities at Raystown Lake, Huntingdon County, Pennsylvania. The location and extent of the shale barren communities were assessed, and various botanical species, including state and federal listed species were identified. An acoustic bat survey was done to revise and update a prior bat survey completed in 2014. In addition, invertebrate surveys of aquatic insects and fresh water mussels were also performed. Finally, numerous nocturnal, xeric-habitat specialist moths were collected to assess the presence or absence of state listed, or other rare and sensitive species, on the shale barrens. A total of 73 potential shale barren areas were identified and mapped. All shale barren endemic species previously known from Huntingdon County were confirmed at Raystown Lake, with the exception of shale barren goldenrod (*Solidago arguta*). ... Aquatic invertebrate sampling yielded specimens of *Calopteryx dimidiata*, which was thought to be extirpated from Pennsylvania and represents a new county record. Some other additional rare, sensitive aquatic insects collected during this study include *Boyeria grafiana*, *Cordulegaster erronea*, ... Results of all these surveys are expected to update the knowledge and understanding of rare, sensitive, state or federal listed species on Raystown Lake. These results are discussed in relation to potential management actions that may assist with the conservation and protection of these species and their habitats. Further, these data can now be used to update the Raystown Lake Master Plan." (Authors)] Address: U.S. Army Engineer Research and Development Center (ERDC) Environmental Laboratory (EL) Waterways

(2019): The role of odonate nymphs in ecofriendly control of mosquitoes and sensitivity of odonate nymphs to inorganic nutrient pollutants. *Applied Ecology and Environmental Research* 17(3): 6171-6188. (in English) ["During the present research, the predatory efficiency of nymphs of six coexisting odonate species i.e., *I. elegans*, *T. aurora*, *P. flavescens*, *L. fulva*, *S. decoloratum* and *C. servilia* was studied by using the 3rd instar larvae of *Cx. quinquefasciatus* as prey. Among the odonate species, there was observed variation in the daily feeding rate. The highest number of mosquito larvae was ingested by the *P. flavescens* nymph ( $47.0 \pm 5.1$  mosquito larvae/day). The predation performance of the odonate nymph was also compared between the day and night times. The feeding rate of nymphs of most odonate species was significantly higher during the daytime as compared to night-time ( $P \geq 0.05$ ). During the present research, feeding rates of odonate nymphs on *Cx. quinquefasciatus* 3rd instar larvae were also studied under varied condition of prey and predator density and water volume. Feeding rate of nymphs of each odonate species was positively correlated with increase in predator and prey density but was negatively correlated with increase in water volume. During the present research, odonate nymphs i.e., *I. elegans*, *T. aurora* and *P. flavescens* were exposed to various concentration of  $NH_4^+$  and  $NO_3^-$  in the laboratory for seven days. Nymph of *P. flavescens* species was found least sensitive to both,  $NH_4^+$  and  $NO_3^-$ . From the findings of the present research it was concluded that *P. flavescens* species is more efficient predator of *Cx. quinquefasciatus* 3rd instar larvae and is highly resistant to increasing water level of  $NH_4^+$  and  $NO_3^-$ ." **19328.** Johansson, F.; Bini, L.M.; Coiffard, P.; Svanbäck, R.; Wester, J.; Heino, J. (2019): Environmental differences

drive differences in the beta diversity of dragonfly assemblages among urban stormwater ponds. Ecological indicators 106(12): 9 pp. (in English) ["Subject: Anisoptera (Odonata), adults, algae, environmental factors, environmental indicators, land use, landscapes, macrophytes, models, oviposition sites, pollutants, ponds, predators, species diversity, stormwater, urban areas, vegetation cover, vegetation types, Sweden Abstract: Stormwater ponds are beneficial to urban landscapes because these man-made systems can reduce the negative effects of flooding in urban areas and restrain the distribution of pollutants. In addition, these systems are especially important to maintain the biodiversity of urban landscapes. Here, we sampled a set of 18 stormwater ponds in the city of Uppsala in Sweden to test the relationship between beta diversity of adult dragonflies and environmental factors (local and land use variables). We analysed the total beta diversity and its two components: replacement and richness difference. We recorded 31 species of Odonata, comprising 61% of the Odonata species in the province of Uppland in Sweden. By itself, this result indicates the importance of stormwater ponds in contributing to biodiversity in urban areas. The richness difference component of beta diversity was higher than the replacement component. Results from generalized dissimilarity models indicated that the richness difference component was mainly related with pond area and total vegetation cover (aquatic vegetation plus vegetation surrounding ponds). Focusing on different vegetation variables separately, models indicated that the beta diversity components were significantly correlated with percentage cover of floating algae scums, emergent aquatic macrophytes and tall shore vegetation. These results are consistent with what is known about the ecology of dragonflies, including the importance of aerial plant structures for perching, shelter from terrestrial and aquatic predators, and for providing oviposition sites. We also found that the stormwater ponds harboured a large part of the regional species pool. These systems are therefore important havens of biodiversity in urban landscapes. Our results also indicate that the management of different types of vegetation is key to maximize the potential of these systems in maintaining regional biodiversity." **19329.** Juracka, P.J.; Dobiáš, J.; Boukal, D.S.; Šorf, M.; Beran, L.; Cerný, M.; Petrušek, A. (2019): Spatial context strongly affects community composition of both passively and actively dispersing pool invertebrates in a highly heterogeneous landscape. *Freshwater Biology* 64(12): 2093-2106. (in English) ["1. The spatial distribution of suitable habitats and dispersal abilities of the constituent taxa jointly affect the structure of metacommunities in standing freshwaters. Most studies exploring spatial effects on aquatic metacommunities, however, focus on at most a few taxonomic groups. 2. Within two consecutive seasons, we studied spatial patterns in the species richness and composition of three passively dispersing and three actively flying freshwater invertebrate groups (rotifers, microcrustaceans and molluscs vs.

hemipterans, aquatic beetles and odonates) in a metacommunity system consisting of 42 newly or recently created fishless pools in a highly heterogeneous Central European sandstone landscape consisting of deep valleys and steep ridges. We hypothesized that the extent to which these dispersal barriers affect invertebrate groups depends on their dispersal mode, and that the ability of each group to colonize new habitats is affected by the landscape morphology. Moreover, we predicted that the history and age of the pools would play a major role in structuring of invertebrate communities. 3. Following the classical island biogeography pattern, habitat size (measured as pool surface area or depth) was the key characteristic influencing species richness for each of the six studied groups (range of explained variation: 10%–58.7%). The number of nearby aquatic habitats (i.e., potential colonization sources) was also an important determinant of species richness for molluscs (18.8%), crustaceans (36.4%) and aquatic beetles (27.2%). After pool size, the most important factor influencing species richness was the presence and functional composition of aquatic macrophytes in the pools, which affected the species richness of odonates (25.2%), aquatic beetles (12.2%), rotifers (11.1%), and crustaceans (8.3%). 4. Valley distances between localities, defined as the shortest distance that avoids crossing steep ridges, explained consistently slightly more variation in species composition (2.6%–12.6%) than did Euclidean distances (1.0%–10.1%) for all six groups. Spatial variables (the valley distance matrix, position of pools within clusters in the landscape, and the number of nearby aquatic habitats) explained more variation in species composition (3.4%–25.4%) than local pool characteristics (2.8%–9.4%) or temporal variation (0%–7.6%) in all taxa except hemipterans, whose species composition was almost equally affected by local (3.3%) and spatial factors (3.4%). 5. We conclude that landscape-level spatial structure in our study area affects the dispersal and metacommunity assembly of both actively and passively dispersing invertebrates more than studied pool characteristics or temporal variation. The observed congruence between groups with different dispersal modes is likely because flying insects follow similar dispersal routes as the key animal vectors of passive dispersers. Our study highlights the importance of including relevant topography features in studies of aquatic metacommunities in complex and heterogeneous landscapes, even for taxa considered to be efficient dispersers." (Authors) The study includes 24 odonate taxa.] Address: Juracka, P.J., Dept Ecol., Fac. Science, Charles Univ., Vinicná 7, Prague 2, 12844, Czech Republic. Email: juracka@natur.cuni.cz

**19330.** Khan, M.K.; Herberstein, M.E. (2019): Sexually dimorphic blue bands are intrasexual aposematic signals in nonterritorial damselflies. *Animal Behaviour* 156: 21-29. (in English) ["Highlights: • Dimorphic male colour evolves by female choice or by male-male interactions. • In damselflies, females did not prefer males with abdominal blue bands. • However, conspicuous blue bands reduced male mating attempts. • Conspicuous male colour here functions as an anti-harassment aposematic signal. Abstract: Sexually dimor-

phic traits in males are thought to evolve via female preference or male–male competition. Alternatively, in species without overt male displays or female mate choice, dimorphic coloration may function as a warning signal to conspecific males thereby avoiding costly harassment. We aimed to determine the function of sexual dimorphic coloration in the damselfly *Xanthagrion erythroneurum* in which males, but not females, have conspicuous blue bands on the tip of the abdomen. We show that the male blue bands and female black abdomen are chromatically and achromatically discriminable against their natural background. Moreover, the male blue bands and their adjacent abdominal segments generate higher internal contrast than female abdominal segments. We conducted two sets of experiments to test alternative hypotheses that the male blue bands are (1) the target of female mate choice, or (2) an intrasexual aposematic signal to avoid male mating harassment. We hid male blue bands by painting them black and measured female preference between the manipulated and the nonmanipulated (control) males. We found no difference in mating success between the control and manipulated males, thereby rejecting the female preference hypothesis. To test whether the blue bands function as a warning signal, we manipulated the females by painting male-like blue bands on their abdomen and measured the male response to those females relative to control females. Females with artificial blue bands on the terminal abdomen were mated less frequently than control females. However, when we painted blue bands on the anterior abdominal segments, the males did not discriminate between control and painted females. Our study demonstrates that dimorphic coloration advertises the males' unprofitability as mates to conspecifics thereby reducing intrasexual harassment." (Authors)] Address: Khan, M.K., Dept Biol. Sciences, Macquarie Univ., Sydney, NSW-2109, Australia. E-mail: bmbkawsar@gmail.com

**19331.** Luhring, T.M.; Vavra, J.M.; Cressler, C.E.; DeLong, J.P. (2019): Phenotypically plastic responses to predation risk are temperature dependent. *Oecologia* 191(3): 709-719. (in English) ["Predicting how organisms respond to climate change requires that we understand the temperature dependence of fitness in relevant ecological contexts (e.g., with or without predation risk). Predation risk often induces changes to life history traits that are themselves temperature dependent. We explore how perceived predation risk and temperature interact to determine fitness (indicated by the intrinsic rate of increase,  $r$ ) through changes to its underlying components (net reproductive rate, generation time, and survival) in *Daphnia magna*. We exposed *Daphnia* to predation cues from dragonfly naiads early, late, or throughout their ontogeny. Predation risk increased  $r$  differentially across temperatures and depending on the timing of exposure to predation cues. The timing of predation risk likewise altered the temperature-dependent response of  $T$  and  $R_0$ . *Daphnia* at hotter temperatures responded to predation risk by increasing  $r$  through a combination of increased  $R_0$  and decreased  $T$  that together countered an increase in mortality rate. However, only *D. magna* that experienced predation cues early in ontogeny showed elevated

$r$  at colder temperatures. These results highlight the fact that phenotypically plastic responses of life history traits to predation risk can be strongly temperature dependent." (Authors)] Address: Luhring, T.M., School Biological Sciences, University of Nebraska-Lincoln, 410 Manter Hall, Lincoln, NE, 68588, USA. Email: tomluhring@gmail.com.

**19332.** Martínez-Lendeck, N.; Osorio-Beristain, M.; Franco, B.; Pedraza-Reyes, M.; Obregón, A.; Contreras-Garduño, J. (2019): Does juvenile hormone prompt males to oxidative stress? *Journal of Experimental Biology* 222 (5): jeb194530: 4pp. (in English) ["In invertebrates, it has been recently reported that secondary sexual characteristics (SSC) reflect the antioxidant defense of their bearers, but it is not known what physiological link maintains the honesty of those signals. Here, we use the damselfly *Hetaerina americana* to test whether Juvenile Hormone plays such a role. First, we analyzed whether oxidative damage is a real threat in natural damselfly populations by examining the accumulation of oxidized guanines as a function of age in males. Then, we injected paraquat (a pro-oxidant agent) and added the Juvenile Hormone analog Methoprene (JHa) to the experimental group and the JHa vehicle (acetone) to the control group, to determine whether JHa increases the levels of pro-oxidants and antioxidants. We found that DNA oxidation increased with age, and levels of hydrogen peroxide and superoxide dismutase, but not catalase or glutathione, were elevated in the JHa group compared to the control group. We propose that Juvenile Hormone is a mediator of the relationship between SSC and antioxidant capacity and based on the literature, we know that JHa suppresses immune response. We therefore suggest that Juvenile Hormone is a molecular mediator of the general health of males, which is reflected in their SSC." A(uthors)] Address: Contreras-Garduño, J. **19334.** Ning, X.; Cheng, C.; Yu, X.; Bu, W. (2019): A research of color pattern variation on thorax of *Coeliccia cyanomelas* (Odonata: Coenagrionoidea: Platycnemididae). *Journal of Environmental Entomology* 41(3): 566-573. (in Chinese, with English summary) ["The color pattern on thorax of male *Coeliccia cyanomelas* varied obviously between populations. This was mainly reflected in whether a pair of spots on the pronotum or not, as well as the size, shape and quantity of the marks on dorsal and lateral surface of synthorax. The geometric morphometrics, and observation of spots on the pronotum, were conducted based on 319 individuals of male *C. cyanomelas* from 34 populations. Almost all individuals from northwest region had a pair of spots on the pronotum, while those in the southeast were missing. The analyses of geometric morphometrics reflected that all samples can be divided into northwest and southeast types based on the shape of marks on lateral synthorax. Individuals of both types occurred in the overlapping area. Results from two methods in this study were coincident, which indicated a significant variation on color pattern of male *C. cyanomelas*. Geometric morphometric is very useful in analysis of the variation tendency of color pattern of Odonata, and can provide evidences for the evolutionary history and the formation of geographical pattern of species." **19335.** Oliveira-Junior, J.M.B.; Juen, L. (2019): Structuring of dragonfly communities (Insecta: Odonata) in Eastern Amazon: Effects of environmental and spatial factors in preserved and altered streams. *Insects* 2019, 10, 322: 18 pp. (in English) ["The evaluation of the effects of environmental factors on natural communities has been one of the principal approaches in ecology; although, over the past decade, increasing importance has been given to spatial factors. In this context, we evaluated the relative importance of environmental and spatial factors for the structuring of the local odonate communities in preserved and altered streams. Adult Odonata were sampled in 98 streams in eastern Amazonia, Brazil. The physical features of each stream were evaluated and spatial variables were generated. Only environmental factors accounted for the variation in the Odonata community. The same pattern was observed in Zygoptera. For Anisoptera, environmental factors alone affect the variation in the community, considering all the environments together, and the altered areas on their own. As the two Odonata suborders presented distinct responses to environmental factors, this partitioning may contribute to an improvement in the precision of studies in biomonitoring. We thus suggest that studies would have a greater explanatory potential if additional variables are included, related to biotic

interactions (e.g., competition). This will require further investigation on a finer scale of environmental variation to determine how the Odonata fauna of Amazonian streams behaves under this analytical perspective." **19336.** Pavel, A.B.; Selma Menabit, S. Skolka, M.; Lupascu, N.; Pop, I.-C.; Opreanu, G. Stanescu, I. Scriciu, A. (2019): New data regarding the presence of two insect larvae species – *Gomphus (Stylurus) flavipes* (Odonata) and *Palingenia longicauda* (Ephemeroptera) – in the lower sector of the Danube River. *Geo-Eco-Marina* 25/2019: 2019-140. (in English) ["The paper presents data regarding two larvae insect populations – *Stylurus flavipes* and *Palingenia longicauda* (Olivier, 1791), inhabiting in the communities existing at the water/sediment interface along the Danube River. *S. flavipes* is one of the most important indicator species, listed in Annex IV of the EU Habitats Directive (EU Directive 92/43/EEC) and included in the IUCN Red List of Threatened Species, 2014. This species of dragonfly has become an endangered species in most Western European countries due to water pollution and river regulation. The other important larvae species, mayfly *P. longicauda*, listed in Annex II of the Bern Convention, is considered critically endangered in Europe. Both require a specific habitat conditions in order to complete their life cycle. During the spring campaigns conducted during 2012-2015, the presence of the two species was reported in 26 profiles from the Lower Danube Sector, *S. flavipes* in 18 profiles, and *P. longicauda* in 10 profiles. The most abundant occurrences were recorded in 2015, at Km 4 – Măcin Arm (59.2 ind/m<sup>2</sup> for *S. flavipes*, respectively, in 2012, at Km 8 – Sf. Gheorghe) (125.8 ind/m<sup>2</sup>) for *P. longicauda*. The presence or absence of larvae in samples, as well as their abundance, are strictly dependent on ecological conditions, the type of substrate representing the decisive factor in the microdistribution of the two larvae." **19337.** Pires, M.M.; Bender Kotzian, C.; Sganzerla, C.; Prass, G.; Schmidt Dalzochio, M.; Périco, E. (2019): Diversity of Odonata (Insecta) in Seasonal Deciduous Forest fragments in southern Brazil (state of Rio Grande do Sul), with a new record for the state and comments on the seasonal distribution of the species. *Biota Neotrop.* 19(4) e20190769: 12 pp. (in English, with Portuguese summary) ["We present an Odonata (Insecta) check list of species occurring in a fragment of the Seasonal Deciduous Forest (Atlantic Forest biome) from the central region of the state of Rio Grande do Sul (RS), southern Brazil, along with a list of the odonate species recorded in this phytoecological region for the state. In addition, we provide comments on the seasonal distribution of the species occurring in the study area. Two streams

and seven farm ponds located in the middle course of the Jacuí River basin were surveyed between December 2007 and February 2009. Overall, we recorded 49 species from 21 genera and six families. *Argia serva* had its first occurrence record mentioned for the state, elevating to 183 the total number of Odonata species occurring in Rio Grande do Sul. The number of species recorded in the study area corresponds to ~26% of the known Odonata diversity in RS. Libellulidae was the most species-rich family (22 species, ~45% of the total), followed by Coenagrionidae (18 species, 37% of the total). The checklist for the Seasonal Deciduous Forest in RS indicated the occurrence of 83 species of Odonata in this phytoecological region (~45% of the known odonate species in the state). This elevated diversity could be related to the density of the vegetation structure. In the study area, 20 species were found in streams, and 45 in farm ponds. Species occurrence showed marked seasonal patterns in the study area, with 88% of the species recorded from summer to autumn, and no species detected in streams in the winter. Moreover, 70% of the species were recorded in either one or two seasons in farm ponds, while 65% occurred solely in one season in streams. This result indicates that the life cycle of Odonata in southern Brazil is strongly influenced by seasonal patterns in temperature." **19338.** Prokop, J.; Krzeminska, E.; Krzeminski, W.; Rosova, K.; Pecharova, M.; Nel, A. (2019): Ecomorphological diversification of the Late Palaeozoic Palaeodictyoptera reveals different larval strategies and amphibious lifestyle in adults. *Soc. open sci.* 6: 190460: 10 pp. (in English) ["The Late Palaeozoic insect superorder Palaeodictyoptera exhibits a remarkable disparity of larval ecomorphotypes, enabling these animals to occupy diverse ecological niches. The widely accepted hypothesis presumed that their immature stages only occupied terrestrial habitats, although authors more than a century ago hypothesized they had specializations for amphibious or even aquatic life histories. Here, we show that different species had a disparity of semiaquatic or aquatic specializations in larvae and even the supposed retention of abdominal tracheal gills by some adults. While a majority of mature larvae in Palaeodictyoptera lack unambiguous lateral tracheal gills, some recently discovered early instars had terminal appendages with prominent lateral lamellae like in living damselflies, allowing support in locomotion along with respiratory function. These results demonstrate that some species of Palaeodictyoptera had aquatic or semiaquatic larvae during at least a brief period of their post-embryonic development. The retention of functional gills or gill sockets by adults indicates their amphibious lifestyle and habitats tightly connected with a water environment as is analogously known for some modern Ephemeroptera or Plecoptera. Our study refutes an entirely terrestrial lifestyle for all representatives of the early diverging pterygote group of Palaeodictyoptera, a greatly varied

and diverse lineage which probably encompassed many different biologies and life histories." (Authors) The paper includes references to Odonata.] Address: Prokop, J., Dept of Zoology, Faculty of Science, Charles University, Viničná 7, CZ-128 00, Praha 2, Czech Republic

**19339.** Sansault, E.; Baeta, R.; Rivière, T. (2019): Suivi odonologique des mardelles du Petit Eplin, saison 2018. Association Naturaliste d'Étude et de Protection des Écosystèmes CAUDALIS: 60 pp. (in French) [Indre-et-Loire, France; "Although the species range is significant, with 37 species observed in 2018 for 45 known historically, only three species are present on more than half of the mardelles (*Sympetrum sanguineum*, *Lestes dryas* and *Libellula quadrimaculata*). However, in terms of numbers and number of breeding sites, only *S. sanguineum* and *L. dryas* dominate the procession and together account for almost half of the Odonata numbers reported in 2018 (nearly 2,300 individuals observed). ... Conclusion: The Ruchard mardelles are a natural formation that appeared between 15,000 and 30,000 years ago through a phenomenon that is still poorly understood but which is known to be rare in our country. Their extensive use by pastoralists for thousands of years has, over the last forty years, given way to coniferous monocultures. This transformation of use has led to profound changes in the habitats present: the moors have been replaced by maritime pines and the mardelles have mostly been drained or filled in and are still under significant pressure. As far as Odonata are concerned, the sector remains one of the richest in the department, with 45 known species (of which 37 were observed during the 2018 season). The composition of the assemblage is quite unique, as it is dominated by a very common species, *Sympetrum sanguineum*, and by a fairly rare species, *Lestes dryas*. However, we note the absence of several very demanding heritage species such as *Leucorrhinia pectoralis* or *Sympetrum danae*. The latter, last observed on the site in 2013, is critically endangered in the Centre-Val de Loire region and could disappear rapidly if no measures are taken to conserve its breeding sites. A large-scale study on ways of conserving certain mardella habitats and restoring others could be carried out rapidly in conjunction with the State services (DDT, DREAL) and the owner (Groupement forestier de Cravant-Saint-Benoît). The conservation actions to be implemented could include the signing of a management agreement and the drafting of management plans, the carrying out of a hydrological study that could lead to work to modify the network of drains so that the area once again plays its role as a climatic and hydric buffer. All these measures could allow the mobilisation of European credits on the local territory via a large-scale LIFE-type project supported politically by the local authorities and technically by the associations. Such a project would be effective in restoring habitats considered to be priorities because of their poor state of conservation, while at the same time giving the local area an economic boost in the short term (involvement of local companies in the restoration work, setting up a sheep or cattle rearing project to supply local communities and schools with local meat, etc.) and in the long term (significant tourist value,

educational projects, return of ecosystem services provided free of charge by these natural habitats, fight against global warming, etc.)" (Authors/ DeepL)] Address: Sansault, E., Association Naturaliste d'Étude et de Protection des Écosystèmes CAUDALIS, 1, rue de la Mairie, 37520 La Riche, France. **19340.** Schilder, R.J.; Stewart, H. (2019): Parasitic gut infection in *Libellula pulchella* causes functional and molecular resemblance of dragonfly flight muscle to skeletal muscle of obese vertebrates. *Journal of Experimental Biology* 222: 10 pp. (in English) ["We previously demonstrated the existence of a naturally occurring metabolic disease phenotype in *Libellula pulchella* dragonflies that shows high similarity to vertebrate obesity and type II diabetes, and is caused by a protozoan gut parasite. To further mechanistic understanding of how this metabolic disease phenotype affects fitness of male *L. pulchella* in vivo, we examined infection effects on in situ muscle performance and molecular traits relevant to dragonfly flight performance in nature. Importantly, these traits were previously shown to be affected in obese vertebrates. Similarly to obesity effects in rat skeletal muscle, dragonfly gut infection caused a disruption of relationships between body mass, flight muscle power output and alternative pre-mRNA splicing of troponin T, which affects muscle calcium sensitivity and performance in insects and vertebrates. In addition, when simulated in situ to contract at cycle frequencies ranging from 20 to 45 Hz, flight muscles of infected individuals displayed a left shift in power–cycle frequency curves, indicating a significant reduction in their optimal cycle frequency. Interestingly, these power–cycle curves were similar to those produced by flight muscles of non-infected teneral (i.e. physiologically immature) adult *L. pulchella* males. Overall, our results indicate that the effects of metabolic disease on skeletal muscle physiology in natural insect systems are similar to those observed in vertebrates maintained in laboratory settings. More generally, they indicate that study of natural, host–parasite interactions can contribute important insight into how environmental factors other than diet and exercise may contribute to the development of metabolic disease phenotypes." **19341.** Vršanský, P.; Sendi, H.; Aristov, D.; Bechly, G.; Müller, P.; Ellenberger, S.; Azar, D.; Ueda, K.; Barna, P.; Garcia, T. (2019): Ancient roaches further exemplify 'no land return' in aquatic insects. *Gondwana Research* 68: 22-33. (in English) ["Highlights: •No insects returned to land after adapting to aquatic habits. •Aquatic insect family/terrestrial insect family ratio stabilizes from Triassic. •Semiaquatic cockroaches were widespread since Jurassic to present. •Semiaquatic eoblattid roaches were present since Carboniferous. Abstract: Among insects, 236 families in 18 of 44 orders independently invaded water. We report living amphibiotic cockroaches from tropical streams of UNESCO BR Sumaco, Ecuador. We also describe the first fossil aquatic roach larvae (6 spp.; n = 44, 1, 1, 1, 1) from the most diverse tropical

Mesozoic sediments (Middle Jurassic Bakhar Fm in Mongolia, Kimmeridgian Karabastau Fm in Kazakhstan; Aptian Crato Fm in Brazil), and the Barremian Lebanese and Cenomanian Myanmar ambers. Tropic-limited occurrences are trophic- (biomass/litter-fall), structural- (diversity) and also abiotic-factor-dependent (high temperatures). Diverse Paleozoic aquatic eoblattids are here (re)described from the lower Permian sediments of Elmo, U.S.A. and Chekarda, Russia. They competed with true cockroaches to reach water prior to the Mesozoic. Due to different evolutionary rates or periodical changes in water characteristics, non-adapted terrestrial insects repeatedly invaded the aquatic realm with well adapted hydrobionts. Obscurely, most aquatic lineages still survive. In contrast with Crustacea, aquatic-terrestrial reversal is absent. A single principal lineage, namely of moths, ancestral to butterflies (origination of modern insects from ephemerals and dragonflies is questioned), evolved from insects with aquatic immature stages, and none from aquatic adults. The rest of the orders are terrestrial-derived. The proposed reason for the lack of land return is the character of numerous aquatic adaptations related to reductions, which are unlikely to be resuppressed. The aquatic insect family/terrestrial insect family ratio over time reveals a sharp rise from the Late Carboniferous to Late Triassic followed by lasting stability. Diversification of aquatic insects seems consistent with a  $62.05 \pm 0.02$  Ma periodicity." (Authors)] Address: Bechly, G., Biologic Institute, 16310 NE 80th Street, Redmond, WA 98052, USA. **19343.** Bruus, M.; Rasmussen, J.J.; Strandberg, M.; Strandberg, B.; Sørensen, P.B.; Larsen, S.E.; Kjær, C.; Lorenz, S.; Wiberg-Larsen, P. (2020): Terrestrial adult stages of freshwater insects are sensitive to insecticides. *Chemosphere* 239, January 2020, 124799: 9 pp. (in English) ["Highlights: • Five of the six tested species were more sensitive to imidacloprid than the honeybee, when considering LD50 per individual. • Three of the six species tested were more sensitive to imidacloprid than the honeybee, when LD50 per g dw was considered. • All test species were more sensitive to lambda-cyhalothrin than the honey bee, irrespective of how LD50 was calculated. • The ranking of juveniles and adults according to sensitivity to lambda-cyhalothrin was not identical. Abstract: Terrestrial adult stages of freshwater insects may be exposed to pesticides by wind drift, over-spray, contact or feeding. However, studies addressing insecticide effects on freshwater invertebrates focus primarily on the impact of pesticides reaching the streams and potentially harming the aquatic juvenile stages. This is also reflected in the current risk assessment procedures, which do not include testing of adult freshwater insects. In order to assess the potential impact of insecticides

on adult stages of freshwater insects, we exposed six common species to the insecticides Karate (lambda-cyhalothrin) and Confidor (imidacloprid). Dose-response relations were established, and LD50 estimates were compared to those of the honey bee, *Apis mellifera* L. (Hymenoptera: Apidae), which is the standard terrestrial test insect when pesticides are evaluated prior to commercial release. Generally, the tested species were more sensitive to the studied insecticides than the honey bee. In order to examine whether the sensitivity of adult stages of freshwater insects corresponds with the sensitivity of the juvenile stages of the same species, the ranking of the two life stages with respect to the toxicity of Karate was compared, revealing some correspondence, but also some dissimilarities. Our results strongly indicate that terrestrial adult stages of aquatic insects are not adequately protected by current risk assessment procedures." **19344.** Buczynski, P.; Buczyńska, E.; Jirak-Leszczynska, A. (2020): Dragonflies (Odonata) of the Ojców National Park. *Parki nar. Rez. Przyr.* 39(1): 43-71. (in Polish, with English summary) ["In 2017-2019, the dragonfly fauna was studied in the Ojców National Park (southern Poland). This small park (2145.62 ha) protects the nature of the Polish Uplands. Its main axes are the valleys of two streams (Prądnik and Sąsówka) with little standing water, which is almost exclusively artificial. One of the streams (Prądnik) is heavily loaded with inflows from three wastewater treatment plants. The field work covered 52 sites, of which 43 were studied systematically and 40 dragonfly species were found. The most prevalent were *Aeshna cyanea* and *Libellula depressa*, Red-listed and protected species were only *Ophiogomphus cecilia*, *Orthetrum coerulescens* and *Sympetrum depressiusculum*. The authors analysed the occurrence of these species and the fauna of individual aquatic habitats (springs, streams, fish ponds, small water bodies) and discussed them against the background of fragmentary historical data. The odonatofauna of the park was not very rich compared to other national parks of Poland, it was also characterized by low numbers of individuals and very small numbers of species recorded in most sites (average 3.3) – with 28.8% of the sites without any dragonflies and up to 48.1% of the sites had neither autochthonous nor probably autochthonous species. Dragonflies in the springs were extremely rare and not numerous, the stream fauna was also poor, and in Prądnik it was clearly degraded by sewage inflows. The few centres of dragonfly diversity were found at two fish ponds, two artificial small water bodies located in the open area and one beaver pond. Without artificial waters, the park's fauna would probably be at least half the species poorer. Based on the collected data, the Ojców National Park was assessed as an area of minor and local significance for the protection of dragonflies, with not very rich and surprisingly strongly transformed fauna. **19346.** Cham, S. (2020): On the discovery of a 'new' population of *Orthetrum coerulescens* (Fabricius) (Keel Skimmer) in a chalk quarry and factors affecting its continued survival. *Journal of the British Dragonfly Society* 36(1): 11-21. (in English) ["*O. coerulescens* was first discovered at Sundon Quarry, Bedfordshire in 2017. This is a chalk quarry and hence is atypical of other sites where *O. coerulescens* is found. In 2018 and 2019, higher numbers of adults were recorded, along with larvae and exuviae, confirming the presence of a breeding population. The Sundon population is one of the more inland populations in Britain and is some distance from the next known breeding site. It is considered to be vulnerable due to the small-scale nature of the habitat. Shallow seepages and runnels in base-rich sites are a scarce type of habitat and may explain the under reporting of any association of *O. coerulescens* with such sites. The continued survival of this colony of *O. coerulescens* will depend on a number of factors including whether the site can be managed to maintain the open seepage habitat and water supply that the species requires." **19352.** Hazra, M.; Hazra, T.; Sarkar, S.K.; Bera, S.; Khan, M.A. (2020): First fossil dragonfly from India. *Current Science* 119(7): 1204-1207. (in English) ["In the Indian wetland palaeoecosystem, no dragonfly has been reported from the Cenozoic sediments until now. Here, we report a well-preserved fossil dragonfly (Odonata: Anisoptera) recovered from the late Neogene sediments of the Chotanagpur plateau, Jharkhand, eastern India. It is characterized by well-preserved head, thorax and a long cylindrical abdomen with terminalia and four wings with longitudinal veins, cross-veins and characteristic small pterostigma at the apex. These significant morphological attributes reveal a close resemblance of the fossil specimen with modern dragonflies of the family Libellulidae (order: Odonata, sub-order: Anisoptera). To the best of our knowledge, there is no reliable occurrence of dragonfly in the Indian fossil record. The core distribution of the dragonfly, suggests that it thrived under a tropical, warm, humid climate during the depositional period. The fossil specimen was found associated with prolific and diversified tropical angiospermic plant remains, vertebrates and invertebrates that provided a suitable palaeo-ecological niche for the dragonfly to survive. In addition, the fossil material and associated angiospermic flora indicate the terrestrial as well as freshwater lacustrine environment in Chotanagpur plateau during the depositional period." (Authors) Günter Bechly wrote at 24-11-2021: "The fossil from India is certainly not a dragonfly and the reconstructed morphology is already downright ridiculously impossible. I am not even sure if it is a fossil insect at all and not rather a plant remnant."] Address: Khan M.A., Centre of Advanced Study, Dept of Botany, University of Calcutta, 35, B.C. **19355.** Liu, Y.; Luo, X.; Zeng, Y.; Deng, M.; Tu, W.; Wu, Y.; Mai, B. (2020): Bioaccumulation and biomagnification of hexabromocyclododecane (HBCDD) in insect-dominated food webs from a former e-waste recycling site in South China. *Chemosphere* 240, February 2020, 124813: (in English) ["Highlights: • Occurrence of HBCDD were investigated in insects and their predators. • BMF of  $\alpha$ -HBCDD >1 in poikilotherms while <1 in homeotherms. • Trophic magnification of  $\alpha$ -HBCDD was found in aquatic but not in terrestrial food web. Abstract: Hexabromocyclododecane (HBCDD) has frequently been detected in wildlife. However, there is limited research on its bioaccumulation and biomagnification in insect-dominated aquatic and terrestrial food webs. This study investigated the occurrence of HBCDD in insects and their predators collected from a former e-waste contaminated pond and its surrounding region. The concentrations of  $\Sigma$ HBCDD (sum concentrations of  $\alpha$ -,  $\beta$ -, and  $\gamma$ -HBCDDs) ranged from nd to 179 ng g<sup>-1</sup> lipid weight.  $\alpha$ -HBCDD was the predominant diastereoisomer in all biotic samples, and the contribution of  $\alpha$ -HBCDD was higher in predators than in prey insects. A significantly positive linear relationship was found between  $\Sigma$ HBCDD concentrations (lipid weight) and trophic levels based on  $\delta^{15}\text{N}$  in aquatic organisms ( $p < 0.05$ ), while trophic dilution was observed in the terrestrial food web. This result indicates an opposite trophic transfer tendency of HBCDD in terrestrial and aquatic ecosystems. The biomagnification factor (BMF) for  $\alpha$ -HBCDD was higher in terrestrial birds (2.03) than in frogs (0.29), toads (0.85), and lizards (0.63). This may be due to differences between poikilotherms and homeotherms in terrestrial ecosystems." (Authors) The authors included into their analysis odonate larvae (aquatic food web) and "Aeshnidae" and "Libellulidae" (terrestrial food web)] Address: Wu, Y., Research Institute of Poyang Lake, Jiangxi Acad. of Sciences, Nanchang, 330012, PR China. The guide covers the 32 species that may be seen in Cyprus. Each species has a page devoted to information on distribution, behaviour, phenology and preferred locations, as well as illustrations by Richard Lewington. For all but 4 species there is also at least one full-page colour photograph. Each species page shows the name of the species in Greek as well as the scientific name. In addition, the English common name is shown in the appendices along with the scientific and Greek names. (Dieter Prestel)] Address: to be ordered at: <https://nibuk.de/>

**19358.** Perron, M.A. (2020): The value of urban ponds for Odonata and plant biodiversity. Dissertation, Dept of Biology, University of Ottawa, Ottawa, Ontario, Canada. 242 pp. (in English) ["Urbanization involves the conversion of natural areas to impervious surfaces, which can lead to an increase in the frequency and severity of flood events in cities. To mitigate flood risk, stormwater ponds are constructed to manage urban runoff. Stormwater ponds can also be colonized by wildlife, but their suitability as habitat is disputed due to potential toxicological risks. This study assessed the suitability of stormwater ponds as habitat for the bioindicators Odonata (dragonflies and damselflies) and determined environmental factors that impact their community structure. Odonata (adults, nymphs and exuviae) were sampled at 41 stormwater ponds and 10 natural reference ponds across the National Capital Region of Canada, with a subset of ponds sampled over four years (2015-2018). Plant communities, water quality and surrounding land cover were analyzed at each pond to determine their impacts on Odonata community structure. Overall, stormwater ponds had lower Odonata abundance and a greater variation in species richness and community structure compared to natural ponds but had comparable dragonfly reproduction rates. Plants were the most significant driver of Odonata communities, as stormwater ponds with a high richness of native wetland plants had higher Odonata abundance and community structures similar to natural ponds. Water quality was the second most important driver of Odonata communities with dragonflies showing greater sensitivity to urban contaminants than damselflies. While stormwater ponds had higher concentrations of trace elements than natural ponds (e.g. Ni, V, As), concentrations were generally below toxic levels for all elements except copper and chloride, the latter likely an input from winter road salting. Surrounding land cover was the least important factor affecting Odonata communities. In conclusion, this research demonstrated the importance of local-scale factors related to plants and water quality in sustaining Odonata communities and specifies recommendations for stormwater pond design and maintenance that enhance urban biodiversity." (2020): On the firing line – interactions between hunting frogs and Odonata. *International Journal of Odonatology* 23(3): 199–217. (in English) ["Frogs are important predators of Odonata. We investigated frogs catching Odonata prey by means of slow-motion filming in the field in order to understand the prey–predator interactions. In particular, we aimed to analyse kinematics of captures, and of Odonata fleeing, through evaluation of frame-by-frame filming; 122 (20%) of 613 events were analysed. While dragonflies were ovipositing, frogs were sitting and waiting motionless, or they sneaked slowly towards the intended prey. The speed of the lashing tongue was much higher than the start and flight velocities of Odonata during escape attempts. The reaction time of Odonata was around  $45 \times 10^{-3}$  s, and it was not correlated to capture rate. The fleeing behaviour of Odonata cannot be considered to be stereotypical. The usual fleeing measure was to evade sideways to the jump direction of the frog, with the individual turning their body to one side and flying away from the frog. Perched odonates escaped by overturning to one side, sometimes falling into the water, or by flying in a loop. To escape, individuals were observed flying backward with the head down, in two cases. From the video clips, capture rates were counted. Large Anisoptera escaped more often than small Zygoptera. Anax imperator females mostly escaped after capture by fighting with strong wing beats, even when pulled under water by the frog." (2020): Neonicotinoid insecticide concentrations in agricultural wetlands and associations with aquatic invertebrate communities. *Agriculture, Ecosystems and Environment* 287 (2020) 106678: 11 pp. (in English) ["Neonicotinoids are considered a superior insecticide for agricultural pest management, although their impacts on non-target insects is a rising concern. Aside from laboratory and mesocosm studies, limited research has been directed towards the role neonicotinoids may have in structuring aquatic invertebrate communities in field settings. Therefore, we simultaneously collected aquatic invertebrate and surface water samples from 26 wetlands within a highly modified agricultural landscape of Nebraska's Rainwater Basin during spring 2015. Water samples were tested for six different neonicotinoids, nutrients, and physical properties. Trace levels of clothianidin and imidacloprid were the only neonicotinoids detected,

occurring in 85% and 15%, respectively, of wetlands sampled. All measurements for clothianidin and imidacloprid were below chronic toxicity benchmarks set by the United States Environmental Protection Agency. Neonicotinoid concentrations were significantly lower ( $W_{26}, 0.05 = 42.5$ ) at wetlands with vegetative buffer strips >50m wide compared to wetlands with vegetative buffers strips <50 m. Although neonicotinoids were below benchmark concentrations proposed by government regulations, a significant negative association between neonicotinoid concentrations and aquatic invertebrate biomass was observed across all wetlands studied (Parameter Estimate = -0.031; SE = 0.014)." **19364.** Scribano, G.; Balestrieri, A.; Gazzola, A.; Pellitteri-Rosa, D. (2020): Strong behavioural defensive responses of endemic *Rana latastei* tadpoles induced by a native predator's odour. *Ethology* 126(9): 922–930. (in English) ["Prey species must constantly acquire information on predator identity, abundance and dangerousness from the environment. In aquatic habitats, this information is mainly propagated by water-borne chemical signals, either predator-specific odours or prey alarm cues. Anuran larvae innately respond to conspecific alarm cues and are able to associate them to predator cues during their lifetime. In this study, we investigated the anti-predatory responses of *R. latastei* tadpoles exposed to either conspecific or heterospecific alarm

cues and a native predator's (*Anax imperator* larvae) odour. Pre- and post-stimulus behaviours of each tadpole were recorded by a digital camera and analysed by a source executable software for image-based tracking. We found that Italian agile frog tadpoles responded to fasted dragonfly odour by strongly reducing their activity, both in terms of the amount of time they spent active and path length covered in comparison to control groups. Contrary to previous studies, predators' diet had a negligible effect on tadpole response and our experiment did not bring any evidence of the phylogenetic-relatedness hypothesis. The innate or early-in-development recognition of dragonfly larvae is clearly adaptive and may increase tadpole survival with relatively low costs, but, at the same time, may increase the risk of ignoring novel potential threats." **19367.** Späth, J.; Nording, M.; Lindberg, R.; Brodin, T.; Jansson, S.; Yang, J.; Wan, D.; Hammock, B.; Fick, J. (2020): Novel metabolomic method to assess the effect-based removal efficiency of advanced wastewater treatment techniques. *Environmental Chemistry* 17(1): 1-5. (in English) ["Unprecedented levels of chemicals of anthropogenic origin are currently released into surface waters globally. Wastewater treatment plant effluent has been identified as a major source, containing a broad mixture of pharmaceuticals and consumer chemicals. Therefore, there is a need for implementation of advanced wastewater treatment techniques,

such as ozonation and adsorption methods, to reduce the contamination. However, there are conflicting findings on the toxicity of treated effluent and only limited possibilities for assessing the effect-based removal efficiency (EBRE) of different treatment techniques. Here, we describe a metabolomics approach to detect perturbations in fatty acid catabolic pathways as a proxy for biological effects. Metabolites in three fatty acid pathways were analyzed in *Coenagrion hastulatum* larva by liquid chromatography coupled to mass spectrometry. The larvae were exposed for one week to either conventionally treated effluent (activated sludge treatment), effluent additionally treated with ozone or effluent additionally treated with biochar filtration and results were compared with those from tap water control exposure. Five lipoygenase-derived oxylipins (9,10,13-TriHOME, 9,12,13-TriHOME, 9-HODE, 9-HOTrE, and 13-HOTrE) decreased in response to conventionally treated effluent exposure. By using an additional treatment step, oxylipin levels were restored with exception of 9,10,13-TriHOME (ozonated effluent), and 9-HOTrE and 13-HOTrE (effluent filtered with biochar). In conclusion, exposure to wastewater effluent affected fatty acid metabolite levels in damselfly larvae, and a subset of the analyzed metabolites may serve as indicators for biological effects in biota in response to effluent exposure. To that effect, our findings suggest a new metabolomics protocol for assessing EBRE." (Authors)] Address: Späth, Jana, Dept of Chemistry, Umeå University, 90187 Umeå, Sweden. **19368.** Start, D. (2020): Abundance and traits link predator ontogeny to prey communities. *Ecology* 101(6) e03044. 7 pp. (in English) ["Function and abundances shape species interactions and thus ecological communities. While communities are often summarized as the mean function of each species, intraspecific variation in traits and thus function is an important driver of community composition. Ontogeny is a common source of intraspecific variation, but while age-related functional changes can alter species interactions, so too can the effects of those functions on the density of the focal organism. For instance, ontogenetic variation can trigger higher levels of cannibalism, reducing abundances and altering interspecific interactions. I manipulate ontogenetic variation in damselfly larvae [*Lestes congener*] to show that intraspecific variation can impact communities through two distinct mechanisms. First, within-species differences affect population sizes, and thus indirectly shape communities (indirect effect). In particular, ontogenetic variation resulted in smaller damselfly populations, likely because of increased cannibalism rates, and thus ontogenetically diverse populations had a smaller total effect on their prey. Second, trait variation can affect communities by creating differences in the strength of per capita species interactions (direct effect). In this case, damselfly populations with greater age variation had smaller per capita effects on prey communities. I conclude that ontogeny of a single species can directly and indirectly shape community composition." **19370.** Streib, L.; Kattwinkel, M.; Heer, H.; Ruzik, S.; Schäfer, R.B. (2020): How does habitat connectivity influence the colonization success of a hemimetabolous aquatic insect? - A modeling approach. *Ecological Modelling* 416, 15 January 2020, 108909: 12 pp. (in English) [Highlights: • Process-based meta-population model for hemimetabolous freshwater insects. • Analysis of how habitat connectivity affects patch colonization. • ANOVA of key habitat parameters. • Patch colonization success strongly influenced by habitat connectivity. • Habitat patch number most important, followed by landscape permeability. Abstract: Climate and land-use change constitute major threats to biodiversity. Beside pure habitat loss, changing environmental conditions are likely to result in decreasing landscape permeability and increasing landscape fragmentation. This compromises habitat connectivity and, thereby increases threats to meta-population persistence. Comprehensive theoretical knowledge and general understanding of key parameters affecting habitat connectivity are therefore mandatory to assess risks of environmental change. However, related studies are scarce for hemimetabolous freshwater insects, which depend on both aquatic and terrestrial sites to complete their life cycle. We developed a process-based, spatially explicit meta-population model for a hemimetabolous freshwater insect, parameterized based on the traits of a damselfly [*Coenagrion mercuriale*], and analyzed the influence of varying landscape permeability on patch colonization for differently structured coextensive habitat networks. The in total 675,000 networks were set up by varying (1) landscape scenarios, representing different levels of permeability, (2) stream networks and (3) derived habitat patch assemblages, using least-cost path analysis. We found that habitat connectivity in general strongly determined the proportion of colonized habitat patches (Spearman's  $\rho = 0.64$ ). Moreover, a multi-factorial ANOVA of the parameters used for habitat network set up showed that the number of habitat patches had the

largest effects on the colonization success (18.6 % explained variance) followed by varying proportions of three landscape types incurring increasing dispersal costs (13.1 %) and the spatial arrangement of habitat patches (7.1 %). The introduced model generated theoretical knowledge how changing environmental conditions (e.g. landscape permeability) can influence the habitat connectivity of hemimetabolous freshwater species and, thus, has the potential to support conservation through habitat management within changing landscapes. Its design facilitates future adaptation to real hemimetabolous species and real-world habitats." **19371.** Su, G.; Dudley, R.; Pan, T.; Zheng, M.; Peng, L.; Li, Q. (2020): Maximum aerodynamic force production by the wandering glider dragonfly (*Pantala flavescens*, Libellulidae). *Journal of Experimental Biology* 223, jeb218552. 19 pp. (in English) ["Maximum whole-body force production can influence behavioral outcomes for volant taxa, and may also be relevant to aerodynamic optimization in microair vehicles. Here, we describe a new method for measuring maximum force production in free-flying animals, and present associated data for the wandering glider dragonfly. Flight trajectories were repeatedly acquired from pull-up responses by insects dropped in mid-air with submaximal loads attached beneath the center of body mass. Forces were estimated from calculations of the maximum time-averaged acceleration through time, and multiple estimates were obtained per individual so as to statistically facilitate approximation of maximum capacity through use of the Weibull distribution. On a group level, wandering glider dragonflies are here estimated to be capable of producing total aerodynamic force equal to ~4.3 times their own body weight, a value which significantly exceeds earlier estimates made for load-lifting dragonflies, and also for other volant taxa in sustained vertical load-lifting experiments. Maximum force production varied isometrically with body mass. Falling and recovery flight with submaximal load represents a new context for evaluating limits to force production by flying animals." **19376.** Vilenica, M.; Pozojevic, I.; Vuckovic, N.; Mihaljevic, Z. (2020): How suitable are man-made water bodies as habitats for Odonata? *Knowl. Manag. Aquat. Ecosyst.* 2020, 421, 13. 10 pp. (in English, with French summary) ["Many studies have reported a negative impact of freshwater habitat modification on biota. Nevertheless, some man-made water bodies have proven to be valuable for biodiversity conservation as they can harbour many species. We investigated 36 man-made water bodies to determine their suitability as habitats for Odonata. Larvae were sampled in littoral, during the summer months of 2016 and 2017. At each sampling site, ten samples were collected using a benthos hand net. A total of 21 Odonata species was recorded. Odonata assemblages mainly consisted of common widespread species. Yet, at Vlaèine Reservoir, located in the Dinaric Western Balkan ecoregion, we also recorded a rare and endangered Mediterranean species, *Lindenia tetraphylla*. Aquatic and riparian vegetation, water level fluctuations and dissolved oxygen concentration had the highest influence on Odonata, showing that manmade water bodies with a well-developed riparian zone and aquatic vegetation, and with low daily and seasonal water level fluctuations, can provide suitable habitats for diverse Odonata species. Odonata are among the sensitive freshwater insects widely used as ecological indicators and umbrella species, therefore these results about their assemblages in heavily modified and man-made habitats could contribute to future conservation activities of freshwater biota and habitats." (2020): Linear differentiation of chromosomes of *Anisogomphus bivittatus* selys, 1854 from India (Odonata: Anisoptera: Gomphidae). *International Journal of Entomology Research* 5(2): 120-122. (in English) [Live adult male specimens of *Anisogomphus bivittatus* of family Gomphidae have been collected from Andretta, Himachal Pradesh (India). Male germ cell chromosomes of the species have been described on the basis of conventional staining, Cbanding, silver nitrate staining and sequence specific staining. The species possesses  $2n$  ( $\sigma$ ) =23m, as the chromosome number and  $X0$  ( $\sigma$ )/ $XX$  ( $\rho$ ) type sex determination. Dark terminal C-bands are present on all the autosomal bivalents, while m bivalent is C-negative and X chromosome is C-positive throughout the length. Terminal light/dark NOR's are present on all autosomal bivalents including m bivalent, while X chromosome possesses terminal dark NOR on one side and light NOR on other side. During sequence specific staining, all the autosomal bivalents except m bivalent show more CMA3 bright signals than DAPI signals at chiasmatic ends and X chromosome is also more CMA3 bright than DAPI.] Address: Walia, G.K., Department of Zoology and Environmental Sciences, Punjabi University, Patiala, Punjab, India

**19379.** Zheng, D. (2020): Odonatans in lowermost Cenomanian Kachin amber: updated review and a new hemiphlebiid damselfly. *Cretaceous Research* 118, 104640. (in English) ["Odonatans are rare in amber deposits, and only four fragmentary specimens were recorded in Lebanese, Jordanian, Charentes and South Dakota ambers except for Kachin amber. This study reviewed the odonatans in lowermost Cenomanian Kachin amber and commented 11 odonatans, which were previously placed in the family level. Until now, over 350 odonatans have been found in Kachin amber, including 38 species of three extant suborders, and representing the most diverse and abundant dragonfly assemblage in amber inclusions. The dominated odonatans include the damselflies *Burmahemiphlebia zhangi* and *Mesomegaloprepus magnificus*, and the damsel-dragonfly *Burmaphlebia reifi*, accounting for ca. 79 % of all odonatans. The Kachin odonatans include the earliest records of the damselfly *Perilestidae*, *Platycnemididae* and *Platystictidae*, and the youngest records of the true dragonfly *Araripegomphidae* and *Stenophlebiidae*, contributing to exploring the origination and evolution of these families. Hemiphlebiidae is the dominant family in Kachin amber, represented by the species *Burmahemiphlebia zhangi* with ca. 160 species been recorded. It is surprising that the hemiphlebiid damselfly is abundant, but the diversity is very low with only two

species been previously reported. Herein, a new hemiphlebiid damselfly, *Kachinhemiphlebia lini* gen. et sp. nov., is described by the unique characters: Arc slightly distal of Ax2 in both fore- and hindwings; and a well-defined AA ending on posterior wing margin below Ax2. This is the second genus of the Hemiphlebiidae in Kachin amber." **19380.** Aliyev, S.; Mammadova, V.F.; Abdullayeva, L.R. (2021): Macrozoobenthos of Alijanchay river - the primary indicator of biodiversity within the Greater Caucasus in the territory of Azerbaijan. *Ukrainian Journal of Ecology* 11(6): 54-62. (in English) ["The article provides information on the biodiversity of the Alijanchay, one of the left tributaries of the Kura River, which originates in the highlands and is formed by inland waters and its main component macrozoobenthos, its species composition, biocenosis distribution, and ecological features. It is known that macrobenthic organisms are actively involved in forming the biological productivity of water bodies, the natural biofiltration of water. At the same time, biological indicators are organisms and form a link in the food chain in the ecosystem. Certain species are the first or second interim owners of parasites. It is worth mentioning some species, which prevent the regular operation of hydro-technical facilities. The river is mainly polluted by household waste. Recently, the development of agriculture and the increase in the number of fertilizers and various drugs applied to the soil have impacted the ecological stability of the river. Thus, the decrease in the species and number composition of fish formed in the river proves it again. The main task of the study is to assess the current state of biodiversity in the river, the general ecological status of the river, and determine the level of impact of natural and anthropogenic impacts on macrozoobenthos. The main focus here is done on macrobenthos, however, the forest and vegetation of riparian zones. During the study period, 154 species of organisms have been found, where 80 species of found organisms (52%) belong to river macrozoobenthos, 42 species (27%) to plants, and 32 species (21%) to vertebrates." **19382.** Antol, A.; Sniegula, S. (2021): Damselfly eggs alter their development rate in the presence of an invasive alien cue but not a native predator cue. *Ecology and Evolution* 11(14): 9361-9369. (in English) ["Biological invasions are a serious problem in natural ecosystems. Local species that are potential prey of invasive alien predators can be threatened by their inability to recognize invasive predator cues. Such an inability of prey to recognize the presence of the predator supports the naïve prey hypothesis. We exposed eggs of *Ischnura elegans*, to four treatments: water with no predator cue (control), water with a native predator cue (perch), water with an invasive alien predator cue (spinycheek crayfish) that is present in the damselfly sampling site, and water with an invasive alien predator cue (signal crayfish) that is absent in the damselfly sampling site but is expected to invade it. We measured egg development time, mortality between ovipositing and hatching, and hatching synchrony. Eggs took longer to develop in the signal crayfish group (however, in this group, we also observed high green algae growth), and there was a trend of shorter egg development time in the spinycheek crayfish group than in the control group. There was no difference in egg development time between the perch and the control group. Neither egg mortality nor hatching synchrony differed between groups. We suggest that egg response to signal crayfish could be a general stress reaction to an unfamiliar cue or an artifact due to algae development in this group. The egg response to the spinycheek crayfish cue could be caused by the predation of crayfish on damselfly eggs in nature. The lack of egg response to the perch cue could be caused by perch predation on damselfly larvae rather than on eggs. Such differences in egg responses to alternative predator cues can have important implications for understanding how this group of insects responds to biological invasions, starting from the egg stage." **19383.** Antón-Tello, M.; Britto, V.O.; Gil-Delgado, J.A.; Rico, E.; Dies, J.I.; Monrós, J.S.; Vera, P. (2021): Unraveling diet composition and niche segregation of colonial waterbirds in a Mediterranean wetland using stable isotopes. *Ibis* 163(3): 913-927. (in English) ["Rice fields and waterbirds are an example of a synergy that can occur between agriculture and conservation. This connection is especially relevant during the farming period, when nesting waterbirds need to obtain resources to cover their energy requirements and that of their chicks in rice fields. However, new farming techniques may potentially put at risk the fulfilment of this

role. Studies on how species use rice fields to feed during this critical period, are essential to understand waterbird population dynamics and to optimize conservation measures. At present, several species of colonial birds in l'Albufera de València (Spain) that depend on trophic resources available in rice fields have declining populations and decreases in productivity. We therefore assessed trophic niche segregation in the diet of chicks, of a waterbird community composed of seven species through stable isotope analyses of carbon ( $\delta^{13}\text{C}$ ) and nitrogen ( $\delta^{15}\text{N}$ ) obtained from chick blood and tissue samples of potential prey. According to trophic niche widths, chicks of Black-headed Gull *Chroicocephalus ridibundus* and Gull-billed Tern *Gelochelidon nilotica* showed a similar diet, although Gull-billed Tern had a major trophic specialization. The Western Cattle Egret *Bubulcus ibis* fed its chicks in a wider range of different habitats, with organisms located at the base of the food chain and with a greater importance of terrestrial prey than other species. Conversely, the Glossy Ibis *Plegadis falcinellus* had a more differentiated diet, mostly in freshwater habitats and mainly consuming odonates. Grey Heron *Ardea cinerea*, Little Egret *Egretta garzetta* and Squacco Heron *Ardeola ralloides* showed overlap between their niches, largely explained by the presence and abundance of cyprinid fish and odonates in their diets. Our results suggest a less important role than expected of Red-swamp Crayfish *Procambarus clarkii*, and a more important role of odonates despite being a less energy-rich prey. In conclusion, the diet of generalistic species of waterbirds in this study suggests that their trophic niches can overlap when relative prey abundance is high." (2021): Aquatic macroinvertebrates in endo- and exocarstic ecosystems of the department of Santander, Colombia. *Memorias II Congreso colombiano de espeleología 2021*: 146-156. (in Spanish, with English summary) ["Aquatic macroinvertebrates associated to endokarst and exokarst ecosystems have been little studied in Colombia. From 2016 to 2019, explorations have been carried out in Santander caves to recognize the fauna that live in these ecosystems. In other departments such as Cesar and Antioquia, studies are scarce, especially those that consider aquatic macroinvertebrates. In this study, 13 sampling points of endo and exokarst ecosystems of Santander. The samplings were carried out using hand nets, a Surber sampler and D-net, as a result, specimens of 50 species of aquatic macroinvertebrates were collected. The orders with the highest number of taxa were Diptera, Coleoptera, Hemiptera and Odonata. It is important to highlight the discovery of a new species of the genus *Telmatotrepes* (Hemiptera: Nepidae). 11 species with no bibliographic antecedents in caves were found. Therefore, the number of records of aquatic macroinvertebrates in endokarst and exokarst ecosystems of Santander has increased significantly." (Authors) Taxa are treated at genus level.] Address: Aristizábal, H.: E-mail: hernaris@equalambiental.com

B.Sc. thesis, Facultad de Ciencias Agrarias, Universidad de Guayaquil: xx + 65pp. (in Spanish, with English summary) [Ecuador "The following research seeks to observe the effect of the traps in two batches under study in Cacao (*Theobroma cacao* L), which was carried out at the south coast Experimental Station of INIAP, to develop the following objectives 1) Carry out assemblies of the entomofauna present in two agricultural production systems in cocoa cultivation, 2) Identify the main beneficial insects associated with cocoa cultivation, 3) Determine the population levels of insects found in two different crop production systems of cocoa. Two types of traps were used: a) Traps: yellow b) Trap with 3-liter plastic bottles. In the present test: it was possible to collect insects belonging to the following orders: Hymenoptera, Hemiptera, Diptera, Coleoptera, Lepidoptera, Blattodea, Odonata [= *Erythemis vesiculosa* (Fabricius, 1775)]. In the agroforestry lot, 296 individuals of the beneficial entomofauna and in the monoculture study lot, 832 individuals associated with the crop were captured" (Author).] Address: not stated

**19386.** Attaullah, M.; Ullah, I.; Ali, M.; Maula, F.; Ilahi, I.; Ahmad, B.; Khwaja, S (2021): Diversity of the Anisoptera & Zygoptera (Odonata: Insecta) of Swat, Pakistan. Brazilian Journal of Biology 83 • 2023: 8 pp. (in English, with Portuguese summary) ["Odonates are important biological control agents for the control of insect pests and insect disease vectors of medical and veterinary importance. The present study was conducted to evaluate the odonate fauna of Swat, Pakistan from March to October 2019. A total of 200 specimens of odonates were collected from diverse habitats. The collected specimens of the order Odonata belonged to 5 families, three families of Anisoptera namely Libellulidae, Gomphidae and Aeshnidae while two families of Zygoptera (Chlorocyphidae and Coenagrionidae). The specimens were categorized into 12 genera and 22 species. Libellulidae was the dominant family (n = 138) accounting for 69% of the odonate fauna. Orthetrum was the dominant genus (n = 73) of Anisoptera accounting for 36.5% of the odonate fauna. The least dominant genera were Anax, Paragomphus and Rhyothemis (n = 5 each) accounting each for 2.5% of the odonate fauna. In Zygoptera, the dominant genus was Ceryagrion (12.5%) and the least dominant genus was Ischnura (6%). *Pantala flavescens* was the most abundant odonate species in the study area recorded from all surveyed habitats. Shannon Diversity Index (H) was 2.988 and Simpson Diversity Index (D) was 0.95 for the collected odonate fauna. The highest abundance of Odonata was recorded in August, September and May while no odonate species were recorded in January, February, November and December. Lotic water bodies were the most suitable habitats with abundant odonate fauna. *Anax immaculifrons* was the largest sized odonate species having a wingspan of 53.2±1.63 mm and body length of 56.3 ± 0.4 mm. The present study shows the status of odonate fauna of Swat, Pakistan in diverse habitats and seasonal variation throughout the

year. Further work is recommended to bridge the gaps in the existing literature." (Authors)] Address: Ilahi, I., Dept Zoology, University of Malakand, Chakdara, Dir Lower, Khyber Pakhtunkhwa, Pakistan. E-mail: ikramilahi@uom.edu.pk

**19387.** Barmiento, S.H.; Schrama, M.; de Snoo, G.R.; van Bodegom, P.M.; van Nieuwenhuijzen, A.; Vijver, M.G. (2021): Experimental evidence for neonicotinoid driven decline in aquatic emerging insects. PNAS November 2, 2021 118 (44) e2105692118; 8 pp. (in English) ["Significance: Survey data show a large-scale decline in insects. This global decline is often linked to human actions in intensive agricultural areas. To investigate whether this decline has a causal relationship with neonicotinoid insecticides, we performed an outdoor experiment with representative surface water concentrations of the neonicotinoid thiacloprid. We exposed naturally formed aquatic communities to increasing neonicotinoid concentrations and monitored insect emergence during a 3-mo period. We show that increasing neonicotinoid concentrations strongly decreased the abundance and biomass of five major insect orders that together comprised >99% of the 55,574 collected insects as well as the diversity of the most species-rich freshwater family, thus showing a causal relation between insect decline and neonicotinoids. Abstract: There is an ongoing unprecedented loss in insects, both in terms of richness and biomass. The usage of pesticides, especially neonicotinoid insecticides, has been widely suggested to be a contributor to this decline. However, the risks of neonicotinoids to natural insect populations have remained largely unknown due to a lack of field-realistic experiments. Here, we used an outdoor experiment to determine effects of field-realistic concentrations of the commonly applied neonicotinoid thiacloprid on the emergence of naturally assembled aquatic insect populations. Following application, all major orders of emerging aquatic insects (Coleoptera, Diptera, Ephemeroptera, Odonata, and Trichoptera) declined strongly in both abundance and biomass. At the highest concentration (10 µg/L), emergence of most orders was nearly absent. Diversity of the most species-rich family, Chironomidae, decreased by 50% at more commonly observed concentrations (1 µg/L) and was generally reduced to a single species at the highest concentration. Our experimental findings thereby showcase a causal link of neonicotinoids and the ongoing insect decline. Given the urgency of the insect decline, our results highlight the need to reconsider the mass usage of neonicotinoids to preserve freshwater insects as well as the life and services depending on them." **19388.** Bastos, R.C.; Brito, J.; Cunha, E.; Cruz, G.M.; Pereira, J.L.S.; Vieira, J.; Juen, L. (2021): Environmental impacts from human activities affect the diversity of the Odonata (Insecta) in the Eastern Amazon. International Journal of Odonatology 24: 300-315. (in English) ["Land use influences the biodiversity of stream systems by changing the chemical composition of the water and the physical structure of

the habitat. The present study evaluated the influence of these processes on the diversity metrics of Odonata at regional and local scales, testing the hypothesis that the two odonate suborders Anisoptera and Zygoptera will respond differently to habitat and landscape variables. The study focused on 13 sites in the municipality of Barcarena, Pará, Brazil. We found no significant impact from regional factors, although anisopterans were more affected by water temperature and Habitat Integrity Index (HII). The HII indicated that the local forest was stable, but anisopteran richness was negatively correlated with HII. It was indicating that these species favoured open areas with less riparian cover. Even though zygopterans did not exhibit a similar systematic pattern, the reduced abundance of *Chalcopteryx rutilans*, a species associated with better-preserved habitats, may indicate that some sites lack the habitat integrity necessary to establish populations of this species. These findings highlight the importance of preserving the riparian forest to maintain the health of the stream systems. We recommend more studies that focus on the broader geographic and temporal scales to account for factors such as the anthropogenic gradient and historical land use patterns." (Authors)] Address: Bastos, R.C., Graduate Program in Ecology, Federal Univ. Federal do Pará, Rua Augusto Correia, Nº 1, Bairro Guamá, CEP: 66.075-110, Belém, Pará, Brazil. **19389.** Belenguier, L. (2021): Suivi de *Leucorrhinia dubia* et *Somatochlora arctica* par relevé des exuvies: résultats sur trois tourbières Auvergnates en 2015 (Odonata: Libellulidae, Corduliidae). *Martinia* 35(4): 13-22. (in French, with English summary) ["A monitoring of the emergence of *L. dubia* and *S. arctica* over the 2015 season was carried out on three peat bogs in Auvergne: The results contribute to the knowledge of these two species by quantifying the populations, specify the phenology on the studied area and calculating the sex-ratio at emergence. The results confirm the presence of an important population of *L. dubia* on the peat bog of the Plaine Jacquot, even if the productivity (number of exuviae reported on the surface of the peat pits) is lower than that reported in the bibliography, which leads to propose hypotheses to explain this finding. For *S. arctica*, the population in the Vallat peat bog is large. The data collected confirm that the period of emergence of *L. dubia* in this zone is on average from May to July, with a peak generally between early and mid-June, and that the period of emergence of *S. arctica* is on average from May to July, with a peak generally between mid-May and mid-June. The sex ratio at emergence for both species is in favor of females. Additional perspective of study are proposed to improve our knowledge of these two heritage species." **19390.** Bodas, A. (2021): Investigating the influence of educational media on children's views on conservation. MSc. thesis, Faculty of the Department of Psychological & Brain Sciences, Villanova University: 57 pp. (in English) ["Encouraging individuals, especially children, to decrease their use

of natural resources is critical to creating sustainable communities. I investigated whether children's environmental views can be positively influenced by watching educational media about conservation. I measured 4-and-5-year-olds' (N = 56) knowledge, self-efficacy and environmental worry before and after showing them an episode of the PBS show Nature Cat. Children who watched an episode about conservation did not learn significantly more about conservation strategies as compared to a Comparison condition, who watched an episode about dragonflies. There was also no difference between conditions in self-efficacy ratings. Notably, however, children in the Experimental condition were significantly more concerned for the environment at post-test. These findings suggest that exposure to nature-related educational media may increase children's awareness of environmental problems and concern for the environment." (Author)] Address: not stated

**19391.** Borsos, S. (2021): Exuvium adatok Somogy megye szitakötő faunájához (Insecta: Odonata). *Natura Somogyensis* 36: 25-34. [Data for the dragonfly fauna of Somogy county (Insecta: Odonata) based on samples of exuviae: "The 2168 exuviae found during the collections can be classified into 31 species, 56% of the 55 dragonfly species known so far from Somogy County. Among them, 8 are protected (*Aeshna isocetes*, *Gomphus flavipes*, *G. vulgatissimus*, *Onychogomphus forcipatus*, *Ophiogomphus cecilia*, *Epithea bimaculata*, *Somatochlora flavomaculata*, *Libellula fulva*) and 1 is highly protected (*Cordulegaster heros*) according to the currently in force FM Decree 66/2015 (26.X.). In the Hungarian Red List (2017) 4 species are listed, Endangered (EN): *E. bimaculata*, Vulnerable (VU): *O. cecilia*, *C. heros*, *S. flavomaculata*. *C. heros* is a species classified as threatened (NT) in the European Red List (2010). Based on the exuviae found, the most species-rich habitats were found in Lake 9 (Barcs), the Red Bank (Barcs) and the Gyótapusztai fishpond (Marcali). It is noteworthy that at Barcs, all four river dragonfly exuviae were found in the Dráva, demonstrating that this stretch of the Dráva is also an ecologically valuable and diverse habitat." **19392.** Brasil, L.S.; Alves de Andrade, A.F.; Ribeiro, B.R.; Spigoloni, Z.A.; Juen, L.; De Marco Jr, P. (2021): A niche-based gap analysis for the conservation of odonate species in the Brazilian Amazon. *Aquatic Conservation* 31(5): 1150-1157. (in English) ["1. Despite the current rates of deforestation and the expected climatic changes, protecting species in their natural habitats is still the simplest, cheapest, and most effective way of safeguarding biodiversity. Here, the network of protected areas in the Brazilian Amazon was evaluated to assess its effectiveness in safeguarding species of Odonata. 2. Ecological niche models were built to assess the suitability of the habitat for 503 Amazonian odonate species. Then, the effectiveness for the protection of odonate species of three classes of protected areas (strictly protected area, sustainable use area, and indigenous territory) was evaluated. 3. Approximately 30% of the species

are protected within the network of protected areas. These findings highlight the importance of protected areas for safeguarding most odonate species in the Amazon. For under-represented or gap species, additional resources are still needed for effective management and protection on some private properties, which need to set aside land for conservation. In this way, it is possible to preserve habitats for odonate species and guarantee their conservation in the Amazon." **19393.** Braumiller, C. (2021): Libellenfauna der südlichen Niederen Tauern. Diplomarbeit, Karl-Franzens-Universität Graz: 84 pp. (in German, with English summary) ["The dragonfly fauna of the southern Lower Tauern was investigated. The habitats and the occurrence of the species were surveyed. For this purpose, ten study sites were selected in the municipalities of Krakau, Schöder, St. Peter am Kammerberg and Oberwölz, each of which was visited on four dates between June and September 2020. The habitats were determined according to the guidelines for "biotope type mapping". Dragonflies could be detected at each water body. The numbers of individuals and species were discussed in relation to the ground level, lake level, seasonal occurrence, habitats and degree of endangerment. A total of 18 species were detected of which 14 were classified as native. The lowest area is located at 1059 m and the number of species and individuals decreases with increasing altitude" (Author) <https://unipub.uni-graz.at/obvugrhs/download/pdf/6434339?originalFilename=true>; *Calopteryx virgo*; *Coenagrion hastulatum*; *C. puella*; *Enallagma cyathigerum*; *Erythromma najas*; *Ischnura elegans*; *Lestes sponsa*; *Platycnemis pennipes*; *Pyrrhosoma nymphula*; *Aeshna cyanea*; *A. grandis*; *A. juncea*; *Cordulia aenea*; *Libellula depressa*; *L. quadrimaculata*; *Somatochlora metallica*; *Sympetrum danae*; *S. vulgatum*] Address: not stated

**19394.** Bried, J.T. (2021): Odonata species diversity, distributions, and status in a rare sand prairie-savanna wet-scape. *International Journal of Odonatology* 24: 197-214. (in English) ["Inland sand areas scattered across the North American eastern deciduous forest and western tallgrass prairie ecotone are known for supporting pyrogenic early-successional vegetation and specially adapted terrestrial faunas. Many of these globally and regionally rare systems contain functionally connected wetland networks ("wet-scapes") potentially important for aquatic insects. Sampling adults, nymphs, and exuviae in a remnant sand prairie-savanna wet-scape in Illinois, USA, I assessed odonate species diversity (alpha, gamma, beta), distributions (spatial, temporal, abundance), and rarity status. In one field season (12 sites, 12 visits) I found more than a third of Illinois odonate species and close to half of the state's lentic breeding odonates, including a new state record (*Erythemis vesiculosa*). Richness averaged 25.8 species per site, reducing to 12.4 species with removal of nonbreeding occurrences. Three sites including a shrub swamp, beaver pond, and forested vernal depressions complex made significant contributions

to beta diversity, dependent on general versus breeding occurrences. Majorities of Anisoptera species (70%) and Zygoptera species (53%) bred at three or fewer sites. Eight species flew during all or most of the study period (late May to early October) whereas 14 species were detected on a single survey. Status classification derived from the observed spatial, temporal, and abundance distributions resulted in 24 common or very common species, 20 uncommon or rare species, and 10 vagrants across the wet-scape. These context-specific classifications may be combined with diversity and breeding patterns and other information in wet-scape prioritization schemes." **19395.** Carbonell, J.A.; Wang, Y.J.; Stoks, R. (2021): Evolution of cold tolerance and thermal plasticity in life history, behaviour and physiology during a poleward range expansion. *Journal of Animal Ecology* 90(7): 1666-1677. (in English) ["Many species that are moving polewards encounter novel thermal regimes to which they have to adapt. Therefore, rapid evolution of thermal tolerance and of thermal plasticity in fitness-related traits in edge populations can be crucial for the success and speed of range expansions. We tested for adaptation in cold tolerance and in life history, behavioural and physiological traits and their thermal plasticity during a poleward range expansion. We reconstructed the thermal performance curves of life history (survival, growth and development rates), behaviour (food intake) and cold tolerance (chill coma recovery time) in the aquatic larval stage of the damselfly *Ischnura elegans* that is currently showing a poleward range expansion in northern Europe. We studied larvae from three edge and three core populations using a common-garden experiment. Consistent with the colder annual temperatures, larvae at the expansion front evolved an improved cold tolerance. The edge populations showed no overall (across temperatures) evolution of a faster life history that would improve their range-shifting ability. Moreover, consistent with damselfly edge populations from colder latitudes, edge populations evolved at the highest rearing temperature (28 °C) a faster development rate, likely to better exploit the rare periods with higher temperatures. This was associated with a higher food intake and a lower metabolic rate. In conclusion, our results suggest that the edge populations rapidly evolved adaptive changes in trait means and thermal plasticity to the novel thermal conditions at the edge front. Our results highlight the importance of considering besides trait plasticity and the evolution of trait means, also the evolution of trait plasticity to improve forecasts of responses to climate change." is described for the first time, represent the first complete life cycle described for an odonate in Mexico. The 17 larval instars obtained are described and illustrated in detail, from prolarva through F-0. Two egg batches of different females were obtained in the field and were subsequently reared in the laboratory. Eggs and larvae of the batches were raised under 26°C controlled temperature conditions until they reached instars F-6 and F-5. An extra collection of wild organisms was made in order to complete the life cycle from F-5. Only four of the wild larvae managed to complete the last five missing larval instars at 30°C. Larvae of the youngest instars (F-15 to F-8) were fed nauplii of *Artemia franciscana*, while F-7 to F-0 were fed larvae of Culicidae and Chironomidae. Larval life cycle from F-0 to F-16 lasted average of 186 days." (Authors)] Address: Carrillo-Lara, Diana, Inst. de Ecología A.C. Red de Biodiversidad y Sistemática. **19397.** Cezário, R.R.; Lopez, V.M.; Gorb, S.; Guillermo-Ferreira, R. (2021): Dynamic iridescent signals of male copperwing damselflies coupled with wing-clapping displays: the perspective of different receivers. *Biological Journal of the Linnean Society* 134(1): 229-239. (in English) ["Dynamic signals are a widespread phenomenon in several taxa, usually associated with intraspecific communication. In contrast, dynamic iridescent signals are detectable only at specific angles of illumination; hence, the animal can hide the signal to avoid detection when necessary. This structural coloration is mostly dependent on the illumination, the contrast against the background and the vision of the receiver. Complex behavioural displays can be coupled with structural coloration to create dynamic visual signals that enhance these functions. Here, we address whether iridescence of the males of a damselfly that inhabits dark rainforests, *Chalcopteryx scintillans*, can be considered a dynamic visual signal. We analyse whether coloration is perceived by conspecifics, while reducing detectability to eavesdroppers against three types of backgrounds. Our results suggest that the visual background affects the detectability of male hindwings by different receivers, mostly predators and prey. We discuss whether these results and the angle dependence of colour could indicate a mechanism to avoid unwanted intraspecific interactions or even to lure both predators and prey. We conclude that the main functions of the dynamic iridescent signal are to communicate with conspecifics while hindering the signal for prey, adding evidence of the multifunctionality of structural coloration coupled with behavioural displays in animals." **19398.** Chitsaz, N.; Siddiqui, K.; Mariana, R.; Chahlac, J. (2021): An experimental study of the aerodynamics of micro corrugated wings at low Reynolds number. *Experimental Thermal and Fluid Science* 121, 1 February 2021, 110286. (in English) ["Highlights: • PIV was used to study the flow over reconstructed micro-corrugated Odonata wings. • We

employed a non-destructive photogrammetry method to fabricate the wing. • The accuracy of corrugation patterns with fabricated wing was evaluated by Micro-CT. • Photogrammetry is advantageous to reconstruct the corrugated wing of MAVs. • The obtained aerodynamic results of corrugated wing benefit next generation of MAVs. Abstract: In this paper, an experimental study was performed to examine the flow characteristics of fabricated micro corrugated wings by fully mimicking the real 3D Odonata wing. For this purpose, a true scale hind wing from the *Orthetrum caledonicum* species with a semi span length of 60 mm was reconstructed by non-destructive close-range photogrammetry and fabricated with an advanced 3D printer. The accuracy of the proposed reconstruction technique was evaluated and compared with a 3D model of the same wing created using a Micro-Computed Tomography (CT) scanning technique to show that the close-range photogrammetry method was able to predict the pattern of micro corrugation of the wings with satisfactory fidelity. To do that, the corrugation patterns of both reconstructed wings were compared at different sections of the wings. Then, high-resolution Particle Image Velocimetry was used to investigate the flow field of the wing during gliding flight at three low Reynolds numbers  $Re=5\times 10^3$ ,  $Re=8\times 10^3$  and  $Re=12\times 10^3$ , and angle of attack  $10^\circ$ . The results include free stream velocity, vorticity distribution, boundary layer, and flow visualization. The velocity contour and vorticity boundary layer of both wings were compared experimentally. The flow behavior around the corrugated patterns reconstructed from both methods were compared with satisfactory agreement. The support the theory that the corrugations of the wing act as turbulators to generate unsteady vorticity to transition the boundary layer from laminar to turbulent quickly, leading to delayed stall and improved aerodynamic performance. Moreover, this study shows the application of the presented photogrammetry method for corrugated wing reconstruction, which is fast, low-cost, non-destructive, with high replication accuracy for the next generation of micro air vehicles." **19399.** Choo, M.Z.J.; Low, B.W.; Ngiam, R.W.J.; Yeo, D.C.J. (2021): Predation of mosquitos by odonates in a tropical urban environment: insights from functional response and field mesocosm experiments. *Biological Control* 161, October 2021, 104702. (in English) ["Highlights: • Predation by urban odonates on *Aedes albopictus* larvae was evaluated. • Laboratory experiments showed high feeding response (Type II) at low prey density. • Field mesocosm experiments showed little predation impact on community composition. • Predation on naturally-colonizing mosquito larvae in mesocosms was size-selective. • Odonates can potentially be used as predators of mosquitoes in urban environments. Abstract: Mosquito borne diseases (e.g., dengue fever, Zika fever, chikungunya fever) are a recurring problem worldwide. Using the natural predators of mosquitoes, such as

odonates, provides an alternative, more sustainable approach towards vector control. We assessed the biological control potential of the larvae of three common urban odonates (*Crocothemis servilia*, *Ischnura senegalensis*, *Orthetrum sabina*) using laboratory-based functional response and field-based mesocosm experiments. Functional response experiments using fourth instar *Aedes albopictus* mosquito larvae as prey revealed Type II functional responses in all three odonate species, highlighting their predatory efficiencies at low prey densities and demonstrating that urban odonates can consume substantial numbers of mosquito larvae (up to 44 per day) under experimental conditions. Complementary field-based experiments, however, showed little impact of odonate larvae predation on the overall composition of naturally colonizing aquatic macroinvertebrate communities, but revealed substantial size-selective predation by odonate larvae on mosquito larvae. Our results provide the first assessment of the predation efficiencies of urban odonate larvae, and highlight their potential as biological control agents of mosquitoes and other aquatic insect pests in highly modified urban landscapes." **19400.** Córdoba-Aguilar, A.; San Miguel-Rodríguez, M.; Rocha-Ortega, M.; Lanz-Mendoza, H.; Cime-Castillo, J.; Benelli, G. (2021): Adult damselflies as possible regulators of mosquito populations in urban areas. *Pest Management Science* 77(10): 4274-4287. (in English) ["Background: Dragonfly and damselfly larvae have been considered as possible biocontrol agents against young instars of mosquito vectors in urban environments. Yet, our knowledge about adult odonate predation against mosquito adults is scarce. We quantified daily and annual predation rates, consumption rates and prey preferences of adult *Hetaerina vulnerata* male damselflies in an urban park. A focus on predation of mosquito species was provided, quantified their arbovirus (dengue, chikungunya and Zika) infection rates and biting activity. Results: Foraging times of *H. vulnerata* overlapped with those of maximum activity of hematophagous mosquitoes. The most consumed preys were Diptera and Hymenoptera and, in lower quantities, Hemiptera, Coleoptera, Trichoptera, Psocoptera, and Neuroptera. Of note, 7% of the diet was represented by hematophagous dipterans, with 2.4% being *Aedes aegypti* and *A. albopictus*. Prey abundance in the diet coincided with that of the same species in the environment. The arboviral infection rate (dengue, chikungunya and Zika) was 1.6% for *Ae. aegypti* and *Ae. albopictus*. The total biting rate of these mosquito vectors was 16 bites per person per day, while the annual rate of infectious bites was 93.4. Conclusion: Although 2.4% for both *Aedes* species seems a low consumption, considering the presence of 12 odonate species at the park, it can be argued that adult odonates may play a relevant role as mosquito vector regulators, therefore impacting the spread of mosquito-borne diseases. Our study outlines the need of further research on the topic on the possible role of adult odonates for mosquito biocontrol." (Authors)] Address: Córdoba-Aguilar, A., Depto

**19401.** Chuirazzi, C.; Ocampo, M.; Takahashi, M.K. (2021): Influence of prey diet quality on predator-induced traits in wood frog tadpoles (*Lithobates sylvaticus*). *Amphibia-Reptilia* 42(3): 331-341. (in English) ["Diet quality and predation are two critical factors in determining the growth and development of organisms. Various anurans are susceptible to phenotypic changes influenced by these factors. Yet, few studies examined prey diet quality as potential influence over predator-induced traits. Using wood frog tadpoles (*Lithobates sylvaticus*) as a model species, we investigated the effects of three diet compositions (plant-based, animal-based, omnivorous) crossed with presence or absence of chemical cues from predatory dragonfly larvae (*Aeshnidae*). After 35 days, we recorded 11 morphological measurements, Gosner stage, and intestinal length of tadpoles to assess phenotypic changes under the six different experimental conditions. Our results showed the additive effects of both diet quality and predator chemical cue without detection of interactions between the two. Tadpoles receiving the omnivorous diet grew and developed faster with wider denticle rows than those receiving the plant or animal diets. The growth and development of tadpoles receiving only the animal diet were significantly hindered. These results emphasize the importance of diet quality in the growth and development of larval wood frogs. Chemical cues from predators significantly reduced tadpole body size but, in contrast to previous findings, did not affect tail size. Our experimental procedure of providing water containing predator and injured conspecific chemical cues on a weekly basis likely provided relatively weak predation risk perceived by tadpoles compared to previous studies using caged predators. The predator environment in our experiment, however, represents one ecologically relevant scenario in which predation risk is not urgent." **19403.** Clement, R.A.; Saxton, N.A.; Standing, S.; Arnold, P.R.; Johnson, K.K.; Bybee, D.R.; Bybee, S.M. (2021): Phylogeny, migration and geographic range size evolution of

Anax dragonflies (Anisoptera: Aeshnidae). *Zoological Journal of the Linnean Society*, zlab046, <https://doi.org/10.1093/zoolinnear/zlab046>: (in English) ["The genus *Anax* is a group of cosmopolitan dragonflies noted for its conspicuous migratory behaviours and large size. Here we present the first dated, species-level, multigene, molecular phylogeny for the group to test generic and species-limits, as well as the evolution of migration and range size. Using five mitochondrial and nuclear gene regions (COI, COI/COII, CYTB/ND1, ITS1 and PRMT) from 20 species, we reconstructed a phylogeny of *Anax* using both a Bayesian and maximum likelihood approach. We found that *Anax* (including its hypothesized sister group *Hemianax*) forms a monophyletic group, and that 12 out of 20 species tested positive for monophyly were also monophyletic. The monophyly of several species of *Anax* is less clear. Migratory behaviour, which is known to occur in at least nine species, is recovered as the ancestral behaviour, which was lost and subsequently gained at least three times. Geographic range size seems to be tightly associated with migratory behaviour." (Authors)] Address: Clement, Rebecca, Computational Biol. **19404.** Deacon, C.; Samways, M.J. (2021): Urban threats and conservation measures relating to aquatic arthropods on the iconic Table Mountain, South Africa: a review. *Basic and Applied Ecology* 56: 192- 212. (in English) ["Highlights: • Mountainous areas are attractive for human colonization. • In South Africa, mountains host high levels of aquatic arthropod endemism. • There are often trade-offs between urbanization and biodiversity conservation. • Urbanization presents several novel threats to freshwater conservation. • Threats can and have been mitigated to encourage arthropods in urban spaces. Abstract: Mountains supply essential resources, making them attractive areas for human settlement. Variation in elevation in mountainous areas determines local and regional climates, leading to complex biodiversity patterns. Mountains in the Cape Floristic Region have high species richness and beta diversity, and very high levels of local endemism. Table Mountain is an iconic mountain in the region, and unusual, as it is in the centre of the city of Cape Town. It is exceedingly rich in biodiversity, including many localized endemic species. However, increasing urbanization in the area is adversely affecting the local biodiversity, especially in the lowlands. Climate change effects to date are minimal, but projected to interact with the impacts of urbanization. Here we review the biodiversity patterns of green and blue spaces in and around Cape Town, including Table Mountain, focusing on aquatic arthropods. We also review the major threats that lead to biotic impoverishment, and provide information on current conservation efforts aimed at protecting the rich biodiversity of Table Mountain and its surrounds. Finally, we focus on the shortcomings of existing conservation actions, and then provide conservation strategies to limit aquatic arthropod biodiversity losses, based on actions that have already worked well. To ensure protection of all arthropods, freshwater habitats across all elevations require further conservation

action. Education and creating awareness must continue to close the gaps between scientists, conservation practitioners and civil society as a crucial part of the conservation plan." **19405.** Deacon, C.; Samways, M.J.; Pryke, J.S. (2021): Relative importance of ecological versus biological traits in driving range sizes of African dragonflies. *Journal of Biogeography* 48(6): 1309-1321. (in English) ["Aim: Ecological traits (e.g. biotope specialisation and habitat preference) and biological traits (e.g. mobility and life history) are highly variable among species. In insect conservation, considerable focus has been on ecological generalisation, with species occupying many biotope types (generalists) often assumed to be widely distributed, whereas species occupying few biotope types (specialists) are assumed as rare and localised. Although this may be valid in most cases, there is an increasing recognition that functional traits, such as insect mobility and life history, have similar importance as drivers of range size among species. Here, we investigate ecological and biological traits simultaneously to determine their relative importance as drivers of range size variation. We hypothesise that ecological traits are primary drivers, whereas biological traits related to mobility and life history are less important drivers of range size. Location: Sub-Saharan Africa. Taxon: 115 sub-Saharan dragonfly species. Methods: Five measures of species range size were obtained from the Odonata Database of Africa. Number of biotope types occupied by adults and larvae, larval habitat preference and adult biological trait information were collated from published sources. We explore the relationships between ecological and biological traits. Using linear mixed models and model averaging, we determine the relative importance of number of biotope types occupied, overall habitat preference and traits related to mobility and life history that drive dragonfly range size while accounting for phylogenetic relationships among focal species. Results: Dragonflies occupying more biotope types had wider ranges, although these relationships were overall weak. Dragonflies with longer and later breeding seasons had wider ranges. Overall habitat preference and mobility traits had low importance in our models. Main conclusions: Ecological versus biological traits are interactive in shaping the geographical ranges of dragonfly species across Africa. Single traits are weak predictors of species range sizes and we recommend investigating multiple traits simultaneously to improve the accuracy of predictions. In doing so, more informed decisions can be made to ensure effective large-scale conservation of dragonflies." (Authors)] Address: Deacon, C., Dept of Conservation Ecology and Entomology, Stellenbosch University, South Africa. E-mail: charldeacon@sun.ac.za

**19406.** Dinesh, V.; Leenamma, J.; Josekumar, V.S. (2021): Spatial variation of benthic Odonate (Odonata: Insecta) community structure in the urban River Killiyar in southern Kerala, India. *Journal of Aquatic Biology & Fisheries* 9: 99-108. (in English) ["The spatial variation of benthic odonate

community assemblage in various zones (upper, middle, and lower zones) of the urban river Killiyar was assessed using the tools of geographic information system (GIS) and investigated their interaction with select water quality parameters. Benthic odonate larvae collected during this study belong to predators–engulfers of the functional feeding groups. A total of 147 individuals of 12 genera across nine families of benthic odonate taxa were recorded in this study. Out of the total taxa observed, Gomphidae comprised 34% individuals, followed by Libellulidae (33%). The former taxa were the dominant family in all the zones except the lower zone. The spatial analysis demonstrated high diversity and richness in the stations of the middle zone while moderate diversity in the rest of the stations. The population density observed was high at station Idappazhanji (K10). The distribution of taxa was relatively higher in the middle zone than that of other zones. The taxa Libellulidae was observed in most stations and directly associated with water temperature, pH, and dissolved oxygen. The major drivers that govern benthic odonate community assemblages in Killiyar were pH and dissolved oxygen. Investigating the community assemblage using GIS tools is novel and provides a better understanding of the ecology of odonate larval communities and their association with water quality. The outcome of this study supports the formulation of management strategies to protect the odonate diversity and conservation of their habitats, the riverine ecosystems in the urban landscapes in particular." **19408.** Dow, R.A.; Ahmad, R.; Butler, S.G.; Choong, C.Y.; Grinang, J.; Ng, Y.F.; Ngiam, R.W.J.; Reels, G.T.; Steinhoff, P.O.M.; Unggang, J. (2021): Previously unpublished Odonata records from Sarawak, Borneo, part VI: Miri Division including checklists for Niah, Lambir Hills, Loagan Bunut and Pulong Tau National Parks. *Faunistic Studies in Southeast*

*Asian and Pacific Island Odonata* 36: 1-94. (in English) ["Records of Odonata made from 2005 to 2020 in Miri Division in Sarawak are presented, including records from Lambir Hills, Loagan Bunut, Niah and Pulong Tau National Parks. Primary types of Odonata originating from Miri Division are listed. Surveys of more than one day duration in Miri Division and covered here are tabulated with the funding source where appropriate; four of the surveys covered here were funded by the International Dragonfly Fund. One hundred and eighty-eight species are listed based on surveys made by the authors, of which *Macromia jucunda* Lieftinck, 1955, had not been recorded from Borneo before, *Burmagomphus arthuri* Lieftinck, 1953 is a new record for Miri Division and *Camacinia gigantea* (Brauer, 1867) has only been recorded from the Division recently with the only published record in a difficult to access publication (Choong (2020)). At least 48 more of the species listed were recorded from Miri Division for the first time in surveys covered in this report, although the records have been published (in most cases with no details beyond division and district in Dow (2021)) before. Two forms of *Xiphiagrion cyanomelas* Selys, 1876 are recorded and the likelihood that they represent different species is discussed. A possibly new, large sized, species of *Macromia* allied to *M. westwoodii* Selys, 1874 is recorded and discussed. Other notable records not published with details before include *Rhinocypha stygia* Förster, 1897, *Rhynoneura caerulea* Kimmins, 1936, *Dysphaea lugens* (Selys, 1873), *Euphaea ameeke* van Tol & Norma-Rashid, 1995, *Euphaea basalis* (Laidlaw, 1915), *Amphicnemis new* sp. cf. *mariae* Lieftinck, 1940 (previously recorded from Usun Apau National Park), *Anaciaeschna jaspidea* (Burmeister, 1839), *Heliaeschna uninervulata* Martin, 1909, *Borneogomphus* sp., *Heliogomphus borneensis* Lieftinck, 1964, *Ictinogomphus acutus* (Laidlaw, 1914), *Chlorogomphus* sp., *Macromia corycia* Laidlaw, 1922, *Idionyx montana* Karsch, 1891, *Hylaeothemis clementia* Ris, 1909, *Orchithemis xanthosoma* Laidlaw, 1911, *Rhyothemis fulgens* Kirby, 1889, *Rhyothemis regia* (Brauer, 1867), *Tetrathemis* sp. cf. *platyptera* Selys, 1878, *Tramea phaeoneura* Lieftinck, 1953 and *Tramea* sp. cf. *virginia* (Rambur, 1842). The habitat preferences of *Dysphaea lugens* are discussed. A male-male tandem of *Coeliccia nigrohamata* Laidlaw, 1918 is reported. The somewhat peculiar distribution of *Argiocnemis rubescens rubeola* Selys, 1877 and *Pseudothemis jorina* Förster, 1904 in Sarawak is discussed. Activity of the apparently normally crepuscular *Heliaeschna uninervulata* in the middle of the day is reported. An interesting morphological detail of some female *Chlorogomphus* from Sarawak is discussed. The likelihood that *Macromia corycia* is a junior synonym of *M. gerstaeckeri* Krüger, 1899 is discussed. The possibility that the range of *Rhyothemis regia* is expanding in Sarawak is remarked upon. The identity of *Tramea* sp. cf. *virginia* is discussed. With the records presented here at least 222 species of Odonata are known from Miri Division and with the addition of *Macromia jucunda* to the known fauna, 309 species have now been recorded from Sarawak. More detailed specimen records are given in Appendix 1 and a revised checklist of Odonata from Lambir Hills National Park and the first checklists from Loagan Bunut, Niah and Pulong Tau

National Parks are given in Appendix 2." (Authors)] Address: Dow, R.A., Inst. Biodiversity & Environmental Conservation, Univ. Malaysia Sarawak, 94300 Kota Samarahan, Sarawak, Malaysia. E-mail: rory.dow230@yahoo.co.uk

**19409.** Dow, R.A.; Orr, A.G. (2021): On the identity of two species of *Tyriobapta* (Odonata: Libellulidae) from Sundaland. *Notulae odonologicae* 9(7): 296-305. (in English) ["The genus *Tyriobapta* Kirby, 1889, includes three species, all originally described from Borneo. The genotype, *T. torrida* is common in much of Sundaland where it inhabits a variety of standing and slowly flowing freshwater habitats in forest. The two other species, *T. kuekenthali* (Karsch, 1900) and *T. laidlawi* Ris, 1919, are much less often encountered. Recent literature has confused these two species, with their identities being reversed, as is clearly evinced by the original descriptions. This note remedies this misconception." **19411.** Dumont, H.J.; Schneider, T.; Vierstraete, A.; Borisov, S.N. (2021): Biogeography and relationship of the Gomphidae of Europe, North Africa, and the Middle East (Odonata). *Odonatologica* 50(1/2): 17-42. (in English) ["Around 27 species of predominantly riverine Gomphidae occur in the vast region encompassing Europe as far as the Urals, the Maghreb, the Mediterranean Basin, and the Middle East up to the west side of the Indus valley, including Arabia, Iran, and Baluchistan. They are the remains of a pre-Pleistocene fauna that we estimate at twice the current number. We analyse the relationships, losses, and their causes at the molecular level and, not surprisingly, confirm the widely held opinion that the ice age is overwhelmingly responsible. Much extinction of European-West Asian and North American species took place in Beringia, presumably in an early phase of the glaciation. Recolonization between

glacial stages can be evaluated for the final stage, the Würm-Wisconsin glaciation. Differences in the orientation of mountain chains allowed more species to survive in North America than in Eurasia. They recolonized Canada, Europe, the Russian Far East, and Japan. From China, 16 additional gomphids are moving west through Siberia. Some reach the Ob valley but in others disjunctions persist. There are, for example, no *Stylurus* species in Pakistan, India, Bangladesh, and Thailand. Numerous preglacial survivors currently occur in Mediterranean and Middle Eastern refuges. Beside ice, aridity played a role in limiting the fauna. Oriental species advanced into the Middle East and Anatolia, but there was apparently never enough running water in Baluchistan to allow a large-scale movement of gomphids towards Europe. Rather to the contrary, the southeastern-most gomphid is *Gomphus amseli*, with type locality at the Heri Rud in Afghanistan, which forms a cline towards the west. Pakistan is even more impoverished in gomphids than Europe but is home to one small genus, *Anormogomphus*, that extends from northern India to eastern Anatolia. Africa also contributed little to the Palaearctic fauna. No *Gomphus* extends further south than the Maghreb, where several endemic species occur. *Paragomphus sinaicus* is a desert species that does not occur south of the Sahara. The richest populations are situated in Oman. Two colonies coincide with the position of the shores of Lake Megachad, in the foothills of the Sahara-Sahel mountains of Air, Tibesti and Ennedi. Perhaps biotic factors like interspecies competition explain its range better than environmental factors. Around 8500 BP, the most recent riverine contact with the Nile via the Wadi Howar facilitated contact and crossing of the Red Sea, but Saharan populations could be older. Arabia was presumably invaded via the Sinai Peninsula, terra typica of the species." (Authors) *Gomphus maroccanus* Lieftinck, 1966] Address: Dumont, H.J., Univ. Gent, Inst. Animal Ecology, K.L. **19412.** Elsowayeb, A.A.; Aboshaala, F.; Ghaliow, M.; Samraoui, B. (2021): *Lindenia tetraphylla* new to Libya (Odonata: Gomphidae). *Notulae odonologicae* 9(8): 372-377. (in English) ["We report on the first record of *L. tetraphylla* in Libya. A total of 21 individuals of this species are the first documented records for this species in this country. All individuals were mature, observed in June in two non-consecutive years (2019 and 2021), suggesting local reproduction at two sites south of Misurata city. Habitats were man-made wetlands surrounded by lush vegetation. These observations and recent others from North Africa suggest that this species is progressively recovering parts of its western range lost during the 20th century, establishing itself now within a wide coastal and sub-coastal region in the countries bordering the southern Mediterranean. Further investigations are warranted to confirm the status, and to assess the life cycle and dispersal of *L. tetraphylla* in Libya." **19414.** Faillace, C.A.; Sentis, A.; Montoya, J.M. (2021): Eco-evolutionary consequences of habitat warming and fragmentation in communities. *Biological Reviews* 96(5): 1933-1950 (in English) ["Eco-evolutionary dynamics can mediate species and community responses to habitat warming and fragmentation, two of the largest threats to biodiversity and ecosystems. The eco-evolutionary consequences of warming and fragmentation are typically studied independently, hindering our understanding of their simultaneous impacts. Here, we provide a new perspective rooted in trade-offs among traits for understanding their eco-evolutionary consequences. On the one hand, temperature influences traits related to metabolism, such as resource acquisition and activity levels. Such traits are also likely to have trade-offs with other energetically costly traits, like antipredator defences or dispersal. On the other hand, fragmentation can influence a variety of traits (e.g. dispersal) through its effects on the spatial environment experienced by individuals, as well as properties of populations, such as genetic structure. The combined effects of warming and fragmentation on communities should thus reflect their collective impact on traits of individuals and populations, as well as trade-offs at multiple trophic levels, leading to unexpected dynamics when effects are not additive and when evolutionary responses modulate them. Here, we provide a road map to navigate this complexity. First, we review single-species responses to warming and fragmentation. Second, we focus on consumer–resource interactions, considering how eco-evolutionary dynamics can arise in response to warming, fragmentation, and their interaction. Third, we illustrate our perspective with several example scenarios in which trait trade-offs could result in significant eco-evolutionary dynamics. Specifically, we consider the possible eco-evolutionary consequences of (i) evolution in thermal performance of a species involved in a consumer–resource interaction, (ii) ecological or evolutionary changes to encounter and attack rates of consumers, and (iii) changes to top consumer body size in tri-trophic food chains. In these scenarios, we present a number of novel, sometimes counter-intuitive, potential outcomes. Some of these expectations contrast with those solely based on ecological dynamics, for example, evolutionary responses in unexpected directions for resource species or unanticipated population declines in

top consumers. Finally, we identify several unanswered questions about the conditions most likely to yield strong eco-evolutionary dynamics, how better to incorporate the role of trade-offs among traits, and the role of eco-evolutionary dynamics in governing responses to warming in fragmented communities." **19415.** Faria, A.P.J.; Paiva, C.K.S.; Calvão, L.B.; Martins Cruz, G.; Juen, L. (2021): Response of aquatic insects to an environmental gradient in Amazonian streams. *Environmental Monitoring and Assessment* volume 193, Article number: 763 (2021): 12 pp. (in English) ["The increasing land use in the Amazon region has resulted in the widespread substitution of forest areas with pasture and bauxite mining. These land uses reduce the forest cover of streams and modify their characteristics, reducing the diversity of aquatic insect assemblages. In the present study, we aimed to identify the threshold of the assemblages of the larvae of insects of the orders Ephemeroptera, Plecoptera, and Trichoptera (collectively known as EPT), and adults of the order Odonata, along an environmental gradient of land use and land cover (LULC). We sampled 30 streams along an environmental gradient determined by the proportion of forest, pasture, and bauxite mining observed within the catchment of each stream. We identified 12 taxa associated with forest (nine positively and three negatively) and four negatively associated with pasture. However, no taxa were associated explicitly with the bauxite mining gradient. As forest is converted to pasture, the abundance and frequency of occurrence of the taxa sensitive to pasture are reduced, reflecting their environmental sensitivity and their potential as sentinels of preserved streams. The identification of the thresholds of the EPT and odonates taxa allowed us to determine which of these organisms are positively or negatively associated with the environmental gradient of LULC in Amazonian streams. We hope that the results of the present study can be applied in future biomonitoring programs, particularly for monitoring the response of aquatic insects to the degradation of streams." **19416.** Fraleigh, D.C.; Heitmann, J.B.; Robertson, B.A. (2021): Ultraviolet polarized light pollution and evolutionary traps for aquatic insects. *Animal Behaviour* 180: 239-247. (in English) ["Highlights: • We document a new type of pollution, ultraviolet polarized light pollution (UVPLP). • UVPLP is created by artificial objects and occurs nocturnally and diurnally. • Of six families of aquatic insect field-tested, only one used UVPLP to locate water. • UVPLP can attract animals to artificial surfaces, creating evolutionary traps. Abstract: When animals are misguided by evolved behavioural cues to preferentially make mistakes, they are caught in an

evolutionary trap. Aquatic insects rely heavily on polarized light cues to locate bodies of water necessary for oviposition and mating. However, where artificial objects (e.g. asphalt, buildings) are at least as effective at polarizing light as natural water bodies, aquatic insects may instead prefer to oviposit on those surfaces where their eggs fail to hatch. These objects are known to create evolutionary traps by polarizing light in the visible range (390–700 nm), yet their potential for creating evolutionary traps via the reflection of ultraviolet (UV) wavelengths (<380 nm) remains largely unknown. We surveyed the natural and artificial environment to understand the properties of objects that can polarize natural and artificial sources of UV light and conducted a multiple-choice field experiment to test the importance of UV polarized light in guiding habitat selection behaviour in six families of aquatic insects. We found that UV polarized light was associated with natural water bodies, was a common component of the man-made environment created by sunlight reflecting off vehicles, buildings and solar panels during the day, and originating from lamplight with a UV component at night. One of the six families of aquatic insects we examined was preferentially attracted only to UV polarized light sources, indicating that UV polarized light is a cue used in habitat selection. These results highlight a quantitatively new type of ecological light pollution capable of creating evolutionary traps for polarotactic insects at night, or even during the day." (2021): Territorial damselflies are larger and show negative allometry in their genitalia. *Biological Journal of the Linnean Society* 134(3): 697-706. (in English) ["The 'functional allometry' hypothesis proposes that the variation in allometric patterns of sexually selected traits is related to their function. We hypothesize that the allometric patterns for genitalia of aggressively territorial organisms are different from those in non-territorial organisms and predict that in aggressively territorial species, where body size is related directly to reproductive success, males must allocate more resources to body size than to genitalia. We studied 59 species of damselflies in 51 genera. Species were divided into three categories: highly territorial and aggressive; low aggressive; and not aggressive. We measured the length of the genital ligula, the width at the basis and its maximum width, and we used body length and wing length as descriptors of body size. The slope of allometric relationships was estimated using ordinary least squares and reduced major axis regressions. Our results indicated first, that territorial damselflies are larger and that body length and wing length are not equivalent as estimators of body size in odonates. Second, ordinary least squares and reduced major axis regressions provided different results in some of the analyses. Third, we found that aggressive species have less steep allometric slopes than non-aggressive species, both for the length of the ligula and for the width at its basis." (2021): Demographic traits and behavior of *Hetaerina cruentata* (Odonata: Calopterygidae) in ecosystems of the Andean region of Colombia. *International Journal of Odonatology* 24: 261-273. (in English) ["Demography and territorial behavior of *Hetaerina cruentata* was studied along three lowland streams located at Norte de Santander department in the Colombian Andean region. Adult damselflies (N: 278) were individually marked, and using their recapture histories we estimated survival, longevity, sex ratio, age groups and population size at each location. We found no evidence for survival differences between ages and sexes. However, the proportion of resighted individuals was lower for females, and the sex ratio was male-biased in all populations. Although we recorded few reproductive events, a high number of male-male agonistic interactions were registered around midday. During reproductive behavior, we observed brief wing displays as signals between males and females, and the formation of the tandem position, followed by the intramale sperm translocation and copulation (mean duration 11.3 min). After copulation, the pair in tandem looked for suitable sites to oviposit, and then the male broke tandem and perched on the vegetation while the female laid eggs partially or completely underwater. The recapture probability was time-dependent, which suggests that the alternation of rainy and sunny days during the study may be generating differences in the demography of the three *H. cruentata* populations." **19422.** Geraldo de Carvalho, F.; Duarte, L.; Nakamura, G.; Dubal dos Santos Seger, G.; Juen, L. (2021): Changes of phylogenetic and taxonomic diversity of Odonata (Insecta) in response to land use in Amazonia. *Forests* 2021, 12, 1061. <https://doi.org/10.3390/f12081061>: 15 pp. (in English) ["Changes in natural habitats for human use can alter the distribution of biodiversity, favoring species that are more tolerant to environmental disturbance. Usually, these species comprise clades of habitat generalists, which have biological mechanisms to colonize environments with different environmental conditions. However, such effects are still poorly understood for most biological groups, such as the Amazon odonates. Therefore, this study aims to evaluate the effects of land use along an environmental gradient on the phylogenetic and taxonomic diversity of Odonata in the Amazon. We tested the following hypotheses: In deforested areas (e.g., pasture for cattle, palm plantation, and logging), the Odonata community will be more taxonomically and phylogenetically impoverished than in forested areas. We assume that the modification of the natural habitat causes loss of specialist forest species and favors specialist species of open areas and/or habitat generalists. Data sampling was performed in 195 streams under different land-use types: livestock areas, palm monoculture, timber exploitation, and forest areas taken as reference sites. Our results showed that anthropogenic impacts affected the phylogenetic diversity of odonates and the increase in shrub vegetation was related to the increase in the phylogenetic diversity of communities. On the other hand, shrub vegetation is indicative of disturbed areas, where secondary vegetation predominates, with less canopy cover due to the absence or discontinuity of the native tree cover in these habitats. Nonetheless, species richness and abundance were not related to the effects of anthropogenic land use. Finally, our results suggest that the phylogenetic diversity of Amazonian odonates is related to riparian vegetation structure." **19423.** Guadin, B.; Gazzola, A.; Balestrieri, A.; Scribano, G.; Martín, J.; Pellitteri-Rosa, D. (2021): Effects of a group-living experience on the antipredator responses of individual tadpoles. *Animal Behaviour* 180: 90-99. (in English) ["Highlights: • Tadpoles reared alone were not very active even in predator-free tubs. • Predator-exposed tadpoles were bolder in the presence of conspecifics' cues. • However, this was observed only in tadpoles from the highest density treatment. Abstract: The tendency to aggregate during the larval stage is widespread and highly variable among anuran species. Several studies have highlighted the link between tadpole group density and their activity level, confirming that, usually, living in groups brings several antipredator benefits. However, nearly all studies have focused on the average behavioural responses of tadpoles tested in groups. In this study, we explored the effects of living in groups of three different sizes (1, 5 and 25 individuals per group) on the antipredator behaviour of individual green toad, *Bufo balearicus*, tadpoles. We first assessed their basal activity and then examined changes in mobility rate and total distance after exposure to the chemical cues of predatory dragonfly, *Aeshna cyanea*, larvae. For both the pre- and poststimulus activity levels, we also tested the effects of the presence of conspecifics' chemical cues in the experimental tub. Our results showed that (1) a previous brief (8 days) experience of group living is sufficient to affect the basal level of activity of individual tadpoles, which increased with group size; (2) tadpoles that were reared alone did not lower their activity further when exposed to predators' odour; (3) the antipredator response of high-density-reared tadpoles decreased in the presence of conspecifics' cues, supporting the so-called dilution effect, which, anyway, may need a minimum group size to be apparent. We conclude that both previous group-rearing experience and current perception of the surrounding environment may affect antipredator behaviour in individual tadpoles." **19424.** Guillermo, R.; Juen, L. (2021): Odonate ethodiversity as a bioindicator of anthropogenic impact. *International Journal of Odonatology* 24: 149-157. (in English) [Mnesarete pudica, harassment, courtship, contest, chase, patrol "The increasing use of dragonflies and damselflies as models in studies on biodiversity in the last decades has unraveled several features of natural processes and mechanisms for species conservation. Nevertheless, biodiversity is a polysemic concept that resolves multiple dimensions that, together, enroll what we observe as species and lineages diversity. One of these dimensions is Ethodiversity, which may represent the individual diversity of behavioral traits and higher organization levels. Hence, measures of Ethodiversity may be used as indicator tools to measure such dimensions of biodiversity. However, we still lack methods and protocols to measure this diversity. Therefore, here we addressed whether damselfly behaviors may act

as indicators of environmental impacts. We collected behavioral data of 120 males in two sites, one in an ecological reserve and another in an impacted habitat. Our results show differences in behavioral syndromes and behavioral integrity when comparing populations in impacted and conserved environments. In conclusion, we hope that these results stimulate future endeavors to create a methodological framework to assess behavioral diversity." (Authors)] Address: Guillermo, R., Lestes Lab, Univ. **19425.** Guillermo-Ferreira, R. (2021): Wing-clapping in the damselfly *Mnesarete pudica* - a mating call? (Odonata: Calopterygidae). *Odonatologica* 50(1/2): 43-54. (in English) ["Wing-clapping is a conspicuous and poorly understood behavioural trait in damselflies. Its function has long been debated and several hypotheses have been proposed to explain why damselflies clap their wings, even when there is no other damselfly nearby. Here, I outline the existing hypotheses: (i) the territorial declaration hypothesis, which suggests that wing-clapping is used by males to proclaim territorial ownership to rivals; (ii) the thermoregulation hypothesis, which suggests that wing-clapping cools the body; and (iii) the courtship hypothesis, which suggests that wing-clapping is integral to the courtship behaviour of males. To these I add a fourth hypothesis, the mating call effect, which states that males use wing-clapping as a conspicuous signal to attract mates, prior to courtship. I tested these hypotheses in the neotropical calopterygid *Mnesarete pudica*. The investigation was conducted in the field in Minas Gerais and São Paulo, Brazil, with frequencies of different behaviours being recorded by direct observation of marked individuals. The results show no support for the territorial, thermoregulation, or the courtship hypotheses. A strong association between wing-clapping and other potential signals such as brief flights and perch shifts is evident. I conclude that wing-clapping behaviour in *Mnesarete pudica*, and perhaps in other damselflies, may increase male conspicuousness to females and attract them to territories." **19428.** Haug, J.T.; Müller, P.; Haug, C. (2021): Fossil dragonfly-type larva with lateral abdominal protrusions and implications on the early evolution of Pterygota. *iScience* 24, 103162, October 22, 2021: 10 pp. (in English) ["Highlights: - A new dragonfly-type larva was found in Kachin amber (Myanmar, 99 million years old). - The larva possesses a terminal filum, which is not known in modern dragonfly larvae. - It also exhibits lateral abdominal protrusions where in other lineages gills occur. - This find makes an aquatic larva in the ground pattern of Pterygota more likely. Summary: Aquatic larvae are known in three early branches of Pterygota: Ephemeroptera, Plecoptera and Odonata. A common origin of these larvae has been suggested, yet also counterarguments have been put forward, for example, the different position of larval gills: laterally on the abdomen in Ephemeroptera, terminally in Odonata, variably in Plecoptera. We discuss recent fossil findings and report a new dragonfly-type larva from Kachin amber (Myanmar), which possesses ancestral characters such as a terminal filum, maintained in ephemeropterans, but lost in modern odonatan larvae. The new larva possesses lateral protrusions on the abdominal segments where in other lineages gills occur. Together with other fossils, such as a plecopteran retaining lateral gills on the abdomen, this indicates that lateral protrusions on the abdomen might have well been an ancestral feature, removing one important argument against the idea of an aquatic larva in the ground pattern of Pterygota." surface for implant applications. *Materials Today Chemistry* 22, December 2021, 100622: (in English) ["Highlights: • Mechano-bactericidal titanium can be easily and cheaply fabricated by hydrothermal etching. • Surface topographical features can be tuned based on defined fabrication parameters. • The bactericidal mechanism is due to mechanical interaction and downstream metabolic effects. • Efficacy is determined by surface morphology and biological characteristics of bacteria. • Hydrothermally etched titanium is permissive to host tissue and suitable for implantation. Abstract: The growing demand for titanium-based implants and the subsequent rise in implant-associated infections necessitate novel developments in anti-infective technologies. Recent research has drawn inspiration from nature to solve this problem. The nanoscale topography observed on cicada and dragonfly wings serves as a blueprint for synthetic analogs which seek to kill bacteria on contact through mechanical forces. This type of interaction has been dubbed the mechano-bactericidal effect. Various techniques have been utilized to mimic and improve upon these natural bactericidal surfaces. Alkaline hydrothermal etching is a simple and cost-effective technique to fabricate nanoscale protrusions on titanium and its alloys. This review aims to consolidate the current knowledge surrounding how fabrication parameters lead to varying surface topographies on titanium substrates, and subsequently, how surface topography and bacterial characteristics affect bactericidal activity. The bactericidal mechanism of hydrothermally etched titanium is inferred from comparisons with similar mechano-bactericidal biomaterials. The hostility of hydrothermally etched titanium toward bacteria is discussed in contrast to the observed host cell compatibility. Last, suggestions are made for the standardization of terminology in this emerging field.] Address: Vasilev, K., Academic Unit of STEM, Univ. of South Australia, Mawson Lakes, Adelaide, 5095, South Australia, Australia. **19431.** Hill, M.J.; Wood, P.J.; Fairchild, W.; Williams, P.; Nicolet, P.; Biggs, J. (2021): Garden pond diversity: opportunities for urban freshwater conservation. *Basic and Applied Ecology* 57: 28-40. (in English) ["Urbanisation is increasing globally, degrading terrestrial and freshwater habitats and reducing faunal and floral richness. Whilst the potential for garden ponds to serve as important biodiversity resources in urban areas has been documented in a limited number of studies, quantifying the contribution of garden

ponds to urban freshwater diversity has been largely neglected. This study aims to quantify the taxonomic richness, community composition and conservation value of aquatic macroinvertebrates in domestic garden and non-urban ponds. Taxonomic richness was significantly lower in garden ponds than non-urban ponds at an alpha and gamma scale. A greater richness of Odonata, Coleoptera, Gastropoda and Hemiptera were recorded in non-urban ponds. Garden ponds were found to support compositionally different macroinvertebrate communities compared to non-urban ponds, influenced by variation in water depth and conductivity. A total of 23 taxa were recorded from garden ponds only. Non-urban ponds had a significantly higher conservation value compared to garden ponds (87% of garden ponds were of low or moderate conservation value, while only 35% of non-urban ponds were in these categories). Although urban garden ponds currently support limited macroinvertebrate diversity and have lower conservation value, they contribute to the regional species pool and their potential to limit future urban biodiversity loss is significant. Given their high abundance and popularity within the urban landscape, clear guidance is required for pond-owners on how to best manage garden ponds to support and sustain biodiversity. For this to be achieved, research is required to increase fundamental understanding of urban pond ecology, and the development of evidence led garden pond management practices." **19432.** Ivanova, E.P.; Linklater, D.P.; Medina, A.A.; Le, P.; Baulin, V.A.; Nguyen, H.K.D.; Curtain, R.; Hanssen, E.; Gervinskas, G.; Ng, H.S.; Truong, V.K.; Luque, P.; Ramm, G.; Wösten, H.A.B.; Crawford, R.J.; Juodkazis, S.; Maclaughlin, S. (2021): Antifungal versus antibacterial defence of insect wings. *Journal of Colloid and Interface Science* 603: 886-897. (in English) ["Highlights: • We present a novel concept of dual defence against surface colonisation of insect wings by bacteria and fungi. • The antifouling and antibacterial properties of insect wings can be attributed to the unique combination of nanoscale structures on the wing surface. • The robust fungal-repelling properties of damselfly wing surfaces were demonstrated to arise from the presence of entrapped air, facilitated by the surface nano-topography. Abstract: Hypothesis: The ability exhibited by insect wings to resist microbial infestation is a unique feature developed over 400 million years of evolution in response to lifestyle and environmental pressures. The self-cleaning and antimicrobial properties of insect wings may be attributed to the unique combination of nanoscale structures found on the wing surface. Experiments: In this study, we characterised the wetting characteristics of superhydrophobic damselfly *Calopteryx haemorrhoidalis* wings. We revealed the details of air entrapment at the micro- and nano scales on damselfly wing surfaces using a combination of spectroscopic and electron microscopic techniques. Cryo-focused-ion-beam scanning electron microscopy was used to directly observe fungal spores and conidia that were unable to cross the air-liquid interface. By contrast, bacterial cells were able to

cross the air-water interface to be ruptured upon attachment to the nanopillar surface. The robustness of the air entrapment, and thus the wing antifungal behaviour, was demonstrated after 1-week of water immersion. A newly developed wetting model confirmed the strict Cassie-Baxter wetting regime when damselfly wings are immersed in water. Findings: We provide evidence that the surface nanopillar topography serves to resist both fungal and bacterial attachment via a dual action: repulsion of fungal conidia while simultaneously killing bacterial cells upon direct contact. These findings will play an important role in guiding the fabrication of biomimetic, anti-fouling surfaces that exhibit both bactericidal and anti-fungal properties." **19434.** Kaiser, A.; Parkinson, D. (2021): Projet LIFE Ardenne liégeoise: réponse des libellules et papillons de jour aux travaux de restauration. *Naturalistes Belges* 2021, *Les Naturalistes belges* 102(1): 1-29. (in French, with English summary) ["During the 20th century, human activities and the abandonment of traditional agricultural practices led to the degradation of natural habitats on the Belgian high plateaux of the Liège Ardennes. The goal of the Ardenne liégeoise LIFE project (2012-2020) was to restore these habitats and to improve ecological connectivity between the Plateau des Tailles and the Hautes Fagnes. The aim of this paper is to provide an overview of the responses of dragonflies and butterflies to restoration actions undertaken within the framework of the project. On the basis of standardised transects and data obtained from regional naturalist databases, we show a generally positive and rapid response of dragonflies. In particular, many peat bog specialists expanded their range within the perimeter of the project by its completion. Butterflies show a more contrasted response and species associated with wet grasslands show negative trends in the study region despite restoration actions. Dragonfly and butterfly monitoring should continue to confirm these trends and refine their evaluation....Increase in peatland specialist

species: All 8 typical bog species (*Aeshna juncea*, *A. subarctica*, *Coenagrion hastulatum*, *Leucorrhinia dubia*, *L. rubicunda*, *Orthetrum coerulescens*, *Somatochlora arctica* and *Sympetrum danae*) were recorded in the project area, both during the period 2006-2014 and 2015-2019. Fig. 7 shows the number of bog species observed per site for the periods 2006-2014 and 2015-2019, for the selection of 20 sites where water works were undertaken. In the period 2006-2014, seven of these sites had no peatland species and three had only one peatland species, showing that the majority of sites where waterworks were undertaken were initially (very) poor in peatland species. After the restoration work was completed, all sites had at least one peatland species, with the number varying between 1 and 8 (dominant value: 3). It was possible to observe all typical bog species on one site (Fagne de Malchamps) during the period 2015-2019. This increase in the number of sites in this selection of 20 sites is also visible on a more global scale: Table 5 shows the number of sites occupied by each peatland species at the scale of the project area (49 sites in total), for the two periods considered. Six species (*Aeshna juncea*, *Coenagrion hastulatum*, *Leucorrhinia dubia*, *L. rubicunda*, *Orthetrum coerulescens* and *Sympetrum danae*) were detected in a greater number of sites than in the reference period, while the number of sites occupied by the other two species (*Somatochlora arctica* and *Aeshna subarctica*) remained stable. For the majority of species, apparent local extinctions are nevertheless noted. Progression of pioneer species and the case of *Leucorrhinia pectoralis*: Pioneer species have also benefited greatly from the creation of new water bodies (on 24 of the 49 sites concerned by the project), as shown by the progress of *Libellula depressa* and *Ischnura pumilio*. The case of *Leucorrhinia pectoralis* is more complex. This species was first observed in 2010 at a site on the Plateau des Tailles (Grande Fange de Bihain), then again at the same location in 2012. In the following years, the number of sightings and the sites where the species is observed increases. Numbers vary greatly from one year to the next (maximum of seven individuals observed simultaneously at the same site) and observations are mainly concentrated in even-numbered years, especially in 2012 and 2018, years of leucorrhines influx. Of the 25 observations reported since 2010, 15 concerned single individuals and only one observation explicitly mentioned the presence of females. It should be noted that only two sites are frequented several years, which leads to a constant increase in the number of cumulative sites where the species is contacted. Thus, between 2010 and 2019, 14 sites had at least one record of *L. pectoralis*." (2021): Contamination status on the neonicotinoid insecticide for the habitats of endangered dragonfly *Libellula angelina* Selys, 1883 in Japan). *Tombo* 63: 1-7. (in Japanese, with English summary) ["*Libellula angelina* Selys, 1883 has been designated as a critically endangered species on the Red List of the Japanese Ministry of the Environment. Amongst Japanese dragonfly species its decline is particularly strong. The authors publish the results of the analysis of the occurrence of neonicotinoid-type agricultural chemicals performed in April 2019 of almost all breeding locations of this species. The analysis of 14 samples of 6 locations found low concentrations of clothianidin in three samples from two locations. On the other hand it detected the presence of Fipronil, which is known to affect the larvae of

dragonflies strongly, in all samples. Moreover, in eight of the fourteen samples the pollution concentrations exceeded the environmental standard. It is possible that the recent decline of this species is caused by tins chemical substance." (Authors)] Address: Karube, H., Kanagawa Prefect. Mus. Nat. Hist., 499 Iryuda, Odawara, Kanagawa, 250, Japan. E-mail: paruki@nh-kanagawa-museum.jp

**19439.** Kawata, N., Yoshida, M., Udono, K. & Sugimura, M. (2021): Behaviour and morphological characteristics of a gynandromorph individual of *Nannophya pygmaea* Rambur, 1842 (Libellulidae: Odonata). *Tombo* 63: 8-15. (Japanese, with English summary) ["A gynandromorph of *N. pygmaea* was observed in Toyota City, Aichi Prefecture. There is no detailed report on the behavior of gynandromorph individual of Odonata in Japan. Although no reproductive behavior was observed, the gynandromorph had mud on its distal abdomen, which implies ovipositional or oviposition-like behavior. In addition, no territorial behavior like males was performed. These observations suggest that the behavior of this specimen may be closer to that of females, rather than of males. In its morphology, female characteristics appear strongly, except for the left side of the head and thorax, suggesting its behavior may related." **19442.** Kietzka, G.J.; Pryke, J.S.; Gaigher, R.; Samways, M.J. (2021): 32 years of essential management to retain value of an urban dragonfly awareness pond. *Urban Ecosystems* 24: 1295-1304. (in English) ["Pond construction in urban areas can mitigate loss of aquatic insects by providing refuges. Urban ponds are also an interface between civil society and aquatic insects, especially via charismatic dragonflies. Ponds have therefore been constructed specifically for dragonfly conservation awareness in many countries. Yet they require regular management, especially when an inflow to a shallow pond supplies inorganic and organic material, leading to vegetation overgrowth and natural infilling, rendering a pond back into a stream, unsuitable for many lentic species. Here, we assess changes in dragonfly diversity over a 32-year period at a pond constructed for dragonfly conservation awareness, and which underwent system changes: stream->pond vegetation overgrowth and infilling and then following restoration from stream->pond. Adult male dragonflies and 13 environmental variables were recorded along 31 transects, and compared with previous data collected at the same sites before pond construction and then in the short- and medium-term after. Years when the system comprised a pond had higher dragonfly abundance and species richness than when a stream, and both increased after the pond was restored. Shortly after restoration, the dragonfly assemblage closely resembled that of the earlier pond. Vegetation cover and alien vegetation presence were significant drivers of dragonfly assemblage change and decreased dragonfly abundance and species richness. Lessons learned here for maintaining a dragonfly awareness pond include periodical dredging to remove excessive vegetation overgrowth and infilling from organic and inorganic matter, and aim for high microhabitat heterogeneity using selective management of marginal vegetation, alongside a range of flow regimes." (Authors)] Address: Kietzka, Gabriella, Dept of Conservation Ecology & Entomology, Stellenbosch Univ., Private Bag X1, Matieland 7602, South Africa. E-mail: gabikietzka@gmail.com

**19444.** Kolar, V.; Vlašánek, P.; Boukal, D.S. (2021): The influence of successional stage on local odonate communities

in man-made standing waters. *Ecological Engineering* 173, December 2021, 106440: 10 pp. (in English) ["Highlights: • We compared odonate communities in sandpit ponds and fishponds. • Community composition differed between habitat types despite similar diversity. • Aquatic vegetation, water depth and bottom substrate shaped local communities. • Diverse habitats beget diverse odonate communities in man-made standing waters. Abstract: Man-made freshwater habitats are an important part of the European landscape, especially in areas with mostly absent or degraded natural habitats. To assess the role of different man-made standing waters in anthropogenic landscapes, we surveyed adult odonate communities in a cluster of 20 water bodies including fishponds and sandpit ponds in early and ongoing successional stages. We found 35 odonate species (i.e., 47% of the fauna of the Czech Republic), but their presence differed significantly among the three habitat types. The highest species diversity, driven mainly by the presence of generalists, was found in fishponds. Sandpit ponds in an early successional stage hosted the least diverse communities dominated by pioneer and vagrant species. Specialist species occurred in both types of sandpit ponds, especially those in an ongoing successional stage, more than in fishponds. Although the dragonfly biotic index did not differ among the three types of localities, all four species from the national Red list recorded during the study occurred only in sandpit ponds. The main environmental drivers of local odonate communities included the coverage of shoreline by emergent vegetation, water depth and bottom substrate; the latter two characteristics largely corresponded to the distinction between sandpit ponds and fishponds. We conclude that both sandpit ponds and fishponds play an important role in maintaining freshwater biodiversity that requires a mosaic of habitats in different successional stages." **19445.** Koperski, P. (2021): Linear and nonlinear effects of nutrient enrichments on the diversity of macrobenthos in lowland watercourses. *Aquatic Ecology* 55: 1011-1031. (in English) ["The study concerns the relationships between taxonomic, functional and phylogenetic diversity of benthic invertebrates inhabiting watercourses and abiotic parameters associated with excessive nutrients load (concentration of Kjejdahl nitrogen, nitrates, phosphorus, organic carbon and dissolved oxygen, values of BOD5 and electrolytic conductivity). The research used data on the species composition of leeches, molluscs and larval forms of odonates and chironomid dipterans. Their description using mathematical functions allowed to determine whether the diversity reaches maximal values at extreme or moderate values of nutrients enrichment. In most cases, statistically significant relationships were unimodal—the highest diversity was observed at intermediate values of nutrients content and associated parameters, however the different patterns of relationships, monotonic and inverse quadratic, were also observed. Indirect impacts of nutrients enrichment on diversity

were found as the most significant relationships. Significant responses of functional diversity were clearer and stronger than responses of taxonomic and phylogenetic diversity. The identification of fauna to the species level allowed for obtaining precise results that could enable selection of appropriate parameters for effective assessment of environmental degradation." (Author) "The most common and the most numerous species were: *Calopteryx splendens*, *C. virgo*, *Platycnemis pennipes* and *Gomphus vulgatissimus* ] Address: Koperski, P., Institute of Functional Biology & Ecology, Faculty of Biology, Univ. of Warsaw, Biological & Chemical Research Center, Zwirki i Wigury 101, 02-089 Warsaw, Poland. **19447.** Laakso, L.K.; Ilvonen, J.J.; Suhonen, J. (2021): Phenotypic variation in male *Calopteryx splendens* damselflies: the role of wing pigmentation and body size in thermoregulation. *Biological Journal of the Linnean Society* 134(3): 685 - 696. (in English) ["For ectothermic insects, their colour and size are important determinants of body temperature: larger bodies require more heat to reach a certain temperature, and dark colours absorb heat more efficiently. These dark colours are expressed using melanin, which has been intimately linked with the thermoregulatory capabilities of insects. Melanin is also linked with immune defence and is often used as a secondary sexual character in insects. There is a potential trade-off situation between thermoregulatory capabilities, immune defence and secondary sexual characters, all of which use melanin. Some *Calopteryx* damselflies, such as *Calopteryx splendens*, have melanin-based wing pigmentation that is sexually selected and drives intra- and interspecific territorial aggression. Our goal was to study experimentally how the wing pigmentation and body size of *C. splendens* males affect their thermoregulation and, especially, their ability to become active (hereafter, 'activate') after being cooled down. Our results were in line with our hypotheses, showing that individuals with larger wing spots had significantly faster activation times than those with smaller wing spots, and that individuals with larger body size had significantly slower activation times than those with smaller body size. Both variables showed an interaction and are

therefore important in damselfly warm-up and activation. We discuss the role of wing pigmentation and thermoregulation in the behavioural patterns observed in *Calopteryx* species." (Authors)] Address: Laakso, Linda, Dept Biol., Univ. of Turku, FI-20014 Turku, Finland. E-mail: lklaak@utu.fi

**19448.** Landmann, M.; Schlick-Steiner, B.; Steiner, F.M.; Landmann, A. (2021): Connectivity within isolation: dispersal, population genetics, and conservation of the rarest European damselfly. *Insect Conservation and Diversity* 14(6): 800- 813. (in English) ["1. *Coenagrion hylas* (Trybom, 1899) has a very limited distribution in Europe, lives in very small, isolated populations, has rather specialised habitat demands, and is regarded as the rarest damselfly of Europe. 2. Using a combination of capture-mark-recapture and population genetics, we aimed to evaluate the state of the populations in the Tyrolean Lech valley and to test whether exuviae from this species are usable as a DNA source. DNA was extracted from midleg tibiae and exuviae and genotyped with species-specific microsatellite markers. The results from the capture-recapture and the genetic methods were congruent. 3. *C. hylas* has an unexpectedly high tendency to disperse within the valley, covering distances of up to 30 km, and lives longer than other damselflies, with an average longevity of 12 days and a maximum lifespan of at least 40 days. Low inbreeding coefficients and low ranges of genetic differentiation across sites provide evidence of panmixia, with no clear signs of inbreeding. The current population size is estimated at 1150 males based on the recapture data. 4. We further demonstrated that exuviae deliver a sufficient amount of DNA, which will be important for future monitoring. Although *C. hylas* currently shows appropriate viability at most Lech valley sites, our study indicates that management measurements, such as creating stepping stone habitats, are crucial to maintain the current population status. Given the high dispersal capability of the species, such management measurements seem promising." (Zygoptera: Lestidae). *Zootaxa* 4990(3): 511-541. (in English) ["The Brazilian fauna of Lestidae contains two genera (*Archilestes* Selys, 1862 and *Lestes* Leach in Brewster, 1815) with 14 species, many of which are poorly defined and/or known only by primary literature. To improve the knowledge of the Brazilian species of the genus *Lestes* we examined 97 specimens pertaining to 11 of the 13 described species. Additionally, a new species is described here in honor to Prof. Dr. Paulo De Marco Júnior: *Lestes demarcoi* (Holotype and Allotype: Brazil: Amazonas, Manaus, Reserva Adolpho Ducke, Acará trail, 02°55'46" S & 59°58'22" W, 62 m, 13.iv.2009, collected in tandem, U.G. Neiss leg. and deposited in FAAL). Diagnostic illustrations of all species are provided. Color photographs of live individuals of *Lestes dichrostigma* Calvert, 1909, *Lestes forficula* Rambur,

1842 and *Lestes paulistus* Calvert, 1909 are also present." (Authors)] Address: Lencioni, F.A.A., Rua Anibal, 216, d. Coleginho, Vila Zezé, Jacareí, CEP (ZIP) 12310-780, São Paulo, Brazil. E-mail: lencioni.odonata@gmail.com

**19450.** Liberto, B.; Studinski, J. (2021): Abundance and habitat associations of disjunct and regionally rare populations of *Leucorrhinia glacialis* and *L. hudsonica* in the Appalachian Mountains (Odonata: Libellulidae). *Odonatologica* 50(3/4): 187-202 -202. (in English) ["*Leucorrhinia glacialis* and *L. hudsonica* are boreal anisopterans common in Canada and the north-eastern USA but are rare in central Appalachia, where they are isolated at the extreme southern edge of their range. Adult and larval anisopteran surveys were conducted at 24 wetlands in central Appalachia to determine the number of populations and habitat associations of *L. glacialis* and *L. hudsonica*. A mark-recapture study at wetlands containing either of the two target species was conducted to estimate the population size and daily survival. Cormack-Jolly-Seber (CJS) and Jolly-Seber analyses were conducted for the populations of *L. glacialis* and *L. hudsonica*, and multivariate techniques explored habitat and community associations. *L. hudsonica* were found in three wetlands, with the largest population estimated at 34 individuals. *Leucorrhinia glacialis* were found in two wetlands, with one population estimated at 351 and the other being too large (i.e., not enough recaptures) to apply CJS methods. All wetlands containing populations of *L. glacialis* and *L. hudsonica* were permanent, acidic, and fishless, and dispersal from their natal ponds was rarely observed. Most of the wetlands containing these species were created by beaver, with some ponds rapidly shrinking due to a lack of dam maintenance. The isolation and rarity of habitats supporting *L. glacialis* and *L. hudsonica* in this region, coupled with the species' poor dispersal abilities and apparent reliance on beaver, suggests an uncertain future for these locally rare anisopterans. The protection of these rare habitats and populations, along with possible translocation efforts and beaver management, may increase these species' chances of persistence." **19451.** Lima, J.C.; Moreira, R.A.; Neto, A.J.G.; Andrade, D.; Freitas, E.C.; Daam, M.A.; Rocha, O. (2021): Metal toxicity can affect dragonfly nymphs and ostracods predation rates and food selectivity: Ecological implications on food webs. *Water, Air, & Soil Pollution* 232, issue 7, id. 288. (in English) ["Predation is known to play a prominent role in maintaining ecosystem structure and functioning. Despite metals being known to potentially affect predation in aquatic ecosystems, few studies have been conducted, so far, with the aim of evaluating this interplay. In the present study, the effects of four metal salts (copper, cadmium, mercury, and manganese) on the feeding rates and food preference of *Tremea cophisa* and of the ostracod *Chlamydotheca* sp. were studied by performing laboratory ecotoxicity tests. Food preference was evaluated by offering four prey species to dragonfly nymphs and three to adult large ostracods. In general, the food preference of both predator species after

being exposed to metal salts was not altered, compared with controls, but the feeding rate of *T. cophisa* decreased in comparison with controls, after exposure to each metal salt, except manganese. Contrastingly, predation rates of *Chlamydotheca* sp. increased after metal salt exposure. This difference in response can be explained by differences in life-history traits of these two organisms. Both species individuals preferred soft-bodied prey (Oligochaeta, Chironomidae) over water-dwelling crustaceans that are likely to be more difficult to prey upon. Tests evaluating the effects of metals and other chemicals on predation behavior may lead to a better understanding of biotic interactions that can be restricted by chemical stress, improving our understanding of possible food web disruptions underlying chemical stress." **19452.** Matthews, P.G.D. (2021): How insects transition from water to air: Respiratory insights from dragonflies. *Comparative Biochemistry and Physiology Part A: Molecular & Integrative Physiology* 253, March 2021, 110859. (in English) ["Highlights: • Dragonfly nymphs reinvaded aquatic environment using tidally-ventilated rectal gill. • Nymphs hyperventilate in hypoxia but show no response to hypercapnia. • Nymphs maintain high hemolymph pCO<sub>2</sub> compared with other water-breathing animals. • Approaching metamorphosis nymphs breathe bimodally, increase pCO<sub>2</sub> and HCO<sub>3</sub><sup>-</sup>. • Dragonflies experience small rise in pCO<sub>2</sub> and HCO<sub>3</sub><sup>-</sup> as they move to breathing air. Abstract: The transition of animal life from water onto land is associated with well-documented changes in respiratory physiology and blood chemistry, including a dramatic increase in blood pCO<sub>2</sub> and bicarbonate, and changes in ventilatory control. However, these changes have primarily been documented among ancestrally aquatic animal lineages that have evolved to breathe air. In contrast, the physiological consequences of air-breathing animals secondarily adopting aquatic gas exchange are not well explored. Insects are arguably the most successful air-breathing animals, but they have also re-evolved the ability to breathe water multiple times. The juvenile life stages of many insect lineages possess tracheal gills for aquatic gas exchange, but all shift back to breathing air in their adult form. This makes these amphibiotic insects an instructive contrast to most other animal groups, being not only an ancestrally air-breathing group of animals that have re-adapted to life in water, but also a group that undergoes an ontogenetic shift from water back to air across their life cycle. This graphical review summarizes the current knowledge on how blood acid-base balance and ventilatory control change in the dragonfly during its water-to-air transition, and highlights some of the remaining gaps to be filled." (in English) ["Risk-spreading behaviour is often exhibited by animals as a response to unpredictably variable environments. Using field and laboratory studies, we tested the hypothesis that *Sympetrum vicinum* dragonflies spread the risks of winter environments by laying eggs across a terrestrial-aquatic gradient. *Sympetrum vicinum* eggs that overwintered in terrestrial and benthic-limnetic habitats had significantly higher hatching success compared with eggs that overwintered in littoral sites. Low success may have been caused by hypoxia due to excess sediment in the littoral samples in the lab. While hypoxia experienced under winter conditions (4°C) had no negative effect on hatching success, hatching in hypoxic and anoxic water significantly decreased hatching success. Opportunistic egg predation by a winter-active caddisfly significantly decreased egg hatching success. Because *S. vicinum* eggs have a relatively low supercooling point (-26.25°C), freezing may not be a significant source of mortality in terrestrial or aquatic sites. By ovipositing in both terrestrial and aquatic environments, female dragonflies may be balancing the unpredictable risks of both the failure to inundate the eggs and egg predation. Our research highlights the potential for biotic interactions during winter to shape the behaviour and life-history of aquatic invertebrates." **19457.** McDevitt-Galles, T.; Carpenter, S.A.; Koprivnikar, J.; Johnson, P.T.J. (2021): How predator and parasite size interact to determine consumption of infectious stages. *Oecologia* 197(3): 551-564. (in English) ["Parasites are important players in ecological communities that can shape community structure and influence ecosystem energy flow. Yet beyond their effects on hosts, parasites can also function as an important prey resource for predators. Predators that consume infectious stages in the environment can benefit from a nutrient-rich prey item while concurrently reducing transmission to downstream hosts, highlighting the broad importance of this interaction. Less clear, however, are the specific characteristics of parasites and predators that increase the likelihood of consumption. Here, we determine what combination(s) of predator and parasite morphological traits lead to high parasite consumption. We exposed the infectious stages (cercariae) of five trematode (fluke) taxa to aquatic insect predators with varying foraging strategies and morphologies. Across the 19 predator-parasite combinations tested, damselfly predators in the family Coenagrionidae were, on average, the most effective predators of cercariae, consuming between 13 and 55% of administered cercariae. Large-bodied cercariae of *Ribeiroia ondatrae* had the highest average vulnerability to predation, with 37-48% of cercariae consumed. The interaction between predator head width and cercariae tail size strongly influenced the probability of consumption: small-bodied predators were the most effective consumers, particularly for larger tailed parasites. Thus, the likelihood of parasite consumption depended strongly on the relative size between predator and parasite. Our study helps establish that predation on free-living parasites largely follows a broader predator-prey framework. This will help to identify which predator and parasite combinations will likely have high consumptive interactions, potentially reducing parasite transmission in natural populations." **19458.** Mendoza-Penagos, C.C.; Batista Calvão, L.; Juen, L. (2021): A new biomonitoring method using taxonomic families as substitutes for the suborders of the Odonata (Insecta) in Amazonian streams. *Ecological Indicators* Volume 124, May 2021, 107388: 12 pp. (in English) ["Highlights: • The family-level provides an effective tool for the biomonitoring of streams using odonates. • The use of family-level keeps essential ecological information of the species-level community. • Aggregate measures such as abundance can be very useful when higher taxonomic levels are used in biomonitoring. • The use of family-level could be advantageous in terms of time and financial resources. Abstract: Odonata have been widely used as bioindicators of environmental quality in different types of ecological research. In general, the taxonomic level used is the species, but higher taxa, such as the family, have received less attention. Assuming that higher taxa can reproduce the impacts that occur at the species level, we use facets of diversity at the community to assess if Odonata families could be an efficient tool for the

assessment of environmental impact in Amazon streams. We first assessed to what extent each family retains ecological information from the ecological diversity of the species of the suborder (Anisoptera or Zygoptera). We then quantified the degree of congruence between different taxonomic levels in the Odonata. Next, we evaluated the effects of environmental integrity on the facets of diversity of the families. Finally, we evaluated whether ecological thresholds can be detected using a family-level approach. We sampled adult odonates in 98 streams in the eastern Amazon, in the municipalities of Paragominas, Santarém, and Belterra, in the Brazilian state of Pará. The habitat integrity index (HII) was used to assess the environmental integrity of each stream. The congruence between the different taxonomic levels was evaluated using a Procrustes analysis. The degree of correlation of diversity facets was evaluated between families and each suborder. Linear mixed models and matrix regressions were used to measure the influence of environmental integrity on the diversity facets of the families. Higher-level ecological thresholds were detected using the TITAN analysis. The results of the analyses indicated a high degree of congruence between species-level and higher levels (family and suborder). The ability of the families to represent the diversity facets of the suborder is influenced by the abundance of individuals and the number of species in the family. The environmental integrity of the streams affects the facets of diversity of the families systematically, although cumulative measurements, such as abundance, appeared to be more advantageous as biomonitoring tools. The similarity of the responses observed at species and family levels supports the use of odonate families for the detection of ecological thresholds in stream environments. The sum of the evidence indicates that a family-level approach is effective for the identification of alterations in the environmental integrity of streams, providing valuable insights into the facets of diversity of the odonate community. The adoption of a family-level approach in environmental monitoring programs could optimize the investment of resources, in particular through the identification of specimens by non-specialists, permitting a significant increase in sampling effort and replication." **19460.** Nafisah, N.A.; Soesilohadi, R.C.H. (2021): Community structure of dragonfly (Ordo: Odonata) in natural forest and tourist sites Petungkriyono Forest, Central Java, Indonesia. *Journal of Tropical Biodiversity and Biotechnology* 6(3): 9 pp. (in English) ["Petungkriyono forest is a tropical rainforest with high biodiversity. The increasing tourism activities in Petungkriyono lead to land conversion. Dragonfly (order Odonata) is a good bioindicator for aquatic and terrestrial. This study aimed to compare the community structure of Odonata in natural forests and tourist sites. The method of collecting imago Odonata was done by direct searching, samples were captured using sweep netting. The results showed that the dragonflies found in all locations consisted of the same family, 2 families (Gomphidae and Libellulidae) from the suborder Anisoptera and 6 families (Calopterygidae, Chlorocyphidae, Coenagrionidae, Euphaidae Platycnemididae, and Platystictidae) from Zygoptera. The total species of dragonflies found in Sokokembang were 15 species with a total of 293 individuals, Tirta Muncar 13 species of 287 individuals, Karanggondang 17 species of 276 individuals, and Curug Lawe 14 species of 242 individuals. The highest relative abundance of individuals was in the natural forest of Sokokembang is *Drepanosticta spatulifera* (26.28%) and in Karanggondang *Vestalis luctuosa* (24.64%), while in the tourist forests of Tirta Muncar and Curug Lawe were *Euphaea variegata* (34.84% and 28.51%). The structure of the Odonata community is based on the Shannon-Wiener diversity index in the natural forests of Sokokembang (2.18) and Karanggondang (2.21) at the tourist sites of Tirta Muncar (1.84) and Curug Lawe (2.11). The results showed that the structure of the Odonata community based on the level of the diversity index value, evenness index, and dominance index in natural forests and tourist sites in Petungkriyono forest was not significantly different." **19461.** Nilsson-Örtman, V.; Rowe, L. (2021): The evolution of developmental thresholds and reaction norms for age and size at maturity. *PNAS* 118(7) e2017185118 (in English) ["Significance: Why most—but not all—organisms mature earlier in better growth conditions remains a mystery. Theory suggest that a solution may lie in the existence and evolution of critical size thresholds during development. The threshold model makes two unique predictions on the evolution of reaction norms between species and the effect of food reductions within species. We test this model experimentally using five damselfly species aligned along an ephemeral–permanent gradient, finding strong support for each prediction. Permanent habitats favor large thresholds and early maturation in better conditions, whereas ephemeral habitats favor small thresholds producing the rarer pattern with delayed maturation. The evolution of developmental thresholds is critical for understanding natural and human-induced variation in age and size at maturity. Developing organisms typically mature earlier and at larger sizes in favorable growth conditions, while in rarer cases, maturity is delayed. The rarer reaction norm is easily accommodated

by general life history models, whereas the common pattern is not. Theory suggests that a solution to this paradox lies in the existence of critical size thresholds at which maturation or metamorphosis can commence, and in the evolution of these threshold sizes in response to environmental variation. For example, ephemeral environments might favor the evolution of smaller thresholds, enabling earlier maturation. The threshold model makes two unique and untested predictions. First, reaction norms for age and size should steepen, and even change sign, with decreases in threshold size; second, food reductions at sizes below the threshold should delay maturation, while those occurring after the threshold should accelerate maturation. We test these predictions through food manipulations in five damselfly species that theory suggests should differ in threshold size. The results provide strong support for the threshold model's predictions. In all species, early food reductions delayed maturation, while late reductions accelerated maturation. Reaction norms were steeper, and the effect of food reductions changed from decelerating to accelerating at a much smaller size in species from ephemeral habitats. These results support the view that developmental thresholds can account for the widespread observation of negative correlations between age and size at maturity. Moreover, evolution of the threshold appears to be both predictable and central to the observed diversity of reaction norms for age and size at maturity." (2021): Heavy metals accumulation in dragonflies (Odonata) and their habitats in district Swabi, Khyber Pakhtunkhwa, Pakistan: Assessing dragonfly bionomics in the region. *Bulletin of Environmental Contamination and Toxicology* 107(5): 838-847. (in English) ["The current study aimed to examine the bionomics of dragonflies and heavy metal accumulation in their bodies and environment (sediments and water) from district Swabi, Khyber Pakhtunkhwa, Pakistan. A total of 1683 dragonflies were collected from May to September, 2018 in 4 tehsils (administrative subdivisions) of district. *Orthetrum prunosum neglectum* was the most abundant species followed by *O. anceps* and *O. chrysostigma luzonicum*. Highest abundance was observed in July and August corresponding to maximum temperature and rainfall. Dragonflies displayed preferable abundance within agricultural lands and on elevation ranging from 206 to 506 m. Heavy metal analysis of sediments and water samples from 4 tehsils showed significant differences in mean concentrations of Pb, Zn, Cu, and Fe. Abundance among districts was negatively associated with Fe levels in water while the species diversity had a significant positive relationship with Fe in sediments. Accumulation of metals in each body part significantly varied among species. *N. tullia tullia* and *O. anceps* specifically demonstrated their tolerance to high concentrations of heavy metals." **19465.** Oldak, K.A. (2021): Proposal of the monitoring methodology of the Green Hawker *Aeshna viridis* Eversmann, 1836 (Odonata: Aeshnidae). *Folia Pomer. Univ. Technol. Stetin., Agric., Aliment., Pisc., Zootech.* 358(57): 15-28. (in English) ["*A. viridis*, ... is listed in Appendix II of the Bern Convention as well as Annex IV of the Habitats Directive. The decline in the range and abundance of *A. viridis* is associated with a strong dependence of this species on the presence of *Stratiotes aloides* in the water body and results from a decrease in the number of suitable habitats. So far, attempts to develop a monitoring methodology for this species have been made in several European countries, including Sweden, Denmark and the Netherlands. This article presents a proposal for a monitoring methodology based on the evaluation of indicators of population condition in the

form of exuviae density and number of adults, and indicators of habitat condition: the area of the water body covered by *S. aloides*, the presence of dense and undivided patches of *S. aloides*, succession in the water body and anthropopressure. The concept of population condition assessment methodology is based on observation of adult specimens and collecting exuviae, avoiding larvae sampling, which is invasive and associated with technical difficulties. The concept of the habitat condition assessment methodology, in turn, is based on strong association between *A. viridis* and *S. aloides*. It is proposed to monitoring *A. viridis* population on a minimum of several research areas within the country, on a two-year cycle. The presented proposal of the monitoring methodology requires pilot studies to be carried out within the *A. viridis* localities in order to determine the validity of assumptions made in the monitoring methodology." **19466.** Oliveira de Resende, B.; Santos Ferreira, V.R.; Juen, L.; Silvério, D.; Ramos Cabette, H.S. (2021): Seasonal fluctuations in the structure of the larval odonate community of a stream in the Cerrado–Amazon forest transition zone. *Aquatic Ecology* 55: 861-873. (in English) ["Climatic seasonality provokes considerable variability in the physical conditions of streams. Although few studies have assessed systematically the temporal effects of climate on aquatic communities, the diversity and structure of odonate larval assemblages (suborders Anisoptera and Zygoptera) are predicted to be influenced by seasonality. To evaluate this hypothesis, we tested the predictions that (1) the genera and abundance richness of zygopteran and anisopteran larvae will decrease during periods of high precipitation, (2) the genera richness and abundance of the two suborders will be associated inversely with temperature, and (3) the composition of the zygopteran assemblage will be more affected by seasonality, in particular precipitation, than that of the Anisoptera, whose composition will be influenced primarily by temperature. We collected odonate larvae every three months over a 6-year period at a stream located in the Cerrado–Amazon forest transition zone and compared these data with data on the local climate from the same period. Our results indicate that the seasonal variation in precipitation had a significant effect on the abundance of both odonate suborders, but that, while the anisopteran genera richness was affected by precipitation, the zygopteran richness was not. We showed that temperature affected the abundance of both suborders, but had no effect on genera richness. As we predicted, the composition of the zygopteran larval assemblage was affected more by the climatic variables than the Anisoptera. In addition, while the Zygoptera were affected primarily by precipitation, the Anisoptera were influenced most by temperature. The results indicate that the timing of the emergence of odonate larvae is synchronized with the months preceding the rainy season, when a high density of larvae are recorded, which may reflect a strategy for both the avoidance of the effects of fluctuations in water

levels and the exploitation of the relatively abundant food sources found in the terrestrial environment. Temperature also appears to contribute to this synchrony, by either accelerating or delaying the process of larval emergence." **19468.** Oliveira-Junior, J.N.B.; Teodósio, M.A.; Juen, L. (2021): Patterns of co-occurrence and body size in dragonflies and damselflies (Insecta: Odonata) in preserved and altered Amazonian streams. *Austral Entomology* 60(2): 436-450. (in English) ["Interspecific interactions, such as competition, are among the key factors that determine the distribution, abundance and diversity of organisms in natural communities of aquatic ecosystems. However, a marked reduction in the environmental integrity of streams may lead to modifications of the natural dynamics of these communities, including co-occurrence patterns and body size. In the Amazon, the replacement of forests by production systems is one of the leading causes of alterations to riverine ecosystem. The insects of the order Odonata (dragonflies and damselflies) are predators known to compete for environmental resources but are also sensitive to environmental changes such as those caused by shifts in land use. In this scenario, the present study evaluated species co-occurrence and body size patterns in adult odonates found at preserved and altered Amazonian streams, to determine whether there are morphological differences among the species that enable their coexistence. During the study, 98 streams in the eastern Amazon region were sampled, and a habitat integrity index (HII) was used to evaluate the integrity of each stream (based on variables such as the condition of the riparian vegetation and channel, and land use). Ten male individuals were selected from each species, and nine morphometric measurements were taken from each individual. A total of 3588 specimens were collected and distributed in nine families, 49 genera and 134 species. We found a non-random pattern of co-occurrence in the species of the

odonate suborder Zygoptera and a random pattern in the Anisoptera, in both preserved and altered streams. We found morphological divergence between pairs of zygopteran species, in the whole sample and both categories of stream integrity separately. No such morphological divergence was found in the pairs of anisopteran species. The distribution patterns of odonate species are limited by specific environmental processes, especially in preserved environments and in specialists, such as most zygopterans. Zygopteran species have more specific microhabitat requirements, which could explain this pattern, whereas anisopterans prefer open environments, which usually have a greater supply of resources, although there tends to be less microhabitat heterogeneity, which leads to reduced competition. Given this, future studies should use limiting similarity (e.g. morphological attributes) in addition to environmental and spatial factors to better understand the factors structuring these communities. Among these mechanisms, the effects of common ancestry (phylogenetic inertia) and biogeography are important factors that should also be considered in future studies." **19470.** Parr, A.J. (2021): Migrant and dispersive dragonflies in Britain during 2020. J. Br. Dragonfly Society 37(2): 69-81. (in English) ["Following a dramatic season in 2019, the year 2020 turned out to be a quieter one for migrant dragonflies in Britain, though there were still several highlights. A number of these probably relate to the legacy of past influxes, but significant fresh immigration also clearly took place. The migrant season started with a few mature *Sympetrum fonscolombii* arriving during mid-late May, but by early June several instances of local emergence by this species had also been reported. Successful overwintering of larvae resulting from breeding attempts made during the species' near record breaking year in 2019 had presumably been aided by the mild winter of 2019/20. *Anax parthenope* also started to appear in early June. In many ways, the highlight of spring was, however, the discovery of significant numbers of *Aeshna isoceles* in the Weymouth area of Dorset, almost 250 km from the nearest known UK breeding

population. Although the evidence is only circumstantial, it could well be that these sightings reflect a recently-established breeding population, perhaps initiated by migrants arriving during 2018 when *A. isoceles* was noted in the adjacent county of Devon. Late spring and summer saw further appearances of *S. fonscolombii* and *A. parthenope*, with the latter species going on to have an excellent year, with reports from some 75 sites. Although many individuals must have been immigrants, *A. parthenope* does now also seem to be becoming increasingly established as a resident in Britain. Another highlight of summer was the good showing by *Aeshna affinis*, which was reported not just from its Essex and Kent strongholds, but also from many other areas of southern Britain. This is the third year in a row that records have been quite widespread, and both the establishment of new breeding populations and an increase in immigration and/or internal dispersal seem to be involved. Finally, also of note during mid 2020 were several records of *Ischnura pumilio* well away from the species' core range. The later part of the season saw some large gatherings of *Aeshna mixta*, plus an unexpected series of records of this species caught overnight in moth traps, the exact significance of which currently remains uncertain though it may well reflect night-time migration. Also of interest were a scattering of records of locally-bred second-generation *S. fonscolombii*, though in unexceptional numbers. Mid September saw the start of a substantial influx of *Anax ephippiger* which went on until November. Once a great rarity in Britain, arrivals of *A. ephippiger* are now very much 'expected', particularly in autumn. It will be informative to see whether this trend is sustained." **19472.** Pereira Mendes, T.; Montag, L.F.; Alvarado, S.T.; Juen, L. (2021): Assessing habitat quality on alpha and beta diversity of Odonata larvae (Insect) in logging areas in Amazon forest. Hydrobiologia 848: 1147-1161. (in English) ["The present study evaluated the effects of habitat quality on the alpha and beta diversity of odonate larvae under conditions of reduced impact and conventional logging. We hypothesized that the variation in the abiotic conditions found in areas of conventional logging would result in a greater loss of alpha and beta diversity in these areas in comparison with areas of reduced-impact logging and native forest. The

study area was located in northeastern Pará state, in northern Brazil. We analyzed data from 10 control streams, located in areas of preserved native forest, 11 streams in forest harvested by reduced-impact logging, and nine streams in areas that had been logged conventionally. Environmental factors such as dissolved oxygen, woody debris, water temperature, sediments, and canopy cover were the principal predictors of the diversity of the Odonata. Our results showed that turnover was the principal component structuring beta diversity in the three areas (native forest, reduced impact and conventional logging). The results of the present study indicate that management initiatives based on reduced-impact logging techniques could be adopted to guarantee socio-economic benefits while minimizing the impacts of logging on local biodiversity." **19475.** Pintanel, P.; Tejedo, M.; Salinas-Ivanenko, S.; Jervis, P.; Merino-Viteri, A. (2021): Predators like it hot: Thermal mismatch in a predator-prey system across an elevational tropical gradient. *Journal of Animal ecology* 90(8): 1985–1995. (in English) [Ecuador "Climate change may have dramatic consequences for communities through both direct effects of peak temperatures upon individual species and through interspecific mismatches in thermal sensitivities of interacting organisms which mediate changes in interspecific interactions (i.e. predation). Despite this, there is a paucity of information on the patterns of spatial physiological sensitivity of interacting species (at both landscape and local scales) which could ultimately influence geographical variation in the effects of climate change on community processes. In order to assess where these impacts may occur, we first need to evaluate the spatial heterogeneity in the degree of mismatch in thermal tolerances between interacting organisms. We quantify the magnitude of interspecific mismatch in maximum ( $CT_{max}$ ) and minimum ( $CT_{min}$ ) thermal tolerances among a predator-prey system of dragonfly and anuran larvae in tropical montane (242–3631 m) and habitat (ponds and streams) gradients. To compare thermal mismatches between predator and prey, we coined the parameters maximum and minimum predatory tolerance margins ( $PTM_{max}$  and  $PTM_{min}$ ), or difference in  $CT_{max}$  and  $CT_{min}$  of interacting organisms sampled across elevational and habitat gradients. Our analyses revealed that: (1) predators exhibit higher heat tolerances than prey ( $\sim 4$  °C), a trend which remained stable across habitats and elevations. In contrast, we found no differences in minimum thermal tolerances between these groups. (2) Maximum and minimum thermal tolerances of both predators and prey decreased with elevation, but only maximum thermal tolerance varied across habitats, with pond species exhibiting higher heat tolerance than stream species. (3) Pond-dwelling organisms from low elevations (0–1500 m a.s.l.) may be more susceptible to direct effects of warming than their highland counterparts because their maximum thermal tolerances are only slightly higher than their exposed maximum environmental temperatures. The greater relative thermal tolerance of dragonfly naiad predators may further increase the vulnerability of lowland tadpoles to warming due to potentially enhanced indirect effects of higher predation rates by more heat-tolerant dragonfly predators. However, further experimental work is required to establish the individual and population-level consequences of this thermal tolerance mismatch upon biotic interactions such as predator-prey." variation in the dragonfly *Erythrodiplax media* (Odonata: Libellulidae) among South American grassland physiognomies. *Neotropical Entomology* 50: 736-747 . (in English) ["We assessed the intraspecific morphological variation in *E. media* Borror 1942 among grassland physiognomies ("Coastal," "Highland," and "Steppic") in the South Brazilian Campos. We measured six morphological traits (total body length, thorax height, length, and width of the fore- and hindwings) from 90 specimens (60 males and 45 females). We tested the effect of the grassland type on the set of traits using one-way MANOVA and principal component analysis (PCA) (separately for each sex). Grassland physiognomy affected the morphology of males and females. In both sexes, the PCA mostly opposed the specimens of the Coastal from the Highland and Steppic grasslands. The first PCA axis separated specimens according to body lengths, thorax heights, and wing width, while the second PCA axis opposed specimens according to wing length and thorax height from specimens with broader wings and longer body lengths. Males from the Coastal had longer body lengths and shorter thorax heights than Highland and Steppic grasslands, while males from the Steppic had longer fore- and hindwings than specimens from the Coastal and Highland grasslands. Females from the Coastal had significantly shorter forewings than specimens from the Steppic grasslands and shorter hindwings than Highland grasslands. Our results are likely explained by the differences in climate and habitat complexity among grassland types and indicate that the processes driving odonate performance vary among grassland biotopes. This study potentially indicates that dragonflies are sensitive to changes in the vegetation structure in South American subtropical grasslands." (2021): Aquatic insects transfer pharmaceuticals and endocrine disruptors from aquatic to terrestrial ecosystems. *Environmental Science & Technology* 55: 3736-3746. (in English) ["A wide range of pharmaceuticals and endocrine disrupting compounds enter freshwaters globally. As these contaminants are transported through aquatic food webs, understanding their impacts on both aquatic and terrestrial ecosystems remains a major challenge. Here, we provide the first direct evidence of the transfer of pharmaceuticals and endocrine disruptors through the aquatic-terrestrial habitat linkage by emerging aquatic insects. We also show that the type of insect metamorphosis and feeding behavior determine the bioaccumulation patterns of

these contaminants. Adult Trichoptera, an important food source for riparian predators, showed an increased body burden of pharmaceuticals and endocrine disruptors. This implies that terrestrial predators, such as spiders, birds, and bats, are exposed to mixtures of pharmaceuticals and endocrine disruptors of aquatic origin, which may impact their physiology and population dynamics. Overall, our study provides valuable insights into the bioaccumulation patterns and trophic cross-ecosystem transfer of these contaminants, from aquatic primary producers to terrestrial predators." **19479.** Raczynski, M.; Stoks, R.; Johansson, F.; Sniegula, S. (2021): Size-mediated priority effects are trait-dependent and consistent across latitudes in a damselfly. *Oikos* 130(9): 1535-1547. (in English) ["Variation in hatching time (phenology) might cause size differences within populations resulting in size-mediated priority effects (SMPEs) shaping intraspecific interactions. These phenology-driven effects potentially can be strengthened by seasonal time constraints caused by a short growth season, and depend on latitude. Here the single and combined effects of phenology and latitude-associated time constraints on SMPEs in larvae of an aquatic insect, the damselfly *Lestes sponsa*, are studied. We did so by rearing larvae in groups of 16 individuals with different phenology (hatching date) thereby imposing strong intraspecific competition, resulting in cannibalism. We thereby manipulated in a fully crossed way time constraints (combination of temperature and photoperiod: thermo-photoperiod) in larvae from low-latitude and more time constrained high-latitude populations, and examined effects on life history (survival, development, growth) and physiology (fat and protein contents, and phenoloxidase activity as a measure of immune function). Phenology, time constraints and latitude of origin had strong effects on life history, but only the time constraint affected the physiology. We detected a SMPE for survival that, however, was not stronger under time constraints and was consistent in strength between latitudes. Phenology and time constraints interacted for development and growth in a direction suggesting adaptive responses to time constraints but these life history traits did not show SMPEs. We provided important insights in the study of SMPEs thereby showing these to be trait-dependent and not more pronounced under experimentally manipulated or latitude-associated time constraints. Our study thereby makes an important addition to geographic variation in SMPEs, a largely neglected topic." **19480.** Ramil, N.H.; Abdul Manaf, N.F. (2021): Species diversity of dragonfly (Arthropoda: Odonata) and its relationship with air parameters at SG. Muar, Kuala Pilah. *Journal of Academia* 9(2): 30-39. (in English) ["The study of diversity and distribution of dragonfly, and their relationship with air parameters including temperature (°C) and humidity

(%) at Sungai Muar, Kuala Pilah, Negeri Sembilan was carried out on 14 and 15 March 2020. The sampling of dragonfly was done in two parts of Sungai Muar, Kuala Pilah. For each site, the sampling was conducted in the morning and evening with the air temperature and humidity were recorded at the same time using hygrometer and digital thermometer clock humidity temperature HTC-1. Method that has been used for this study are net sweeping. The samples were collected, preserved and identified until species level. A total of 231 individuals were recorded with *Ischnura elegans* from Coenagrionidae family as a dominant species with 145 individuals, while the lowest abundance is *Pseudagrionidae* sp. of Coenagrionidae family with one individual only. For the relationship, there is no significant linear correlation between air parameters with individual number of dragonflies. As a recommendation, the other parameters including air and water parameters should be measured to increase our understanding on the abiotic parameters effects towards the survivability of dragonfly. This research give benefit to society and ecology where it provides knowledge and understanding about dragonfly species and the function of dragonfly as indication of environmental quality. Besides, this research can be used as guidelines for future research and update the checklist of dragonfly in Sungai Muar, Kuala Pilah." **19483.** Santos, F.; Nicasio, K.; Silva, K.; Martins, J.; Périco, E.; Dalzochio, M.; Veras, D.; Cajaiba, R.L. (2021): Can artificial ponds retain dragonfly (Insecta: Odonata) biodiversity? A preliminary study in the Brazilian Amazon. *Austral Entomology* 60(4): 698-706. (in English) ["Although ponds are rich ecosystems for the maintenance of aquatic biodiversity, in many regions of the world, they have been adversely affected by anthropogenic changes in surrounding landscapes. Dragonflies (Insecta: Odonata) are characterized by larval phases that are closely associated with aquatic ecosystems and can accordingly serve as useful indicators of the quality of these environments. In this study, we evaluated the patterns of abundance, richness, and taxonomic composition of adult Odonata in artificial and natural ponds located in the Legal Amazon of Maranhão, which have been exposed to different levels of disturbance. We analysed how the composition of the Odonata assemblages varies between natural and artificial ponds and also assessed to what extent artificial ponds and degraded natural ponds are able to maintain Odonata biodiversity. Our results indicate that the abundance, richness, and composition of Odonata among the monitored ponds were adversely impacted by more disturbed landscapes, with greater abundance and richness being recorded in preserved natural ponds. Although the degraded artificial and natural ponds have Odonata diversities comparable to those of the preserved natural ponds, the latter tend to be characterized by unique and exclusive species, thereby indicating the urgent need for measures designed to protect these natural ecosystems." **19486.** Silva, L.F.R.; Castro, D.M.P.; Juen, L.; Callisto, M.; Hughes, R.M.; Hermes, M.G. (2021): Functional responses of Odonata larvae to human disturbances in neotropical savanna headwater streams. *Ecological Indicators* 133, December 2021, 108367: (in English) ["Highlights: • Trait-based approach for assessing Odonata larvae responses to anthropogenic impact. • Odonata larvae have different traits comparing least and highly disturbed streams. • Odonata larvae traits can be a useful tool for assessing anthropogenic impacts. Abstract: Headwater streams are facing increasing disturbances from human pressures worldwide, thus better knowledge about bioindicators, particularly aquatic insect responses to various pressures and stressors, are urgently needed. Multiple trait-based approaches consider

species attributes filtered by the environment, allowing them to persist in ecosystems under environmental pressures. Because this approach has been minimally explored in Odonata larvae, we aimed to understand how anthropogenic stressors structure Odonata larval assemblages in neotropical savanna streams by using multiple trait-based approaches. We hypothesized that a set of stressors—such as reduced substrate heterogeneity, poor water quality, natural land cover converted to pasture and agriculture, and reduced local riparian canopy cover—select Odonata functional traits. We collected 3209 Odonata larvae from 186 neotropical savanna headwater stream sites and used 39 environmental variables and seven traits in 23 categories related to their functional roles in Odonata genera. To assess associations between trait categories and environmental variables, we applied RLQ and fourth-corner statistical analyses. We found strong relationships between environmental variables and sets of Odonata biological traits that were separated into two main groups. Zygoptera genera (*Perilestes*, *Allopodagrion*, *Heliocharis*, *Argia*, *Epipleoneura*, *Mnesarete/Hetaerina*, *Psaironeura*) have elongated body shapes, caudal lamellae respiration, conforming thermoregulation, and endophytic oviposition. Such traits favor assemblages in conditions similar to reference streams, including denser riparian vegetation, good water quality, and diverse flows and substrate. Therefore, they are more sensitive to changes in those conditions. On the other hand, Anisoptera genera (*Gomphoides*, *Archaeogomphus*, *Macrothemis*, *Brechmorhoga*, *Gynothemis*, *Phyllocycla*) have cylindrical body shapes, internal gill respiration, endothermic thermoregulation, and burrowing behavior. Those traits facilitate their survival in intermediate or disturbed stream sites, characterized by riparian deforestation, increased erosion and siltation, and higher levels of total dissolved solids and conductivity. Therefore, using Odonata larval traits can be a valuable tool for assessing and monitoring anthropogenic impacts on neotropical savanna streams." (Authors)] Address: Silva, Larissa, Univ. Federal de Lavras, Setor de Zoologia Comparada, Depto de Biologia, Laboratório de Sistemática e Biologia de Insetos, CEP 37200-900 Lavras, Minas Gerais, Brazil. **19487.** Silva, L.F.R.; Castro, D.M.P.; Juen, L.; Callisto, M.; Hughes, R.M.; Hermes, M.G. (2021): A matter of suborder: are Zygoptera and Anisoptera larvae influenced by riparian vegetation in Neotropical Savanna streams? *Hydrobiologia* 848: 4433-4443. (in English) ["Initial Odonata larval distributions are primarily influenced by adult females at the moment of oviposition. However, after oviposition, the larvae are strongly associated with environmental conditions. In the case of both adults and larvae, anthropogenic disturbances that change these conditions may alter the composition and structure of Odonata assemblages. Therefore, based on the differing environmental requirements of Zygoptera and Anisoptera adults and larvae, together with their morphological and physiological differences, we suspected differing riparian preferences of larvae and adults for each suborder. We evaluated the richness and abundance of Odonata larvae. We hypothesized that Zygoptera larvae

would have greater richness and abundance in streams with canopy shading, lower temperature ranges, and high physical habitat heterogeneity. On the other hand, Anisoptera larvae would be more abundant in streams without canopy cover. We sampled 186 headwater stream sites in the Neotropical Savanna along an anthropogenic disturbance gradient and used a model selection approach to test our hypotheses, correlating environmental metrics with Odonata larval richness and abundance. We found higher richness of Zygoptera larvae in shaded sites with canopy cover >5 m high, whereas bare ground without riparian vegetation was important for Anisoptera richness and abundance. Our results indicated that Odonata larvae follow the same distribution, richness and abundance patterns as adults. Anthropogenic disturbances related to the removal or reduction of riparian vegetation can favor Anisoptera over Zygoptera larval assemblages in streams. Preserving riparian canopy cover is needed to maintain the richness of Zygoptera larvae in Neotropical Savanna streams." **19489.** Simonsen, T.J.; Djernæs, M.; Fogh Nielsen, O.; Olsen, K. (2021): A tale of two Skimmers: complex relationships between DNA barcodes, distributions and taxonomy in European *Orthetrum cancellatum* and *O. coerulescens*. *International Journal of Odonatology* 24: 316-331. (in English) ["We explore the genetic diversity and phylogeography of the dragonflies *Orthetrum cancellatum* and *O. coerulescens* in Europe based on mitochondrial and nuclear DNA. *Orthetrum cancellatum* has a clear division between a group comprising Maltese, Italian, and central and northern European populations, and a group comprising mainly populations from southwestern and southeastern Europe, as well as some northern European specimens. We propose that the two groups represent two different Glacial refugia, one in the Italian Peninsula and one in the Balkans where the species survived during the Weichsel Glaciation. *Orthetrum coerulescens* shows a more complex pattern, although it too

can be divided into two groups. One group comprise all the specimens we have identified as *O. coerulescens* anceps from their phenotype as well as specimens from Spain, Montenegro, and Pakistan, and some specimens from Italy, Poland and Bulgaria. The other group comprise all other specimens from central and northern Europe, almost all specimens from Italy and Bulgaria, and all specimens from Malta. We propose that the latter group represents an Italian Glacial refugium from which the species spread to both central Europe, Malta and southern Balkan (Bulgaria) after the end of the Weichsel Glaciation. As specimens from Spain and Bulgaria, which were identified as *O. coerulescens* *coerulescens* group with specimens identified as *O. coerulescens* *anceps* we conclude that the two subspecies mix more or less freely across the Mediterranean and question the validity of two subspecies." **19490.** Sparrow, D.J.; De Knijf, G.; Sparrow, R.L. (2021): Diversity, status and phenology of the dragonflies and damselflies of Cyprus (Insecta: Odonata). *Diversity* 2021, 13, 532: 13pp. (in English) ["Based on literature data, unpublished material and the results of the year-round monitoring at selected sites island-wide by the Cyprus Dragonfly Study Group since 2013, we acquired an excellent knowledge of the diversity and status of the Odonata of Cyprus. Altogether, 37 species are on the island's checklist. *Ischnura pumilio*, *Aeshna affinis* and *Brachythemis impartita* were only very rarely recorded in the past but are considered to be no longer present. The single record of *Calopteryx virgo* from 1930 is in our opinion a misidentification and has been removed from the checklist. The island has a rather impoverished odonate fauna compared to neighbouring countries. There are no endemic species, but the island is home to some range of restricted species of which *Ischnura intermedia* is the most important. Flight seasons determined for the 31 species with sufficient data were generally found to be longer than reported for other countries in the Eastern Mediterranean. This may be due to intensive year-round monitoring but could also result from Cyprus' warmer climate. Very wide annual variations were found in the abundance of all species over the seven years and show an almost immediate response to the wide fluctuations in Cyprus' annual rainfall levels." (Authors)] Address: Sparrow, D.J., Cyprus Dragonfly Study Group, PO Box 62624, 8047 Paphos, Cyprus. E-mail: davidrospfo@hotmail.com

**19491.** Stand-Perez, M.A.; Montes-Fontalvo, J.; Perez-Gutierrez, L.A. (2021): Sixteen new records of Odonata for Colombia from the Araracuara Region (Perilestidae, Calopterygidae, Heteragrionidae, Megapodagrionidae, Polythoridae, Coenagrionidae, Aeshnidae, Gomphidae, Libellulidae). *Notulae odonatologicae* 9(8): 378-388. (in English) ["A field trip to collect Odonata was carried out in Southern Serranía de Chiribiquete National Natural Park, Araracuara Region, Colombia. A total of 40 species were collected, of which 17 are new records for the country: *Hetaerina charca*,

*Epipleoneura spatulata*, *Metaleptobasis gibbosa*, *Neoneura desana*, *N. luzmarina*, *N. fulvicollis*, *N. joana*, *Phoenicagrion paulsoni*, *Protoneura tenuis*, *Oxystigma petiolatum*, *Perisolestes romulus*, *Epigomphus paludosus*, *Zonophora regalis*, *Micrathyria hippolyte*, *Uracis ovipositrix*, and *Ypirangathemis calverti*. The genera *Schistolobos*, and *Ypirangathemis* are reported for the first time for Colombia. A map of localities, photographs of the species, and notes on dragonfly and damselfly conservation are provided." (Authors)] Address: Stand-Perez, M.A., Red de Biol. **19492.** Starnes, T.; Clausnitzer, V. (2021): Chapter 5: The status and distribution of freshwater odonates. In: Starnes, T. and Darwall, W.R.T. (eds.) (2021). Identification and validation of Western African freshwater Key Biodiversity Areas. Gland, Switzerland: IUCN: 53-61. (in English) ["At the time of publishing this report, the western Africa region included 307 species of freshwater odonates belonging to 13 families according to the Red List. Of these 307 species, 50 species are endemic to the region. These endemic species are largely forest dependent, either along streams or in swamp forests and are concentrated in the lower areas. Of the 307 species of odonate addressed in this work, five are Critically Endangered, seven are Endangered and two are Vulnerable, amounting to 14 globally threatened species (Table 5.1). Since the previous report on the western African Odonata in Dijkstra et al. (2009), 19 species have changed Red List category due to new information (nongenuine changes). There have been no genuine status changes during this time. Eight species have been moved from DD to LC, due to new information concerning their status and distributions, and one from DD to NT; *Phyllomacromia lamottei* is thought to be endemic to the Nimba Mts region. One species – *Trithemis dubia* – was moved from LC to DD due to unresolved taxonomy. *Azuragrion buchholzi* has moved from NT to LC due to a number of additional localities extending its known range in Cameroon and Gabon. Three species have been downlisted from VU to LC due to new records improving the prospects of these species; they are *Agrioncnemis angustirami*, *Nubiolestes diotima* and *Paragomphus sinaiticus*. Conversely, three species have been uplisted from VU to EN, citing new information on threats to these species; they are *Africocypha centripunctata*, *Ceragrion citrinum* and *Umma purpurea*. One species, *Neodythemis takamandensis*, has been downlisted from CR to LC due to several new records in Gabon significantly extending its range. The numbers in parentheses in Table 5.1 are taken from the previous regional report on western African freshwater biodiversity (Dijkstra et al., in Smith et al., 2009), and were based partly on regional assessments. Besides a number of new species being assessed since that time, the difference between the numbers reported is partly due to the use here of Global rather than Regional assessments e.g. *Afroaeschna scotias* is globally LC although it was assessed in 2006 as regionally VU, and partly due to status changes e.g. *Agrioncnemis angustirami* has undergone a nongenuine status change from VU to LC. One CR species *Pseudagrion mascagnii* was not included in this analysis

because its entire range is marked as 'Presence uncertain' in the Red List. However, the Red List assessment (Dijkstra, 2010c) states that the species is known from type pair collected at Regent in Sierra Leone, described in 2004 (Terzani & Marconi, 2004). A study on biodiversity hotspots and threatened dragonfly species in Africa did show that only 58% critically endangered and 60% endangered dragonfly species are found in formally protected areas, whereas 80% of species listed as vulnerable occur in protected areas (Simaika et al., 2013). Especially in western Africa there is a lack of protected areas in the biodiversity hotspots, especially of rare species (Pinkert et al., 2020)." **19493.** Stefani-Santos, G.; Avila, W.F.; Clemente, M.A.; Henriques, N.R.; Souza, A.S.B.; Vilela, D.S.; Souza, M.M. (2021): Odonata (Insecta) communities along an elevational gradient in the Atlantic forest of southeastern Brazil, with the description of the female of *Heteragrion mantiqueirae* Machado, 2006. *International Journal of Odonatology* 24: 178-196. (in English) ["Despite the important role of the order Odonata in ecosystems, there is a lack of information about dragonfly communities in several regions, high elevation sites, and environmentally protected areas in Minas Gerais State, Brazil. Our objective was to assess the abundance and richness of dragonfly and damselfly communities along an elevational gradient in the Atlantic Forest, southeastern Brazil. This study was conducted in the Fernão Dias Environmental Protection Area, Mantiqueira Mountain region, Gonçalves, Minas Gerais State, in sites covered by Seasonal Semideciduous and mixed forests. This is the first study of Odonata communities in the region. Samplings were carried out on 17 days from October 2019 to March 2020 at three elevation ranges (low, mid, and high). A total of 293 specimens, distributed in 39 species and 9 families, were sampled. Elevation did not influence the richness or abundance of dragonflies but altered community composition. Some species were found to be exclusive to high-elevation sites, such as *Heteragrion mantiqueirae* Machado, 2006, which was recorded for the first time in Minas Gerais and we provide a description and diagnosis of the single female collected in tandem. A novel species of the genus *Brechmorhoga* was found to occur at mid and high elevations. The composition of dragonfly communities depends on the degree of preservation and extension of forest areas. Therefore, conservation of forests in Gonçalves is crucial for preserving Odonata diversity in Minas Gerais State." **19495.** Stryjecki, R.; Zawal, A.; Krepski, T.; Stępien, E.; Buczyńska, E.; Buczyński, P.; Czachorowski, S.; Jankowiak, L.; Pakulnicka, J.; Sulikowska-Drozd, A.; Pešič, V.; Michonski, G.; Grabowski, M.; Jabłońska, A.; Achrem, M.; Olechwir, T.; Pietrzak, L.; Szlauer-Lukaszewska, A. (2021): Anthropogenic transformations of river ecosystems are not always bad for the environment: Multi-taxa analyses of changes in aquatic and terrestrial environments after dredging of a small lowland river. *PeerJ* 9:e12224: 21 pp. (in English) ["Rivers are one of the most commonly transformed aquatic ecosystems. Most papers present significantly negative effects of activities such as dredging or channel regulation on the ecological status of rivers. The purpose of this work was to compare the response of various groups of invertebrates (Mollusca, Hydrachnidia, Odonata, Heteroptera, Coleoptera and Trichoptera) to an intervention involving dredging in conjunction with the removal of riparian vegetation. Habitat diversity increased after the dredging, and more individuals and species were caught than before the dredging. The increase in habitat diversity after the dredging translated into an increase in the species diversity of most investigated groups. Individual groups of invertebrates showed varied responses to the dredging, depending on the role of the terrestrial phase in their life cycle: the greater the role of the terrestrial phase in the life cycle, the more the group was affected by changes in the terrestrial environment following the intervention. In consequence, the intervention had the greatest negative impact on insects, and among these,

on adult Odonata. The following conclusions can be drawn: (1) Dredging can benefit a previously anthropogenically transformed river ecosystem by increasing habitat diversity; (2) Odonata are particularly useful for assessing the impact of this type of intervention on invertebrate communities. They can be considered good indicators of habitat disturbances in both aquatic and terrestrial ecosystems." **19496.** Subrero, E.; Pellegrino, I.; Cucco, M. (2021): Different stress from parasites and mate choice in two female morphs of the blue-tailed damselfly. *Evolutionary Ecology* 35: 687-704. (in English) ["In Odonates, female colour polymorphism is common and implies the presence of two or more female types with different colours and behaviours. To explain this phenomenon, several hypotheses have been proposed that consider morph frequency, population density, the presence of parasites, and mating behaviour. We studied the blue-tailed damselfly *Ischnura elegans*, a species with a blue androchrome morph and two gynochrome morphs (the common green infuscans, and the rare orange rufescens-obsolata). The size of adult males and females, the presence of parasites, and pairing behaviour between males and the three female morphs was assessed in field conditions throughout the reproductive season in NW Italy. Moreover, growth and emergence success of larvae produced by the different morphs was analyzed in standardized conditions. In the field, males showed a preference for the gynochrome infuscans females, despite a similar frequency of androchrome females. In test conditions, male preference for the infuscans females was also observed. Paired males and paired androchrome females were larger than unpaired individuals, while there were no differences in size between paired and unpaired infuscans females. Males and androchrome females were more parasitized than infuscans females. The survival and emergence success of larvae produced by androchrome females was higher than those of offspring produced by the infuscans females. Our results suggest that a higher survival of progeny at the larval stage could counterbalance the higher parasitism and the lower pairing success of andromorph adult females and highlight the importance of considering the whole life-cycle in polymorphism studies." **19497.** Susanto, M.A.; Bahri, S. (2021): Diversity and abundance dragonflies (Odonata) at Mount Sigogor Nature Reserve area, Ponorogo Regency, East Java, Indonesia. *Journal Biota* 7(2): 101-108. (in English) ["Mount Sigogor Nature Reserve area is a mountainous tropical rain forest, administratively located in Pupus Village, Ngebel District, Ponorogo Regency, East Java, Indonesia. One of the main functions of this nature reserve is as a water catchment area for the villages around the nature reserve area. Water sources and flows within the Mount Sigogor Nature Reserve area have the potential as natural habitat for dragonflies. This

study aims to determine the diversity and abundance of dragonflies in the Mount Sigogor Nature Reserve Area. The method of collecting dragonflies data used the Visual Day Flying method by recording the diversity of dragonflies species and counting the number of individuals from each observed dragonflies species. The data obtained were analyzed using the Relative abundance, Shannon-Wiener Heterogeneity Index and the frequency of Presence. The results of the research conducted showed that there were 14 species from 7 families with a total of 464 individuals. The Shannon-Wiener diversity index shows that the diversity value is  $H' = 1.81$ . Meanwhile, the presence frequency analysis showed that there were four species with a value of 100% which were classified as abundant Frequency of Presence, namely *Euphaea variegata*, *Vestalis luctuosa*, *Rhinocypha anisoptera* and *Coeliccia membranipes*." **19499.** Teder, T.; Kaasik, A.; Tait, K.; Tammaru, T. (2021): Why do males emerge before females? Sexual size dimorphism drives sexual bimaturism in insects. *Biol. Rev.* 96(6): 2461-2475. (in English) ["Conspecific females and males often follow different development trajectories which leads to sex differences in age at maturity (sexual bimaturism, SBM). Whether SBM is typically selected for per se (direct selection hypothesis) or merely represents a side-effect of other sex-related adaptations (indirect selection hypothesis) is, however, still an open question. Substantial interspecific variation in the direction and degree of SBM, both in invertebrates and vertebrates, calls for multi-species studies to understand the relative importance of its evolutionary drivers. Here we use two complementary approaches to evaluate the evolutionary basis of SBM in insects. For this purpose, we assembled an extensive literature-derived data set

of sex-specific development times and body sizes for a taxonomically and ecologically wide range of species. We use these data in a meta-analytic framework to evaluate support for the direct and indirect selection hypotheses. Our results confirm that protandry – males emerging as adults before females – is the prevailing form of SBM in insects. Nevertheless, protandry is not as ubiquitous as often presumed: females emerged before males (= protogyny) in about 36% of the 192 species for which we had data. Moreover, in a considerable proportion of species, the sex difference in the timing of adult emergence was negligible. In search for the evolutionary basis of SBM, we found stronger support for the hypothesis that explains SBM by indirect selection. First, across species, the direction and degree of SBM appeared to be positively associated with the direction and degree of sexual size dimorphism (SSD). This is consistent with the view that SBM is a correlative by-product of evolution towards sexually dimorphic body sizes. Second, within protandrous species, the degree of protandry typically increased with plastic increase in development time, with females prolonging their development more than males in unfavourable conditions. This pattern is in conflict with the direct selection hypothesis, which predicts the degree of protandry to be insensitive to the quality of the juvenile environment. These converging lines of evidence support the idea that, in insects, SBM is generally a by-product of SSD rather than a result of selection on the two sexes to mature at different times. It appears plausible that selective pressures on maturation time per se generally cannot compete with viability- and fecundity-mediated selection on insect body sizes. Nevertheless, exceptions certainly exist: there are undeniable cases of SBM where this trait has evolved in response to direct selection. In such cases, either the advantage of sex difference in maturation time must have been particularly large, or fitness effects of body size have been unusually weak." (Authors) This meta study includes data of Odonata.] Address: Teder, T., Dept of Zoology, Institute of Ecology and Earth Sciences, University of Tartu, Vanemuise 46, Tartu, EE-51003, Estonia

**19500.** Theischinger, G.; Toko, P.S.; Richards, S.J. (2021): A remarkable new species of Papuagrion Ris, 1913 from New Guinea (Odonata: Coenagrionidae). *Odonatologica* 50(1/2): 131-141. (in English) ["A new species of the coenagrionid damselfly genus *Papuagrion* is described from the lowlands of the Purari River basin in Gulf Province, Papua New Guinea. *Papuagrion forceps* sp. nov. is a large (abdomen + appendages 46.5-47.2 mm) slender species with a pre-dominantly black and brown abdomen. The male is unique in the genus in having superior appendages that are minute in comparison to the inferior appendages, with lower branches that are not visible in profile. The new species is currently known only from the type locality, where a male and a female were perched among low foliage in a remnant patch of lowland rainforest." **19501.** Theodoropoulos, C.; Karaouzas, I. (2021): Climate change and the future of Mediterranean freshwater macro-invertebrates: a model-based assessment. *Hydrobiologia* 848: 5033-5050. (in English) ["Mediterranean-climate rivers are projected to warm by 0.5–4°C and river flows to decline by 34% by 2071–2100. Using data from 191 Greek streams / rivers, we projected macroinvertebrate responses to 12 climate change scenarios for 2071–2100 to identify critical hydro-thermal limits beyond which irreversible responses are triggered and to assess the potential of environmental flows to mitigate the ecological impacts of climate change. Overall, macroinvertebrate assemblages will be less diverse, represented mostly by limnophilic, warm-dwelling taxa. Ephemeroptera, Plecoptera, Trichoptera and some Diptera will be replaced by Odonata, Amphipoda, Gastropoda and Heteroptera. Moderate average warming (1–1.8 °C) will not significantly affect assemblage abundance and richness but extreme warming (= 5 °C) will shift to limnophilic-type assemblages even in non-lentic hydrological conditions. Our models predict irreversible macroinvertebrate responses at = 3°C average warming combined with = 50% average flow decrease, or = 5°C warming regardless of flow decrease, or = 90% flow decrease regardless of warming. Beyond these limits, cold-dwelling taxa such as Limnephillidae and Potamanthidae will almost disappear (abundance: –87%), replaced by warm-dwelling Physidae (+100%) and Coenagrionidae (+97%). Environmental flows could mitigate the impacts of warming, compensating macroinvertebrates for up to 3°C when 50% decreased flows are provided, and for up to 5°C when flows within the 0–25% range are provided." (Authors)] Address: Theodoropoulos, C., Institute of Marine Biological Resources and Inland Waters, Hellenic Centre for Marine Research, 46.7 km Athens-Sounio Ave., 19013, Anavyssos, Greece

**19502.** Uboni, C.; Borsato, V.; Bacaro, G. (2021): Odonate fauna assemblages in the "Cansiglio Forest" (Insecta: Odonata). *Rendiconti Lincei. Science Fisiche e Natrali* 32: 899-910. (in English) ["Odonata is considered a "flagship" group of insects and its investigation is of primary importance especially for protected areas where freshwater ecosystems occur. In this study, we focused on Odonate fauna in the "Cansiglio Forest" (Veneto, Italy), a karst area where the only checklist available dates back more than 40 years ago. In order to update the Odonate adult distribution in the area, we selected 21 ponds that were sampled monthly, from May to August, during a 2-years survey. In total, 21 species (belonging to 14 genera and 5 families) have been recorded: we confirmed 15 species from the previous species list and we added to the whole species list 6 new species. Dominant families were represented by Libellulidae (33%) and Aeshnidae (23%), the most common genus was *Sympetrum* (19%), and the most frequent species was *Coenagrion puella* (63%). In term of patterns of species richness, highly grazed and pastured ponds exhibited the lower number of species and individuals, as a probable response to the high level of animal disturbance on the vegetation and due to the eutrophication processes. Our results are important also in terms of conservation and management of freshwater sites

belonging to Natura 2000 site. ... In detail, we confirmed the following species: *Lestes barbarus*, *Sympecma fusca*, *Enallagma cyathigerum*, *Coenagrion scitulum*, *C. puella*, *Aeshna cyanea*, *A. affinis*, *Anax imperator*, *Libellula depressa*, *L. quadrimaculata*, *Crocothemis erythraea*, *Sympetrum striolatum*, *S. meridionale*, *S. fonscolombii*, *S. sanguineum*. On the contrary, we did not confirm the following species: *Ischnura elegans*, *Aeshna mixta*, *Orthetrum cancellatum*, *O. brunneum*, *Sympetrum vulgatum*, *S. flaveolum*, *Leucorrhinia pectoralis*. Considering the last two species, their present lack in the study can be justified with the major threats connected with their ecology. It is known that *S. flaveolum* populations are in decline due to intensive grazing activity that damage pond banks especially during the reproductive period, and for grazing animal dejections that contribute to the phenomena of water eutrophication." **19503.** Utseth, H. (2021): Insect community response to recent rewetting of drained bogs in Southeastern Norway. MSc thesis, Faculty of Environmental Sciences and Natural Resource Management: IV + 34 pp. (in English, with Norwegian summary) ["During the last five years, Norway has rewetted almost 80 drained mires to reduce climate emissions, limit the risk of natural disasters, and to prevent further loss of biodiversity. Even more mires are planned to be rewetted over the next five years despite limited knowledge on how mire fauna responds to the measures. Therefore, this study used insects to discover possible community alterations resulting from drainage and rewetting of ombrogenous mires, more commonly known as bogs, in the southeastern part of Norway. Changes in densities of insect orders and four target butterfly species were assessed through a transect study comparing seven newly rewetted bogs to adjacent and otherwise comparative drained and pristine areas. The findings revealed a general similarity in the overall composition of insect orders, butterflies, and water insects, despite some alterations within specific orders among the three treatments. Drained bogs generally had higher abundances of dipterans and hymenopterans compared to pristine areas, and lower abundances of orthopterans. These responses might derive from drainage favoring species preferring temporal water sources and forest development, rather than bog specialists. Insect communities in rewetted bogs were more similar to drained bogs than to pristine, with the exception of a reversing response in the order of hymenopterans. Additionally, rewetted bogs stood out in their high abundance of odonates, likely due to the increased access to artificial pools from dammed ditches. As the observations of target butterflies were few and the samplings were conducted shortly after rewetting, further assessments of lower taxa and long-term studies of responses are necessary to better understand the potential of bog rewetting for insect communities....In this study, the odonate abundance in pristine bogs resembled that of drained ones, while they were the most abundant in rewetted bogs. One explanation behind higher abundances in rewetted sites might be the increased access to open water and ponds

due to dammed ditches (Eian, 2021). Since odonates have a larval stage generally dependent upon water, these dams might increase the availability of suitable larval habitats for some species (Beadle et al., 2015; Strobl et al., 2020). Even though drained bogs also can contain some ditches filled with water, these shallow and narrow pools might not be suitable habitats for all species (Elo et al., 2015). Another explanation can be that the study design itself has affected the number of odonates recorded for the different treatments. Transects in rewetted bogs always crossed a minimum of one ditch perpendicularly. In pristine bogs with open waters, the transect were usually located next to the ponds due to unsafe ground surrounding the water. This have impacted how close and frequently transect counts were to open water and may also have influenced the results if some species of odonates prefer to stay closer to water. However, an American study of adult dragonflies' land use around open water found unaffected abundances of dragonflies up to 160 meters from the closest pond (Bried & Ervin, 2006), suggesting that at least several dragonflies should not be notably affected by transects crossing by or directly over open waters." **19506.** van der Schans, J. (2021): Waargenomen libellen 2020. *Nieuwewetbrief Het Merkske* 8: 30-32. (in Dutch) [Verbatim: "Last year's mild winter and a wet March made it look promising for the dragonflies in 2020. Ponds and pools filled with water and warm weather forecasts. But this will be a different story, because suddenly we have to deal with a large observer effect on our monitoring. As described in other articles of this newsletter, we suddenly had to deal with another exotic 'critter' which closed borders that did not normally exist and forced us to stay at home on the Belgian side of the border. As fellow observers talk about 'our front or backyard', there was no way to get there during the Lock-down. These areas are so close and yet suddenly so far away. The occasional sneak across the border via forest tracks and shortcuts in the hope of not being stopped. The observer effect, in this case not being able to go to the beautiful fens and pools, is therefore the reason that few species and low numbers were counted. Due to the lock-down and closing of the borders, some species have certainly been missed. Fortunately, in April and May it was fine (warm) dragonfly weather and *Pyrrhosoma nymphula* was observed first, followed by *Libellula depressa* and *L. quadrimaculata*. Remarkable was the frequently observed *Cordulia aenea*, which clearly enjoys life in the Merkske. Due to the great heat in the summer, there was, in contrast to last year, only a small influx of southern species. *Anax parthenope* knows to return to some popular pools every year and may reproduce in the area. *Sympetrum meridionale* was seen at three sites in Belgium and one site in the Netherlands where uncoloured dragonflies were observed, indicating local hatching and thus confirming a small population. *Leucorrhinia pectoralis* and *L. rubicunda* are still observed in small numbers. *L. dubia* was seen in 2020 at three locations in the Belgian part, two of which are new locations and one new location on the Dutch side. That is very promising. In contrast to last year, few *Sympetrum fonscolombii* and *Orthetrum coerulescens* was seen, but there were higher numbers of *S. sanguineum*. Of course, the observer effect mentioned above could be the cause. The large numbers of damselflies seen throughout the year were striking. Species like *Ischnura pumilio* and *Lestes virens* were common, together with *Lestes sponsa* and to a lesser extent *Coenagrion scitulum*. The populations of *Calopteryx virgo* and *C. splendens* seem stable but the low water level of the Merkske during the drought of last summer(s) is worrying. The life of the dragonfly larvae takes place under water. In the Dutch and Belgian part together

43 different species have been observed this year, 3 less than last year. *Sympetrum danae* and *Ceriagrion tenellum* are species that have almost disappeared. Even the heat-loving *Crocothemis erythraea* has only been observed in a few places. The national trend of declining dragonfly populations will certainly also apply to 't Merkske. The drought at the end of August and September also dried up deeper pools and fens, so 2021 will be an exciting year again. I would like to end with a quote that I ended with last year, "It even gives opportunities for new species". (Author/DeepL)] Address: not stated

**19507.** Van Eupen, C.; Maes, D.; Herremans, M.; Swinnen, K.R.R.; Somers, B.; Luca, S. (2021): The impact of data quality filtering of opportunistic citizen science data on species distribution model performance. *Ecological Modelling* 444: 11pp, Suppl. (in English) ["Highlights: • Stringent filtering of unstructured data should not be performed blindly. • Data quality is higher in verified or more detailed species records. • Both absolute and relative sample size are important in stringent filtering. • Decreasing sample size by filtering does not always decrease model performance. • Impact of stringent filtering on model performance differs among taxonomic groups. Abstract: Opportunistically collected species occurrence data are often used for species distribution models (SDMs) when high-quality data collected through standardized recording protocols are unavailable. While opportunistic data are abundant, uncertainty is usually high, e.g. due to observer effects or a lack of metadata. To increase data quality and improve model performance, we filtered species records based on record attributes that provide information on the observation process or post-entry data validation. Data filtering does not only increase the quality of species records, it simultaneously reduces sample size, a trade-off that remains relatively unexplored. By controlling for sample size in a dataset of 255 species, we were able to explore the combined impact of data quality and sample size on model performance. We applied three data quality filters based on observers' activity, the validation status of a record in the database and the detail of a submitted record, and analyzed changes in AUC, Sensitivity and Specificity using Maxent with and without filtering. The impact of stringent filtering on model performance depended on (1) the quality of the filtered data: records validated as correct and more detailed records lead to higher model performance, (2) the proportional reduction in sample size caused by filtering and the remaining absolute sample size: filters causing small reductions that lead to sample sizes of more than 100 presences generally benefitted model performance and (3) the taxonomic group: plant and dragonfly models benefitted more from data quality filtering compared to bird and butterfly models. Our results also indicate that recommendations for quality filtering depend on the goal of the study, e.g. increasing Sensitivity and/or Specificity. Further research must identify what drives species' sensitivity to data quality. Nonetheless, our study confirms that large quantities of volunteer generated and opportunistically collected data can make a valuable contribution to ecological research and species conservation." **19510.** Vilenica, M.; Kulijer, D.; Gligorovic, B.; Gligorovic, A.; De Knijf, G. (2021): Distribution, habitat requirements, and vulnerability of *Caliaeschna microstigma* at the north-western edge of its range (Odonata: Aeshnidae). *Odonatologica* 50(3/4): 203-225. (in English) ["More than a decade of field surveys of *Caliaeschna microstigma* (Schneider, 1845), at the north-western edge of species' distribution in Bosnia & Herzegovina, Croatia, and Montenegro recorded its presence at 135 localities, of which 107 were previously unknown. Our sampling located populations north-west of the species' previously known range limit. Literature and new data showed that the species was most frequently observed in karst springs (42 % of all known localities) and streams (34 %) and, to a lesser extent, also in rivers (24%). Although it was observed over a wide range of altitudes,

from sea level to mountainous regions (865 m a.s.l.), 72 % of the localities were below 200 m a.s.l., and 43 % below 50 m a.s.l. Reproduction attempts and/or successful reproduction was recorded at approximately half the localities (53%, n = 71), mostly in the Mediterranean but also in the Alpine bio-geographical region. Most of the localities with *C. microstigma* present are suffering from various anthropogenic threats, such as domestic and constructional waste disposal, capture of spring water, and urban and agricultural impacts. This study contributes to a better understanding of the species' distribution and provides new insight into its habitat and microhabitat preferences." **19511.** Walia, G.K.; Katnoria, N. (2021): Chromosome characterization of four calopterygid damselflies with cytogenetic review of family Calopterygidae (Odonata: Zygoptera). *J. Adv. Zool.* 42(1): 107-117. (in English) ["Taxonomically, in family Calopterygidae, 183 species under 21 genera have been reported worldwide. Out of these, cytogenetic data pertains to only 22 species which is only 12% of the known species. In India, 9 species under 6 genera are present, while only 2 species has been studied cytogenetically. The present study has been conducted to linearly characterize the chromosomes of 4 species (*Matrona nigripictus*, *Neurobasis chinensis*, *Vestalis apicalis* and *Vestalis gracilis*) of family Calopterygidae by conventional staining, C-banding, silver nitrate staining and sequence-specific staining and also compiled the cytogenetic data of the family. The species were collected from Meghalaya, Goa, Kerala, Himachal Pradesh states of India. All the species possesses  $2n=25m$  as the diploid chromosome number with XO-XX sex determination except *Neurobasis chinensis* with  $2n=23$ , characterized by the presence of two equal sized large autosomal bivalents originated by the autosome fusion. C-banding and silver nitrate staining results depict the presence of C-bands and NOR's on the terminal positions of autosomal bivalents, while X chromosome and m bivalent show variation in distribution of C-heterochromatin and NOR's. Sequence-specific staining represents the complement of all the species as AT-rich due to more DAPI bright signals. All the cytogenetically studied species have been catalogued including the presently studied species and the list has been updated to 23 species." **19512.** Worthen, W.B.; Fravel, R.K.; Home, C.P. (2021): Downstream changes in odonate (Insecta: Odonata) communities along a suburban to urban gradient: Untangling natural and anthropogenic effects. *Insects* 2021, 12(3), 201: 19 pp. (in English) ["Simple Summary: Dragonflies are sensitive to natural and human-caused variation in the aquatic and terrestrial habitats where their larvae and adults live. For example, a reduction in shady vegetation, as a consequence of increasing stream size or streamside deforestation, often causes a reduction in specialized forest species

and an increase in generalist species. We surveyed larvae and adults at 15 sites along the Reedy River in Greenville Co, SC, USA, from headwater sites in forested suburban landscapes through the urban core of the city of Greenville. We described the sediment characteristics and shoreline vegetation in two 4 m × 20 m plots at each site, and measured the percentage of developed land, forested land, grasslands, and wetlands within 500 m of each plot center. At a small scale, within plots, larval abundance and diversity increased with increasing amounts of dead debris that may provide a refuge from predators. Adult abundance and diversity correlated with the amount of aquatic and shoreline vegetation used as perches. At a large scale, diversity responded more to natural changes in habitat than urbanization: damselfly diversity increased downstream and dragonfly diversity was greatest in sunny, open habitats with fields, wetlands, and open water. Abstract: The community structure of lotic odonates changes downstream, but it is difficult to untangle natural and anthropogenic causes. We surveyed larvae and adults at 15 sites along the Reedy River in Greenville Co., SC, USA, from sites in forested suburban landscapes through the urban core of the city of Greenville. We used principal component analyses and Akaike information criteria models to describe the relationships between larval and adult community descriptors (abundance, richness, and diversity) and habitat characteristics at several spatial scales, including water chemistry, sediment and detritus, aquatic and streamside vegetation, and the percent cover of landforms in the surrounding landscape. At all scales, larval abundance, richness, and diversity correlated with the amount of detritus. At a small scale, adult indices correlated with the amount of sunlight and streamside vegetation. Zygopteran community composition was nested at a large scale; richness and diversity did not correlate with changes in the landscape but increased downstream. Anisopteran composition was also nested, but richness correlated with the percent cover of field, wetland, and open water in the habitat and was unrelated to downstream site position. Landscape transformation affected anisopterans more than zygopterans by opening habitats that facilitate these generalist heliotherms." **19513.** Xu, J.H.; Liu, T.; Zhang, Y.; Zhang, Y.-N.; Wu, K.; Lei, C.; Fu, Q.; Fu, J.-J. (2021): Dragonfly wing-inspired architecture makes a stiff yet tough healable material. *Matter* 4(7): 2474-2489. (in English) ["Highlights: •A universal fabrication methodology for the stiff yet tough healable material. •The fabricated nanocomposite shows exceptionally enhanced strength and toughness. •3D-interconnected MXene framework enables fast NIR laser responsive healing property. •The nanocomposite demonstrates great potential for high-temperature EMI shielding. Abstract: Progress and potential: Mechanical robust yet healable materials have many promising engineering applications from intelligent architecture to the auto industry. However, most of them possess ultralow fracture toughness that significantly limits their application because of the possible catastrophic fracture mode caused by small defects or cracks. In this work, we

propose a previously unreported strategy that imitates the microstructure of dragonfly wings to make stiff, brittle, and healable materials become a defect-tolerant nanocomposite with stable crack propagation behavior. Except for unprecedentedly mechanical enhancement, the dragonfly wing-inspired continuous MXene framework confers a nanocomposite with exceptional thermal stability, fast NIR-responsive healing performance, and excellent electromagnetic interference shielding capability. This unique and scale-up produced nanocomposite may find applications in harsh environments with superior mechanical, healable, and functional properties. Summary: Mechanically robust and healable polymers are in high demand for the intelligent architecture, aerospace engineering, and auto industry; however, most of them suffer from brittle fracture owing to the inherent conflict between stiffness and toughness within polymer systems. Inspired by the microstructure of dragonfly wings, we show how brittle, stiff, and healable materials can become defect tolerant by strategies ranging from molecular design to structural processing. Transition metal carbides/carbonitrides form an interconnected mechanical framework, similar to the rigid nervure in dragonfly wings, to stabilize the growth and slow down the extension of crack, while the initially glassy healing polymer closely bonds to rigid framework through powerful interfacial supramolecular interactions, playing a key role in the soft membrane dissipating stress energy. Compared with initial polymers, the obtained SP/MXene (SPM) nanocomposite exhibits an increase in fracture toughness and flexural strength (54.3- and 25.0-fold, respectively), exceptional thermal stability, mechanical and functional repairability, and good electromagnetic interference shielding." **19514.** Yamada, S.; Urabe, J. (2021): Death-feigning behaviours increase survival rate of littoral cladocerans under predation by odonate larvae. *Freshwater Biology* 66(11): 2030-2037. (in English) ["1. Because littoral cladocerans are common prey for odonate larvae, they are ideal organisms to examine prey and predator interactions in aquatic habitats. Although death-feigning behaviour observed in littoral cladocerans is viewed as a trait to reduce predation risk, no study has examined the effectiveness of death-feigning at reducing mortality. We studied the effectiveness of death-feigning behaviour by two littoral cladocerans, *Chydorus sphaericus* and *Oxyurella tenuicaudis*, against the odonate larvae of *Sympetrum frequens*. 2. We first examined how the odonate larvae detected the prey and found that the larvae consumed active cladocerans, even under dark conditions, but they did not consume anaesthetised cladocerans, indicating that the larvae detect the prey using mechanical cues such as vibrational currents created by the prey individuals. 3. We then observed behavioural events of odonate larvae and prey cladocerans using a video-recording system to count the number of cladocerans that showed death-feigning behaviours when odonate larvae attacked and those that were not consumed when they showed

death-feigning behaviours. 4. We observed a total of 1,099 behavioural events in prey-predator interactions. On average, the odonate larvae pursued 63% of the cladocerans encountered, attacked 89% of the cladocerans pursued, and successfully captured only 29% of the cladocerans with the first attack. Among the cladocerans that were not captured, 38% of the individuals continually swam, but 62% ceased to move and exhibited death-feigning behaviours. The odonate larvae's capture rate for cladocerans exhibiting the death-feigning behaviours fell significantly short of that for cladocerans that were continually swimming. 5. The experiments clearly showed that the littoral cladocerans' death-feigning behaviour effectively decreased predation rate by odonate larvae. The results suggest that the death feigning serves as an adaptive behaviour to reduce mortality risk in littoral cladocerans under predation by such predators that can detect prey using mechanical cues such as those of vibrational currents." **19515.** Zhou, X.; Tan, Y.; Yi, X.; Wu, S.; Zhang, L.; Guo, A. (2021): Communities of adults dragonflies in rice fields in tropic and subtropic region in Hainan, China. *Chinese Journal of Tropical Crops* 42(9): 2711-2716. (in Chinese, with English summary) ["Dragonflies are increasingly used as the biological indicators to evaluate environmental quality. There are also many species of dragonflies in rice fields in Hainan Province. In order to make clear the community composition of dragonflies in rice fields in Hainan Province, the adult dragonflies were sampled in first and second rice seasons in 2017 in Sanya and Wenchang. The dragonfly community (n = 18 species, Tab. 1) was stable in different growth stages of two rice seasons in Hainan, with 5-15 species and (3.7±0.67) - (14.0±0.57) dragonflies per hundred clusters. The diversity index of dragonfly community was 2.007-2.193, the evenness index was 0.786-0.808, and the dominant concentration index was 0.148-0.190. 15 species from 3 families of adult dragonflies were collected in rice ecosystem in tropic region and 17 species from 2 families in subtropic region respectively and 11 species were both in Sanya and Wenchang. The similarity of community species was 0.701, and the similarity of dominant species was 0.857. In the first and second seasons there were significant differences in the number of individuals at tillering, flowering and fruiting stages in Sanya, while there were no significant differences in Wenchang. *Agriocnemis femina*, *Ceriatogon auranticum* and *Neurothemis tullia* may be sensitive to the change of environmental pollution in rice fields." **19516.** Kaye Brewer, S.K. (1997): The foraging behavior of *Anax junius* (Odonata: Aeschnidae) and its potential as a behavioral endpoint in pesticide testing. PhD thesis, Iowa State University: VI + 86 pp. (in English) ["I examined the foraging behaviour of the green damer dragonfly nymph, *Anax Junius*, to assess the suitability of odonate foraging behaviour as a sensitive endpoint for monitoring contaminant exposure. Odonates are potentially excellent organisms for work in biomonitoring programs because: 1) they have complex foraging strategies that tightly couple sensory cues and mechanical responses: 2) their ecology is well-studied: and 3) they are often the dominant invertebrate predator in fishless systems. Thus they have the potential to structure communities through predation. I tested 1) the possibility that nymphs may regulate populations through frequency-dependent foraging and 2) the relationship between head capsule cholinesterase (ChE) levels in nymphs exposed to an organophosphorus insecticide and subsequent foraging behaviour. Functional response models were developed for nymphs fed exclusively midges or amphipods and for nymphs fed mixed prey. Nymphs fed only midges exhibited a sigmoidal type III response (a prerequisite for frequency-dependent foraging): nymphs fed only amphipods exhibited a hyperbolic type II response. These results were reversed in mixed prey trials. Regardless of densities of prey offered, a higher percentage of midges were eaten compared to amphipods. Dragonflies did follow a simplified optimal foraging model based on energy maximization but they did not consistently exhibit frequency-dependent selection. ChE levels were slightly elevated in treated nymphs and foraging behaviours between treated and control groups were not statistically significant, most likely because of high variability in ChE activities within the control group and across treated groups. My results suggest that certain animals may be unsuitable for routine pesticide monitoring and prior to incorporating any species into a biomonitoring program, careful consideration of the species' sensitivity to the contaminant needs to be considered. Further work is needed to determine other factors that may influence ChE levels in species as well." (Authors)] Address: not stated

**19517.** McNamara, D. (1997): Dragonfly Spotting. The Bulletin of the Amateur Entomologists 56: 251. (in English) [Verbatim: In the Denham area on the 9th September 1987 it

was a typical "quality" British summer's day - blue skies, fresh but warm, little wind, and plenty to look at. Denham has a series of waterways, the River Colne in particular, the Frays, Alderbourne, and Misbourne, lots of ponds and lakes - some natural and others the result of gravel extraction (which still goes on in parts), streams and drainage ditches. Even the Grand Union Canal contributes to the flora and fauna of the area, its sedentary flow being a much cleaned-up act compared to ten years ago. This is a splendid area for dragonflies. The main problem with identification is the variability of adult insects and in particular the various colour stages they go through - new emergers being in some cases quite unlike older ones. Also there are similarities between close relatives. However, with a novice's luck and a good guide book, four species were identified with reasonable confidence: *Calopteryx splendens*, *Enallagma cyathigerum*; *Aeshna mixta*, *Sympetrum striolatum*. **19518.** Robinson, J.V.; Novak, K.L. (1997): The relationship between mating system and penis morphology in ischnuran damselflies (Odonata: Coenagrionidae). Biol. J. Linn. soc. 60(2): 187-200. (in English) ["Zygoptera belonging to the genus *Ischnura* are unusual amongst damselflies because of the variety of mate guarding techniques employed by males of different species. The lack of post-copulatory guarding combined with lengthy copulations in one group of ischnuran species suggest that these males guard females in copula. An examination of the accessory penes of species in this group indicates that all but one species have considerable microspination on the distal end (the flagella) of their penes that can function in sperm displacement. The flagella of these species are long and thin compared to those of other ischnurans. This is likely an adaptation to gain access to the spermatheca of the female. Two species tandem guard their mates during ovipositing. These species are the only ischnurans missing a stout pair of basal spines on the penultimate segments of their penes. They have considerable microspination over much of their penes but their flagella are of only moderate length and stout. Ischnurans that do not mate guard have short, stout flagella and most species examined from this group (5 of 7) have little microspination on their flagella tips. It is proposed that females of these species mate only once and therefore their males do not displace sperm. The relationship between mating system

and penis morphology in ischnuran damselflies (Odonata: Coenagrionidae)." (Authors)] Address: Robinson, J.V., Dept of Biology, Box 19498, I& Universi& of Texas at Arlington, Arlington, Texas 76019, USA

**19519.** Stoks, R.; Knijf, G. de; Jannis, G. (1997): De status van *Lestes barbarus* in België. *Gomphus* 13(1-2): 8-13. (in Dutch, with French summary) ["Before 1994 *Lestes barbarus* appeared very rarely and sporadically in our country. Since then the number of observations has increased dramatically (especially in 1995, with 100 contacts at 71 sites). The paper analyses the data by demonstrating breeding in several sites by the presence in consecutive years, by early periods of presence in sites known from the previous year (while in other sites the observations were made later in the season) and by direct evidence such as findings of larvae and neonates. With regard to the environments frequented, the almost constant presence of *Juncus effusus* and the drying out of many observation sites are noted; the diversity of physiognomy of the latter is however very high. The author concludes with a discussion on the chances of sustainability of these populations and the possible competition with *Lestes sponsa*." ## 1998

**19521.** Grell, H.; Grell, O.; Voß, K. (1998): Erfolgskontrolle von biotopgestaltenden Maßnahmen im Agrarbereich; Kleingewässer. Auftraggeber: Landesamt für Natur und Umwelt: 64 pp + Annex- (in German) [From April to October 1998, 100 shallow waters were studied in the north and east of Schleswig-Holstein. The waters are located in the outwash plains (22), in the young moraine (47) and on the Baltic Sea coast (31). Their bottom consists of clay, fen, anemic bog or sand. The size of the water bodies varies between 60 sqm and 9 ha. The water depth usually does not exceed one metre, and many water bodies have extensive alternating water zones. The small water bodies are mainly dug water bodies, while the large water bodies are almost exclusively the result of damming measures or rewetting. At least 85 of the water bodies are biotope creation measures carried out by various agencies. The vegetation and flora of the water bodies were studied, as well as the animal groups birds, reptiles, amphibians, grasshoppers, dragonflies and water beetles. Between 4 and 12 inspections of the water bodies were carried out. In addition, the loud calling amphibian species tree frog, fire-bellied toad, natterjack toad and green toad were surveyed in 7 areas. 204 specific plant species of the water bodies and banks were recorded, including 46 species of the Schleswig-Holstein Red List (hereafter "RL"). Furthermore, 36 breeding bird species (RL: 12), 4 reptile

species (RL: 3), 10 amphibian species (RL: 5), 5 specific grasshopper species (RL: 3), 32 dragonfly species (RL: 12) and 52 water beetle species (RL: 12) were recorded. All groups of organisms studied, with the exception of the water beetles which were only sampled at random, colonised the large water bodies significantly better than the small water bodies. The preference for large water bodies was particularly pronounced in the case of birds and reptiles. Furthermore, with the exception of the water beetles, all the organism groups studied showed a significantly higher species richness as well as a stronger occurrence of endangered species in the water bodies that were in an early to middle stage of succession. In contrast, species diversity was generally significantly lower in the more silted-up, shaded waters. In many older water bodies, extensive use, especially extensive riparian use, resulted in the long-term maintenance of early and intermediate successional stages. The water bodies showed marked natural differences with regard to their floristic and faunistic colonisation. Specific, often endangered species could be identified from several organism groups for all soil types or the corresponding natural areas. Even water bodies, which were heavily impaired by former intensive use and fertilisation, sometimes had a species-rich and/or rare colonisation, especially with regard to their bird, dragonfly and water beetle fauna. It is suggested that in future the creation of large, shallow backwaters with extensive alternating water zones should be promoted. To ensure the long-term preservation of early and middle succession stages, the water bodies should be extensively grazed." (Authors/DeepL)] Address: Landesamt für Natur & Umwelt, Hamburger Chaussee 25, 24220 Flintbek, Germany

**19522.** Oonk, M.M.A.; Giesen, T.G. (1998): Reproductietoets voor libellen in de Overasseltse en Hatertse Vennen. Opdrachtgever Staatsbosbeheer Regio Gelderland Arnhem. Giesen & Geurts, Ulf: 78 pp. (in Dutch) [Objective: In 1995 and 1996, commissioned by Staatsbosbeheer Regio Gelderland, it was investigated which of the dragonfly species, observed as exuvium in 1985 and 1986 in the Overasseltse en Hatertse Vennen, are still reproducing today. The aim of the study is to show whether the dragonfly population has been maintained since 1986. Possible changes in the population could be related to applied or neglected management, and possibly be translated into advice. In addition, the requirements of the present dragonflies (larvae) to the structure and vegetation of the banks as an ideal place for the larvae to hatch can be determined. For the management of ponds and banks it is also important to find out where on the bank the dragonflies hatch. Finally, by extrapolating the numbers of exuvia found in relation to the vegetation type, an overall estimate can be made of the quantities of dragonflies present. Method 64 permanent quadrats were set out in 17 fens to be studied in such a way that a sample area of the most important bank types was obtained. These PQs were thoroughly searched for exuviae a number of times. Results When ponds that were examined for exuviae in both '85/'86 and '95/'96 are compared, it appears that the number of species in five of the 13 ponds to be compared has increased. For the remaining ponds, there is a moderate to strong decrease in the number of species found. The most significant decline took place in Roelofsven, Oriolusven and Ketelven. Two species were not found, namely *Somatochlora metallica* and *Erythromma najas*. Strong decline was observed in *Leucorhinia dubia*, *L. rubicunda*, *Aeshna juncea* and *Pyrrosoma nymphula*. The data of each plot were extrapolated to exuviae per 10m<sup>2</sup> and plotted against the attractiveness of the plots (determined

on the basis of factors important to dragonflies). This gave rise to a significant correlation. Finally, for each species found, specific biotope requirements were described and related to the fens studied. Management in general it can be said that if the management in the fen area is aimed at maintaining stable dragonfly populations, it is essential to make the ponds as varied as possible without losing the characteristics of the individual ponds. Large-scale development measures, such as plowing, grubbing up and cleaning up after long periods of 'doing nothing', do not provide sufficient buffering or escape possibilities for species that do not benefit from these changes in the landscape in the short term. It would benefit most species if the management carried out was small-scale, with all ponds in the area being dealt with in a kind of rotation system in the longer term. This prevents every fen from having the same layout and being at the same stage of succession." (Authors/Deepl.) Address: Giesen & Geurts, Biologische Projekten, 't Goor 9, 7071 PC Ulf, The Netherlands

**19523.** Rambach, P.; Buchwald, R. (1998): Limnologische und vegetationskundliche Untersuchungen von Grundwasserbächen der südlichen Oberrheinebene. I. Riedkanal bei Wasenweiler (Freiburger Bucht, Südbaden). Mitt. bad. Landesver. Naturkunde u. Naturschutz N.F. 17(1): 59-84. (in German) ["The Riedkanal, a groundwater-influenced watercourse of the Upper Rhine Plain in Baden, runs in the channel system of the former East Rhine, which flowed through the low terrace between Kaiserstuhl and Tuniberg during the Würm Ice Age. As part of a diploma thesis at the Albert-Ludwigs-Universität Freiburg i.Br., the watercourse was investigated from May to October 1993 at four sites with regard to its physico-chemical factors and colonisation by macrozoobenthos; in addition, the Neugraben was analysed at two sites as a tributary polluted by wastewater. At the same time, the vegetation of these two watercourses was surveyed at a total of 18 sampling sites. Similarities and differences to typical lowland streams according to Braukmann (1987) were identified. The animal population largely consists of typical representatives of lowland streams such as *Asellus aquaticus*, *Gammarus pulex*, *G. roeseli*, *Polycelis ni gra*, *Polycelis tenuis*, *Dendrocoelum lacteum* and *Sialis lutaria*. Similarly, the strong dominance of crustaceans is characteristic of lowland streams. However, clear differences to lowland streams were also found, which can be attributed to the influence of groundwater. The cold stenothermy, which is not only limited to the narrow source area, and the constant oxygen deficit are unusual features for lowland streams. These milieu factors also characterise the animal and plant biocoenosis and distinguish the Riedkanal as a representative of the type "groundwater stream" according to Carbiener et al. (1987, 1990) or the "groundwater-dominated lowland stream" according to Timm (1994). Thus, groundwater macrophytes such as *Sium erectum*, *Nasturtium officinale*, *Veronica anagallis-aquatica* and *Callitriche obtusangula* colonise the entire longitudinal course of the watercourse studied. The occurrence of spring brook species such as *Arrenurus cylindratus*, *Hygrobatas prosiliens*, *Hygrobatas fluviatilis*, *Lebertia fimbriata*, *Lebertia sparsicapillata*, *Elmis aenea*, *Gammarus fossarum*, *Sericostoma personatum* and *Silo nigricornis* not only in the vicinity of the spring is a special feature of groundwater-dominated streams. The "dampening" influence of groundwater streams on the load of surface inflowing water is shown by the example of the tributary Neugraben. The study points to the necessity of typifying lowland streams not only according to geochemical conditions, but on a second level additionally with the help of the respective hydrological situation - e.g.

degree of groundwater influence. The macrophytes of the two study waters were related to a chain of plant communities which - following Carbiener et al. (1987, 1990) - was established for the natural area of the Upper Rhine Plain in southern Baden in a sequence of increasing trophic levels. While for the Riedkanal there was a slight shift from B-C to C in the longitudinal course, a sequence from (E-)D to (D-)C could be determined for the eutrophic Neugraben." (Authors/Deepl.) *Calopteryx virgo*, *Chalcolestes viridis*] Address: Buchwald, R., Institut für Biologie & Umweltwissenschaften, Carl von Ossietzky Univ. Oldenburg, Oldenburg, Germany

**19525.** Hirose, Y. (2000): The molecular evolutionary genetic analysis of Japanese Odonata by mitochondrial DNA sequence. Tombo 42. 2-13. (in Japanese, with English summary) ["The classification of Insecta has been made mainly by the morphological differentiation. In the case of Odonata, the cadual appendages, the vein structure and the form of thorax and abdominal macula are assumed to be the important discernible characters. These morphological properties, however, could be subtly varied by their geographical and environmental conditions. So the detail classification between species and subspecies has been confusing by researcher's various opinions. Specially, the species classified in Cordulidae which inhabit in the area from Japan to Europe shared so many similarities in their morphologies that many of them could not be positioned clearly in terms of taxonomy. As to Cordulidae in Japan, the seven genera, twenty species and two subspecies are being recorded by Ishida (1988). According to him, the *Somatochlora graeseri aureola* and the *Somatochlora graeseri graeseri* which distribute in Hokkaido are classified in subspecies but there is no differentiation in their form of the cadual appendages which seemed to be the standard classificina points of Odonata. The differentiation in female abdominal macula and fulvid in the base of wing are the only differentiation. Moreover, according to past studies, both subspecies were collected in the same area so it was thought to be contradiction to divide them on subspecies in terms of taxonomy. In Ishida's classification, Asahina (1950) classified the *Macromiinae* which belongs to Cordulidae as an independent family. These studies shows the classification done is not adequate method and it is necessary to review the morphological classification with adding some supplementary technique in classifying Cordulidae. On the other hand, in Insecta, all base sequence of mitochondrial DNA of *Drosophila yakuba* was defined by Lansman (1985) from 1983 to 1985. Since Lansman's study, a series of studies seeking genetic distance by using the DNA base sequence came to be done. In the area of the fishes for which a lot of studies has done, Maya et al. (1996) defined the mt DNA 12 region and 866 base of 16 S rRNA region to clarify the relationship of interspecies for Cyclothone in which the relatives of the line had not been cleared. This ribosomal RNA region is higher in preservability than the other protein coding region of mtDNA so that it is recognized as the effective region as the genetic marker to study mass genetics and evolutionary researches (Nei, 1990) of interspecies. From the mutation comparison of the base sequence in this region, it is expected

to establish the adequate phylogenetic systematics. This study focused on Corduliidae to which a lot of problems were pointed out on the morphological classification and analyzed mt DNA 12 and 16S rRNA region. Moreover, the relationship between each group was clarified based on the obtained result to assume a new criterion of the morphological classification, and the problem in the classification was also clarified. In addition, it was tried to elucidate the process of speciation at the present age by adding ten genera and eleven species of Odonata from Japan and by using the base sequence of mtDNA 12..16 S rRNA region to estimate the divergence times. In analyzing the base sequence, after amplifying the both regions of mtDNA-12 and 16S rRNA by the PCR (Polymerase Chain Reaction) method then processing the direct sequence for the obtained PCR product by the Dye terminator method, the base sequence was defined. As a result, 355 bases for 12S rRNA region and 514 bases for 16S rRNA region were estimated as the base sequence, then the genetic distance and the phylogenetic tree were made by substituting the difference of the base among groups in the Kimura's genetic distance formula. [The Clustal W (Multiple alignment and molecular phylogenetic Tree-making software) in National Institute of Genetics was used.] Comparing the phylogenetic tree obtained by analyzing the base sequence of mtDNA, with the current morphological classification, the obtained findings of each problem were brought together and described as follows. 1) As to the classification of *Somatochlora graeseri aureola* and *S. graeseri graeseri* which was assumed to be in the relation of subspecies under the current morphological classification, the comparison of the base sequence of mtDNA, there was no difference at all between them so they were seemed to be in the identical species. 2) Considering the relationship of *Somatochlora graeseri aureola* and *Somatochlora uchidai* which was defined as different species, the base sequence of mtDNA was also so high compared with other species that it was presumed that they were species which had differentiated the most recently in the Cordulidae genus. 3) As for the relationship of Cordulidae and the Macromiinae in which the definition in the morphological classification differed by each researcher and was not clarified, it was found from the base sequence in mtDNA that the Macromiinae had diverged from the ancestral strain first then the Libellulidae diverged secondly. As a result, it seemed to be questionable to classify Macromiinae which had diverged before Libellulidae did as a subfamily and preferable to classify it as an independent family. It is uncertain why the result shown above was obtained at this point. In addition to the result above, to estimate the divergence time of Anisoptera from the ancestral strain, in which Cordulidae belongs, the amino acid substitution rate ( $2.0 \times 10^{-8}$ ) of 12 and 16S rRNA and the difference of the base between the both species were calculated by substituting these figures in Kimura's formula (1980). Consequently, it was found that the group from the Zygoptera average to Anisozygoptera diverged about two hundred and million years ago and the group from Anisozygoptera to the Anisoptera average about a hundred and seventy million years ago. Although the fossil *Epiphlebia superstes* of which the estimated time was three hundred and million years ago was found, the divergence times of Odonata after this was completely unknown. It seemed to be very meaningful to be able to presume the concrete divergence times. Finally, in this research, it was realized to reexamine the problems of the morphological classification as a traditional method by using the biochemical genetic index and show the clear relationship of the groups which had not been so clarified. Moreover, by analyzing the DNA base sequence, new findings which differed from the

traditional classification could be obtained." (Author)] Address: Email: ezotombo9@yahoo.co.jp

## 2002

**19526.** Suga, C.; Tsukiji, K., Takeda, S. (2002): Effects of pesticides on rate of emergence of dragonfly larva. Annual reports of the society of plant protection of north Japan 53: 155-157. (in Japanese) ["Results and discussion The first hatching of dragonflies was observed on 6 August, and the development of dragonfly hatching shells continued until the end of October. The number of dragonfly larvae in June and July is shown in Fig. 1. The number of dragonfly larvae in the insecticidal zone was lower than in the other zones, but the analysis of variance did not show any significant difference (5% risk rate). The number of dragonfly larvae in the herbicide and fungicide plots was lower than that in the other plots. The number of hatched eggs in the herbicide and fungicide plots was almost the same as that in the control plot (Fig. 2). This suggests that the herbicides and fungicides had no effect on dragonfly larvae, but the insecticides either indirectly reduced the number of dragonfly larvae by acting on their prey organisms or directly affected their growth. However, it was not possible to determine which of the two was the main cause in this study. In addition to dragonfly larvae, several other aquatic organisms were observed in the insecticide treatments (Table 2). The occurrence of dragonfly larvae in this study was about one month later than that in normal paddy fields. The reason for this delay is that the hatching of dragonflies was delayed because the waterlogging started later than the usual flooding of rice fields, and the growth of dragonflies was delayed because they were not fed with food. The density of adult dragonflies in the control site was 76.3 dragonflies/m<sup>2</sup>, which was much higher than the reported density of hatchlings (8 dragonflies/m<sup>2</sup>)(3) in untreated paddy fields. However, this value is considered to be reasonable because the test was conducted in paddy soils that were judged to have produced many eggs in the previous year. In the fungicide-treated area, the hatching period was later than in the control area (Fig. 3). Since dragonflies hatch in a uniform manner, we tested the emergence rate of hatching shells at the end of August and found  $61.7 \pm 12.6\%$  in the fungicide-treated plots, which was not significantly different from  $85.5 \pm 12.6\%$  in the control plots (risk rate 5%). Since only about 5 adults hatched very late and the experimental system was inadequate, it can be assumed that this is within the margin of error. However, unlike actual paddy fields, the present study was conducted under conditions where there was no water runoff or infiltration into the ground by waterways, etc., and no organisms that prey on dragonfly larvae were present." **19527.** Wells, F.; Metzeling, L.; Newall, P. (2002): Macroinvertebrate regionalisation for use in the management of aquatic ecosystems in Victoria, Australia. Environmental Monitoring and Assessment 74(3): 271-294. (in English) ["The development of a broader, more holistic approach to aquatic ecosystem management has been called for in recent years. Physical and chemical objectives alone are no longer considered sufficient for the protection of aquatic ecosystems and should be supplemented with biological objectives. The ubiquitous and sedentary nature of macroinvertebrates [including Aeshnidae], combined with their measurable response to environmental conditions, favour their use as important indicators in environmental policies.

To establish biological objectives, there is a need for a regional framework to limit the variability between ecosystems. Past studies have demonstrated that an a posteriori regionalisation approach may be more useful than an a priori approach in explaining single component (e.g. macroinvertebrates) patterns across ecosystems. This is particularly important as aquatic resource management agencies often focus on one or two components of the ecosystem to assess environmental health. This study uses an a posteriori method to delineate and describe biological regions based on edge and riffle macroinvertebrate data. The regionalisation will provide a framework for setting biological objectives, based on the range of reference conditions measured within each separate region. The objectives will include regional checklists for taxa and biotic indices. Predictive modelling in the style of RIVPACS or AUSRIVAS will also be used within each region to develop objectives, incorporating local, regional and systematic features as predictor variables." ## 2003

**19528.** Buchwald, R. (2003): Vegetationskundliche und ethologische Aspekte bei der Habitatwahl von Libellen, dargestellt am Beispiel der Glänzenden Binsenjungfer und der Gefleckten Heidelibelle in den Karst-Hochebenen Mittelitaliens. *Berichte der Reinhold-Tüxen-Gesellschaft* 15: 89-104. (in German, with English and Italian summaries) ["The present long-year study deals with investigations on habitat choice of two dragonfly species with special reference to the importance of floristic composition and vegetation structure. Some karst plateaus of Central Italy possess a large number of standing waters which differ predominantly in hydrological conditions and vegetation. Due to these differences I separated four vegetation types in the permanent and temporary waters. The Odonata species *Lestes dryas* and *Sympetrum flaveolum* showed marked differences in abundance and frequency in these four vegetation types. In particular, dragonflies of both species failed to appear or occurred only in low numbers when the waters dried up early in the reproductive season. Using a floristic-phytosociological and a hydrological-structural approach, more detailed analyses on some parameters of the vegetation, the morphology, the soil and the hydrological conditions of the waters pointed out that abundance and frequency of both species are correlated mainly with the following factors: aspect (physiognomy) of the vegetation, vegetation height in the peripheral and central parts of the waters, vegetation colour, and the degree of steepness at the margin of the aquatic habitat. The imagoes of both species preferred permanent or temporary waters with flat shore and vegetation which was dominated by green (to brown or yellow) stands of the growth forms "large sedge" and "rush(-like)"; the minimum height of the vegetation was (30-)35 cm (for *L. dryas*) respectively 20 cm (for *S. flaveolum*) in the peripheral parts and 35 cm (for *L. dryas*) respectively 25 cm (for *S. flaveolum*) in the central parts of the waters. The present study reveals that both the floristic-phytosociological and the hydrological structural approach give important information about the specific bond to vegetation and the habitat choice of the dragonfly species investigated here. Additional eco-behavioural studies should be carried out to verify and understand the present results by other approaches and methods." (Author)] Address: Buchwald, R., Institut für Biologie und Umweltwissenschaften, Carl von Ossietzky Universität Oldenburg, Oldenburg, Germany

**19529.** Burtch, M. (2008): The effects of algae leaf coverage and flow rate on oviposition choice in *Calopteryx maculata*. Report, UMBS Evolution 390, University of Michigan, Ann Arbor, MI: 16 pp. (in English) ["Female *Calopteryx maculata* are endophytic egg layers; they place their eggs within floating aquatic vegetation. In this study artificial oviposition leaf patches were created and placed in different sites along the Maple River near Pellston, MI. The varying flow rates were recorded and after 48 hours the leaf patches were collected. The egg number or oviposition sites were counted on each leaf along with the percent algae leaf coverage. The effect of algae leaf coverage and flow rate on oviposition preference were statistically measured; algae leaf coverage did not affect oviposition frequency ( $p > 0.05$ ) and intermediate stream flow was preferred over slower and faster flow rates as oviposition sites ( $p < 0.05$ ). The reason for this correlation is unknown, however, it could relate to the optimal conditions for egg growth and development. It is impossible to know whether oviposition flow/rate preference is the result of the male or female's choice. More research of egg development and observational data would provide more insights into the reasoning for intermediate flow oviposition preference." (Author)] Address: not stated

**19530.** Heitkamp, U. (2008): Zur Wirbellosenfauna des NSG „Denkershäuser Teich“ in Süd-Niedersachsen. Kommentierte Artenliste. *Naturkundliche Berrichte Fauna Flora Süd-Niedersachsen* 13: 65-107. (in German) ["The data material of this publication on the invertebrates of Denkershausen Pond was collected between 1984 and 1987 and between 1999 and 2005. The limnofauna with the macrobenthos fauna of the tributaries as well as the small crustaceans and the other invertebrates including the insects of the pond and ditches were recorded. Complete data are available on the turbellarians, molluscs and odonates, while those of the other groups had to remain more or less incomplete due to the survey methodology. As far as recorded, the current situation of the species is compared with that of the 1980s and KRUEL's (1940) results from the early 1930s. From the terrestrial area, especially the group of hay ticks is documented in detail. In addition, data material on the web spiders, isopods, short-winged beetles and day butterflies was evaluated. Altogether, the work represents a documentation of the faunistic state of the pond area from different historical periods. It completes previous publications on ground beetles, ground-dwelling spiders and weavers as well as vertebrates (excl. birds) of the Denkershausen pond. ... In the 2000s and 1984-86, 21 dragonfly species were recorded at the pond, 13 of which were indigenous species (Table 7). The most common species were the Great Skylark and the Horseshoe damselfly. KRUEL (1940) identified three further species, the Southern rush damselfly, the bat damselfly and the large pomegranate, which no longer occur at the pond. The 21 species correspond to approx. 31 % of the dragonfly species recorded so far in Lower Saxony." (Author/DeepL)] Address: Heitkamp, U. Bergstr. 17, 37130 Gleichen-Diemarden, Germany

**19531.** McMunn, M. (2008): Oviposition preference in the Dark-Winged Damselfly (*Calopteryx maculata*). Report, Joint project for Evolution and Natural History (BIO 390), University of Michigan, Ann Arbor, Michigan: 13 pp. (in English) ["Our study investigated preference of oviposition in *Calopteryx maculata*, the dark-winged damselfly. Artificial damselfly territories were created using several leaves of *Sparganium americanum* fixed in place in a river, at known

flow rates for 48 hours. On each leaf total eggs were counted and algal coverage was measured. We found that *C. maculata* oviposits more frequently in areas of intermediate flow rate, approximately 0.2-0.4 m/s. We also found that algal coverage was more common in this flow rate range, suggesting that damselflies oviposition choice is not affected by the presence of algae and that there is a relatively narrow window of optimum flow rate for oviposition." **19535.** Partridge, R. (2012): A swarming of Migrant Hawkers. *Bulletin of the Amateur Entomologists' Society* 71: 181. (in English) [Verbatim: On the evening of Sunday the 2nd of September 2012, after a long day in the garden, my wife and I decided to go for a walk around one of our local gravel pits in Block Fen, Cambridgeshire. It was a very fine evening, warm, calm and still sunny at 19-00 hours. Dragonflies were much in evidence, particularly Common Darters, *Sympetrum striolatum*, *S. sanguineum*, *Aeshna grandis* and *A. mixta*. As we rounded a corner in one of the most overgrown parts of the bank, we could see immediately some unusual behaviour amongst a group of dragonflies; they were very low to the ground, just a foot or two above the vegetation, and flying madly back and forth in the tightest of circles. When we approached for a closer look, they took no notice of us – we were able to stand within a yard of all the activity. A dozen or fifteen dragonflies were involved, all were *A. mixta* as far as I could tell, and all appeared to be males. We could now see what they were so intent upon. A large anthill was here and there were many flying ants coming up out of it, climbing the grass stems and taking off. These weakly-flying, and probably quite juicy, insects were an easy target for the Hawkers, and they must have taken hundreds of them if the feeding frenzy continued for any length of time. I am sure that this has been observed many times before but I have not yet come across an account of it in the literature that I have.] Address: Partridge, R., 11 New Rd, Mepal, Ely, Cambridgeshire CB6 2AP, UK. **19538.** Fan, T.; Zhang, R.; Fan, F.; Liu, Z.; Xiong, J. (2014): A water surface small target detection approach inspired by

dragonfly vision mechanism. *WIT Transactions on Engineering Sciences* 94: 151-157. (in English) [oas 63; "Weak and small target detection technique is widely used in military and industry applications. The targets are weak and small in the image when targets are far from the imaging system. Under this complex condition, the image has very low SNR and it is difficult to detect the targets On this situation, a weak and small target detection approach based on dragonfly compound eye is proposed in this paper. Dragonfly compound eye has obvious characteristics of polarized light, and it can detect the surface of water and the targets on water accurately The new method uses the polarization characteristics of dragonfly compound eye to get the polarization image of targets, and then completes the weak small target detection. The experimental data shows that this new target detection method has advantages of high precision and small false alarm rate." **19539.** Winkler, C. (2014): Die Heuschrecken- und Libellenfauna im Umfeld des Winderatter Sees - Erfassungen in den Jahren 2013 und 2014. Auftraggeber: Winderatter See-Kielstau e.V., Förderverein für Natur und Umwelt, Willfried Janßen, Osterdorf 2, 24975 Ausacker. Auftragnehmer und Bearbeitung: Christian Winkler, Faunistische Gutachten, Bahnhofstr. 25, 24582 Bordesholm, Germany: 48 pp. (in German) [Schleswig-Holstein, Germany; "In 2013 and 2014, surveys of the dragonfly and grasshopper fauna were carried out in the area of Lake Winderatt. In addition to the lake, the approximately 100-hectare study area also included adjacent semi-open pasture landscapes belonging to the Schleswig-Holstein Foundation for Nature Conservation, a forest area, two wooded areas and the westernmost part of the Hadeby depression, which is characterised by wet grassland fallows. The dragonflies were recorded on the basis of the imagines at 11 shore sections of Lake Winderatt and at 23 small water bodies. All survey waters were checked on six dates between 20.06. and 01.10.2013 and on 26.05.2014. A total of 28 dragonfly species were recorded, 26 of which were classified as potentially native. *Lestes virens* and *Coenagrion lunulatum* (potentially native) are classified as "critically endangered" throughout the country. The latter is listed as "threatened with extinction" in the nationwide Red List. Furthermore, two "declining" species were found: *Aeshna juncea* and *Sympetrum flaveolum*. *Sympecma fusca* is another species that is very rare in the region. [...] Finally, from the point of view of dragonfly and grasshopper protection, deficits of the study waters and sample areas are pointed out and protection and development measures are presented (Tables 6 and 7). Deficits related to the current grazing management can only be identified at certain points and are not classified as serious at the level of the study area and its sub-areas." **19542.** Bagheri, Z.M.; Wiederman, S.D.; Cazzolato, B.S.; Grainger, S.; O'Carroll, D.C. (2015): Robustness and real-time performance of an insect inspired target tracking algorithm under natural conditions. *Computational Intelligence, 2015 IEEE Symposium Series* : 97-102. (in English) ["Many computer vision tasks require the implementation of robust and efficient target tracking algorithms. Furthermore, in robotic applications these algorithms must perform whilst on a moving platform (ego motion). Despite the increase in computational processing power, many engineering algorithms are still challenged by real-time applications. In contrast, lightweight and low-power flying insects, such as dragonflies, can readily chase prey and mates within cluttered natural environments, deftly selecting their target amidst distractors (swarms). In our laboratory, we record from 'target-detecting' neurons in the dragonfly brain that underlie this pursuit behavior. We recently developed a closed-loop target detection and tracking algorithm based on key properties of these neurons. Here we test our insect-inspired tracking model in open-loop against a set of naturalistic sequences and compare its efficacy and efficiency with other state-of-the-art engineering models. In terms of tracking robustness, our model performs similarly to many of these trackers, yet is at least 3 times more efficient in terms of processing speed." **19543.** Boda, R. (2015): A kétcsíkos hegyiszitaköto (*Cordulegaster heros* Theischinger, 1979) életciklusának vizsgálata hegyvidéki vízfolyásokban: lárvális fejlődés, élőhelypreferencia és kirepülési viselkedés. PhD thesis, School of Biology and Sports Biology, Ecology Program, University of Pécs: 126 pp. (in Hungarian, with English summary) ["Studies on the life history of the Balkan Goldenring (*Cordulegaster heros* Theischinger, 1979) in mountain streams: larval development, habitat preference and emergence behaviour. - The main aims of our work were to provide well-based basic information on life cycle (including larval development and emergence period), habitat preference, spatiotemporal microdistribution of the Balkan Goldenring, a charismatic dragonfly species with special importance for nature conservation, and to explore the role of the environmental factors determining all of these aspects, as detailed as possible. Our basic results may encourage the development of specific nature conservation action and successful species conservation programme. In order to explore the whole life cycle of the species, we used two different sampling procedures, which are both recommended for Odonates: 1) Quantitative samplings of larval assemblages were performed at eight sampling sites throughout a year with monthly intervals 2) Quantitative collection of exuviae were conducted at two sites in the emergence periods in two consecutive years. In parallel with samplings, morphometrical measurements were also performed on every captured individual, and local (water chemistry, streambed morphology, hydrology, habitat structure), vegetational (litoral vegetation types, naturalness, presence/absence of plant species, vegetation structure) and regional (climatic features and stream network position) factors were also measured

and/or determined. New scientific results have been achieved, as follows: 1. We provided new faunistic data for the species from 69 sampling sites. We detected the occurrence of the species from 19 streams for first time. Thus, we contributed significantly to the clarification of the Balkan Goldenring distribution in the South-Transdanubian region. 2. We determined the numbers of the last larval instars and the time which the larvae spent in each instar. Based on the spatiotemporal microdistribution of the larval stages we described larval development processes and determined the duration of the larval development: in the Mecsek Mountains, larval development of the species lasts at least three, but at last four years depending on the biotic and abiotic characteristics of the habitat and the weather conditions. 3. We explored the emergence dynamics and its schedule: the emergence period of the species in the Mecsek Mountains was prolonged and less synchronized. 4. We proved that beyond the differences among the streams the variation in the type and microhabitat structure of the mesohabitats plays important role in forming spatiotemporal microdistribution of the species. 5. We confirmed that the distribution of the larval stages within a stream section, because of the mesohabitat preference with different strength in different larval stages, is affected in different degree by the riffle-pool structure. This refined and supplemented our knowledge on the multilevel habitat preference of the species. 6. We described in detail the distances travelled by the larvae from the water margin to the emergence site. We found significant differences in these distances between streams and sides of a given stream. We clearly explained these differences with different composition and structure of the littoral vegetation of the habitats. We found that the larvae must leave the ground/water surface and climb vertically before the beginning of the emergence process, and emergence always happens in upright position. 7. We described in detail the emergence substrate selection process and proved that the most important emergence substrate is the tree trunk, regardless of its current cover. The variation in emergence substrate choice increases with increasing of the variation in available substrate types, but the domination of the tree trunks is remained throughout. The distribution of the available substrate resources affect, but not significantly define, the emergence-substrate selection.] Address: not stated

**19545.** El Souki, M.; Blanco-Belmonte, L.; Lasso, C.A.; Mora-Day, J.; Magalhães, C.; Pisapia, D.; Mora, A.; Lasso-Alcalá, O.F.M. (2015): Composición y distribución de la comunidad de insectos acuáticos en un gradiente espacial del alto río Cuyuní, Guayana venezolana. *Mem. de la Fund. La*

*Salle de Cienc. Nat.* 2015 ("2011"), 71(175–176): 79-103. (in Spanish, with English summary) ["Composition and distribution of the community of aquatic insects in a spatial gradient of the Cuyuní River, Venezuelan Guayana: Richness, composition and distribution of the communities of aquatic insects were estimated along a longitudinal gradient of the Cuyuní River and its tributary (Uey River), basin of the Essequibo. Samplings were carried out for 13 days in January 2008 in 36 sampling stations distributed in five focal areas (AF) to cover the heterogeneity of habitats. Species richness was higher in the high basin of the Uey, least disturbed area. The composition of species in the gradient appears to be related with changes in transparency, depth, temperature, and total solids in suspension. The higher and media basin of river Uey corresponded to black, transparent and less deep waters with the majority of the species belonging to the orders Plecoptera, Trichoptera and Ephemeroptera. In the low river Uey and Cuyuní River stations, the main species corresponded to the orders Odonata, Hemiptera and Coleoptera, associated with higher temperatures, deeper and less transparent waters and where this change in species composition was probably influenced by the disruption caused by the mining activity observed and reflected in the increase of dissolved and suspended material." **19546.** Gies, M.; Sondermann, M.; Hering, D.; Feld, C.K. (2015): Are species distribution models based on broad-scale environmental variables transferable across adjacent watersheds? A case study with eleven macroinvertebrate species. *Fundam. Appl. Limnol.* 186/1–2: 63-97. (in English) ["Species distribution models (SDMs) allow the prediction of the spatially explicit presence and absence of species based on environmental predictors that reflect the species' habitat requirements. In river macroinvertebrates, the habitat is often defined at very fine scales spanning one to several tens of square meters (e.g., substrate preferences). Such habitat information, however, is usually not available for entire river networks at the large scale, which limits the application of SDMs in conservation ecology. In this study, we present SDMs of eleven lotic macroinvertebrate species based on two broad-scale environmental variable groups: land use (derived from ATKIS high resolution land cover map) and physical habitat structure (derived from regional surveys in Germany). The actual species distributions were scanned through a field survey at 225 sites in two adjacent watersheds in a mountainous region (river Ruhr and Lenne, Federal State of North Rhine-Westphalia, Germany). The aim of this study was, first, to test the usefulness of broad-scale variables in SDMs using measures of model goodness-of-fit and predictive power. Second, local habitat variables (physico-chemistry and meso-scale substrates) were included in SDMs to examine model improvement. Third, we tested the transferability of models of the same species between the two watersheds. Due to the similar environmental characteristics of both watersheds, we hypothesized concordant SDMs for both watersheds. Overall, we found a reliable performance and predictive power of models of *Dinocras cephalotes* in both watersheds. Models of several other species performed fair in the Ruhr (*Leuctra geniculata*, *Silo piceus*, *Siphonurus lacustris*) but not in the Lenne system or vice versa (*Hydropsyche instabilis*). Broad-scale SDMs included predictors on physical habitat quality as well as riparian land use at a similar extent. Only for five models the

SDMs including fine-scale predictors (e.g., physico-chemistry, microhabitat distribution) outperformed those models with broad-scale predictors only (AUC > 0.70). We suggest that species specifically distributed in upstream reaches explicitly respond to fine-scale variables due to stronger dependency of their occurrences on local conditions. Model transferability from one watershed to another was low (transferability index < 0.6), thus revealing SDMs not only to be species-specific but also variable across adjacent watersheds. We suggest that the transferability was limited not only by actual environmental differences between both watersheds, but also by legacy land use effects that may continue to affect the recent distribution of macroinvertebrates." **19547.** Golfieri, B.; Surian, N.; Hardersen, S.; Maiolini, B. (2015): Towards a MORE comprehensive assessment of river ecological conditions: application of a new dragonfly-based index in northern Italy. REFORM. D7.5 Conference proceedings 'Novel approaches to assess and rehabilitate modified rivers': 109-115. (in English) ["In this study we analysed the relationships between the Morphological Quality Index (MQI) and three biotic indices that are based on different riverine organism groups (dragonflies, diatoms and benthic macroinvertebrates). The study was carried out in fifteen river reaches in the alluvial plains of northern Italy. Benthic macroinvertebrates and diatoms are good indicators of water quality, but seem not to be sensitive to hydro-morphological degradation, while dragonflies provide information about the ecological integrity and habitat heterogeneity of both the aquatic breeding sites and the surrounding terrestrial areas, due to their amphibious life cycle and their well known ecological requirements. Starting from a dragonfly-based assessment system proposed in Austria, we developed a multimetric index, the Odonate River Index (ORI), which assesses the conditions of the whole river corridor, because also secondary channels and ponds in the floodplain are sampled. MQI and ORI turned out to be highly correlated, while no significant relationships were found between MQI and the indices that are based on diatoms (i.e. ICMi) and benthic macroinvertebrates (i.e. STAR\_ICMi). These results suggest that dragonflies are good indicators of the ecological integrity of river corridors at reach scale, also reflecting morphological quality, and that the ORI provides information on the ecological condition of rivers not covered by the other bioindicators." (Authors)] Address: Golfieri, B., Dept of Geosciences, University of Padova, Via G. Gradenigo 6, Padova, 35131, Italy

**19548.** Ileperuma Arachchi, I.S.; Wickramasinghe, S. (2015): Resource partitioning and niche Overlap in three sympatric species of dragonflies (Anisoptera: Libellulidae) in Anuradhapura District, Sri Lanka. Proceedings of the International Forestry and Environment Symposium 2015 of the Department of Forestry and Environmental Science, University of Sri Jayewardenepura, Sri Lanka: (in English) [Verbatim: "Resource partitioning in ecological communities bears profound connection with the coexistence of closely related species. As a mechanism, it assists species with similar characteristics to thrive in the environments where they can utilise resources in different levels in spatial and temporal scale via niche partitioning. As ecologically important insects, dragonflies are well-studied in many aspects globally but poorly assessed locally. The current study was conducted under the main objective of identifying the

mechanism of resource partitioning in three sympatric most common skimmer species; *Brachythemis contaminata*, *Crocothemis servilia servilia* and *Rhyothemis variegata* variegata in two tank ecosystems in Anuradhapura district, Sri Lanka. The study was conducted from May-August 2014 simultaneously in Nabadagaswewa tank (NW) and Mihintale tank (MT). Data collection was carried out 08:00 to 10:00 hrs in the morning and 13:00 to 15:00 hrs in the evening. Land-water interface at the tank was used for the study in both sites. Scan sampling was used to obtain data on resource utilisation by the three skimmer species. Randomly selected individuals were observed for 30 seconds in each observation point. Vegetation variables (bank vegetation density and height, aquatic vegetation density and height) were measured using two belt transects (25×1 m<sup>2</sup>) in both habitats. The three species were more active in the morning hours (08:00 to 10:00 hrs) and shows different levels of perch and fly heights in the morning and evening hours. *R.v. variegata* was recorded using heights of <100 cm in both habitats. *B. contaminata* and *C.s. servilia* showed high spatial niche overlap (Oij=0.716) in NW and in MT highest spatial niche overlap was observed between *C.s. servilia* and *R.v. variegata* (Oij=0.473). The broadest niche breadth was exhibited by *C.s. servilia* (B=0.46) in NW while *B. contaminata* showed the highest (B=0.23) in MT. *R.v. variegata* showed the lowest niche breadth in both habitats (NW: B = 0.39, MT: B=0.09). Relationship between the species abundance and vegetation heights and densities shows that vegetation height and bank vegetation densities were negatively correlated with the abundance of the three skimmer species. This study depicts ways of resource partitioning among the three sympatric skimmer species minimising interspecific competition and favoring their co-existence. Further, it highlights the extent of spatial niche overlap is influenced by the habitat characteristics especially the vegetation structure and resource availability." **19550.** Kloskowski, J.; Trembaczowski, A. (2015): Fish reduce habitat coupling by a waterbird: evidence from combined stable isotope and conventional dietary approaches. *Aquatic Ecology* 49: 21-31. (in English) ["Aquatic consumers can function as habitat couplers by using allochthonous subsidies of prey that migrate across ecosystem boundaries. We examined the relative use of allochthonous (invertebrates—terrestrial or living on littoral vegetation; immigrating amphibians) versus autochthonous (aquatic invertebrates, fish) resources by the red-necked grebe *Podiceps grisegena*, a generalist predator, on fishless ponds versus ponds stocked with common carp *Cyprinus carpio*. We combined conventional methods of diet estimation with stable carbon and nitrogen analyses of egg yolks and putative prey of grebes. Pre-laying grebes were observed to take mainly adult amphibians on fishless ponds and fish on stocked ponds. Alimentary tract analyses gave more weight to invertebrate prey, especially leaf beetles *Donaciinae*, apparently picked off water or emergent plants. Bayesian isotopic mixing models did not reveal predominance of a single food source but indicated that in the presence of fish grebes received relatively less energy for egg formation from amphibians and leaf beetles. Overall, our results show that grebes relied more on allochthonous resources (range of means 50–97 % of the biomass contribution estimated by different assessment methods) in the absence than in the presence of fish (8–23 %). We suggest that habitat coupling by waterbirds may be controlled by fish, which can suppress external prey subsidies, apart from being an attractive food for piscivorous birds." (Authors) The study includes "Odonata".] Address: Kloskowski, J., Dept of Nature Conserv., Institute Biol., Maria Curie-Skłodowska Univ., Akademicka 19, 20-033 Lublin, Poland. **19552.** Le Naour, A. (2015): Etude de l'occupation de l'espace et des déplacements de deux espèces utilisées pour la cohérence nationale des Trames Verte et Bleue: *Leucorrhinia caudalis* et *Emys orbicularis*. Structure d'accueil, A.N.E.P.E. Caudalis, 9 Rue du Nouveau Calvaire, 37100 Tours: 41 pp. (in French, with English summary) ["Biodiversity is suffering a major crisis of extinction. The "Trames verte et bleue" policy aims to curb this erosion. In this context, displacement and site occupancy in two species associated with both aquatic and terrestrial environment: the lilypad whiteface (*Leucorrhinia caudalis*) and European pond turtle (*Emys orbicularis*). Both are considered as "national coherence" species and were studied in the south of Indre-et-Loire, France. The lilypad whitefaces were equipped and monitored using passive transponders (Recco System) during their maturation phase, and European pond turtles were equipped with i-GotU GT-120 GPS data loggers at the beginning of spring. The results show that lilypad whitefaces disperse more and more from their emergence site over time, and they are not found on water. During this period, they don't select any terrestrial habitat in particular. For the European pond turtle, home range includes several types of habitats, and areas with tussocks of sedge and willow flooded and marshy woodlands are selected by individuals. Crops areas are used as egg-laying habitat, which may cause conservation issues. Very few large dispersal events occurred in both species in this study, suggesting that such movements remain rare. Results suggest that *L. caudalis* progressively colonize the canopy, and then are undetectable with the Recco technology. For European pond turtle, marshy woodlands have been clearly identified as corridors. Thanks to innovative monitoring technologies, the study highlights the importance of habitat diversity for the life cycle and is therefore a challenge for the conservation of both species." **19555.** Lin, Y.-q. (2015): Design of new vortex-based flow chips to capture particles. Department of Mechanical and Electrical and Mechanical Engineering Master Program Thesis Tamkang University; 2015 (2015/01/01), P1 - 78: (in English) ["This work presents the design of a new flow chip to capture particles. A dragonfly wing blocks along the centerline of a microchannel to generate multiple vortex in the corrugated grooves streamwisely. These multiple vortex in the dragonfly wing are used to capture more particles. Different from the conventional vortex-based flow chips with rectangular grooves along the both sides channel wall, the dragonfly wing grooves here in is designed to capture central -part particles novelly. The chord length of the dragonfly wing is 806  $\mu\text{m}$  and thickness ratio is 7.5 %. Through the CFD simulation result (by COMSOL or FEMLAB), the inlet velocity of 0.52m/s can induce obvious vortex pattern in the corrugated dragonfly wing inserted in a microchannel of 200 $\mu\text{m}$  wide. The inclined angle of 50° at the channel entrance can provide enough initial vorticity strength beneficial to the particle capture rate of 4% per dragonfly wing structure. This work also tried two dragonfly structure cascadedly connected together. When the thickness ratio of the dragonfly wing double, the cascaded two-wing case can increase the capture ratio up to 6%. These simulation message reveals the usefulness of increasing the particle capture ratio of flow array design. It's also good for the integration and application in tumor cell capture, sorting and separation in the future.] Address: not stated

**19556.** Maples, M.J. (2015): An investigation of the effect of malathion on adaptive plasticity of *Pseudacris sierra*. MSc thesis, Faculty of California Polytechnic State University, San Luis Obispo: XI + 56 pp. (in English) ["This thesis is composed of two chapters. Chapter one reviews what is known about adaptive plasticity in response to predators, describes the physiological systems involved in such plasticity, and outlines the evolutionary consequences of adaptive plasticity. Chapter two describes a scientific experiment that investigates how malathion may impact adaptive plasticity in the Sierran Treefrog, *Pseudacris sierra*. Anuran tadpoles suffer high mortality rates due to predation. In response to strong selective forces relating to these high predation rates, tadpoles evolved the ability to adaptively respond to predators through morphological and behavioral plasticity. The morphological and behavioral responses are varied and depend on the hunting strategy of the predator, and the adaptive responses may be influenced by other biotic and abiotic factors. Tadpoles detect alarm cues released from tadpoles being eaten and kairomones that are released by predators. Tadpoles respond to these signals by

changing tail and body shape along with a reduction of activity level, which enables tadpoles to escape predators more effectively. These changes in morphology can occur within a week, and behavioral changes can occur within 15 minutes. The adaptive responses are critical for increasing survival rates of tadpoles to metamorphosis and may have important evolutionary consequences for anurans. Amphibians are in decline worldwide, and pollutants are considered to be a major contributor to these declines. Every year 5.2 billion pounds of active ingredients of pesticides are applied worldwide, and these application rates have led to ubiquitous low-level contamination of aquatic ecosystems. How low-level contamination of pesticides directly and indirectly affect how tadpoles respond to their predators is poorly understood. One potential indirect effect of pesticides is the inhibition of adaptive plasticity. Pesticides have been shown to modulate corticosterone levels in tadpoles. Corticosterone is the most likely mediator of the physiological response that results in adaptive morphological change. If the physiological system of tadpoles relies on corticosterone as the mediator of adaptive response, and pesticides can modulate corticosterone levels, then pesticides may inhibit or negatively impact adaptive responses to important biotic factors, like predators. Pesticides have been shown to weaken immune systems, affect developmental and physiological pathways that lead to malformations, and cause direct mortality in anurans. Little research has investigated the effect of pesticides on adaptive morphological and behavioral plasticity in response to predators. Adaptive phenotypic responses to predators increase survival rates to metamorphosis and are important in stabilizing amphibian populations through time. If pesticides influence the ecological interactions of tadpoles and their predators, this could play a part in amphibian declines. In the experiment explained in Chapter two, I tested the hypothesis that malathion at a concentration of 0.1 mg/L inhibits anti-predator morphological and behavioral responses of *Pseudacris sierra* to the predatory dragonfly larvae *Anax junius*. The results of this experiment show that malathion alone caused the tail muscle depth to increase to the same magnitude as tadpoles that only experienced a predator's presence. Malathion also caused a significant increase in tail depth, demonstrating that malathion directly causes morphological change. The experiment did not support the hypothesis that malathion inhibits adaptive plasticity, and malathion had no impact on behavioral plasticity. The results from this experiment give evidence that an ecologically relevant concentration of malathion can influence morphological components that are critical in escaping depredation events, which could affect predator-prey interactions." **19557.** Mischiati, M.; Lin, H.-T.; Herold, P.; Imler, E.; Olberg, R.; Leonardo, A. (2015): Internal models direct dragonfly interception steering. *Nature* 517: 333-338. (in English) ["Sensorimotor control in vertebrates relies on internal models. When extending an arm to reach for an object, the brain uses predictive models of both limb dynamics and target properties. Whether invertebrates use such models remains unclear. Here we examine to what extent prey interception by dragonflies (*Plathemis lydia*), a behaviour analogous to targeted reaching, requires internal models. By simultaneously tracking the position and orientation of a dragonfly's head and body during flight, we provide evidence that interception steering is driven by forward and inverse models of dragonfly body dynamics and by models of prey motion. Predictive rotations of the dragonfly's head continuously track the prey's angular position. The head-body angles established by prey tracking appear to guide systematic rotations of the

dragonfly's body to align it with the prey's flight path. Model-driven control thus underlies the bulk of interception steering manoeuvres, while vision is used for reactions to unexpected prey movements. These findings illuminate the computational sophistication with which insects construct behaviour." **19558.** Murugan, K.; Sanoopa, C.P.; Madhiyazhagan, P.; Dinesh, D.; Subramaniam, J.; Panneerselvam, C.; Roni, M.; Suresh, U.; Nicoletti, M.; Alarfaj, A.A.; Munusamy, M.A.; Higuchi, A.; Kumar, S.; Perumalsamy, H.; Ahn, Y.-A.; Benelli, G. (2015): Rapid biosynthesis of silver nanoparticles using *Crotalaria verrucosa* leaves against the dengue vector *Aedes aegypti*: what happens around? An analysis of dragonfly predatory behaviour after exposure at ultra-low doses. *Natural Product Research: Formerly Natural Product Letters* 30(7): 826-833. (in English) ["*Aedes aegypti* is a primary vector of dengue, a mosquito-borne viral disease infecting 50–100 million people every year. Here, we biosynthesised mosquitocidal silver nanoparticles (AgNP) using the aqueous leaf extract of *Crotalaria verrucosa*. The green synthesis of AgNP was studied by UV–vis spectroscopy, SEM, EDX and FTIR. *C. verrucosa*-synthesised AgNPs were toxic against *A. aegypti* larvae and pupae. LC50 of AgNP ranged from 3.496 ppm (I instar larvae) to 17.700 ppm (pupae). Furthermore, we evaluated the predatory efficiency of dragonfly nymphs, *Brachydiplax sibirina*, against II and III instar larvae of *A. aegypti* in an aquatic environment contaminated with ultra-low doses of AgNP. Under standard laboratory conditions, predation after 24 h was 87.5% (II) and 54.7% (III). In an AgNP-contaminated environment, predation was 91 and 75.5%, respectively. Overall, *C. verrucosa*-synthesised AgNP could be employed at ultra-low doses to reduce larval population of dengue vectors enhancing predation rates of dragonfly nymphs." **19560.** Nitzany, E. (2015): Local motion signals - Prevalence, responses and interactions. Ph.D. thesis of Computational Biology, Cornell University: XI + 125 pp. (in English) ["Extraction of local motion signals is crucial for our survival. Lack of information from local motion signals will significantly reduce our ability to discriminate objects from background, avoid obstacles, and navigate. Despite the apparent effortlessness with which we perceive visual motion, there are indications that the underlying neural computations are complex. Three kinds of local motion signals have been distinguished, based on the kinds of spatiotemporal correlations that generate them: Fourier (F), based on 2-point correlations [1]; non-Fourier (NF), based on 4-point correlations [2]; and glider (G), based on 3-point correlations [3]. G signals have two subtypes, expansion and contraction, associated with objects that are looming and receding, respectively. Detection of isolated G and NF signals cannot be mediated by a purely multiplicative cross-correlator or a purely quadratic motion energy model. G signals have recently attracted substantial attention, following the demonstration that a wide range of species (human [3], macaque [4, 5], zebrafish [6], dragonfly [5], and fruitfly [7]) respond to them in similar ways suggesting that there are advantages to using these signals in visual tasks. This work expands the above lines of research in several respects. First, our computational work shows that these motion signals appear in natural scenes and characterizes the basic statistical relationships between them [8]. Second, we report neurophysiological recordings in two distinct visual-specialist species (macaques and dragonflies) that demonstrate that at the neuronal level, cells response in a similar manner to motion signals in many respects, although there are subtle differences in responses between the species. This convergence at the algorithmic and neural-implementation levels indicate the fundamental biological importance of using the many kinds of motion signals to guide behaviour. Finally, we carried out a psychophysical experiment to probe human ability to use multiple kinds of local motion signals simultaneously to solve simple directional task. We found that humans can combine different kinds of motion signals to solve this task, and, interestingly, that sensitivity to different kinds of motion signals is context-dependent." **19561.** Noskovic, J.; Rakovská, A.; Porhajasová, J.; Babosová, M.; Ceryová, T. (2015): Assessment of impact of agroecosystems on macrozoobenthos communities of important protected areas in southwestern part of the Slovak Republic. *Research Journal of Agricultural Science* 47(1): 111-119. (in English) ["Macrozoobenthos as an important component of all aquatic habitats is very diverse community of aquatic invertebrates, which are either throughout its life, or during the developmental stages bound to the water. Representatives of this community are extremely sensitive to environmental conditions in which they live, but especially to the qualitative properties of water. They are suitable bio-indicators of any characteristics changes of their habitat. Therefore, permanent occurrence, but, for the majority of the representatives of the benthic fauna, relatively long development cycle conducted in water, can significantly influence not only natural factors, but also human activities. In this work we present results of the occurrence of macrozoobenthos communities in two nature reserves in southwestern part of the Slovak Republic: Žitavský luh and Alluvium Žitavy, while also evaluate the potential impacts of agricultural activities on the species and numerous representations in the monitored habitats. In 2006 and 2007, we are

on each monitored aquatic habitats, in six sampling sites at regular quarterly intervals collected total of 48 water samples, together with biological material. In Nature Reserve Žitavský luh we recorded in 24 taken samples 25, 966 individuals, determinate to be 135 species of benthic fauna. In Nature Reserve Alluvium Žitavy by collecting of 24 samples of water we obtained only 12, 708 individuals, 126 species of this ecological group of individuals. Determined species were included in the 15 systematic groups: Turbellaria, Gastropoda, Bivalvia, Oligochaeta, Hirudinea, Isopoda, Amphipoda, Ephemeroptera, Odonata, Heteroptera, Megaloptera, Coleoptera, Trichoptera, Diptera (without Chironomidae) and Chironomidae. Of these, the numerically and percentage the most involved on the structure of macrozoobenthos community Gastropoda, Isopoda, Ephemeroptera and individuals of families Chironomidae. The contrary, the lowest share in numerous, species and percentage representation had Megaloptera, Turbellaria and Odonata. From the total number of 177 determined species of benthic fauna in the territory of Slovakia is 23 species protected by law under the legislation of the State Nature and Landscape Conservation, included primarily to the species categories: VU - vulnerable and LR: nt - near threatened. In the monitored period were structure and biodiversity of macrozoobenthos communities of Nature Reserve Žitavský luh compared with structure and biodiversity of Nature Reserve Alluvium Žitavy richer and more balanced. Significant negative impact of agriculture on the macrozoobenthos community in that period in monitored aquatic habitats was not recorded." **19564.** Rezende, R.; Marques Leite, G.F.; De-Lima, A.K.S.; Filho, L.A.; Costa Chaves, C.V.; Holler Prette, A.C.; Spriger Freitas, J.; Gonçalves Júnior, J.F. (2015): Effects of density and predation risk on leaf litter processing by *Phylloicus* sp.. Austral Ecology 40(6): 693-700. (in English) ["The allochthonous detritus that accumulates in the substrate of streams is used by aquatic invertebrate shredders for shelter and food. Shredders are considered rare in tropical systems, and little information is available about the role of density effects and predation risk (associated with the perception of predators by prey) in relationship to the resources used by these organisms. The aim of this study was to examine experimentally the effects of increased predation risk and of the density of *Phylloicus* sp. [Trichoptera] (i.e. of two types of biological relationships) on the processing of the leaf litter of *Nectandra megapotamica* (Spreng.) Mez. *Phylloicus* sp. can use leaf litter for case building and as a food resource. The density effect was measured using four treatments that differed only in the number of individuals (one, two, three or four). A second experiment with five treatments was performed to test the risk of non-lethal predation on detritus consumption (shelter and food) by *Phylloicus* sp. (T1: Caddisfly; T2: Mayfly; T3: *Asytanax* sp./fish; T4: Damselflies; T5: Stonefly). A single *Phylloicus* and one other organism (a potential predator blocked with 0.5?mm fine mesh) were placed in each tank (0.002?m3 volume). We observed a negative effect of density on per capita litter consumption (experiment 1). The low density of *Phylloicus* may be a natural factor that decreases intraspecific competition. In the presence of fish, *Phylloicus* showed the lowest amount of litter processing observed in the experiment, indicating top-down control (experiment 2). In treatments that involved the presence of invertebrates (non-predatory and predatory), *Phylloicus* showed the highest amount and an intermediate amount of leaf litter processing, respectively (experiment 2). This observation also suggests that the predation effect is more probable for specific predator-prey pairs. Population density and predation risk in *Phylloicus* may be important factors controlling leaf litter processing." **19566.** Robin, J. (2015): Les libellules du Tarn-et-Garonne. Synthèse fin 2014. Bulletin de la Société des sciences naturelles de Tarn-et-Garonne N° Spécial 2: 146 pp. (in French) ["For a long time, the Tarn-et-Garonne was a department [France] that was little surveyed by odonatologists. Since 2005, several local naturalists have launched various inventory campaigns. They culminated in 2007 with the preliminary atlas of the odonates of Tarn-et-Garonne. This work had the advantage of presenting a departmental distribution of these insects for the first time and updating the list of known species in the department. This new summary is based on a larger number of observations and bibliographical sources, presents the location of the species more precisely and provides new information on the habitats used by these insects in our department. It allows us to conclude that 51 species are currently reproducing on a permanent basis, 2 are occasional migrants and at least 5 species need to be confirmed (doubtful indigenous species and/or old citations). Two taxa could still be discovered in our department. However, many surveys still need to be encouraged to ensure homogeneous coverage of the whole of our territory and to establish a more precise conservation status for each species." **19570.** Swan, T.S. (2015): Distribution, occurrence, and identification of mosquito species in the Tongatapu Island Group, Kingdom of Tonga. MSc. thesis, Water Resource Management, University of Canterbury: 129 pp. (in English) ["Mosquitoes pose a serious threat to the economy, health status, and biosecurity of countries around the world. Mosquitoes kill an average of 700,000 people per year. The global expansion of air, sea, and land transport networks has greatly enhanced the spread of mosquitoes internationally. In the Pacific, the number of mosquito-borne diseases occurring has been on the rise in recent years, possibly as a result of human-mediated dispersal of larvae and adult mosquitoes. The Kingdom of Tonga has had numerous outbreaks of dengue fever and chikungunya virus in recent years. Previous research has catalogued species occurrences and distributions throughout Tonga. However, it is unknown whether new species have arrived in Tonga, and if distribution of previously found species has changed since the last comprehensive survey in 2006. Present research aims to update the literature by conducting a mosquito survey at 84 sites across the four islands of Tongatapu, Pangaimotu, 'Oneata, and 'Eua to record the distribution and occurrence of mosquito larvae. Nine mosquito species were collected: Aedes aegypti Linnaeus, A. albopictus Skuse, A. tongae Edwards, A. horrescens Edwards, A. vexans nocturnus Theobald, Culex annulirostris Skuse, C. albiverticillatus Edwards, C. quinquefasciatus Say and C. sitiens Wiedemann. The collection of A. albopictus is the second time that this species has been recorded in Tonga. Moreover, the spatial extent of this species throughout Tonga was

far greater than previously recorded. A major outcome of this survey has been the creation of an identification key for the mosquito larvae species of Tonga. This key should increase the accuracy of positive mosquito larvae identifications in Tonga. Mosquitoes were more frequently collected in artificial (e.g., used car tyres, fuel drums, containers) than natural (e.g., pools, ponds, tree holes) habitats. Car tyres, water containers, fuel drums, fridges, washing machines, and ponds were the most common habitats in which mosquito larvae were found. *Aedes aegypti*, *A. albopictus*, and *C. quinquefasciatus* were the three most common mosquito species collected, whereas *A. tongae*, *A. horrescens*, *A. vexans nocturnus*, *C. annulirostris*, *C. sitiens*, and *C. albinervis* were less frequently found. Multiple logistic regression analyses indicated that habitat volume had a significant positive effect on the presence of *A. albopictus* and *A. tongae*, whereas conductivity had a significant positive effect on the presence of *C. annulirostris*. Additionally, the volume by temperature interaction was a significant predictor of species presence for *A. aegypti*, *A. albopictus*, and *C. annulirostris* (as habitat volume increases, the effect of temperature went from neutral to negative). This suggests that larger, cooler habitats favour colonisation by these species. The number of artificial habitats (particularly used car tyres) present may have significantly increased since previous studies. Management should therefore focus on implementing community-run mosquito projects aimed at reducing the number of artificial habitats capable of being colonised by mosquito larvae. Covering, tipping out water, and infilling these habitats with soil to prevent mosquito oviposition is a pragmatic and straightforward mosquito control solution. This should immensely reduce the abundance of mosquitoes and help prevent disease outbreak in Tonga." (Author) The study includes references to Odonata.] Address: Swan, T.S., School Biol. Sciences & Waterways Centre for Freshwater Management, Univ. of Canterbury, Christchurch, New Zealand

**19571.** Vieira, V.; Cordero-Rivera, A. (2015): *As Libélulas dos Açores e Madeira*. Edição: Amigos dos Açores - Associação Ecológica: 122 pp. (in Spanish) [This book "Is a contribution to the knowledge of biodiversity of the Azores and Madeira, aimed at the general public, and focusing on the Odonata of the islands. The book provides comprehensive information, in an accessible but scientifically rigorous language, trying to be useful for a large audience, including amateur and professional odonatologists, but also any person with an interest on nature. The information provided includes the relationship between dragonflies and the freshwater ecosystems of the Azores and Madeira (lakes, ponds and rivers), and highlights the relevance of odonates for human society, as agents of biological control of insect pests, and its role in conservation biology and evolution. The damselfly *Ischnura hastata* is presented as a gemstone of the Azorean islands, because it is the only case known of parthenogenesis in the order Odonata. The book is richly illustrated with pictures and describes the different stages of development of dragonflies, and includes data about their habitat, their occurrence in the islands and geographic distribution. The authors transmit their enthusiasm for dragonflies, looking to attract young readers to the fascinating world of biodiversity and natural history of the two Atlantic archipelagos." **19573.** Zeyghami, S.; Dong, H. (2015): Study of turning takeoff maneuver in free-flying dragonflies: effect of dynamic coupling. *Fluid Dynamics (physics.flu-dyn)* Cite as: arXiv:1502.06858 [physics.flu-dyn]: (in English) ["Turning takeoff flights of several dragonflies were recorded during which a dragonfly takes off while changing the flight direction at the same time. Center of mass was elevated about 1-2 body lengths. Five of these maneuvers were selected for 3D body surface reconstruction and the body orientation measurement. In oppose to conventional banked turn model, which neglects interactions between the rotational motions, in this study we investigated the strength of the dynamic coupling by dividing pitch, roll and yaw angular accelerations into two contributions: one from aerodynamic torque and one from dynamic coupling effect. The latter term is referred to as Dynamic Coupling Acceleration (DCA). The DCA term can be measured directly from instantaneous rotational velocities of the insect. We found a strong correlation between pitch and yaw velocities at the end of each wingbeat and the time integral of the corresponding DCA term. Generation of pitch, roll and yaw torques requires different aerodynamic mechanisms and is limited due to the other requirements of the flight. Our results suggest that employing DCA term gives the insect capability to perform a variety of maneuvers without fine adjustments in the aerodynamic torque." **19574.** Zeyghami, S.; Dong, H. (2015): Coupling of the wings and the body dynamics enhances damselfly maneuverability. *Fluid Dynamics arXiv:1502.06835v1 [physics.flu-dyn]* : 10pp. (in English) ["In flapping flight, motion of the wings through the air generates the majority of the force and torque that controls the body motion. On the other hand, it is not clear how much effect the body motion imposes on the wings. We investigated this connection via analyzing fast yaw turns of three different species of damselfly. In this combined experimental and theoretical study, we show that

the dynamics of the wings and the body are coupled together in low frequency flapping flight. As a result, damselflies benefit from a passive mechanism for enhancing the bilateral wing pitch angle asymmetry to sustain the body rotation. A physics-based model derived from this mechanism is proved valid for linking morphology, kinematics and dynamics of the wing and the body of the flying insects in fast turning maneuvers." **19575.** Zhao, H.; Meng, Q.; Li, Y. (2015): On diversity of Odonata in the west of Jilin province. *Journal of Beihua University ( Natural Science)* 15(6): 821-825. (in Chinese, with English summary) ["The resources of Odonata in the west of Jilin Province were investigated randomly from May 2011 to September 2013. There were 47 species of dragonfly which belong to 9 families and 28 genera among which Gomphidae, Libellulidae, Coenagrionidae and Lestidae were dominant species in west of Jilin. The individuals and species number of Sympetrum were the most abundant in Libellulidae, Trigomphus are the most in Gomphidae Ischnura is the most in Coenagrionidae but the individuals and species number had no significant difference among genera in Lestidae. Diversity index of dragonfly showed an obvious rising trend with temperature rising and richness of nutrition levels in Spring and reached the peak in July and then diversity index decreased. Evenness index wasn't changed greatly the dominant concentration index was appeared in May and had a slight fluctuation later." (Authors)] Address: Zhao, H., College of Forest, Beihua Univ., Jilin 132013 China

**19576.** Zhao, H.; Meng, Q.; Zhao, H. (2015): Community structure and adult seasonal dynamics of Odonata in western Jilin. *Journal of Northeast Forestry University* 43(1): 107-109-113. (in Chinese, with English summary) ["A successive investigation on the resource of Odonata was conducted in western Jilin. There are 47 species of Odonata in the western region of Jilin, belonging to 9 families and 28 genera. Among them, the levels in the Anisoptera are significantly higher than those in the Zygoptera, the genus number and species number are maximum in Libellulidae, and Gomphidae, Libellulidae, Coenagrionidae and Silk Coenagrionidae are the dominant groups in the region. The evolution of Odonata adult communities in the western region of Jilin changes with the seasons. In May, the number of dragonfly communities increases slowly, significantly from June to July, and both the number of species and the number of individuals show a declining trend from August to September, and the dominant species is different in May to September." **19577.** Zhou, Z.; Sorensen, S.; Zeng, H.; Hawrylycz, M.; Peng, H. (2015): Adaptive image enhancement for tracing 3D morphologies of neurons and brain vasculatures. *Neuroinformatics* 13: 153-166. (in English) ["It is important to digitally reconstruct the 3D morphology of [dragonfly] neurons and brain vasculatures. A number of previous methods have been proposed to automate the reconstruction process. However, in many cases, noise and low signal contrast with respect to the image background still hamper our ability to use automation methods directly. Here, we propose an adaptive image enhancement method specifically designed to improve the signal-to-noise ratio of several types of individual neurons and brain vasculature images. Our method is based on detecting the salient features of fibrous structures, e.g. the axon and dendrites combined with

adaptive estimation of the optimal context windows where such saliency would be detected. We tested this method for a range of brain image datasets and imaging modalities, including bright-field, confocal and multiphoton fluorescent images of neurons, and magnetic resonance angiograms. Applying our adaptive enhancement to these datasets led to improved accuracy and speed in automated tracing of complicated morphology of neurons and vasculatures. ... Particularly, as shown in Figure 7b, our enhanced image has captured and enhanced both dendrites and axons while other approaches failed. We tested 30 confocal images of dragonfly neurons which have smaller scales and better SNR (Gonzalez-Bellido et al. 2013)" (Authors)] Address: Peng, H., Janelia Farm Research Campus, Howard Hughes Medical Institute, Ashburn, Virginia 20147, USA. ## 2016

**19578.** Khan, J.; Saifullah; Zia, A. (2016): Biodiversity of dragonflies and their life threatening factors in Tehsil Chamla and Daggar of district Buner, Khyber Pakhtunkhwa, Pakistan. *Pakistan Journal of Zoology* 48(4): 1077-1082. (in English) ["The study was aimed at determining species composition, relative abundance and habitat preference of adult dragonflies in relation to increasing aquatic and air pollution in Tehsils Dagger and Chamla of district Buner, Khyber Pakhtunkhwa. For this, surveys were conducted during May to October, 2013 and eleven species with seven genera were recorded. Among these, three species (*Trithemis festiva*, *Orthetrum pruinosum neglectum* and *Trithemis aurora*) were found constant, while three (*Orthetrum anceps*, *Sympetrum commixta* and *Orthetrum triangulare*) were observed to be moderate and two (*Onychogomphus bistrigatus* and *Palpopleura sexmaculata*) were found to be infrequent in their occurrence. Perennial riverine habitats represented four species, seasonal streams with inhabiting three species and springs with only two dwelling species. Only one species was recorded from crop fields and ponds. For seasonal occurrence, 119 dragonflies were observed in July while seven in October. The aquatic and air pollution from huge number (n=600) of marble factories in Daggar and more use of pesticides in Chamla were observed to affect drastically the dragonfly population in the area. Present study therefore emphasizes conservation of Odonata fauna by implanting proper treatment plant for marble and pesticidal wastes." (Authors)] Address: Khan, J., Dept of Zoology, Abdul Wali Khan University, Mardan, Buner Campus, Khyber Pakhtunkhwa, Pakistan

**19579.** Wan, Y.-q.; Zhang, H.-j. (2016): Summary on the family Platycnemididae study (Odonata Zygoptera) in China. *Journal of Shaanxi University of Technology ( Natural Science Edition)* 32(2): 70-74. (in Chinese, with English summary) ["The family of Platycnemididae is a species relatively few in number. The researchers can only rely on identification and classification of the morphological features to conduct relevant studies. This paper has overviewed the research history and domestic research status of Platycnemididae as well as the classification errors or disputes. The paper proposed that *Platycnemis pierrati* Navas, *Copera tokyoensis* Asahina and *Platycnemis foliosa* Navas is the junior synonym of *Copera marginipes* Rambur, *Copera rubripes* Navas and *Platycnemis foliacea* Selys, respectively. The classification of *Coellicia cyanomelas* Ris, *Coellicia didyma* Selys, and *C. sexmaculatus* Wang should be promoted for further study." (Authors)] Address: not stated in English

**19580.** Zhao, Y.; Wang, D.; Tong, J.; Sun, J. (2016): Nano-mechanical behaviour of the membranous wings of dragonfly *Pantala flavescens* Fabricius. *Journal of Bionic Engineering* 13: 388-396. (in English) [The dragonfly has excellent flying capacity and its wings are typical 2-dimensional composite materials in micro-scale or nano-scale. The nanomechanical behavior of dragonfly membranous wings was investigated with a nanoindenter. It was shown that the maxima of the reduced modulus and nanohardness of the in-vivo and fresh dragonfly wings are about at position of 0.7L, where L is the wing length. It was found that the reduced modulus and nanohardness of radius of the wings of dragonfly are large. The reduced modulus and nanohardness of Costa, Radius and Postal veins of the in-vivo dragonfly wings are larger than those of the fresh ones. The deformation, stress and strain under the uniform load were analyzed with finite element simulation software ANSYS. The deformation is little and the distribution trend of the strain is probably in agreement with that of the stress. It is shown that the main veins have better stabilities and load-bearing capacities. The understanding of dragonfly wings' nanomechanical properties would provide some references for improving some properties of 2-dimensional composite materials through the biomimetic designs. The realization of nanomechanical properties of dragonfly wings will provide inspirations for designing some new structures and materials of mechanical parts." (Authors)] Address: Zhao, Y., The College of Mechanical and Power Engineering, Henan Polytechnic University, Jiaozuo 454000, China

**19581.** Zia, A. (2016): Zygoptera in Himalayan Foot Hills of Pakistan. IDF-Report 96: 1-60. (in English) ["In 2014, 56 localities in four provinces of Lesser Himalaya in Pakistan were studied. A total of 28 species have been recorded. A female of the data deficient, threatened species *Coelliccia vacca* was recorded from Charhaan. The record of *Drepanosticta carmichaeli* is a new addition to the list of Odonata of Pakistan, and expand the range of this species further to the west. The taxonomical status of *Ischnura aurora aurora* – considered common in Pakistan, following baseline literature of Fraser (1933) – now turns out to be *Ischnura aurora rubilio*." **19583.** Naraoka, H. (2017): Diurnal activity and reproductive behavior of *Platycnemis echigoana* Asahina, 1955 in Aomori prefecture (Odonata: Platycnemididae). *Tombo* 59: 85-95. (in Japanese, with English summary) ["Diurnal activity and reproductive behavior of a Japanese endemic damselfly, *Platycnemis echigoana* was observed at Rokkasho Village in Aomori Prefecture, Japan during 2011-2016, and was compared with the populations of central Honshu. The adult season of the Rokkasho population was from June to August. Adult were active in sunny areas on weeds of a forest floor during 8:00-18:00 h and most individuals rested on a tree at night. But, some individual spent the night on the forest floor. Mate searching flights were long (mean: 16.7s) by males that flew about in a wave-like pattern over weeds and shrubs, seen from 8:00-16:00 h with a peak from 9:00-12:00 h. On the other hand, the flights for feeding and shift were short (mean: 2.5s and 3.6s, respectively) and were seen all day. Copulation was seen from 8:00-15:00 and divided into three stages (Miller & Miller, 1981; mean duration I: 39m33s, II: 1m33s, III: 10s). Oviposition occurred from ca. 9:00-16:00 at pools, small ponds and water courses. Eggs were laid into the tissue of plant on and in the water. The adult season and most reproductive behavior of the Rokkasho population were almost the same as that of central Honshu. But, the long duration of mate searching flight by males and the resting on the forest floor at night were behavior that was seen in the Rokkasho population only." (Authors)] Address: Naraoka, H., 36-22, Motoizumi, Fukunoda, Itayanagi-cho, Kita-gun, Aomori Prefecture, 038-3661, Japan. E-mail: sbnkq127@ybb.ne.jp

**19584.** Ortega-Salas, H. (2017): Sistemática y distribución del género *Paraphlebia* Selys in Hagen (Odonata: Thaumatoeuridae) en México y Centroamérica. MSc thesis, Universidad Nacional Autónoma de México: 131 pp. (in Spanish) ["For more than a century the genus *Paraphlebia* has remained one of the least known in Mexico and Central America. The use of wing colouration and the relative position of the RP3 vein have been, until now, the only diagnostic characters available to separate the species of this genus. This paper provides a taxonomic revision of the genus including the redescription of *P. zoe*, *P. hialina*, *P. quinta* and *P. duodecima*; the formal synonymy of *P. abrogatata* with *P. quinta*; as well as the description of 10 new species distributed in Mexico, Guatemala, Honduras and Nicaragua. New diagnostic characters and a dichotomous key for the identification of males of the known species are proposed, maps with the known distributions of all species are presented, and finally, the first phylogenetic hypothesis for the genus is presented based on the 12S, 16S, 28S and CO1 genes, where two clades are differentiated and found to be congruent with the morphology of the fences." (Author/DeepL) Also see: Ortega-Salas, H.; Gonzalez-Soriano, E.; Jocque, M. (2022): Untangling the waterfall damselfly: a review of the Mesoamerican genus *Paraphlebia* Selys in Hagen, 1861 (Odonata: Thaumatoeuridae) with descriptions of 11 new species. *Zootaxa* 5089(1): 1-66.] Address: Ortega-Salas, H., Departamento de Zoología, Instituto de Biología, UNAM, Apartado Postal 70-153, México. **19585.** Sakai, M.; Suda, S.; Okeda, T.; Washitani, I. (2017): Identifying priority habitats and monitoring species for conservation and restoration of lentic Odonata habitats: assemblage nestedness on Amami-Oshima Island, Japan. *Ecological Research* 32(5): 693-702. (in English) ["We investigated Odonata faunal and habitat characteristics (fo-

rest cover, emergent, submerged, floating-leaved and floating plant covers, pond area, NO<sub>3</sub><sup>-</sup>, chemical oxygen demand, and presence/absence of a nonnative fish) in 10 ponds on Amami-Oshima Island. In total, 26 species of six odonate families were found, and we detected significant nestedness of species composition among the ponds (22 species in the most species-rich pond, and 8 species in the most species-poor pond). Species found only in the most species-rich ponds were: *Anax nigrofasciatus nigrofasciatus*, *Acisoma p. panorpoides*, *Agriocnemis famina oryzae*, *Rhyothemis severini*, *Anaciaeschna martini*, *Hemicordulia okinawaensis*, *Lyriothemis elegantissima*, and *Hydrobasis-leus croceus* (hereafter referred to as the rare species). These rare species are generally known to preferentially inhabit ponds with lush emergent plants and/or to prefer cooler habitats shaded by forest cover, such as *Anax nigrofasciatus nigrofasciatus*, *Anac. martini*, *He. okinawaensis*, and *L. elegantissima*. In contrast, the common species also found in species-poor ponds were: *Ischnura senegalensis*, *Pantala flavescens*, *Anax parthenope julius*, *Ictinogomphus pertinax*, and *Tramea virginia*, which are known to prefer an open water surface as spawning habitat. These differences in habitat preference between the rare and common species may be among the major reasons for the significant positive effects of percent forest cover and emergent plants on Odonata species richness. These results suggest that nestedness helped identify precise habitat characteristics and rare species that should be considered for conservation and restoration of lentic habitats on Amami-Oshima Island." (Authors)] Address: Sakai, M., Faculty of Science and Engineering, Chuo University, 1-13-27 Kasuga, Bunkyo-ku, Tokyo 112-8551, Japan. Email: boundary.0008@gmail.com

**19586.** Trapero-Quintana, A.; Reyes-Tur, B. (2017): Emergence patterns of Odonata (Insecta) from a lotic habitat in Eastern Cuba. *Revista de Biología Tropical* 65(2): 807-818. (in Spanish, with English summary) ["The emergence patterns of tropical odonates (dragonflies and damselflies) are scarcely known. We studied the emergence patterns of odonates in a freshwater lotic system in Giro, Northern Santiago de Cuba, between January and December 2008. We visited the locality between 09:00 and 14:00, on a weekly basis, and collected exuviae from a fixed section (8 x 1 m<sup>2</sup>) offshore, along the riparian vegetation. We collected data on species composition and, for each species, abundance, relative biomass and emergence pattern. We collected 443 exuviae belonging to 22 species: seven Zygoptera and 15 Anisoptera. Half of the annual Odonata emergence took place in the dry season (December to March) with the highest value in February (25 %). For species for which we found seven or more exuviae per month, *Enallagma coecum* and *Macrothemis celeno* tended to be a synchronal emergence. We also found temporal segregation of the emergence pattern between *M. celeno* and *Protoneura capillaris*, *Neoneura maria*, *Progomphus integer* and *Scapanea frontalis*. These differences were probably related to the highest annual fluctuations of temperature, relative humidity and number of rainy days per month. We concluded that there is an asynchrony and heterogeneity in Odonata emergence times in the studied freshwater lotic system." (Authors)] Address: Trapero-Quintana, A., Depto de Biología, Universidad de Oriente. Ave. Patricio Lumumba s/n. Santiago de Cuba 90500, Cuba. trapero76@gmail.com

**19587.** Vilaça, Z.A.S. (2017): Distribuição espacial da riqueza de Odonata (Fabricius, 1793) em relação às ecorregiões neotropicais: determinantes ambientais e restrições à

dispersão. Dissertação (Mestrado em Biodiversidade Animal) - Universidade Federal de Goiás, Goiânia: 214 pp. (in Portuguese, with English summary) ["The distribution of biological diversity is one of the major questions for science. Several theories were proposed in attempt to understand the patterns and process that regulate the richness of extant species: species-energy theory, metabolic theory of ecology, habitat heterogeneity, and tropics as museum, cradle or casino. Terrestrial ecoregions are land units that contain similar biotic and abiotic factors, what makes them more alluring and efficient for conservation planning and land use than using geopolitical divisions, still used by several conservation institutions and governments. Odonata is one of the oldest orders of insect, belonging to the clade Paleoptera. Those insects, for being tightly related to environmental conditions and vegetation structure, are widely utilized as bioindicators and in studies of spatial patterns. In this thesis, we evaluated the lack of knowledge around Odonata geographic distribution in the Neotropical region and the way that its species composition is affected by both climate and space." **19588.** Vilenica, M. (2017): Ecological traits of dragonfly (Odonata) assemblages along an oligotrophic Dinaric karst hydrosystem. *Ann. Limnol. - Int. J. Limnol.* 53 : 377-389. (in English) ["Ecological traits of dragonfly larvae in tufa-depositing habitats of the Dinaric karst were studied monthly over a one-year period (2007–2008). The study encompassed various lotic karst habitats (springs, mountainous rivers, streams, tufa barriers) and microhabitats (angiosperms, mosses, cobbles, sand, silt with leaf litter). The aims of the study were to identify dragonfly composition, abundance and spatial distribution, their habitat and microhabitat preferences, and to determine the most important environmental factors explaining dragonfly assemblages in the studied hydrosystem. The dragonfly fauna was composed of eight species, *Onychogomphus forcipatus* (Linnaeus, 1758) was the most widespread and the most numerous. Water temperature, ammonium and oxygen concentrations had the highest influence on dragonfly assemblages. The most favorable habitat type were tufa barriers, less favorable were lower lotic habitats, while dragonflies were almost completely absent from upper lotic habitats and their springs. Dragonfly larvae preferred microhabitats with inorganic substrates (i.e. cobbles and sand) and slower water velocity, while they mostly avoided mosses associated with the strongest current. This study provides an important contribution to the knowledge of dragonfly ecology in lotic habitats of the Dinaric karst." (Author)] Address: Vilenica, Marina, Univ. of Zagreb, Faculty of Teacher Education, Trg Matice hrvatske 12, 44250 Petrinja, Croatia. E-mail: marina.vilenica@gmail.com

## 2018

**19589.** Baeta, R.; (ANEPE CAUDALIS) (2018): Suivi diachronique des populations ligériennes de *Stylurus flavipes* et d'*Ophiogomphus cecilia* en région Centre Val-de-Loire (Saison 2018 – Quatrième année de suivi à l'échelle régionale). Association Naturaliste d'Étude et de Protection des Écosystèmes CAUDALIS / Agence de l'Eau Loire Bretagne: 13 pp. (in French) ["In 2018, the 45 grids surveyed were spread over nearly 300 km of the Loire and corresponded to a cumulative length of 38 km of banks surveyed, all sessions combined. The regional database for the 2018 season thus contains information on 3,800 exuviae collected

and identified (Fig. 2). At the scale of the grids, *Onychogomphus forcipatus* was contacted on 42 of the 45 grids surveyed, *Ophiogomphus cecilia* on 38 and *Stylurus flavipes* on 12, i.e. a very clear decrease for the latter species compared to 2017. The differences between species are even more marked if we look at the transects. Thus, only 14 of 331 transects (4%) were validated for *Stylurus flavipes*, whereas 117 were validated for *Ophiogomphus cecilia* (35%) and 239 for *Onychogomphus forcipatus* (72%). However, these relative abundances vary between departments (Fig. 3) and depend on the upstream-downstream position of the surveyed grids (see maps in the appendix). A summary of the raw data collected by ANEPE Caudalis on the 8 grids monitored in Indre-et-Loire in 2018 is available in the appendix in the form of 2 tables (Tab. SI & SII). All the data have been transferred in SINP format to the DREAL Centre Val de Loire. In 2018, the Loire was relatively dry at the beginning of the season, with two small peaks in mid-May and mid-June. (Fig. 4). It was only from 17 June onwards that the levels of the Loire began to fall more steadily, reaching a low water level around mid-July. The absence of a particularly high flood and the random distribution of the 45 meshes monitored thus made it possible in 2018 to carry out the protocol on meshes with varied facies representative of the banks of the Loire River in our region (Fig. 5).

1. Phenologies of emergence: Although the first surveys were carried out slightly before 15 May (first pass on 30 April) and slightly after 15 August (last pass on 30 August), the surveys generally followed the dates defined in the protocol (Fig. 6). Harvesting was thus carried out on 100 different dates. The implementation of exuviae collections during this period allowed the peak of *Onychogomphus forcipatus* emergence to be well integrated, but it seems that the emergence of *Ophiogomphus cecilia* was already well underway during the first exuviae collections (Fig. 7). Finally, the very low number of *Stylurus flavipes* exuviae collected in 2018 does not allow us to model an emergence phenology. However, based on a direct visualization of the raw data, it seems that the peak of emergence was well taken into account and took place from mid-June to the end of July (Fig. 7).

2. Effects of biotic and abiotic variables: A global statistical analysis was carried out in 2017 on all the data collected in the Centre - Val de Loire since the monitoring protocol for the Loire gomphs (Baeta, 2017). It therefore does not seem appropriate to re-launch an analysis of this type this year with only one more year of data. An analysis of all the data produced over the first five years of deployment of this monitoring will be carried out in 2019. This will take into account all the data produced in the Loire basin and not just the data relating to the Centre - Val de Loire region.

IV. OUTLOOK: Deployed in the Centre - Val de Loire region for four years now and active in the four major regions through which the Loire flows, this protocol is one of the great successes of the National Action Plan for Odonates. With a clearly basin-oriented scope, the objective for the coming years will be to ensure the continuity of this monitoring on this scale as well as to optimise the analysis of the data produced and the exploitation of the results through presentations at various conferences related to the monitoring of biodiversity in the Loire and/or the implementation of monitoring protocols." **19591.** Pitcher, K.A.; Soluk, D.A. (2018): Fish presence and inter-patch connectivity interactively alter the size of emergent insects in experimental enclosures. *Ecosphere* 9(3):e02118. 17 pp. (in English) ["Structural habitat complexity (SHC) and functional habitat connectivity (FHC) are the basic components that make up the physical architecture of an ecosystem, and can have substantial impacts on predator-prey interactions. These structural components influence animal behaviors such as inter-patch movement, foraging, and competition, and can impact community structure/dynamics in terrestrial and aquatic ecosystems. The effects of SHC and FHC on predator-prey dynamics within an ecosystem may also have important cascading effects on neighboring ecosystems by altering the movement of individuals across ecosystem boundaries. For example, when aquatic insects emerge as adults, they enter terrestrial ecosystems where they become an important food resource for terrestrial predators. Using a multiple patch, predator enclosure design in ponds, we tested whether altering intra-patch plant stem densities (SHC) and inter-patch distances (FHC) would influence the impact a predatory fish has on the biomass, quality, and trophic composition of emergent insects. As expected, fish significantly reduced emergent insect biomass (33%  $\pm$  7.6, mean  $\pm$  SE). Intra-patch stem densities (SHC) did not significantly alter fish effects; however, inter-patch distance (FHC) did significantly alter the impact of fish on the size of some emergent insects. Damselflies that emerged in treatments with fish present and shorter inter-patch distances were significantly larger, 4.1  $\pm$  0.1 mg/m<sup>2</sup> compared to 3.3 mg/m<sup>2</sup>  $\pm$  0.1 in the long/fish treatments. In fish treatments, this effect on damselfly size resulted in greater reductions in total emergent insect biomass in long inter-patch distance treatments (47.3%  $\pm$  6.9) compared to short inter-patch distance treatments (20.5%  $\pm$  12.4). Our results suggest that physical components of a habitat, such as inter-patch distances, have important impacts on predator-prey dynamics within habitats. These altered predator-prey dynamics can then have cascading effects on adjacent habitats by influencing the abundance, trophic composition, and quality of exported trophic subsidies." **19592.** Reiss, M.; Chiffard, P. (2018): Different forest cover and its impact on eco-hydrological traits, invertebrate fauna and biodiversity of spring habitats. *Nature Conservation* 27: 85-99. (in English) ["Headwater springs in the German Low Mountain Ranges are local ecotone habitats and biogeographical islands embedded in and interlinked with their adjacent landscape. The structure of forests reflects the eco-hydrological conditions in substrate type occurrence, micro-habitat richness and biodiversity in forest springs. This study considers effects from different forest land cover by comparing spring habitats in deciduous beech forests and coniferous spruce forests on eco-hydrological structures and biodiversity. Study areas include six different forest landscapes in the Low Mountain Ranges in Central Germany in Hesse and Thuringia. Hydro-morphological structure mapping and invertebrate sampling was executed within a multi-habitat

sampling regime, which involves sampling plots being allocated according to the cover ratio of the occurring substrata. Aquatic and terrestrial spring zones are considered with respect to an ecotone approach. Some in situ measurements were implemented, such as pH values, to assess the acidity of the spring water. Results show obvious differences in acidity, substrate type cover ratios and biodiversity in deciduous and coniferous forest springs. Conifer forest springs were found tending to acidification while deciduous forest springs were slightly alkaline. Deciduous forest springs had higher cover ratios of organic microhabitats as well as a higher biodiversity in species richness and total number of individuals. Although it was not possible to clearly distinguish one direct key factor of fauna assemblages, negative effects from forest management practices (e.g. monoculture plantations of conifer forest) on spring habitats can be concluded." **19593.** Adámek, Z.; Mikl, L.; Šlapanský, L.; Ludik, J.; Ha-lačka, K (2019): The diet of predatory fish in drinking water reservoirs – how can they contribute to biomanipulation efforts?. *Folia Zoologica* 68(4): 215-224. (in English) ["Efforts to positively influence ecological processes and water quality by manipulating the fish community (biomanipulation) are of particular importance in drinking water reservoirs. One of the principle measures employed is to increase the abundance of predatory fish species as a means of reducing planktonophagous and benthophagous cyprinids. However, there is little information available on the effectiveness of different predatory fish in biomanipulation exercises. We examined the diet of the five dominant predatory species (pike *Esox lucius*, zander *Sander lucioperca*, asp *Leuciscus aspius*, European catfish *Silurus glanis*, and perch *Perca fluviatilis*) in five representative reservoirs in the Morava River drainage basin (Czech Republic). Fish prey made up 75 % of total food intake, with undesirable small cyprinids dominant by biomass (40 %). European catfish and asp were not taken as prey and showed no sign of cannibalism. On the other hand, predation on conspecific predatory species (including cannibalism) was relatively high in perch, pike and zander, thereby reducing their net benefit overall. This little-considered aspect of predatory feeding needs to be taken into consideration in future biomanipulation stocking strategies. ... Invertebrate dietary items comprised zooplankton; water bugs; mayfly, Gomphidae nymphs; caddisfly and chironomid larvae; and water beetle (Dytiscidae) larvae." **19594.** Guliyeva, A.S. (2019): Species composition and quantitative distribution of larvae of dragonflies (Odonata) in the new ecological conditions of the lake Mehman. 37th International Scientific Conference on Economic and Social Development – "Socio Economic Problems of Sustainable Development" - Baku, 14-15 February 2019: 985-988. (in English) ["The paper presents new data on species composition, number and distribution of the larvae of dragonflies (Odonata) in new environmental conditions of the different habitats of in the lake Mehman. Field works conducted in 2015 - 2017 in the lake Mehman resulted in the rearings of 25 species and forms of dragonfly larvae. Seven of these L.

*dryas*, *S. fusca*, *E. viridulum*, *I. pumilio*, *O. cancellatum*, *L. depressa*, *L. quadrimaculata*, *Cordulia* sp. are new to the lake. Species *Lestes virens*, and *I.elegans*, were found in winter, spring and autumn of 2015 and winter and autumn of 2017; *C.scitulum* winter and autumn of 2015; *C.hastulatum* - winter, spring and autumn of 2017; *E. fatime* in winter and autumn of 2015 - 2017; in winter and spring of 2015 - 2017. Species *C. mercuriale*, *C. scitulum*, *L. virens*, *I. elegans*, *C. puella*, *E. najas*, *O. albistylum* are observed in the lake in all seasons and are dominated by widespread. It should be noted that the decrease in the number of larvae of dragonflies in the summer, especially at depths of up to 0.5 m is due to their intensive consumption by fish and water birds and emergence of adult dragonflies which leave the lake. On the other hand, in summer period, the volume of oxygen in shallow water of the lake Mehman greatly reduced, and as a result of evaporation of water, the amount of salts in water is increased. In such circumstances, the probability of occurrence of freshwater organisms in the benthos is naturally decreased. The study of the distribution of larvae of dragonflies on specific habitats of the lake revealed their maximum development on plant and silty habitats, and the minimum - on black silty sand. Changes in biomass of benthic organisms as well as larvae of dragonflies, which developed very poor is analyzed. Poor development of dragonfly larvae in the lake Mehman characterized, on the one hand with their intensive consumption by fish and water birds and on the other hand - the steady worsening of the environmental conditions of the lake." (Author) Some of the taxa are in need of re-examination.] Address: Guliyeva, Sanubar A., Azerbaijan State Univ. of Economics (UNEC), Azerbaijan. Email: Sama2013@bk.ru

**19595.** Hess, M. (2019): Mercury concentrations in aquatic insects of two Maine coastal streams: Temporal patterns of mercury in aquatic insect biosentinels and implications for methylmercury flux. MSc. thesis, Ecology and Environmental Sciences, The University of Maine: XIII + 111pp. (in English) ["Mercury (Hg) is a widespread water quality concern because it is a potent neurotoxin that biomagnifies through food webs, posing risk to biota higher in the food chain. Aquatic insects are effective for characterizing relative Hg risk in freshwater food webs because they live and forage in aquatic habitats where Hg is present and converted to its more toxic bioavailable form, methylmercury (MeHg). Specifically, dragonfly nymphs (Odonata) are increasingly being used as a Hg bioindicator. Therefore, I (Chapter 1) conducted a systematic review of the literature to evaluate the utility of dragonflies as biosentinels for Hg. Dragonfly nymphs have been used throughout the world to provide baseline Hg concentrations within waterbodies, analyze factors affecting bioaccumulation in invertebrates, and determine Hg concentrations within food webs. Dragonfly adults have been used for monitoring Hg concentrations as vectors into and among terrestrial habitats and food webs. There has been an increase in the use of dragonflies for Hg monitoring in the last 10 years, with more than half of the studies in the review conducted after 2009. However, research evaluating temporal Hg variability in dragonfly nymphs is limited, which can have important implications for monitoring programs and risk assessment because risk to wildlife may be under- or overestimated due to sample timing asynchrony with representative life-history events or body burden variation. Thus, I (Chapter 2) assessed the temporal variation in total mercury (THg) concentrations in similar aged cordulegastrid dragonfly nymphs from two coastal Maine streams over the course of one year. When we accounted for stream, there was no overall temporal pattern in dragonfly

THg concentrations throughout the year. We found that the two streams had similar annual mean THg concentrations; however, within stream variation of THg among months was high and differed among months. Therefore in temperate streams, multiple collections, ideally in different seasons, could be warranted to obtain a robust estimate of Hg concentrations within a lotic ecosystem. Besides dragonfly nymphs, other aquatic insects also serve as an important link in the MeHg pathway in that they transfer MeHg from single-celled organisms to larger predators in the aquatic environment. Additionally, emergent aquatic insects make up a substantial proportion of the diet of many riparian terrestrial consumers and are a primary mechanism by which MeHg is incorporated into terrestrial systems. Therefore, I (Chapter 3) aimed to determine taxonomic composition, biomass, temporal trends, MeHg concentrations, and MeHg flux of emerging aquatic insects in two coastal streams in Maine using weekly emergence trap collections. Different stream reaches harbored different aquatic insect communities and thus, yielded differences in cross-ecosystem subsidies biomass and temporal flux with respect to aquatic insect emergence. These differences shed light on which organisms were vectors for MeHg and the timing of MeHg pulses to the terrestrial environment in natural systems. My research indicate that remote protected natural streams, such as those in Acadia National Park, can yield high MeHg concentrations in biota and thus, large amounts of MeHg flux to the terrestrial environment and predators." **19597.** Oliveira-Junior, J.M.B.; Juen, L. (2019): The Zygoptera/Anisoptera ratio (Insecta: Odonata): a new tool for habitat alterations assessment in Amazonian streams. *Neotropical Entomology* 48(4): 552-560. (in English) ["The accumulation of scientific knowledge is far outstripped by the rate of environmental disturbance from human activities in aquatic habitats. This highlights the need to develop effective proxy measures of aquatic biodiversity that can demonstrate changes in communities associated with human activities. We evaluated whether the relative abundance and species richness of Anisoptera and Zygoptera can be used as a tool to measure environmental impacts on Amazonian streams. Adult of Anisoptera and Zygoptera were sampled in 50 Amazonian streams, in the municipality of Paragominas (Pará state), Brazil, using an entomological handnet. The physical features of each stream were evaluated using an index of environmental integrity (HII). We collected a total of 1769 Odonata specimens, representing 97 species (56 were Zygoptera and 41 were Anisoptera). Habitat

modification resulted in an inversion in the proportional abundance and species richness of Anisoptera and Zygoptera, where Zygoptera diversity decreased with the loss of habitat integrity, whereas Anisoptera diversity increased with habitat disturbance. A decline of 0.1 in the habitat integrity index score resulted in an increase of approximately 13 individuals and 11 species of Anisoptera, with the exact opposite effect observed for the Zygoptera. In summary, the Odonata proved to be a useful model for the assessment of Amazonian streams, with sites where more than 54% of the Odonata species were Zygoptera being classified as preserved, and those dominated by Anisoptera species (>?59%) being considered degraded. This approach has clear applications for environmental impact assessments, as it reduces the influence of sampling effort and collector experience on assessment outcomes, and does not rely upon specialist knowledge, given that members of the two suborders are easily distinguished from one and other in the field." **19598.** Olthoff, M. (2019): Untersuchung der Libellenarten *Leucorrhinia pectoralis* (FFH Anh. II), *Aeshna subarctica* und *Somatochlora arctica* in Mooregebieten des Kreises Borken - Bewertung durchgeführter und geplanter Wiedervernässungsmaßnahmen in den NSG „Burlo-Vardingholter Venn“ und „Hündfelder Moor“ anhand ausgewählter Indikatorarten. Im Auftrag der Stiftung Natur und Landschaft Westmünsterland: 17 pp. (in German) ["In 2019, the nature reserves Burlo-Vardingholter Venn and Hündfelder Moor (district of Borken) were surveyed for selected species of Odonata (*Leucorrhinia pectoralis*, *Aeshna subarctica*, *Somatochlora arctica*) threatened with extinction in North Rhine-Westphalia. Fortunately, the FFH Annex II species *Leucorrhinia pectoralis* was found to be present on the ground in both bogs. With over 50 individuals, the Burlo Vardingholter Venn is one of the most numerous occurrences of this species in the country. In the Hündfelder Moor, the species was found on the ground for the first time. The species has benefited in particular from the rewetting measures in the fen edge areas, which have led to an increased supply of mesotrophic fen waters. While *S. arctica*, which has been known to occur on the ground for 20 years, was confirmed in the Burlo-Vardingholter Venn, (potential) evidence of its presence on the ground was found for the first time in the Hündfelder Moor. This species has also benefited from the rewetting measures carried out in both moor areas. The habitats preferred by *S. arctica* had sufficient water flow - despite the extreme (summer) drought in 2018 and 2019. The occurrence of *Aeshna subarctica* in the Hündfelder Moor, known since 2010, was confirmed in 2019. However, several bog waters where the species was recorded a few years ago could no longer be confirmed as habitats of the species due to insufficient water levels. The species was only observed at a few peat pits in the south of the Hündfelder Moor. In particular, the detection of the first two species in the rewetted areas of both moorlands is considered a success of the nature conservation measures implemented. Further rewetting measures planned in the Hündfelder Moor are welcomed from the point of view of dragonfly protection. In future measures, the known breeding waters should be preserved and under no circumstances filled in. Furthermore, it is recommended to create new water bodies in the area of dry peat bodies that are less important from a nature conservation point of view, following the example of old peat diggings. These should ideally be small-scale and have shallow banks and no contact with the mineral subsoil. In

addition to the species studied in this project, numerous other endangered damselflies (e.g. *Coenagrion lunulatum*, *Ceragrion tenellum*, *Aeshna juncea*, *Leucorrhinia rubicunda*, *L. dubia*) would benefit from this." (Author/DeepL.) Address: Olthoff, M., Waldweg 66, 48163 Münster, Germany

**19600.** Schiedewitz, S. (2019): Untersuchungen zur Diversität der Tagfalter und Libellen in der Hägebachau nördlich von Samswegen. *Naturschutz im Land Sachsen-Anhalt* 56: 27-60. (in German) ["Between 2018 and 2020, 43 dragonfly species were recorded in the project area. The high total number of dragonfly species is due to the diverse biotope structures as well as the successful embedding of the water bodies in large-scale, insect-rich grasslands. The current mosaic of marshy alder swamp forest, large open water areas, dense and loose reed beds, sunny and shaded riparian zones with abundant deadwood, floating and diving leaf vegetation, silted-up and water-bearing ditch sections, strongly warmed shallow water areas and peat moss-covered marsh zones produces a variety of ecological niches so that dragonflies with a wide range of demands on their aquatic and terrestrial habitats can coexist. In total, eight of the nine endangered, rare or declining dragonfly species found in the area colonise the water bodies within the year-round pasture. The high species diversity along the dammed ditch system indicates that the integration of water body sections into near-natural grazing areas with low stocking density has a positive effect especially on those species that colonise open, sunny shallow waters with sparse riparian vegetation and would disappear from the water bodies as succession progresses. The cattle gently take over regular, spatially-temporally staggered mowing of lowland moorland ditches, as recommended in the literature, in order to counteract the decline of certain dragonfly species. The migration of *Coenagrion mercuriale* into the project area is an example of how the natural development of vegetation along watercourses, while at the same time gently keeping the riparian zones open by large grazing animals, can create new habitat structures that are being lost in many places through other practices. While intensive grazing of watercourse margins usually has a negative impact on existing biotope structures and thus also on existing populations, extensive grazing in the riparian zone creates valuable micro-biotopes that are warmed to varying degrees by the sun and can thus be important for the larval development of thermophilic dragonfly species. The shifting of soil material along the edges of the banks can also lead to the formation of fish-free margins, which reduces the predation pressure on dragonfly larvae. The occurrence of various, partly rare bog dragonflies indicates that the renaturation of the fen also promotes specialised species that have declined or disappeared elsewhere due to impairment or loss of important biotopes. The natural development of the marsh zones in the ditches particularly promotes species whose larvae develop in loose, moist peat moss cushions, protected

from enemies, where they can also survive temporary drying out of the water bodies. Since, in addition to the grazed riparian zones, there are also extensive stretches of water where the growth is only temporarily browsed or not browsed at all, sufficient habitat structures are preserved for the species that are bound to sunny reed belts and abundant riparian vegetation. The described deformation of certain watercourse margins by cattle footfall and browsing is distributed over several, mostly widely spaced watering points and is thus limited to only small-scale "disturbance points" in relation to the total bank length of all integrated ditches. The obviously positive effects of extensive grazing of riparian zones presented here are by no means a recommendation for the integration of water bodies into "conventional" standing pastures, which are intensively overgrazed in high stocking density due to a superficial economic benefit. On such areas, nutrient inputs (supplementary feeding), the complete loss of riparian vegetation and massive trampling damage usually lead to impairment of the aquatic and terrestrial habitats of dragonflies and other species." (2020): Use of macro invertebrates to assess the quality of Seybouse River (North-East of Algeria). *Ukrainian Journal of Ecology* 10(4): 60-66. (in English) ["The theme is based on the determination and the impact of pollution on the aquatic fauna of Seybouse River in the Wilaya de Guelma. This study aimed to evaluate the physicochemical properties of water, to determine the macro-benthic invertebrates of this ecosystem. The money samples of water are taken (November - May) at three stations at different depths, including a very polluted one at downstream of the Wadi. Several physicochemical parameters were measured (pH, electrical conductivity, turbidity, BOD5 MES, water temperature and salinity). The Bi-monthly sampling of macro invertebrates revealed the existence of 40 taxa, divided into 4 branches (amphibians, molluscs, arthropods, and annelids), made up of 2344 identified individuals, and distributed according to the bathymetry, where the majority are Arthropods with 95.38%. The annelids represent 3.71%, collected mainly at the level of the strongly anthropized site C. Therefore, the distribution of the macrobenthic fauna depends on the physico-chemical parameters, on the geographical position. Maintaining a standard water quality in this aquatic ecosystem requires continuous monitoring of its physicochemical characteristics." **19604.** Chu, Y.J.; Ganesan, P.B.; Ali, M.A. (2020): Fluid-structure interaction simulation on flight performance of a dragonfly wing under different pterostigma weights. *Journal of Mechanics* 37: 216-229. (in English) ["The dragonfly wings provide insights for designing an efficient biomimetic micro air vehicle (BMAV). In this regard, this study focuses on investigating the effect of the pterostigma weight loading and its spatial location on the forewings of dragonfly by using the fluid-structure interaction simulation. This study also investigates the effect of change in the wing elasticity and density on the wing performance. The forewing, which mimics the real dragonfly wing, is flat with a 47.5mm span and a 0.4mm thickness. The wing was set to cruise at 3 m/s with a constant flapping motion at a frequency of 25 Hz. This study shows that a small increase of pterostigma loading (11% of wing weight) at the tip of the wing significantly improves the lift to drag ratio, CL/CD, which has 129.16% increment in comparison with no loading. The lift to drag ratio depends on the pterostigma location, pterostigma loading, elastic modulus and density. The results of this study can be used as a reference in future BMAV wing optimization design." **19605.** Derbuch, G. (2020): Folgekartierung der Libellenfauna im Nationalpark Gesäuse (Monitoring, EZ), Endbericht, November 2020. Auftraggeber: Nationalpark Gesäuse GmbH, Fachbereich Naturschutz & Forschung, Mag. Alexander Maringer, Weng 2, A-8913 Admont, Austria: 46 pp. (in German) ["In 2019 and 2020, the objective of this project was to map selected dragonfly species first recorded by Russ (2010) around 10 years ago at various water bodies in the Gesäuse National Park and just outside it. Russ was able to identify 30 species, whereas the present study identified 20. This considerable difference is due to the fact that two species-rich water bodies in the valley have either lost

a great deal of their value (Paltenspitz) or no longer exist (pond near Gstatterboden). The majority of species are widespread and common species. No species of the Annexes of the Habitats Directive were found. It is gratifying to note the presence of the endangered species *Leucorrhinia dubia* on the Gscheideggkogel, *Somatochlora flavomaculata* on the Paltenspitz and *Coenagrion hastulatum* in the Haselkar. In addition, the almost endangered *Somatochlora alpestris* is found on the bogs of the Drahbank, the Gscheideggkogel and the Neuburgmoos. With 11 species, the Life project pond on the Paltenspitz has proved to be the richest in species - 10 years ago, however, there were 24 there (!), and the qualitative decline is also evident. The pond must be rehabilitated, opened and dredged. The small water bodies on the Haselkaralm currently have 8 species, but only in water bodies that are protected from cattle and have natural siltation vegetation. Six species fly at Sulzkarsee, in significantly higher individual densities than 10 years ago - an indication that the control of minnows and nutrient input has been successful. The small peaty mire waters in the Neuburgmoos, the Drahbank and at the Gscheideggkogel are constant in terms of dragonfly fauna, with isolated occurrences of stenotopic and nature conservation-relevant species (*L. dubia*, *S. alpestris*). The pond at the Weidendom and the Hechtlacke also show no qualitatively or quantitatively relevant changes. change - they are generally species-poor. No dragonflies were found at three of the selected sites (Lettmairau, Brucksattel, Gstatterboden pond). There is an increased need for action at the Paltenspitz (dredging) and the Neuburgmoor (fencing). It has been shown that two surveys are not sufficient to provide a representative insight into the local dragonfly population. of the local dragonfly populations. In comparison, the RVS species protection for environmental planning issues provides for 4-6 inspections per year, depending on the type of water body." **19606.** Enss, J., Joest, R.; Lorenz, A. (2020): Libellenzönsen renaturierter und nicht-renaturierter Abschnitte der Ruhr und der Lippe, zweier großer Fließgewässer in Nordrhein-Westfalen. *Libellula* 39(3/4): 149-171. (in German, with English summary) ["In this paper dragonfly and damselfly communities in restored and non-restored stretches of the rivers Ruhr and Lippe are compared. From May to September 2017 a total of 52 transects were visited monthly to record adult dragonflies and damselflies and to collect exuviae with a standardised protocol. The data set contains 3,248 records of 23 species from eight families (14 % Exuviae). Remarkable are records of *Onychogomphus forcipatus* at restored stretches of the Ruhr and *Ophiogomphus cecilia* mostly at restored stretches of the Lippe. Both species were on the verge of extinction in North-Rhine-Westphalia. At the lowland river Lippe the number of species and the number of individuals were higher compared to the lower mountain river Ruhr. Both species richness and number of individuals were generally, if not always significantly, higher in restored stretches compared to non-restored stretches of both rivers. The higher species richness is mostly due to a higher number of species typical of standing waterbodies which profit from this type of habitat in the floodplains created by the restoration measures. The number of explicitly riverine species did not differ in restored and non-restored stretches of the Lippe while there was one more riverine species in restored stretches of the Ruhr. However, the number of individuals of explicitly riverine species was higher in restored

stretches of both rivers. Due to low detection rate, the recording of exuviae only gave convincing results for the Lippe which correspond to observations from studies by other authors. River restoration measures lead to an increase in both number and abundance of dragonfly and damselfly species and therefore is judged favourably. Due to their positive reactions Odonata can therefore be used as indicators for river restoration measures." **19607.** Fait, P.; Demierre, E.; Ilg, C.; Oertli, B. (2020): Small mountain reservoirs in the Alps: New habitats for alpine freshwater biodiversity? *Aquatic Conservation: Marine and Freshwater Ecosystems* 30(4): 617-630. (in English) ["1. Today, aquatic biodiversity suffers from many pressures linked to human activities, including climate change, which particularly affects alpine areas. Many alpine freshwater species have shifted their geographical distribution to colder areas, but a reduced availability of suitable habitats is also forecasted. New artificial water bodies could provide habitat enhancement opportunities, including small mountain reservoirs built to overcome a lack of snow during winter. 2. To investigate the role of reservoirs as a habitat for freshwater invertebrates, a case study was conducted on eight reservoirs in the Swiss Alps. The study aimed to compare the water quality and freshwater biodiversity of the reservoirs with those of 39 natural and newly excavated ponds. Data were collected on physico-chemistry, freshwater habitat structure, and aquatic insects (dragonflies and aquatic beetles). 3. The study showed that the mountain reservoirs investigated did not differ from natural ponds in terms of surface area, conductivity, and trophic level. Similarly to natural ponds, reservoirs showed signs of impairment owing to surface runoff carrying pollutants linked to ski tourism. They presented a low diversity of mesohabitats, and in particular lacked vegetation. Compared with natural ponds, the species richness in reservoirs was lower for dragonflies but not for beetles. At the regional scale, the community from the reservoirs was a subset of the natural ponds community, supporting 38% of the regional species richness for these two insect groups. 4. The results suggest that mountain reservoirs are likely to be important for biodiversity in alpine areas, both as habitats and as stepping stones for species shifting their geographical range. These water bodies can be enhanced further by some nature-friendly measures to maximize benefits for biodiversity, including margin revegetation or the creation of adjacent ponds. Ecological engineering needs to be innovative and promote freshwater biodiversity in artificial reservoirs." **19608.** Gauci, C. (2020): Emergence of seven odonate species, based on exuviae collection, from four small artificial ponds at Ghadira Nature Reserve, Malta. *J. Br. Dragonfly Society* 36(2): 109-130. (in English) ["The Ghadira Nature Reserve, Malta is a saline marshland. The construction of three small fresh water ponds in the early nineteen nineties, together with the addition of a fourth in 2017, attracted a number of odonate species. Seven species reproduce regularly in them, with another two ovipositing sporadically. The regular collection and counting of exuviae provides an accurate count of the numbers and species emerging. For this purpose, in 2019, exuviae were collected twice weekly from mid-March to mid-December. The most numerous

species emerging from each of the four ponds was *Crocothemis erythraea*. Most, if not all, of the seven species had two (in some cases three) generations annually. Birds were the main predators of larvae, both during the growth period and at emergence, and of teneral; [a kingfisher - *Alcedo atthis* - is documented preying on a teneral *C. erythraea*]. Spiders and possibly Painted Frogs took what appeared to be an insignificant number of teneral." (Author)] Address: Gauci, C., 28 Triq il-Kissier, Mosta, Malta MST1822, Malta

**19609.** Kamarajan, B.P.; Muthusamy, A. (2020): Survival strategy of *Pseudomonas aeruginosa* on the nanopillar topography of dragonfly (*Pantala flavescens*) wing. *AMB Expr* (2020) 10:85: 12 pp. (in English) ["Discovery of nanopillars on the surface of the insect wings had led to the understanding of its bactericidal property. Nanopillar topography is deterrent to only those bacteria that are attached, or in close contact with the nanopillars. The present study investigated the variation in the viability of *Pseudomonas aeruginosa* strains PAO1 (virulent) and ATCC 9027 (avirulent) on the wing surface of dragonfly (*Pantala flavescens*). Viability study indicated that only 0.2% ATCC 9027 survived when incubated with wing for 48 h in Phosphate buffered saline, while under the same conditions 43.47% PAO1 survived. Enumeration of *Pseudomonas* attached to wing surface suggested that, the number of PAO1 attached on the wing surface was three times lesser than ATCC 9027. Propensity of attachment of *P. aeruginosa* strains PAO1 and ATCC 9027 on the wing surface investigated using scanning probe microscope indicated that *P. aeruginosa* ATCC 9027 showed adhesion to 88% of regions and, PAO1 showed adhesion to only 48% regions tested on wing surface. PAO1 survived the bactericidal effect of wing surface by evading attachment. Three clinical isolates tested which showed viability similar to PAO1 strain, also showed lower propensity to attach to wing surface. Transcriptional level analyses using RT-PCR suggested that flagellar genes (*fliE* and *fleS*) were downregulated and genes responsible for reversible to irreversible attachment (*gcbA* and *rsmZ*) were upregulated in ATCC 9027 than PAO1 on wing surface, indicating relatively higher attachment of ATCC 9027 on wing surface. The study suggests that virulent strains of *P. aeruginosa* may evade attachment on wing surface. The results gain significance as bioinspired surfaces are being created towards developing antibacterial medical implants and other antibacterial surface applications." (2020): Diversidad y patrón de emergencia de libélulas en un hábitat léntico del Jardín Botánico Nacional de Cuba. *Revista del Jardín Botánico Nacional* 4: 119-130. (in Spanish, with English summary) ["The transference of biomass to terrestrial ecosystems is carried out in part by the adults of aquatic insects after their emergence from water, as it is in the case of odonates. The aim of this study is to characterize the emergence pattern of an odonate assemblage in an artificial lentic habit at of the National Botanical Garden of Cuba, from the harvest of exuviae. Fifty two samplings were carried out with a frequency of once a week, and an interval of seven to nine days, in four transect of 8 m<sup>2</sup>. To characterize the emergence, the seasonal climate model was considered: rainy, poorly rainy and transition seasons. The change in climatic variables and habitat characteristics was registered, and was related to the emergence pattern. The variation in the use of resources during emergence was

described. The emergence with a constant volume of water turned out to be asynchronous, with a predominance of accidental species and unequal abundance distribution. The rainy period was the season with the highest percentage of emergence, in which rainfall and relative humidity were the factors that most influenced the emergence pattern. The plants were the most used emergence substrate, and the decrease in vegetation cover corresponded to the alternative use of other substrates." (Authors)] Address: Lim-Franco, Gabriela, Departamento Curatorial, Museo Nacional de Historia Natural, Calle Obispo # 61 entre Oficios y Baratillo, Habana Vieja, La Habana, Cuba. CP: 10100. **19611.** Moura, L.P.; Marques Couceiro, S.R.; Juen, L.; Silas Veras, D. (2020): Congruence of the composition of Odonata between dry and rainy seasons in the Maranhense Cerrado. *International Journal of Odonatology* 23(4): 305-314. (in English, with Spanish summary) ["In tropical streams, seasonality has a strong influence on heterogeneity, altering available resources and affecting the carrying of organisms, substrate and organic matter. This causes changes in the limnological variables, as well as in the species composition. The aim of our study was to evaluate the response of the congruence of the Odonata community in two seasons in streams of the transition between Cerrado and Caatinga. Ten tributary streams of the river Itapecuru in Caxias, in eastern of Maranhão, were sampled from July to December 2017 (lowest precipitation) and from January to June 2018 (highest precipitation). A total of 386 specimens were collected, 160 in the season with the lowest precipitation and 226 in the season with the highest precipitation. There was no congruence of response for the order Odonata between the seasons; however, if the suborders are treated separately, Zygoptera presented a high congruence of larvae, but not Anisoptera. Thus, in environments that face strong water stress and due to the ecophysiological differences of the suborders, the sampling of only one seasonal period does not provide consistent data on the species composition (Zygoptera showed similarity in the composition between drought and rainy seasons, but not Anisoptera), losing important information about local diversity. If the focus is on biodiversity, the use of suborders can establish patterns of diversity and adaptation between seasons, in view of the existing ecophysiological differences." **19613.** Parr, A.J. (2020): Migrant and dispersive dragonflies in Britain during 2019. *J. Br. Dragonfly Society* 36(2): 67-83. (in English) ["The year 2019 was a truly impressive one for migrant dragonflies in the UK, featuring alongside the heady days of 1995 and 2006. It was thus a record year for sightings of both *Anax ephippiger* and *A. parthenope*. The former species saw three separate influxes - during late

winter/early spring, during summer and again during the autumn. The summer influx was notable for the presence of multiple individuals at several sites, and breeding behaviour was reported on several occasions, though no progeny were positively identified later in the season. *Anax parthenope* appeared at over 80 sites in the UK during summer, these sightings including only the third-and fourth-ever records for Scotland. Although there was clearly a major influx, records were received from many sites that had also recorded the species over the previous few years, and it seems that breeding populations in Britain may now at last be becoming more widespread. In addition to the impressive arrivals of *A. ephippiger* and *A. parthenope*, *Sympetrum fonscolombii* also appeared in near-record numbers, with reports from almost 150 sites during the year. At Drift Reservoir in Cornwall, some 120 individuals were present during the second week of July, though most of these then rapidly moved on. Successful breeding was noted at a number of sites, with emergences occurring from late August onwards. However, given the size of the early season influxes, the number of such breeding sites seemed smaller than might perhaps have been expected. Other highlights of 2019 included the sighting of two male *Crocothemis erythraea* (Scarlet Darter) along the south coast during high summer. One site - Longham Lakes in Dorset - had also recorded the species in 2017, which could just be a coincidence, but might hint at the presence of an undiscovered breeding colony nearby. Good numbers of *Aeshna affinis* (Southern Migrant Hawker) were seen away from their Thames Estuary strongholds for the second year in succession, with records coming from many of the areas that had reported the species during 2018, as well as from new areas such as coastal south Wales. This species now seems to be becoming increasingly widespread in southern Britain. *Aeshna isocetes* (Norfolk Hawker) also continued its range expansion in south-east England, with a record even from Medmerry RSPB Reserve in West Sussex. The expansion of both *A. affinis* and *A. isocetes* may be linked to a combination of both internal dispersal and immigration from the Continent. Amongst our recent colonist damselflies, both *Chalcolestes viridis* and *Erythromma viridulum* showed substantial range expansion during 2019, particularly along the east coast. The most northerly site in Britain for *C. viridis* is now in North-east Yorkshire, while *E. viridulum* was recorded as far north as County Durham." **19614.** Riva-Murray, K.; Bradley, P.M.; Brigham, M.E. (2020): Methylmercury—total mercury ratios in predator and primary consumer insects from Adirondack streams (New York, USA). *Ecotoxicology* 29: 1644-1658. (in English) ["Mercury (Hg) is a global pollutant that affects biota in remote settings due to atmospheric deposition of inorganic Hg, and its conversion to methylmercury (MeHg), the bioaccumulating and toxic form. Characterizing biotic MeHg is important for evaluating aquatic ecosystem responses to changes in Hg inputs. Aquatic insects possess many qualities desired for MeHg biomonitoring, but are not widely used, largely because of limited information regarding percentages of total mercury (THg) composed of MeHg (i.e., MeHg%) in various taxa. Here, we examine taxonomic, spatial, and seasonal variation in MeHg% of stream-dwelling predator and primary-consumer insects from nine streams in the Adirondack region (NY, USA). Predator MeHg% was high (median 94%) and did not differ significantly among five taxa. MeHg% in selected dragonflies (the most abundant predators, Odonata: Aeshnidae and Libellulidae)

exhibited little seasonal and spatial variation, and THg concentration was strongly correlated with aqueous (filtered) MeHg (FMeHg;  $r_s = 0.76$ ). In contrast, MeHg% in primary consumers—shredders (northern caddisflies [Trichoptera: Limnephilidae]) and scrapers (flathead mayflies [Ephemeroptera: Heptageniidae]), were lower (medians 52% and 35%, respectively), and differed significantly between taxa, among sites, and seasonally. Correlations of THg with FMeHg were weak (shredders,  $r_s = 0.45$ ,  $p = 0.09$ ) or not significant (scrapers,  $p = 0.89$ ). The higher MeHg% of predators corresponded with their higher trophic positions (indicated by nitrogen stable isotopes). Results suggest obligate predators hold the most promise for the use of THg as a surrogate for MeHg biomonitoring with aquatic insects within the Adirondack region." (2020): Seasonal insect migrations: massive, influential, and overlooked. *Frontiers in Ecology and the Environment* 18(6): 335-344. (in English) ["During seasonal changes around the globe, trillions of insects are on the move. Many insect populations, including butterflies, moths, hoverflies, and dragonflies, make repeated seasonal migrations each year. It is only during the past century that biologists have come to accept the concept of insect migration, and new research using radar, citizen science, and stable isotopes has revealed unexpected insights about this phenomenon. Drawing on these findings, we demonstrate how seasonal insect movements are both massive and ecologically influential, with consequences for food webs, nutrient transport, pollination, and infectious disease. Responding to environmental changes, some mobile insect populations are declining or shifting the timing and extent of their journeys. We suggest research and policy priorities for investigating and protecting insect migrations. Outcomes from such work could transform strategies for agricultural pest control and wildlife conservation, and could help preserve the ecological functions performed by migratory insects." **19619.** Adedire, C.O.; Adeyemi, J.A.; Owokoniran, G.O.; Adu, B.W.; Ileke, K.D. (2021): Effects of application of copper-based fungicides in cocoa plantations on the abundance and diversity of macroinvertebrates in adjacent rivers in Southwestern Nigeria. *Ife Journal of Science* 23(2): 13 pp. (in English) ["This study investigated the relationship between the levels of fungicide pollution and the abundance and diversity of macroinvertebrate fauna in three river systems: Aponmu, Oruwo, and Owena in south-western Nigeria, which are in close proximity to cocoa plantations. For each river, three sites were selected for the collection of water and sediment samples from April to July, 2018. Prior to sample collection, the physicochemical parameters (electrical conductivity, total dissolved solutes, pH, temperature, and dissolved oxygen) were determined. Also, aquatic macroinvertebrates were collected, and were identified to generic level, where possible. The levels of copper and sulphate in the samples were determined following standard procedures. The range of mean values for the physicochemical parameters were: 0.07-0.20 mS/cm, 60.00 – 154.00 ppm, 24.60 – 28.13 °C, 6.97 – 7.43, and 0.87 – 2.87 mg/L for electrical conductivity, total dissolved solutes, temperature, pH, and dissolved oxygen respectively. The range of mean values for copper and sulphate in sediment samples were 30.58 – 56.63 mg/Kg and 787.12 – 978.33 mg/Kg respectively while those for the water samples were 2.86 – 6.93 mg/L and 476.6 – 685.58 mg/L respectively. A total of nineteen (19) macroinvertebrate genera comprising Insecta (14), Gastropoda (3), Crustacea (1), and Bivalvia (1) were recorded. Taxa richness and species diversity were higher in river Owena in comparison to rivers Aponmu and Oruwo. The high abundance of the taxa: Potamididae, Gerridae, Notonectidae, Libellulidae, and Platycnemididae in the sampled rivers notwithstanding the pollution levels is an indication that these taxa are capable of thriving in polluted aquatic systems." Volatiles & Essential Oils* 8(6): 1792-1798. (in English) ["The article presents the results of odonatafauna of the Khorezm oasis in the north - western part of Uzbekistan for 2020-2021. Observations were made at seven points in different biotopes of the oasis. Observations were made in the spring-summer-autumn seasons, when the temperature rose above +20 C. According to the results, 23 species of odonatafauna belonging to 5 families and 8 subfamilies were identified. They are divided into three groups according to their dominance: D = dominant, SD = subdominant R = rare species. Accordingly, dominant species account for 17%, subdominant species for 22%, and rare species for 61%. There are 11 palearctic species (47.8%), 7 cosmopolitan species (30.4%), 2 holarctic and transpalearctic species each (8.7%), and 1 Australia-Asian species (4.3%)."] (Authors)] Address: Akhmedova M.Sh, Khorezm Mamun Academy, 220900, Khiva, Markaz Str., 1, Uzbekistan

**19622.** Al Mousa, M.A. (2021): Studies on the Odonata and Trichoptera of high-elevation lakes of northern Colorado and Southern Wyoming. MSc thesis, Colorado State University, Fort Collins, Colorado: VIII + 178 pp. (in English) ["Freshwater biodiversity loss is a major concern, and global warming is already causing a significant role in species extinctions. The main goal of this research was to provide a baseline for specific aquatic insect species distributions at high-elevation lentic habitats in Northcentral Colorado and Southern Wyoming. I provided occurrence records of the Hudsonian Emerald dragonfly (*Somatochlora hudsonica*, HED) in Northcentral Colorado and Southern Wyoming. The HED is the only Colorado dragonfly listed as threatened by the US Forest Service. It was ranked as critically imperiled in Colorado and vulnerable in Wyoming. I used Maxent (Maximum entropy), a machine learning program that uses species presence data and environmental variables to predict the potentially suitable habitat for species. Maxent was used to plot a map of the potentially suitable habitats of HED. Temperature seasonality, mean temperature of wettest quarter, precipitation of warmest quarter, precipitation of driest quarter, and precipitation seasonality were the key environmental factors for predicting the occurrence of HED in appropriate high-elevation lakes of Northcentral Colorado and Southern Wyoming with an accumulated contribution of 91%. Results of this study provided baseline data for the US

Forest Service to assist to evaluate the conservation status of HED and potentially initiate protection plans in two national forests (The Arapaho & Roosevelt National Forest and the Medicine Bow & Routt National Forest) in Colorado and Wyoming. I report adult caddisflies from 136 montane and alpine lentic habitats, primarily lakes, of seven northern Colorado counties for the first time. My objective was to provide species records of adult and larval caddisflies from high-altitude lentic habitats that are not generally well sampled. These lakes may be potentially impacted by current and future global climate change scenarios. Field collection of adults and rearing of larvae were included with available unpublished and published records, resulting in 541 confirmed records of caddisfly species. Forty-nine species, representing 24% of all known Colorado caddisflies are documented. Seven families and 24 genera are represented. The Limnephilidae comprised 76% of the 49 recorded species. The other six families were usually represented by only one to four species. Distribution maps are presented for the six families and the most common limnephilid species. Montane and alpine lakes are vulnerable ecosystems likely to be impacted by climate change. Comprehensive faunal surveys are key to understanding long-term biodiversity changes and establishing conservation needs and priorities. In addition, species lists of taxa are important to monitor future faunal biodiversity changes." (Author)] Address: not stated

**19623.** Augustine, B.; Eo, J.; Kim, M.-H.; Kim, M.-K.; Choi, S.-K.; Yeob, S.-J.; Bang, J.-H.; Danquah, O. (2021): Effects of temperature and water management in rice fields on larval growth of *Pantala flavescens* (Odonata: Libellulidae). *Korean Journal of Environmental Biology* 39(4): 536-541. (in English) ["*P. flavescens* is a dominant Odonata species in the rice fields in Korea. To determine the effects of different temperatures on its larval growth and emergence, field and laboratory experiments were conducted. Larval growth was also monitored in mono-cropping and double-cropping rice fields. The growth of larvae was monitored every week by measuring the head width. In the field experiment, no difference was found in larval growth and emergence between the control temperature and +1.9°C of the control temperature. The larval growth was greater at 23°C than at 20°C laboratory temperatures, and no emergence was recorded at either temperature after eight weeks of monitoring. There was a quadratic relationship between larval growth and temperature in an incubator at five temperature regimes of 15, 20, 25, 30, and 35°C. Midseason water drainage caused the extinction of the existing individuals and newly hatched larvae dominated after re-watering in the rice fields. Larval size was greater in double-cropping fields than in mono-cropping fields in late July but the tendency was reversed in early August. The results of this study suggest that temperature warming will directly promote the larval growth of *P. flavescens* and indirectly influence seasonal growth via changes in water management in rice fields." (Authors)] Address: Eo, J., National Institute of Agricultural Sciences, Wanju 55365, Republic of Korea. E-mail. eo.jiny@korea.kr

**19624.** Basooma, A.; Teunen, L.; Semwang, N.; Bervoets, L. (2021): Trace metal concentrations in the abiotic and biotic components of River Rwizi ecosystem in Western Uganda, and the risks to human health. *Heliyon* 7(11): e08327: 13 pp. (in English) ["Highlights: • Surface waters at Katenga and Kayanja were contaminated with gold and mercury. • Concerning metals the surface water was generally safe for human consumption at most sites. • The sediment trace metal levels posed no ecological risks to the benthic biota. • Arsenic and mercury concentrations in *Brycinus sadleri*

muscle posed a potential human health risk. Abstract: The distribution of metals in the Rwizi River ecosystem was investigated and human health risks were assessed. Samples of water, sediment, damselfly larvae (*Ceriatrigon glabrum*) and fish species (*Brycinus sadleri* and *Barbus altianalis*), were collected at six sites. In all samples the trace elements As, Al, Au, Cd, Co, Cu, Fe, Hg, Mn, Pb, Zn, were quantified. Sediment samples near the gold mine had significantly higher concentrations of Hg, Fe and Al although all the concentrations were below the probable effect concentrations (PEC). The dissolved concentrations of trace metals were within the European standards and WHO drinking water guidelines. However, Fe and Mn concentrations exceeded the standards at three sites. The damselfly larvae were good indicators of local metal pollution. The fish species accumulated metal levels in the order gills>liver>muscle for most metals except for Hg. Multiple regressions between accumulated metals in damselfly with environmental metal levels showed only for Au and Cd significant positive relationships. Relating environmental metal levels and physico-chemical characteristics to the levels in the invertebrates, only for Cu and Pb significant relationships were found. With respect to the measured metals, the fish were safe for human consumption in most cases although *Brycinus sadleri* posed a potential health risk due to a As hazard quotient (HQ) of 2.2 that exceeded the critical value of 1. Similarly, the maximum edible risk-free quantity (Q) for As in *Brycinus sadleri* was 1.5 g (95 % CI), less than the minimum risk free quantity of 31.5 g. In conclusion, the river water was safe for drinking but the extraction of gold using Hg should be replaced with an environmentally friendly method or an effective wastewater treatment should be instituted. People should be cautioned from consuming *Brycinus sadleri* to avoid potential health hazards." **19625.** Behr, H. (2021): Fotonachweis von *Stylurus flavipes* (Odonata: Gomphidae) in Schwerin. *Virgo* 24: 79. (in German) [On 15 August 2020, a photo record (Fig. 1) of a female of *S. flavipes* was made in the former Wüstmark gravel pit near Schwerin in Mecklenburg-Western Pomerania, Germany. This site is far away (at least 60 km) from the previously known larval habitats on the Elbe in this federal state. Especially female imagines of this stenotopic species were relatively rarely observed close to the breeding water. In the literature, records at distances of up to 25 km (Wildermuth & Martens 2019) or 35 km (Menke et al. 2016) from the nearest river have been described. Mauersberger (2013) also reports colonisation of suboptimal water bodies, smaller rivers and canals, as well as individual finds in Brandenburg that cannot be assigned to any reproductive habitat. Overall, the species, which is protected throughout Europe under Annex IV of the Habitats Directive, appears to have been recolonising suitable habitats at the western limit of its distribution since the 1990s, following considerable population declines on large rivers in Central and Western Europe (Wildermuth & Martens 2019). From Mecklenburg-Western Pomerania, observations of this stream valley species are so far only available from the Elbe region (Bönsel & Frank 2013)."] (Author/DeepL)] Address: Behr, H., Herrengrabenweg 57, 19061 Schwerin, Germany. **19626.** Beukema, J.J. (2021): Upstream and downstream movements in adults of stream-dwelling Odonata. *Odonatologica* 50(3/4): 239-250. (in English) ["Based on data from

the literature on along-stream movements of adult stages of Odonata, comparative preference for upstream or downstream movement is evaluated. The great majority of publications reported upstream movement. Upstream migration was reported particularly in species of Calopterygidae and Gomphidae. Upstream movements are potentially functional: they compensate for downstream larval drift. The mechanism behind the net directed movements, however, is unknown and controversial. Movements in general may be largely undirected, but, in the presence of downstream drift by larvae an innate tendency either to move upstream or to stay at upstream locations is expected." **19627.** Blow, R.; Willink, B.; Svensson, E.I. (2021): A molecular phylogeny of forktail damselflies (genus *Ischnura*) reveals a dynamic macroevolutionary history of female colour polymorphisms. *Molecular Phylogenetics and Evolution* 160 (2021) 107134: 12 pp. (in English) ["Colour polymorphisms are popular study systems among biologists interested in evolutionary dynamics, genomics, sexual selection and sexual conflict. In many damselfly groups, such as in the globally distributed genus *Ischnura* (forktails), sex-limited female colour polymorphisms occur in multiple species. Female-polymorphic species contain two or three female morphs, one of which phenotypically matches the male (androchrome or male mimic) and the other(s) which are phenotypically distinct from the male (heterochrome). These female colour polymorphisms are thought to be maintained by frequency-dependent sexual conflict, but their macroevolutionary histories are unknown, due to the lack of a robust molecular phylogeny. Here, we present the first time-calibrated phylogeny of *Ischnura*, using a multispecies coalescent approach (StarBEAST2) and incorporating both molecular and fossil data for 41 extant species (55% of the genus). We estimate the age of *Ischnura* to be between 13.8 and 23.4 millions of years, i.e. Miocene. We infer the ancestral state of this genus as female monomorphism with heterochrome females, with multiple gains and losses of female polymorphisms, evidence of trans-species female polymorphisms and a significant positive relationship between female polymorphism incidence and current geographic range size. Our study provides a robust phylogenetic framework for future research on the dynamic macroevolutionary history of this clade with its extraordinary diversity of sex-limited female polymorphisms." **19628.** Bota-Sierra, C.A.; Flórez-V, C.; Escobar, F.; Sandoval-H., H.; Novelo-Gutiérrez, R.; Londoño, G.A.; Cordero-Rivera, A. (2021): The importance of tropical mountain forests for the conservation of dragonfly biodiversity: A case from the Colombian Western Andes. *International Journal of Odonatology* 24: 233-247. (in English) ["Forests have been widely recognized as key habitats for odonate (dragonflies and damselflies) biodiversity, but the importance of forests for holding odonate biodiversity remains understudied in tropical mountains, one of the most diverse ecosystems on the planet. Here we describe the odonate assemblage composition along the elevation gradient in the Tamá Mountains (Colombian Cordillera Occidental). We analyzed the effects of elevation, habitat, and suborder on species richness and endemism. We found that the richest assemblage occurred in the foothills between 300 and 600 m, where the biotas of the Chocó biogeographic region and

the Tropical Andes converge. Anisoptera richness was higher in open habitats, that of Zygoptera higher in forests. Richness and endemism decreased with elevation, and no relation between habitat and richness was found. However, the number of endemic species was strongly related to forests, which harbored 25 out of 28 endemic species. Also, forest odonates had narrower elevation ranges than open-habitat odonates. These patterns can be explained because tropical mountains were historically covered by forests, while open habitats derived from human activities (i.e., pastures) that have flourished in the past centuries. The forest odonate assemblages at different elevations have been evolving for millions of years, in relatively stable ecological conditions, which could promote the high number of forest endemics in the tropical mountains. Our results emphasize the role of tropical mountain forests in the conservation of Odonata diversity." **19629.** Brito, J.S.; Michelan, T.S.; Juen, L. (2021): Aquatic macrophytes are important substrates for Libellulidae (Odonata) larvae and adults. *Limnology* 22: 139-149. (in English) ["Understanding the role of abiotic and biotic factors on biological communities is a challenge for ecologists. Individuals of the order Odonata have a close connection with these factors, which can influence the establishment of each stages of life. This study evaluated the relationship between habitat complexity and limnological variables on the diversity of Libellulidae larvae and adults. Our hypotheses were that (i) limnological variables would have a greater influence than habitat complexity on larvae and (ii) habitat complexity would influence more adults. Forty-six sampling sites were evaluated in the Brazilian Amazon region. Our results indicated the effects of limnological variables and habitat complexity on both life stages, with higher influence of the first on larvae and the second on adults, mainly for species composition. The abundance of the *Eichhornia azurea*, which has enormous morphological plasticity, together with the presence of a range of other macrophyte species provides different habitat architectures, with more suitable microhabitats for different odonates. The habitat complexity metrics had combined effects on the larvae, presumably because of the greater availability of refuges from predators and food sources. In contrast, in the adults, the relationship with habitat complexity is associated with the availability of ovipositing sites and perches." **19631.** Büsse, S.; Tröger, H.-L.; Gorb, S.N. (2021): The toolkit of a hunter – functional morphology of larval mouthparts

in a dragonfly. *Journal of Zoology* 315(4): 247-260. (in English) ["The diversity of mouthpart specializations in insects is staggering. As a direct consequence thereof, the knowledge about the mouthpart geometry, muscle attachment and feeding kinematics is incomplete for the vast majority of insect taxa – as it is for dragonflies. The adult dragonflies catch their prey in flight, while the aquatic larvae prey under water – both life stages being key predators in their biotopes. To gain insights into the functional morphology of the biting-chewing mouthparts of larval *Anax imperator*, we combined results from micro computed tomography ( $\mu$ CT), confocal laser scanning microscopy (CLSM) and high-speed videography. *Anax imperator* larvae were filmed during the feeding process to describe the movement and coordination of the mouthparts. These results, together with  $\mu$ CT-data, allowing for a comprehensive visualization of the 3D-geometry and corresponding musculature of each mouthpart. The material composition of the cuticle strongly influences the strength, mobility and durability of the cuticular components of the mouthparts. With this paper, we elucidate the anatomy, geometry and material composition of *A. imperator*'s larval mouthparts in the light of the feeding process. Furthermore, we try to lay a foundation for functional morphological comparisons of mouthparts (1) between dragonfly species belonging to different eco-types according to their food preferences and feeding habits or even (2) between different insect groups." **19632.** Buskirk, J. van; Smith, D.C. (2021): Ecological causes of fluctuating natural selection on habitat choice in an amphibian. *Evolution* 75(7): 1862-1877. (in English) ["We estimated natural selection targeting three traits related to habitat choice in a frog (*Pseudacris maculata*) breeding in pools on the rocky shores of Isle Royale, Michigan, over 16 years. Our aim was to identify the form and ecological causes of annual variation in directional and correlational selection as expressed in the survival and growth of tadpoles. We found directional selection favoring early breeding, but pool choice was under weak stabilizing selection. However, the form of stabilizing selection and the position of the optimum trait value shifted among years with the severity of disturbance and the intensity of biotic interactions. In years when wave wash and pool desiccation were severe, selection shifted to favor tadpoles in habitats where these risks were less pronounced. If predatory dragonfly larvae [*Aeshna juncea*] were abundant, selection favored tadpoles in small pools where dragonflies did not occur. When intraspecific competition was strong, selection favored early broods within a broader range of pool types. The agents of selection in this study-biotic interactions and disturbance-are common to many ecological systems and frequently exhibit temporal variation; this suggests that fluctuating selection may be widespread in natural populations." (2021): Tunable omnidirectional antireflection coatings inspired by inclined irregular nanostructures on transparent Blue-Tailed Forest Hawk dragonfly wings. *Langmuir* 37(31): 9490-9503. (in English) ["Randomly arranged inclined irregular nanostructure-covered blue-tailed forest hawk dragonfly wings are highly transparent for wide viewing angles. Inspired by the dragonfly wings, monolayer silica colloids are self-assembled on shape memory polymer-coated substrates and utilized as plasma etching masks to pattern disorderly arranged inclined irregular conical structures. The structures build gradual refractive index transitions at various angles of incidences, resulting in omnidirectional antireflection performance over the whole visible wavelength region. In comparison with a bare substrate, the optimized structure-covered substrate presents 10% higher optical transmission at 0° and even 41% higher optical transmission at an angle of incidence of 75°. Importantly, by manipulating the structural configuration of the shape memory polymer-based structures, the corresponding antireflection characteristics can be instantaneously and reversibly eliminated and recovered after drying out of common household liquids or applying contact pressures in ambient environments. The tunable omnidirectional antireflection coatings are prospective candidates for realizing optical modulation, which exhibits an enormous application value in smart windows, intelligent display screens, optical components, and novel optoelectronic devices.] Address: Chen, Y.-H., Dept Chemical Engineering, Nat. **19639.** De, K.; Sarkar, A.; Singh, K.; Uniyal, V.P.; Johnson, J.A.; Hussain, S.A. (2021): Diversity of aquatic insects and biomonitoring of water quality in the upper Ganga River, a Ramsar site: a preliminary assessment. *Journal of Threatened Taxa* 13(13): 20011-20018. (in English) ["Monitoring of freshwater habitats through aquatic insects is widely used. A study was carried out in March, 2019 at 14 sites in the Upper Ganga River between Brijghat and Narora, a riverine Ramsar site in India, to document the diversity of three major aquatic predatory insect groups—Odonata, Coleoptera, and Hemiptera—and determine their biomonitoring potential. The study recorded three species of Coleoptera, four Hemiptera, 14 dragonflies, and eight damselflies. The Shannon diversity index (H') ranged from 2.465 to 2.782, Pielou's Evenness index (J') from 0.841 to 0.894, and Berger-Parker index of dominance (d) from 0.122 to 0.243. Families Libellulidae (Odonata), Coenagrionidae (Odonata) and Gerridae (Hemiptera) had high relative abundance and

dominant status. The stream invertebrate grade number-average level (SIGNAL2) score (for family) ranged from 2.316 to 3.174, lying within quadrant 2 of the SIGNAL2 (family) quadrant diagram. This suggested that the water in the area is likely to have high levels of turbidity, salinity, or nutrients, caused naturally or by anthropogenic activities, and the water has low levels of most toxic chemicals." (Authors)] Address: De, K., Department of Life Sciences, Sri Sathya Sai University for Human Excellence, Navanihal, Okali Post, Kamalapur, Karnataka 585313, India

**19640.** De Knijf, G.; Wils, C.; Maes, D. (2021): IUCN Rode Lijst van de libellen (Odonata) in Vlaanderen. Rapporten van het Instituut voor Natuur- en Bosonderzoek 2021 (59): 58 pp. (in Dutch, with English summary) ["The Red List criteria of the International Union for Conservation of Nature (IUCN) are intended to be an easily and widely understood system for classifying species at high risk of extinction. However, while the Red List may focus attention on those taxa at the highest risk, it is not a means of setting priorities for conservation measures for their protection. These Red List criteria recommend revising Red Lists every ten years. The previous Red List dated from 2006. Because many new data have become available and the status of several species has changed since then, the current state of dragonflies in Flanders was assessed according to the international IUCN Red List criteria. For this, we used four of the five possible IUCN-criteria, namely changes in distribution (IUCN criterion A), the area size (IUCN criterion B) and the estimated population size (IUCN criteria C and D). In total, 59 species were evaluated against these criteria and then assigned to the corresponding IUCN Red List category. Some new species have recently colonised Flanders (*Coenagrion scitulum*, *Aeshna affinis*, *Anax parthenope* and *Sympetrum meridionale*) and are now classified as resident species, due to their rapid expansion. A total of: „\* 5 species are Regionally Extinct in Flanders: *Coenagrion mercuriale*, *Nehalennia speciosa*, *Aeshna subarctica*, *Epitheca bimaculata* and *Oxygastra curtisii*; „\* Seven species are Critically Endangered: *Coenagrion hastulatum*, *C. lunulatum*, *Somatochlora arctica*, *Leucorrhinia caudalis*, *L. pectoralis*, *Sympetrum depressiusculum* and *S. flaveolum*; „\* Four species are Endangered: *Aeshna juncea*, *Cordulegaster boltonii*, *Leucorrhinia rubicunda* and *Sympetrum danae*; „\* Four species are Vulnerable: *Gomphus vulgatissimus*, *Leucorrhinia dubia*, *Sympetrum pedemontanum* and *S. vulgatum*; „\* One species is Near Threatened: *Gomphus pulchellus*; „\* The remaining 43 species are of Least Concern. We discuss the IUCN-criteria used per species and compare the new Red List with the previous Red Lists by means of the so-called Red List Index. Overall, dragonflies and damselflies in Flanders are doing better than in previous decades. This is mainly due to species of nutrient-rich waterbodies that are doing markedly better than in the past as a result of habitat restoration, creation of new ponds (e.g. garden ponds) and waters in an urban or industrial context, and to species that benefit from climate warming. The group of 'southern' species enabled to successfully colonize Flanders also contributed to an increase in the number of Least Concern species. However, species from nutrient-poor waterbodies (fens, peatbogs and other oligotrophic waters) continue to perform poorly and deserve special attention in nature policy and nature management. Populations of several species decreased dramatically in the last 5 years. Those species are negatively affected by still too high nitrogen deposition in Flanders, increased warm weather and extreme drought events leading to (partially) desiccation of these kinds of waters, and in many cases from too intensive management of

their terrestrial habitat, resulting in the cutting of shrubs and trees near their reproductive biotopes. The drawing up of one or more Species Protection Plans is therefore more than urgently needed if we do not want to have these species disappear permanently from Flanders.] Address: Knijf, G. de, Research Institute for Nature and Forest (INBO), Havenlaan 88 bus 73, 1000 Brussels, Belgium. **19641.** de Vries, R.; Middelbos, R. (2021): A minor invasion of the Yellow-winged darter (*Sympetrum flaveolum*) in the Netherlands in 2020. *Brachytron* 22(1/2): 3-12. (in Dutch, with English summary) ["An invasion of *S. flaveolum* reached the Netherlands in August 2020. The first observation was made on 12 August, and on 14 August at least 40 individuals were observed on the island of Terschelling. Observations were made during August and September from 18 localities in the northern half of the Netherlands, including 37 individuals on 21 August in Eemshaven. Aggregations of dozens of individuals had not been observed in the Netherlands since 2008. Both recent aggregations were only seen on one day and consisted solely (Terschelling) or in large majority (Eemshaven) of males. The contemporary arrival of wandering individuals of *S. danae* at both locations corresponds with observations of this species during earlier influxes of *S. flaveolum* in Western Europe. Like earlier invasions, this influx occurred after persistent eastern winds coming from northern Germany, Poland and countries further eastwards. It is thus likely that the Dutch invasions of *S. flaveolum* originated in these countries. The number of *S. flaveolum* that reached the Netherlands in 2020 was only a fraction of the size of previous invasions. This strong decline is most probably a reflection of the strong decline of this species in Germany and Poland, and possibly even more countries in Central and Eastern Europe." **19643.** Dossi, F.; Leitner, P.; Graf, W. (2021): Age matters: substrate-specific colonization patterns of benthic invertebrates on installed large wood. *Aquatic Ecology* 54: 741-

760. (in English) ["Large wood (LW) is an indispensable element in riverine ecosystems, especially in lower river parts. The presence of LW significantly shapes local hydraulics, morphology, the nutrient budget; promotes overall river dynamics; and additionally presents a unique habitat for numerous benthic invertebrate species. Therefore, LW is recognized as valuable asset for river restoration measures. Experiences from previous projects show that ecological responses on LW implementation measures vary greatly. That complicates comparisons and estimations on the success of planned measures. Methodological inconsistencies and thus reduced transferability of the results is one major issue. Additionally, wood quality aspects are suspected to be important factors affecting benthic invertebrate colonization patterns. The focus of this study is therefore to consistently assess the ecological significance of installed LW and concrete samples of similar size and shape in terms of benthic invertebrate colonization and to further test, if the condition of wood affects the benthic invertebrate colonization. Our results show that (1) installed LW serves as an abundantly and heterogeneously colonized habitat, (2) the state of decay of LW pieces significantly affects benthic invertebrate colonization in terms of density and diversity and (3) even rare or threatened taxa closely associated to LW were abundantly present on the installed logs, emphasizing the suitability of the chosen approach." (in Spanish, with English summary) ["Species composition and spatial patterns of butterflies and dragonflies are determined and interpreted in six areas of wetlands South of Artemisa and Mayabeque provinces, Western Central Cuba. Four sites were located along the South Dam. There were observed 41 butterflies and 20 dragonflies species. In relation to the total Cuban species in each group, local proportion was 22 % and 23 %, respectively. Butterflies exhibited spatial connectance (47 %) higher than the dragonflies' (35 %). Dissimilarity species composition among sites was high in both groups. The road to Mayabeque Beach was the most connected locality in butterflies and the stretch of the South Dam associated to Majana Beach was the most connected locality in dragonflies. The spatial pattern in butterflies was significant nested and in dragonflies did not differ from random. There was a distinct core in butterflies of habitat generalist species. The most abundant butterfly species were *Anartia jatrophae*, *Ascia monuste* y *Phoebis sennae*. It is worth to mention among dragonflies to *Pantala flavescens* and *Miathyria marcella* as abundant species, *Erythrodiplax berenice* as habitat specialist, and *Telebasis dominicana* as uncommon species." **19649.** Gefen, E.; Matthews, P.G.D. (2021): From chemoreception to regulation: filling the gaps in understanding how insects control gas exchange. *Current Opinion in Insect Science* 48: 1-6. (in English) ["The study of how insects control their gas exchange and ventilatory patterns has long been hampered by a general lack of information on the location and behavior of their central and peripheral respiratory chemoreceptors. However, the molecular insights gleaned from *Drosophila* larvae and their behavioral responses to ambient O<sub>2</sub> could provide a way forward. Firstly, whether td neurons do indeed function as peripheral respiratory chemoreceptors in *Drosophila* should be demonstrated directly through electrophysiological investigation. Identifying the same or similar neurons expressing aSGCs and/or Grs in the central and peripheral other insects, particularly locusts and cockroaches, would then allow the role of these putative chemoreceptors to be further investigated in a well-studied model for insect gas exchange regulation. In particular, determining how these respiratory chemoreceptors integrate with CPGs, and thus how they are involved in regulating episodic and continuous gas exchange patterns, will require investigations using insects known to display these patterns. But given the diverse neuroanatomy of different insect groups, the configuration in *Drosophila* is unlikely to be universal. Thus, the location and number of respiratory chemoreceptors is expected to differ between insect groups, just as vertebrates show a diversity of internally and externally oriented respiratory receptors. For example, the deaf-ferented thoracic ganglia of a locust can sense and respond to hypoxia and hypercapnia, indicating that, in these insects at least, peripheral td neurons are not necessary for respiratory chemoreception. While this could indicate that neurons expressing aSGCs and CO<sub>2</sub>-sensitive Gr receptors are present within the locust's thoracic ganglia, peripheral respiratory chemoreceptors are likely to still play a modulatory role in the intact insect. Moreover, the substantial developmental plasticity of neural elements associated with density-dependent polyphenism, bimodal breathing and holometabolous metamorphosis suggests that extrapolating the mechanistic underpinning of gas exchange in a specific life stage in one insect order to all insects in general may hinder the quest for a general explanation for the adaptive value of variation in gas exchange patterns in insects." (2021): When ecology fails: How reproductive interactions promote species coexistence. *Trends in Ecology & Evolution* 36(7): 610-622. (in English) ["That species must differ ecologically is often viewed as a fundamental condition for their stable coexistence in biological communities. Yet, recent work has shown that ecologically equivalent species can coexist when reproductive interactions and sexual selection regulate population growth. Here, we review theoretical models and highlight empirical studies supporting a role for reproductive interactions in maintaining species diversity. We place reproductive interactions research within a burgeoning conceptual framework of coexistence theory, identify four key mechanisms in intra- and interspecific interactions within and between sexes, speculate on novel mechanisms, and suggest future research. Given the preponderance of sexual reproduction

in nature, our review suggests that this is a neglected path towards explaining species diversity when traditional ecological explanations have failed." **19651.** Guimarães, A.T.B.; Rodrigues, A.S.; Pereira, P.S.; Silva, F.G.; Malafaia, G. (2021): Toxicity of polystyrene nanoplastics in dragonfly larvae: An insight on how these pollutants can affect benthic macroinvertebrates. *Science of The Total Environment* 752, 141936: 8 pp. (in English) ["Highlights: • Polystyrene nanoplastic (PS NPs) represent an ecological risk to benthic macroinvertebrates. • PS NPs cause REDOX imbalance in *Aphylla williamsoni* larvae. • Larvae exposed to PS NPs show decreased acetylcholinesterase activity (neurotoxic effect). • PS NPs can accumulate in dragonfly larvae. Abstract: Although nanoplastics (NPs) are known to be toxic to several groups of animals, the effects of such a toxicity on freshwater benthic macroinvertebrate communities remain unknown. Thus, the aim of the current study is to test the hypothesis that polystyrene nanoplastics (PS NPs) (34µg/L - 48h of exposure) lead to biochemical damage in *Aphylla williamsoni* larvae. Data have evidenced high bioaccumulation factor in the analyzed individuals; this finding indicates that, similar to sediments, water is also part of aquatic systems and favors PS NPs retention in dragonfly larvae. Despite the lack of evidence about the interference of these pollutants in the nutritional status of the analyzed animals, their bioaccumulation was associated with REDOX imbalance featured by concomitant increase in the number of evaluated oxidative stress biomarkers (nitric oxide and lipid peroxidation) and antioxidants (antioxidant activity against the DPPH radical and the superoxide dismutase enzyme). On the other hand, the reduced acetylcholinesterase activity observed in larvae exposed to PS NPs has suggested the neurotoxic effect of these pollutants, with potential impact on their nerve and neuromuscular functions. Therefore, the current study is pioneer in showing that PS NPs can affect the health of the investigated larvae, even at small concentrations, for short exposure-time; this outcome reinforces the ecotoxicological risk of these pollutants for freshwater benthic macroinvertebrates." **19655.** Ishak, M.; Norhisham, A.R.; Thomas, S.M.; Nurhidayu, S.; Ghazali, A.; Azhar, B. (2021): Physicochemical properties as driver of Odonata diversity in oil palm waterways. *Frontiers in Forests and Global Change* 4:613064: 13 pp. (in English) ["Large-scale oil palm agriculture has caused deforestation in the tropics, but also degrades stream water quality and reduces aquatic biodiversity. Though the outcomes of industrial-scale oil palm plantations for biodiversity have been explored extensively, the consequences of small-scale oil palm agriculture for freshwater macroinvertebrate fauna are poorly understood. Here, we explored the impacts of small-scale oil palm agriculture on aerial adult Odonata, which, due to their inherent sensitivity to habitat degradation, represent useful indicators of wider ecosystem health. We surveyed riparian corridors of man-made waterways in natural habitats converted into agricultural lands in both peat swamp and mangrove forest, comprising a total of 60 sampling units across a region of Peninsular Malaysia where such small-scale agricultural practices are widespread. We hypothesized that physicochemical water quality of oil palm waterways together with riparian vegetation influence Odonata species richness and composition. Our results revealed that Odonata species richness increased with dissolved oxygen, water temperature and vegetation cover, but decreased with water level, pH, and total dissolved solids. Species composition was influenced by both dissolved oxygen and pH. The present study provides valuable insights into the effects of small-scale oil palm agriculture for water quality of associated aquatic habitats, and subsequent responses of adult Odonata. Therefore, smallholders should reduce the use of chemical pesticides and fertilizers to improve the conservation value of oil palm waterways for both Odonata and aquatic fauna more generally, in order to be certified as biodiversity-friendly agriculture." **19658.** Khelifa, R. (2021): Observations on the response of dragonflies to the British Columbia 2021 historic heat wave. *Argia* 33(3): 13-14. (in English) ["I studied dragonflies in 20 experimental ponds (15×25 m) at the University of British Columbia (UBC) in 2020 and 2021. My work in 2020 was quite extensive. I made daily visits to the site from late May to September, which helped me to have good knowledge of which species live there and how they commonly behave. I documented 17 species (12 dragonflies and five damselflies), including *Anax junius*, *Rhionaeschna multicolor*, *Aeshna interrupta*, *Libellula forensis*, *Libellula quadrimaculata*, *L. julia*, *Sympetrum illotum*, *S. corruptum*, *S. vicinum*, *Pachydiplax longipennis*, *Erythemis collocata*, *Pantala hymenaea*, *Enallagma carunculatum*, *E. boreale*, *Ischnura cervula*, *I. perparva*, and *Lestes disjunctus*. These species are quite common in the Vancouver region. In the early season of 2021, I saw a similar dragonfly assemblage to that of 2020 with comparable abundances and behavior, a sort of déjà vu situation. Up until the heat wave in late June 2021, I observed a few unexpected changes in the composition and the behavior of the assemblage. First, the diversity increased. I saw two new species that I had not seen at the ponds or within a 5 km radius — *Libellula julia* and *Pantala hymenaea*. While the first species exists in lower British Columbia, the latter has rarely been observed in the entirety of British Columbia. In fact, this is the third historical record of the species in British Columbia. The first record of *P. hymenaea* goes back to 1986 by Robert A. Cannings who wrote that, "with climate warming, the species will be observed more often (Cannings 2002)." Besides that, I noticed an abrupt decline in the flight activity of *Rhionaeschna multicolor* during midday; a species that used to stay active during the entire day. This species is probably the most abundant and one of the most visible dragonflies at the site (Khelifa 2021). So it was easily noticeable when it was not detected. Searching the surrounding bushes and trees, I found individuals perched in shaded areas during the hottest period of the day and they became active again later in the afternoon. Such behavior was not observed in 2020. Interestingly, I observed an increase in the frequency of bathing behavior in different species where individuals quickly drop on the water surface and splash their bodies a few times. This display allows dragonflies to cool down and drink water. Seeing this frequent bathing behavior reminded me of dragonflies in North Africa where temperatures are often extreme throughout the summer (Khelifa 2015). Additionally, there was an increase in the abundance of *Libellula quadrimaculata* and *Erythemis collocata* during the heatwave, probably due to the recent immigration from other sites." (Author)] Address: Khelifa, R., Biodiversity Research Center, University of British Columbia, 2212 Main Mall, Vancouver. B.C. V6T1Z4, Canada. Email: rassimkhelifa@gmail.com

**19659.** Khelifa, R.; Deacon, C.; Mahdjoub, H.; Suhling, F.; Simaika, J.P.; Samways, M.J. (2021): Dragonfly conservation in the increasingly stressed African Mediterranean type

ecosystems. *Front. Environ. Sci.* 9:660163. 16 pp. (in English) ["Freshwater habitats worldwide are experiencing many threats from environmental and anthropogenic sources, affecting biodiversity and ecosystem functioning. In Africa, particularly in Mediterranean climate zones, rapid human population growth is predicted to have great impact on natural habitats besides naturally occurring events such as unpredictable drought frequency and severity. Here, we analyze the potential correlation between odonate assemblage conservation priority (measured with the Dragonfly Biotic Index: DBI) and the magnitude of climate change and human perturbation in African regions with a dominant Mediterranean climate, namely Northern (NAR: Morocco, Algeria and Tunisia) and Southern African region (SAR: South Africa). Using a compilation of studies assessing odonate assemblages in lotic and lentic habitats of both regions (295 sites in NAR and 151 sites in SAR), we estimated DBI, temporal change in average annual temperature (T), annual precipitation (P), and human footprint index (HFI) in each site, then we tested whether sites with different levels of DBI were associated with different magnitudes of climatic and anthropogenic change. We estimated past (between 1980–1999 and 2000–2018) and future changes (between 1980–1999 and 2081–2100) in T and P based on three CMIP6 scenarios representing low (SSP126), moderate (SSP245), and high emission (SSP585), as well as the change in HFI from 1993 to 2009. We found that assemblages with higher DBI (i.e. higher conservation priority) encountered lower increase in T and slightly greater decrease in P than assemblages with lower DBI (i.e. lower conservation priority) in NAR during 1980–2018, but are projected to experience higher increase in T and lower decrease in P in future projections for 2081–2100. In SAR, the increase in T was mostly similar across assemblages but the decline in P was higher for assemblages with higher DBI during 1980–2018 and 2081–2100, suggesting that assemblages of higher conservation priority in SAR are threatened by drought. While HFI showed an overall increase in NAR but not in SAR, its temporal change showed only minor differences across assemblages with different DBI levels. We discuss the importance of management plans to mitigate the effects of climatic and anthropogenic threats, so improving conservation of odonate assemblages in these regions." (Authors)] Address: Khelifa, R., Biodiversity Research Center, University of British Columbia, 2212 Main Mall, Vancouver. B.C. V6T1Z4, Canada. Email: rassimkhelifa@gmail.com

**19660.** Khelifa, R.; Mahdjoub, M.; Samways, M.J. (2021): Combined climatic and anthropogenic stress threaten resilience of important wetland sites in an arid region. *Science of the Total Environment* 806, 150806: 11 pp. (in English) ["Highlights: • Protected wetlands are heavily affected by climate change and anthropogenic perturbation. • These changes are detrimental in regions where the climate is already extreme and variable. • North African Ramsar sites witnessed alarming changes in climate and human influence. • Climate change is projected to be severe in areas with high conservation value. Abstract: Climate change and anthropogenic perturbation threaten resilience of wetlands globally, particularly in regions where environmental conditions are already hot and dry, and human impacts are rapidly intensifying and expanding. Here we assess the vulnerability of Ramsar wetlands of six North African countries (Western Sahara, Morocco, Algeria, Tunisia, Libya, and Egypt) by asking three questions: (1) what are the recent anthropogenic changes that the wetlands experienced? (2) what are the projected future climatic changes? (3) how wetlands with different conservation priorities and globally

threatened species are impacted by anthropogenic pressures? We used climatic data (historical and future projections) from World Clim 2, drought index (SPEI), and human footprint index (HFI for 2000 and 2019) to estimate anthropogenic pressures, as well as waterbird conservation value (WCV: a metric indicating conservation priority of sites) and the breeding distribution of three threatened waterbird species (*Aythya nyroca*, *Marmaronetta angustirostris*, and *Oxyura leucocephala*) to understand how biodiversity is impacted by anthropogenic pressure. We found that temperature, precipitation, drought, and human footprint index (HFI) increased during earlier decades. Interestingly, areas with high HFI are projected to encounter lower warming but more severe drought. We also found that WCV was positively correlated with the magnitude of current HFI, indicating that sites of high conservation value for waterbirds encounter higher levels of anthropogenic pressure. The breeding range of the three threatened species of waterbirds showed a marked increase in HFI and is projected to experience a severe increase in temperature by 2081–2100, especially under the high emission scenario (SSP8.5) where environmental temperature becomes closer to the species critical maximum. Our results highlight the importance of integrating new conservation measures that increase the resilience of North African protected wetlands to reduce extinction risk to biodiversity." (Authors) The paper includes references to Odonata.] Address: Khelifa, R., Biodiversity Research Center, Univ. of British Columbia, 2212 Main Mall, Vancouver, B.C. V6T1Z4, Canada. **19661.** Korichi, R.; Almi, A.; Hammadi, Z.; Zehani, A.; Zinat, H.; Bouzid, A. (2021): Ecologie et diversité de la communauté d'odonates dans quelques habitats du Sahara Nord-Algérien. *Algerian journal of arid environment* 11(2): 22-40. (in French, with English summary) ["Odonata diversity is examined in the northeastern region of the Algerian Sahara by sampling 12 potential sites (one chott, 7 palm groves and 4 lakes) on a 470 km transect. This region of the lower Sahara is endowed with the most important oases and several wetlands, a geomorphology with a south-north slope involving a drainage network and an altitude gradient. A lack of updated studies in this region prompts a specific inventory and ecological analysis of the odonate stand over a 22 months period between 2012 and 2020 to determine the variables and scales that maintain this stand. The odonatafauna recorded corresponds to 21 species divided into 7 Zygoptera and 14 anisoptera (52.4% Libellulidae; 33.3% Coenagrionidae and 14.3% Aeshnidae). The distribution type indicates that accidental category represents 66.7% of the population. The accessory species correspond to 23.8% while 4.7% are ubiquitous and constant respectively. At low elevation sites (-100 m), the Shannon-Weaver diversity index shows its highest value (2.70 bits). The lowest value ( $H' = 1.35$  bits) is noted at altitude above 300 m. The spring migration of *Anax ephippiger* is observed in Ouargla (south-east of Algeria) towards the north. Spring and summer are the richest in species, with 2 and 15 species respectively. The breeding status indicates that for the most part the species are indigenous whose reproduction is probable to certain (*Crocothemis erythraea*) in the drains in palm groves. The IUCN status reveals that 2 species are endangered (*Coenagrion mercuriale* and *Acisoma panorpoides ascalaphoides*). The species *Enallagma deserti* is endemic to North Africa." **19664.** Lee, D.J.L.; Matthews, P.G.D. (2021): How insects transition from water to air: Respiratory insights from dragonflies. *Comparative Biochemistry and Physiology, Part A* 253 (2021) 110859: 6 pp. (in English) ["The transition of animal life from water onto land is associated with well-documented changes in respiratory physiology and blood chemistry, including a dramatic increase in blood pCO<sub>2</sub> and bicarbonate, and changes in ventilatory control. However, these changes have primarily been documented among ancestrally aquatic animal lineages that have evolved to breathe air. In contrast, the physiological consequences of air-breathing animals secondarily adopting aquatic gas exchange are not well explored. Insects are arguably the most successful airbreathing animals, but they have also re-evolved the ability to breathe water multiple times. The juvenile life stages of many insect lineages possess tracheal gills for aquatic gas exchange, but all shift back to breathing air in their adult form. This makes these amphibiotic insects an instructive contrast to most other animal groups, being not only an ancestrally air-breathing group of animals that have re-adapted to life in water, but also a group that undergoes an ontogenetic shift from water back to air across their life cycle. This graphical review summarizes the current knowledge on how blood acid-base balance and ventilatory control change in the dragonfly during its water-to-air transition, and highlights some of the remaining gaps to be filled." **19665.** Lee, S.-D.; Back, S.-J.; Kang, H.-K. (2021): Analysis of the correlation between ecological status and location environment by cultivated land restoration type of Geumgang riverine ecobelt. *J. People Plants Environ* 24(4): 389-401. (in English) ["Background and objective: The purpose of this study is to investigate the ecological status of six areas around Geumgang River that used to be farmlands before they were restored as a riverine ecobelt. This study aims to analyze the correlation between the location environment and ecological status of the sites to identify the environmental factors affecting them. Methods: The sites are classified into four types according to restoration: terraced paddy fields, flat paddy fields, artificial wetland, and landscape forest. The survey items were divided into land use status, plant ecology, and animal ecology. Results: In terms of plant ecology, terraced paddy fields showed favorable naturalness with the rate of native species above 90% and the naturalization index below 10%. In terms of animal ecology, the total number of species found in these areas was biggest in terraced paddy fields, followed by flat paddy fields, artificial wetland, and landscape forest. Regarding species diversity, terraced paddy fields also showed abundant species with an average of 1.05 to 1.09. The results of the correlation analysis showed that the forest area around the sites had the most significant effect on species diversity. The grassland and open water area showed a positive correlation with the total number of animal species and the number of dragonflies, confirming that the marshy grassland had a positive effect. As the cultivated land and urbanized area around the sites increased, it had a negative effect on the distribution of native species and the number of animal species that appeared, and a positive effect on the naturalization index. Conclusion: It is necessary to establish preemption and restoration plans for sites such as grasslands adjacent to the forest and terraced paddy fields in order to promote resilience of the diverse species returning to the purchased lands." **19667.** Mamat, N.; Abu, A.; Yusoff, N. (2021): Classification and morphology of *Rhinocypha* spp. (Odonata): a comprehensive taxonomic study within the females. *Zoological Studies* 60:47. doi:10.6620/ZS.2021.60-47. 21 pp. (in English) ["Studies on Odonata have gained attention worldwide as

well as locally in Malaysia. Although there is a wealth of data available to be utilized for solving taxonomic problems, ecological and behavioural research areas are more favoured than taxonomy and systematics. Thus, there are confusions over how to correctly identify closely related and sympatric species, especially in female odonates. One such example is in the genus *Rhinocypha*. Consequently, the present study focuses on taxonomic work, employing multi-approaches in the form of morphological (morphological diagnostics, Field Emission Scanning Electron Microscope (FESEM) and geometric morphometric analysis), applying the molecular technique. Seventeen morphological characteristics were created to differentiate between the females of *Rhinocypha* spp. A FESEM was used on the female's ovipositor to focus on the anal appendages and sheathing valve (V3). Also, the phylogenetic patterns expressed by COI and 16S rRNA genes, and canonical variate analysis for the wing geometric morphometric revealed three clusters that supported the distinction of the *Rhinocypha* group. In summary, this study effectively developed an integrated approach of classic morphological and trendy molecular, combined with FESEM microscopy techniques, which provided corroborative evidence and resolved taxonomic uncertainties." **19668.** Marinov, M. (2021): A taxonomic and biogeographic discussion on *Rhyothemis regia* (Brauer, 1867) from Samoa and neighbouring islands with introduction of *Rhyothemis regia uveae* subsp. nov. (Odonata: Libellulidae). *Faunistic Studies in Southeast Asian and Pacific Island Odonata* 35: 1-33. (in English) ["Records of *R. regia* from its eastern distribution range (Swains Island excluded) are reviewed and specimens compared morphologically and by wing colouration to congeners of newly obtained material collected in the field or deposited in entomological collections. The origin of the female holotype of *R. r. chalcoptilon* (Brauer, 1867) has been investigated with new hypotheses of the collector, locality and the probable sampling dates proposed. The holotype was probably mislabelled as from Samoa, while the most likely type locality was Niuafo'ou Island, Tonga. New nomenclature changes are suggested which: assigns *R. r. chalcoptilon* to the population from Niuafo'ou Island, reinstates *R. r. armstrongi* Fraser, 1956 for individuals from Samoan archipelago and introduces a new nomen *R. r. uveae* subsp. nov. for Wallis Island. Biogeography of the species within the investigated area is reviewed and the possible origin of current populations hypothesised. Future hypotheses testing is necessary involving a larger sample size from within the entire species range and comparing them morphologically and molecular to other congeneric from the region, such as *R. phyllis* (Sulzer, 1776) and *R. princeps* Kirby, 1894. The latter two species are briefly discussed in relation to the working hypotheses but due to lack of sufficient material final conclusions are not proposed." **19670.** Medina Espinoza, E.F. (2021): Análisis del ensamblaje adulto de Odonata (Insecta) en cuerpos de agua de la estación biológica Los Amigos, Madre de Dios. Universidad Nacional Agraria La Molina. Facultad de Ciencias. Depto Acad. de Biología: IV + VI + 70 pp. (in Spanish, with English summary) ["Freshwater ecosystems are one of the most polluted environments worldwide. Madre de Dios is one of the Peruvian departments that harbors a great diversity of species and one of the main threats it faces is the loss of forests due to gold mining, which has negative effects on its water bodies. Little ecological information is known about Peruvian Odonata, which are freshwater insects. The present study analysed the adult odonate assemblage diversity in three aquatic environments within the Los Amigos biological station (a blackwater pond, an oxbow lake and a stream) in May and October of 2018. A total of 46 species were recorded, belonging to 25 genera and six families. The most represented families were Libellulidae and Coenagrionidae. The assessment sites showed similar diversity values using Hill numbers. However, differences were found in the species composition in the three water bodies assessed, including between lakes. This was because, although they shared a considerable number of species, the relative abundances of each species varied depending on the assessment site. Therefore, dragonfly assemblages in the Los Amigos biological station change according to the body of water where they are found. This highlights the importance of knowing the taxa that are part of the assemblages of the different types of freshwater environments in order to better understand the changes that might occur in these types of ecosystems." **19672.** Mola, L.M.; Fourastié, M.F., Agopian, S.S. (2021): High karyotypic variation in *Orthemis* Hagen, 1861 species, with insights about the neo-XY in *Orthemis ambinigra* Calvert, 1909 (Libellulidae, Odonata). *CompCytogen* 15(4): 355-374. (in English) ["The American dragonfly genus *Orthemis* Hagen, 1861 is mainly found in the Neotropical region. Seven of 28 taxonomically described species have been reported from Argentina. Chromosome studies performed on this genus showed a wide variation in chromosome number and a high frequency of the neoXY chromosomal sex-determination system, although the sexual pair was not observed in all cases. This work analyzes the spermatogenesis of *Orthemis discolor* (Burmeister, 1839), *O. nodiplaga* Karsch, 1891 and *O. ambinigra* Calvert, 1909 in individuals

from the provinces of Misiones and Buenos Aires, Argentina. *Orthemis discolor* has  $2n=23$ ,  $n=11+X$  and one larger bivalent. *Orthemis nodiplaga* exhibits the largest chromosome number of the order,  $2n=41$ ,  $n=20+X$  and small chromosomes. *Orthemis ambinigra* shows a reduced complement,  $2n=12$ ,  $n=5+neo-XY$ , large-sized chromosomes, and a homomorphic sex bivalent. Fusions and fragmentations are the main evolutionary mechanisms in Odonata, as well as in other organisms with holokinetic chromosomes. *Orthemis nodiplaga* would have originated by nine autosomal fragmentations from the ancestral karyotype of the genus ( $2n=22A+X$  in males). We argue that the diploid number 23 in *Orthemis* has a secondary origin from the ancestral karyotype of family Libellulidae ( $2n=25$ ). The complement of *O. ambinigra* would have arisen from five autosomal fusions and the insertion of the X chromosome into a fused autosome. C-banding and DAPI/CMA3 staining allowed the identification of the sexual bivalent, which revealed the presence of constitutive heterochromatin. We propose that the chromosome with intermediate C-staining intensity and three medial heterochromatic regions corresponds to the neo-Y and that the neo-system of this species has an ancient evolutionary origin. Moreover, we discuss on the mechanisms involved in the karyotypic evolution of this genus, the characteristics of the neo sex-determining systems and the patterns of heterochromatin distribution, quantity and base pair richness." **19673.** Monnerat, C.; Wildermuth, H.; Gonseth, Y. (2021): Rote Liste der Libellen. Gefährdete Arten der Schweiz. Umwelt-Vollzug Nr. 2120: 70 pp. (in German, with French and Italian summaries) ["The Red List of dragonflies in Switzerland 2021 is based on the criteria and endangerment categories of the IUCN (2001, 2017). Of the 75 species assessed, 27 (36 %) are threatened: 3 (4 %) are extinct in Switzerland (RE), 4 (5 %) are Critically Endangered (CR), 9 (12 %) are Endangered (EN) and 11 (15 %) are Vulnerable (VU). 6 (8 %) species are potentially threatened (NT). Nearly half of the Red List species (13) inhabit fens and raised bogs, habitats that are threatened at all altitudes. The proportion of endangered species is lower in other habitat types: springs, small watercourses and ditches (4), rivers and lakeshores with wave action (6), small stillwaters (6). These three habitat types also each harboured a species that was already extinct in Switzerland. The present Red List replaces that of Gonseth & Monnerat (2002). The number of species in the endangerment categories (RE, CR, EN, VU) is very similar: the 2002 list contained 26, the revised version includes 27 species. In the meantime, a third species has become extinct in Switzerland. The situation of several species formerly threatened with extinction or highly endangered (CR, EN) has improved thanks to revitalisation measures of upland moors, rivers and streams. In addition, specific species promotion measures have contributed to the improvement of the situation. Thanks to these measures to promote dragonflies, the calculated Red List indices show a positive trend. For the non-endangered species, the balance is also positive, as their populations are mostly stable or have sometimes even increased. The species that depend mainly on fens and other habitats with naturally fluctuating water levels, or the boreoalpine species that depend on raised bogs and acidic fens, are suffering from the ongoing deteri-

oration of habitat quality. Moreover, prediction models suggest that their endangerment will continuously increase with climate change in the coming decades" (Authors/DeepL)] Address: Monnerat, C., Info fauna, Bellevaux 51, 2000 Neuchâtel, Switzerland. E-mail: christian.monnerat@unine.ch

**19674.** Morrill, A.; Kaunisto, K.M.; Mlynarek, J.J.; Sippola, E.; Vesterinen, E.J.; Forbes, M.R. (2021): Metabarcoding prey DNA from fecal samples of adult dragonflies shows no predicted sex differences, and substantial inter-individual variation, in diets. *PeerJ* 9:e12634 <https://doi.org/10.7717/peerj.126>: 20 pp. (in English) ["Sexes often differ in foraging and diet, which is associated with sex differences in size, trophic morphology, use of habitats, and/or life history tactics. Herein, strikingly similar diets were found for adult sexes of *Leucorrhinia intacta*, based on comparing 141 dietary taxa identified from the metabarcoding of mitochondrial DNA archived in feces. Arthropods in > 5% of samples included five species of dipterans, two hemipterans, two spider species and one parasitic mite. The mite was not traditional prey as its presence was likely due to DNA contamination of samples arising through parasitism or possibly via accidental consumption during grooming, and therefore the mite was excluded from diet characterizations. Common prey species were found with statistically indistinguishable frequencies in male and female diets, with one exception of an aphid more often found in male diets, although this pattern was not robust to corrections for multiple statistical tests. While rare prey species were often found in diets of only one sex, instances of this were more frequent in the more oft-sampled females, suggesting sampling artefact. Sexes did not differ in the mean prey species richness in their diets. Overall, sexes showed statistically indistinguishable diets both on a prey species-by-species basis and in terms of multivariate characterizations of diet composition, derived from presence-absence data of prey species analyzed via PERMANOVA and accumulation curves. Males and females may have similar diets by being both opportunistic and generalist predators of arthropods, using the same foraging habitats and having similar sizes and flight abilities. Notably, similarities in diet between sexes occur alongside large interindividual differences in diet, within sexes. Researchers intending on explaining adaptive sex differences in diet should consider characteristics of species whose sexes show similar diets." The focus was on mowing, reed removal and the removal of woody plants in the vicinity of the watercourse. In order to ensure long-term success against the invasive neophytes, it is absolutely necessary to continue the measures." (Author/DeepL)] Address: Jörg Müller. Email: JoergMueller78@web.de

**19677.** Mulyaningsih, B.; Ummiyati, S.R.; Hadisusanto, S.; Edyansyah, E. (2021): Fauna associated with Malayan filariasis transmission in Banyuasin, South Sumatra, Indonesia. *Veterinary World* 14(7): 1954-1959. (in English) ["Background and Aim: *Brugia malayi* is known to be zoonotically important because it can be transmitted from animals (mammals and primates) to humans or from humans to humans through mosquito vectors. This study was conducted to explore the fauna associated with Malayan filariasis transmission in Sedang village, Suak Tapeh District, Banyuasin Regency, South Sumatra Province, Indonesia. Materials and Methods: A cross-sectional research design with an observational and analytical approach was applied in this study, and it was conducted in May 2018. Mosquitoes were collected twice using human bait both inside and outside the house from 6:00 p.m. to 6:00 a.m. The presence of competitors, predators, and reservoir hosts in the areas of five breeding habitats of *Mansonia* spp. was observed. The presence of microfilaria was confirmed under a microscope in night blood samples of inhabitants and cats. The presence of infective larvae (L3) of *B. malayi* was identified microscopically and based on the polymerase chain reaction method in female *Mansonia* mosquitoes. Results: A total of 12 mosquito species were found, among which *Mansonia univittata* was the dominant mosquito, and the predominant competitor was *Mansonia annulifera*. Dragonflies, as predators were found in two breeding habitats and fish were found in one breeding habitat. The L3 of *B. malayi* were not identified in the mosquitoes, and the microfilariae of *B. malayi* were not found in the blood samples of inhabitants and cats. Conclusion: Although *Mansonia* mosquito population was abundant in Banyuasin Regency, the mosquito was not confirmed as an intermediate host of *B. malayi*, and the cat was not confirmed as a reservoir of *B. malayi* in the location." **19678.** Nakanishi, K.; Yokomizo, H.; Hayashi, T.I. (2021): Population model analyses of the combined effects of insecticide use and habitat degradation on the past sharp declines of the dragonfly *Sympetrum frequens*. *Science of The Total Environment* 787, 147526: 10 pp. (in English) ["Highlights: • Populations of *Sympetrum frequens* in rice fields declined sharply in the late 1990s. • We analyzed causes of the declines by numerical simulations using a population model. • The model reproduced well the past sharp population declines. • Habitat degradation and highly toxic insecti-

cides greatly affected population decline. • Our results suggested the sharp declines were caused by the combined effects of both. Abstract: In recent decades, many dragonfly species have become threatened with extinction. For example, populations of *Sympetrum frequens*, one of the most common dragonflies in rice paddy fields in Japan, decreased sharply around the late 1990s in many regions. Although previous studies suggested that the use of systemic insecticides (particularly fipronil) was likely a major cause of the decline, agronomic factors other than insecticide use and the combined effects of both have been not examined. Here, we developed an *S. frequens* population model using survival rate parameters associated with the farmland consolidation rate, midsummer drainage, area of crop rotation and abandoned rice paddies, insecticide use, and summer temperature and analyzed the effects of each factor on population dynamics by numerical simulations. Our population models substantially reproduced the past sharp population declines of the dragonfly in three regions. Numerical simulations using hypothetical parameters did not always suggest that the use of systemic insecticides is a sufficient cause of the sharp population declines, as the declines did not occur if the farmland consolidation rate remained at lower levels (before the 1980s). On the other hand, our findings suggest that the use of insecticides with high toxicity is a necessary cause of the sharp population declines, as the declines did not occur when simulated toxicity levels were lower than those actually used. Overall, our numerical simulations suggest that the sharp population declines of *S. frequens* around the late 1990s were caused by the combined effects of insecticide use and farmland consolidation, in which rice paddies are converted to well-drained paddy fields. Conservation planning for dragonflies needs to account for the combined effects of habitat degradation and use of insecticides." **19679.** Noor, S.; Rafiq, N.; Akbar, P.; Zehri, S.; Wali, S.; Shahwani, F. (2021): A preliminary study on aquatic insect diversity and abundance in relation to fluctuating physiochemical parameters of an artificial pond. *Serangga* 26(4): 175-188. (in English) ["This preliminary study was conducted from April to October 2019, and hold the first account to outline the diversity of aquatic insects with influence to the fluctuating physiochemical parameters in the pond of Sardar Bahadur Khan Women's University Quetta, Pakistan. The collection of 722 individuals in total presented four orders (Hemiptera, Ephemeroptera, Diptera and Odonata) and seven families. These individuals were labeled to generic level as *Gerris* sp., *Notonecta* sp., *Anopheles* sp., *Thaumatococcus* sp., *Sympetrum* sp., *Orthetrum* sp. and *Heptagenia* sp. Shannon-Weininger diversity and Simpson's diversity index revealed greater values for backswimmers and mayflies (*Notonecta* and *Heptagenia* sp.). Additionally, Margalef's richness index was also recorded highest (1.163) for backswimmers. Amongst physiochemical parameters, water temperature was ordinated in Gaussian's species packing model. This ordination illustrated wider curve for *Notonecta* sp. and narrower curve for *Anopheles* sp., suggesting the maximum and minimum tolerance (temperature) range for these species in this specific pond community. Water pH of the pond also altered slightly and ranged from 9.13-10.3 during April to August. As of the total dissolve solids (TDS), this study observed a raised from 253.16 mg/L to 432.11 mg/L till the end. Since aquatic insects play vigorous role in the stability of aquatic ecosystems, more relevant studies

are required to be conducted to evaluate the broader range of these insects." (Authors)] Address: Noor, Sabina, Dept of Zoology, Sardar Bahadur Khan Women University, 87300 Quetta, Pakistan. Email: sabina.noor15@yahoo.com

**19681.** Opie-odonates (2021): Liste de référence des Odonates de France métropolitaine. *Martinia* 35(5): 23–26, annex- (in French) [Odonatology, like all disciplines in the natural sciences, is in constant evolution. The discovery of new taxa or the observation of taxa in geographical areas where they were not previously known, progress in genetics and phylogeny require the regular updating of species lists. In this context, Opie-odonates has decided to update the previous reference list of Odonata of metropolitan France of the French Odonatological Society (Boudot & Dommanget, 2015). For the editors, it is neither a question of doing something new at all costs nor of remaining stuck in the past, but of making well-founded choices that follow the progress of knowledge such as changes in the geographical distribution of taxa or their phylogenetic position. Furthermore, the growing recognition of Odonata in environmental policies - as in the previous national action plan for Odonata (Dupont, 2010) and the new national action plan for dragonflies (Houard et al., 2020), as well as their better understanding by the general public through awareness-raising activities, for example - requires the establishment of common reference systems, which also requires the common use of a well-defined lexical field and vocabulary. We therefore felt it necessary to review the French names associated with scientific binoms. Taxa The updating or not of the name of certain taxa in the list is based on the relevance of the taxon. Some subspecies have been deleted (e.g. *Calopteryx splendens* and *Cordulegaster boltonii*) where there is a broad consensus in recent literature that they are invalid. Others, such as *Orthetrum coerulescens* *anceps*, have been retained because further studies are needed (Mauersberger, 1994). Species that have not been observed or rarely observed for a long period of time have nevertheless been retained, as they belong, according to the current state of knowledge, to the metropolitan Holocene fauna. For example, *Sympecma paedisca*, which has probably disappeared since 1962 from its only known site in Isère, is considered as "unrecorded" in mainland France since 1970, but remains on the list. Indeed, the rediscovery of *Nehalennia speciosa* in France in 2007 (Dehondt et al., 2009) or the return of certain species to geographical areas from which they were presumed to have disappeared, such as *Stylurus flavipes* and *Ophiogomphus cecilia* in the Rhône river basin for example (Grand et al, 2011; Lambert et al., 2012), encourage us to be cautious about the notion of extinction and to keep the record of presumed extinct species, in the light of our current knowledge. Of course, the arrival of new spe-

cies, such as *Trithemis kirbyi* or *Selysiothemis nigra* (San- nier, 2015; Polette et al., 2017; Lohr, 2021), also justified the updating of this list. French names The Opie-odonates, in the continuity of the French Society of Odonatology, underlines that the scientific names (governed by the International Code of Zoological Nomenclature) must be used as a priority by all odonatologists, be they professionals or amateurs, specialists, naturalists in all texts intended to be disseminated to interested persons or to be published. The use of French names is indicated in the context of awareness-raising and popularisation operations (essentially for the general public). There are no vernacular names (from the Latin *vernaculus*, "of the country, indigenous, national", names derived from popular tradition) in the proper sense in France for the various species of Odonata. There is also no list of standardised names as for ornithology (Lepage, 2021). All French names are taken from the literature and therefore vary from one author to another. Savard (1987) presents the differences between the names given to taxa outside the binominal scientific nomenclature, i.e. between vernacular names and vulgar names. The French names proposed here are, as far as possible and with minor modifications, those published by Robert (1958). This author was the first to use French names wisely in a 20th century publication, partly based on the writings of Selys-Longchamps (1850). We have chosen not to introduce new names, as these are likely to create new difficulties, except when the taxon had no French name, such as *Trithemis kirbyi*, or when we wished to simplify it, as with *Lestes macrostigma*, by retaining the epithet group "à grand stigmas", which is shorter and more in keeping with the binominal name. We also chose not to follow the translation of Philippe Jourde (Dijkstra & Lewington, 2007; Dijkstra, Schröter & Lewington, 2021) for the sake of consistency with previous publications of the French Odonatological Society. Furthermore, only taxa from mainland France are included in this list. The question of assigning a French name that could be superimposed on the binominal name arose during the drafting of this updated list. The binominal name is the reference for all writings of a scientific nature (publications, reports, studies, proceedings, etc.). As mentioned above, scientific names should be used as a priority. Consequently, the use of French names remains marginal and should be favoured in communication to the general public. In this context, the excessive complexity of French names, such as the systematic differentiation of genera, or the traceability of names according to the evolution of scientific names, does not seem very relevant for a name intended for neophytes. A similar logic can be found in other naturalist disciplines. For example, in botany, French names have retained their vernacular and folkloric character. For example, in botany, French names have retained their vernacular and folkloric character, as can be seen from the 24 different French names of plants of various species and families used in botany, including the word rose (Rose, 2021). Or, in ornithology and the French names of birds, it should be remembered that the swallows of mainland France are grouped together under the French name *Hirondelle* in different genera. On the other hand, between the different editions of the Guide Ornitho (Mullamey et al., 1999 and reissues) or on the Avibase website (Lepage, 2021), the French genus name of the different tits has not followed the changes in the genus of the scientific names. For this reason, we have not retained the differentiation or grouping of genera in French. Thus, the *Calopteryx* remain *Calopteryx* and most of the *Coenagrionidae* and *Platynemididae* remain *Agrionidae*. The only exception to this method is Vander Linden's *Agrion*, *Erythromma lindenii*, which we have renamed *Naiad* in

order to be consistent with the other two species of our metropolitan fauna of the genus *Erythromma*. This exception is explained by the evocation of an imaginary associated with the term *Naiad* (i.e. a female divinity of rivers and springs) which is interesting in the odonatological context and which may also resonate with the general public. On the other hand, the genus name *Dragonfly* has been used and reused for taxa that are not of the genus *Libellula*. It seemed to us that *Scarlet Dragonfly* and *Globetrotting Dragonfly* were more evocative names and easier to remember than *Crocothemis* or *Pantale* for the general public. The same reasoning was applied to the *Aeschnidae*, of which only the French genera *Aeschna* and *Anax* were retained. The successive revisions of the place of *Macromia* and *Oxygastra* (at one time in the *Libellulidae*, then in the *Corduliidae*, now in a separate family or *incertae sedis*) did not seem to us to require a different French genus from the widely used *Cordulie*. Perenniality of French names: As we mentioned in the introduction, the discovery of new taxa or the observation of taxa in geographical areas where they were not known, as well as progress in genetics and phylogeny, require the regular updating of species lists with their binominal names. What consequences can be drawn from this for French names? As mentioned above, a modification could be envisaged when a change occurs in the nomenclature, but it can be assumed that this continuous instability would only confuse the public for which these names are intended. The idea, let us remember, is not to propose a French name that replaces the scientific name, but a name that the general public (and thus outside naturalists) can appropriate, and ensure a certain durability. For example, on an information panel for river restoration work, the *Agrion de Mercure* will be easily adopted by the general public, without having to consider renaming it the day that, after a hypothetical scientific study, its binominal name changes. The French name would thus retain a status equivalent to the *nomen protectum* of taxonomy. Moreover, since French names are only to be used for popularisation, they are not intended to be given to species not present in territories where French is used. The example of Askew (2004), who, in his book on European fauna, only mentions English names for species present in the United Kingdom, should be noted. This seems to us to be a reasonable limit to the attribution of French names. One can only regret the Anglo-American tendency to attribute English names to all species of the globe<sup>1</sup> and to generalise their use in exchanges where the binomial name is not always mentioned. It even happens that the same English name covers several different species<sup>2</sup>. In essence, these elements become inaccessible to the reader who is not initiated into the odonatafauna of the geographical area in question." **19683.** Peng, X.; Gao, Y.; Song, X.; Du, Y. (2021): Characterization and phylogenetic analysis of the complete mitochondrial genome of *Neurothemis fulvia* (Odonata: Anisoptera: Libellulidae). *Mitochondrial DNA Part B* 2021 6(2): 620-621. (in English) ["*Neurothemis fulvia* is a dragonfly of wet forests and usually perches on fallen logs and shrubs. In this study, we sequenced and analyzed the complete mitochondrial genome (mitogenome) of *N. fulvia*. This mitogenome was 15,459bp long and encoded 13 protein-coding genes (PCGs), 22 transfer RNA genes (tRNAs), and 2 ribosomal RNA unit genes (rRNAs). The nucleotide composition of the mitogenome was biased toward A and T, with 70.5% of A + T content (A 38.8%, T 31.7%, C 16.6%, and G 12.9%). Gene order was conserved and identical to most other previously sequenced Libellulidae dragonflies. Most PCGs of *N. fulvia* have the conventional start codons ATN (six ATG, three ATT, and two ATC), with the exception of *cox1* and *nad1* (TTG). Except for four PCGs (*cox1*, *cox2*, *cox3*, and *nad5*) end with the incomplete stop codon T—, all other PCGs terminated with the stop codon TAA or TAG. Phylogenetic analysis showed that *N. fulvia* got together with *Tramea virginia* with high support value. Libellulidae had a close relationship with Corduliidae, the relationships ((*Hydrobasileus* + *Brachythemis*) + (*Orthetrum* + (*Acisoma* + (*Neurothemis* + *Tramea*)))) were supported in Libellulidae." **19684.** Pestana, G.C.; Mateus-Barros, E.; Brasil, L.S.; Guillermo-Ferreira, R. (2021): A scientometric analysis on pre- and post-copulatory traits in Odonata. *International Journal of Odonatology* 24: 215-226. (in English) ["In the last decades, studies on sexual selection in odonates have shown a relationship between mating success and costly sexual ornaments, mainly male characters. Here, we conducted a scientometric analysis to assess the state of art of studies on sexual selection in odonates, especially on the role of male ornamentation (pre-copulatory traits) and sperm competition (post-copulatory traits). We found 51 papers focused on sexual ornamentation and 34 on sperm competition. Only one study simultaneously addressed both pre- and post-copulatory traits, nevertheless without an integrative approach. Results show that calopterygids are extensively studied regarding pre-copulatory traits (i.e., male wing pigmentation), while libellulids are mostly studied in post-copulatory traits (e.g., sperm competition) focused research. These preferences seem to be related to characteristics like presence of ornamentation and territoriality, large body size, variation and complexity of sperm removal structures, respectively. For the post-copulatory traits, sperm removal is frequently addressed, but few other strategies, like the investment in sperm quality and quantity, are investigated. Finally, we demonstrate that it is necessary to conduct studies

focused on addressing the relationship between pre- and post- mating sexual traits." (Authors)] Address: Pestana, Gabrielle Cristina, Dept Hydrobiol., Federal Univ. of São Carlos, São Carlos, Brazil. E-mail: jpestana@ua.pt

**19686.** Petzold, F. (2021): Abschluss der Basiserfassungen für ein landesweites Libellenmonitoring in Thüringen. *Landschaftspflege und Naturschutz in Thüringen* 57(1): 11-18. (in German, with English summary) ["Between 2010 and 2018, the basic surveys for the establishment of a Thuringia-wide network of dragonfly monitoring waters were carried out. 700 water bodies were surveyed and 58 dragonfly species were detected. In total, more than 21,000 additional data sets were made available for the state's species recording programme. For the first time, up-to-date data collected according to a uniform methodology are now available for the entire area of Thuringia. The diversity of the dragonfly fauna in the individual districts is primarily determined by the landscape features, the availability of water bodies and the intensity of use. The most species-rich dragonfly fauna was found in the Altenburger Land district. Excavation waters, unused ponds and small reservoirs were the water body types with the highest species diversity. The results of the baseline surveys are an important basis for stock and endangerment assessments and thus form a sound basis for planning measures to conserve or improve biodiversity in the sense of the Thuringian Strategy for Biodiversity Conservation. In addition, they Supplement the data collected in the FFH monitoring sample plots and thus enable re-liable Statements to be made on the development of populations and the distribution of FFH appendage species over the entire area. In addition, they Supplement the data collected in the FFH monitoring sample plots and thus enable reliable Statements to be made on the development of populations and the distribution of species listed in the Appendix of the EU Habitats Directive over the entire area. By comparing the data with those of subsequent monitoring rounds, well-founded Statements can be made on population developments, which is of particular interest against the background of changes in climate and land use." **19687.** Pimenta, P.M.; Vilela, D.S.; Pelli, A. (2021): Urbanization promotes the local extinction of odonatas in veredas

from Minas Gerais/Brazil. *International Journal of Hydrology* 5(6): 296-300. (in English) ["The order Odonata is one of the most fascinating among insects, with an estimated 6,000 described species. Little is known about the Odonata fauna in many regions of Brazil; including Vereda's areas. This unique plant formations occur only in Brazil. Despite being considered a preservation area, for over 70 years; there are a continuous degradation of this unique formation. The aim of this study was to survey the species of Odonata that occur in four areas of Veredas, within the urban perimeter of Uberaba/Minas Gerais. Two points were selected in the central region and two peripheral points. Four collections were carried out on sunny days, with two people intercepting the flight with entomological nets in May, September, December 2018 and March 2019. The total number of adults captured was 163. In the central points of the city we find generalist species, while in the peripheral points we find individuals endemic to Veredas and indicators of preserved environments. Data indicate that the Veredas have been severely abandoned by the Government and damaged by urbanization, and that the Odonata are an appropriate group to monitor the integrity of this type of environment, which gives rise to several important rivers in the region." (Authors)] Address: Pelli, A., Instituto de Ciências Biológicas e Naturais. Universidade Federal do Triângulo Mineiro. Av. Frei Paulino, 30. Uberaba/MG CEP 38025-180, Brazil.

**19688.** Powell, E.C.; Painting, C.J.; Hickey, A.J.; Machado, G.; Holwell, G.I. (2021): Diet, predators, and defensive behaviors of New Zealand harvestmen (Opiliones: Neopilionidae). *The Journal of Arachnology* 49(1): 122-140. (in English) ["The Neopilionidae is a highly diversified harvestman family in New Zealand, comprising eight genera and 28 species. Although individuals of many species are abundant in the field, basic information on their natural history is absent. Here we describe the diet, predators, and defensive behaviors of 13 species across three genera, *Forsteropsalis* Taylor, 2013, *Mangatangi* Taylor, 2013, and *Pantopsalis* Simon, 1879. Using three years of field observations, we first identify food items for this family, finding that New Zealand neopilionids are opportunistic, generalist foragers with a diet composed of a wide variety of prey and scavenged soft-bodied invertebrates, including worms, amphipods, species from nine orders of insects [including Odonata, Anisoptera], and two orders of arachnids (including conspecifics). We then describe the first known invertebrate predators of New Zealand harvestmen, including seven spider species, and conduct a review of the literature to collate a list of 32 species of native and non-native vertebrates (frogs, lizards, fish, birds, and mammals) that prey on harvestmen, including neopilionids. Finally, we describe the defensive behaviors of neopilionids, providing the first reports of autotomy and thanatosis in the family. In general, the diet of New Zealand neopilionids is similar to other harvestman species, and the list of predators includes mostly insectivorous taxa known to feed on harvestmen elsewhere. The defensive repertoire of neopilionids includes behaviors recorded for other species of Eupnoi, such as leg autotomy, but also unique behaviors that are only known for species of Dyspnoi and Laniatores, such as thanatosis." **19689.** Pruvot, Y.Z.M.; Rene de Roland, L.A. (2021): Food habits of the Malagasy Pond Heron (*Ardeola idae*) during the breeding season in northern Madagascar. *Journal of Heron Biology and Conservation* 6:1 [online]: 12 pp. (in

English) ["We studied the diet of the endangered Malagasy Pond Heron (*Ardeola idae*) at a monospecific colony in Sofia Lake, in northern Madagascar during one breeding season from November 2018 to March 2019. Two complementary methods were used: 1) the collection of pellets followed by a laboratory analyses and 2) the direct observation of prey taken by the species. Based on 4,062 identified prey items from the 193 pellets, the diet of the Malagasy Pond Heron was composed of invertebrates including insects (81.34%), spiders (4.68%), crustaceans (1.90%), gastropods (0.86%), and vertebrates such as fishes (5.59%), frogs (3.40%) and lizards (2.24%). A large variety of insect families was identified, of which Tenebrionidae (13.47%), Hydrophilidae (11.05%), Acrididae (9.35%), Libellulidae (8.39%) and Dytiscidae (6.92%) were the most dominant. Three species of fish (*Cyprinus carpio*, *Channa* sp. and *Tilapia* sp.) and two species of frogs (*Boophis* sp. and *Rana* sp.) were also identified. The main prey items varied significantly through the five months of the breeding season. Coleopterans (Tenebrionidae and Hydrophilidae) were the most abundant group in all months and their consumption was greatest in March. Orthopterans (Acrididae) and Odonatans (Libellulidae) were consumed mainly in November and February, respectively. The consumption of fish was greatest in February and March. Frogs were captured most frequently in February. These results confirm that the Malagasy Pond Heron is a generalist and opportunistic in its feeding habitats. Conservation measures for this endangered heron should not only take place at nesting sites, but also in foraging areas surrounding the nesting colonies." **19690.** Rechulicz, R.; Plaska, W. (2021): The diet of non-indigenous *Ameiurus nebulosus* of varying size and its potential impact on native fish in shallow lakes. *Global Ecology and Conservation* 31, November 2021, e01881: 10 pp. (in English) ["The brown bullhead (*Ameiurus nebulosus*) is a non-native, invasive fish species in Europe, and since it is sometimes present in high numbers in aquatic ecosystems, it may affect their functioning. The aim of the study was to determine the composition of the diet of *A. nebulosus* depending on its body size; the body size at which the brown bullhead becomes a predator and what share of its diet consists of fish. We determined the diet composition, frequency, and biomass of individual food types for 260 *A. nebulosus* individuals belonging to three classes in two shallow lakes. Analysis of the diet of *A. nebulosus* showed that it was highly varied, which manifested as a wide range of food types (15 types) as well as changes in its composition depending on the size of the fish. The nature of the habitat may influence the composition of the diet of *A. nebulosus*, which was most evident in the smallest individuals (total length <135 mm). Our observations showed that in Central European conditions, *A. nebulosus* with a length of more than 135 mm is able to feed on fish, and the share of fish in the food biomass increased with its total length, reaching even an 80% share of the biomass. In newly invaded areas, *A. nebulosus* can affect various groups of organisms by feeding on them. It can also compete with native fish species for food, but its main effect may be predation." (Authors) The study includes "Odonata".] Address: Rechulicz, R., Dept of Hydrobiology and Protection of Ecosystems, University of Life Sciences in Lublin, Dobrzańskiego 37 str., 20-262 Lublin, Poland. **19691.** Ribeiro, C.; Juen, L.; Rodrigues, M.E. (2021): The

Zygoptera/Anisoptera ratio as a tool to assess anthropogenic changes in Atlantic Forest streams. *Biodiversity and Conservation* 30: 1315-1329. (in English) ["The changes in land use caused by human activities have directly impacted aquatic ecosystems, making these environments some of the most threatened places on the planet. It is increasingly necessary and urgent to develop tools to identify and assess the effects of human impacts on ecosystems and biodiversity. This study aimed to evaluate whether the Zygoptera/Anisoptera ratio can be an effective tool to measure ecological changes in Atlantic Forest streams. Adult Odonata were collected in 42 streams. An environmental integrity index was used as a measure of environmental change. The Zygoptera/Anisoptera ratio was efficient in classifying the state of preservation of streams; therefore, habitats with a proportion equal to or greater than 67 and 52% of richness and abundance of the suborder Anisoptera can be considered altered. Meanwhile, streams representing a proportion of 54 and 67% of richness and abundance of the suborder Zygoptera can be considered little altered or preserved. The proportions of responses were close to the proposals for streams in the Amazon rainforest region. The ease of identifying the specimens in the different suborders of Odonata is practical, enabling the implementation of participatory monitoring with quick responses for monitoring in the aquatic ecosystems assessed in the region. It is important to test the Zygoptera/Anisoptera ratio for a broader validation in biomes where this evaluation has not yet been carried out. In the future, this will enable the implementation of networks for monitoring the integrity of aquatic environments quickly, effectively and at a low cost." (Authors)] Address: Rodrigues, M.E., Laboratório de Organismos Aquáticos, Departamento de Ciências Biológicas, Universidade Estadual de Santa Cruz (UESC), Ilhéus, BA, Brazil

**19692.** Rivas-Torres, A.; Rashni, B.; Waqa-Sakiti, H.; Tuiwawa, M.; Lorenzo-Carballa, M.O.; Beatty, C.D.; Cordero-Rivera, A. (2021): *Nesobasis rito* sp. nov. (Zygoptera: Coenagrionidae), a new species of forest damselfly from Vanua Levu, Fiji. *Zootaxa* 5082(2): 101-117. (in English) ["*Nesobasis rito* sp. nov. (Holotype male, Fiji, Vanua Levu, Drawa, 31 v 2018, A. Rivas-Torres leg.) from the comosa group is here described, illustrated, diagnosed, and compared with morphologically close species of the genus. *Nesobasis rito* can be distinguished from its related congeners by the shape of the caudal appendages and the ligula. The most similar species are *N. comosa* and *N. heteroneura*, which, like *N. rito*, have the caudal appendages covered by dense setae (especially the first species), but the shape differs clearly in lateral view, with *N. rito* having longer and more slender appendages, and a basal tooth clearly seen in dorsal view, absent in other members of the comosa group. The specific status of the collected specimens is also supported by the results of genetic analyses, where *N. rito* appears as a well-supported monophyletic clade. *Nesobasis rito* also has a distinct distribution from its most similar congeners: it is found on Vanua Levu, while *N. comosa* is found on Viti Levu and the closely related *N. heteroneura* is found on Viti Levu and Ovalau. All species of this group are found in streams with native forest riparian vegetation on their respective islands." **19693.** Sanpapao, P.; Ponza, S.; Tawong, W.; Phongchaisit, P.; Pongpadung, P. (2021): Diversity of macrobenthic fauna and its relationship with environmental factors in the

Yom River. *Wichcha Journal* 40(2): 118-132. (in Thai, with English summary) ["Studies on the diversity of macrobenthic fauna and environmental factors were carried out to assess the quality of water resources and investigate the correlation of environmental factors with macrobenthic fauna in the Yom River. The field surveys were conducted at 16 sampling stations. Samples were collected in the winter season (January 2018), summer season (April 2018), and the rainy season (July 2018). The results showed that 47 families from 3 phyla of macrobenthic fauna were identified. The dominant benthic fauna group were Unionidae (10.67%) Viviparidae (10.46%) Chironomidae (8.22%) and Tubificidae (7.44%). The Shannon-Wiener diversity index Magalef index and Evenness index were  $2.07 \pm 0.07$ ,  $0.67 \pm 0.09$ , and  $1.87 \pm 0.09$ , respectively. Canonical correspondence analysis revealed that Diptera, Haplotoxida, and Lumbriculida showed a positive correlation with some parameters such as pH, water temperature, turbidity, BOD, chlorophyll a, ammonia, nitrite, nitrate, and total organic matter, while Hemiptera, Odonata, Decapoda, Trichoptera, and Ephemeroptera showed the positive correlation with total dissolved solids, conductivity, alkalinity and transparency. After assessing the water quality using the ASPT value (mean value of  $5.11 \pm 0.85$ ) and comparing it with the standard index of surface water quality, it was concluded that water quality reached mesotrophic status and surface water quality CLASS 3. These results can be beneficial in monitoring water quality and controlling effluents from various activities to conserve the water resources in the Yom River." (Authors) Odonate taxa are treated at family level.] Address: Pongpadung, P.: Email: piyawatp@nu.ac.th

**19694.** Sarashina, M.; Yoshida, T. (2021): Diet composition of the invasive American Bullfrog (*Lithobates catesbeianus*) in Onuma Quasi-National Park, Hokkaido, Japan. *Current Herpetology* 40(1): 77-82. (in English) ["An invasive alien species American bullfrog (hereafter, 'bullfrog') is found in freshwater lakes in Onuma Quasi-National Park, Hokkaido, Japan. Bullfrog commonly feeds on red swamp crayfish in many areas. However, red swamp crayfish has not been confirmed in Komuna Lake, Onuma Quasi-National Park. The purpose of this study is to examine the trend of predation on native biomes in areas without crayfish presence. We detected the dietary composition of bullfrogs. The stomach contents of 469 individuals were analyzed and classified. The stomach contents of adult frogs accounted for 67.4% of volume were vertebrates including Actinopterygii and Amphibia such as Japanese crucian carp, topmouth gudgeon, bullfrog juveniles, bullfrog tadpoles and Japanese common toad. Further, aquatic animals were preyed more than terrestrial animals in volume (60.0%) and frequency (90.0%). From these results, bullfrogs in Onuma Quasi-National Park used most conspicuous alien aquatic species such as alien fish and frogs of the same species as food resources and further revealed that these alien aquatic species function as a substitute food for the crayfish. While the majority of bullfrog food resources are alien aquatic species, several rare aquatic animals were also preyed on. In the future, it will be necessary to investigate the predation pressure of bullfrogs on local biodiversity." (Authors) Taxa including Odonata are treated at order level.] Address: Sarashina, M., Link-us, 1-25, Toyohira 2-jo 7-chome, Toyohira, Sapporo, 062-0902, Japan

**19695.** Schneider, T.; Vierstraete, A.; Müller, O.; van Pelt, G.J.; Caspers, M.; Ikemeyer, D.; Snegovaya, N.; Dumont, H.J. (2021): Taxonomic revision of Eastern part of western Palearctic Cordulegaster using molecular phylogeny and

morphology, with the description of two new species (Odonata: Anisoptera: Cordulegasteridae). Diversity 2021, 13, 667. <https://doi.org/10.3390/d13120667>: 50 pp. (in English) ["Taxonomy of the genus Cordulegaster Leach in Brewster, 1815 in the Eastern part of the Western Palaearctic is poorly resolved. A two-step approach was applied: sequences of mitochondrial and nuclear DNA fragments were used to sort specimens; poorly known or new taxa with their phenotypic variation were described. The existence of two traditional groups (boltonii- and bidentata group) was confirmed. Cordulegaster coronata Morton, 1916, however, belongs to a different group. Molecular-analysis supported three known and one new species (C. heros Theischinger, 1979, C. picta Selys, 1854, C. vanbrinkae Lohmann, 1993, and C. kalkmani sp. nov.) in the boltonii-group. In the bidentata-group, all specimens from West-Turkey belonged to C. insignis Schneider, 1845, all specimens further east to a complex of four closely related species, which we name charpentieri complex (C. amasina Morton, 1916, stat. rev., C. mzymtae Bartenev, 1929 C. charpentieri (Kolenati, 1846), stat. rev. and C. cilicia sp. nov.). The following taxa: C. insignis nobilis Morton, 1916, syn. nov., C. nachitschevanica Skvortsov & Snegovaya, 2015, syn. nov. C. plagionyx Skvortsov & Snegovaya, 2015, syn. nov. and the Caucasian subspecies C. insignis lagodechica Bartenev, 1930, syn. nov., were synonymized with C. charpentieri. Finally, we provide a key for all Western Palaearctic Cordulegaster." (Authors)] Address: Schneider, T., Arnold-Knoblach-Ring 76, 14109 Wannsee, Germany. Email: thomas.rs@gmx.de

**19697.** Shivaraju; Venkateshwarlu, M (2021): Faunal diversity of Durgadahalli Lake of Tumakuru, Karnataka State, India. Journal of Environmental Studies 7(1): 6 pp. (in English) ["The aquatic organisms are the good indicators of health of an aquatic ecosystem and represent the balanced ecosystem. The present study was conducted to understand the current status of faunal diversity in Durgadahalli Lake, located in the North-East of Tumakuru district, at distance of 15 km from Tumakuru city in Karnataka. It lies at 13° 13' 56" N latitude and 77° 25' 30" E longitude. It receives water mainly from rain-fall with an average of 620 mm and from Jayamangalli river. The Lake comparatively smaller with rich aquatic faunal diversity and recorded 20 species of zooplankton, 9 species of aquatic insects belonging to Hemiptera, Coleoptera, Odonata and Diptera, One molluscan shell, 2 amphibia species (frog) and one reptilian species (turtle). The water collected and analyzed from five selective sampling stations of the Lake from 2016 to 2019. Not many

reports are available on Durgadahalli Lake with respect to faunal diversity. Keeping it in mind, we have selected Durgadahalli Lake for the present study on ecology and aquatic faunal diversity." (Authors) The following odonate species are said to occur: *Libellago andamanensis* (Fraser, 1924), *Gomphidia kodaguensis*, Fraser, 1923, and *Tramea transmarina*, Brauer, 1867] Address: Shivaraju, Dept of Studies and Research in Applied Zoology, Jnana sahyadri, Shankaraghatta, Kuvempu Univ., Shivamogga-577, 451, Karnataka, India; Email: 1993shivarajugiri@gmail.com

**19698.** Suchitra, G.; Chethan, B.K. (2021): Occurrence and relative abundance of dragonflies in Mysuru city, Karnataka, India. Journal of Entomology and Zoology Studies 9(6): 180-183. (in English) ["A field study was conducted to find out the status, occurrence and relative abundance of dragonflies in Mysuru city, Karnataka during April 2020 to May 2021. Sampling was done by line transect method, collected data from 4 study areas were subjected to estimate relative abundance of species. A total of 28 species under 3 families were recorded. Family Libellulidae was found to be most dominated with 26 species followed by Aeshnidae and Gomphidae with 1 species respectively. Based on the relative abundance 18% of species were very common while, 36% were common and 46% were uncommon. The study revealed occurrence of 5 very common species of dragonflies in all the study areas. The results of this study provide baseline data of dragonfly diversity of Mysuru city for research on their biology and conservation." (Authors)] Address: Suchitra, G., Dept of Zoology, Maharani's Science College for Women, Mysuru, Karnataka, India

**19699.** Takahashi, M.; Okude, G.; Futahashi, R.; Takahashi, Y.; Kawata, M. (2021): The effect of the doublesex gene in body colour masculinization of the damselfly *Ischnura senegalensis*. Biology Letters 17: 20200761. 6 pp. (in English) ["Odonata species display a remarkable diversity of colour patterns, including intrasexual polymorphisms. In the damselfly (*Ischnura senegalensis*), the expression of a sex-determining transcription factor, the doublesex (*Isdsx*) gene is reportedly associated with female colour polymorphism (CP) (gynomorph for female-specific colour and andromorph for male-mimicking colour). Here, the function of *Isdsx* in thoracic coloration was investigated by electroporation-mediated RNA interference (RNAi). RNAi of the *Isdsx* common region in males and andromorphic females reduced melanization and thus changed the colour pattern into that of gynomorphic females, while the gynomorphic colour pattern was not affected. By contrast, RNAi against the *Isdsx* long isoform produced no changes, suggesting that the *Isdsx* short isoform is important for body colour masculinization in both males and andromorphic females. When examining the expression levels of five genes with differences between sexes and female morphs, two melanin-suppressing genes, black and ebony, were expressed at higher levels in the *Isdsx* RNAi body area than a control area. Therefore, the *Isdsx* short isoform may induce thoracic colour differentiation by suppressing black and ebony, thereby generating female CP in *I. senegalensis*. These findings contribute to the understanding of the molecular and evolutionary mechanisms underlying female CP in Odonata." **19700.** Tavakol, M.R.; Tooski, M.Y.; Jabbari, M.; Javadi, M. (2021): Effect of graphene nanoparticles on the strength of sandwich structure inspired by dragonfly wings under low-

velocity impact. *Polymer Composites* 42(10): 5249-5264. (in English) ["Dragonfly's wings are highly specialized flying organs that are well adapted to the flying behavior of each dragonfly, mainly consisting of veins and membrane. The effect of graphene nanoparticles on a novel foam-based sandwich panel structure inspired by microstructural features of dragonfly wings has been investigated under low-velocity impact. Composite and nanocomposite sandwich veins are made of E-glass/epoxy layers, in which different percentages of graphene nanoparticles are combined with its resin. Polyurethane foam was also used for its core. According to the performance of the samples made after testing and cutting the samples in transverse and longitudinal directions, the internal structure of the vein was examined. Sandwich panels with this type of structure under impact can prevent damage propagation in the vein. The sandwich structure with 0.3% nano indicated more stable behavior in energy absorption and impact resistance than other samples." **19701.** Thiele, V.; Blumrich, B.; Berlin, A.; Kasper, D. (2021): Erfassung und Bewertung der Libellen-, Heuschrecken- und Großschmetterlingsfauna des Siebendorfer Moores in Mecklenburg (Odonata, Orthoptera, Lepidoptera). *Virgo* 24: 3-16. (in German) ["In the year 2020, the Siebendorfer Moor was examined for the occurrence of dragonflies, butterflies and moths and grasshoppers. 10 species of damselflies and 17 species of dragonflies were found in the project area, including the FFH species large white-faced darter (*Leucorrhinia pectoralis*). The dragonfly fauna (n=27 species) of the study area was dominated by species whose larvae show a clear preference for stagnant to poorly flowing water (limnophilic), plant substrates, moor-like conditions and constantly water-bearing rivers. The most optimal settlement exists in the central fen area near the peat cuttings. The butterfly and moth fauna was relatively poor in species. 77 moths and 22 day-flying species were detected. The biocenosis was characterized by taxa from the swamp forests, reeds, herbaceous vegetation and mixed deciduous forests, with a gradient from east (peat cuttings) to west (grassland areas). Many species already reflect hygrophilic to mesophilic conditions, which can be seen as positive for the development of the fen. 14 species of grasshoppers have been identified. The currently detected grasshopper species mainly belong to the mesophilic to hygrophilic or hygrophilic taxa, which allows the conclusion that the habitats are already well suited for the typical wet meadow species. These associations can be found particularly on the areas adjacent to the peat cuttings and smaller bodies of water in the central area of the Siebendorfer Moor." **19702.** Tochiewa, F.T.; Tochiew, T.Y. (2021): Ecological and faunal analysis of dragonflies (Odonata) of suborders Zygoptera, Caloptera in Republic of Ingushetia. *E3S Web of Conferences* 265, 01033 (2021): 7 pp. (in English) ["In this work, we adhere to the systematics proposed by the school of odonatologists B.F.Belyshev, that is, the order is subdivided into three suborders: Anisoptera, Zygoptera and Caloptera. In this article, we first characterize the suborders Zygoptera, Caloptera. The article provides a systematic composition and an overview of taxa common in the RI. [one]. On the basis of literature sources, brief characteristics of

suborders, families and genera are given, and the problems of taxonomy and nomenclature of individual species and basic information on the distribution of taxa found in the study area are discussed. Analysis of the existing stream of literary information on dragonflies indicates that there are still problems, the solution of which requires close attention. First of all, this is the lack of research on the Caucasian regional odonatofaunas." (Authors)] Address: Tochiewa, Fatima, Ingush State University, Republic of Ingushetia, Magas, Russia. E-mail: fatimatociewa7@gmail.com

**19703.** Tochiewa, F.T.; Tochiew, T.Y.; Izmailova, M.A.; Dudarova, Kh.Yu. (2021): Influence of hydrological regimes on the ecological balance of the environment: case study of the Republic of Ingushetia. *IOP Conf. Ser.: Earth Environ. Sci.* 867 012111: 5 pp. (in English) ["Dragonflies are amphibious insects whose existence is associated with water bodies that are necessary for the development of larvae. Different types of dragonflies differ in the requirements for the choice of habitats. In mountain species, preferences depend on the height of the habitat. The analysis of the existing flow of literary information on dragonflies indicates that there are still problems that require close attention. First and foremost, this is insufficient study of Caucasian regional odonata faunas. Of all the unique Caucasian regions, the territories of the Dagestan and Chechen Republics were the least studied with regard to dragonflies. This is caused by the acute shortage of specialists and the difficulties of studying the group of animals of this original and unique region, which is located at the biogeographic crossroads of various faunas. Siberian, European, Mediterranean, Ethiopian, Central and East Asian dragonfly species fly together within these territories. A significant number of scientific articles are devoted to Caucasian dragonflies, testifying to the unique fauna of dragonflies in the region. At the same time, there are many unresolved issues of the taxonomic nature of some dragonfly species, their propagation, distribution over high-altitude zones, life cycles of ontogenesis, and some environmental issues, in particular, the phenology of the group in the peculiar and unique physical, geographical and landscape conditions of the Republic of Ingushetia. There is a relatively extensive literature on the dragonflies of the Caucasus, while there is no purposeful summary of the ecological-faunal, ecological-geographical and zoogeographic features of this group of insects in the Republic of Ingushetia. Another problem that has not yet been solved is the establishment of patterns of dragonfly propagation along the altitude gradient, as well as the peculiarities of the formation of odonotocomplexes in various high-altitude zones of the Republic of Ingushetia." **19704.** Trapero-Quintana, A.; Casenave-Cambet, A.C.; Lim-Franco, G. (2021): Diversidad y patrones de emergencia de libélulas (Odonata: Insecta) en Chutines, Guantánamo, Cuba. *Boletín de la Sociedad Entomológica Aragonesa* 69: 217-226. (in Spanish, with English summary) ["Emergence is the process by which larvae of aquatic insects emerge from the water and enter the air as adults. Little is known about the emergence patterns for tropical odonates. The purpose of this study is to characterize the emergence pattern of an odonate assemblage in a permanent lentic habitat of Chutines, Guantánamo, from the collect of exuviae. 30 samplings were carried out with a frequency of once a week and seven to nine days apart, in four transects of 8m<sup>2</sup>. To characterize the emergence, the seasonal climate model of: rainy, dry and transitional periods

was considered. Changes in climate variables and habitat characteristics were recorded and related to the emergence pattern. The study shown that the emergence pattern in a constant water volume is asynchronous, with a predominance of accidental species and uneven abundance distribution. The stage with the highest percentage of emergence was the dry season, from which temperature and relative humidity were significantly correlated parameters." **19708.** Wasscher, M.; Dijkshoorn, D.; de Vries, R.; Kloen, J.-F. (2021): Does the dragonfly biting midge *Forcipomyia paludis* co-occur with the Great fen-sedge *Cladium mariscus* in the Netherlands and Belgium?. *Brachytron* 22(1/2): 13-25. (in Dutch, with English summary) ["An overview is given of the localities where the dragonfly midge (*Forcipomyia paludis*) has been found in the Netherlands and Belgium. Following the hypothesis that the distribution of this species corresponds with the occurrence of the Great fen-sedge (*Cladium mariscus*), we searched for new localities of the species by checking thousands of photos of dragonflies for the presence of the midge on their wing veins. This resulted in nine new locations in the Netherlands and one in Belgium, which brings the total numbers of locations of *F. paludis* to 24 (the Netherlands) and 7 (Belgium). *Cladium mariscus* occurs on 21 and 4 of these locations respectively. The most important locations of *F. paludis* in both countries are locations where *C. mariscus* grows extensively. Incidentally, *F. paludis* was found at locations where *C. mariscus* is not locally present but is found at a distance up to 25 km. These observations might refer to midges attached to the wings of their dispersing hosts. The larva of *F. paludis* has not yet been described, but might be found in the thick litter layer between *C. mariscus* plants." (Authors)] Address: Wasscher, M., Minstraat 15bis, 3582 CA Utrecht, The Netherlands. Email: marcel.hilair@12move.nl

**19709.** Wasscher, M.; de Vries, R.; Dijkshoorn, D.; Kloen, J.-F. (2021): Co-occurrence of the dragonfly biting midge *Forcipomyia paludis* and the Great fen-sedge *Cladium mariscus* in Europe. *Libellula* 40(1/2): 1-17. (in English, with German summary) ["The dragonfly biting midge *Forcipomyia paludis* (Diptera: Ceratopogonidae) has been found in many parts of Europe and adjacent countries such as Morocco, Turkey and Georgia, but has a remarkably scattered distribution, with at most a few dozen localities in the countries where it occurs. Its presence appears to be strongly concurrent with the presence of the Great fen-sedge *Cladium mariscus*, a marsh plant with a wide but scattered distribution within Europe. Both species co-occur across the entire known range of *F. paludis*. However, *F. paludis* was also found on a few localities where the Great fen-sedge has not been reported. In most cases these localities are within a limited distance of Great fen-sedge localities, or refer to incidental observations in which *F. paludis* might have been attached to dispersing dragonflies. A probable discrepancy between the two species was found in the southwest of Baden-Wuerttemberg. This overlap in distribution suggests that the presence of *F. paludis* is linked to that of the Great fen-sedge. It is therefore probable that the larvae of *F. paludis* develop in Great fen-sedge stands, where a humid litter layer of dead leaves is formed. This habitat presents similar conditions as those preferred by many other Ceratopogonid larvae. However, the concurrence that is described here does not prove a decisive ecological link while we did find a few exceptions. Additionally, first records for Estonia, Denmark, Portugal and Turkey are reported here." (Authors)] Address: Wasscher, M., Minstraat 15bis, 3582 CA Utrecht, The Netherlands. **19714.** Baaloudj, A.; De los Ríos-Escalante, P.R.; Esse, C. (2022): Benthic community ecology for Algerian river Seybouse. *Brazilian Journal of Biology* 84, e251566: 12 pp. (in English, with Portuguese summary) ["The Seybouse is the second largest river basin in Algeria, hosting an important biodiversity and providing various ecosystem services. This watershed is highly influenced by agricultural and industrial activities, which threaten its biodiversity and ecosystem integrity. The use of benthic macroinvertebrates as biological indicators has a long tradition in developed countries and integrated into all assessments of the ecological quality of river systems. However, the macroinvertebrates of many North African regions are still not well studied, including those of the Seybouse river. The aim of this study is to assess the inventory and ecological role of benthic macroinvertebrates in inland waters of the Seybouse River and determine the impact of pollution on their spatial distributions. We sampled the benthic macrofauna of Wadi Seybouse and its affluents using regular surveys in three sites, of which one was in the upper Seybouse Bouhamdane in Medjez Amar and two in the middle Seybouse. Between December 2019 and May 2020, 10 physico-chemical parameters (pH, EC, OD, water speed, NO<sub>3</sub>, Salinity, NO<sub>2</sub>, MES, turbidity, depth) were measured in order to establish a health state diagnosis of these aquatic ecosystems. The complementary biological approach by the analysis of populations of macroinvertebrates identified 7482 individuals and 40 taxa divided into five classes: Crustaceans which were the most dominant, insects with the main orders (Ephemeroptera, Diptera, Trichoptera, Heteroptera and Odonata), Molluscs, Nematodes and Annelids. The physico-chemical analyzes and the application of the organic pollution indices indicated a strong to excessive pollution for all sites, especially in Seybouse upstream." (Authors) Odonata are treated a sub-order level.] Address: Baaloudj, A., University of 8 May 1945 Guelma, Faculty SNV-STU, Laboratoire de Biologie, Eau et Environnement, Guelma, Algeria. Email: bafef@yahoo.fr

**19715.** Bowles, D.E.; Kleinsasser, L.J. (2022): Environmental determinates of distribution for dragonfly nymphs (Odonata: Anisoptera) in urban and non-urban East Texas streams, USA. *Hydrobiology* 1(1): 67-88. (in English) ["We collected environmental and habitat data for nymphs of 12 dragonfly species (Odonata: Anisoptera) from 91 stream sites throughout eastern Texas, including urban and non-urban locations. Understanding the relationship of dragonflies to habitat structure and other environmental variables is crucial for the purpose of conserving these insects and better using them as predictive tools for water quality assessments, and refining tolerance values. The objectives of this study were to determine the key environmental variables influencing the diversity and distribution of dragonflies in eastern Texas streams, and further determine if differences in those factors could be observed between urban and non-urban sites. We collected samples separately from benthic habitats and woody snag habitats. Significantly fewer sites were observed to have dragonfly species on snag habitat (mean = 1.25) compared to benthic samples (mean = 14.67) (t-test, p = 0.001). The number of dragonfly species collected among non-urban streams (mean = 9.83) was not significantly different than urban streams (mean = 6.08; t-test, p = 0.07). Detrended correspondence analysis of benthic and snag habitat data collected from non-urban and urban locations showed that most of the species are oriented most closely to benthic habitats in non-urban streams. Snag

habitat was shown to be poorly ordinated for all of the species. A canonical correspondence analysis of 29 water quality and habitat variables as environmental determinants of dragonfly diversity and distribution showed that distributional relationships among species are complex and often described by multiple environmental factors." **19717.** Chen, R.-Y.; Lai, C.-L.; Chen, J.-C.; Wu, M.-X.; Yang, H. (2022): Omnidirectional / unidirectional antireflection-switchable structures inspired by dragonfly wings. *Journal of Colloid and Interface Science* 610: 246-257. (in English) ["Randomly arranged irregular inclined conical structure-covered dragonfly wings, distinguished from periodic conical structure-covered cicada wings, are with high optical transparency for wide viewing angles. Bioinspired by the antireflective structures, we develop a colloidal lithography approach for engineering randomly arranged irregular conical structures with shape memory polymer-based tips. The structures establish a gradual refractive index transition to suppresses optical reflection in the visible spectrum. By manipulating the configuration of structure tips through applying common solvent stimulations or contact pressures under ambient conditions, the resulting unidirectional antireflection and omnidirectional antireflection performances are able to be instantaneously and reversibly switched. The dependences of structure shape, structure inclination, structure arrangement, and structure composition on the switchable antireflection capability are also systematically investigated in this study." **19718.** Chitsaz, N.; Siddiqui, K.; Marian, R.; Chahl, J.S. (2022): Numerical and experimental analysis of 3D Micro-Corrugated Wing in gliding flight. *Journal of Fluids Engineering* 144(1): 11 pp. (in English) ["In this study, computational fluid dynamics analysis was performed on a three-dimensional model of a Libellulidae wing to determine aerodynamic performance in gliding flight. The wing is comprised of various corrugated features alongside the spanwise and chordwise directions, as well as twist. The detailed features of real 3D dragonfly wing models, including all the corrugations through both span and chord, have not been considered in the past for a detailed aerodynamic analysis. The simulations were conducted by solving the Navier-Stokes equations to demonstrate gliding performance over a range of angles of attack at low Reynolds numbers. The numerical model was validated against experimental data obtained from a fabricated corrugated wing model using particle image velocimetry. The numerical results demonstrate that bio-inspired wings with corrugations compared to flat profile wings generate more lift with lower drag, trapping the vortices in the valleys of wing corrugation leading to

delayed flow separation and delayed stall. The experimental and numerical results demonstrate that the methodology presented in this study can be used to measure bio-inspired 3D wing flow characteristics, including the influence of complex corrugations on aerodynamic performance. These findings contribute to the advancement of knowledge required for designing an optimized bioinspired micro air vehicle." **19721.** Encarnación-Luévano, A.; Escoto-Moreno, J.A.; Villalobos-Jiménez, G. (2022): Evaluating potential distribution and niche divergence among populations of the world's largest living damselfly, *Megaloprepus caerulatus* (Drury, 1782). *Diversity* 2022, 14, 84. 16 pp. (in English) ["*M. caerulatus* is a Neotropical species with a highly specialised niche, found from Mexico to Bolivia, primarily in mature tropical forests lower than 1500 masl. It is also the damselfly with

the largest wingspan in the world. Recent studies found strong genetic isolation among populations of *M. caerulatus*. Further studies found genetic and morphological divergence, but ecological divergence was not tested. Here, we test for ecological divergence by evaluating niche differences among populations of *M. caerulatus* in Los Tuxtlas (Mexico), Corcovado (Costa Rica), Barro Colorado (Panama), and La Selva (Costa Rica). We used Ecological Niche Modelling (ENM) to compare potential distribution ranges, and we estimated the breadth and overlap of the ecological niche using equivalence and similarity tests. The potential distributions estimated with ENM were heavily fragmented and we found no geographic overlap of potential distributions among populations. However, we found geographic correspondence between populations with a close phylogenetic relationship. Even though all similarity tests were non-significant, the results of the equivalence tests suggest niche divergence between Corcovado and the other three populations, but also between Barro Colorado (Panama) and La Selva. These results show evidence of strong ecological divergence in Corcovado and Barro Colorado populations." **19722.** Felker, A.S. (2022): Dragonflies of the family Kennedyidae (Odonata: Archizygoptera) from the mid-upper Triassic of Kyrgyzstan. *Paleontological Journal* 1/2022: 75-84. (in Russian, with English summary) ["Two new species of Kennedyidae: *Kennedyia madygensis* sp. nov. and *K. ferganensis* sp. nov. are described from the Middle-Upper Triassic deposits Dzhayloucho (Madygen) locality in Kyrgyzstan based on the new material collected 2007 and 2009. *K. carpenteri* Pritykina, 1981 is redescribed and variation in its discoidal and other structures is demonstrated. Structure and transformation of the Nodus in Kennedyidae is discussed." (Author)] Address: Felker, A.S., Borisyak Paleontological Institute, Russian Academy of Sciences, Moscow, Russia

**19723.** Fletcher, D.E.; Lindell, A.H.; Stankus, P.T.; Fulghum, C.M.; Spivey, E.A. (2022): Species- and element-specific patterns of metal flux from contaminated wetlands versus metals shed with exuviae in emerging dragonflies? *Environmental Pollution* 300, 118976. (in English) [Highlights: • 9 metals evaluated in emerging dragonflies and their exuviae from contaminated wetland. • Larger amounts of some metals (Cu, Zn, and Mg) were retained in the emergent dragonflies. • Some elements (Al, Fe, Mn, Pb) were largely shed with exuviae. • Metals shed in exuviae can moderate metal export from wetlands. • Importance of factors influencing metal flux differed among species. Abstract: Dragonfly adults and their aquatic immature stages are important parts of food webs and provide a link between aquatic and terrestrial components. During emergence, contaminants can be exported into terrestrial food webs as immature adults fly away or be shed with their exuviae and remain in the wetland. Our previous work established metals accumulating in dragonfly nymphs throughout a contaminated constructed wetland designed to regulate pH and sequester trace metals from an industrial effluent line. Here, we evaluated the concentration and mass of metals leaving the wetland in flying emergents versus remaining in the wetland with the shed exuviae in 10 species of dragonflies belonging to 8 genera. Nine elements (Cu, Zn, Cd, Mn, V, Mg, Fe, Al, Pb)

were evaluated that include essential and nonessential elements as well as trace and major metals. Metal concentrations in the emergent body and exuviae can differ by orders of magnitude. Aluminum, Fe, Mn, and Pb were largely shed in the exuviae. Vanadium and Cd were more variable among species but also tended to be shed with the exuviae. In contrast, Cu, Zn, and Mg showed a higher tendency to leave the wetland with an emerging dragonfly. Metals shed in dragonfly exuviae can moderate the transport of metals from contaminated wetlands. Taxonomic- and metal-specific variability in daily metal flux from the wetland depended upon concentration accumulated, individual body mass, and number of individuals emerging, with each factor's relative importance often differing among species. This illustrates the importance of evaluating the mass of metals in an individual and not only concentrations. Furthermore, differences in numbers of each species emerging will magnify differences in individual metal flux when calculating community metal flux. A better understanding of the variability of metal accumulation in nymphs/larvae and metal shedding during metamorphosis among both metals and species is needed." **19724.** George, S.D.; Duffy, B.T.; Baldigo, B.P.; Skaros, D.; Smith, A.J. (2022): Condition of macroinvertebrate communities in the Buffalo River Area of concern following sediment remediation. *Journal of Great Lakes Research* 481: 183-194. (in English) ["The lower 10 km of the Buffalo River, a tributary to Lake Erie, was designated as an Area of Concern (AOC) in 1987 through the Great Lakes Water Quality Agreement because sediment contamination and habitat alteration from past industrialization caused several Beneficial Use Impairments (BUIs). Extensive remediation efforts conducted between 2011 and 2015 removed approximately 688,100 cubic meters of contaminated sediment from the Buffalo River AOC, and subsequent chemical analysis of sediments indicated that most remedial goals had been achieved. Benthic macroinvertebrate communities and sediment toxicity were evaluated in the AOC and an upstream reference area in 2017 and 2020 to determine whether remediation has improved benthic conditions sufficiently that the benthos BUI designation can be removed. Community condition was characterized using the New York State multi-metric index of biological integrity and bed sediments were used for 10-day toxicity tests with *Chironomus dilutus* and *Hyalella azteca*. Macroinvertebrate communities were classified as moderately to slightly impacted at most AOC sites compared to slightly impacted at most reference sites, but toxicity tests did not identify any evidence of toxicity in sediments from the AOC. A linear mixed effects model indicated that total organic carbon concentration in sediments, distance upstream from the river mouth, and the relative dominance of zebra mussels *Dreissena polymorpha* were the primary predictors of macroinvertebrate community condition. These findings are consistent with those from other AOCs in New York which indicate that contemporary benthic communities are generally shaped by legacy habitat alterations rather than AOC-specific sediment contamination and toxicity." (Authors) Taxa include Odonata, and are treated at order level.] Address: George, S.D., U.S. Geological Survey, New York Water Science Center, 425 Jordan Road, Troy, NY 12180, USA

**19725.** Goertzen, D.; Schneider, A.-K.; Eggers, T.O.; Suhling, F. (2022): Temporal changes of biodiversity in urban running waters – Results of a twelve-year monitoring

study. *Basic and Applied Ecology* 58: 74-87. (in English) ["Freshwater biodiversity underlies severe threats, mainly suffering from habitat degradation by anthropogenic land use, in particular by urbanisation. However, recent long-term studies indicate recovery of stream macroinvertebrate diversity due to improved water quality at least in North America and Europe. We monitored macroinvertebrates at 56 urban stream sites over a 12-year period (2009–2020) in Braunschweig, a German urban district. We utilised these data to investigate spatio-temporal changes in taxon richness and assemblage structure as well as factors potentially affecting the resulting patterns. Overall taxon richness was increasing over the study period, comprising both all taxa and taxa being indicators for healthy stream conditions. 53.6% of the sites had significant positive trends becoming most eminent since 2014, despite decelerating since 2018, the beginning of an extra-ordinary dry period. Only 10.7% of the study sites had negative trends. Assemblage structure was shaped by environmental factors like stream width and water quality. Over-average taxon richness including positive trends and higher numbers of indicator taxa of healthy stream conditions was found in streams with higher flow velocity, good saprobic conditions and more natural streambed structure. In contrast, low taxon richness and predominance of tolerant taxa were found in streams with more degraded conditions. Most of the environmental conditions having positive effects on taxon richness were improved by various programs set up by the environmental authorities. We therefore conclude, if urban stressors like organic pollution and structural degradation can be mitigated by revitalisation and water quality improvement, urban streams can have good potential for increasing biodiversity and improving ecological functioning." (Authors)] Address: Goertzen, Diana, Technische Universität Braunschweig, Institute of Geocology, Langer Kamp 19c, Braunschweig 38106, Germany. Email: d.goertzen@tu-braunschweig.de

**19726.** Hawke, T.; Bino, G.; Shackleton, M.E.; Ross, A.K.; Kingsford, R.T. (2022): Using DNA metabarcoding as a novel approach for analysis of platypus diet. *Scientific Reports* volume 12, Article number: 2247. 10 pp. ["Platypuses (*Ornithorhynchus anatinus*) forage for macroinvertebrate prey exclusively in freshwater habitats. Because food material in their faeces is well digested and mostly unidentifiable, previous dietary studies have relied on cheek pouch assessments and stable isotope analysis. Given DNA metabarcoding can identify species composition from only fragments of genetic material, we investigated its effectiveness in analysing the diet of platypuses, and to assess variation across seasons and sexes. Of the 18 orders and 60 families identified, Ephemeroptera and Diptera were the most prevalent orders, detected in 100% of samples, followed by Trichoptera, Pulmonata, and Odonata (86.21% of samples). Caenidae and Chironomidae were the most common families. Diptera had a high average DNA read, suggesting it is an important dietary component that may have been underestimated in previous studies. We found no variation in diet between sexes and only minimal changes between seasons. DNA metabarcoding proved to be a highly useful tool for assessing platypus diet, improving prey identification compared to cheek pouch analysis, which can underestimate soft-bodied organisms, and stable isotope analysis which cannot distinguish all taxa isotopically. This will be a useful tool for investigating how platypus prey diversity is impacted by habitat degradation as a result of anthropogenic stressors." (Authors)] Address: Hawke, T., Centre for Ecosystem Science, School of Biological, Earth & Environmental Sciences, UNSW, Sydney, NSW 2052, Australia.

**19727.** Herrmann, A.; Grabow, K.; Martens, A. (2022): The invasive crayfish *Faxonius immunitus* causes the collapse of macroinvertebrate communities in Central European ponds. *Aquatic Ecology*. (in English) ["The invasive crayfish *Faxonius immunitus* is regarded as a threat to amphibians and macroinvertebrates in the Upper Rhine Valley, Germany, eradicating macrophytes and establishing high-density populations in stagnant waters. This study investigates the macroinvertebrate community structure of five conservation ponds south of Karlsruhe, Germany, to identify effects caused by this invasive crayfish. Two of the ponds had a high population density of *F. immunitus*, two were expected to have lower crayfish densities as they had been habitat modified with gravelled water beds as a crayfish management approach, and one pond was known to be free of crayfish but contained fish. The macroinvertebrate communities were analyzed considering their species richness and composition. The relative density of *F. immunitus* within the samples was regarded as a representative indicator for crayfish population density and tested for its influence on the ordination along with habitat composition and abiotic factors using distance-based redundancy analysis. *F. immunitus* was identified as a driving factor of the macroinvertebrate communities of sampled ponds. Additionally, this study indicates that gravelling ground beds as a management method for invasive burrowing crayfish species does not significantly influence the community composition but can minimize indirect effects caused by *F. immunitus*." **19728.** Hopkins, I.; Farahnak, A.; Gill, A.; Newman, L.P.; Danaher, J. (2022): Australians' experience, barriers and willingness towards consuming edible insects as an emerging protein source. *Appetite* 169, 1 February 2022, 105832: 9 pp. (in English) ["Increasing global populations and limitations on the natural resources required in food production such as land and water will place further pressure on an already strained food production system. To meet the future food production requirements, it is essential to find viable alternatives to current food sources, without the high resource challenges. Protein production is of particular concern and insects are a nutritious and sustainable source yet, despite a rich history in parts of the world, Australians have been reluctant to adopt the practice as a societal norm. This study aimed to explore Australian consumers' experiences with edible insects, identify barriers to consumption, and explore possible factors that may motivate Australians to consume insects. A total of 601 participants (23.8% male, 76.2% female), completed an online survey using a variety of open-ended questions; 5- or 7-point Likert scales and check-all-that-apply questions. Consumer willingness was measured through self-reporting willingness-to-try insects or insect-based foods. Results indicated 35.4% of participants had previously consumed insects, with Orthoptera (crickets, grasshoppers) the most commonly consumed order (60.1%). Participants with no previous experience consuming insects cited 'lack of opportunity' as the main reason (57.2%). 'Increased accessibility' (56.6%) and 'increased nutrition knowledge' (56.6%) were identified as major factors that may increase the likelihood of future insect consumption. Participants reporting that they were willing to try insects were most likely to accept 'insect-based flour' (65.6%) and 'chocolate-covered ants' (52.1%). By providing increased opportunity, accessibility and education of insect-based food products, a higher pro-

portion of Australians may be willing to eat insects, particularly if presented in indistinguishable forms (i.e. flour). This may lead to a greater acceptance of insects as an alternative, more sustainable protein source than previously anticipated....'Odonata (dragonflies)' were the least consumed with 1.4% of participants reporting previous consumption." **19729.** Itrac-Bruneau, R.; Doucet, G. (2022): Somatochlora arctica (Odonata: Corduliidae) dans le Massif du Morvan: découverte d'une station majeure pour la Bourgogne-Franche-Comté et comparaison avec d'autres stations. *Martinia* 36(1): 1-12. (in French, with English summary) ["S. arctica in Morvan Massif: discovery of a major station for Bourgogne-Franche-Comté region and comparison with other stations. - In 2021, eight stations (three of the four historical and five potential) were prospected searching for S. arctica in the Morvan Massif in Burgundy. The species was found in only two stations: a historical station, updating data of almost 30 years old located in Roussillon-en-Morvan (Saône-et-Loire department) and a second one, new, on a small bog of about 0,64 ha located in the town of Arleuf (Nièvre department). With 23 exuviae collected from the 492 m<sup>2</sup> of favorable larval habitat in two passages and a remarkable density for the region of 467/ha, the latter seems important in terms of taxon conservation. This synthesis also shows that only two stations shelter the species permanently (historic station of Saint-Agnan (Nièvre department) and the station discovered in 2021). Thus, at the scale of the Morvan Massif, only one station can be considered in good state of conservation and is home to a viable population. The others are either severely degraded requiring restoration actions or only support the species sporadically". **19730.** Lozano, F.; del Palacio, A.; Ramos, L.S.; Granato, L.; Drozd, A.; Muzón, J. (2022): Recovery of local dragonfly diversity following restoration of an artificial lake in an urban area near Buenos Aires. *Basic and Applied Ecology* 58: 88-97. (in English) ["Urban lakes are environments prone to severe environmental deterioration if an effective management policy is not carried out by local governments. However, management aimed only at facilitating access and recreation for citizens can negatively affect the environmental health of these ecosystems since the pristine ecosystem structure is not recovered. In this paper we present early results of a governmental restoration program based on pond cleaning and native vegetation recovery at an artificial lake of the city of Avellaneda (Saladita Norte Reserve), part of the Metropolitan Area of Buenos Aires, one of the largest urban areas with the highest concentrations of inhabitants of the world. We used odonates as indicators because of their quick response to changes in environmental quality. Besides, we tested if the NDVI can be used as a surrogate to monitor changes in dragonfly diversity in managed areas. Since the intervention was carried out during the winter and there were no previous data on the richness or diversity of odonates, we analyzed their response to the intervention comparing it with a lake of similar origin and characteristics but with a different use and management (Saladita Sur Reserve). We recorded in Saladita Norte 81% of the regional diversity, including three newly recorded species, while the lake Saladita Sur, only amounted to 21% of the regional

diversity. The NDVI did not reflect the observed changes in the structural complexity of the vegetation and therefore could not be used as a surrogate. These early results indicate that management practices such as the increase of native vegetation on the banks (especially in grassland areas), keeping a diverse floating vegetation and the cleaning and removal of wastes from the water, promote a significant and rapid increase in the levels of biodiversity." (Authors)] Address: Muzón, J., Inst. Limnol. "Dr. R.A. Ringuelet", C.C. 712, AR-1900 La Plata, Argentina. E-mail: jmuzon@undav.edu.ar

**19731.** Maneechan, W.; Prommi, T.O. (2022): Occurrence of microplastics in edible aquatic insect *Pantala* sp. (Odonata: Libellulidae) from rice fields. *PeerJ* 10:e12902 <http://doi.org/10.7717/peerj.12902>: 13 pp. (in English) ["Background. Microplastic (MP) contamination has been discovered in aquatic systems throughout the world. They are well known as contaminants in aquatic species, but there is a gap in understanding about pathways of MP contamination into humans (i.e., through aquatic animals). The goal of this study is to assess MP contamination in an edible aquatic insect (*Pantala* sp.) living in rice fields. Methods. *Pantala* sp. was tested for MPs. The study concentrated on three distinct anatomical compartments (whole body, gastrointestinal tract, and body without gastrointestinal tract), each of which was examined separately. For the physical identification and chemical analysis of MPs, a stereomicroscope and a Fourier transformed infrared spectroscope (FT-IR) were used, respectively. Results and Discussion. The microplastics content was 121 in the whole body, 95 in the gastrointestinal tract, and 66 in the body without the gastrointestinal tract, with an average of 1.34 1.11, 1.06 0.77, and 0.73 0.51 abundance/ individual, respectively. The most common MPs discovered during this study were fragments, followed by fibers and rods. The chemical analysis by FT-IR confirmed three different polymers, including polymethyl methacrylate (PMMA), polyethylene terephthalate (PET), and polypropylene (PP). There was no significant difference in MP abundances among the sample types (Kruskal-Wallis chi-squared D 2.774, df D 2, p D 0:250). The findings suggest that eating an edible aquatic insect (Odonata: *Pantala* sp.) could be one way for humans to ingest MPs." **19732.** Minot, M.; Husté, A. (2022): Genetic diversity and structure of *Anax imperator* Leach, 1815 populations (Odonata: Aeshnidae) in ponds at regional and European scales. *Diversity* 2022, 14, 68. <https://doi.org/10.3390/d14020068>: 17 pp. (in English) ["Anthropogenic activities cause loss and fragmentation of natural habitats and have strong effects on population maintenance by increasing their isolation. Pond ecosystems are scattered waterbodies that can interact as a network connected by dispersal events of freshwater organisms. Identifying local genetic differentiations and understanding how gene flow occurs across these networks is essential to prevent risks associated with environmental perturbations. This study aimed to investigate genetic diversity and structure of *Anax imperator* Leach, 1815 populations at both regional and European scales using seven microsatellites markers. Seven populations of *A. imperator* were sampled in northwestern France and four populations were sampled in Italy (Sicily), Czech Republic, Switzerland and United Kingdom (U.K.). French populations presented a low genetic differentiation indicating a high gene flow and

confirming dispersal events of this species between ponds at regional scale. No pattern of isolation by distance was found at the European scale. The populations presented a low genetic differentiation and no pattern of isolation by distance, suggesting historical or current movements of individuals. Only the U.K. population presented a significant genetic differentiation from other European populations, suggesting that the English Channel might act as a barrier to gene flow for *A. imperator*. However, Bayesian analysis showed that some dispersal events could occur between the U.K. and France (Normandy), probably facilitated by prevailing winds." **19733.** Morales, J.; Negro, A.I.; Lizana, M. (2022): Patterns of odonata assemblages in lotic and lentic systems in the Sanabria glacial lake complex in Sierra Segundera (NW Spain). Diversity and biogeographical analysis. Bol. R. Soc. Esp. Hist. Nat., 116: 23-39. (in Spanish, with English summary) ["We studied the community of odonates on the southern watershed of the Sierra Segundera glacial lake complex, from the valley area (Tera river and Sanabria lake, 1000 m.a.s.l.) to the high mountain lakes and peat bogs (>1500 m.a.s.l.). The maximum richness was detected at the source of the River Tera from the lake, while on the east coast and part of the south coast there are no Odonata populations or breeding and emergence habitats; this is due to the tourist pressures on the shoreline. Eighteen taxa were found to reproduce in the lake, including the endangered species *Macromia splendens*. Only *Sympetrum flaveolum*, *Aeshna juncea* and *Enallagma cyathigerum* were located exclusively at altitude mountain range. The specific turnover among ecosystems is from 30 to 14, in a 700 m gradient from the valley to the lake complex. Adults were captured in flight between weeks 18 and 44 of the calendar year. The circum-mediterranean biogeographical component dominates with species of mediterranean-western, franc-iberian and ibero-maghreb distribution, but with euro-siberian, holarctic and palaeartic species distribution; and all the holarctic chorotype species known in Spain were recorded. No African migratory dragonflies in meridional drift were found in the three summers sampled." (Authors)] Address: Morales, J., Áreas de Biología Animal y Ecología. Universidad de Salamanca. E-37007. (2022): Calcium and strontium stable isotopes reveal similar behaviors of essential Ca and nonessential Sr in stream food webs. Ecosphere 13(2) e3921. 19 pp. (in English) ["Recent studies showed the potential of stable isotopes of the macronutrient calcium ( $\delta^{44/40}\text{Ca}$ ) and nonessential strontium ( $\delta^{88/86}\text{Sr}$ ) as new trophic level indicators in terrestrial vertebrates and marine teleost fishes. In this study, we tested whether similar Ca and

Sr isotopic fractionation trends existed in macroinvertebrate-dominated stream food webs compared to vertebrates despite their physiological differences. We have determined the  $\delta^{44/40}\text{Ca}$  and  $\delta^{88/86}\text{Sr}$  values as well as the  $^{87}\text{Sr}/^{86}\text{Sr}$  ratios of stream macroinvertebrates and small gobies and their potential metal sources (stream water, periphyton, and terrestrial plant litter) in upper and lower reaches of two streams in the Lake Biwa catchment, central Japan. The  $^{87}\text{Sr}/^{86}\text{Sr}$  ratios revealed that stonefly nymphs, crustacea, and gobies mostly relied on aquatic Sr sources. Higher  $^{87}\text{Sr}/^{86}\text{Sr}$  ratios of some crane fly and caddisfly larvae, mayfly, dobsonfly, and dragonfly nymphs [Gomphidae] indicated greater terrestrial contributions via plant litter. Positive correlations between the  $\delta^{44/40}\text{Ca}$  and  $\delta^{88/86}\text{Sr}$  values implied that similar Ca and Sr sources existed, and that Ca and Sr stable isotopes underwent similar fractionation trends although Sr was not essential. The  $d^{44/40}\text{Ca}$  and partly the  $\delta^{88/86}\text{Sr}$  values were positively correlated with Sr/Ca ratios and negatively with  $\delta^{15}\text{N}$  values indicating trophic effects on Ca and Sr stable isotopes. The enrichment of  $^{44}\text{Ca}$  and  $^{88}\text{Sr}$  in large filter-feeding caddisfly larvae was a notable exception from these trophic trends. Our data confirm that the trophic  $^{44}\text{Ca}$  and  $^{88}\text{Sr}$  depletion observed for marine teleost fishes and terrestrial vertebrates also applied to macroinvertebrate-dominated stream food webs despite their different physiologies indicating that shared mechanisms of Ca and Sr isotopic fractionation may exist at the cellular or molecular level between these taxa." **19736.** Ogunwa, T.; Abdullah, E.; Chahl, J. (2022): Modeling and control of an articulated multibody aircraft. Applied Sciences 2022, 12, 1162. 36 pp. (in English) [Hemicordulia australiae (Rambur 1842); "Insects use dynamic articulation and actuation of their abdomen and other appendages to augment aerodynamic flight control. These dynamic phenomena in flight serve many purposes, including maintaining balance, enhancing stability, and extending maneuverability. The behaviors have been observed and measured by biologists but have not been well modeled in a flight dynamics framework. Biological appendages are generally comparatively large, actuated in rotation, and serve multiple biological functions. Technological moving masses for flight control have tended to be compact, translational, internally mounted and dedicated to the task. Many flight characteristics of biological flyers far exceed any technological flyers on the same scale. Mathematical tools that support modern control techniques to explore and manage these actuator functions may unlock new opportunities to achieve agility. The compact tensor model of multibody aircraft flight dynamics developed here allows unified dynamic and aerodynamic simulation and control of bioinspired aircraft with wings and any number of idealized appendage masses. The demonstrated aircraft model was a dragonfly-like fixed-wing aircraft. The control effect of the moving abdomen was comparable to the control surfaces, with lateral abdominal motion substituting for an aerodynamic rudder to achieve coordinated turns. Vertical fuselage motion achieved the same effect as an elevator, and included potentially useful transient torque reactions both up and down. The best performance was achieved when both moving masses and control surfaces were employed in the control solution. An aircraft with fuselage actuation combined with conventional control surfaces could be managed with a modern optimal

controller designed using the multibody flight dynamics model presented here." (Authors)] Address: Ogunwa, T., UniSA STEM, University of South Australia, Adelaide 5095, Australia. Email: titilayo.ogunwa@mymail.unisa.edu.au

**19738.** Pan, Y.; Long, Y.; Hui, J.; Xiao, W.; Yin, J.; Ya, L.; Li, D.; Tian, X.; Chen, L. (2022): Microplastics can affect the trophic cascade strength and stability of plankton ecosystems via behavior-mediated indirect interactions. *Journal of Hazardous Materials*, Available online 4 February 2022, 128415: (in English) ["Highlights: • PE microplastics reduced heart rate and hopping frequency of grazers. • PE microplastics reduced grazing rate of grazers. • Microplastics increased the positive impacts of damselflies on algal growth. • PE microplastics reduced reproductive capacity for grazer species. • PE microplastics reduced the stability and persistence of a plankton ecosystem. Abstract: The negative effects of microplastics on the normal growth of aquatic organisms have been well studied, but relatively little is known about their potential adverse effects on the function and stability of aquatic ecosystems. We investigated here the effects of polyethylene (PE) microplastics on several aspects of plankton ecosystems, including *Daphnia magna* behavior, the grazing rate of *D. magna* on *Chlorella vulgaris* cells, trophic-cascade effects in the *C. vulgaris*-*D. magna*-larval damselfly food chain, the life-history of *D. magna*, and the stability and persistence of the *D. magna*-larval damselfly system. PE microplastics decreased the *D. magna* grazing rate as a result of reductions in their heart rate and hopping frequency. In the trophic-cascade experiment, PE microplastics increased the foraging success of larval damselflies on grazers due to hopping inhibition in grazers, which ultimately strengthened the trophic-cascade effect on algal growth. Long-term exposure to PE microplastics reduced the stability and persistence of the grazer population via increased predation risk and reduced reproductive capacity for grazer species. This study provides evidence that microplastics can affect the trophic cascade strength and stability of plankton ecosystems via behavior-mediated indirect interactions, suggesting that microplastics have more extensive impacts on aquatic ecosystems than presently recognized. Environmental implication: The massive production and environmental releasing of microplastics have become ubiquitous in the global environment. The

negative effects of microplastics on the normal growth of aquatic organisms have been well studied, but little is known about potential adverse effects on the function and stability of aquatic ecosystems. Here, we found that microplastics increased the positive impacts of larval damselflies on algal growth, and reduced the stability and persistence of plankton ecosystems via a behavior-mediated indirect interaction. To our knowledge, this is the first systematic study assessing the effects of microplastics on the community-level characteristics of a freshwater ecosystem. Synopsis: PE microplastics affect trophic cascade strength and reduce the stability and persistence of plankton ecosystems via behavior-mediated indirect interactions." **19739.** Pelealu, G.V.E.; Nangoy, M.J.; Tarore, D. (2022): Keanekaragaman capung di Sungai Rayow, Desa Kembes, Kecamatan Tombulu, Kabupaten Minahasa. *Zootec* 42(1): 25-32. (in Indonesian, with English summary) ["Dragonflies are a group of insects belonging to the phylum Arthropoda and belonging to the order Odonata. The diversity of dragonflies in the ecosystem has a big role, such as: as a component of biodiversity that plays an important role in the food chain, as natural enemies, and as an indicator of the quality of the aquatic environment. The Rayow River is one of the dragonfly habitats. This river is located in Kembes village, Minahasa regency, North Sulawesi province. This study aims to identify and analyze the diversity of dragonflies in the Ralow river, Kembes, Minahasa. The research procedure used includes surveying the research site, determining the point of sampling, taking samples, and identification in the laboratory using an identification book. The research in the field used purposive random sampling method. Data analysis includes abundance (N), species richness index (R), species diversity index (H'), and evenness index (E). species diversity index using the Shannon-Wiener index. The results of the study found an abundance of dragonflies found in the Rayow river as many as 1002 individuals, consisting of 2 sub orders, 6 families, 13 genera, and 21 species of dragonflies. The highest diversity index of dragonflies was found in rivers in secondary forest areas at 2.67, followed by rivers in plantation areas at 2.57, and the lowest diversity index was found in rivers in residential areas at 2.28. The conclusion is based on the research of dragonflies found in the Ralow river, Kembes, Minahasa consisting of 21 types of dragonflies. The highest dragonfly diversity index was found at station 1, namely in the secondary forest ecosystem river 2.67 followed by the plantation area river 2.57 and the lowest was found in the residential area river 2.28. The diversity index of dragonflies in the river Ralow, Kembes, Minahasa is categorized as moderate diversity." **19741.** Ribeiro-Brasil, D.R.G.; Brasil, L.S., Veloso, G.K.O.; Pio de Matos, T.; Silva de Lima, E.; Dias-Silva, K. (2022): The impacts of plastics on aquatic insects. *Science of the Total Environment* 813 (2022) 152436: 11 pp. (in English) ["Highlight: • Agriculture with black macroplastics is harmful to aquatic insects. • Aquatic insects contribute to the degradation of plastic during digestion. • Aquatic insects with abundant food consume less microplastic. • MPs accumulate in the Malpighian tubule excretory system. • Aquatic insects prefer to oviposit on plastic surfaces. Abstract: Environmental contamination by plastics and its negative effect on biodiversity have been well-documented in several types of organisms, especially in marine environments. Therefore, it is necessary to assess the impacts of plastic on other organisms such as aquatic insects, which predominantly inhabit freshwaters. It is widely known that these organisms are sensitive to environmental change, especially by contamination. Therefore, this study aimed at testing the hypothesis that aquatic insects are impacted by plastic contamination. We made a systematic search for international papers related to plastics and aquatic insects in databases such as Google Scholar, Web of Science, and Scopus. We obtained 1217 studies of which 40 discussed the impacts of contamination by plastics on aquatic insects. We identified two main impacts: the first one is caused by the use of black macroplastic to protect crops from contact with the soil in agriculture. These black macroplastics attract tons of adult aquatic insects (terrestrial stage) that mistake the plastic surface for water because they select oviposition sites through phototaxis or polarotaxis. The second one comes from water contamination that can originate from the inadequate disposal of plastics, which harms young aquatic insects (aquatic phase) when they feed, reproduce, and construct shelters. Our results show the negative impacts of plastics on both larvae and adult aquatic insects. Despite the large knowledge gap regarding the impacts of plastic on aquatic insects, the evidence above is sufficient to consider these organisms important in global discussions regarding the impacts of plastic on biodiversity." (Authors) Searching results in Odonata are poor, and omit relevant studies. ] Address: Ribeiro-Brasil, Danielle, Ecology & Conservation Lab. **19742.** Rochlin, I.; White, G.; Reissen, N.; Martheswaran, T.; Faraji, A. (2022): Effects of aerial adulticiding for mosquito management on nontarget insects: A Bayesian and community ecology approach. *Ecosphere* 13(1), e3896: 15 pp. (in English) ["Diseases transmitted by mosquitoes are emerging across the globe in a broad range of urbanized, rural, and natural environments inhabited by their vector

species. Because applications of insecticides remain the most effective, and often the only available tool to prevent or control mosquito-borne disease outbreaks, their use and scope continue to expand. However, the effects of multiple insecticide applications targeting adult mosquitoes on nontarget insect communities remain poorly characterized. To remedy this knowledge gap, we conducted an evaluation of five aerial insecticide applications on insect communities in a natural environment near Salt Lake City, Utah. Employing a before–after–control–impact approach, we assessed abundance and community composition changes over the study period utilizing Bayesian and community ecology analytical methods. We observed no discernible effects on most insect taxa, and there were no changes in the overall insect community composition. The abundance of Diptera, Coleoptera, and Hemiptera declined in control and treatment sites, Odonata increased over the period of the study, and Hymenoptera and Lepidoptera remained similar, suggesting seasonal trends rather than treatment effects. The only consistently detectable treatment effect was on nonbiting midges (Diptera: Chironomidae), that are closely related to mosquitoes taxonomically and have similar body size and diel activity. Midge abundance declined by 79.9% (95% credible interval: 58.4–91.9). Overall posttreatment abundance decline of 62.2% (95% credible interval: 22.5–87.8) was also detected for leafhoppers (Hemiptera: Cicadellidae), but, these declines were inconsistent and may be attributed to natural variability rather than the treatment effect. Treatment frequency, location, life-stage targeting, and application techniques may mitigate the effects of mosquito control on nontarget insects to allow protecting human health while limiting environmental impacts." **19743.** Rodríguez, C.; Jurado, Y.; Rodríguez, V. (2022): Structure of drifting aquatic insects and its relationship with the benthos aquatic insect community, in a section of the Zarati River, Province of Coclé, Panama. *Tecnociencia* 24(1): 45-71. (in Spanish, with English summary) ["Sampling was conducted to determine the numeric structure of drifting aquatic insects and their relationship with the benthic insect numeric structure, in a section of the Zarati River, Coclé, Panama. Field work took place once a week, during June to September 2019 for a total of 12 sampling campaigns in the selected river section. For collection of drifting insects, two traps with an area of 0,176 m<sup>2</sup> and 500 µm were used and placed against the current. Drifting traps remained submerged during the sampling period and were emptied every 12 hours from 06:00 to 18:00 h and 18:00 to 06:00 h, while D-Nets were used for benthic insect collection. A total of 3 984 aquatic insects were collected, where 1 387 belonged to the drifting and 2 597 to the benthic groups, respectively. The most abundant orders of the drifting group were Ephemeroptera, Trichopteran, Diptera and Coleoptera, whereas the benthic group most abundant orders were Trichopteran, Ephemeroptera, Odonata and Heteropteran. The highest aquatic insect abundance in the drifting group was recorded during nocturnal periods implying behavioral drifting, supporting the hypothesis that drifting as a predation escape mechanism. Jaccard similarity index between aquatic insect genera in the drifting group and benthic group was IJ = 52 %. This indicates that the largest part of taxa move through drifting and the fraction of drifting aquatic insects numeric structure is a reflex of the benthic numeric structure." **19746.** Santos, A.A.; Nel, A.; Rodríguez-Barreiro, I.; Sender, L.M.; Wappler, T.; Diez, J.B. (2022): Insect and plant diversity in hot-spring ecosystems during the Jurassic-Cretaceous boundary from Spain (Aguilar Fm., Palencia). *Biology* 2022, 11, 273. 19 pp. (in English) ["Simple Summary: In this study, we show and identify new plant and insect remains found in travertine deposits from the Jurassic-Cretaceous boundary of the Aguilar Formation (Palencia, North Spain). From this hot-spring palaeoenvironment, we have identified the presence of dragonflies of the families Cymatophlebiidae and Aktassiidae, representing the first report of these families for the Iberian Peninsula. In addition, we find

a flora dominated by Bennettitales and the presence of ferns that differ from other floras of the same age and geographical area. The unusual environmental and palaeoecological conditions of this hot-spring environment are also discussed, suggesting that this niche was an "ecological oasis" for some plants and insects. Abstract: Hydrothermal palaeoenvironments are very uncommon in Upper Jurassic and Lower Cretaceous deposits worldwide. We present new plant and insect remains from travertines formed during the Jurassic-Cretaceous boundary in northern Spain (Aguilar Fm., Palencia province). A total of 136 plant specimens and three insect wings were collected and studied. This entomofauna consists of dragonfly (Odonata) wings including Cymatophlebiidae and an undetermined new genus and species of Aktassiidae, representing the first report of these families for the Iberian Peninsula. The fossil flora shows different morphotypes of plants, which have been tentatively assigned to three different genera. The taphocoenosis of the flora was dominated by Bennettitales (98.5%) including cf. *Pterophyllum* sp., *Ptilophyllum* cf. *acutifolium*, *Ptilophyllum* cf. *pecten*, *Ptilophyllum* cf. *pectiniformis* and cf. *Ptilophyllum* sp., and the occasional presence of ferns (1.5%) represented by the taxon *Cladophlebis* cf. *denticulata*. The presence of the Anisoptera *Cymatophlebia* cf. *longialata* suggests a higher affinity for a Tithonian age of the studied site, and the anatomy and palaeogeographical distribution of this species suggest capacity to migrate for rather long distances. The floristic composition of the site differs remarkably from other Tithonian-Berriasian floras of the Iberian Peninsula. The presence of Odonata and the distinctive flora in (semi)arid conditions could be due to the hot-spring providing an environmental niche with constant conditions of warmth and humidity forming an "ecological oasis". **19748.** Sherlock, C.; Femie, K.J.; Munno, K.; Provencher, J.; Rochman, C. (2022): The potential of aerial insectivores for monitoring microplastics in terrestrial environments. *Science of the Total Environment* 807 (2022) 150453: 10 pp. (in English) ["Highlight: . Microparticles (MP) found in tree swallows (.83%) at WWTP & reference sites. . At both sites, fecal sacs of chicks (90%) contained MPs and all were fibers. . Reference chicks had more MPs (feces) that were larger, more diverse in GI tracts. . Reference birds had more aquatic diet versus WWTP chicks had more terrestrial diet. MP numbers were not correlated between sample types or with chick condition and size. Abstract: Limited research has been conducted on microplastics in terrestrial ecosystems

and biota, despite being some of the most ubiquitous environmental pollutants. We investigated the presence of microplastics (over 125  $\mu\text{m}$ ) in tree swallow (*Tachycineta bicolor*) chicks (10 d. o.), an aerial insectivore whose diet involves terrestrial and/or freshwater sources. Swallows nested immediately downstream (300 m) of the discharge pipe of a large, urban wastewater treatment plant (WWTP) or at a rural conservation area (40 km apart). Anthropogenic microparticles (including microplastics) were identified in nearly all WWTP chicks (90%; N = 20) and reference chicks (83%; N = 20). All microparticles were fibers (100%) in the gastro-intestinal (GI) tracts of WWTP nestlings, whereas unexpectedly, they were more diverse in the GI tracts of reference chicks, with ~15% characterized as pre-production plastic pellets. The fecal sacs of most nestlings (90%) contained microparticles, and all were characterized as fibers suggesting their excretion by tree swallows. Compared to WWTP chicks, the reference chicks had more microparticles in their fecal sacs and larger particles (length, width) in their GI tracts, likely reflecting the more aquatic-based diet of the reference chicks fed insects caught adjacent to the nearby dam, compared to the more terrestrial-based diet of the WWTP chicks. The numbers of microparticles were not correlated between GI tracts and fecal sacs, nor with the chicks' condition or size (weight, organs, feathers). We commend sampling macroinvertebrate prey to permit stronger conclusions regarding WWTPs as possible sources of microplastics for swallows, and to determine if such macroinvertebrates may be a non-lethal method to characterize microparticle diversity ingested by birds as presently identified in chicks' GI tracts. We conclude that sampling fecal sacs only, while not indicative of the diversity of microplastics ingested by terrestrial passerines (e.g., tree swallows), is useful for determining their exposure to microparticles." **19749.** Simonsen, T.J.; Glahder, M.; Pape, T.; Olsen, K.; Djernæs, M. (2022): Rhapsody in emerald: phylogenetic framework for Lestidae with reference to the systematic position of Chalcolestes Kennedy. *International Journal of Odonatology* 25: 16-21. (in English) ["We reconstruct a phylogenetic framework for the zygopteran family Lestidae based on a molecular dataset comprised of sequence data from the genes COI, 16S, 18S, 28S, and ITS1+2 from 41 ingroup taxa and 8 outgroup taxa with emphasis on the systematic position of the genus Chalcolestes Kennedy. We recover Lestidae as monophyletic with good statistical support. The family falls into two subequal clades. One, comprising the genus *Sympecma* Burmeister and *Lestes* Leach sensu lato (including the genus *Archilestes* Selys) is poorly to moderately supported. While the other, comprising the genera *Austrolestes* Tillyard, *Indolestes* Fraser, *Orolestes* McLachlan, and *Chalcolestes* is strongly supported. *Chalcolestes* is recovered as sister to the Oriental genus *Orolestes* with strong support. Our results thus support that *Chalcolestes* is a valid genus not closely related to *Lestes*. Monophyly of *Lestes* requires inclusion of the New World genus *Archilestes*, and our results support the need for a thorough revision of *Lestes*. ... Three main conclusions can be drawn from our results despite the somewhat limited taxon sampling. First, there is no phylogenetic support for dividing Lestidae into the subfamilies Lestinae and Sympecmatinae. Second, *Lestes* as currently defined is almost certainly not a monophyletic group, and we agree with Dijkstra and Kalkman (2012) that a phylogenetic revision of the genus is much needed. Third, *Chalcolestes* is a valid

genus that is not closely related to other European genera of Lestidae—neither *Lestes* nor *Sympecma*. Instead, the genus is most likely the sister group to *Orolestes* and placed in a clade with otherwise Oriental-Australian genera. Other than the much-needed revision of *Lestes* sensu lato, several high profile aspects of Lestidae phylogeny and systematics remain to be solved. The relationship and delimitation of *Austrolestes* and *Indolestes* remain unclear, and the two genera in combination should be the subject of a phylogenetic taxonomic revision. The higher-level phylogeny of Lestidae should be the subject of phylogenomic analyses in the mould of Bybee et al. (2021) and include also *Platylestes* and *Sinhalestes*. Such a study should address the phylogenetic position of *Sympecma*, identify natural divisions that can be used for a subfamily and tribal classification, and resolve the biogeography of the family including the geographical origin of *Chalcolestes*." (Authors)] Address: Simonsen, T.J., Natural History Museum Aarhus, 8000 Aarhus C, Denmark. Email: t.simonsen@nathist.dk

**19750.** Snegovaya, N.Yu. (2022): Odonata collected in 2021 in Azerbaijan, including new data on *Gomphus schneiderii* Selys, 1850 and *Libellula pontica* Selys, 1887. *International Dragonfly Fund - Report 168*: 1-23. (in English) ["This paper presents the results of a study on the odonate fauna in Azerbaijan. The survey was conducted in the summer of 2021 and covered 24 localities in twelve districts. A total of 34 species from 9 families was recorded. New localities for *Gomphus schneiderii* Selys, 1850 and *Libellula pontica* Selys, 1887 are reported. A formerly published record of *Gomphus vulgatissimus* from Khachmaz, Nabran village, has to be corrected into *G. schneiderii*." **19751.** Späth, J.; Brodin, T.; McCallum, E.; Cervený, D.; Fick, J.; Nording, M.L. (2022): Metabolomics reveals changes in metabolite profiles due to growth and metamorphosis during the ontogeny of the northern damselfly. *Journal of Insect Physiology* Volume 136, January 2022, 104341: 8 pp. (in English) ["Highlights: • Baseline metabolism of damselflies at different ontogenetic stages. • 212 compounds annotated in three larval stages and adult damselflies. • Shift from protein catabolism to lipid catabolism across metamorphosis. • Metabolites affected by effluent exposure depend on ontogenetic stage. Abstract: Many insects have complex life cycles where a drastic ontogenetic change happens between the larval stages and the adult stage, i.e. metamorphosis. Damselflies are widely distributed and ecologically important semi-aquatic insects with a complex life cycle. Phenotypic changes over damselfly ontogeny have been documented, however, if and how metabolite profiles are also changing is currently unknown. Here we used a metabolomics methodology to gain insights into the metabolic changes during the life cycle of the *Coenagrion hastulatum*. Hatchlings of wild-caught damselflies were reared in the laboratory and metabolomics analyses using liquid chromatography and gas chromatography coupled to mass spectrometry were carried out at three larval stages and on adult damselflies. Additionally, a subset of larvae was exposed to wastewater effluent to assess how metabolite profiles responded to an environmental stressor. A total of 212 compounds belonging to several classes (e.g. amino acids, fatty acids, sugars) were annotated. Across metamorphosis, we found that damselflies shifted from protein catabolism to lipid catabolism. Wastewater effluent exposure resulted in ontogenetic stage-dependent changes of individual

metabolites, but not to a marked extent. Overall, our study is one of the first to describe changes of metabolite profiles during ontogeny of an insect, and it provides a first step towards a greater understanding of the physiological changes occurring during general insect—but especially damselfly—ontogeny." **19752.** Streib, L.; Juvigny-Khenafou, N.; Heer, H.; Kattwinkel, M.; Schäfer, R.B. (2022): Spatiotemporal dynamics drive synergism of land use and climatic extreme events in insect meta-populations. *Science of The Total Environment* 814, 25 March 2022, 152602: (in English) [nv; "Highlights: • Ecosystem risks often emerge from interactions of co-occurring stressors. • At higher spatiotemporal scales, research on stressor interactions is not very developed. • Scenarios of two global change stressors were simulated for insect meta-populations. • Interactions were driven by the continuous stressor, and changed over time. Abstract: Ecosystems are increasingly threatened by co-occurring stressors associated with anthropogenic global change. Spatial stressor patterns range from local to regional to global, and temporal stressor patterns from discrete to continuous. To date, most multiple stressor studies covered short periods and focused on local effects and interactions. However, it remains largely unknown how stressors with different spatiotemporal patterns interact in their effects over longer periods. In particular, at higher spatial scales, biotic dynamics in ecological networks complicate the understanding of stressor interactions. We used a spatially explicit meta-population model for a generic freshwater insect, parameterized based on traits of the European damselfly *Coenagrion mercuriale*, to simulate scenarios of discrete climatic extreme events and continuous land use-related stress. Climatic extreme events were modeled as recurring mortality in all patches, whereas land use permanently influenced meta-populations via patch qualities and network connectivity. We found that the risk of discrete climatic extreme events to meta-populations depended strongly on the proportion of land use types, with effects ranging from negligible to extinction. Land use-related stress limited recovery in meta-populations from effects of climatic extreme events, resulting in synergistic stressor interactions. Moreover, the spatial configuration of land use type influenced the combined stressor effects with clustered configurations resulting in lower effects compared to a random configuration. Finally, we found that combined stressor effects can vary with the time point at which they were determined, indicating that inconclusive results in multiple stressor research can partly be due to differences in the time of determination. We conclude that conservation should focus on regional landscape management to mitigate risks on meta-populations from future, intensified extreme climate events. Reducing land use effects, thus improving patch quality and network connectivity, can compensate for effects of additional discrete stressors and, in turn, synergistic interactions." **19753.** Susanto, M.A.D. (2021): Inventory and identification dragonfly Family Libellulidae at Slamet Reservoir, Surabaya, East Java. *Journal of Biology and Instruction* 1(2): 40-50. (English, with Indonesian summary) ["Slamet Reservoir is an artificial reservoir located in the lowlands of urban areas. The existence of this reservoir with a stagnant

water habitat type has great potential to become a natural habitat for various types of dragonflies, especially the Libellulidae family. This study aims to inventory and identify the types of dragonflies in the family Libellulidae in the Slamet Reservoir. In this study, the Visual Encounter Survey (VES) method was modified by using the Belt Transect method. This method is an observation by following a predetermined circular line. Sampling was carried out by catching adult dragonflies using insect nets and then preserving them using 50% acetone. After preservation, the body part of the dragonfly was measured using a caliper. The results showed that in the Slamet Reservoir there were 12 species of dragonflies from the Libellulidae family with a total of 131 individuals. The species with the highest relative abundance value in the Slamet reservoir is *Brachythemis contaminata* with a value of 51.15%. While the species with the lowest relative abundance values were *Acisoma panorpoides*, *Dip-lacodes trivialis* and *Pantala flavescens* with a value of 0.76%." (2022): Naive Poison Frog tadpoles use bi-modal cues to avoid insect predators but not heterospecific predatory tadpoles. *Journal of Experimental Biology* (2021) 224, jeb243647: 9 pp. (in English) ["For animals to survive until reproduction, it is crucial that juveniles successfully detect potential predators and respond with appropriate behavior. The recognition of cues originating from predators can be innate or learned. Cues of various modalities might be used alone or in multi-modal

combinations to detect and distinguish predators but studies investigating multi-modal integration in predator avoidance are scarce. Here, we used wild, naive tadpoles of the Neotropical Poison Frog *Allobates femoralis* (Boulenger, 1884) to test their reaction to cues with two modalities from two different sympatrically occurring potential predators: heterospecific predatory *Dendrobates tinctorius* tadpoles and dragonfly larvae. We presented *A. femoralis* tadpoles with olfactory or visual cues, or a combination of both and compared their reaction to a water-control in a between-individual design. In our trials, *A. femoralis* tadpoles reacted to multimodal stimuli (a combination of visual and chemical information) originating from dragonfly larvae with avoidance but showed no reaction to uni-modal cues or cues from heterospecific tadpoles. In addition, visual cues from conspecifics increased swimming activity while cues from predators had no effect on tadpole activity. Our results show that *A. femoralis* tadpoles can innately recognize some predators and likely need both visual and chemical information to effectively avoid them. This is the first study looking at anti-predator behavior in Poison Frog tadpoles. We discuss how parental care might influence the expression of predator avoidance responses in tadpoles." **19757.** Tazunoki, Y.; Tokuda, M.; Sakuma, A.; Nishimuta, K.; Oba, Y.; Kadokami, K.; Miyawaki, T.; Ikegami, M.; Ueno, D. (2022): Comprehensive analyses of agrochemicals affecting aquatic ecosystems: A case study of Odonata communities and macrophytes in Saga Plain, northern Kyushu, Japan? *Environmental Pollution* 292, Part A, 1 January 2022, 118334: 9 pp. (in English) ["Highlights: • Negative effect of pesticides to odonata populations was investigated. • Comprehensive analysis with AIQS was used to quantify pesticides in water samples. • Insecticides, fungicides, and herbicides were detected in water environment. • Negative relationships were found between insecticides and abundance of odonates. • Fungicides and herbicides were not related to abundance of odonates and macrophytes. Abstract: The negative influence of agrochemicals (pesticides: insecticide, fungicide, and herbicide) on biodiversity is a major ecological concern. In recent decades, many insect species are reported to have rapidly declined worldwide, and pesticides, including neonicotinoids and fipronil, are suspected to be partially responsible. In Japan, application of systemic insecticides to nursery boxes in rice paddies is considered to have caused rapid declines in *Sympetrum* (Odonata: Libellulidae) and other dragonfly and damselfly populations since the 1990s. In addition to the direct lethal effects of pesticides, agrochemicals indirectly affect Odonata populations through reductions in macrophytes, which provide a habitat, and prey organisms. Due to technical restrictions, most previous studies first selected target chemicals and then analyzed their influence on focal organisms at various levels, from the laboratory to the field. However, in natural and agricultural environments, various chemicals co-occur

and can act synergistically. Under such circumstances, targeted analyses might lead to spurious correlations between a target chemical and the abundance of organisms. To address such problems, in this study we adopted a novel technique, "Comprehensive Target Analysis with an Automated Identification and Quantification System (CTA-AIQS)" to detect wide range of agrochemicals in water environment. The relationships between a wide range of pesticides and lentic Odonata communities were surveyed in agricultural and non-agricultural areas in Saga Plain, Kyushu, Japan. We detected significant negative relationships between several insecticides, i.e., acephate, clothianidin, dinotefuran, flubendiamide, pymetrozine, and thiametoxam (marginal for benthic odonates) and the abundance of lentic Eiprocta and benthic Odonates. In contrast, the herbicides we detected were not significantly related to the abundance of aquatic macrophytes, suggesting a lower impact of herbicides on aquatic vegetation at the field level. These results highlight the need for further assessments of the influence of non-neonicotinoid insecticides on aquatic organisms." **19758.** Valente-Neto, F.; Piovezan-Borges, A.C.; Urbieta, G.L.; Samways, M.J.; Roque, F. (2022): Research networks should improve connectivity for halting freshwater insect extinctions. *Ecological Entomology* 47(1): 63-75. (in English) [1. Avoiding freshwater insect extinctions requires studies assessing causal links between a human pressure and biodiversity measures (threats), the state of biodiversity through time (status), and solutions to manage species loss. However, an imbalance between these different approaches on declines of freshwater insects and the distribution of the studies between countries may have implications for implementing conservation knowledge into practical conservation actions. 2. Here, we evaluate country co-authorship relationships through quantitative bibliometric analysis to identify networks of research collaboration on freshwater insects extinction, and how this overall network is modified by the type of studies (status, threats, and solutions). 3. We detected that authors from developed countries dominated the networks, and most studies assessed threats to freshwater insects, knowledge which is part of a research network involving multiple countries. The status network of research collaboration was clearly more disconnected in comparison with the network of all studies, whereas the solution network showed the greatest connectivity. 4. These results reveal that an increase in research collaboration is required for all approaches assessed here, because many megadiverse countries are not present in the networks. This is especially required for status and solution studies. Expansion of research collaboration should decrease inequalities between developed and developing countries, achieved by funding conservation studies in developing countries. Studies should also decrease classical inequalities, including those related to sexual orientation, gender identity, and ethnic minorities. These recommendations would benefit freshwater insect conservation science and practice." **19759.** Vilenica, M.; Rebrina, F.; Matonickin Kepcija, R.; Šegota, V.; Rumišek, M.; Ružanovic, L.; Brigic, A. (2022): Aquatic macrophyte vegetation promotes taxonomic and

functional diversity of Odonata assemblages in intermittent Karst Rivers in the Mediterranean. *Diversity* 2022, 14(1), 31; <https://doi.org/10.3390/d14010031>: 21 pp. (in English) ["Assemblages of adult Odonata were studied in four intermittent karst rivers encompassing macrophyte-rich (MRH) and macrophyte-poor habitats (MPH) in southern Europe, where temporary lotic habitats are the predominant freshwater type but are still understudied. With a total of 25 recorded species, the studied habitats support species-rich Odonata assemblages, as already shown for intermittent rivers in the Mediterranean. Aquatic macrophyte abundance, conductivity, and water velocity are the most significant determinants of Odonata assemblages in the studied IRES. MRH promote higher Odonata abundance and the taxonomic and functional diversity of their assemblages compared to the MPH. Odonata assemblages in MRH are characterized by higher values of body size and a higher share of species preferring lentic and temporary hydrological conditions. Moreover, their assemblages are characterized by various patterns of nymphal development and drought resilience strategies. In contrast, MPH are preferred by lotic species, with nymphal development all year round and with no specific drought-resisting strategies. Our results contribute to the knowledge of diversity and ecological requirements of dragonflies and damselflies in IRES habitats, which could provide scientific background for future conservation activities and bioassessment protocols of such habitats and their biota. ... In total, 25 Odonata species were recorded (Table 3). Overall, the most numerous species was *Platynemesis pennipes* (Pallas, 1771), which was also most frequently recorded at MRH. *Calopteryx virgo* was the most numerous species at MPH (Table 3). Species recorded in low numbers (less than 20 individuals) were *Sympetrum fonscolombii*, *S. sanguineum*, *S. meridionale*, *Cordulegaster heros*, *Aeshna affinis*, *Crocothemis erythraea*, *Orthetrum cancellatum*, and *Somatochlora meridionalis* (Table 3)." **19760.** Xu, M.; Fincke, O.M. (2022): To harass or to respect: the economy of male persistence despite female refusal in a damselfly with scramble mate competition. *International Journal of Odonatology* 25: 7-15. (in English) ["In sexual conflict, males are often thought to gain fitness benefits from harassing females over mating. Yet when harassment itself incurs costs to males and if alternative, receptive females are available in a local population, theory predicts that when confronted with a female refusal, a male's choice of persisting or retreating is determined in part by the likelihood of achieving a mating. We tested that prediction in the damselfly *Enallagma hageni*, whose males compete by intense scramble competition, resulting in widespread mating harassment toward females, which have a high level of control over mating. Using captive individuals of *E. hageni* in outdoor insectaries, we quantified male persistence in mating after refusals by pre- and post-oviposition focal females whose egg content we quantified after observations. We documented a novel, context-dependent head-turning refusal signal of sexual non-receptivity, most often displayed in tandem pairs by post-oviposition females that typically carried few mature eggs for males to fertilize. Male persistence was less likely to result in mating with post-oviposition females compared with pre-oviposition females carrying a clutch of mature eggs. Accordingly, males were less likely to persist following refusal signals given by post-oviposition females, supporting the theoretical prediction. Compared with a re-

fusal signal known as wing spread, head-turning was significantly more effective in deterring harassing males. Our results suggest that despite on-going sexual conflict over mating, cooperation benefits both sexes when females use the honest signal of non-receptivity because they carry few mature eggs that males could fertilize." **19761.** Zouaïmia, A. Adjami, Y.; Zebba, R.; Youcefi, A.; Bensakhri, Z.; Bensouilah, S.; Amari, H.; Ouakid, M.-L.; Houhamdi, M.; Mahdjoub, H.; Khelifa, R. (2022): Phenology of the regionally Critically Endangered dragonfly *Urothemis edwardsii* in the National Park of El Kala, Northeast of Algeria. *Nature Conservation Research* 7(1): 9 pp. (in English, with Russian summary) ["In the Mediterranean, *Urothemis edwardsii* is one of the most threatened dragonfly species with a relict population restricted to the northeast of Algeria. Despite the recent subtle local expansion in the geographic distribution of the species during the past decade, studies on the life history of the species are still lacking. We carried out a study on the phenology of emergence and flight season on Lake Bleu, Northeast-Algeria. Using repeated sampling of exuviae and marking of adults during two seasons (2018 and 2019), we estimated the population size, sex ratio, and the temporal pattern of emergence and flight season. The first year (2018) was considerably drier than the second year (2019). We collected a total of 576 and 887 exuviae and 711 and 655 adults in 2018 and 2019, respectively. The sex ratio at emergence was slightly female-biased with 57.1% in the first year and equal to unity (50.5%) in the second year, respectively. The species started its emergence earlier in the dry year (2018). The emergence of the species was quite asynchronous where 50% of the population emerged after 11 days and 16 days in 2018 and 2019, respectively. The difference in population size (based on exuviae) and the temporal pattern of emergence and flight season were likely due to differences in weather between the two years. The current study provides useful information on the life history and plasticity of *U. edwardsii*, which could be used for the management of this locally Critically Endangered dragonfly." MSc thesis, Dept of Biology, Carleton Univ., Ottawa, Ontario: XIII + 91 pp. (in English) ["In the first chapter, I found that natural high levels of *Limnochares americana* (Lundblad) tend to negatively affect the survivorship and significantly reduce the time to female maturation of its damselfly host, *Enallagma ebrium* (Hagen). I observed that damselflies increase their grooming behaviours when they are being colonised by mite larvae. However, I did not observe any adaptive host response, i.e., an increase in reproductive effort, by adult males or females. In the second chapter, I investigated the causes of sex biases in parasitism by *L. americana* observed for field-caught *Nehalennia irene* (Hagen) and *Leucorrhinia frigida* (Selys). I also used *Enallagma ebrium* (Hagen), to test for the occurrence of a sex bias in engorgement size of *L. americana*. I found that *N. irene* showed no sex biases in parasitism in the laboratory whereas *L. frigida* females were more susceptible to mite colonisation than males. I also found that mites attained a larger size on *E. ebrium* females in the laboratory but not in the field." (Author)] Address: not stated

**19764.** Petitjeannin, M. (1998): Introduction aux élevages de larves aquatiques d'insectes Reunionais. Rapport de stage de fin de maîtrise. Observatoire Reunionais de l'eau, Parc de la Providence, 97489 Saint-Denis, France: 39 pp. (in French) ["Insects represent 80% of the world's fauna. Thanks to their tremendous adaptability, they have colonized all continental, equatorial and aquatic environments. In La Reunion, the ORE has identified 26 families of insects whose larvae are aquatic. In Europe in particular, the larvae of certain insects make it possible to assess the quality and

study running and lake water systems. These studies are based on the diversity and size of populations and therefore on a detailed knowledge of the insects and their development, i. e. larvae, nymphs and adults. They therefore require the master of systematics. The determination of larvae up to the species is often very difficult, even impossible. Indeed, the specific characteristics of the species are generally carried on the male genitalia of imago [imago = adult insect]. To overcome this difficulty, many authors recommend breeding larvae in order to obtain adults. Thus, in order to improve knowledge of Reunion Island insects, the ORE and Insectarium du Port have joined forces to carry out a breeding study of aquatic insect larvae. This project has started through an internship that took place during July and August 1998 to set up an eievage implementation method. For a first test, it is the order of Odonates which was retained, represented at the Reunion by 2 families of Dragonflies (Anisopteres) and 1 family of Demoiselles (Zygopteres). Indeed, it possessed three major assets: the larvae are sensitive to pollution, predators therefore easy to feed and rather easy to breed. Moreover, the adults are known by MM GUILLERMET C and COUTEYENS from the Insectarium. Larvae were collected from about ten sites and placed in aquanums at the Port Insectarium to allow them to continue their development. The difficulty consists in creating an artificial environment close to their natural environment. In parallel, in the ORE laboratory, the morphological characteristics of each individual were observed in order to try to identify and differentiate them. It was possible to establish the experimental conditions necessary for the development of larvae. Thanks to this work and the knowledge of the Insectarium staff, 8 different larvae were identified: 4 Coenagnonidae (Demoiselles) out of 6 described in Reunion Island, 1 Aeshnidae (Dragonflies) on 2, 3 Libellulidae (Libellules) out of 8. Of these eight, three are identified as *Anax imperator* (Aeshmidae), *Pantala flavescens* (Libellulidae) and *Ishnura senegalensis* (Coenagnonidae), following the success of the first stage of this project, it would be interesting to continue it in order to deepen the fine determination of Odonate larvae and to reschedule to other orders. The continuation of breeding is essential because it will make it possible to better understand the Reunionese insect fauna and therefore their ecology and their sensitivity to environmental degradation." (Author/DeepL)] Address: Petitjeannin, Mathilde, Observatoire Reunionais de l'eau, Parc de la Providence, 97489 Saint-Denis, France. E-mail: ore@runtel.fr

**19765.** Abbott, J.C. (1999): Biodiversity of dragonflies and damselflies (Odonata) of the south-central nearctic and adjacent neotropical biotic provinces. Ph.D. Dissertation. Univ.

of North Texas, Denton, Texas: 911 pp. (in English) ["The south-central United States serves as an important biogeographical link and dispersal corridor between Nearctic and Neotropical elements of western hemisphere odonate faunas. Its species are reasonably well known because of substantial collections, but there has been no concerted effort to document the extent of biodiversity and possible geographic affinities of dragonflies and damselflies of this region. The recent discoveries of *Argia leonorae* Garrison, *Gomphus gonzalezi* Dunkle and *Erpetogomphus heterodon* Garrison from southern and western Texas and northern Mexico suggest that Odonata species remain to be discovered in this area, particularly from far south Texas and northern Mexico. I have documented a total of 12,515 records of Odonata found in 408 counties within the south-central U.S. A total of 73 species of damselflies and 160 species of dragonflies was revealed in the region. The 233 (197 in Texas) Odonata species are distributed among 10 families and 66 genera. Illustrated family, generic, and species-level keys are provided. Since the beginning of this work in the Fall of 1993, one species has been added each to the Louisiana and Oklahoma faunas, and 12 species have been added, previously unreported from Texas, including four new to the U.S. The area of highest Odonata biodiversity overall (161 spp.) is in the Austroriparian biotic province. The greatest degree of faunal similarity between the south-central U.S. and other intra-continental regions was observed for the eastern (64%) United States. Diversity is a function of area, and as expected, the numbers of breeding birds and Odonata, in each contiguous U.S. state are positively correlated ( $r=0.376$ ,  $n=33$ ,  $p=0.031$ ). There is, however, no strong correlation between land area and species diversity within the region, but those natural biotic provinces (Austroriparian, Texan, Balconian) where aquatic systems and topographic heterogeneity are the greatest provide a broader spectrum of potential Odonata habitats and thus support a greater number of Odonata species." **19766.** Frey, J., (1999): Practical aspects of biotope mapping in cities: methods, problems and solutions. An example of Mainz, Germany. *Deinsea* 5: 41-56. (in English) ["Biotope mapping of Mainz" - this is the name of a research project commissioned by the City of Mainz and carried out by an interdisciplinary group of geographers, biologists and environmental planners at Mainz Univ. between 1993 and 1997. The project's goal was not only to gather, analyse and evaluate data relating to urban biotopes, but also to apply and - if necessary - modify the 'Basic program for biotope mapping in urban areas', which was set up by a working group at the German Federal Nature Conservancy in 1993. In conformity with the legal mandate, the work followed the strategy of integrated nature conservation, i.e. simultaneous protection of biotic, abiotic and aesthetic resources, which is considered as an inevitable component of sustainable development in urban areas. Some of the methodological aspects recommended in the 'Basic program' and completed in the 'Biotope mapping of Mainz' are: the application of a well-structured biotope type reference key, the elaboration of a microsite key with relevance to flora, fauna and aesthetics, very detailed mapping and description of biotope types, subtypes and variations, as well as mappings and descriptions of the phenomena of nature, recreational activities and environmental impacts related to biotope types. Further, the 'Biotope mapping of Mainz' supplemented some new spatial aspects and assessment procedures that

might eventually get planning authorities more adopted to the idea of sustainable land use in populated areas, such as the environmental zoning of the landscape within the city limits, the delimitation and description of 'urban landscape units' in detail (including climate, soil and water conditions, flora and fauna as well as historical and cultural features), the development of environmental quality targets and standards specified for each 'urban landscape unit', the assessment of the unit's biotope types with reference to the established environmental quality standards, and last, suggestions and recommendations for urban planning and environmental management. With the items mentioned, the research project 'Biotope mapping of Mainz' made its scientific outcome more accessible and understandable. As a consequence, it is reported that local planning authorities are applying the project's findings and giving a positive feedback of the results." (Author) In APPENDIX 1 the biotope subtype '5520 - Ponds with slightly disturbed embankments' and its fauna with bioindicative value is described. (2003): Naturschutzorientierte Untersuchungen zur Bestandssituation dreier europaweit geschützter Libellenarten auf Metapopulationsniveau unter Einsatz eines Geographischen Informationssystems (GIS). Programm Lebensgrundlage Umwelt und ihre Sicherung. Abschlussbericht. Förderkennzeichen BWC 20001: 26 pp. (in German) ["All available data on the occurrence of the dragonfly species *Coenagrion mercuriale*, *Leucorrhinia pectoralis* and *Ophiogomphus cecilia* in Baden-Württemberg were compiled and entered into the GIS and database. For *Coenagrion mercuriale*, a habitat model was created that allows the selection of areas with particularly favourable conditions for the species in the Upper Rhine Plain. From digital data on land use (ATKIS) and a slope model (from the digital elevation model DHM 50), cost surfaces were generated and, taking into account the dispersal behaviour and the quality of the individual occurrences (patches), species-specific dispersal models were created, from which information on the degree of connectivity or isolation between the patches and thus on the structure of the metapopulations was obtained. The model also incorporated findings from marking experiments and other field trials conducted with *C. mercuriale*. By combining the dispersal model and the habitat model, areas were identified where planning and implementation of maintenance and development measures are both particularly urgent and have above-average prospects of sustainable success. For *Leucorrhinia pectoralis*, a cartographic documentation of the most important occurrence areas with a total area of a good 85 ha was carried out. This provides the basis for future detection and quantification of negative changes in the habitats of the species. An aerial photo analysis showed that serious negative habitat changes for the species can be detected within five years due to succession processes. Maintenance measures are therefore urgent and a permanent task. The project provided the impetus to design further research projects, for which funding has already been approved. Among other things, these serve to close the very clear knowledge gaps on the current distribution situation and habitat requirements of *Ophiogomphus cecilia* in southwest Germany. The methods developed in the project will thus find further use. At the same time, they represent a promising approach for similar questions in related fields. A synoptic evaluation of the results of the project will lead to concrete proposals for action for nature conservation administration, which are particularly needed for the fulfilment of the reporting obligation prescribed in the Habitats Directive (Article 17)."] (Authors/Deepl)] Address: Hunger, H., Institut für Naturschutz und Landschaftsanalyse (INULA), Wilhelmstraße 8, 79098 Freiburg, Germany. **19772.** Russell, D.B. (2004): Numerical and experimental investigations into the aerodynamics of dragonfly flight. Ph.D. thesis, Cornell Univ.: XV + 137 pp. (in English) ["Dragonflies are one of the most maneuverable of the insect flyers. They are capable of sustained gliding flight as well as hovering, and are able to change direction very rapidly. Exactly how they use their wings to generate aerodynamic forces remains unknown. A new method was developed for solving 2D incompressible viscous flow problems [46] in order to numerically model the uid response and forces generated by multiple flapping wings. This nite difference scheme uses the streamfunctionvorticity formulation on a regular grid, and handles multiple moving irregular boundaries. To test the usefulness of this model, dragonflies were

tethered to a vertical force sensor and lmed using high-speed digital video. This allowed the correlation of specific wing kinematics to the vertical force generated, so that when these kinematics are modeled numerically the forces calculated can be compared with experiment. The results include detailed descriptions of two distinct wing kinematic patterns, out of four observed. These kinematics resemble motions described by previous researchers in free flight conditions except for the phase between the fore and hind wings. The forces calculated from applying the numeric method to a 2D approximation of these movements compare well to measured forces. The differences seen can be attributed to 3D effects and to the simplified wing cross-section used in the model. We show that wing inertia is a large component of the instantaneous forces experienced by a dragonfly, and that the dragon y generates productive force during both the downstroke and the upstroke. The counterstroking behavior seen in free flight is shown to require less power than the in-phase motion observed in the tethered dragonfly, while producing the same average vertical force. We also show evidence suggesting that during hovering flight wing rotation is passively driven by fluid forces, while during forward flight rotation at the end of the downstroke is actively driven by the dragonfly. Finally, the effectiveness of applying such a 2D model to the problem is examined, and suggestions are made for future research to improve modeling ability.] Address: Russell, D., Theoretical and Applied Mechanics, Cornell Univ., Ithaca, New York 14853, USA

**19776.** Yamauchi, T. (2005): The research of dragonfly in city park in the Tamagawa River region. Toyama Biological Society, Yoshihama: 17 pp. [ "This survey was conducted over a short period of two years, and with a limited number of people and limited time, so there is still a sense of a general lack of information. There is an undeniable feeling that there is still a general lack of information. There are many other urban parks in the Tama River basin, and many smaller water bodies suitable for dragonflies exist, such as ponds in private gardens. There are many other urban parks in the Tama River basin, as well as many smaller water bodies suitable for dragonflies, such as ponds in private gardens. It is difficult to cover all such water bodies in a survey, and the findings obtained in this study are therefore intended to be positioned as a sample only. The survey was conducted in the same way as the survey of the other water bodies. However, we were able to identify more species of dragonflies than expected during this survey. In particular, large, highly migratory species, such as the Maltese dragonfly, [...] These dragonflies are thought to be migrating from one generation to the next in a network of small riparian areas scattered in densely populated residential areas. The dragonflies are thought to be migrating from one place to another, repeating generations. The reason why there have been fewer records of the yellow damselfly and the red damselfly compared to the red damselfly is that these damselflies are not active during the daytime. The reason why there have been fewer records of the Japanese oak and the Japanese oak may be that these are dusk-flying species that are not active during the daytime, and that surveys in the morning and evening at dusk have not been sufficient. Further scrutiny reveals that these dragonflies are not active during the daytime. Further examination would have increased the number of sites where these dragonflies have been recorded. Thus, this survey revealed the existence of dragonflies that make good use of the environment created by humans. However, they are However, their populations are still small and they are surviving in small numbers, barely clinging to the few remaining water bodies. The park environment used by local residents tends to prioritise convenience, and even if a pond or other water feature is built, it may not be safe for children to enter, or it may be infested with bowflies. Even if a pond or other water feature is built, it is not always managed in a way that it is protected by a concrete revetment, the water depth is kept very shallow and the sediments in the pond are constantly cleaned out. Many parks have adopted a management approach whereby the ponds are concrete-walled, the depth of the water is very shallow and the sediments are constantly cleaned. In fact, some of the parks surveyed were such water bodies. However, such water bodies can be described as barren environments from a biological point of view, as there is no food chain in the water. Even if a highly fecund species were to fly in and spawn in these waters, they would

not be able to reproduce. Even if a highly fecund species flies in and lays eggs, the larvae and larvae are removed if they are unlucky when they hatch. Very fast-growing cormorant dragonflies (from hatching). It is difficult for any but the very fast-growing *C. ubiculatus* (hatching to fledging in about 40 days) to breed in these water bodies. However, even if these water bodies were to be covered with fallen leaves and soil on the bottom and planted with water-parasitic plants such as gingerbread along the shore, the number of dragonflies that fly in and breed in shallow water would increase dramatically. The number of dragonflies that fly and breed, even at shallow depths, is thought to increase dramatically. Although pseudo, this would bring the area closer to the aforementioned water bodies with a rich dragonfly fauna. Furthermore, a park with such a modified water body can be created. The more parks with such modified water areas are created, the more small and medium-sized dragonfly species, which previously had difficulty in migrating over long distances, will increase. If the local government develops the area with these points in mind, not only dragonflies but also a rich biota will be formed, and local children will be provided with a place where they can easily come into contact with nature close at hand. The local community will be nurtured and enriched." ] <http://www.tokyuenvironment.or.jp/wp/wp-content/uploads/2011/02/5804c671e3-23fac4a4df619507c19c691.pdf>.

**19780.** Mikat, M. (2007): [Contribution to the ecology and ethology of Lestidae (Odonata, Lestidae)]. Støedoškolská odborná èinnost 2006/2007 obor 04 – Biologie: 63 pp. (in Czech) ["Conclusion: This paper summarizes the results of the study of populations using the mark-recapture method from 2006. The thesis deals mainly with the species *L. sponsa*, *L. virens*, *L. barbarus* and *S. fusca*. 2269 darters were tagged and 1154 recaptures were made. Approximately half of the tagged and recaptured individuals belonged to *L. sponsa*. The current abundance of individuals at the wetland was calculated using the Lincoln-Petersen index. This abundance has evolved over the study period. It is significantly (si 3-6 times) lower than the total population size Population size was calculated using the Schnabel index and in the Mark Program. The presence of the majority of females outside the wetland is likely to have the greatest influence on the skewed sex ratio at the wetland The probability of capturing individuals of all species was strongly dependent on time and the sex of the individual The observed population size is 4000 individuals for *L. sponsa*, around 700 individuals for *L. virens*, 500 individuals for *L. barbarus* and 400 individuals for *S. fusca*. Species of *Lestes* hornwort prefer generally dry wetlands. This preference is least pronounced in *L. sponsa*. *S. fusca* has been observed more in flooded wetlands. In *L. barbarus*, a preference for less overgrown sites was observed. Most of the recaptured individuals were caught at the marking site Some individuals, on the other hand, covered distances longer than 400 m. The most frequently migrating species was *S. fusca*, while the lowest proportion of migrations was found for *L. barbarus*. In the species *L. virens* and *L. sponsa*, females migrated more than males." **19781.** Ökologische Bildungsstätte Oberfranken (2007): Mögliche Auswirkungen des Klimawandels auf Moorbellen in Nordwestoberfranken (Wiederholungskartierung). Unveröffentlichtes Gutachten im Auftrag des Bundes Naturschutz, Nürnberg: 58 pp, maps. (in German) ["Extensive inventories of dragonfly species have been available from Northwest Upper Franconia since the end of the 1970s. In recent years, there have been increasing indications from various parts of the study area that the dragonfly species typical of north-western Upper Franconia in boggy waters and bogs (*Coenagrion hastulatum*, *Aeshna juncea*, *Somatochlora arctica*, *Leucorrhinia dubia*, *L. pectoralis*, *L. rubicunda*) have suffered severe population losses. The reasons for the population decline of the damselfly could also be climate change: Many studies already show that in recent years, due to the often unusually warm and dry weather, more Mediterranean dragonfly species have migrated to Germany and spread. Bog dragonflies, on the other hand, which have a boreal or Euro-Siberian distribution area, prefer a cooler climate and are therefore in principle threatened by climate change. The aim was to monitor the former and current occurrences of bog dragonfly species in northwest Upper Franconia, to check the condition of the habitats, to develop concrete protection measures for

the occurrences and to check whether a possible influence of climate change on bog dragonfly species is already detectable. The dragonfly population surveys of the Working Group Ecology Coburg of the German Nature Conservation Association, which started in the late 1970s, as well as numerous other dragonfly mappings in the Coburg, Kronach and Lichtenfels area, were evaluated in 2006 with regard to the occurrence of the bog dragonfly species *Aeshna juncea*, *Somatochlora arctica*, *Leucorrhinia dubia*, *L. pectoralis*, *L. rubicunda*. All current and former occurrences of these species as well as other peatland waters that appeared suitable (a total of 41 sample sites) were visited at least three times during the main flight period of the respective species in order to record imagines. The data from the new mapping of damselflies and their habitats were compared with the old data in order to identify population changes or range shifts. In 2006, 33 dragonfly species were recorded in the sample areas, including 13 Red List species. In total, at least one of the above-mentioned dragonfly species was found at 19 of the 41 sample sites investigated. The peat mosaic dragonfly was detected at 9 sites. Compared to the data from the period 1981 - 2003, the species has lost about 60 % of its sites. The sites where the species is found at altitudes up to 400 m above sea level are particularly affected by the decline. The Spear-throated damselfly was found in 16 sample plots in 2006. In comparison with the data from the period 1981 - 2003, a decline in the number of sites by approx. 50 % can be observed. The sites at altitudes of up to 350 m above sea level are particularly affected by the decline. There were 11 records of the damselfly. Half of the occurrences found since 1981 could no longer be confirmed. However, the loss of range was independent of altitude. The species could no longer be found at the 6 known sites of the Large Moss Damselfly, but one new record was found. The Northern damselfly was no longer found at the 5 known sites. The Arctic Emerald Damselfly was found away from one water body. *Crocothemis erythraea* was found for the first time at three ponds. At two typical peat ponds the damselfly was associated with the damselfly! At least for the Peat damselfly and Spear-spotted damselfly, there seems to be a connection with climate change, as the occurrences at climatically favoured altitudes below 400 m and 350 m a.s.l., respectively, were preferably no longer occupied. In the case of the other damselfly species, there is a strong suspicion that climate change plays a role in the sharp decline in occurrence. Concrete conservation measures were then proposed for the occurrences of the damselfly in order to stabilise the population and - if possible - also to enable dispersal or reintroduction." (Author/DeepL) [https://www.oekologische-bildungsstaette.de/medien/pdf/Moorlibellen\\_2007.pdf](https://www.oekologische-bildungsstaette.de/medien/pdf/Moorlibellen_2007.pdf)] Address: Ökologische Bildungsstätte Oberfranken, Beyer, S., Unteres Schloß, 96268 Mitwitz, Germany. ## 2008

**19783.** Blanckenhagen, B. von (2008): Nachuntersuchung 2008 zur Verbreitung der Großen Moosjungfer (*Leucorrhinia pectoralis*) in Hessen (Art der Anhänge II und IV der FFH-Richtlinie). Unveröffentlichtes Gutachten im Auftrag von Hessen-Forst FENA, AVENA: 31 pp. + Anhang- (in German) [As a species listed in Annexes II and IV of the Habitats Directive (92/43/EEC), *Leucorrhinia pectoralis* is of particular conservation and political interest. Thus, the state of Hessen (Germany) is also obliged to designate special protection areas for the dragonfly species and to monitor and document the status of the Hessian populations. The present species support concept provides an overview of the current population situation of *L. pectoralis* in Hessen as well as in the natural areas and districts of Hessen. The description of the ecology is followed by an explanation of general threats and the resulting general measures for the protection of the species. Within the framework of the report, surveys of the distribution of *L. pectoralis* were carried out in three regions in central and northern Hesse by means of field surveys. For the three occurrences - in the Burgwald, on the Lahnberge near Marburg and in the Reinhardswald - area-specific measures were finally proposed to improve the conservation status of the populations and to safeguard the population. Based on the studied water bodies and other suitable water bodies in the study areas, a regional network concept was developed to maintain as much habitat as possible for *L. pectoralis* and to enable the colonisation of new water bodies. In addition, the possibilities and limits of a supra-regional habitat network are presented and the importance of "stepping stone biotopes" is discussed. For the southern Hessian occurrences, some of which are located in FFH areas, the respective FFH baseline data collections were evaluated with regard to proposed measures for the conservation and development of *L. pectoralis*. Translated with [www.DeepL.com/Translator](http://www.DeepL.com/Translator) (free version)] Address: von Blanckenhagen, B., Kaffweg 8, 35039 Marburg, Germany. E-mail: benno.v.blanckenhagen@web.de

**19786.** Schiel, F.-J. (2008): Die Libellenfauna der Kiesgrube Reiselfingen. Veränderungen zwischen 1993 und 2007. *Mercuriale* 8: 37-44. (in German) ["Species spectrum and population changes of the dragonfly fauna of the Reiselfingen gravel pit (MTB 8116) are presented for the period between 1993 and 2007. The Reiselfingen gravel pit, which

is operated on a large scale by dry mining, is located in the west of the Baar nature reserve at 730 m above sea level, on the northern edge of the Wutach gorge. Over a 15-year period of observation, the number of dragonfly species increased from 18 in 1993 to 30 in 2005-2007; the number of certain to probably native dragonfly species increased from 14 to 19 during this period. The increase in species numbers is attributed to a combination of three factors: (1) a very slow, successive saturation of the species range due to a low number of stillwaters in the surrounding area, (2) a spread of heat-loving species due to climate warming, and (3) the successive increase in the range of waters after 1993 due to the creation and maturation of conservation waters. The number of species records continued to rise between 2002 and 2007. At the same time, however, the continuities and population sizes of several marsh species in particular declined again significantly; this is attributed to the increasing shading of shallow riparian and alternating water zones as a result of woody growth." **19789.** Bradley, T.J.; Briscoe, A.D.; Brady, S.G.; Contreras, H.L.; Danforth, B.N.; Dudley, R.; Grimaldi, D.; Harrison, J.F.; Kaiser, J.A.; Merlin, C.; Reppert, S.M.; VandenBrooksk, J.M.; Yanoviak, S.P. (2009): Episodes in insect evolution. *Integrative and Comparative Biology* 49(5): 590-606. (in English) ["Synopsis: This article derives from a society-wide symposium organized by Timothy Bradley and Adriana Briscoe and presented at the 2009 annual meeting of the Society for Integrative and Comparative Biology in Boston, Massachusetts. David Grimaldi provided the opening

presentation in which he outlined the major evolutionary events in the formation and subsequent diversification of the insect clade. This presentation was followed by speakers who detailed the evolutionary history of specific physiological and/or behavioral traits that have caused insects to be both ecologically successful and fascinating as subjects for biological study. These include a review of the evolutionary history of the insects, the origins of flight, osmoregulation, the evolution of tracheal systems, the evolution of color vision, circadian clocks, and the evolution of eusociality. These topics, as covered by the speakers, provide an overview of the pattern and timing of evolutionary diversification and specialization in the group of animals we know as insects." (Authors) The paper includes references to Odonata.] Address: Bradley, T.J., Dept of Ecology & Evolutionary Biology, Univ. of California Irvine, Irvine, CA 92697-2525, USA. E-mail: tbradley@uci.edu

**19790.** Cano-Villegas (2009): Expansión de *Trithemis kirbyi* Sélys, 1891 (Odonata: Libellulidae) en la provincia de Málaga (sur de la Península Ibérica). Boletín de la Sociedad Entomológica Aragonesa 44: 589-572. (in Spanish, with English summary) ["*T. kirbyi* is recorded, for the first time, from Ciudad Real (first record from Castilla La Mancha) and Huelva (Andalusia). The presence in the province of Badajoz (Extremadura) is also confirmed. The increment of its distribution range to inland and the Atlantic coast is shown with this new data." (Authors)] Address: Cano-Villegas, F.-J., C/ Montemayor, 4 1º-2; 14003 –Córdoba, Spain. Email: fjcanovi2@hotmail.com

**19791.** Koch, B.; Wildermuth, H.; Walter, T. (2009): Einfluss der Habitateigenschaften auf das Verbreitungsmuster von *Coenagrion mercuriale* an einem renaturierten Fließgewässer im Schweizer Mittelland (Odonata: Coenagrionidae). Libellula 28(3/4): 139-158. (in German, with English summary) ["Distribution pattern of *C. mercuriale* and habitat characteristics on a revitalized stream in the Swiss Midlands — Only few and isolated populations of the Southern Damselfly exist in Switzerland and the species is considered as critically endangered. The recent discovery of a hitherto unknown population of *C. mercuriale* on a revitalized stream in the Canton of Zurich caused a study to be made on the size and the distribution pattern of the population along a heterogeneously structured 2.15 km-stretch. In summer 2007, the abundance of *C. mercuriale* was recorded at 215 sections and data on physical parameters were collected. The results of statistical analyses showed that the distribution pattern of *C. mercuriale* was significantly affected by the width of the watercourse, depth of the water, cover of the water vegetation, cover and width of the riparian vegetation and cover by trees higher than three metres. The composition of the riparian vegetation that could be classified into six different groups using a cluster analysis also exhibited an effect on the distribution. *C. mercuriale* preferred sites with relatively wide and deep water, luxuriant aquatic vegetation, wide intermittent but jaggy riparian vegetation and little cover by trees shading the water surface. Riparian vegetation that was mainly composed of *Carex* spp., *Lythrum salicaria* or *Phalaris arundinacea* was most densely colonized by *C. mercuriale*. In contrast, sections overgrown predominantly by *Filipendula ulmaria* and *Epilobium hirsutum* were generally avoided. Additionally, data on the local dragonfly fauna were collected and 14 streams in the neighbourhood of the study site were examined for their suitability for colonization by *C. mercuriale*. In total 21 Odonata species were recorded. Maintenance of the habitat by patchy clearance of dense riparian vegetation, aiming at the promotion of the

local population, was conducted in the frame of a conservation programme in late 2007 and early 2008. Censuses carried out during the flying season 2008 showed that the measures adopted had a positive effect on *C. mercuriale*." (Authors)] Address: Koch, Bärbel, Via Grütti 21, 6855 Stabio, Switzerland. E-mail: baerbel.koch@hotmail.com

**19792.** Lockwood, M. (2009): Els odonats del PP.NN de l'Alt Pirineu 2009. Parc Natural de l'Alt Pirineu. Generalitat de Catalunya, Departament de Medi Ambient i Habitatge. Oxygastra, Grup d'estudi deis odonats de Catalunya: 40 pp. (in Catalan, with English summary) ["In 2009, the odontological surveys were repeated in the PP.NN of the Alt Pirineu, which had started in 2007 and continued in 2008. In 2008 it became clear that the set of ponds in the Baciver area Pudo-Garrabea has a high specific wealth of odonts; in 2009 it was possible to verify that this area really is exceptional within the framework of the central Pyrenees, since surveys in the central and eastern sectors of the PP.NN of the Alt Pyrenees at the headwaters of the rivers Noguera de Cardós and Noguera de Vallferrera have revealed that these last sectors harbor a very impoverished odontofauna. In the lakes of Guerosso and Flamicella no odonate was observed, while in Guiló, Romedo, Mariola and Montarenyó only detect *Aeshna juncea*, the only species that seems to be well distributed throughout the high area of the park. The explanation of this phenomenon is neither simple nor entirely clear. Obviously, the western sector of the natural park has a series of habitats very suitable for odonates – a profusion of small ponds with good growth of macrophytes and vertical vegetation (which the adults use as watchtowers and through which the larvae climb when metamorphosing). On the other hand, in the Aiguamoll de Guiló, as an example, there is only one pond/wetland, which is very enclosed between the mountains that surround it, while in the ponds of Romedo or Mariola there are few macrophytes and a general absence of the vertical vegetation. The grazing load seems to be greater outside the western sector: in Baciver there are flat meadows where cows and horses can freely roam, while in places like Guiló the cattle tend to congregate around the only pond there has And when the waters of the pond are not very deep, the animals can enter to graze the vegetation, muddying the water and trampling the vertical stems that many odonate species need. But we also think it is significant that the Baciver sector is very close to the Aran Valley, an excellent natural corridor through which Eurosiberian species such as *Leucorrhinia dubia* will have passed to colonize the nearest natural park areas ; the rest of the park, on the other hand, is much more isolated from this entrance route and on the south face of the great barrier of the axial Pyrenees. Possibly, however, *L. dubia* is on the way to expansion or regression, since there are no studies that confirm or deny if this taxon was present in the natural park previously or if in the past there were more diverse odonate communities in the central sectors and oriental However, during fieldwork in 2009, it was possible to establish what could be an oviposition site of *Cordulegaster bidentata* near Burg, and the presence of a total of 29 species in the natural park has been confirmed. However, it has not been possible to find *Leucorrhinia pectoralis*, cited once in 1992, and it is given as extinct in Catalonia. In addition, the counts of the Odonats Bioindicadors project were carried out in the Noguera de Cardós river, and it is expected to continue with these counts in the coming years." **19793.** Maibach, A. (2009): Gestion intégrée des éléments naturels et de la biodiversité en forêt secondaire (forêts de la région de Suchy, canton de Vaud, Suisse). III. Suivi de la colonisation par les libellules (Insecta, Odonata) d'un bassin aménagé de crues aménagées de manière naturelle. Bulletin de la Société Vaudoise des Sciences Naturelle 91(3): 217-233. (in French, with English summary) ["This pond was dug at the beginning of 1992 near the village of Suchy, with the aim of buffering the flow of water coming from the surrounding forested area. The development of dragonfly populations was followed over 5 years (1993-1997) from the second season following the digging of the pond. Our study shows a very rapid development of populations with 27 species present at the end of the survey (the sixth season after digging). However, the proportion of the autochthonous species (those with complete development in the site) develops more slowly, from 43% during the second year post-creation until 81% during the sixth year. Colonisation follows in the classic manner with the quick appearance of pioneers (generalist species) and the progressive arrival of specialists, whose proportion reaches 45% at the end of the survey. Colonisation of the Suchy pond appears to be relatively quick in comparison to other ponds in the vicinity. Favourable factors for this colonisation and for the resulting biodiversity, particularly in terms their contribution to safeguarding rare or threatened species, are analysed and discussed." (Author)] Address: Maibach, A., Bureau d'études en environnement A. Maibach Sàrl, La Poya 10, CP 99, 1610 Oron-la-Ville, Switzerland. Email: alain.maibach@amaibach.ch

**19794.** Nandy, S.; Babu, R. (2009): On a collection of dragonflies (Odonata: Anisoptera) from Andaman and Nicobar islands. Rec. zool. Surv. India 109(4): 35-51. (in English) ["The paper deals with some collection of 15 species of Anisoptera from Andaman and Nicobar Islands. In this present study, *Neurothemis intermedia atlanta* Ris and *Tamea basilaris burmeisteri* Kirby have been recorded for the first time from Andaman & Nicobar Islands (South Andaman), Also *Orthetrum pruinatum neglectum* (Rambur) is recorded newly from Andaman Islands (North and South Andaman) and *Trithemis aurora* (Burmeister) is recorded newly from Nicobar Islands. Distributions of *Potamarcha congener* (Rambur) from North Andaman, four species [*Crocothemis servilia servilia* (Drury), *Diplacodes trivialis* (Rambur), *Lathrecista asiatica asiatica* (Fabricius) and *Orthetrum sabina sabina* (Drury)] from Middle Andaman and four species [*Diplacodes trivialis* (Rambur), *Orthetrum sabina sabina* (Drury), *Neurothemis fulvia* (Drury) and *Tholymis tillarga* (Fabricius)] from Little Andaman are newly recorded. A consolidated list of 44 species of Anisoptera, so far recorded from these Islands is provided along with distribution within Andaman & Nicobar Islands." (Authors)

**19795.** "The history of odonatological exploration of the archipelago is reviewed and the 44 known Anisoptera species are listed with reference to the islands where they occur (North Andaman, Middle Andaman, South Andaman, Little Andaman, Nicobar). *Neurothemis intermedia atlanta* and *Tamea basilaris burmeisteri* are new for the archipelago. *Orthetrum pruinatum neglectum* was known from Nicobar but it is new for N & S Andaman, whereas *Trithemis aurora* was known from all Andaman isls and it is for the first time recorded from Nicobar." **19796.** Padilla, D.P.; Gonzalez-Castro, A.; Nieves, C.; Nogales, M. (2009): Trophic ecology of the Southern Grey

Shrike (*Lanius meridionalis*) in insular environments: the influence of altitude and seasonality. Journal of Ornithology 150: 557-568. (in English) ["The seasonal diet and prey selection of the Southern Grey Shrike (*Lanius meridionalis*) was studied in two different insular habitats: shrub environments of the Canary Islands in coastal and high mountain zones. We measured, in each season, food availability and prey size in order to determine prey size selection of shrikes along an altitudinal gradient. Moreover, we compared the diet patterns observed with those documented on the continent, to determine if Southern Grey Shrikes in the islands' high mountain zone (which has a continental climate) showed seasonal diet variation similar to those in northern continental areas. We analysed a total of 1,139 shrike pellets collected in 1 year and identified 10,179 prey items. Numerically arthropods (91%), and in terms of biomass lizards (70%) were the main prey consumed by the shrikes. The proportions of the main prey items differed significantly between seasons and habitats. Diet in the coastal areas was less variable than in the high mountain zone. The greater seasonal climatic variation in the high mountain zone was associated with diet patterns similar to those found in some northern continental areas, such as the Iberian Peninsula and southern France. Finally, shrikes selected the largest prey in the high mountain habitat. This suggests that foraging behaviour in this species is related to climatic conditions, as the biggest and most profitable prey were consumed in the most harsh habitats." (Authors) The diet includes "Odonata".] Address: Padilla, D.P., Island Ecology and Evolution Research Group (IPNA-CSIC), Avda. **19797.** Rytuba, J.J.; Hothem, R.L.; May, J.T.; Kim, C.S.; Lawler, D.; Goldstein, D. (2009): Environmental impact of the Contact and Sonoma mercury mines on water, sediment, and biota in Anna Belcher and Little Sulphur Creek watersheds, Sonoma County, California. U.S. Geological Survey Open-File Report 2008-1381 [http://pubs.usgs.gov/of/2008/1381/]: 76 pp. (in English) ["Conclusions: Calcines and waste rock eroded from the Contact and Sonoma mines have contributed Hg-enriched sediment to Anna Belcher and Little Sulphur Creeks. A significant amount of calcines still remains at the Contact Mine, and natural cementation of calcines by magnesite only partially mitigates erosion of the calcines. The calcines have very high Mg concentration, 14-15 % because of the magnesite cement, but relatively low Hg concentrations, 3.7 to 65 ppm, (one sample with 200 ppm Hg exceeded the range). Mercury concentration in the calcines increases with decreasing grain size, resulting in about 350% higher Hg concentration in the finest grain-size fraction (<20 μm) as compared to the largest grain-size fraction (2,830 μm). Unusually high concentrations of tellurium, up to 2.8 ppm, are present in the calcines. The Sonoma Mine calcines are not cemented, but are covered by vegetation that serves to limit erosion and the release of Hg-enriched sediment. The Hg concentrations in the Sonoma Mine calcines are relatively low (14.8-91.4 ppm). Mercury concentration increases with decreasing grain size, but the highest Hg concentration occurs in the coarsest grain-size fraction, indicating that HgS remains encapsulated in the larger fragments. Calcines from both mines have elevated concentrations of Co, Cr, and Ni that reflect the serpentinite host rock. Concentrations of Hg T and MMeHg in waters sampled at and downstream from the Contact and Sonoma mine areas are dependent on flow conditions. Highest concentrations occur under high-flow conditions (104-13,900 ng/L for Hg T, and 0.046-17 ng/L for

unfiltered MMeHg). The highest concentrations of Hg T and MMeHg occurred in waters in a side tributary to Anna Belcher Creek that receives runoff from the Sonoma mine area. Below the mine area, Hg T concentrations in water samples from Anna Belcher and Little Sulphur Creeks were relatively low, meet the 50 ng/L USEPA criterion (USEPA, 1999), and are near or below the water-quality objective of 12 ng/L. The highest concentration of MMeHg occurs in pond water samples from above the Sonoma Mine workings. MMeHg concentration in samples from Anna Belcher and Little Sulphur Creek is relatively low. Methylation of mercury is highest in the pond, as indicated by the MMeHg in sediment, and relatively low in the lower reach of Anna Belcher Creek. Anna Belcher Creek flows through the north side of the Contact Mine calcine pile and, during storm events, Hg-enriched sediment is released into the creek. This release of Hg-enriched sediment results in variable but always-elevated concentrations of Hg (4.7 to >100 ppm) in the bed-load sediment downstream from the mine area. Hg-enriched sediment from Anna Belcher Creek increases the Hg concentration of sediment in Little Sulphur Creek for at least 2 km downstream from the confluence. The highest concentration of MMeHg in the invertebrate samples was in water boatmen (Corixidae) samples from the Sonoma Mine pond. The MMeHg concentration was 16 times higher than mean values found in a comparable taxon, water striders (Gerridae), from a reference site. The data for biota from the Sonoma pond are consistent with the high percentage of MMeHg found in the pond sediment, which indicates a high level of MMeHg production in the pond environment. In Anna Belcher Creek downstream from the mine area, MMeHg concentrations in dragonfly larvae (Aeshnidae, Libellulidae, and Cordulegastridae) samples were much higher than those in Aeshnidae samples from the reference site. The highest value recorded for the Cordulegastridae samples from the creek at the Twin Falls site was 13 times higher than the reference value. No statistical difference was noted between rainbow trout samples from the two Anna Belcher sites, but the concentrations from both sites were statistically higher than those in brown trout from a reference site. The biota data indicate that the Hg-enriched sediment released from the Contact and Sonoma mines and then methylated in both pond and stream environments is bioaccumulated in both invertebrates and fish." **19807.** Chovanec, A. (2013): Bewertung der Renaturierungsmaßnahmen an der Krems (OÖ) im Bereich Ansfelden / Oberaudorf aus libellenkundlicher Sicht. Im Auftrag

des Amtes der Oberösterreichischen Landesregierung, Abt. Oberflächengewässernwirtschaft: 52 pp. (in German) ["Conclusions The measures carried out on the lower Krems in the Ansfelden / Oberaudorf area resulted in an increase of the habitat availability relevant from a dragonfly point of view. The species spectrum detected includes rhithral and potanal species of the water type-specific dragonfly associations, but the occurrence of the most indicative species is limited to only a few sections within the study area. The section (D) with the highest number of individuals also fell dry from August 2013 onwards. The study area has a high potential for dragonflies, and the following measures are recommended to stabilise and strengthen the populations of the water-type-specific species: Increase the structural offer in the main channel of the Krems: Demand the development of gravel banks (cf. e.g. WILDERMUTH & KURY 2009), such as upstream of the inflow area into the left bank tributary (Fig. 23). Increased dotation of the left-bank tributary and transformation into a permanently flowing tributary through hydraulic engineering measures (instead of two "water bodies" - a perennial backwater area and a temporarily flowing section)." **19808.** Kang, S.R.; King, S.L. (2013): Effects of hydrologic connectivity on aquatic macroinvertebrate assemblages in different marsh types. Aquat. Biol. 18: 149-160. (in English) ["Hydrologic connectivity can be an important driver of aquatic macroinvertebrate assemblages. Its effects on aquatic macroinvertebrate assemblages in coastal marshes, however, are relatively poorly studied. We evaluated the effects of lateral hydrologic connectivity (permanently connected ponds: PCPs; temporary connected ponds: TCPs), and other environmental variables on aquatic macroinvertebrate assemblages and functional feeding groups (FFGs) in freshwater, brackish, and saline marshes in Louisiana, USA. We hypothesized that (1) aquatic macroinvertebrate assemblages in PCPs would have higher assemblage metric values (density, biomass, Shannon-Wiener diversity) than TCPs and (2) the density and proportional abundance of certain FFGs (i.e. scrapers, shredders, and collectors) would be greater in freshwater marsh than brackish and saline marshes. The data in our study only partially supported our first hypothesis: while freshwater marsh PCPs had higher density and biomass than TCPs, assemblage metric values in saline TCPs were greater than saline PCPs. In freshwater TCPs, long duration of isolation limited access of macroinvertebrates from adjacent water bodies, which may have reduced assemblage metric values. However, the relatively short duration of isolation in saline TCPs provided more stable or similar habitat conditions, facilitating higher assemblage metric values. As predicted by our second hypothesis, freshwater PCPs and TCPs supported a greater density of scrapers, shredders, and collectors than brackish and saline ponds. Aquatic macroinvertebrate assemblages seem to be structured by individual taxa responses to salinity as well as pond habitat attributes." **19813.** Consatti, G.; Martins dos Santos, D.; Renner, S.; Périco, E. (2014): Presença de Odonata em áreas preservadas e não preservadas nas matas ciliares do Rio Taquari, RS. *Revista de Iniciação Científica da ULBRA* 12: 57-65. (in Portuguese, with English summary) ["In nature, the riparian forest acts as filters and protection against erosion, serving also as shelter for fauna. The Odonata order is composed by organisms which are sensitive to environment changes, its life cycle is aquatic and terrestrial, doing so, these insects can be potential bioindicators. The main goal of this project was to compare the odonate richness and abundance, in preserved and degraded riparian zones along the Taquari River margins. Were collected 81 specimens, belonging to 24 species. We found a significant difference in the abundance and richness, between the preserved and degraded areas. We suggest that such difference can be attributed to the better vegetation conditions found on the preserved areas, which consequently increases the biodiversity." **19814.** Dalecky, V. (2014): The influence of forest management to forest populations of dragonflies *Cordulegaster* (Odonata: Cordulegastridae) in selected Moravia and Silesia region. *SilvaNet* 2014: 26-27. (in Czech) ["From the preliminary results [...] it can be concluded that, despite the often intensive management, the populations of forest rheophilic dragonflies are not extremely threatened. The most common risk arises from clear-cut mining or the processing of calamitous mining that directly connects to watercourses. If riparian vegetation with a minimum width of approx. 2 m is preserved, the biggest negative effect, the washing of the surface layer of soil into water courses, is prevented. The nature of the riparian vegetation is most suitable diverse with a mixture of trees, shrubs and herbaceous undergrowth of various ages, which prevents the aforementioned negative influence." **19815.** Ezquerro, C.Z.; Asso, T.L.; Rodríguez Saldaña, J.I.; Martínez, E.; López, R.Z.; Marín, A.C. (2014): Libélulas y Caballitos de Agua de La Rioja (Odonata). Colección: Ciencias de la Tierra, nº 33: 362 pp. (in Spanish) ["Odonata are a very ancient group, whose morphology has changed very little over time for more than 200 million years. Moreover, they form a worldwide assemblage of about 6,000 species. A tiny group compared to the specific richness of Lepidoptera (175,000) or Coleoptera (350,000). But curiously, odonates have become a group of animals of great interest due to their beauty, their harmlessness and for being one of the few orders of insects that does not include any pest species, and which, on the contrary, has very positive effects on humans, by ridding us of a large number of insects that come into conflict with us (mosquitoes, for example) or with our

agriculture and livestock. In La Rioja, 49 of the 77 species of odonates that inhabit the Iberian Peninsula have been found (23 damselflies and 26 dragonflies). The odonata-fauna of La Rioja is mainly Mediterranean, with a small component of Nordic species that live mainly in the Sierra, and another small number of elements of African origin that live in the Ebro Valley. With this monograph, magnificently illustrated with photographs of the species, our aim is to take a step forward in the knowledge of the biodiversity of La Rioja; to open a new door to more specific studies; and above all, to provide the first support to anyone interested in identifying, knowing where they live, when they fly and what problems the Odonata currently living in our region are experiencing." **19816.** Fan, T.; Zhang, R.; Fan, F.; Liu, Z.; Xiong, J. (2014): A water surface small target detection approach inspired by dragonfly vision mechanism. *WIT Transactions on Engineering Sciences* 94: 151-157. (in English) ["Weak and small target detection technique is widely used in military and industry applications. The targets are weak and small in the image when targets are far from the imaging system. Under this complex condition, the image has very low SNR and it is difficult to detect the targets. On this situation, a weak and small target detection approach based on dragonfly compound eye is proposed in this paper. Dragonfly compound eye has obvious characteristics of polarized light, and it can detect the surface of water and the targets on water accurately. The new method uses the polarization characteristics of dragonfly compound eye to get the polarization image of targets, and then completes the weak small target detection. The experimental data shows that this new target detection method has advantages of high precision and small false alarm rate." (2014): Observações sobre a criação de ninfas de *Brechmorhoga Kirby, 1894* (Insecta: Odonata) em condições artificiais. *Revista Brasileira de Biociências* 12(4): 206-209. ["Observations on rearing of *Brechmorhoga Kirby, 1894* (Insecta: Odonata) nymphs under artificial conditions). The goal of this work was to contribute to the improvement of a rearing method for *Brechmorhoga* that would allow a greater success in adult emergence. We sampled a total of 300

*Brechmorhoga* nymphs in association with a macrophyte in the Been stream, southern Amazonas state, Brazil. Out of the 300 sampled nymphs, only 60 were appropriate for rearing outside their natural habitat, as they were in the penultimate and last developmental stages. The tested methods for nymph rearing were: no substrate, artificial substrate (filter paper strips) and natural substrate (macrophyte). All methods were tested in laboratory and greenhouse. All adults obtained were recorded in the greenhouse vivaria with macrophyte. The results of the log-rank test showed a significant difference between treatment with natural substrate in laboratory and in greenhouse; and between treatments without substrate and with natural substrate in laboratory. We concluded that the rearing of *Brechmorhoga* under artificial conditions was more efficient in the presence of macrophytes in greenhouse vivaria." species of adult Odonata are preliminarily described and illustrated anatomically. The ovaries extend from the anterior margin of the mesopostscutum under the apodeme to the 8th abdominal segment. Those occupy the greater part of the abdominal cavity, and unite at the gonopore in ventral side of the 8th segment. The ovarioles open dorsally and sequentially into each calyx, previously known as a part of the lateral oviduct. The calyces store many matured eggs, and the lateral oviducts open into the common oviduct at the posterior part of the 8th abdominal segment. Each entire ovary is covered with a thin membrane, which is probably presumed to be homologous with the peritoneal sheath as is known in adults of some dipteran species in structure. The ovarioles are counted one by one in 15 species based on fresh material. The numbers of ovarioles per individual is range from 166 to 256 in *Ischnura senegalensis* (Rambur, 1842) and 568 up to 1459 in *Orthetrum albistylum* (Brauer, 1848). The numbers also usually vary in each species, however, those are more stable in number in such groups as Zygoptera and Libellulidae than the others." **19822.** Lorenzo-Carballa, M.O.; Cordero-Rivera, A. (2014): Odonates. Dragonflies and Damselflies. In: Pablo Vargas, Rafael Zardoya (Eds): The tree of life. Publisher: Sinauer Associates: 353-363. (in English) ["Odonates currently include about 30 families and almost 6000 species, found on all continents except Antarctica. The relationships between the families based on DNA sequences have in most cases proven to be inconsistent with previous classifications, such as the sister relationship between Zygoptera (damselflies) and Epirocta (primarily dragonflies). The results of the most recent phylogenetic analyses, based on both molecular and morphological characters, have helped to clarify some of these relationships, although debate continues over the position of certain groups, such as the Epiophlebiptera. The fossil record indicates the appearance of the Odonata in the Late Carboniferous, with a wide diversification in the Permian and finally the evolution of the groups extant today in the Jurassic and Cretaceous. Their body structure, as well as certain lifestyles observed in extant species, appear to have changed little since then. They present some morphological characteristics that are unique among insects, of which the most notable is the presence of secondary male genitalia separate from the testes, a feature that determines a unique reproductive behavior involving two points of contact between male and female during copulation, and makes them an appropriate group to test new theories on sexual conflict. One question of debate is whether the polychromatism observed in many species is an ancestral character, a question that will be answered with the development of robust phylogenies. Among the most successful speciation mechanisms in this group are those related to the selective pressures exerted by predatory ray-finned fishes, with very remarkable examples in some genera." **19829.** Abdul Hamid, M.F. (2016): Aerodynamic models for insect flight. Ph.D. thesis, Univ. of Manchester: 164 pp. (in English) ["Numerical models of insect flapping flight have previously been developed and used to simulate the performance of insect flight. These models were commonly developed via Blade Element Theory, offering efficient computation, thus allowing them to be coupled with optimisation procedures for predicting optimal flight. However, the models have only been used for simulating hover flight, and often neglect the presence of the induced flow effect. Although some models account for the induced flow effect, the rapid changes of this effect on each local wing element have not been modelled. Crucially, this effect appears in both axial and radial directions, which influences the direction and magnitude of the incoming air, and hence the resulting aerodynamic forces. This thesis describes the development of flapping wing models aimed at advancing theoretical tools for simulating the optimum performance of insect flight. Two models are presented: single and tandem wing configurations for hawk moth and dragonfly, respectively. These models are designed by integrating a numerical design procedure to account for the induced flow effects. This approach facilitates the determination of the instantaneous relative velocity at any given spanwise location on the wing, following the changes of the axial and radial induced flow effects on the wing. For the dragonfly, both wings are coupled to account for the interaction of the flow, particularly the fact that the hindwing operates in the slipstream of the forewing. A heuristic optimisation procedure (particle swarming) is used to optimise the stroke or the wing kinematics at all flight conditions (hover, level, and accelerating flight). The cost function is the propulsive efficiency coupled with constraints for flight stability. The vector of the kinematic variables consists of up to 28 independent parameters (14 per wing for a dragonfly), each with a constrained range derived from the maximum available power, the flight muscle ratio, and the kinematics of real insects; this will prevent physically-unrealistic solutions of the wing motion. The model developed in this thesis accounts for the induced flow, and eliminates the dependency on the empirical translation lift coefficient. Validations are shown with numerical simulations for the hover case, and with experimental results for the forward flight case. From the results obtained, the effect of the induced velocity is found to be greatest in the middle of the stroke. The use of an optimisation process is shown to greatly improve the flapping kinematics, resulting in low power consumption in all flight conditions. In addition, a study on dragonfly flight has shown that the maximum acceleration is dependent on the size of the flight muscle." **19830.** Adu, B.W.; Kemabonta, K.A.; Ogbogu, S.S. (2016): Composition and abundance of odonates at Alatori stream, south-west Nigeria. UNILAG Journal of Medicine, Science and Technology 4(1): 96-110. (in English) ["Odonata are sensitive to human disturbance both as adults that are on wings and as larvae that are aquatic. This attribute suggests their usage as assessment tool for determination of human disturbance within the ecosystem. Alatori stream in Akure Forest Reserve was studied from May 2008 to April 2010 in order to determine the water quality and abundance of Odonata species of the stream. Adults and larvae specimens were sampled throughout the sampling period. A total of 767 adult specimens and 108 larvae were collected. Only

45.4% of the penultimate and ultimate larvae collected eclosed (emerged) to teneral adults. The composition of Odonata families occurring at the stream showed that Libellulidae was the highest (281) followed by Chlorocyphidae (158) while the lowest was Megapodagrionidae (5). The occurrence of members of the families Megapodagrionidae, Chlorocyphidae and Calopterygidae indicates that the stream ecosystem can sustain species with narrow niches. Seven physico-chemical variables: temperature (water and ambient), pH, turbidity, electrical conductivity, dissolved oxygen, water current velocity and depth of the stream were examined and analysed. Analysis of variance (ANOVA) result revealed that conductivity, temperature and water depth played a major role in determining the community structure of odonate assemblage in the stream. The mean ( $\pm$ ) standard deviation of electrical conductivity ( $184.25 \pm 6.37 \mu\text{S/cm}$ ) of the water was indicative of an unpolluted freshwater system with stable habitat structure. The study suggests that the water quality of Alatori stream is healthy and can sustain Odonata and other fauna within the ecosystem." (Authors)] Address: Adu, B., Dept of Biology, Federal Univ. of Technology, Akure, Ondo State, Nigeria

**19831.** Adu, B.W.; Kehinde, K.K.A.; Ogbogu, S.S. (2016): Monitoring of environmental disturbance using abundance and distribution of red-vein and dark-vein species of genus *Trithemis* (Odonata: Libellulidae). *Zoologist (The)* 14: 31-36. (in English) ["Environmental changes as a result of human disturbance in Akure Forest Reserve were investigated for a period of twelve months using abundance and diversity of Red-vein and Dark-vein *Trithemis* species as an assessment tool. Four study sites (AGO, ALA, APO, and ROD), based on type of water bodies and landscapes, were identified and selected for this study. Diversity indices and Dragonfly Biotic Index (DBI) were used to compare the assemblages of the odonate species in the study-sites. A total of 199 specimens were collected out of which 121 and 78 were Red-vein and Dark-vein species respectively. Members of this genus differ in their dispersal capacities and coloration. Based on Dragonfly Biotic Index (DBI) used and the pattern of distribution of *Trithemis* (Red-vein and Dark-vein species), in the forest ROD and APO were the least disturbed site with the highest DBI value of 9. AGO with DBI value of 2 was the most disturbed site. The pattern of distribution of this species revealed that Akure Forest Reserve is degenerating, a situation that could lead to loss of biodiversity if urgent conservative measures were not put in place." (Authors) The study includes the following species: *Trithemis aenea*, *T. annulata*, *T. arteriosa*, *T. hecate*, *T. kirby*, *T. grouti*, *T. furva*, *T. imitata*] Address: Adu, B.W., Dept of Biol., Federal Univ. Technology, Akure, Ondo State, Nigeria. Email: williamsadubabs@yahoo.com

**19832.** Allison, S.E. (2016): Variation in female mating behavior and success in the damselfly, *Calopteryx maculata*. M.Sc. thesis, Dept of Biology, James Madison Univ.: VI, 25 pp. (in English) ["Traditionally, the study of sexual selection has focused on the evolution of elaborate male traits and how they enhance the ability to out-compete other males directly (access to females) and indirectly (access to desirable territories or resources). Female trait studies have focused most on evolved preferences for male traits. While we know much about how sexual selection acts on males, there is a deficit of equivalent study on females. In insects, including damselflies, male size and pigmentation are positively correlated with fat reserves and immune abilities, and therefore with male competitive ability. Here, we show that phenotypic variation that has been well-documented in

males of the Ebony jewelwing damselfly, *Calopteryx maculata*, is also present in females of the species. We measured female mating success and behaviour of *C. maculata* at Smith Creek in Rockingham County, Virginia. Males were marked with multiple colours of fluorescent powder that was transferred to females when mating. Uniquely-numbered females were digitally scanned and repeatedly observed throughout the summer. We determined that there is significant variation in female mating frequency, wing pigmentation, size, and shape. The study of trait variation within females, and thus the opportunity for selection to act on those traits, is essential in understanding how evolution on females may have contributed to sex differences, and may change the way we think about the role of females in sexual selection." **19833.** Arimoto, S.; Sakiko Ando, S.; Kmeil, A.; Nomura, T.; Hara, Y.; Nakashima, A. (2016): Changes of the diversity of dragonfly in the 1998–2015 in Mohko–Fudodani, Kainan City, Wakayama Prefecture, central Japan. [Nankin creatures] 58(1): 56-62. (in Japanese, with English title) ["The changes in the dragonfly fauna observed between 1998 and 2015 in the Menzhi Fudo Valley, where a small dragonfly pond was created in 1998, were summarised as follows The following is a summary of the changes in the dragonfly fauna observed between 1998 and 2015 in the Menzhi Fudo Valley, where a small dragonfly pond was created in 1998. (1) In the Mengzifudo Valley, 65 species of dragonflies in 9 families were observed during the period. (1) 65 species of dragonflies in nine families were observed in the Menzhi Fudo Valley. The number of these species increased rapidly after the construction of the dragonfly ponds, but they remained established. The number of dragonfly species increased rapidly after the construction of the dragonfly ponds. The number of dragonfly species observed in the study area was 65 in 9 families during the study period. Among the dragonfly species identified, eight species are on the national Red List and 15 species are from the Japanese Red List. (2) Among the dragonfly species identified, eight species on the national Red List and 15 species on the Wakayama Prefecture Red List were included. The number of dragonfly species identified included eight national Red List species and 15 Wakayama Prefecture Red List species. Some of these species were identified after the construction of the dragonfly ponds and became established. The number of dragonfly species included in the list was 8 national species and 15 species from the Wakayama Prefecture Red List. The majority of species that were present before the construction of the dragonfly ponds continued to be established in the area. However, overall, the list of species was not very large. However, overall, the number of confirmed species peaked in 2002. However, the number of confirmed species gradually decreased after peaking in 2002. This is due to canopy development and This was thought to be due to the progression of vegetation succession, such as canopy development and an increase in dragonfly pond plants. However, the factors that determined this were not within the scope of this study. However, the factors that determined this could not be identified within the scope of this survey." (2016): Diversity and habitat preference of Odonata fauna (Insecta) in Kaziranga-Karbi hills, Central Assam, Northeast India. *Ambient Science* 3(2): 64-68. (in English) ["Diversity of Odonata and their habitat preference was studied in a landscape between Kaziranga National Park and Karbi Hills of Assam. During study period we recorded total 82 species of odonates from 51 genera and 10 families out of which, Anisoptera represented by 43 species and Zygoptera represented by 39 species. Family

Libellulidae was the most dominant family with 36 species among the Anisoptera than after family Coenagrionidae with 20 species among Zygoptera. Among the six selected habitats, stream and river sites hold highest species (45) and lowest species found in human habitations (21). Among the recorded species *Orthetrum pruinosum*, *Orthetrum sabina* and *Pantala flavescens* were found to be occupied in all types of habitats. Sørensen's Similarity index of all the six habitats for odonates species composition during study periods had maximum values CLWP (0.77) and lowest value FA-GL (0.26). A checklist of odonates for central Assam has also been forwarded." (Authors)] Address: Boruah, B., Dept of Wildlife and Biodiversity Conservation, North Orissa Univ., Odisha, India

**19838.** Buczyński, P.; Zawal, A.; Buczyńska, E.; Stępień, E.; Dabkowski, P.; Michoński, G.; Szlauer-Lukaszewska, A.; Pakulnicka, J.; Stryjecki, R.; Czachorowski, S. (2016): Early recolonization of a dredged lowland river by dragonflies (Insecta: Odonata). *Knowl. Manag. Aquat. Ecosyst.*, 417, 43: 11 pp. (in English, with French summary) ["The influence of dredging on the dragonfly assemblages of the small regulated lowland River Kr'piel (north-western Poland) was analyzed a short time after the dredging. Dragonfly assemblages were destroyed, but they began to recover rapidly. Many biocoenotic indices reached high values at just six months after the dredging. The recolonization first occurred as a result of larval drift, and then, via dispersion of adult dragonflies. This process took place in conditions different from the prevailing conditions in the period before dredging, in terms of microhabitat availability and physico-chemical conditions. Compared to the previous assemblage, the emerging assemblage was more typical of assemblages found in small, natural running waters. Therefore, dredging (carried out for economic reasons) could be regarded as a process that unintentionally had a positive influence on odonate assemblages. Currently, when most small watercourses are regulated, dredging that is properly planned and controlled has proven to protect the natural fauna. It is worthwhile to apply lessons learned from examples of active fauna protection to what is currently known as "the rotational model" for dredging." **19839.** Büsse, S. (2016): Morphological re-examination of *Epiophlebia laidlawi* (Insecta: Odonata) including remarks on taxonomy. *International Journal of Odonatology* 19(4): 221-238. (in English) ["*Epiophlebia* is the only known taxon of Odonata that is neither part of the Zygoptera nor Anisoptera. Previously, two species of *Epiophlebia* were recognized, restricted to areas in Japan (*E. superstes*) and the Himalayas (*E. laidlawi*). Recently, the group gained attention with the description of new species from China – *E. sinensis* and *E. diana* – while a subsequent genetic study suggested only one species of *Epiophlebia*. To clarify these conflicting hypotheses this study focused on the under-recorded *E. laidlawi*. This study elucidated the morphology of this species in comparison to *E. superstes*, representing the first comparative study of *Epiophlebia* species. Furthermore, it presents notes on the taxonomic conditions of this group. With this study, a first step is made to resolve the confusion regarding the taxonomic status of the described *Epiophlebia* species. A number of anatomical characters –

for example the different shape of the vertex of the head, the distinct colour patterns of the head, thorax and the abdomen or the differences in the shape of the hamulus anterior and posterior in the secondary male genitalia – confirmed the species status of *E. laidlawi* and underlined its distinctness from *E. superstes*. However, in the Chinese species *E. sinensis* and *E. diana* a re-examination is advised; especially in *E. diana* the species status is questionable." **19840.** Bybee, S.; Córdoba-Aguilar, A.; Duryea, M.C.; Futahashi, R.; Hansson, B.; Lorenzo-Carballa, M.O.; Schilder, R.; Stoks, R.; Suvorov, A.; Svensson, E.I.; Swaegers, J.; Takahashi, Y.; Watts, P.C.; Wellenreuther, M. (2016): Odonata (dragonflies and damselflies) as a bridge between ecology and evolutionary genomics. *Frontiers in Zoology* 201613: 46: 20 pp. (in English) ["Odonata present an unparalleled insect model to integrate evolutionary genomics with ecology for the study of insect evolution. Key features of Odonata include their ancient phylogenetic position, extensive phenotypic and ecological diversity, several unique evolutionary innovations, ease of study in the wild and usefulness as bioindicators for freshwater ecosystems worldwide. In this review, we synthesize studies on the evolution, ecology and physiology of odonates, highlighting those areas where the integration of ecology with genomics would yield significant insights into the evolutionary processes that would not be gained easily by working on other animal groups. We argue that the unique features of this group combined with their complex life cycle, flight behaviour, diversity in ecological niches and their sensitivity to anthropogenic change make odonates a promising and fruitful taxon for genomics focused research. Future areas of research that deserve increased attention are also briefly outlined." (Authors) "Conclusions: Further development of genomic resources for Odonata could strongly improve research on microevolution driven by anthropogenic environmental changes. Integrating genomic data with the extensive field ecology knowledge of many species could be a major leap forward in the field of eco-evolutionary dynamics [207]. Phenotypic change can come about by adaptation, plasticity or an interaction of the two [207]. Disentangling contributions from these effects is important, as they are expected to be associated with different patterns, rates, limits and costs [207]. Moreover, population genomics could allow the prediction of hybridisation rates and improve the precision of demographic inferences by using dragonflies and damselflies as bioindicator species. This would allow us to plan conservation efforts best suited for Odonata itself, other co-occurring species and their environment. Transcriptomic analyses would allow the identification of genes and molecular processes likely to respond to selection due to climate change and habitat loss (which can be studied across a complex life cycle in Odonata), as recently done by Lancaster et al. [182]. Additionally, reduced representation sequencing approaches for genotyping (e.g. RAD, ddRAD, GBS) make it possible to develop and sequence many markers in nonmodel species [208], e.g. by sequencing large pools of individuals [209], and hence allow for the detection of outlier loci under selection. Such transcriptomic and genomic studies would benefit from the availability of reference transcriptomes and genomes so that annotation of differentially expressed genes and outlier loci is possible." ] Address: Bybee, S., Brigham Young Univ., Provo, UT 84606, USA. **19842.** Chauhan, P.; Wellenreuther, M.; Hansson, B. (2016): Transcriptome profiling in the damselfly *Ischnura elegans* identifies genes with sex-biased expression. *BMC Genomics* 201617:985. DOI: 10.1186/s12864-016-3334-6: 12 pp. (in English) ["Background: Sexual dimorphism occurs widely across the animal kingdom and has profound effects on evolutionary trajectories. Here, we investigate sex-specific gene expression in *Ischnura elegans*, a species with pronounced sexual differences including a female-limited colour polymorphism with two female-like gynochrome morphs and one male-mimicking, androchrome morph. Whole-organism transcriptome profiling and sex-biased gene expression analysis was conducted on adults of both sexes (pooling all females as well as separating the three morphs) to gain insights into genes and pathways potentially associated with sexual development and sexual conflict. Results: The de novo transcriptome assembly was of high quality and completeness (54 k transcripts; 99.6% CEGMA score; 55% annotated). We identified transcripts of several relevant pathways, including transcripts involved in sex determination, hormone biosynthesis, pigmentation and innate immune signalling. A total of 1,683 genes were differentially expressed (DE) between males and all females (1,173 were female-biased; 510 male-biased). The DE genes were associated with sex-specific physiological and reproductive processes, olfaction, pigmentation (ommochrome and melanin), hormone (ecdysone) biosynthesis and innate immunity signalling pathways. Comparisons between males and each female morph category showed that the gynochromes differed more from males than the androchrome morph. Conclusions: This is the first study to characterize sex-biased gene expression in odonates, one of the most ancient extant insect orders. Comparison between *I. elegans* sexes revealed expression differences in several genes related to sexual differences in behaviour and development as well as morphology. The differential expression of several olfactory genes suggests interesting sexual components in the detection of odours, pheromones and environmental volatiles. Up-regulation of pigmentation pathways in females indicates a prominent role of ommochrome pigments in the formation of the genetically controlled female colour polymorphism. Finally, the female-biased expression of several immunity genes suggests a stronger immune response in females, possibly related to the high levels of male mating harassment and recurrent matings in this species, both of which have been shown to injure females and expose them to sexually transmitted diseases and toxins contained in seminal fluids." (Authors)] Address: Chauhan, P., Dept of Biology, Lund Univ., Lund, Sweden. Email: Pallavi.Chauhan@biol.lu.se

**19843.** Cheng, Y.-C.; Lin, C.-P. (2016): Dietary niche partitioning of *Euphaea formosa* and *Matrona cyanoptera* (Odonata: Zygoptera) on the basis of DNA barcoding of larval feces. *Journal of Insect Science* 16(1), 73: 1-5. (in English) ["Odonate larvae are commonly considered opportunistic general predators in freshwater ecosystems. However,

the dietary breadth of most odonate larvae in forest streams is still poorly documented. We characterized the prey species and estimated the level of dietary niche overlap of two damselflies, *Euphaea formosa* Hagen 1869 and *Matrona cyanoptera* Hämäläinen and Yeh, 2000 in a forest stream of central Taiwan on the basis of DNA barcoding of larval feces. A collection of 23 successfully identified cytochrome c oxidase 1 (CO1) barcoding sequences suggested that the mayflies (Ephemeroptera), caddisflies (Trichoptera), and midges (Diptera) comprise the majority (43%, 6/14) of prey species consumed by *E. formosa* larvae, whereas the identified prey for *M. cyanoptera* were mainly zooplankton (56%, 5/9). Statistical analysis of dietary overlap indicated that these two species occupy different dietary niches (Pianka's index = 0.219). DNA barcoding analysis of damselfly larval feces was effective in detecting less sclerotized prey such as vertebrates (fish and frog) and small zooplankton. However, a moderately successful rate (<70%) of PCR amplification by universal CO1 primers and a low percentage (<60%) of identifiable sequences in public databases indicate the limitations of naive DNA barcoding in fecal analysis." **19844.** Chovanec, A. (2016): Libellenkundliche Untersuchungen an der restrukturierten Pram (Riedau / Zell) und an der regulierten Trattnach (Schlüßberg) in Oberösterreich im Jahr 2016. Im Auftrag des Amtes der Oberösterreichischen Landesregierung, Abt. Oberflächengewässerswirtschaft: 67 pp. (in German) [Austria: "In the present study, the ecological status of the restructured section of the Pram River in the area from Riedau to Zell as well as of a regulated section of the Trattnach River in the area of Schlüßberg were assessed from the dragonfly point of view, with special consideration of the morphological conditions. This was done on the basis of the Dragonfly Association Index (DAI) and was based - in accordance with the requirements of the Water Framework Directive and the Water Act - on a comparison between a water body type-specific reference condition and the status quo. The method is based on an approach published by the Federal Ministry of Agriculture, Forestry, Environment and Water Management (BMLFUW) (CHOVANEC et al. 2014), which has also been used in Upper Austria in recent years on the Krems and Aschach rivers as well as on the Leitenbach and Sandbach rivers. Pram: A total of 27 species were detected at the three restructured stretches of the Pram and at two mapped small water bodies. This corresponds to 35% of the Austrian species spectrum (78 species). 25 of the 27 species were native. According to the Red List for Austria, three species (all from the river damselfly family / Gomphidae) are "endangered", four species "potentially endangered". With *Ophiogomphus cecilia*, a species was found that is listed in Annexes II and IV of the EU Habitats Directive. A total of 16 species were sighted on the Pram itself, 14 of which were native. The assessment was based exclusively on the ground-dwelling species sighted on the Pram. The application of the DAI results in a very good dragonfly ecological status for the entire section, whereby it must be emphasised that the numbers of individuals of individual species of the guideline-compliant associations were very low. Trattnach: Six dragonfly species were recorded at the study section on the regulated Trattnach, which corresponds to 8% of the species inventory recorded for Austria. Of the 6 species, four were native. Two species are "potentially endangered" according to the Red List, one is "endangered". None of the species is listed in the Annexes of the Habitats Directive. The DAI calculation

results in moderate dragonfly ecological status for the entire section. This relatively good assessment can be explained primarily by the punctual occurrence of *Onychogomphus forcipatus* on a small gravel bank. An assessment of the dominant condition of the Trattnach without the gravel bank results in the unsatisfactory dragonfly ecological condition." (Author/DeepL)] Address: Chovanec, A., Krotenbachgasse 68, 2345 Brunn am Gebirge, Austria. E-mail: andreas.chovanec@bmlfuw.gv.at

**19845.** Chuang, C.-J.; Liu, C.-D.; Patil, R.A.; Wu, C.-C.; Chang, Y.-C.; Peng, C.-W.; Chao, T.-W.; Liou, J.-W.; Liou, Y.; Ma, Y.-R. (2016): Impact of cuticle photoluminescence on the color morphism of a male damselfly *Ischnura senegalensis* (Rambur, 1842). *Scientific Reports* | 6:38051 | DOI: 10.1038/srep38051: 8 pp. (in English) ["In this study *I. senegalensis* was first found to produce strong photoluminescence (PL) emissions from various coloured-body portions, such as the eighth abdominal segment of the tail. The colours of the coloured-body portions can be enhanced or modified by the PL emissions for assistance in reducing intrasexual and male harassment, and improving mature mating and conspecific identity. Therefore, the PL emissions that contribute to the colour modification and coloration are involved in the cuticle evolution of the damselflies. The micro-PL confocal images verify that the PL emissions can strongly influence the surface colours of the cuticle, and demonstrate why *I. senegalensis* is called a bluetail. ... The Damselfly *Ischnura senegalensis* (Rambur, 1842) was first found to emit strong PL emissions from the various coloured-body portions of the compound eyes, thorax front, wings, and eighth abdominal segment of the tail. There is an obvious difference in appearance of the colours of the coloured-body portions in the PL image and those in the optical image, indicating that the PL emissions act as biological pigments and multilayer structures and can modify the colours or coloration of the coloured-body portions. This PL phenomenon is strongly related to cuticle evolution in the damselflies. The ultrathin histological sections of the various specific body portions of the damselfly *Ischnura senegalensis* were examined by confocal fluorescence microscopy and TEM. Micro-PL confocal and TEM images of the ultrathin histological sections of the various specific body portions show that The cuticle PL does impact on the colour morphism of a male damselfly *Ischnura senegalensis*, and it helps to reduce intrasexual and male harassment and to signal mature mating and conspecific identity." **19846.** Cicort-Lucaciu, A.-S.; Sas-Kovács, I.; Covaciu-Marcov, S.-D. (2016): Non road human influence upon road mortality on three secondary roads from the Vâlsan river protected area, Romania. *Muzeul Olteniei Craiova. Oltenia. Studii și comunicări. ătiințele Naturii* 32(2): 99-106. (in English, with Romanian summary) ["Human activities, unrelated to road, but taking place in its proximity, can modify the amplitude of road mortality in some animal groups. This is the case of bees, wasps and Coleoptera Geotrupidae on three secondary roads from the Vâlsan river basin, Romania. Black locust plantations near a road attract bees in the blooming period, increasing their chance of falling victim on the road. Coleoptera Geotrupidae are frequently killed on roads used by the local people's cows, being attracted by manure. Wasps come on the roads for feeding on the corpses of other road killed animals, while they are sometimes killed. Only in two days on the three secondary roads there were killed 899 individuals, from 50 taxa, mostly invertebrates.

The differences of the road mortality by roads and periods were not significant." (Authors) "Odonata" are harmed, but quite moderately.] Address: Covaciu-Marcov, S.-D., Univ. of Oradea, Faculty of Sciences, Dept of Biology; 1, Universităţii, Oradea 410087, Romania. E-mail: severcovaciu1@gmail.com

**19847.** Conesa Garcia, M.A.; Serrano Leon, J.P. (2016): La larva F0 y exuvia de *Calopteryx xanthostoma* (Charpentier, 1825), (Odonata: Calopterygidae). Boletín Asociación Odonatológica de Andalucía 4: 31-40. (in Spanish, with English summary) ["The F0 larval morphology and exuviae of *Calopteryx xanthostoma* (Charpentier, 1825), (Odonata: Calopterygidae). As a result of the genetic study of the genus *Calopteryx* Leach, 1815, in the palearctic fauna, *Calopteryx xanthostoma* (Charpentier, 1825) and *Calopteryx splendens* (Harris, 1782), have been separated. Both species can be easily distinguished in their adult specimens; however, the same does not apply to their larvae. There are few bibliographic references to *C. xanthostoma* larvae and, at present, no morphological criteria has been proposed to allow a clear separation between these two species in their larval level. In this paper a morphological study of larvae F0 and exuviae *C. xanthostoma* seeks to alleviate this lack of information." (Authors)] Address: Conesa García, M.A., Universidad Animal. **19848.** Cottin, C.; Kronshage, A.; Kriger, D. (2016): Schätzung eines Libellenbestands im Naturschutzgebiet Heiliges Meer mit der Rückfangmethode der Biostatistik. Fachhochschule Bielefeld, Forschungsreihe des Fachbereichs Ingenieurwissenschaften und Mathematik 4: 1-17. (in German) ["*Lestes virens* lives in the nature reserve "Heiliges Meer" [Nordrhein-Westfalen, Germany]. Ecologists are interested in determining the approximate population size of these animals. of these animals. The specimens cannot be easily counted; however, it is known, that they rarely leave their relatively limited habitat. It is therefore a good idea to estimate the population size using the so-called recapture method. In this method dragonflies are captured and marked. Subsequently (for example, on the next day), dragonflies are caught again and an estimate of the size of the total population is determined from the ratio of marked dragonflies caught again to the total number of dragonflies caught. However, this method, which may seem relatively simple mathematically, has many aspects that are far from trivial when it comes to formulating statements about the quality of the estimated value. In detail, depending on the exact model assumptions, there are also different variants for calculating such estimators, with specific advantages and disadvantages. Using the dragonfly example, such modelling tasks in statistical ecology will be examined in more detail in this article - following on from the bachelor's thesis of the third author." **19849.** DuBois, R.; Van den Broek, F. (2016): What is the incomparable *Anax longipes* (Comet Darner) doing in Wisconsin?. *Argia* 28(3): 16-18. (in English) ["In 2014, *A. longipes* was reported at four new sites. Repeated observations and photographs of males were made by Edgar Spalding and Karl Legler at a pond in Middleton Hills west of Madison in Dane County on 31 May, 2 June, and 8 June. An ovipositing female was photographed by Margo Dolan at Mystery Pond at the Schlitiz Audubon Center near Lake Michigan in

northern Milwaukee County on 16 June. A male was reported by Paul Sparks near the Milwaukee River, also in northern Milwaukee County, on 20 June. At least one male was seen and Pond (Fig. 2) at the Forest Beach Migratory Preserve near Lake Michigan in Ozaukee County on 30 June, 1 July, and 4 July. In 2015 Freda again photographed two males at the Clubhouse Pond on 21 June and continued to observe them there for several days. Also in the summer of 2015 Matt Berg observed a male flying with several *Anax junius* (Common Green Darner) males at Paradise Lake in Douglas County. No adults of *A. longipes* were seen at the Forest Beach Clubhouse Pond in 2016, but on 28 June Freda found a single exuvia of *A. longipes* while searching the entire perimeter of the pond (Fig. 3). Additional complete searches of the shoreline around the Clubhouse Pond and two other wetlands on the property on 7 July, and just at the Clubhouse Pond on 5 August, did not turn up any other exuviae of *A. longipes*, although many exuviae of *A. junius* and a variety of species of skimmers were found on these dates." **19851.** Garlet, J.; Corrêa Costa, E.; Boscardin, J. (2016): Survey of insect in Eucalyptus spp. plantation by light trap in Sao Francisco de Assis, RS. *Ciência Florestal*, Santa Maria 26(2): 365-374. (in Portuguese, with English summary) ["The cultivation of eucalyptus has become an important economic activity in Brazil. However, with the increase of the plantation areas, some entomological problems tend to increase in the same proportion. The constant monitoring of the insects associated with homogeneous planting systems is very important in order to seek the development of programs for integrated pest management. Thus, the purpose of this study was to perform a survey on the insect populations associated with *Eucalyptus* spp., in São Francisco de Assis, RS. The collects were carried out by light traps from July 2008 to August 2009 in three-year-old stands with the species: *Eucalyptus dunni*, *Eucalyptus grandis* and *Eucalyptus grandis* x *Eucalyptus urophylla*. The insects collected were analyzed using the faunistic indices, frequency, abundance, diversity, and constancy. The correlation between the pest species identified and the meteorological variables for the period were also performed. We collected 3623 individuals belonging to eight orders (Blattodea, Coleoptera, Dermaptera, Hemiptera, Hymenoptera, Lepidoptera, Mantodea and Odonata [Libellulidae]). Three species and three genus of Lepidoptera defoliators considered of economic importance were identified: *Automeris illustris*, *Eupseudosoma* sp., *Sabulodes* sp., *Sarsina* sp., *Thyrinteina amobia* and *Agrotis ipsilon* as well as the borer *Phoracantha semipunctata*. Our results show that there are important pest species of *Eucalyptus* already established in the region therefore some constant monitoring is required so that these species do not cause damage to plantations." **19853.** Hafiane, M.; Hamzaoui, D.; Attou, F.; Bouchelouche, D.; Arab, A.; Alfarhan, A.H.; Samraoui, B. (2016): Anthropogenic impacts and their influence on the spatial distribution of the Odonata of Wadi El Harrach (North-central Algeria). *Revue d'Écologie* 71(3): 239-249. (in English, with French summary) ["In spite of a relatively good knowledge of the odonatafauna of the Maghreb, some large areas like the centre of Algeria have remained little explored. These areas have witnessed a demographic explosion and an agro-industrial development over the last century which have adversely impacted most natural ecosystems. Wadi El Harrach, an intermittent river that cuts through the Mitidja plain, near Algiers, is notorious for its pollution and represents a good model to investigate anthropogenic impacts on freshwater communities. In line with the increasing use of assessment methods developed to monitor and evaluate the ecological integrity of running waters, we sampled Odonata of Wadi El Harrach and measured various abiotic parameters representative of the water quality of the habitat. Both data sets were jointly used to analyse the correspondence between the two assessments. Results indicated congruence between both approaches and highlighted the potential of Odonata as reliable bioindicators of ecological conditions of lotic ecosystems." (Authors)]

**19855.** Holzinger, W.; Komposch, B. (2016): Bestandssituation der Großen Quelljungfer (*Cordulegaster heros* Theischinger, 1979) im Bezirk Mattersburg Große Quelljungfer: Larve und Lebensraum (Blumaugraben). Auftraggeber: Amt der Burgenländischen Landesregierung, Abteilung 5 – Anlagenrecht, Umweltschutz & Verkehr, Europaplatz 1, 7000 Eisenstadt, Austria. GZ: 5/N.A-10044-5-2015. Auftragnehmer: ÖKOTEAM - Institut für Tierökologie und Naturraumplanung, Bergmannsgasse 22, 8010 Graz, Austria: 44 pp. (in

German) ["Ökoteam was commissioned by the Office of the Provincial Government of Burgenland in August 2015 to prepare this expert report. The commission relates to the Large Spring Damselfly (*Cordulegaster heros* Theischinger, 1979), a dragonfly species native to Austria and listed in Annex II of the Habitats Directive (code: 4046), and includes the following questions: \* Are there such important occurrences of the Large Spring Damselfly (*Cordulegaster heros* Theischinger, 1979) in the district of Mattersburg that a listing in the Natura 2000 network of protected areas is recommended? \* Can these occurrences be covered by the existing European nature reserve AT 1123323 Mattersburger Hügelland or should additional areas be designated as protected areas for the species? \* How are the populations of the species in any protected areas to be classified (presence, conservation status)? \* What threats could these populations face and what protective measures could be taken for the species? \* How should further monitoring be carried out? According to the commission, the focus of the study was on the existing Natura 2000 site "Mattersburger Hügelland" (AT1123323). A total of 42 stretches of water were investigated for the occurrence of the damselfly. The majority of the sections are located in the Natura 2000 site. The mapping was carried out by searching for larvae directly in the water body. The field work was carried out on four dates in May 2016. A section of at least 50 m in length was defined at each of the water bodies surveyed, which is homogeneous with regard to the habitat parameters and impairments relevant to the assessment. The number of animals was recorded, differentiated according to large and small larvae. In addition, eight essential habitat parameters were recorded. The assessment of the conservation status of a species is carried out in accordance with the requirements of the Habitats Directive according to the criteria \*status of the population, \*habitat quality and \*impairments. For this purpose, the assessment scheme developed by Ökoteam (2016) for Styria was adopted with slight modifications. *Cordulegaster heros* was detected at 18 of the 42 water body sections investigated. A total of 124 larvae of the species were found, as well as several records of the two-striped damselfly (*Cordulegaster bidentata*). Seven of the breeding waters are at least partially located in the existing Natura 2000 site. Four of them (Marzer Bach-Zubringer I, Auwiesenbach, Auwiesenbach-Zubringer and Romersee-Zubringer) show an excellent conservation status of *C. heros*. Currently, the conservation status in the area is assessed as 'good', the population's share of the national stock in the continental region is in the category 'C'. In order to improve this assessment, it is recommended to extend the area to include the Blumaugraben, the Hochbergbach 1, the Auwiesenbach and/or the Kaltwasserbach. Proposals for the protection of stocks include the establishment of buffer strips (10 m on both sides of the watercourse) and a more natural watercourse design in the future. In addition, it is proposed to conduct future monitoring surveys according to the method applied here." **19856.** Holzinger, W.; Zimmermann, P.; Payandeh, R.; Payandeh, S. (2016): Bestandssituation der Großen Quelljungfer *Cordulegaster heros* Theischinger, 1979 in der Steiermark und Vorschläge zur Ausweisung von Schutzgebieten. Auftraggeber: Amt der Steiermärkischen Landesregierung, Abteilung 13 - Umwelt und Raumordnung, Referat Naturschutz, 8010 Graz, Stempfergasse 7, Austria. GZ: ABT13-

56O-26/2013-2. Auftragnehmer: ÖKOTEAM - Institut für Tierökologie und Naturraumplanung, Bergmannsgasse 22, A-8010 Graz, Austria: 42 pp. (in German) ["Due to ongoing infringement proceedings, the Republic of Austria and possibly also the Province of Styria are required to designate new protected areas for (among others) the dragonfly species *C. heros*. In this context, Ökoteam was commissioned in summer 2013 to prepare this expert report. The assignment includes the following questions: What is the distribution of *C. heros* in Styria? Where are the main areas of occurrence? Are there well-suited (nationally important) populations of the damselfly within the existing Natura 2000 sites in Styria, so that the species should be re-nominated in these areas to ensure its protection? Is it necessary from a technical point of view to expand existing areas and/or designate new areas in Styria in order to ensure the protection of the species in the Natura 2000 network of protected areas? How are the populations of the species in possible protected areas to be classified (information according to the standard data sheet)? What threats could these populations be exposed to and what protective measures could be taken for the species? The dragonfly is widespread in south-eastern Europe and reaches the north-western limit of its range in eastern Austria. Here, the range boundary runs across Carinthia (Villach area) along the eastern edge of the Alps to Lower Austria. It inhabits smaller, mostly shaded watercourses (preferably river classification number 2) in the planar to colline altitudinal zone. The larvae develop in sandy substrate in water depths below 20 cm and current velocities mostly below 6 cm/s and need three to five years for their development. Hatching occurs on land a few metres from the shore; the adults are the largest dragonflies in Europe and fly from early June to late August. Throughout Europe, the species is considered "Near Threatened" and its populations are declining. Its conservation status is good in the alpine and continental region, "favourable" in Austria, but in the Red Lists of Austria and Carinthia it is classified as critically endangered ("EN"), and in Lower Austria "endangerment is likely". The main cause of threat to the species is the destruction of its habitats by backfilling, piping and shoring. Before the start of this study, only few current distribution data on this species were available from Styria. Therefore, 100 grid squares in the potential distribution area (south-eastern Alpine foothills and Styrian foothills) were randomly selected and potentially suitable watercourse sections were then examined for the presence of larvae. Eight further sites were added due to chance findings and were also included in the data evaluation. Detections were made at a total of 31 water bodies, three of which are located in a Natura 2000 site. These data were used to model the probability of occurrence of the species for the whole of Styria using MaxEnt. Mapping and modelling showed that a relatively widespread distribution can be expected across the entire Alpine foothills of Styria, with the exception of the wider valley flats in the Grazer and Leibnitzer Feld and the flat lowlands of eastern Styria. The most important occurrences are in the hill country between the Grazer Bucht and the Raabtal, in the north-western Grazer Berg- und Hügel-land and in the Windische Büheln. **19857.** Hughes, M.I.; Kaunisto, K.; Suhonen, J. (2016): Large males have fewer water mites (*Arrenurus* sp.) on the Variable Damselfly (*Coenagrion pulchellum*). *Canadian Journal of Zoology* 94(5): 339-343. (in English) ["Ectoparasitic

water mites *Arrenurus* sp. (Dugés, 1834) may affect damselflies in different ways resulting in lower longevity and reproduction success. We studied the variation of water mite occurrence on *C. pulchellum* in relation to the host's sex, location and wing length, and the amount of black pigment on the abdomens of males. In our study we found that water mite prevalence and abundance were higher on females. Location of the populations did not affect the prevalence of water mites, nor did the colouring of males. The prevalence and abundance of water mites was lower on larger males than on smaller ones. Our results suggest that females are likely to have more water mites due to different behaviour and life history strategies. According to our results male body size is a sign of good condition and, thus, of sufficient resources available to be directed to strengthening their immune systems." **19859.** Ilvonen, J.J.; Suhonen, J. (2016): Phylogeny affects host's weight, immune response and parasitism in damselflies and dragonflies. *R. Soc. open sci.* 3: 160421. <http://dx.doi.org/10.1098/rsos.160421>: 9 pp. (in English) ["Host-parasite interactions are an intriguing part of ecology, and understanding how hosts are able to withstand parasitic attacks, e.g. by allocating resources to immune defence, is important. Damselflies and dragonflies show a variety of parasitism patterns, but large-scale comparative immune defence studies are rare, and it is difficult to say what the interplay is between their immune defence and parasitism. The aim of this study was to find whether there are differences in immune response between different damselfly and dragonfly species and whether these could explain their levels of gregarine and water mite parasitism. Using an artificial pathogen, a piece of nylon filament, we measured the encapsulation response of 22 different damselfly and dragonfly species and found that (i) there are significant encapsulation differences between species, (ii) body mass has a strong association with encapsulation and parasite prevalences, (iii) body mass shows a strong phylogenetic signal, whereas encapsulation response and gregarine and water mite prevalences show weak signals, and (iv) associations between the traits are affected by phylogeny. We do not

know what the relationship is between these four traits, but it seems clear that phylogeny plays a role in determining parasitism levels of damselflies and dragonflies." (Authors)

**19867.** Kozminov, S.G.; Ketenchiev, Kh.A. (2016): Preimaginal development dragonflies *Anax imperator* Leach,

1815 (Odonata). Proceedings of Gorsky State Agrarian Univ. 53(3): 164-170. (in Russian, with English summary) ["The preimaginal stage of dragonflies, entering into various biotic and abiotic relationships, being an integral component of aquatic biocenoses, makes the main or only contribution to the production processes of many water bodies. Studies of the preimaginal development of *Anax imperator* were carried out under the conditions of the Kabardino-Balkarian Republic. Preimaginal development is characterized by a change in morphology, a gradual linear increase in the size of the body and its individual parts. 14 age stages were determined, differing in a complex of morphometric, morphological parameters, distinctly combined into eight age groups. The definition of regional criteria for preimaginal development will allow studying the processes of dragonfly variability to changing environmental conditions, and can be used both in applied and theoretical fields of biology. Under experimental conditions, the preimaginal stages of development of dragonflies. *A. imperator* are described in detail, their morphological and morphometric parameters are revealed. In their preimaginal development, dragonflies of this species go through 14 age stages; after 28 days. With increasing age, the time between molts increases: stage 1 up to 4 molts after 3-4 days; 5-7 - 4-7; 9-10 - 8-10; 11-12 - 10-13; 12-13 - 15-16; 14 - final, hatched after 18-20 days. The complex of morphological and morphometric parameters makes it possible to accurately determine the preimaginal stage of development. All age stages are clearly grouped into eight age groups, which can be used in population monitoring, physiological, ethological and many other applied studies." **19868.** Lagesson, A.; Fahlman, J.; Brodin, T.; Fick, J.; Jons-son, M.; Byström, P.; Klaminder, J. (2016): Bioaccumulation of five pharmaceuticals at multiple trophic levels in an aquatic food web - Insights from a field experiment. *Science of The Total Environment* 568: 208-215. (in English) ["Highlights: •A study of uptake of five pharmaceuticals by fish and four aquatic invertebrates. •There are inter-specific differences in uptake of pharmaceuticals. •Highest concentrations were found for the benthic species. •Important to not only consider waterborne exposure in risk assessments. •Important to include organisms from different trophic levels in risk assessments. Abstract: Pharmaceuticals derived from manufacturing and human consumption contaminate surface waters worldwide. To what extent such pharmaceutical contamination accumulates and disperses over time in different compartments of aquatic food webs is not well known. In this study we assess to what extent five pharmaceuticals (diphenhydramine, oxazepam, trimethoprim, diclofenac, and hydroxyzine) are taken up by fish (European perch) and four aquatic invertebrate taxa (damselfly larvae [*Coenagrion* sp.], mayfly larvae, waterlouse, and ramshorn snail), by tracing their bioconcentrations over several months in a semi-natural large-scale (pond) system. The results suggest both significant differences among drugs in their capacity to bioaccumulate and differences among species in uptake. While no support for in situ uptake of diclofenac and trimethoprim was found, oxazepam, diphenhydramine, and hydroxyzine were detected in all analyzed species. Here, the highest bioaccumulation factor (tissue:water ratio) was found for hydroxyzine. In the food web, the highest concentrations were found in the benthic species ramshorn snail and waterlouse, indicating that bottom-living organism at lower trophic posi-

tions are the prime receivers of the pharmaceuticals. In general, concentrations in the biota decreased over time in response to decreasing water concentrations. However, two interesting exceptions to this trend were noted. First, mayfly larvae (primarily grazers) showed peak concentrations (a fourfold increase) of oxazepam, diphenhydramine, and hydroxyzine about 30 days after initial addition of pharmaceuticals. Second, perch (top-predator) showed an increase in concentrations of oxazepam throughout the study period. Our results show that drugs can remain bioavailable for aquatic organism for long time periods (weeks to months) and even re-enter the food web at a later time. As such, for an understanding of accumulation and dispersion of pharmaceuticals in aquatic food webs, detailed ecological knowledge is required." **19869.** Lara-Contreras, J.-C. (2016): Ácaros ectoparásitos (Hydrachnidia) de las especies de libélulas (Odonata) presentes en diferentes humedales de la Sabana de Bogotá. MSc thesis, Universidad Nacional de Colombia, Facultad de Ciencias, Depto de Biología, Bogotá, Colombia: IX + 58 pp. (in Spanish, with English summary) ["This study was aimed to establish relationships between the disturbance associated to activities around the wetlands, physico-chemical variables of water, adult Odonata and larval water mites parasites on dragonflies and damselflies, in different wetlands from Bogotá Savanna located between 2.500 and 2.600 meters of altitude. Eight species of dragonflies and damselflies were found, two morfo-species of *Arrenurus* spp were affecting two species of Zygoptera. A relationship between the disturbance, pH, oxygen, conductivity, nitrites, nitrates, phosphates and water mites abundance was found." (Author)] Address: not stated

**19870.** Linnell, J. D. C., Kaltendorfer, B., Bredin, Y. & Gjershaug, J. O. (2016): Biodiversity assessment of the Fagaras Mountains, Romania. NINA Report 1236: 86 pp. (in English) ["This report aims to summarise the existing knowledge concerning the biodiversity of the Fagaras Mountains, in the southern Carpathians of Romania. It is intended to provide a basis for an assessment of the ecosystem services that are being provided, and that could be provided, by the area. The Fagaras Mountains consist of an uninterrupted 70-80 km long ridge that reaches to over 2500 m in altitude, with many side ridges branching off, creating a highly variable topography. As well as containing Romania's highest mountain, it also contains the largest area of continuous alpine zone habitat in Romania. The slopes are covered with spruce forests at higher altitudes and mixed deciduous forests at lower altitudes. At lower altitudes land-use gives way extensive low-intensity agriculture at the forest-farmland interface, and then more intensive agriculture where soils permit. Most of the mountain range is protected within two Natura 2000 sites that combine to an area of 2436 km<sup>2</sup>, and these adjoin several other Natura 2000 sites, and other Romanian protected areas. Our biodiversity assessment consisted of collecting existing data from published and unpublished sources. Over 72% of the area is forested, with the rest consisting of alpine grasslands (25%) and rock, scree and bogs. Some patches of virgin forest have been identified along the northern slopes of the mountain range, and many areas have not been surveyed. The biodiversity of the Fagaras Mountains has not been as well studied as in many of the neighbouring regions, however, it was still possible to build up a good preliminary species of species diversity for some species groups, including mammals (57

species), birds (130 species), amphibians (17 species), reptiles (13 species), fish (12 species), freshwater crayfish (2 species), butterflies and moths (563 species), beetles (125 species), dragonflies (15 species), spiders (40 species), water-bugs (22 species), water-mites (28 species), lichens (144 species) and plants (895 species). For other species groups such as fungi (19 species), snails (6 species) and crickets (2 species) there is clearly a lot more registration to do before these species lists will become complete. Of these species, a total of 107 are of EU community interest, being listed on either the Habitats Directive or the Birds Directive. Many of the species are also on the national Romanian red list. In terms of its size, species diversity, and ecological integrity the Fagaras Mountains are clearly an area with a very high biodiversity value. The majority of the records we found come from only two areas that have been comparatively well studied (Sinca Noua and the Upper Dambovită river basin). As a result, further studies of new areas and other species groups are clearly going to lead to an increase in the areas known diversity. Most of the area is subject to multiple human land uses, such as forestry, hunting, livestock grazing, the gathering of berries and mushrooms and low-intensity agriculture. These have formerly been conducted with low intensity and in ways that have been largely compatible with biodiversity conservation. However, recent trends have been towards an intensification of all human activities in recent years, most visibly shown by the introduction of poorly regulated clearcutting of forests. In addition, the area has been subject to a lot of poorly planned development, such as small scale hydro-electric plants, second homes and tourist infrastructure. There is therefore a desperate need to establish land-use zoning plans and guidelines for practices (forestry, hunting, livestock grazing, gathering of non-timber forest products, infrastructure development, agriculture) that are compatible with the conservation objectives of the Natura 2000 site. While the urgency of the situation requires that this work start at once to avoid irreversible changes, a great deal of further work to map habitats and species is needed in order to fine tune management guidelines for the specific human activities and land-uses." **19874.** Merlet, F.; Itrac-Bruneau, R. (2016): Aborder la gestion conservatoire en faveur des Odonates. Guide technique. Office pour les insectes et leur environnement & Société française d'Odonatologie. Direction régionale de l'environnement, de l'aménagement et du logement Hauts de France: 96 pp. (in French) ["Conclusion: As Wildermuth & Küry said in their guide Protecting and promoting dragonflies, it is time to take action! This technical guide to conservation management in favour of Odonata is intended to unite the players around a single objective: to preserve dragonflies and their habitats. Prior to any intervention, a manager must ask himself the right questions: what species are present and what are their ecological requirements?

Given this diversity, what are the responsibilities of the site? What is the state of health of the habitats? How can the conservation management of the site be best understood by taking all these elements into account? In order to answer these questions, it is advisable to consult specialists in Odonata in order to better understand the problems of the site. This document should first help the manager to prioritise the steps to be taken. Once the conservation objectives have been defined, it is then necessary, in addition to internal technical skills and the local network, to use this guide to follow the steps listed and target the appropriate action(s). For their part, odonatologists can put their knowledge and naturalist skills to use in conservation. When they detect the presence of a species of heritage interest or a dysfunction of the environment (absence of species characteristic of the habitat, for example) on a site, they can approach the management bodies to alert them. If the site does not have any, the local structures in charge of nature conservation, the competent authorities or the owner can be contacted. They can then propose to become involved in the diagnosis prior to the action (inventory of Odonata, analysis of needs and degradation factors), orient the measures according to the ecological requirements of the species and continue this partnership to evaluate the effectiveness of the measures on Odonata. This guide also offers the odonatologist the possibility of being an actor in conservation by proposing the key elements of successful conservation management. These partnerships between managers and naturalists should enable operations to be implemented under the best possible conditions. More generally, conservation management must be the result of consultation between all the players in the area: cooperation, exchanges and sharing of experience are the guarantees of the success of the action undertaken." **19875.** Michelson, C. (2016): Effects of agricultural land use on tree swallow (*Tachycineta bicolor*) reproduction, body condition and diet. MSc. thesis, Dept of Biology, Univ. of Saskatchewan: IX + 115 pp. (in English) ["Agricultural practices have intensified over the last 50 years, increasing crop production and altering the Canadian Prairie landscape by removing non-cropped habitats and wetlands. The productivity, trophic structure and diversity have changed through increased agrochemical inputs and reductions in yearly rotation and diversification of crop types. Most intensive agricultural practices have negative effects on invertebrate communities that can indirectly affect higher trophic organisms, such as birds. Many populations of aerial insectivorous bird species have been experiencing rapid declines in the last 30–40 years. Dependency on high abundances of aerial insects for reproduction and survival is a common link among all species of this guild. My thesis examined aerial insect abundance as a potential link between agricultural land use and the reproductive ecology, nestling body condition, and diet of an aerial insectivore species, the tree swallow (*Tachycineta bicolor*). My broad goal was to determine whether agriculture has deleterious effects on timing of breeding, reproductive investment and success, and nestling quality, as mediated by food supply and differences in diet. Aerial insect abundance and biomass estimates obtained from passive insect traps which capture primarily aquatic dipterans were similar between agricultural and reference sites during all stages of breeding. However, estimates derived from sweep-net sampling in terrestrial habitats in 2013 indicated higher abundances of aquatic

and terrestrial Diptera at a reference site relative to agricultural sites. Multiple measures of tree swallow productivity were not related to agriculture land use but nestling body condition was significantly lower on agricultural sites. Using stable isotope analysis ( $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$ ), I found site and age specific differences in swallow diets and isotopic niche widths but variation was not consistently related to agricultural land use. Aquatic insect prey (Diptera and Odonata) made up the majority of the diet of swallows but nestlings had a larger proportion of terrestrial Diptera which resulted in larger isotopic niche widths compared to adults. The assimilated isotopic diet of nestling and adult swallows were not strong predictors of body size, mass or condition, suggesting that site differences in the diet do not appreciably affect condition. Nestlings raised on agricultural sites had lower body condition that was not directly linked to their diet alone. This suggests other unmeasured factors related to agricultural land use may affect nestling tree swallows. This study tested responses in an aerial insectivore species to land use and potential shifts in the insect community, which may provide important information for conservation and management decisions for many species within the aerial insectivore guild." Degree Programme in Fine Art, Calligraphy, Satakunnan ammattikorkeakoulu, Satakunta Univ. of Applied Sciences: 32 pp. (in English) ["The purpose of this thesis was to investigate materials and the lifecycle of the dragonfly. The idea was to demonstrate the three stages of the Dragonfly's life, the egg, the nymph and lastly the dragonfly. The script Cnut was analysed and studied, and a practice book produced. Versals were also analysed and studied, and a practice book produced. The colour systems were investigated in colour swatches, these were red, blue and yellow, cyan, yellow, magenta and black, and two red, two blues and two yellows. Different types of Vellum were also investigated and discussed. Different types of Gilding glues were also investigated on paper and vellum. These materials were investigated to be used in the pieces

of calligraphy. A Vellum piece was produced and three pieces illustrating the Lifecycle of the Dragonfly were produced. It was concluded that the two blues, two reds and two yellow colour system was the best one to use for calligraphy as it produced the widest range of colours, also in the use of painting other colours could be supplemented easily in the illustrate the Lifecycle of the Dragonfly. The result of the Gilding experiments was that Gesso and Gums were suited for Vellum and Paper use. Reindeer Vellum was found to be the most suitable for use with Calligraphy.] Address: not stated

**19878.** Mogali, S.; Saidapur, S.; Shanbhag, B. (2016): Influence of desiccation, predatory cues, and density on metamorphic traits of the bronze frog *Hylarana temporalis*. *Amphibia-Reptilia* 37(2): 199-205. (in English) ["We conducted an experiment to understand the influence of ecological factors (desiccation, predation threat and density) on two major metamorphic traits, larval period and size at metamorphosis, in the Indian bronze frog. Tadpoles were reared in groups of 15 (low), 30 (medium) and 60 (high) densities. We created the threat of desiccation by removing 0.5 l water at 10 days intervals until the water quantity reached 0.5 l. Caged dragonfly larvae (*Pantala flavescens*) provided the predation threat. Results show that each ecological factor independently influenced metamorphic traits but not in an interactive way. Under desiccation threat the tadpoles metamorphosed earlier and at smaller sizes compared to those reared in constant water (at corresponding densities) regardless of presence/absence of predator. In contrast, under predation threat, tadpoles metamorphosed early and at a bigger size than those reared without predator regardless of density of rearing, and desiccation threat. Alternatively, an increase in density of rearing delayed metamorphosis with smaller metamorphic size in constant water and also under threat of desiccation regardless of whether predation threat existed or not. Thus, our study revealed that *H. temporalis* tadpoles can modify their response to each ecological factor regardless of what other factors operate simultaneously; the threat of desiccation shortens larval period at the cost of growth. Whereas, predator pressure shortens larval period along with increased growth; while greater density increases larval period and slows down growth in *H. temporalis*."] (Authors)] Address: Shanbhag, B., Dept of Marine Biol., Karnatak Univ. **19879.** Naka, H.; Ikari, K.; Narusawa, K.; Hashimoto, H. (2016): Experimental visualization of three-dimensional flow using flapping model mimicking free-flight of dragonfly by tomography. *Transactions of the Visualization Society of Japan* 36(12): 71-81. (in Japanese, with English summary) ["Dragonflies generate three-dimensional flow to gain aerodynamic forces. However, three-dimensional flow in free-flight of dragonfly is not clarified experimentally. In this study, experimental visualization and particle image velocimetry (PIV) analysis using tomography is carried out to clarify experimentally the three-dimensional flow. The flap simulator mimicking flapping motion of dragonfly is used for visualization because reproducible measurement is important for tomography. The flow is visualized with tomography from front and lateral side of the flap simulator. As a result, straight flight of dragonfly generates swift flow in a posterior direction in the center on the direction of wingspan. Moreover, it is confirmed that the flow is drawn to base-side of wings. It is suspected that the flow pulled by the flow in a posterior direction. Therefore, straight flight of dragonfly does not

generate the extra flow in the direction of wingspan and generates the swift flow in a posterior direction."] (Authors)] Address: Hashimoto, H., Dept of Mechanical Engineering, Faculty of Engineering, Tokai College of Human Sciences (?259-1292 Shimokane, Kanagawa) 4-1-1 Kitakanome, Tsuka City, Japan. (in English) ["A study was conducted on the status and diversity of Odonata fauna in Midnapore, West Bengal and associated areas in various natural and anthropological

habitats from June 2013 to July 2015. Forty-one species of odonates belonging to the 29 Genera and 6 Families were recorded from the study area during study period. Suborder Zygoptera was represented by 2 families and Suborder Anisoptera represented 4 families. Among them 29 species were dragonflies under the families; Aeshnidae, Gomphidae, Libellulidae and Macromiidae whereas the other 12 species were damselflies under 2 families; Coenagrionidae, Platynemididae. Species composition was highest in the family Libellulidae (56%) followed by the family Coenagrionidae (22%). Their status has been assessed in that study area. Species have been classified based on their relative estimate of abundance. Such studies on monitoring the species diversity and abundance can give valuable information and insight on the population status of Odonates." **19885.** Polaskova, V.; Schenkova, J.; Bartosova, M.; Radkova, V. (2016): Aquatic invertebrates of calcareous wetlands in post - mining landscape: a comparison with natural calcareous fens. In 2nd Central European Symposium of Aquatic Macroinvertebrate Research. 2016: 39-[Verbatim: "Although many studies have dealt with vegetation and terrestrial fauna of post-industrial biotopes, comprehensive hydrobiological research on post-industrial wetlands is still rather rare. Due to specific bedrock chemistry of the Sokolov Coal Basin in the north-western Czech Republic, wetlands with calcium carbonate (tufa) precipitation, high conductivity and sulphate concentrations occur in this area. Within post-industrial wetlands, this combination of abiotic conditions is completely unique. Macroinvertebrate assemblages of nine wetlands in two spoil banks were studied in spring and autumn in 2014. In total, 159 taxa (mostly identified at the species level) of Mollusca, Clitellata, Ephemeroptera, Plecoptera, Odonata, Heteroptera, Trichoptera, Coleoptera and Diptera were found. Diptera with 85 taxa was the most diverse group comprising many rare and protected taxa closely associated with specific conditions of the post-industrial calcareous wetlands. Moreover, Diptera assemblages included a high number of spring fen specialists [...]. Despite extreme chemical conditions, calcareous wetlands in post-mining landscape provide important refuges for a high number of aquatic invertebrates, including rare and specialized taxa. Calcareous wetlands of the Sokolov spoil banks can be thus considered as unique biotopes with similar taxa richness as highly threatened and quickly disappearing

spring fens." (Authors)] Address: not stated

**19886.** Porter R.F. (2016): Odonata from Iraq, with three new records. *Notulae odonatologicae* 8(8): 254-260. (in English) ["Twenty-two taxa of Odonata were recorded between 2009 and 2013 in the Peramagroon Mountains (Zagros range) and the Central Marshes of Iraq. *Chalcolestes parvidens*, *Erythromma lindenii* and *Orthetrum chrysostigma* are new records for the country, bringing the national checklist to at least 44 species. The discovered population of *E. lindenii* showed characters transitory to ssp. *zernyi* Schmidt, 1939." **19887.** Rajabi, H.; Ghoroubi, N.; Stamm, K.; Appel, E.; Gorb, S.N. (2016): Dragonfly wing nodus: a one-way hinge contributing to the asymmetric wing deformation. *Acta Biomaterialia* 60: 330-338. (in English) ["Dragonfly wings are highly specialized locomotor systems, which are formed by a combination of several structural components. The wing components, also known as structural elements, are responsible for the various aspects of the wing functionality. Considering the complex interactions between the wing components, modelling of the wings as a whole is only possible with inevitable huge oversimplifications. In order to overcome this difficulty, we have recently proposed a new approach to model individual components of complex wings comparatively. Here, we use this approach to study nodus, a structural element of dragonfly wings which has been less studied to date. Using a combination of several imaging techniques including scanning electron microscopy (SEM), wide-field fluorescence microscopy (WFM), confocal laser scanning microscopy (CLSM) and micro-computed tomography (micro-CT) scanning, we aim to characterize the spatial morphology and material composition of fore- and hindwing nodi of the dragonfly *Brachythemis contaminata*. The microscopy results show the presence of resilin in the nodi, which is expected to help the deformability of the wings. The computational results based on three-dimensional (3D) structural data suggest that the specific geometry of the nodus restrains its displacements when subjected to pressure on the ventral side. This effect, resulting from an interlocking mechanism, is expected to contribute to the dorso-ventral asymmetry of wing deformation and to provide a higher resistance to aerodynamic forces during the downstroke. Our results provide an important step towards better understanding of the structure-property-function relationship in dragonfly wings. Statement of significance: In this study, we investigate the wing nodus, a specialized wing component in dragonflies. Using a combination of modern imaging techniques, we demonstrate the presence of resilin in the nodus, which is expected to facilitate the wing deformability in flight. The specific geometry of the nodus, however, seems to restrain its displacements when subjected to pressure on the ventral side. This effect, resulting from an interlocking mechanism, is suggested to contribute to dorso-ventral asymmetry of wing deformations and to provide a higher resistance to aerodynamic forces during the downstroke. Our results provide an important step towards better understanding of the structure-property-function relationship in dragonfly wings and might help to design more efficient wings for biomimetic micro-air vehicles." **19888.** Robinson, J. (2016): Mercury concentrations in invertebrates from a contaminated wetland, Montague Gold Mines, Dartmouth, Nova Scotia. B.Sc., Thesis, Saint Mary's Univ., Halifax, Nova Scotia: 44 pp. (in English) ["Mercury pollution has become a significant concern to environmentalists over the past several decades. With natural releases of mercury and increasing anthropogenic activities releasing larger quantities of mercury into the environment over the last several decades, harm to organisms and ecosystems is also on the rise. One anthropogenic activity that will be considered in this report is gold mining and its products' bioavailability, via mercury contaminated-tailing material, in aquatic invertebrates at a wetland located in the Montague Gold Mining District in Dartmouth, Nova Scotia. Sediment from the study wetland at Montague Mining District showed significantly elevated total mercury concentrations with all samples far above the Canadian Council of Ministers of the Environment freshwater sediment values. Focal invertebrates (Anisoptera, Zygoptera and Dolomedes) were collected from the study wetland as well and analyzed for total mercury content displaying significantly higher total mercury concentrations than invertebrates of the same sub-order and genus collected from a non-contaminated reference site. Additionally, Anisoptera total mercury levels far exceeded levels found at a similar study conducted at Kejimikujik National Park, indicating this site in particular is of high concern for mercury contamination, bioavailability and potential biomagnification through terrestrial and aquatic food chains. With respect to parental Hg transfer to young, our results suggest that Hg transfer from Dolomedes to their young within their egg sacs is likely. Due to the nature of the odonate and dolomedes lifecycles and their potential to spread contamination not only to terrestrial landscapes, but also to other aquatic habitats, it is clear that the impacts go beyond the boundaries of the Old Stamp Mill wetland." **19889.** Sanmartín-Villar, I.; Cordero-Rivera, A. (2016): Female colour polymorphism and unique reproductive behaviour in Polythore damselflies (Zygoptera: Polythoridae). *Neotropical Entomology* 45(6): 658-664. (in English) ["We studied Polythore damselflies by mark-recapture techniques in the Jatun Sacha Biological Reserve (Ecuador) for a period of 48 days in October–December 2014. Three species were found: Polythore mutata (MacLachlan) was the commonest species (111 individuals marked), Polythore derivata (MacLachlan) was rare (24 individuals) and Polythore concinna (MacLachlan) occasional (four individuals). In P. mutata, we found two phenotypes amongst females, one of them with a white band on the wings, very similar in colouration to the conspecific male (androchrome), and the other with an amber band (gynochrome). The recapture of marked females indicates that both phenotypes are maintained since emergence to maturation and are not age-related (i.e. polymorphism). Androchromes represent 40% of females observed. The colour of the wing band showed an age-dependent change in size with opposite trends between sexes, increasing in males and decreasing in females. Males and females were observed to return to the same forest locations in different days. Courtships and ovipositions involving androchrome females were not observed. No matings were observed in any morph. In contrast, we recorded two consecutive matings of one female P. derivata. We found that Polythore males grasp the mesothorax of females during mating instead of the prothorax as in other Zygoptera. We discuss the rarity of reproductive behaviour in this genus and how female morphs might be maintained." (Authors)] Address: Cordero Rivera, A., Depto

**19890.** Shahr, M.N.A.; Uddin, B.; Khan, M.K. (2016): OdoBD: An online database of ecological and genetic information of the Odonata of Bangladesh. FCRSD2016, Sylhet, Bangladesh: 48- (in English) [Verbatim: Odonata (dragonflies and damselflies) are carnivorous insects distributed in the diverse freshwater reservoirs throughout the world. Bangladesh situated in the South-east Asia, is gifted with the rich network of water resources like ponds, lakes, marshes, rivers, streams and mangrove swamps. This various range of water bodies along with many tropical forest patches has generated suitable habitat for many Odonata species. Till date, scanty of studies have been carried out to annotate the Odonata fauna of Bangladesh. Currently, nearly hundred species is known from Bangladesh, however there is no consolidated database of this taxa for this country, and information on these species remains elusive. The largely unconsolidated information makes large-scale analysis and researches involving Odonates particularly challenging. Thus, we have developed an online database of all the known Odonates from different locations of Bangladesh to generate an integrated and widely accessible source to facilitate studies of ecology, conservation, and genetic analysis. Currently, we have amassed information of 86 different species from all over the country. The database, -named Odonata of Bangladesh (www.Odobd.org), contains information on morphology, habitat, abundance, gene and protein sequences, worldwide distribution and conservation status of the Bangladeshi Odonates and is updated on a regular basis. We have included gender specified photographs with descriptions for better understanding for the novice researchers and naturalists. This database will spread the knowledge of the Bangladeshi Odonates as well as will enhance the opportunities for ecological and genetic research on those species. **19893.** Sonnenburg, H.; Garczorz, T. (2016): Die Libellenfauna des NSG "Donoper Teich - Hiddeser Bent" (Detmold) unter besonderer Berücksichtigung des Hochmoorlebensraumes (Insecta: Odonata). Mitteilungen der Arbeitsgemeinschaft ostwestfälisch-lippischer Entomologen 30(1): 1-17. (in German) ["The results of the dragonfly fauna survey carried out in the Donoper Teich - Hiddeser Bent nature reserve from 2011 to 2014 are presented, supplemented by data from previous years. The main focus of the survey was Hiddeser Bent. The Hiddeser Bent (here especially the eastern area) is characterised by a particular richness of dragonfly species. With the exception of the ubiquitous *Libellula quadrimaculata*, *Sympetrum striolatum* and *Coenagrion puella*, the species recorded mostly occurred in very low densities. Species specific to the high moors of the Hiddeser Bent include *Aeshna subarctica*, *Somatochlora arctica* and *Leucorrhinia dubia*. *Aeshna juncea*, *Orthetrum coerulescens* and *Lestes virens* occurred in small numbers as further species typical of the bog, but not exclusively bound to bog habitats. Despite the immigration of new species, a loss of importance of the Hiddeser Bent for the dragonfly fauna can be assumed, which particularly affects the more demanding species of the raised bogs and acidic, nutrient-poor waters. This is due to the progressive shrinkage process and the drying out of the bog depressions in summer." **19894.** Soomets, E.; Rannap, R.; Lõhmus, A. (2016): Patterns of assemblage structure indicate a broader conservation potential of focal amphibians for pond management. PLoS ONE 11(7): e0160012. doi:10.1371/journal.pone.

0160012: 16 pp. (in English) ["Small freshwater ponds host diverse and vulnerable biotic assemblages but relatively few conspicuous, specially protected taxa. In Europe, the amphibians *Triturus cristatus* and *Pelobates fuscus* are among a few species whose populations have been successfully restored using pond restoration and management activities at the landscape scale. In this study, we explored whether the ponds constructed for those two target species have wider conservation significance, particularly for other species of conservation concern. We recorded the occurrence of amphibians and selected aquatic macro-invertebrates (dragonflies; damselflies; diving beetles; water scavenger beetles) in 66 ponds specially constructed for amphibians (up to 8 years post construction) and, for comparison, in 100 man-made ponds (created by local people for cattle or garden watering, peat excavation, etc.) and 65 natural ponds in Estonia. We analysed nestedness of the species assemblages and its dependence on the environment, and described the co-occurrence patterns between the target amphibians and other aquatic species. The assemblages in all ponds were significantly nested, but the environmental determinants of nestedness and co-occurrence of particular species differed among pond types. Constructed ponds were most species-rich irrespective of the presence of the target species; however, *T. cristatus* was frequent in those ponds and rare elsewhere, and it showed nested patterns in every type of pond. We thus conclude that pond construction for the protected amphibians can serve broader habitat conservation aims in the short term. However, the heterogeneity and inconsistent presence of species of conservation concern observed in other types of ponds implies that long-term perspectives on pond management require more explicit consideration of different habitat and biodiversity values. We also highlight nestedness analysis as a tool that can be used for the practical task of selecting focal species for habitat conservation." **19895.** Suhaila, A.H.; Che Salmah, M.R.; Nurul Huda, A. (2016): Composition and distribution of Odonata larvae and its relationship with physiochemical water quality in northern peninsular Malaysia. Malaysian Journal of Science 35(2): 198-209. (in English, with Malaysian summary) ["A study on composition and distribution for Odonata larvae and their relationship with physicochemical parameters was carried out in selected rivers of Gunung Jerai Forest Reserve, Kedah. Different river physicochemical parameters might influence or affect different type of Odonata composition. Therefore, Odonata larvae were sampled monthly at three selected rivers in Gunung Jerai Forest Reserve which were Teroi, Tupah, Batu Hampar rivers from August 2007 until January 2008 by using a D-frame aquatic net. A total of 253 individuals of 12 genera belonging to nine families of Odonata have been identified. Greatest number of Odonata individuals was recorded in Teroi River (112 individuals) with mean density recorded highest in January 2008 (6.6 ind/m<sup>2</sup>). The major families were Libellulidae, Euphaeidae and Gomphidae. Aeshnidae, Macromiidae, Calopterygidae, Coenagrionidae, Amphipterygidae and Chlorocyphidae represented the minority groups. Libellulidae reported the greatest number of individuals in all study areas, followed by Euphaeidae. Ranking from the highest to the lowest

number of genus collected were *Zygonyx*, *Euphaea*, *Macromia*, *Anax*, *Ophiogomphus*, *Libellago*, *Vestalis* and *Devadatta*, *Neurobasis*, *Cercion*, *Pseudagrion*, *Gomphidictinus*, and *Paragomphus*. The distribution of these genera were significant in different months studied (Kruskal Wallis,  $p < 0.05$ ) in all three rivers. The abundance of individuals collected was strongly influenced by velocity of water. Libellulid *Zygonyx* was the most affected by velocity and biochemical oxygen demand in all studied river. A *Euphaea* larva was influenced by temperature, depth, pH and biochemical oxygen demand. The ecological index (Richness, diversity and evenness index) exhibited poor Odonata communities in all studied rivers. In conclusion, water velocity, biochemical oxygen demand do have influenced on Libellulidae family while temperature, depth, pH and biochemical oxygen demand have influenced on Euphaeidae family." **19896.** Svensson, E.; Nordén, A.; Waller, J.; Runemark, A. (2016): Linking intra- and interspecific assortative mating: consequences for asymmetric sexual isolation. *Evolution* 70(6): 1165-1179. (in English) ["Assortative mating is of interest because of its role in speciation and the maintenance of species boundaries. However, we know little about how within-species assortment is related to interspecific sexual isolation. Most previous studies of assortative mating have focused on a single trait in males and females, rather than utilizing multivariate trait information. Here we investigate how intraspecific assortative mating relates to sexual isolation in two sympatric and congeneric damselfly species (genus *Calopteryx*). We connect intraspecific assortment to interspecific sexual isolation by combining field observations, mate preference experiments and enforced copulation experiments. Using canonical correlation analysis, we demonstrate multivariate intraspecific assortment for body size and body shape. Males of the smaller species mate more frequently with heterospecific females than males of the larger species, which showed less attraction to small heterospecific females. Field experiments suggest that sexual isolation asymmetry is caused by male preferences for large heterospecific females, rather than by mechanical isolation due to interspecific size differences or female preferences for large males. Male preferences for large females and male-male competition for high quality females can therefore counteract sexual isolation. This sexual isolation asymmetry therefore indicates that sexual selection currently opposes a species boundary." **19897.** Takiya, D.; Santos, A.; Pinto, A.; Henriques-Oliveira, A.; Carvalho, A.; Sampaio, B.; Clarkson, B.; Moreira, F.; Avelino-Capistrano, F.; Gonçalves, I.; Cordeiro, I.; Câmara, J.; Barbosa, J.; de Souza, W.; Rafael, J. (2016): Aquatic insects from the Caatinga: checklists and diversity assessments of Ubajara (Ceará State) and Sete Cidades (Piauí State) National Parks, Northeastern Brazil. *Biodiversity Data Journal* 4: e8354. doi: 10.3897/BDJ.4.e8354: 195 pp. (in English) ["Background: Diversity and distribution of Neotropical aquatic insects is still poorly known, with many species to be recorded and many others to be described, due to the small number of taxonomists and sparse faunistic studies. This knowledge is especially poor in the Caatinga Domain in Northeastern Brazil, even though, this region may have played an important historical role in the spatial evolution of faunas of forested areas in northern South

America.

**19898.** New information: Aquatic insect checklists of 96 species from Parque Nacional de Ubajara (Ceará State, Brazil) and 112 species from Parque Nacional de Sete Cidades (Piauí State, Brazil) are presented, representing the following taxa: Elmidae, Epimetopidae, Hydrophilidae, and Torridincolidae (Coleoptera), Hemerodromiinae (Diptera: Empididae), Ephemeroptera, Gerromorpha and Nepomorpha (Hemiptera), Odonata, Plecoptera, and Trichoptera. Because of the scarce number of biological inventories in Northeastern Brazil, several new distributional records (of species, genera, and families) for Brazil, Northeastern Brazil, and Ceará and Piauí states are provided. In addition, several undescribed species were detected, being 26 from Ubajara and 20 from Sete Cidades. Results represent a significant increase to the known fauna of these states, ranging from 13%-70% increase for Ceará and 41% to 91% increase for Piauí. Although both parks are relatively close to each other and within the Caatinga domain, their aquatic fauna display a very high complementarity (89% species), possibly due to structural differences of water bodies sampled in each park. Rarefaction curves based on quantitative light trap samples suggest a much higher expected species richness of aquatic insects at Sete Cidades than at Ubajara National Park. Discussion on biogeographical affinities of this sample of the Caatinga fauna is provided." (Authors) Odonata on pages 144-156.] Address: Pinto, Â.P. **19901.** Thein, P.P.; Choi, S.-W. (2016): Forest insect assemblages attracted to light trap on two high mountains (Mt. Jirisan and Mt. Hallasan) in South Korea. *Journal of Forestry Research* 27(5): 1203-1210. (in English) ["Assemblages of forest insects across two high mountains (Mt. Hallasan: JJ and Mt. Jirisan: JR) in South Korea were compared by collecting insects using an ultraviolet light trap at 20 sites (200–1700 m elevation ranges) from May to October 2013. A total of 2960 individuals, representing 481 species of 10 orders [including Odonata not further specified],

were collected on JJ, compared with 7080 individuals representing 769 species of 14 orders on JR. The estimated number of species on JJ was 667 compared with 952 on JR. The differentiation among habitats ( $\beta$ -diversity) was higher on JJ (4.95) than JR (4.33) because of the island characteristics of JJ. Six insect orders (Lepidoptera, Coleoptera, Diptera, Hymenoptera, Hemiptera and Trichoptera) were dominant on both mountains, suggesting that the light trap captures represented well the insect fauna and is an effective method for investigating forest insect diversity. We concluded that forest insect assemblages on mountains are mainly affected by the elevation and the dominant forest in each elevation. In addition, the insect fauna on each mountain was differentiated by the habitat, which could be correlated with geological history." (Authors) See Table 1 for site information. **19902.** Therry, L.; Janne Swaegers, J.; Dinh, K.V.; Bonte, D.; Stoks, R. (2016): Low larval densities in northern populations reinforce range expansion by a Mediterranean damselfly. *Freshwater Biology* 61: 1430-1441. (in English) ["(1.) Contemporary climate change triggers a poleward range shift in many species. A growing number of studies document evolutionary changes in traits accelerating range expansion (such as growth rate and dispersal-related traits). In contrast, the direct impact of decreasing conspecific densities towards the very edge of the expansion front has been neglected. Density effects may, however, have a profound direct impact on traits involved in range expansion and influence range dynamics. (2.) In this study, we contrast the effects of high conspecific larval density typical for established populations and low larval density typical for newly founded populations at the edge of the expansion front on a set of larval traits that may affect the range dynamics in the poleward moving damselfly *Coenagrion scitulum*. We therefore ran an outdoor mesocosm experiment with a low- and high-density treatment close to the species' northern expansion front. Density effects on survival, growth rate and body size are scored both during the pre-winter growth period and during the subsequent winter period. Additionally, foraging activity was scored at the end of the pre-winter period and body condition [size-corrected body mass, fat content and activity of phenoloxidase (PO)] was scored at the end of the winter period. (3.) The low-density treatment had strong direct positive effects on survival, growth rate and body size of larvae before winter indicating relaxed competition. Lower foraging activity at the low-density treatment indicated higher food availability at low conspecific densities. Interestingly, the initial density treatment had stronger effect than densities experienced at the time of quantification on survival during the pre-freezing winter period and body condition estimates at the end of the experiment, indicating also delayed effects of the initial density treatment. Survival throughout a freezing period indicated extreme winter conditions are not likely a limiting factor in the range expansion of this Mediterranean species. (4.) The increased survival and individual growth rates (through causing shifts in voltinism) at low conspecific density will translate in increased population growth rates. Furthermore, nutritional advantages at low conspecific density may increase investment in dispersal ability. Together, these direct and delayed density-

dependent effects that gradually increase towards the expansion front are expected to accelerate range expansion." (Authors)] Address: Therry, L., Lab. of Aquatic Ecology, Evolution and Conservation, KU Leuven, Deberiotstraat 32, B-3000 Leuven, Belgium. Email: therry.lieven@gmail.com

**19903.** Tran, T.T.; Janssens, L.; Dinh, K.V.; Op de Beeck, L.; Stoks, R. (2016): Evolution determines how global warming and pesticide exposure will shape predator-prey interactions with vector mosquitoes. *Evolutionary Applications*: 13 pp. (in English) ["How evolution may mitigate the effects of global warming and pesticide exposure on predator-prey interactions is directly relevant for vector control. Using a space-for-time substitution approach, we addressed how 4°C warming and exposure to the pesticide endosulfan shape the predation on *Culex pipiens* mosquitoes by damselfly predators from replicated low- and high-latitude populations. Although warming was only lethal for the mosquitoes, it reduced predation rates on these prey. Possibly, under warming escape speeds of the mosquitoes increased more than the attack efficiency of the predators. Endosulfan imposed mortality and induced behavioral changes (including increased filtering and thrashing and a positional shift away from the bottom) in mosquito larvae. Although the pesticide was only lethal for the mosquitoes, it reduced predation rates by the low-latitude predators. This can be explained by the combination of the evolution of a faster life history and associated higher vulnerabilities to the pesticide (in terms of growth rate and lowered foraging activity) in the low-latitude predators and pesticide-induced survival selection in the mosquitoes. Our results suggest that predation rates on mosquitoes at the high latitude will be reduced under warming unless predators evolve toward the current low-latitude phenotype or low-latitude predators move poleward." **19904.** Van Dievel, M.; Janssens, L.; Stoks, R. (2016): Short- and long-term behavioural, physiological and stoichiometric responses to predation risk indicate chronic stress and compensatory mechanisms. *Oecologia* 181(2): 347-357. (in English) ["Prey organisms are expected to use different short- and long-term responses to predation risk to avoid excessive costs. Contrasting both types of responses is important to identify chronic stress responses and possible compensatory mechanisms in order to better understand the full impact of predators on prey life history and population dynamics. Using larvae of the damselfly *Enallagma cyathigerum*, we contrasted the effects of short- and long-term predation risk, with special focus on consequences for body stoichiometry. Under short-term predation risk, larvae reduced growth rate, which was associated with a reduced food intake, increased metabolic rate and reduced glucose content. Under long-term predation risk, larvae showed chronic predator stress as indicated by persistent increases in metabolic rate and reduced food intake. Despite this, larvae were able to compensate for the short-term growth reduction under long-term predation risk by relying on physiological compensatory mechanisms, including reduced energy storage. Only under long-term predation risk did we observe an increase in body C:N ratio, as predicted under the general stress paradigm (GSP). Although this was caused by a predator-induced decrease in N content, there was no associated increase in C content. These stoichiometric changes could not be explained by GSP responses because, under chronic predation risk, there was no decrease in N-rich proteins or increase in C-

rich fat and sugars; instead glycogen decreased. Our results highlight the importance of compensatory mechanisms and the value of explicitly integrating physiological mechanisms to obtain insights into the temporal dynamics of non-consumptive effects, including effects on body stoichiometry." **19905.** Van Dinh, K.; Janssens, L.; Therry, L.; Bervoets, L.; Bonte, D.; Stoks, R. (2016): Delayed effects of chlorpyrifos across metamorphosis on dispersal-related traits in a poleward moving damselfly?. *Environmental Pollution* 218: 634-643. (in English) ["Highlights: •We exposed edge & core larvae of a poleward moving damselfly to chlorpyrifos (CPF). •Chlorpyrifos had no direct effects in the larval exposure stage. •Delayed effects of CPF caused wing malformations and impaired adult immune response. •Delayed effects of CPF reduced flight muscles only in edge males. •CPF may slow down poleward range expansions under global warming. Abstract; How exposure to contaminants may interfere with the widespread poleward range expansions under global warming is largely unknown. Pesticide exposure may negatively affect traits shaping the speed of range expansion, including traits related to population growth rate and dispersal-related traits. Moreover, rapid evolution of growth rates during poleward range expansions may come at a cost of a reduced investment in detoxification and repair thereby increasing the vulnerability to contaminants at expanding range fronts. We tested effects of a sublethal concentration of the widespread pesticide chlorpyrifos on traits related to range expansion in replicated edge and core populations of the poleward moving damselfly *Coenagrion scitulum* reared at low and high food levels in a common garden experiment. Food limitation in the larval stage had strong negative effects both in the larval stage and across metamorphosis in the adult stage. Exposure to chlorpyrifos during the larval stage did not affect larval traits but caused delayed effects across metamorphosis by increasing the incidence of wing malformations during metamorphosis and by reducing a key component of the adult immune response. There was some support for an evolutionary trade-off scenario as the faster growing edge larvae suffered a higher mortality during metamorphosis. Instead, there was no clear support for the faster growing edge larvae being more vulnerable to chlorpyrifos. Our data indicate that sublethal delayed effects of pesticide exposure, partly in association with the rapid evolution of faster growth rates, may slow down range expansions." **19906.** van Grunsven, R.; De Knijf, G. (2016): Portret: Geelvlak heidelibel. *Brachytron* 18(1): 70-72. (in Dutch) ["The decline in Yellow-spotted Dragonflies (*Sympetrum flaveolum*) is obvious (Figure 2), but the absence of invasions does not necessarily mean that everything is fine. This could be pure coincidence, possibly 2016 is another invasion year and suddenly there are Yellow-spotted Dragonflies everywhere again. However, this does not seem likely to us. The invasions have to come from somewhere and for us that is mainly north-east Germany and northern Poland. However, the Yellow-spotted Dragonfly is listed as endangered on the German Red List (Ott et al. 2015) and in Poland the trend is less negative, but even there this species is declining significantly in large parts of the country (pers. med. R. Bernard). After invasions the animals can be found in all kinds of places, they seem to be little critical then. But for long-term

populations and large numbers, they depend on sedge and hollow-point vegetation, grassy marshes that flood in winter and run dry in summer, and on small, stagnant water bodies, such as cattle drinking pools, in agricultural areas. However, the hydrology and landscape in many areas of Central and Eastern Europe have changed significantly in recent decades. Drainage and groundwater extraction have caused many marshes and pools to disappear, and potential habitats to dry up too early in the year. In addition, intensification of agriculture leads to eutrophication, resulting in a compaction of the vegetation, which also makes it unsuitable for *S. flaveolum* (Bernard et al. 2002). Climate change may also cause pools and marshes to dry up too early in the year. Therefore, it is questionable whether the source populations are still large enough to ensure a large invasion and thus repopulate suitable areas in the Low Countries. Therefore, it seems unlikely that our Flemish and Dutch regions will be able to accommodate sustainable populations of *S. flaveolum* in the short term. In the meantime, *S. flaveolum* has become a real rarity here and is no longer a common part of the Dutch and Belgian dragonfly fauna. But you can still, with a lot of luck, come across them somewhere in late summer." **19907.** Venter, H.J.; Bezuidenhout, C.C. (2016): DNA-based identification of aquatic invertebrates – useful in the South African context? *South Afr. Jour. Sci.* 112(5/6) (Art. #2015-0444): 4 pp. (in English) ["The concept of using specific regions of DNA to identify organisms – processes such as DNA barcoding – is not new to South African biologists. The African Centre for DNA Barcoding reports that 12 548 plant species and 1493 animal species had been barcoded in South Africa by July 2013, while the Barcode of Life Database (BOLD) contains 62 926 records for South Africa, 11 392 of which had species names (representing 4541 species). In light of this, it is surprising that aquatic macroinvertebrates of South Africa have not received much attention as potential barcoding projects thus far – barcoding of aquatic species has tended to focus on invasive species and fishes. Perusal of the BOLD records for South Africa indicates a noticeable absence of aquatic macroinvertebrates, including families used for biomonitoring strategies such as the South African Scoring System. Meanwhile, the approach of collecting specimens and isolating their DNA individually in order to identify them (as in the case of DNA barcoding), has been shifting towards making use of the DNA which organisms naturally shed into their environments (eDNA). Coupling environmental and bulk sample DNA with high-throughput sequencing technology has given rise to metabarcoding, which has the potential to characterise the whole community of organisms present in an environment. Harnessing barcoding and metabarcoding approaches with environmental DNA (eDNA) potentially offers a non-invasive means of measuring the biodiversity in an environment and has great potential for biomonitoring. Aquatic ecosystems are well suited to these approaches – but could they be useful in a South African context?" (Authors) The study includes a passing reference to "Odonata".] Address: Venter, Hermoine, Unit for Environmental Sciences and Management, School of Biological Sciences, North-West Univ., Private Bag X6001, Potchefstroom 2520, South Africa. **19908.** Verspui, K.; Wasscher, M.T. (2016): The damselfly and dragonfly watercolour collection of Edmond de Selys

Longchamps: I Agrionines. International Journal of Odonatology 19(3): 1-32. (in English) ["In the nineteenth century Edmond de Selys Longchamps assembled a collection consisting of watercolours, drawings and notes on Odonata. Most illustrations were based on specimens from his extensive odonate collection and were mainly executed by Selys himself and by Guillaume Severin. These illustrations and notes are presently housed in the Royal Belgian Institute of Natural Sciences in Brussels. To make this unpublished information accessible, we digitised this material and it will be presented on the website of this Institute. This first article presents the part of the collection concerning Agrionines (all Zygoptera except Calopterygoidea). The Agrionines are represented by 506 sheets with watercolours, 90 sheets with drawings in ink or pencil and 150 sheets with text. To provide an overview of the collection, subject matter and characteristics of the sheets with illustrations and the text sheets are analysed. The majority (85%) of all sheets with illustrations have been associated with current species names by using references and expert opinions. This information should facilitate searching for various species in the watercolour collection. The rediscovery and documentation of this collection of Selys, that remained largely unknown for almost a century, will hopefully prove useful to those conducting research on the taxonomy of Odonata." **19909.** Wang, X.; Chu, Z.; Babacar D.; Huang, T.; Tang, Z.; He, Z.; Bao, H.; Zhao, B.; Gao, Y.; Hu, X.; Jia, X. (2016): Study on predatory effect of *Ischnura heterosticta* larvae on *Misgurnus anguillicaudatus* larvae. Journal of Fisheries of China 40(12): 1866-1873. (in Chinese, with English summary) ["To investigate the influence of the predator, *I. heterosticta* larvae on survival rate of *Misgurnus anguillicaudatus* larvae, we studied the predatory effect of *I. heterosticta* larvae on *M. anguillicaudatus* larva based on the predator-prey relationship theory. Results of experiments showed that: the predation functional response of *I. heterosticta* larvae to *M. anguillicaudatus* larvae belonged to type Holling-II. With the increase in daily age of *M. anguillicaudatus* larvae, the moment attack ( $a'$ ) and the largest preying amount per day ( $1/Th$ ) declined. The preying amount increased as prey density increased. The predatory function of different sizes of *I. heterosticta* larva to *M. anguillicaudatus* larva had significant differences. For *I. heterosticta* larvae with different body lengths ( $16.3 \pm 0.2$ ), ( $13.1 \pm 0.3$ ), ( $9.8 \pm 0.2$ ) and ( $5.8 \pm 0.3$ ) mm to 3-day-age larvae of *M. anguillicaudatus*, the moment attack and the largest preying amount per day were 0.8349, 0.5724, 0.2002, 0.0432, and 27.39, 18.99, 9.49, 3.14, respectively. With the density of *I. heterosticta* larvae increased, the mutual interference between the individuals led to reduction in the time of a single *I. heterosticta* larva looking for prey. Under intraspecific competition, predator effect rate (E) as a function of density (P) was  $E = 0.1403 \times P - 0.2361$ . With the increase of *M. anguillicaudatus* larvae and *I. heterosticta* larvae density, interference effect increases obviously, predatory efficiency rate (E) drops, but had little impact on preying amount, and the model of interspecific interference was  $Na =$  (Equation presented) The results demonstrated that *I. heterosticta* larva is important predator, which can remarkably reduce the survival rate of *M. anguillicaudatus* larvae." **19910.** Wang, X. (2016): Effects of *Ischnura heterosticta* larvae on predation and control of *Misgurnus anguillicaudatus*

larvae. M.Sc. thesis, Zhejiang Ocean Univ.: 57 pp. (in Diptera larvae *Trichosanthes* Predator-prey effect High-performance cyhalothrin *Chlorella acute* toxicity trapping device) ["After a large number of studies, it was found that the larvae of *I. heterosticta* affected the survival of larvae of loach larvae. However, there is no report on predatory effects of predators on loach. In this paper, we studied the predator-prey effect of Diptera larvae on the larvae of the loach, and established the predator-prey effect model to provide the theoretical basis for the prevention and control of the larvae of the mussel larvae. On this basis, Chrysanthemum, trichlorfon and other insecticides and homemade trapping device on the killing of the damn larvae, for the effective prevention and control of soymilk larvae to provide technical basis. The results of this study are as follows: 1. Predator-prey effect of Duck Soybean larvae on the larvae of the real loach The predation effect of the stellate larvae on the larvae of the larvae was studied by predator-prey method. The results showed that: (1) The predator-prey function of *Drosophila* larvae to Loach was Holling-?. The maximum predation rate  $1/Th$  of the larvae of the mongolica larvae decreased with the increase of the larval age, and the predation increased with the increase of the prey density. (2) The size of the larvae was different The larvae of the three kinds of Diptera larvae were significantly different from the larvae of  $16.3 \pm 0.2$ mm,  $13.1 \pm 0.3$ mm,  $9.8 \pm 0.2$ mm and  $5.8 \pm 0.3$ mm, respectively. The larvae and the maximum predation (3) With the increase of the density of Soybean larvae, the mutual interference between individuals, resulting in a single maiden larvae to find prey time to reduce the species within the species, The relationship between predator-prey (E) and self-density (P) is  $0.2361E - 0.1403P - (28)'$ . (4) With the increase of larvae and larvae density, the interference effect is obvious. And the predation rate E decreased, but it had little effect on its predation, and the inter-species interference reaction model was  $Na = (?)$ . 2, the effective effect of cyhalothrin and trichlorfon on the killing of Diptera larvae using hydrostatic biological test method to carry out the high efficacy of cyhalothrin and trichlorfon two commonly used fishery drugs on the acute toxicity of Diptera larvae Experiment and establish the logarithmic linear regression equation of corresponding mortality - drug mass concentration. The results showed that the sensitivity of the soymilk larvae to cyhalothrin was greater than that of trichlorfon. The half-lethal concentrations of the two drugs at 24h, 48h and 96h were  $6.44 \mu\text{g} / \text{L}$ ,  $5.31 \mu\text{g} / \text{L}$ ,  $4.57 \mu\text{g} / \text{L}$  and  $0.81 \text{mg} / \text{L}$ ,  $0.65 \text{mg} / \text{L}$ ,  $0.56 \text{mg} / \text{L}$ , the safety mass concentration was  $0.89 \mu\text{g} / \text{L}$ ,  $0.11 \text{mg} / \text{L}$ . The acute toxicity test of two commonly used fishery drugs on 5-day-old and 25-day-old loach larvae showed that the lethality of cyhalothrin was less than or equal to 5.8% As the soymilk larvae to kill the drug; and trichlorfon on the damn mother larvae have a significant killing effect, the mortality rate of up to 89.6% or more, can be used as a traditional medicine to kill the damn mothers to use. 3, self-made trapping device on the killing effect of *Dipterocarca* larvae found that Soybean larvae with phototaxis and the use of oil film can lead to suffocation death, in view of this, the use of oil film asphyxia design of the soymilk larvae trap device, and carried out The killing test of the larvae of. The results show that the trapping device has the advantages of simplicity, efficiency, economy, practicality and safety. The setting depth of the device and the setting of the water plants have the influence on the larvae of the suckling bean sores. The device is set at 30-40cm The larvae had significant killing effect on the larvae of *Soya japonica* larvae, and the lethality rate was about 20% -30% at 12h, while the larvae had no lethal effect on the larvae. Therefore, the trapping device can be used as the main technical means

to kill the soymilk larvae in the breeding base of loach.] Address: Wang, X., School of Fishery, Zhejiang Ocean Univ., Zhoushan 316022, China

**19911.** Wei, Y.; Zhu, Y.-y.; Wang, M.-I. (2016): A facile surface-enhanced Raman spectroscopy detection of pesticide residues with Au nanoparticles/dragonfly wing arrays. *Optik - International Journal for Light and Electron Optics* 127(22): 10735-10739. (in English) ["Recent studies have conclusively show that the surface-enhanced Raman spectroscopy (SERS) has been widely used for chemical and biomolecular sensing. In this work, a facile, low-cost, green and rapid method to detect the pesticide residues is presented by using Au nanoparticles/dragonfly wing (AuNPs/DW) arrays as SERS-active substrate. The AuNPs/DW substrate is prepared by decorating the AuNPs on the DW surface with a simple two-step method, meanwhile, the microstructure properties and SERS signal are characterized by the scanning electron microscopy (SEM) and confocal microprobe Raman system. The experimental results show that compared with the conventional Raman spectroscopy, the AuNPs/DW substrate can enhance the Raman signal dramatically due to the largescale nanosized protrusions on the DW surface. The detection limit for rhodamine 6G (R6G) could reach as low as 10<sup>-8</sup> M, which is important for the analysis of the most components and structures of samples. For the application of the three-dimensional AuNPs/DW, the micro-sample of thiram and carbaryl can also be detected quantitatively, and the detection limit both reach up to 10<sup>-7</sup> M. The above phenomenon indicate that three-dimensional nanostructure AuNPs/DW is a promising SERS substrate for the test of samples in low concentration. Hence, our study will provide an effective approach for the rapid, sensitive and stable trace detection of organic molecular species." **19913.** Acorn, J.H. (2017): Entomological citizen science in Canada. *Can. Entomol.* 149: 774-785. (in English) ["Citizen science involves voluntary participation in the scientific process, typically by gathering data in order to monitor some aspect of the natural world. Entomological citizen science, as an extension of traditional amateur entomology, is an active field in Canada, with online databases such as eButterfly and BugGuide attracting both contributors and database users. As well, traditional amateur entomology continues to be important in Canada, as do short-term insect-themed educational events, the involvement of amateurs in entomological societies, and online crowdsourcing initiatives. Success of citizen science projects can be measured in many ways. In terms of published papers that analyse trends in citizen science data, Canadian projects have only begun to deliver. More valuable are particular records that improve our knowledge of geographic ranges and phenology. In terms of the endurance of particular projects, and the willingness of volunteers to participate, citizen science entomology in Canada is clearly a success. However, quality control of citizen science data remains an issue for some projects. As well, challenges remain with respect to balancing the goals of researchers, participants, and supporting institutions." (Author) Citizen science projects also include Odonata.] Address: Acorn, J.H., Dept of Renewable Resources, Univ. of Alberta, Edmonton, Alberta, T6G 2H1, Canada. Email: jacorn@ualberta.ca

**19914.** Baleguel, N.P.; Che, J.N.; Baleguel, P.D. (2017): Efficacy of temephos and permethrin in black fly (*Simulium* spp) control and their effect on non-target entomofauna in a portion of Sanaga Valley in Cameroon. *Revue Scientifique et Technique Forêt et Environnement du Bassin du Congo* 8: 11-18. (in English, with French summary) ["The biodiversity in the Congo Basin can be at once a blessing and a curse. A good example of a curse is the abundance of insects that cause nuisance and morbidity in this area especially onchocerciasis transmitted by black fly (*Simulium* spp) which is a major problem in disturbed environments (climate change). Black fly bites reduce the duration a man can work and increase the likelihood of the transmission of onchocerciasis (river blindness) in the tropical rainforest area of Cameroon. In order to decrease nuisance and morbidity caused by black fly and improve farmers' productivity, a study was conducted between 2007 and 2009 in a portion of Sanaga Valley in Cameroon (Monatele (04° 09' N, 11° 01' E), Ossebe (04° 03' N, 10° 36' E), Songndong (03° 51' N, 10° 15' E), Batombe (03° 51' N, 10° 10' E) and Ka'a (04° 43' N, 12° 24' E)), one of the most infected zones of the country. Black fly and nontarget insects captured were identified using identification keys. Data recorded on sticky traps and artificial breeding sites were used to evaluate the efficacy of temephos and permethrin, and their impact on non-target associated entomofauna in the reproduction sites of *Simulium damnosum*. Both larvicides, temephos and permethrin, are effective in the control of black fly though permethrin caused limited undesirable effects on non-target species. Insects of the Order Odonata [*Brachythemis lacustris*] were more affected by permethrin than insects of the Orders Ephemeroptera, Plecoptera and Tricoptera (EPT), which are the most vulnerable orders. This means that it has limited environmental effects when sprayed as specified in this trial and can be used in the integrated vector management of black

fly." (Author)] Address: Baleguel, N.P., Yaounde Initiative Foundation-Cameroon; P.O. Box 3878 Messa-Yaounde, Cameroon. E-mail: baleguel2001@yahoo.fr

**19915.** Bandara, C.D.; Singh, S.; Afara, I.O.; Tesfamichael, T.; Wolff, A.; Ostrikov, K.; Oloyede, A. (2017): Bactericidal effects of natural nanotopography of dragonfly wing on *Escherichia coli*. *ACS Appl. Mater. Interfaces*, DOI: 10.1021/acscami.6b13666: 6746-6760. (in English) ["Nano-textured surfaces (NTS) are critical to organisms as self-adaptation and survival tools. These NTS have been actively mimicked in the process of developing bactericidal surfaces for diverse biomedical and hygiene applications. To design and fabricate bactericidal topographies effectively for various applications, understanding the bactericidal mechanism of NTS in nature is essential. The current mechanistic explanations on natural bactericidal activity of nanopillars have not utilized recent advances in microscopy to study the natural interaction. This research reveals the natural bactericidal interaction between *E.coli* and a dragonfly wing's NTS using advanced microscopy techniques and propose a model. Contrary to the existing mechanistic models, this experimental approach demonstrated that the NTS of dragonfly wings has two prominent nanopillar populations and the resolved interface shows membrane damage occurred without direct contact of the bacterial cell membrane with the nanopillars. We propose that the bacterial membrane damage is initiated by a combination of strong adhesion between nanopillars and bacterium EPS layer as well as shear force when immobilised bacterium attempt to move on the NTS. These findings could help guide the design of novel bio-mimetic nanomaterials by maximising the synergies between both biochemical and mechanical bactericidal effects." **19916.** Berg, D. (2017): Untersuchungen zur Libellenfauna (Odonata) in der Haseaue bei Gehrde (Landkreis Osnabrück, Niedersachsen). Bc.S. thesis, Fakultät Agrarwissenschaften und Landschaftsarchitektur, Studiengang Landschaftsentwicklung (B.Eng.), Hochschule Osnabrück: V, 88 pp, Anhänge- (in German, with English summary) ["During the year 2016 the diversity of Odonata in the meadows of the river Hase near Gehrde in the district of Osnabrück (Lower Saxony) was analysed. Also the biotope types and the quality of the water body structure of the river Hase were mapped. The biotope mapping based on Drachenfels (2013), the mapping of the water body structure on Rasper (2001 a). 27 Odonata species were detected, of which 23 are indigenous, based on exuviae findings. Besides that, two species are probably indigenous because reproductive behaviour was observed. The two remaining species are possibly or possibly not indigenous. Most of the detected Odonata are considered as widespread. However, the species are differently distributed among the nine standing water bodies and the river Hase in the investigation area. In the case of two exuviae of the genus *Sympecma* the species could not be determined. No species of the family Gomphidae was found. A total of 114 biotope types were mapped in the 62,91 ha large investigation area. 69 biotope types are mapped as mixed biotope types. With a percentage of 17,32 % (10,89 ha) species-poor extensive grassland on dry mineral soil (GET - Artenarmes Extensivgrünland trockener Mineralböden) took the most of the area. The second largest biotope type was sandy farmland (AS - Sandacker), which took 14,52 % (9,13 ha) of the investigated area. 14,19 % (8,93

ha) are covered with grassland seedings (GA - Grünland-Einsaaten). Overall, the quality of the water body structure of the river Hase ranged from quality class 3 (moderately modified) to 7 (completely modified). All river sections featured a completely modified channel development and longitudinal profile, resulting in quality class 7. The quality classes of the cross profile ranged from 3 to 5 (strongly modified), the river bank structure from 5 to 7. With quality classes from 3 to 7, the water body environment showed the most structural differences. An assessing of the river bottom was not possible. Based on the results, notes on care and further development of the investigation area were given, which aim at the support of Odonata." **19917.** Boarman, M.J.S. (2017): Trade-offs and temporal variation in predator-mediated natural selection and sexual selection on the wings of the damselfly *Calopteryx splendens*. Master of Science (MS), Ohio Univ., Biological Sciences (Arts and Sciences): 63 pp. (in English) ["Evolutionary theory predicts a trade-off between sexual selection and natural selection on secondary sexual traits. Understanding the relationship between mating success and predation risk can give insight into the evolutionary dynamics that interact to promote or constrain phenotypic change, yet it has been little studied in the wild. I conducted a two-year cross-sectional field study on *C. splendens* to test for trade-offs between sexual selection and predation risk, and to assess variation in sexual and natural selection. At the study population, the White Wagtail (*Motacilla alba*) captures *C. splendens* in flight, then flies to feeding stations where it removes the wings and consumes the body. I used geometric morphometric techniques to quantify damselfly wing morphology, and compared wing shape and secondary sexual traits of wings from feeding stations to a random sample of wings from the population to quantify the strength, mode, and direction of natural selection on males. Simultaneously, I measured wing traits from individuals caught in the act of mating and compared them to a random sample of wings from the population to quantify the strength, mode, and direction of sexual selection on male wings. By comparing natural selection and sexual selection on wing traits simultaneously, I tested for trade-offs between types of selection. My results suggest that predator-mediated selection fluctuates through time, and is especially variable in how it operates on the size of secondary sexual traits displayed by males. Sexual selection operated almost exclusively on secondary sexual traits, and was consistent across years. Predator-mediated selection acted differently on fore- and hindwings, favoring males with long, narrow forewings and short, broad hindwings. A trade-off between natural and sexual selection was revealed on wing patch characteristics, with males possessing larger and darker wing patches experiencing higher predation rates, while achieving the highest mating success." **19918.** Braatz, E. (2017): Research proposal for odonate fitness in relation to Imidacloprid and varying pH. Retrieved from the Univ. of Minnesota Digital Conservancy, <http://hdl.handle.net/11299/189087>: 36 pp. (in English) ["Both neonicotinoids and varying pH levels affect odonate growth rates, which in turn can affect fitness. This proposal aims to assess how the combined stress of living in nonneutral water (pH = 5.0, 6.0, 8.0, and 9.0) and being exposed to a continuous, sublethal dose of 0.02 µg/L of the neonicotinoid imidacloprid will affect *Anax junius stadia* growth rates. Mortality rates will also be measured." (Author)] Address: not stated

**19919.** Casas, P.A.S.; Sing, K.-W.; Lee, P.-S.; Nuñez, O.M.; Villanueva, R.J.T.; Wilson, J.-J. (2017): DNA barcodes for dragonflies and damselflies (Odonata) of Mindanao, Philippines. Mitochondrial DNA Part A <http://dx.doi.org/10.1080/24701394.2016.1267157>: 9 pp. (in English) ["Reliable species identification provides a sounder basis for use of species in the order Odonata as biological indicators and for their conservation, an urgent concern as many species are threatened with imminent extinction. We generated 134 COI barcodes from 36 morphologically identified species of Odonata collected from Mindanao Island, representing 10 families and 19 genera. Intraspecific sequence divergences ranged from 0 to 6.7% with four species showing more than 2%, while interspecific sequence divergences ranged from 0.5 to 23.3% with seven species showing less than 2%. Consequently, no distinct gap was observed between intraspecific and interspecific DNA barcode divergences. The numerous islands of the Philippine archipelago may have facilitated rapid speciation in the Odonata and resulted in low interspecific sequence divergences among closely related groups of species. This study contributes DNA barcodes for 36 morphologically identified species of Odonata reported from Mindanao including 31 species with no previous DNA barcode records." **19920.** Ceder, P.; Jönsson, C. (2017): Tillväxttakt hos sydvänska populationer av trollsländor (Odonata) i ett varmare klimat - en pilotstudie. Independent thesis Basic level (degree of Bachelor): 16 pp. (in Swedish, with English summary) ["In order to gain better understanding of climate change effects on ecosystems, it is necessary to study the response of different species to predicted climate change. Dragonflies are, due to their ecology, a suitable organism group for conducting such studies. In this pilot study we examined the response in growth- and mortality rate to increased ambient temperatures in an experimental set-up of three temperature levels (20°C, 22°C och 24°C) in larvae of three species from the Aeshnidae family (*Aeshna grandis*, *A. cyanea* and *Anax imperator*). *A. imperator* were, due to insufficient number of collected specimens, excluded in the 22°C temperature regime. The studied species are reproducing in Sweden, but *A. grandis* and *A. cyanea* are native, whereas *A. imperator* is considered newly established since it was first discovered in Sweden in the early 2000's. Our results show that *A. grandis* and *A. cyanea* reacted positively to an increased ambient temperature, in terms of growth rates. However, the response to increased temperatures differed between the two species as *A. grandis* showed both higher growth- and mortality rate, compared to *A. cyanea*. Thus, we assume that both species are likely to benefit from the ongoing climate change, but that interactions between them may change. Further studies are required to elucidate how the two species will be affected in

presence of newly established species, such as *A. imperator*. Although, based on our results, the competitiveness of both native species might increase with rising temperatures - which should be considered in future conservation planning." (Authors)] Address: not stated

**19921.** Chavez Landi, P.A. (2017): Fisiología térmica de un depredador *Dasythemis* sp. (Odonata: Libellulidae) y su presa *Hypsiboas pellucens* (Anura: Hylidae) y sus posibles implicaciones frente al cambio climático. Disertación previa a la obtención del título de Licenciada en Ciencias Biológicas: X, 55 pp. (in Spanish, with English summary) ["Temperature is considered one of the most important abiotic factors in the biology of the organisms. Constant temperature change as a consequence of climate change can influence the physiological responses of the communities' structure. The principal purpose of this study was to determine the variation of the physiological thermal parameters in are species (*Dasythemis* sp. and *Hypsiboas pellucens*), who coexist in the same pond near Mindo (Pichincha), and to evaluate their vulnerability to possible environmental temperature in the future. We used a temperature ramp protocol which increases or decreases the temperature at a gradual rate of 0.25°C min<sup>-1</sup>, the Maximum Critical Temperature (CT<sub>max</sub>) and the Minimal Critical Temperature (CT<sub>min</sub>) were determined, along with the thermal tolerance (CT<sub>max</sub> – CT<sub>min</sub>) for both species. To assess prey's performance, the maximum speed of scape was analyzed, at several temperatures and a temperature gradient was used to determine the preferred temperature of both species. To assess the vulnerability to potential temperature changes we compared micro environmental temperature of the collection ponds during the period March to December 2016 and was compared maximum value with the CT<sub>max</sub> for each specie. The maximum and minimum thermal tolerances were 45.5°C and 6.62°C for the predator 40.4°C and 8.1°C for the prey. The maximum temperature registered in the micro-environment was 38.6°C, and the minimum temperature was 15.9°C. The performance escape speed was 86.72 cm gr<sup>-1</sup> s<sup>-1</sup> at an optimal temperature of 28.1°C. The mean preferable temperature of the prey was 24.4°C and 23.4°C for the predator. In conclusion, there are significant differences in thermal tolerances between the predator and the prey and the prey's preferable temperatures is above the predator's temperature. The tadpoles had a WT (warming tolerance) lower (1.85°C) than dragonfly larvae (6.88°C) would be the most vulnerable to future environmental changes. However, the optimal temperature and temperature frequency in the microenvironment indicate that in the near future climate change could improve species performance." (Author)] Address: not stated

**19922.** Choong, C.Y.; Yasser, M.A.; Nurfarhana-Hizan, H. (2017): Ancient Creatures: Dragonflies and Damselflies of Malaysia. Ministry of Natural Resources and Environment, Putrajaya, Malaysia: 115 pp. (in Bilingual in Malay and English) [This book contains published data and information about the wealth of special dragonflies and damselflies in Malaysia that are presented in a clear and interesting way. The featured images have been selected to enhance the pages of this book, complete with QR codes for additional information from the Malaysia Biodiversity Information System (MyBIS) website. The purpose of the ml website is to establish a repository center that summarizes information on biological diversity in Malaysia. Almost 400 species of Odonata contained in 17 families can be found in Malaysia. At least 180 species are dragonflies and 210 species are damselflies. The biological diversity book 'Ancient Creatures:

Dragonflies and Damselflies of Malaysia' displays a total of 69 species of dragonflies and 73 species of damselflies, most of which can be found throughout Malaysia." **19923.** Chovanec, A. (2017): Die Libellenfauna (Insecta: Odonata) der Klosterneuburger Donau-Au (Niederösterreich): Bewertung, Entwicklungstendenzen und Managementempfehlungen. Wiss. Mitt. Niederösterreich. Landesmuseum 27: 39-68. (in German, with English summary) ["The dragonfly fauna (Insecta: Odonata) of the Danube floodplains in Klosterneuburg (Lower Austria): assessment, development trends and management recommendations The dragonfly fauna of the Danube floodplains in Klosterneuburg (Lower Austria) was investigated in 2015. A total of 31 species (30 of them autochthonous) were recorded at eight water bodies, which corresponds to 40 % of the Austrian inventory of Odonate species and 22 % of the European inventory. Five spp. are threatened according to the Austrian Red List. Remarkable is the record of *Coenagrion scitulum*

("critically endangered"). The values of the Odonata Habitat Indices, the species-specific habitat values and the analyses concerning dragonfly associations indicate, that all habitat types characteristic for floodplain areas are present, but hydrologically dynamic sections and temporary waters only to a limited extend. The Odonate fauna recorded is dominated by limnophilic species typical of open waters, submerged macrophytes and reed as well as riparian trees. The ecological status is classified as "good", but it has to be pointed out, that only few sites are existent serving as suitable habitats for floodplain-specific dragonfly communities. Some of these sites are influenced and endangered by shading, terrestrialisation processes and desiccation. The results obtained in 2015 are compared with surveys carried out in 1999 and 2000 and represent the basis of management recommendations." (Author)] Address: Chovanec, A., c/o Umweltbundesamt, Spittelauer Lände 5, A-1090 Wien, Austria. E-mail: chovanec@ubavie.gv.at

**19924.** Chovanec, A.; Waringer, J.; Holzinger, W.E.; Moog, O.; Janecek, B. (2017): Odonata. In Moog, O. & A. Hartmann (Eds.): Fauna Aquatica Austriaca, 3. Edition 2017. BMLFUW, Wien: 1-18. (in English) ["The catalogue of Odonata with ecological notes of Janecek et al. (2002) represents a reissue of the first edition from 1995. The species inventory of this revised version has been harmonised with the current status of the species occurring in Austria listed by Holzinger et al. (2015). Ecological classifications were based on literature published since 1995 containing detailed information on distribution and ecological requirements of the relevant species (...) Furthermore, regional information from Austria as well as studies dealing with the colonisation of near-pristine river stretches by dragonflies were included (...). Species traits defined as methodological framework for the calculation of the Dragonfly Association Index (Chovanec et al. 2014b, 2015) were also taken into account. Data on typological features of Austrian surface waters were taken from Muhar et al. (2004), Wildermuth & Küry (2009), Wimmer et al. (2012) und Wiesbauer & Denner (2013). The assignment of valency points for species appearing in the hypopotamon was carried out on the basis of the literature published (...). "Litoral" within the zonal distribution was defined as an isolated standing water body. Slowflowing sections or standing patches, particularly in the littoral areas of lowland rivers, were assigned to the respective biocoenotic region. In the case of the distribution of saprobic valency points 44 of the 78 species were classified for the first time, the classification of nine species remained unchanged. The saprobic values of 15 species are now higher due to the changes made in this study, in the case of ten species they are lower now. The revision of the classification of the longitudinal distribution revealed the following changes: three species were classified for the first time, 12 species remained unchanged. Sixty-three species were newly classified: in the case of 53 species the valency points now reflect a stronger preference for running waters in line with a stronger expansion towards the upper rhithral sections. A large portion of those changes concerned species formerly classified as +/- limnobiocenic (expressed by 10 valency points for the littoral), which now show a more split distribution of the points. This fact reflects the increased knowledge of the ecological plasticity of odonate species. Due to this increased knowledge on the ecology of many dragonfly species, we refrained from the usage of a "+" sign indicating lacking or scarce information. The order in the Species inventory follows Wildermuth & Martens (2014)."] (Authors)] Address: Chovanec, A., Umweltbundesamt, Spit-

telauer Lände 5, 1090 Wien, Austria. Email: andreas.-chovanec@bmlfuw.gv.at

**19925.** Chovanec, A. (2017): Libellenkundliche Untersuchungen an Waldzeller / Mühlheimer Ache sowie am Gurtenbach (Oberösterreich) im Jahr 2017. Im Auftrag des Amtes der Oberösterreichischen Landesregierung, Abt. Oberflächengewässerswirtschaft: 63 pp. (in German) [Austria; "The aim of the present study, carried out in 2017, was to evaluate restructuring measures in the upper and lower reaches of the Ach (Waldzeller and Mühlheimer Ache) and the Gurtenbach by means of dragonfly surveys. This was the first time that sections of the metarhithral (Waldzeller Ache, Gurten) and the transitional meta-/hyporhithral were the subject of the determination of the dragonfly ecological status according to the Water Act and the Water Framework Directive (WRG, WFD) in Upper Austria. Similar to fish, the number of dragonfly species is increasing along the stream continuum. The association approach, which had been used in studies conducted mainly on waters in the hyporhithral/epipotamal transition zone, could not be applied due to the lower number of species in the rhithral. Therefore, an assessment approach based on the study of reference species was developed within the framework of this work. The newly developed assessment method is based on the numerical classification of dragonfly species within the Fauna Aquatica Austriaca with regard to their occurrence within biocenotic regions (CHOVANEC et al. 2017). A system of leading and accompanying species was developed for the waters of the metarhithral and the transitional meta-/hyporhithral area of the bioregion "Bayerisch-Österreichisches Alpenvorland". Four study stretches of the Waldzeller Ache, three of the Mühlheimer Ache and four of the Gurtenbach, each 100 m long, were mapped five times. A total of 28 species were detected; this corresponds to 43% of the species spectrum detected for Upper Austria (65 spp.) and 36% of the species spectrum detected for Austria (78 spp.). Twelve species are listed in one of the endangerment categories of the Red List for Austria, two of which are "critically endangered" (*Erythromma lindenii*, *Somatochlora flavomaculata*), five "endangered". No species listed in any of the Annexes of the Habitats Directive or in the European Red List was detected. *Calopteryx virgo* ("potentially endangered"), flagship species in all three sections, was found on the ground in all eleven stretches surveyed. *Onychogomphus forcipatus* ("endangered"), also the leading species, was found on the ground in seven of the eleven stretches. It was absent from the hard-built stretch of the Gurtenbach, from those stretches characterised by strong potamalisation effects and from one - from a morphological point of view monotonous - stretch of the Mühlheimer Ache. The ecological status of all stretches where this species was detected was assessed as "good". The accompanying species *Orthetrum brunneum* ("potentially endangered") was sighted at six of the seven stretches along the Ach, but not at the Gurtenbach. The flagship species *Cordulegaster boltonii* ("endangered") was only found on the uppermost stretch of the Waldzeller Ache in Kraxenberg. Waldzeller Ache (Metarhithral): Good ecological status - despite the residual water situation - was achieved at three of the four stretches investigated. A total of eleven species were sighted here, six of which were native. The fourth stretch showed reduced flow conditions and thus potamalisation effects due to backwater conditions: Although the species inventory increased to 14 species (ten native), the ecological status was "moderate". Mühlheimer Ache (transition area meta-/hyporhithral): A total of 13 species were found on the three stretches, nine of them native. The ecological status of two

stretches was "good", of one "unsatisfactory": The reason for this is the reduced heterogeneity of water morphology, flow and substrate conditions at this stretch. On the lowest stretch ("good"), slight potamalisation effects could be detected. The increase in the number of species in the longitudinal course of the river is well documented in the stretches along the Ach: The stretches of the metarhithral of the Waldzell Ache in "good ecological status" showed a species spectrum of eleven species with six native species, those of the transitional meta-/hyporhithral of the Mühlheimer Ache showed an inventory of 13 species with nine native species. At the metarhithral of the Gurtenbach estuary section, a comparison was made between regulated and restructured sections. The ecological status of the regulated section was rated "unsatisfactory". The mapping revealed the presence of five species, three of which were native. The extremely low numbers of individuals were striking. The two immediately adjacent restructured stretches achieved "good ecological status". A slight potamalisation effect due to the widening of the riverbed in one of the two stretches was reflected in a comparatively high number of species (14, nine native); due to the detection of water body type-specific relevant indicator species, the prerequisite for the classification of "good" was nevertheless met. The fourth stretch had the highest number of species (17, eight native), but there were no indicator and associated species. The ecological status of this stretch was rated "unsatisfactory". As this stretch is hydrologically strongly influenced by backwater from the Inn-Schärding reservoir, it should be classified as "heavily modified" - just like the corresponding water body of the Inn. A total of 23 species were sighted on the Gurtenbach, twelve of them native." (Author/DeepL)] Address: Chovanec, A., Krotenbachgasse 68, 2345 Brunn am Gebirge, Austria. E-mail: andreas.chovanec@bmlfuw.gv.at

**19926.** Collins, S.D.; Abbott, J.C.; McIntyre, N.E. (2017): Quantifying the degree of bias from using county-scale data in species distribution modeling: Can increasing sample size or using county-averaged environmental data reduce distributional overprediction? *Ecology and Evolution* 7(15): 6012-6022. (in English) ["Citizen-science databases have been used to develop species distribution models (SDMs), although many taxa may be only georeferenced to county. It is tacitly assumed that SDMs built from county-scale data should be less precise than those built with more accurate localities, but the extent of the bias is currently unknown. Our aims in this study were to illustrate the effects of using county-scale data on the spatial extent and accuracy of SDMs relative to true locality data and to compare potential compensatory methods (including increased sample size and using overall county environmental averages rather than point locality environmental data). To do so, we developed SDMs in maxent with PRISM-derived BIOCLIM parameters for 283 and 230 species of odonates (dragonflies and damselflies) and butterflies, respectively, for five subsets from the OdonataCentral and Butterflies and Moths of North America citizen-science databases: (1) a true locality dataset, (2) a corresponding sister dataset of county-centroid coordinates, (3) a dataset where the average environmental conditions within each county were assigned to each record, (4) a 50/50% mix of true localities and county-centroid coordinates, and (5) a 50/50% mix of true localities and records assigned the average environmental conditions within each county. These mixtures allowed us to quantify the degree of bias from county-scale data. Models developed with county centroids overpredicted the extent of suitable habitat by 15% on average compared to true locality

models, although larger sample sizes (>100 locality records) reduced this disparity. Assigning county-averaged environmental conditions did not offer consistent improvement, however. Because county-level data are of limited value for developing SDMs except for species that are widespread and well collected or that inhabit regions where small, climatically uniform counties predominate, three means of encouraging more accurate georeferencing in citizen-science databases are provided." (Authors)] Address: McIntyre, Nancy, Dept of Biological Sciences, Texas Tech Univ., Lubbock, TX, USA. E-mail: nancy.mcintyre@ttu.edu

**19927.** Cruz da Silva, E.; Silva da Rocha, T.; Barbosa de Oliveira Junior, J.M. (2017): Efeito de variações temporais e microclimáticas diárias sobre a riqueza de eúécies de Zygoptera (INSECTA: Odonata) em igarapés no município de Santarém-Pa. VIII Congresso Brasileiro de Gestão Ambiental Campo Grande/MS – 27 a 30/11/2017: 5 pp. (in Portuguese) [The physical conditions of the aquatic environment, such as air temperature and humidity, physical parameters of the water, rainfall and environmental luminosity are essential aspects in the distribution pattern of Odonata communities. In this context, the present work aimed to evaluate the effect of daily temporal and microclimatic variations on the species richness of Zygoptera in streams in the municipality of Santarém, Pará, Brazil. Zygoptera adults were sampled in four igarapés during 12 consecutive days (three times in each igarapé), between 06:00 and 18:00 h. In each igarapé, a 100-m stretch was marked, subdivided into 20 segments of five meters each. A Hobo Data Logger was used to measure air temperature, relative humidity and luminosity during 12 hours at five-minute intervals. A total of 383 individuals of Zygoptera were collected. Air temperature and luminosity had a positive effect on Zygoptera species richness ( $r = 0.546$ ;  $p = 0.054$ ;  $r = 0.831$ ;  $p = 0.001$  respectively), there was no effect of relative humidity on species richness ( $r = -0.34$ ;  $p = 0.28$ ). There was higher richness of the individuals in the hours between 10:00 and 14:00 ( $F(11, 132) = 5.565$  and  $p < 0.001$ ). The suborder Zygoptera showed great relationship with the environmental variables temperature and luminosity, possibly because they are thermal conformers. Zygoptera usually occurs in preserved environments. Therefore, it is important to maintain the integrity of the hydric systems for the conservation of the species." **19930.** Dijkstra, K. D-B. (2017): Taxonomy: use the Red List as a registry. *Nature* 546: 599-600. (in English) [Verbatim: Taxonomy and conservation might seem to operate as separate bodies (S. T. Garnett and L. Christidis *Nature* 546, 25–27; 2017). In fact, they are joined at the hip. Taxonomists provide the language to plead conservation's case. And conservationists could be taxonomy's greatest allies — the record of what lives and what might be lost is the field's strongest justification today. The authors call for coordination between taxonomy and conservation, which is already happening informally. The International Union for Conservation of Nature (IUCN) has a huge stake in understanding species, with millions of organisms at risk but only 80,000 assessed so far. Its Red List of Threatened Species provides consistency in species' status. The IUCN also sets guidelines for predicting species' responses to climate change and for classifying the impact of invasive alien organisms. This interpretation of complex data underpins both policy and practice. The Red List is maintained by the IUCN's specialist groups, which include taxonomists. Although a species' taxonomic status is crucial to its conservation status and the data on populations and threats are assessed by strict criteria, no guidelines for species circumscription exist. By formalizing the updating and consistency of its list, the IUCN could provide a certified registry of the life worth conserving. More species could be 'pre-listed' as extant, valid and potentially under threat using the Red List's Not Evaluated status. This would stimulate conservation thinking in taxonomy and promote formation of specialist groups. Because Red List maintenance relies on volunteer input, new funding mechanisms would be needed to expand its structure.] Address: Dijkstra, K. **19931.** Ehikhamele, I.E.; Ogbogu, S.S. (2017): Assessment of the concentrations of some heavy metals and their effects on the macroinvertebrate composition in Igun southwestern Nigeria, using reference site approach. *Journal of Entomology and Zoology Studies* 5(1): 452-458. (in English) ["A survey was conducted from September 2014 to February 2015 to determine the resident aquatic macroinvertebrates and selected heavy metals of Igun and Osu Reservoirs, in Atakumosa West Local Government Area of Osun State, southwestern Nigeria. This was with a view to detecting the effects of gold mining activities on Igun Reservoir using Osu Reservoir as a reference site. Sampling for heavy metals and macroinvertebrate fauna was carried out fortnightly for six months. The collected aquatic macroinvertebrates were preserved in 70% ethanol and identified using appropriate identification keys. Water sample were collected for the determination of heavy metals which include, Cadmium (Cd), Gold (Au), Lead (Pb), Zinc (Zn) and Manganese (Mn), using (Atomic Absorption Spectroscopy) A total of 136 macroinvertebrate specimens representing 17 species in 12 families were collected from Igun Reservoir. Class Gastropoda had the highest number of specimens 61(44.85%), representing five species in three families (Planorbidae, Thiaridae and Physidae). A total of 408 macroinvertebrate specimens representing 32 species in 16

families were collected from Osu Reservoir. Ephemeroptera, represented by six species from two families (Caenidae and Baetidae) had the highest number of specimens, 136 (33.33%). Simpson Diversity Index (1-D) for Igun and Osu Reservoirs were 0.84 and 0.89 respectively. Cd correlated with Mn ( $r = 0.82$ ) while Pb correlated with Mn ( $r = 0.62$ ). Pb also negatively correlated with the abundance of Odonata ( $r = -0.77$ ) in Igun Reservoir while Cd correlated negatively with the abundance of Coleoptera ( $r = -0.58$ ) in Osu Reservoir. The concentration of zinc was within the WHO permissible limits for freshwater while other heavy metals were above the limits in both reservoirs." **19932.** Fadilah, U.; Atmowidi, T.; Priawandiputra, W. (2017): Comparison of aquatic insect assemblages between managed and unmanaged artificial lakes in Indonesia. *Journal of Entomology and Zoology Studies* 5(2): 496-506. (in English) ["Aquatic insects are an example of organisms vulnerable to habitat alteration. Several artificial lakes were constructed with different maintenance pattern (managed and unmanaged) in Bekasi, which could impact development of aquatic insect community differently. Therefore, the present study examined the aquatic insect assemblages between managed and unmanaged artificial lakes in Indonesia from January to June 2016. Additionally, the influences of physico-chemical factors to the aquatic insect communities were assessed. The results showed that the abundance of insects were higher in managed (1059 individuals) than unmanaged lakes (426 individuals) ( $p < 0.05$ , T-test). Significance of the difference of species composition between managed and unmanaged lakes was illustrated by the separated groups in nMDS graph ( $p < 0.001$ , One-way ANOSIM). However, the same dominant species (*Orthetrum testaceum*) was found in both lakes. *O. testaceum* and *Desmopachria latissima* have strong correlation with all physico-chemical parameters. Different management of artificial lakes significantly changed the aquatic insect assemblages and unmanaged artificial lake decreased the abundance of aquatic insect." **19933.** Gazzola, A.; Balestrieri, A.; Ghitti, M.; Paganelli, D.; Galeotti, P. (2017): Behavioural and life history responses to predation risk by common frog tadpoles exposed to two predators during ontogeny. *acta ethologica* 20(5): 235-241. (in English) ["The presence of predators can induce changes in both the morphology and behaviour of Anuran larvae, affecting both their size and developmental stage at metamorphosis and, consequently, the fitness of adult individuals. Tadpoles have been shown to be capable of finely tuning their defensive responses according to the actual risk perceived, which is expected to vary according to the prey-to-predator size ratio. In this study, we exposed common frog (*Rana temporaria*) tadpoles (Gosner stages 28-30), for a period of 2 weeks, to the non-lethal presence of dragonfly larvae (*Anax imperator*) and backswimmers (*Notonecta glauca*). In such a narrow window of time, we expected be-

havioural responses to be similar for both predators and exposure to predation risk to have negligible effects on tadpole development and weight. Overall, tadpoles increased hiding behaviour and were less active when predators were present in the experimental mesocosms, but behavioural responses were constrained to the early phase of the ontogeny and were no longer used when tadpoles reached a threshold size. Developmental rate slightly slowed down for predator treatments in comparison to controls, possibly as a consequence of energetic investment in unrecorded morphological defences. Although variation in laboratory conditions and protocols makes it hard to compare the results of different experiments, our results contribute to verify the consistency of behavioural responses in Anuran larvae." **19934.** Georgieva, G.; Radeva, K.L.; Uzunov, Y.I. (2017): New Data on bottom invertebrates of the Negovan marshes and the adjacent Lesnovska River. *Acta zool. bulg.* 69(1): 89-94. (in English) ["The current study presents recent data of the benthic macroinvertebrate fauna of two pit lakes (the Big Lake and the Small Lake) and the adjacent sector of the Lesnovska River near Negovan Village, western suburb area of the capital city of Sofia, western Bulgaria. The two pit lakes are under different degree of degradation. The Big Lake is still used for excavation of inert materials, while the Small Lake has been abandoned years ago and has slowly restored its quality of a natural wetland. Both lakes have never been studied hydrobiologically apart from several faunistic contributions. In the present study, parameters, indices and metrics indicating the cenotic structure of the benthic community and ecological state of the water bodies were used following the national regulations. The macrozoobenthos density in the Big Lake was lower in comparison to the Small Lake and the Lesnovska River. The river and the Small Lake had high level of faunistic similarity. Some non-indigenous and invasive species were registered in both lakes." **19935.** Geraeds, R. (2017): Observations of dragonflies outside the immediate vicinity of water. The value of an abandoned field for dragonflies. *Brachytron* 19(2): 77-89. (in Odonata, maturation period, habitat, abandoned arable fields) ["Research on dragonflies generally takes place at their reproduction sites. However, the maturation period, between the moment the dragonflies emerge and the time they return to the water, is often spent away from the immediate vicinity of water. Detailed information about the habitats that are used during the maturation period is scarce. For this reason, observations of dragonflies were collected during a research project on reptiles in an abandoned field in the Driestruik Nature Reserve. During 90 days in the period between September 2011 until October 2016, 978 observations of 1242 dragonflies were collected. In total 34 dragonfly species were found: 11 species of damselflies and 23 species of dragonflies. All species with populations in the Driestruik Nature Reserve were found in the abandoned field. In addition, 11 species were found of which no populations are present in the area. These are predominantly species with a preference for flowing water like brooks and rivers. When the observations of the most frequently observed damselflies were examined, it appeared that the majority of the animals use the abandoned field mainly during

the maturation period. From the observations of dragonflies it can be deduced that the former field is used during the maturation period, but that most dragonfly species also frequently use the area during the breeding period. It is striking that most observations (48%) were made in the eastern part of the research area, which with its 0,3 hectare represents approximately 25% of the total investigated area. In contrast to the rest of the area, this part also borders on forest on the north side, making it more sheltered. In addition, the largest variation in vegetation structure is present in this part of the former field. These conditions are likely to result in a warmer microclimate, which is attractive for dragonflies." (Author)] Address: Geraeds, R.P.G., Rijksweg Noord 280, 6136 AH Sittard, Netherlands. **19937.** Gyulavári, H.A.; Tüzün, N.; Arambourou, H.; Therry, L.; Dévai, G.; Stoks, R. (2017): Within-season variation in sexual selection on flight performance and flight-related traits in a damselfly. *Evolutionary Ecology* 31: 21-36. (in English) ["While selection is a key mechanism of evolution, our understanding of within-season variation in sexual selection remains limited. Here, we studied within-season sexual selection on two key performance traits, flight speed and flight endurance, and a set of morphological and physiological phenotypic traits in a natural population of the territorial damselfly *Chalcolestes viridis*. We applied a path analysis approach to address whether the flight-related traits affected mating success directly or indirectly through their effect on the flight performance traits, and whether these selection patterns differed between the first and second half of the reproductive season. While some trait means did not

differ between both parts of the season (flight speed, wing loading and non-allometric wing shape), most traits showed within-season differences (flight endurance, fat content, flight muscle ratio, wing centroid size, body mass and the allometric wing shape). Despite the within-season temporal differences in flight endurance, sexual selection consistently favoured males with a higher flight endurance. None of the detected patterns of sexual selection on the flight-related traits were consistently significant in both periods: while we detected selection on wing loading and wing centroid size in the first half of the season, we detected selection on body mass in the second half of the season. More studies focusing on understudied traits such as performance traits are needed to refine our knowledge of the temporal dynamics of selection patterns in nature. This is important to arrive at a better understanding of the adaptive evolutionary dynamics of traits in natural populations." **19938.** Halimi, E., Papparisto, A. (2017): Data for Aquatic Insects (Odonata) with Environmental Impact on Aquatic Ecosystems in Albania. 1-st International Conference on Social and Natural Sciences Proceedings Vienna, 8-9 April: 80-86. (in English) ["Aquatic insects show a high interest due to their feature to serve like environmental bioindicators. In that study, by analyzing the biodiversity of dragonfly Odonata through the comparison of the data on quantity and quality related to these aquatic insects, we have evaluated the actual environmental situation of aquatic ecosystems for the Kavaja and Divjaka. The period of time when the biological material was collected was 2009-2011. By this study are defined for Odonata Order was 23 species, 17 genera and 8 families of. The most represented group was Anisoptera by 14 species and a frequency of 60.86%. The Libellulidae is the most represented family by 8 species and a frequency of 34.78%. The ecosystems around the Divjaka (Karavasta lagoon) are presented by a frequency slightly higher of species compared to these of Kavaja (Spille). The Odonata in the environment of Divjaka are more represented by 17 species and a frequency of 73.91% while the frequency were lower with 14 species and a frequency of 60.86% to Kavaja. It is an indicator of the quality considerably better of the Divjaka area. In both areas are encountered 8 common species and the "Jaccard index" of similarity coefficient" was 34.78%, which is an indication of small difference among the conditions of environmental quality for these bio-indicator species." **19940.** Haro, R.; Hess, M.; Rolffhus, K.; Sandheinrich, M.; Wiener, J. (2017): Why is mercury concentration in larval spiketail dragonflies (Family Cordulegastridae) consistently greater than in their burrowing relatives, the clubtail dragonflies (family Gomphidae)? 13th The International Conference on Mercury as a Global Pollutant: RP-075- (in English) [Verbatim: "In North America, larval dragonflies are increasingly used as biosentinels for monitoring mercury (Hg) contamination in freshwater food webs. For practical reasons, field studies and monitoring programs alike often do not identify larval dragonflies below the taxonomic level of family. Several studies, however, have recognized that differences in Hg concentration among coincidentally collected families do occur and may be associated with distinct family-level behavioral habits or guilds (e.g., burrowers vs. climbers). Understanding the consistency of these differences among guilds across habitats and water bodies will be important to the refinement of protocols using larval dragonflies as biosentinels. Apart from the implications for monitoring Hg, these guild differences generate basic questions about the intersection of environmental toxicology, behavioral ecology, and phylogeny. Two separate field studies conducted in the north-central states of Wisconsin and Michigan (USA) have shown consistent differences in total mercury (THg) concentration between two intraguild (burrower) families of late-instar larval dragonflies: the spiketails (Family Cordulegastridae) and the clubtails (Family Gomphidae). Across 5 of 6 water bodies, 3 streams and 3 lakes, THg concentration in spiketail larvae was significantly greater than in coincidentally collected clubtail larvae. Furthermore, spiketail THg concentration was often greater than all other co-occurring larvae belonging to non-burrowing guilds (i.e., sprawlers and climbers). Mean (SE) THg concentration across water bodies ranged from 170.9 10.0 497.8 136.2 ng/g dwt. and from 67.0 2.1 165.0 18.2 ng/g dwt. for spiketails and clubtails, respectively. In the 5 water bodies with significant differences, spiketail THg concentrations were between 189% and 558% greater than their clubtail counterparts. An explanation for these differences likely includes voltinism; in the north-central US, spiketails are merovoltine, spending 3 to 4 years as larvae, while clubtails are typically bivoltine, spending 2 years as larvae. However, other factors including the amount of body setae (surface area), differences in burrowing behavior, and the significance of their phylogenetic relationship are explored."] Address: Haro, R., River Studies Center, La Crosse, USA

**19941.** Hayat, M. (2017): Cycle de vie et écologie de Coenagrion mercuriale dans le bassin versant de la Seybouse (Nord-Est de l'Algérie). Doctorat du troisième cycle, Faculté des Sciences, Département de Biologie, Université Badji Mokhtar-Annaba: 75 pp. (in French, with English and Arabian summaries) ["C. mercuriale is a threatened damselfly in most parts of its geographic distribution. It is listed as endangered in North Africa, where no data on its biology or ecology are available. The purpose of this study was to determine the life history traits and demographic parameters of this species in the southern limit of its distribution, to compare of our results with those presented in the literature for the UK (the northern limit of the species distribution) and to determine the latitudinal adaptation of the species. The estimation of the population size showed a very high number with a total of 1765 individuals. The species did not show a winter diapause and produced two generations per year. The first generation was emerged mid spring and the second the late summer. After emergence, adults spent a period of maturation that lasted 3 to 4 days. Afterwards, they

returned to aquatic environments to breed. The reproduction period was positively correlated with male size. However, the rest period was positively correlated with the copulation period. Finally, a seasonal difference in the body size between generations was found with a decrease in the body size in the first generation and an increase the opposite was found in the second generation." **19942.** Herzog, R.; Hadrys, H. (2017): Long-term genetic monitoring of a riverine dragonfly, *Orthetrum coerulescens* (Odonata: Libellulidae): Direct anthropogenic impact versus climate change effects. PLoS ONE 12(5): e0178014. <https://doi.org/10.1371/journal.pone.0178014>: 13 pp. (in English) ["Modern conservationists call for long term genetic monitoring datasets to evaluate and understand the impact of human activities on natural ecosystems and species on a global but also local scale. However, long-term monitoring datasets are still rare but in high demand to correctly identify, evaluate and respond to environmental changes. In the presented study, a population of the riverine dragonfly, *Orthetrum coerulescens* (Odonata: Libellulidae), was monitored over a time period from 1989 to 2013. Study site was an artificial irrigation ditch in one of the last European stone steppes and "nature heritage", the Crau in Southern France. This artificial riverine habitat has an unusual high diversity of odonate species, prominent indicators for evaluating freshwater habitats. A clearing of the canal and destruction of the bank vegetation in 1996 was assumed to have great negative impact on the odonate larval and adult populations. Two mitochondrial markers (CO1 & ND1) and a panel of nuclear microsatellite loci were used to assess the genetic diversity. Over time they revealed a dramatic decline in diversity parameters between the years 2004 and 2007, however not between 1996 and 1997. From 2007 onwards the population shows a stabilizing trend but has not reached the amount of genetic variation found at the beginning of this survey. This decline cannot be referred to the clearing of the canal or any other direct anthropogenic impact. Instead, it is most likely that the populations' decay was due to by extreme weather conditions during the specific years. A severe drought was recorded for the summer months of these years, leading to reduced water levels in the canal causing also other water parameters to change, and therefore impacting temperature sensitive riverine habitat specialists like the *O. coerulescens* in a significant way. The data provide important insights into population genetic dynamics and metrics not always congruent with traditional monitoring data (e.g. abundance); a fact that should be regarded with caution when management plans for developed landscapes are designed." **19943.** Hrdličková, E.; Bulánková, E. (2017): Ecological and hydromorphological evaluation of monitoring sites at the upper Myjava River. Folia faunistica Slovaca 22: 93-101. (in Slovak, with English summary) ["Since 2006 the upper part of the Myjava River has undergone strong changes. Above the monitoring site Myjava NAD (rkm 72.6) a water reservoir was rebuilt to a dry polder in 2006 and the stagnant water has changed into realined channel of the Myjava River. Because of benthic invertebrates has not been monitored at this locality since 2010 we would like to evaluate changes of macrozoobenthos communities at the sampling site Myjava NAD in present and compare them with the sampling site which is relatively undisturbed. This reference site

(hypocrenal) is situated in the beech forest at rkm 82. We assessed physico-chemical parameters, hydromorphology using River Habitat Survey at both localities in 2014 – 2015. Macrozoobenthos was sampled by kicking technique in spring and in autumn 2014 – 2015. The aim of our research was to: 1. Evaluate hydromorphology of selected stream sites; 2. Find out macrozoobenthos structure at these sampling sites 3. Compare changes in metrics found out during monitoring in 2003 – 2013 with our data from 2014. The PCA showed that the structure of macrozoobenthos is influenced first of all by the hydromorphological features of the Myjava River and the physico-chemicals parameters had less influence. Metrics calculated from macrozoobenthos abundance of the site Myjava NAD from the years 2003, 2014, 2015 showed that biological status is better but the site is hydromorphologically disturbed and therefore it belongs to the HMWB. According to the ecological evaluation we found out that the sampling site in the beech forest has a character of a reference site therefore it is unique in the Myjava River basin. Occurrence of the protected species *Cordulegaster heros*, sensitive species *Ibisia marginata* and *Ephemera danica* was threatened by the clearcutting in 2015. We suggest to minimize human impact in the vicinity of the stream at this valuable part of the Myjava River." **19946.** Ito, K.; Sakuraba, N.; Yamaguchi, K. (2017): A control law for vehicle merging inspired by dragonfly behavior. *Artificial Life and Robotics* 22: 153-162. (in English) ["Autonomous control of vehicles has recently attracted considerable attention. In this sense, vehicle merging has become an important topic in this field of research. However, in conventional studies, the controlled vehicle must calculate the movement of other surrounding vehicles to complete the merge, requiring high computational costs. In this paper, we focus on dragonfly behaviour to solve this issue. Indeed, insects can behave adaptively in the complex real world in spite of the limited size of their brains. They reduce the computational requirements of their brain by relying on different properties of their surroundings, basing their intelligent behaviours on simple strategies. The behaviour of a dragonfly when chasing a prey is an example of these strategies. In this study, we address the vehicle merging maneuver by applying dragonfly's strategies to control the movement of the merging vehicle. We propose a simple control method inspired by the aforementioned strategies and, finally, we present simulation results that were conducted to demonstrate the effectiveness of this method." **19947.** Janssens, L.; Tüzün, N.; Stoks, R. (2017): Testing the time-scale dependence of delayed interactions: A heat wave during the egg stage shapes how a pesticide interacts with a successive heat wave in the larval stage?. *Environmental Pollution* 230: 351-359. (in English) ["Highlights: •An egg heat wave affected larval survival and oxidative damage in damselflies [*Chalcolestes viridis*]. •Also larval pesticide exposure had delayed effects on survival and oxidative damage. •An egg heat wave shaped the interaction between a pesticide and a heat wave in larvae. •Successive stressors have delayed effects and can thereby interact across life stages. Abstract: Under global change organisms are exposed to multiple, potentially interacting stressors. Especially interactions between successive stressors are poorly understood and recently suggested to depend on their timing of exposure. We particularly need studies assessing the impact of exposure to relevant stressors at various life stages and how these interact. We investigated the single and combined impacts of a heat wave (mild [25 °C] and extreme [30 °C]) during the egg stage, followed by successive exposure to esfenvalerate (ESF) and a heat wave during the larval stage in damselflies. Each stressor caused mortality. The egg heat wave and larval ESF exposure had delayed effects on survival, growth and lipid peroxidation (MDA). This resulted in deviations from the prediction that stressors separated by a long time interval would not interact: the egg heat wave modulated the interaction between the stressors in the larval stage. Firstly, ESF caused delayed mortality only in larvae that had been exposed to the extreme egg heat wave and this strongly depended upon the larval heat wave treatment. Secondly, ESF only increased MDA in larvae not exposed to the egg heat wave. We found little support for the prediction that when there is

limited time between stressors, synergistic interactions should occur. The intermediate ESF concentration only caused delayed mortality when combined with the larval heat wave, and the lowest ESF concentrations only increased oxidative damage when followed by the mild larval heat wave. Survival selection mitigated the interaction patterns between successive stressors that are individually lethal, and therefore should be included in a predictive framework for the time-scale dependence of the outcome of multistressor studies with pollutants. The egg heat wave shaping the interaction pattern between successive pesticide exposure and a larval heat wave highlights the connectivity between the concepts of 'heat-induced pesticide sensitivity' and 'pesticide-induced heat sensitivity'." **19948.** Janssens, L.; Op de Beeck, L.; Stoks, R. (2017): Stoichiometric responses to an agricultural pesticide are modified by predator cues. *Environ. Sci. Technol.* 51(1): 581-588. (in English) ["Current ecological risk assessment of pesticides fails to protect aquatic ecosystem health. To get better insight in how pesticides may affect aquatic ecosystems, we tested how sublethal pesticide concentrations modify body stoichiometry. Moreover, as interactions with natural stressors may cause underestimates of the impact of pesticides, we also tested whether this pathway depended on the presence of predator cues. Therefore, we exposed damselfly larvae to chlorpyrifos and cues from predatory dragonflies and focused on body stoichiometry and associated explanatory variables (growth rate, RNA : DNA and energy storage molecules). The way the predator cues modulated the pesticide effects strongly differed between endpoints. Exposure to chlorpyrifos affected the key body stoichiometric ratios: chlorpyrifos consistently increased N:P, while its effects on C:N (decrease with predator cues) and C:P (increase without predator cues) strongly depended upon the presence of the natural stressor. These stoichiometric responses could be explained by associated changes in growth, RNA:DNA and in C-rich fat and sugars and N-rich proteins. The observed changes in body stoichiometry may affect the damselflies' food quality, and have the potential to cascade through the food web and shape nutrient cycling." **19949.** Janssens, L.; Stoks, R. (2017): Chlorpyrifos-induced oxidative damage is reduced under warming and predation risk: Explaining antagonistic interactions with a pesticide. *Environmental Pollution* 226: 79-88. (in English) ["Highlights: •Co-exposure to pesticides, warming and predators is common in nature. •Chlorpyrifos increased ROS and oxidative damage and decreased antioxidant defence. •Animals coped better with the pesticide when reared at higher temperatures. •The predator cues lowered the pesticide-induced increase in oxidative damage. •Cross-tolerance and maximum damage levels may explain antagonistic interactions. Interactions with pollutants and environmental factors are poorly studied for physiological traits. Yet physiological traits are important for explaining and predicting interactions at higher levels of organization. We investigated the single and combined impact of the pesticide chlorpyrifos, predation risk and warming on endpoints related to oxidative stress in *Enallagma cyathigerum*. We thereby integrated information on reactive oxygen species (ROS), antioxidant

enzymes and oxidative damage. All three treatments impacted the oxidative stress levels and for most traits the pesticide interacted antagonistically with warming or predation risk. Chlorpyrifos exposure resulted in increased ROS levels, decreased antioxidant defence and increased oxidative damage compared to the control situation. Under warming, the pesticide-induced increase in oxidative stress was less strong and the investment in antioxidant defence higher. Although both the pesticide and predation risk increased oxidative damage, the effects of the pesticide on oxidative damage were less strong in the presence of predator cues (at 20 °C). Despite the weaker pesticide-induced effects under predation risk, the combination of the pesticide and predator cues consistently caused the highest ROS levels, the lowest antioxidant defence and the highest oxidative damage, indicating the importance of cumulative stressor effects for impairing fitness. Our results provide the first evidence for antagonistic interactions of warming and predation risk with a pollutant for physiological traits. We identified two general mechanisms that may generate antagonistic interactions for oxidative stress: cross-tolerance and the maximum cumulative levels of damage." ] Address: Stoks, R., Lab. Aquatische Ecologie, K.U.Leuven, De Beriotstraat 32, B-3000 Leuven, Belgium. E-mail: robby.stoks@bio.kuleuven.ac.be

**19950.** Johansson, F.; Halvarsson, P., Mikolajewski, D.J.; Höglund, J. (2017): Genetic differentiation in the boreal dragonfly *Leucorrhinia dubia* in the Palearctic region. *Biological Journal of the Linnean Society* 121: 294-304. (in English) ["The last glacial period had a strong influence on the population genetic structure of boreal species in southern and central Europe. In addition, recent and current human impact on the boreal environment has led to habitat loss, which also has a large influence on population genetic structure of species. Here we present the spatial genetic structure of the boreal dragonfly *Leucorrhinia dubia* using ddRAD sequencing. We sampled individuals from nine locations in Europe, three in Asia (Russia and Japan) and one location of *L. intermedia* in Japan. Results showed three distinct genetic clusters in Europe. One genetic cluster consisted of individuals sampled from the locations in the Swiss Alps, a second consisted of individuals sampled in the United Kingdom, and a third cluster consisted of individuals from the rest of the seven sampled locations in Europe covering a latitudinal gradient from the French Pyrenees to the north of Finland. There was also a weak support that the French Pyrenees and Austrian Alps samples differentiated from the cluster of the five samples from central and north Europe. We suggest that these clusters reflect historical recolonization patterns since the last glaciation. The *L. dubia* individuals sampled from locations in Asia formed one cluster referring to *L. dubia orientalis* separated from the individuals sampled in European and from the *L. intermedia* locality sampled. Our result suggests that aquatic insects in the fragmented boreal landscape in south central Europe and United Kingdom need conservation consideration." **19951.** Junior dos Santos, J.; Kroth, N.; Breaux, J.A.; Albeny-Simões, D. (2017): Do container size and predator presence affect *Culex* (Diptera: Culicidae) oviposition preferences? *Revista Brasileira de Entomologia* 62(1): 40-45. ["Organisms with complex life cycles typically do not exhibit parental care. Hence, the ability of adult females to choose quality oviposition sites is critical for offspring success.

Gravid females of many insect taxa have the capability to detect environmental conditions in water-holding containers (e.g., resource level, presence of competitors or predators) and to choose the sites that are most suitable for offspring growth and development. Mosquitoes may also detect physical container characteristics related to water permanence such as surface area, volume, or container size, and some species such as those in the genus *Culex* have been shown to prefer larger containers. However, predators may also preferentially colonize larger containers; thus, ovipositing females may face decisions based on cues of site quality that balance the costs and benefits for offspring. We used a field experiment to evaluate the oviposition preferences of two *Culex* species in response to experimental container size and predator abundances within the containers. We found that both species avoided ovipositing in the largest containers, which have high abundances of *Chaoborus* sp. and dragonfly larvae (predators). However, the container size most commonly chosen for oviposition (15-L buckets) also had high mean abundance per liter of dragonfly larvae. These results suggest either prey naiveté or reduced vulnerability of these species to dragonflies compared to *Chaoborus* sp. Other potential mechanisms for the observed patterns are discussed." **19953.** Karlson, E. (2017): Temperature acclimation in dragonfly larvae: which species are more vulnerable to global warming? M.Sc. dissertation, Biology Education Centre & Dept of ecology and genetics/Animal ecology, Uppsala Univ.: 33pp. (in English) ["Climate change is affecting all known habitats on earth. Increased temperatures in aquatic habitats will not only heat the waters but will also cause larger variation in temperature fluctuation. Many animals in aquatic systems are adapted to specific habitats in these waters and may face disadvantages if temperatures changes too much. In my project. I have used larvae of dragonflies and damselflies to examine how they might be affected by changes in water temperature caused by climate change. I sampled damselfly and dragonfly Larvae in three lakes around Uppsala at two water depths, in order to examine whether these species differed in their depth distribution. Larvae exposed to thermal fluctuations should be better at adapting to the increase in temperature from global warming. In a laboratory experiment I tested the ability to acclimate to three temperatures (18, 21 and 24°C) in three species of damselfly larvae (*Ischnura elegans*, *Coenagrion pulchellum*, and *Erythromma najas*), over four different time intervals (1, 2, 12 and 24 hours) for *E. najas* and two time intervals for *I. elegans* and *C. pulchellum*. To measure acclimation. I introduced prey items in a laboratory experiment, and counted how many strikes and captures the larvae managed to do during a 10 mm interval after being acclimated to the four different time intervals. The results of the field sampling in the lakes showed species specific depth distribution differences in dragonfly and damselfly larvae, with the majority of species preferring the surface over the bottom. The results from the temperature acclimation experiments showed that species changed their strikes and capture success on prey over the different time intervals, and especially *E. najas* showed a clear trend that suggest adaptation to temperate changes. Species differed in prey capture behaviour, with *E. najas* having the highest and *C. pulchellum* the lowest number of strikes and capture success. Results also suggested that *E. najas* is able to acclimate to the temperatures over the time period tested. This species also had a wide depth distribution in the lakes, which might explain its faster acclimation, even though a similar depth distribution was found in the non acclimating *C. pulchellum*. The other two species (besides *E. najas*) showed less clear patterns with regard to acclimation and it was difficult to tell if they were able to acclimate to the tested temperatures. My results suggest that damselfly larvae species are able to acclimate in prey capture behaviour over relatively short time periods in response to temperature fluctuations, and they might therefore be able to adapt to increasing temperature fluctuations in the future." **19954.** Khelifa, M.R. (2017): Bioécologie de *Platycnemis subdilata* (Odonata: Platycnemididae) dans le bassin versant de la Seybouse. PhD thesis, Département de Biologie animale et végétale, Faculté des Sciences Biologiques et des Sciences Agronomiques, Université Mouloud Mammeri de Tizi-Ouzou: 101 pp. (in French, with English and Arabian summaries) ["*P. subdilata* is endemic to North Africa (Tunisia, Algeria and Morocco) but it has not been studied since its description in 1849. This study aims to document the distribution, abundance, taxonomy, life history, adult behavior, senescence and demographic parameters of the species in the Seybouse watershed, Northeast Algeria. The results show that *P. subdilata* is the most abundant lotic species in the watershed, estimating a minimum population size of 50,000 mature individuals. The exuvia is easily identifiable compared to other zygopterans of the region because it has a tail-like filament at the end of the caudal gills. In addition, the species presents morphological criteria that differentiate it from *P. pennipes* which is widespread in Europe. *P. subdilata* is univoltine with direct embryonic development and a fairly asynchronous larval development followed by a relatively long emergence season and flight period. Adult behavior is typically non-territorial in which the males use two different techniques to acquire females; one is to wait at reproductive sites and another is to seek within foraging sites. Senescence was recorded in clutch size and the rate of egg deposition. Adult survival depended on age and movement between foraging sites (dispersal), but reproductive success depended on age and sex. This study represents the raw material for future studies on *P. subdilata*." (Author)] Address: Khelifa, R., Biodiversity Research Center, Univ. of British Columbia, 2212 Main Mall, Vancouver. B.C. **19955.** Kulijer, D. (2017): First survey of the dragonfly fauna (Insecta, Odonata) of northwestern Bosnia. *Natura Croatica: Periodicum Musei Historiae Naturalis Croatici*

26(1): 65-80. (in English, with Bosnian summary) ["The results of the first study of the dragonfly fauna in northwest Bosnia are presented. Field surveys were conducted in summer 2012 and 2013, resulting in the identification of 36 species. Out of these, 34 are new for the region. The present paper gives a detailed overview of the results and a comparison of the dragonfly fauna composition of the region studied with the neighboring areas within Bosnia and Herzegovina and Croatia is made. The most abundant species were: *Calopteryx virgo*, *Sympetrum sanguineum*, *Onychogomphus forcipatus*, *Somatochlora meridionalis*, *Calopteryx splendens* and *Platycnemis pennipes*. Noteworthy are the records of *Chalcolestes viridis* and *Coenagrion scitulum*, two species that are rare in Bosnia and Herzegovina, and also *Coenagrion ornatum* and *Cordulegaster heros*, species of European conservation concern. Distribution and the status of these species and the conservation of dragonfly species in the country are briefly discussed. The data collected represent an important contribution to the knowledge of the dragonfly fauna of the Una River basin and Bosnia and Herzegovina." **19956.** Kuncce, W.; Stoks, R.; Johansson, F. (2017): Single and mixture impacts of two pyrethroids on damselfly predatory behavior and physiological biomarkers. *Aquatic Toxicology* 190: 70-77. (in English) ["Highlights: •Damselfly larvae [*Coenagrion puella*] exposed to sub-lethal combination of pyrethroid insecticides. •Exposure to deltamethrin reduces predatory ability. •Combined exposure to deltamethrin and esfenvalerate inhibits the GST detoxification pathway. •Observed effects can eventually result in lower emergence of adults from contaminated ponds. Abstract: Direct mortality due to toxicity of single pesticide exposure along a concentration gradient, while the most common, is only one important parameter for assessing the effects of pesticide contamination on aquatic ecosystems. Sub-lethal toxicity can induce changes in an organism's behavior and physiology that may have population-level ramifications and consequences for ecosystem health. Additionally, the simultaneous detection of multiple contaminants in monitored watersheds stresses the importance of gaining a greater understanding of the toxicities of combined exposures, particularly at low, environmentally relevant concentrations. Using larvae of *Coenagrion puella*, we conducted a combined exposure investigation of two widely-used pyrethroid insecticides presumed to share the same neurotoxic mechanism of action, and estimated their effect on predatory ability, mobility and three physiological biomarkers (Glutathione S-transferase; GST, respiratory electron transport system; ETS, and malondialdehyde; MDA). Deltamethrin exposure (0.065 µg/L and 0.13 µg/L) was found to reduce the predatory ability, but it did not affect the larvae's mobility. Esfenvalerate exposure (0.069 µg/L and 0.13 µg/L), on the other hand, induced no significant changes in predatory ability or mobility. The decrease in predatory ability after the combination exposure (0.067 µg/L deltamethrin and 0.12 µg/L esfenvalerate) did not significantly differ from the impact of the single deltamethrin exposures. Glutathione-S-transferase was induced after single esfenvalerate exposure and the lower deltamethrin concentration exposure, but seemingly inhibited after exposure to the higher concentration of deltamethrin as well as the combination of both pyrethroids. Our data indicate that sub-lethal exposure to deltamethrin reduces predatory ability and suggest that sub-lethal combined exposure to deltamethrin and esfenvalerate inhibits

the GST detoxification pathway. These effects can eventually result in a lower emergence of adults from contaminated ponds." (Authors)] Address: Kuncce, W., Dept of Ecology and Genetics, Animal ecology, Norbyvägen 18 D, Uppsala Univ., SE-752 36 Uppsala, Sweden

**19959.** Lin, H.-T.; Leonardo, A. (2017): Heuristic rules underlying dragonfly prey selection and interception. *Current Biology* 27(8): 1124-1137. (in English) ["Highlights: •Dragonflies use heuristic selection rules to determine which prey to pursue. •Prey angular size and speed, foveation error, and zenith crossing are evaluated. •These rules initialize takeoff for optimal interception flight conditions. •Prey that do not satisfy the rules are usually ignored or pursued unsuccessfully. Summary: Animals use rules to initiate behaviors. Such rules are often described as triggers that determine when behavior begins. However, although less explored, these selection rules are also an opportunity to establish sensorimotor constraints that influence how the behavior ends. These constraints may be particularly significant in influencing success in prey capture. Here we explore this in dragonfly prey interception. We found that in the moments leading up to takeoff, perched dragonflies employ a series of sensorimotor rules that determine the time of takeoff and increase the probability of successful capture. First, the dragonfly makes a head saccade followed by smooth pursuit movements to orient its direction-of-gaze at potential prey. Second, the dragonfly assesses whether the prey's angular size and speed co-vary within a privileged range. Finally, the dragonfly times the moment of its takeoff to a prediction of when the prey will cross the zenith. Each of these processes serves a purpose. The angular size-speed criteria biases interception flights to catchable prey, while

the head movements and the predictive takeoff ensure flights begin with the prey visually fixated and directly overhead—the key parameters that underlie interception steering. Prey that do not elicit takeoff generally fail at least one of the criterion, and the loss of prey fixation or overhead positioning during flight is strongly correlated with terminated flights. Thus from an abundance of potential targets, the dragonfly selects a stereotyped set of takeoff conditions based on the prey and body states most likely to end in successful capture." **19960.** Mabidi, A.; Bird, M.S.; Perissinotto, R. (2017): Distribution and diversity of aquatic macroinvertebrate assemblages in a semi-arid region earmarked for shale gas exploration (Eastern Cape Karoo, South Africa). *PLoS ONE* 12(6): e0178559. <https://doi.org/10.1371/journal.pone.0178559>. 27 pp. (in English) ["This study aims to investigate macroinvertebrate assemblage structure and composition across the three major waterbody types (temporary rivers, depression wetlands and semipermanent dams) of the Eastern Cape Karoo, and to identify important environmental and spatial correlates of macroinvertebrate assemblage composition in the region. A total of 33 waterbodies (9 dams, 13 depression wetlands and 11 rivers) were sampled. Altogether, 91 taxa were recorded in November 2014 and 82 in April 2015. Twenty-seven taxa were common to all three waterbody types (across both sampling occasions), with 17 of these observed in November and 19 in April. The ANOSIM tests revealed significant differences in assemblage composition between the depression wetlands and rivers for both sampling occasions, but dams did not differ from the other waterbody types. SIMPER analyses indicated that the notonectid *Anisops varia* and the corixid *Micronecta scutellaris* were abundant across all three waterbody types during both sampling occasions. The mayfly *Cloeon africanum* and the damselfly *Pseudagrion* sp. were abundant in river habitats during both sampling occasions, while the gastropod mollusc *Bulinus tropicus* and the copepod *Lovenula falcifera* best characterised depression wetlands on both occasions. Non-metric multidimensional scaling ordination highlighted a clear separation of assemblages between November and April, while distance-based Redundancy Analysis revealed that conductivity, altitude, turbidity and pH were the most important variables explaining the variation in macroinvertebrate assemblage patterns. These results provide baseline information which is important for future biological monitoring of impacts associated with hydraulic fracturing activities and climatic changes in the region." **19963.** Mukherjee, P.; Khan, M.M.H. (2017): Abundance of arthropod insect pests and natural enemies in rice field as influenced by rice growth stages and neighboring crops. *Bangladesh J. Agril. Res.* 42(2): 309-319. (in English) ["Studies were conducted to record the abundance of arthropod insect pests and natural enemies in rice fields as influenced by rice growth stages and neighboring crops at the experimental farm of Patuakhali Science and Technology Univ. (PSTU), Dumki, Patuakhali during 2012 in Boro rice season following randomized complete block design. Results indicated that rice-tree habitat showed the highest abundance of leafhoppers (100.75) followed by cricket (16.50), grasshoppers (15.25) and stink bugs (15.25). The lowest abundance of all insect pests was in rice-sesame habitat. No significant differences were found on the abundance of rice bug, rice hispa and stem borer populations. At seedling stage, the highest abundance of leafhopper (94.25) was recorded followed by grasshopper (47.00) and stink bug (26.50) while the lowest was stem borer (0.57) and rice hispa (6.00). At early tillering stage, maximum number of grasshopper (17.25) was recorded followed by cricket (7.00). At maximum tillering stage, the highest abundance of leafhoppers (122.5) was obtained followed by rice bug (62.00) and the lowest was the stink bug (7.00). At panical initiation stage, the highest abundance of rice bug (334.00) was recorded which was followed by leafhoppers (65.25) and the lowest was the cricket (15.75). No population of rice hispa and stem borer was recorded at maximum tillering and panical initiation stages. In case of natural enemies, the highest abundance of lady bird beetle (45.27) and damselfly (16.73) was found in rice-rice habitat. The highest abundance of ichneumonid wasp (57.53) was in rice-tree habitat and ground beetle (28.80) was in rice-sesame habitat. No significant differences were observed on the abundance of dragonfly, spider and dipteran fly among different habitats. Among different growth stages of rice plant, significantly the highest abundance of lady bird beetle was recorded at maximum tillering stage. The highest abundance of ichneumonid wasp and ground beetle was recorded at seedling stage. The highest abundance of damselfly, spider and dipteran fly was at early tillering stage. No significant difference was observed on the abundance of dragonfly among different rice growth stages." "Dragonfly population did not differ significantly within rice habitats. The maximum number of dragonfly was observed in rice-maize habitat (1.50 dragonfly/40 sweeps) followed by rice-sesame and rice-maize habitats. The minimum number of dragonfly was observed in rice-tree habitat (0.42 dragonfly/40 sweeps) (Table 3). In case of different growth stages, dragonfly population also did not differ significantly (Table 4). The highest abundance

was at panicle initiation stage (2.25 dragonfly/40 sweeps) and the lowest was found at seedling stage. No dragonfly population was observed at early tillering stage." (Authors)] Address: Mukherjee, P., Dept Entomology, Patuakhali Science and Technology Univ., Dumki, Patuakhali, Bangladesh

**19964.** Mutlu, O.; Ulak, G.; Akar, F.; Erden, F.; Celikyurt, I.K.; Bektas, E.; Tanyeri, P.; Kaya, H. (2017): Effects of acute administration of adipokinetic hormone on depression, anxiety, pain, locomotion and memory in mice. *Chin J Physiol.* 60(2): 106-113. (in English) ["The neurosecretory cells in the corpus cardiacum of insects synthesize a set of hormones that are called adipokinetic, hypertrehalosemic or hyperprolinemic depending on the insect in question. They are the Adipokinetic Hormone/Red Pigment-Concentrating Hormone (AKH/RPCH) family of peptides. The present study investigated the effects of acute administration of *Locusta migratoria* (Locmi-AKHII) and *Anax imperator* (Anaim-AKH) on depression, anxiety, pain (analgesy), locomotion and memory in mice in forced swimming (FST), elevated plus maze (EPM), hot plate, locomotor activity and passive avoidance tests. Both Locmi-AKH-II (4 mg/kg) and Anaim-AKH (0.25 and 0.50 mg/kg) decreased immobility time (in sec, s) in the FST test. Anaim-AKH (0.5 and 1 mg/kg) increased the percentage of time spent in open arms/total time spent and the percentage of the number of open arm/total arm entries in the EPM test. Anaim-AKH (1 and 2 mg/kg) significantly increased latency (s) (initial time passed) for mice to lick their hind paws or jumping in the hot plate test. Anaim-AKH (4 mg/kg) significantly decreased the total distance (cm) moved, or the speed (cm/s) of movement of the animals in the locomotor activity test. Neither Locmi-AKH-II nor Anaim-AKH altered the retention latency (s) in the passive avoidance test. Both Locmi-AKH-II and Anaim-AKH exerted antidepressant effects, while only Anaim-AKH had anxiolytic and analgesic effects when administered acutely. Anaim-AKH diminished locomotion at higher doses while Locmi-AKH-II had no such effects. Neither Locmi-AKH-II nor Anaim-AKH disturbed learning and memory when acutely administered. Data of our studies suggest clinical potentials of AKH to be used in depression, anxiety and pain without disturbing memory." (Authors)] Address: Mutlu, O., Kocaeli Univ. Medical Faculty, Dept of Pharmacology, 41380, Kocaeli, Turkey

**19965.** Op de Beeck, L.; Verheyen, J.; Olsen, K.; Stoks, R. (2017): Negative effects of pesticides under global warming can be counteracted by a higher degradation rate and thermal adaptation. *Journal of Applied Ecology* 54(6): 1847-1855. (in English) ["1. An alarming finding for biodiversity is that global warming and pesticides often interact synergistically. Yet, this synergism may not capture the full picture because two counteracting processes may reduce the higher impact of pesticides under warming: higher pesticide degradation in the environment and thermal adaptation of populations. 2. We tested for the effects of warming and multiple pulses of the insecticide chlorpyrifos on life history and fitness-related physiological traits in the damselfly *Ischnura elegans*. To assess whether thermal adaptation is able to mitigate the impact of the pesticide under future warming, we exposed replicated populations from a colder, high latitude and from a warmer, low latitude in a common garden rearing experiment at 20 and 24°C (the respective mean summer water temperatures at both latitudes). 3. At the higher temperature pesticide degradation was higher, leading to less accumulation after multiple pulses compared to the lower temperature. Accordingly, the pesticide caused

less mortality and less oxidative damage at the higher temperature. This contradicts the general belief (based on studies that kept pesticide concentrations constant) of a higher impact of pesticides under warming. Furthermore, the reduction of the impact of the pesticide at the higher temperature was more pronounced in the warm-adapted low-latitude populations, indicating a counteracting role of thermal adaptation. 4. Policy implications. Our findings provide proof-of-principle for two key insights that will allow improving ecological risk assessment of pesticides under global warming: (i) higher pesticide degradation in the environment under warming may temper the impact of multiple pesticide pulses; (ii) gradual thermal evolution may further reduce the impact of pesticides at high latitudes under global warming. This knowledge can be very important for policy makers to arrive at a more realistic forecasting of the impacts of chemical pollution and climate change interactions on organisms." **19967.** Outomuro, D.; Söderquist, L.; Johansson, F.; Ödeen, A.; Nordström, K. (2017): The price of looking sexy: visual ecology of a three level predator-prey system. *Functional Ecology* 31(3): 707-718. (in English) ["(1.) Colour signals and colour vision play a pivotal role in intraspecific communication and predator-prey interactions. However, the costs of expressing conspicuous sexual signals at multiple trophic levels have been largely overlooked. Sexual signals can also experience character displacement in sympatric populations of closely-related species, leading to potential changes in conspicuousness. (2.) We here investigate a bird-damselfly-fruit fly predator-prey system, where two closely related damselfly species have conspicuous, sexually selected wing coloration. The damselflies can occur in sympatry and allopatry and reproductive character displacement in the coloration size has been previously reported. (3.) We quantify the damselfly wing reflectance from replicated sympatric and allopatric populations, and use receptor noise models to investigate the visual discriminability of the wing coloration for the bird, damselfly and fly vision systems, against natural backgrounds. We perform electroretinograms to study damselfly eye sensitivity. We also estimate damselfly predation risk in natural populations. (4.) We find that the chromatic component of wing coloration makes males highly discriminable to the predator, but not to the prey. However, female wing coloration is predominantly cryptic for the predator and prey, and interestingly, also for male damselflies. A female being cryptic to conspecifics likely reduces male harassment. The estimates of predation risk partially support the discriminability results. We also show that there is no difference in colour vision sensitivity between the two damselfly species and sexes, and no difference in wing coloration or its discriminability between sympatric and allopatric populations. (5.) Our results suggest that sexually selected traits can be antagonistically selected by predators and prey, and that this antagonistic selection can be sex-dependent: males are paying a large cost in terms of conspicuousness, while females remain mostly cryptic. Our study thus emphasizes the need for investigating visual communication at multi-trophic levels since the

degree of colour discriminability can differ between predators, prey and the focal species." **19968.** Owens, G.L.; Rennison, D.J. (2017): Evolutionary ecology of opsin gene sequence, expression and repertoire. *Molecular Ecology* 26: 1207-1210. (in English) ["Linking molecular evolution to biological function is a long-standing challenge in evolutionary biology. Some of the best examples of this involve opsins, the genes that encode the molecular basis of light reception. In this issue of *Molecular Ecology*, three studies examine opsin gene sequence, expression and repertoire to determine how natural selection has shaped the visual system. First, Escobar-Camacho et al. (2017) use opsin repertoire and expression in three Amazonian cichlid species to show that a shift in sensitivity towards longer wavelengths is coincident with the long-wavelength-dominated Amazon basin. Second, Stieb et al. (2017) explore opsin sequence and expression in reef-dwelling damselfish and find that UV- and long-wavelength vision are both important, but likely for different ecological functions. Lastly, Suvorov et al. (2017) study an expansive opsin repertoire in the insect order Odonata and find evidence that copy number expansion is consistent with the permanent heterozygote model of gene duplication. Together these studies emphasize the utility of opsin genes for studying both the local adaptation of sensory systems and, more generally, gene family evolution." **19969.** Pereira, D.F.G. (2017): Filtros ambientais determinando caracteres funcionais de assembleias de Odonata. Dissertação (Mestrado) - Universidade Federal do Pará, Empresa Brasileira de Pesquisa Agropecuária, Instituto de Ciências Biológicas, Belém, 2017. Programa de Pós-Graduação em Ecologia: X + 28 pp. (in Portuguese, with English summary) ["Species distribution is affected by availability of habitats that fit within the limits of variation of their niche and by interaction with other species. Environmental modifications, especially those of anthropic origin, are increasingly common, and are considered major causes of species extinction during the Anthropocene. Aquatic ecosystems are considered among the most vulnerable on the planet because of its dependence on the surroundings and the drainage system. However, species responses to these changes are not random, and can follow patterns that are caused by the specific functionality or morphology of each taxon. This work's goal was to evaluate if environmental factors work as ecological filters for the establishment of Odonata species through selection of their functional and morphological characters, testing the hypotheses that a) the environment works as a filter over species, by facilitating or hindering characters and b) that due to their thermoregulatory and reproductive requirements, indispensable for colonization and population maintenance, thorax width and oviposition type will be the most affected biological variables. Considering that, we sampled 97 streams in the oriental side of the Brazilian Amazon Forest, distributed over an environmental gradient which covers areas ranging from untouched primary forest to areas extremely modified by agriculture and livestock. We used six functional traits (total body length, fore wing length, fore wing width, thorax width, abdominal

length and oviposition type) and seven environmental variables (habitat integrity index, dissolved oxygen, water temperature, canopy cover, macrophytes cover, pH and conductivity). To evaluate if the environmental variables affected the odonate communities, we used the combination of the RLQ and Fourth Corner analysis, with which we assessed the relation between each of the selected traits with each of the habitat descriptors. Among the studied environmental variables, habitat integrity index presented the largest effect over the community of Odonata, having a negative relation with fore wing width, thorax width and exophytic oviposition, and a positive relation with endophytic oviposition. Macrophytes cover showed a negative relation with abdominal length and a positive relation with thorax width and exophytic oviposition. No other environmental descriptor presented significant relations. The results show that poorly preserved habitats facilitate the occurrence of organisms with larger thorax and the substitution of the endophytic by the exophytic type of oviposition. Since environmental impacts usually do not change Odonata species richness, only community composition, these results point that there is favouritism towards groups of species with those characters, like the Libellulidae family, with detriment to other families or groups (specially of the Zygoptera suborder), what might result in community homogeneity and loss of functional and phylogenetic diversity. Thus, the preservation of primary forest is indispensable for the maintenance of Odonata, being the best way to conserve the different ecophysiological and behavioural groups in the order. The dragonfly communities' responses, directed by morphological and behavioural traits, enlightens ecological response patterns, and the addition of oviposition categories to conservation policies for the Odonata is critical in making them more effective, as they are absolutely necessary for population stability and colonizing new sites." (Author) "Conclusion The results of this study allow us to identify a clear influence of environmental factors on the composition of Odonata assemblages, confirming the hypotheses that the environment works as an environmental filter for certain characters and that thorax width and oviposition would be the characters most influenced. The quality of the environment, measured by the environmental integrity index, in particular, has a marked effect on the composition of the assembly, affecting both morphological and behavioural characters. The morphophysiological/behavioural approach used in this study sheds new light on Odonata distribution patterns (and their determinants), in contrast to traditional approaches, commonly working with suborders independently or with thermoregulatory categories. Therefore, the integration of morphological and behavioral data in Odonata studies (especially on oviposition) is necessary for a better understanding of the processes that determine the occurrence of the species." **19970.** Pfeifer, E.; Markow, T.A. (2017): Population connectivity and genetic diversity in long-distance migrating insects: divergent patterns in representative butterflies and dragonflies. *Biological Journal of the Linnean Society* 122 (2): 479-486. (in English) ["A number of insect species undergo annual and strikingly long-distance migrations. While the census sizes appear to be very large in many of these species, our understanding of their population genetics and interpopulation connectivity remains elusive. Here, we summarize the utility and limitations of mitochondrial DNA barcodes to assess migratory patterns and genetic connectivity

among populations of four well-known species of long-distance, multigenerational insect migrants, *Danaus plexippus* and *Vanessa cardui*, and *Pantala flavescens* and *Anax junius*. We contrast the differences between the two butterfly species, which show low genetic diversity and little or no phylogeographic structuring, with the two dragonfly species which show an intriguing pattern of high genetic diversity and no apparent phylogeographic structure. Although a recent population genetic study of *P. flavescens* reported high gene flow and reduced (or diminished) COI genetic diversity across widely separated geographic regions, suggesting global panmixia, reanalysis of the data from that study revealed high genetic diversity in agreement with other studies on both *P. flavescens* and *A. junius*. The presence of isolated populations of *P. flavescens*, such as found on Easter Island that appear non-migratory, as well as evidence for significant structure among some migratory populations, suggest that concluding global panmixia in *P. flavescens* may be premature. We also suggest that cost-effective barcode analyses would be the method of choice for preliminary analyses of large data sets required to assess migratory routes and connectivity among populations on a global scale." **19971.** Phillips, I.D.; Prestie, K.S. (2017): Evidence for substrate influence on artificial substrate invertebrate communities. *Environmental Entomology* 46(4): 926-930. (in English) ["Cobble baskets are frequently used as a tool to measure differences in benthic macroinvertebrate communities between waterbodies; however, underlying differences in substrate type may influence the resultant colonization of baskets, misrepresenting communities. This study tests the hypothesis that cobble basket placement influences the resulting benthic macroinvertebrate community. Cobble basket arrays (n=74) were deployed in Dog Lake, Saskatchewan, in 2011 (97 d) and 2012 (95 d) on cobble habitats and soft or sandy substrates ~100 m apart. Baskets placed on cobble substrate had significantly higher Shannon-Weaver diversity relative to those placed on soft substrate in both years, and higher % EPT (Ephemeroptera Plecoptera Trichoptera) in 2011, but total density was not significantly different. Nonmetric multidimensional scaling revealed that the community was different between both treatments, characterized by higher densities of *Gammarus lacustris* Sars in baskets placed on soft sediment in both years, higher densities of *Aeshna* sp. and *Mystacides* sp. on cobble substrate in 2011, and higher densities of *Helobdella stagnalis* (L.) and *Glossophinia complanata* (L.) on cobble substrate in 2012. The results were consistent with the hypothesis that baskets placed on cobble substrate versus soft substrate will result in differing community colonization. The resulting recommendation for monitoring and assessment using cobble baskets in lakes is that baskets be placed on comparable substrate type when comparing between lakes, and that cobble beds be chosen as a more appropriate substrate for deployment, as the added habitat complexity of baskets on soft sediment may act as an attractant and not reflect the true community composition of that habitat." **19972.** Pinkert, S.; Brandl, R.; Zeuss, D. (2017): Colour lightness of dragonfly assemblages across North America and

Europe. *Ecography* 39: 1-8. (in English) ["Dark-coloured ectotherms absorb energy from the environment at higher rates than light-coloured ectotherms. The thermal melanism hypothesis (TMH) states that this physical mechanism links the colour lightness of the body surfaces of ectotherms to their thermal environment and hence to their geographical distribution. Studies on different insect taxa in Europe found support for this prediction of the TMH. However, whether these results hold also for other biogeographical regions remains unclear. Here, we quantify and map the colour lightness of dragonfly species in North America and directly compare our results to previously published findings for Europe. We estimated the colour lightness of 152 North American dragonfly species from published illustrations, compiled their distribution data from the literature and combined all these data with six biologically relevant environmental variables. We evaluated the importance of phylogenetic autocorrelation for the spatial variation of mean colour lightness of dragonfly assemblages (grid cells of approximately 50 km × 50 km size) by repeating all analyses also for the phylogenetically predicted component of the colour lightness of species and the species-specific deviation from this prediction. We also accounted for spatial autocorrelation with autoregressive error models. All statistical approaches showed that dragonfly assemblages from both continents consistently tended to be darker coloured in regions with cold climates and lighter coloured in regions with warm climates. Regression slopes, however, were significantly less steep, and the amount of variance explained by environmental variables was lower for North America than for Europe. Our results highlight the importance of colour lightness for the distribution of dragonfly species, but they also indicate that idiosyncrasies of the continents modify the general pattern." **19973.** Pinkert, S.; Dijkstra, K.-D.B.; Zeuss, D.; Reudenbach, C.; Brandl, R.; Hof, C. (2017): Evolutionary processes, dispersal limitation and climatic history shape current diversity patterns of European dragonflies. *Ecography* 41(5): 795-804. (in English) ["We investigated the effects of contemporary and historical factors on the spatial variation of European dragonfly diversity. Specifically, we tested to what extent patterns of endemism and phylogenetic diversity of European dragonfly assemblages are structured by (i) phylogenetic conservatism of thermal adaptations and (ii) differences in the ability of post-glacial recolonization by species adapted to running waters (lotic) and still waters (lentic). We investigated patterns of dragonfly diversity using digital distribution maps and a phylogeny of 122 European dragonfly species, which we constructed by combining taxonomic and molecular data. We calculated total taxonomic distinctiveness and mean pairwise distances across 4,192 50 km × 50 km equal-area grid cells as measures of phylogenetic diversity. We compared species richness with corrected weighted endemism and standardized effect sizes of mean pairwise distances or residuals of total taxonomic distinctiveness to identify areas with higher or lower phylogenetic diversity than expected by chance. Broken-line regression was used to detect breakpoints in diversity-latitude relationships. Dragonfly species richness peaked in central Europe, whereas endemism and phylogenetic diversity decreased from warm areas in the south-west to cold areas in the north-east and with an increasing proportion of lentic species. Except for species richness, all measures of diversity were consistently higher in formerly unglaciated areas

south of the 0°C isotherm during the Last Glacial Maximum than in formerly glaciated areas. These results indicate that the distributions of dragonfly species in Europe were shaped by both phylogenetic conservatism of thermal adaptations and differences between lentic and lotic species in the ability of post-glacial recolonization/dispersal in concert with the climatic history of the continent. The complex diversity patterns of European dragonflies provide an example of how integrating climatic and evolutionary history with contemporary ecological data can improve our understanding of the processes driving the geographical variation of biological diversity." **19974.** Rach, J.; Bergmann, T.; Paknia, O.; DeSalle, R.; Schierwater, B.; Hadrys, H. (2017): The marker choice: Unexpected resolving power of an unexplored CO1 region for layered DNA barcoding approaches. *PLoS ONE* 12(4): e0174842. <https://doi.org/10.1371/journal.pone.0174842>: 14 pp. (in English) ["The potential of DNA barcoding approaches to identify single species and characterize species compositions strongly depends on the marker choice. The prominent "Folmer region", a 648 basepair fragment at the 5' end of the mitochondrial CO1 gene, has been traditionally applied as a universal DNA barcoding region for metazoans. In order to find a suitable marker for biomonitoring odonates (dragonflies and damselflies), we here explore a new region of the CO1 gene (CO1B) for DNA barcoding in 51 populations of 23 dragonfly and damselfly species. We compare the "Folmer region", the mitochondrial ND1 gene (NADH dehydrogenase 1) and the new CO1 region with regard to (i) speed and reproducibility of sequence generation, (ii) levels of homoplasy and (iii) numbers of diagnostic characters for discriminating closely related sister taxa and populations. The performances of the gene regions regarding these criteria were quite different. Both, the amplification of CO1B and ND1 was highly reproducible and CO1B showed the highest potential for discriminating sister taxa at different taxonomic levels. In contrast, the amplification of the "Folmer region" using the universal primers was difficult and the third codon positions of this fragment have experienced nucleotide substitution saturation. Most important, exploring this new barcode region of the CO1 gene identified a higher discriminating power between closely related sister taxa. Together with the design of layered barcode approaches adapted to the specific taxonomic "environment", this new marker will further enhance the discrimination power at the species level." **19975.** Razeng, E.; Smith, A.E.; Harrison, K.A.; Pavlova, A.; Nguyen, T.; Pinder, A.; Suter, P.; Webb, J.; Gardner, M.G.; Box, J.B.; Thompson, R.; Davis, J.; Sunnucks, P. (2017): Evolutionary divergence in freshwater insects with contrasting dispersal capacity across a sea of desert. *Freshwater Biology* 62(8): 1443-1459. (in English) ["1. Arid landscapes pose arguably one of the greatest challenges to dispersal of aquatic insects, and may drive speciation in taxa

with low dispersal potential. We investigated genetic divergence in aquatic insects with high and low dispersal potential between two regions within the Australian arid zone. We used two dragonfly species [*Diplacodes haematodes*, *Orthetrum caledonicum*] to infer patterns for strong-dispersing species, and mayfly species from two genera to represent weak-dispersing species. Based on dispersal-related traits of the taxa, we predicted that dragonflies would show little divergence between and within the two geographical regions, while mayflies would show evidence of genetic isolation, with divergence timing associated with aridification in Australia. 2. Samples were collected from perennial pools in ephemeral stream networks in central and western Australia. The two study regions are separated by approximately 1,500 km of predominantly dune desert. Collected insects were sequenced for one mitochondrial and one nuclear marker. We investigated spatial distribution of haplotypes, estimated divergence dates for identified mayfly lineages, and performed phylogenetic reconstruction to investigate relationships with known congeners. 3. Both dragonfly species showed evidence of recent or ongoing gene flow between the central and western Australian study regions. In contrast, mayflies showed evidence of ancient, but not recent, gene flow between regions, with species-level CO1 divergence within regions. We found 11 previously unknown putative mayfly species, that if confirmed could double the known diversity within these genera in Australia. Timing of divergence events for mayflies coincided with the development of the Australian arid zone, and phylogenetic relationships are similar to divergence patterns found in other Australian arid taxa. 4. The findings of this study suggest that aridification is more likely to be a driver of diversification in taxa with low dispersal potential than in those with high dispersal potential. This is because effective aerial dispersal is integral for maintaining gene flow when aquatic connections are lost between distant populations, and reduced gene flow can promote genetic divergence." **19976.** Rivas-Torres, A., Sanmartín-Villar, I.; Gabela-Flores, M.V.; Cordero-Rivera, A. (2017): Demographics and behaviour of *Heteragrion cooki*, a forest damselfly endemic to Ecuador (Odonata). *International Journal of Odonatology* 20(2): 123-135. (in English) ["Damselflies adapted to forest habitats are expected to be negatively affected by the disturbance of riparian forests, due to the change in insolation when trees are cleared. In this paper, we compare survivorship and behaviour of two populations of *Heteragrion cooki* by means of mark-recapture methods and focal observations of adults. We found similar densities of males (but not of females) in both streams, and similar recapture rates, higher for males (50%) than for females (20%). Body size was also significantly different between populations, with smaller individuals in the shadiest stream. The analysis of daily survival rates indicated that in the shaded stream, males survived better than females, whereas in the sunnier stream survival was similar between sexes, but varied over time. Furthermore, in the sunny stream, body size was negatively correlated with survival. Males arrived earlier than females to the stream, with a maximum activity between 13 and 16 hours. They defended small patches of the stream, exhibiting high site fidelity and aggressive behaviour against conspecific males. Copulation, which was very rarely seen in the stream, lasted about six minutes. Pairs in tandem remained for an average of 45 minutes laying eggs on roots

and lianas. We found that *H. cooki* was not drastically affected by the loss of riparian vegetation, maintaining similar densities of males in both streams, probably because small remnants of native forests were still found near to the stream." **19977.** Roh, C. (2017): Hydrodynamics of insects. Part 1. Jetting of the dragonfly larvae. Part 2. Honeybee at the air-water interface: Surfing with the capillary wave. Ph.D. thesis, California Institute of Technology. doi:10.7907/Z97P8-WFW. <http://resolver.caltech.edu/CaltechTHESIS:060820-17-183218154> : 103 pp. (in English) ["This thesis presents the study on the hydrodynamics of two insects commonly known for their aerial adaptation: the dragonfly and the honeybee. Part 1: Anisopteran dragonflies live underwater in their larval stages. The key factor for their aquatic adaptation is the modified hindgut chamber that is used as a pump. The two main functions of this biological pump are jet propulsion and respiration. Both functions involve jetting and refilling of the chamber through an orifice guard by a tri-leaflet anal valve. Despite it being a unique machinery among insects, associated hydrodynamic studies are limited thus far. In the first part of this thesis, various aspects of the hydrodynamics of the dragonfly larvae's ventilatory flow are studied. The flow visualization showed that the respiratory flow is laminar but the propulsion flow is turbulent. The hydrodynamic force analysis showed that jetting and refilling phase forces are dominated by quasi-steady momentum flux and unsteady acceleration, respectively. Finally, simultaneous measurement of the anal valve kinematics and jet flow showed that the larvae could influence the direction and magnitude of the jet by controlling the anal valve leaflets. Part 2: Water-collecting honeybees often fall onto water surfaces. However, bees trapped by the "stickiness" of the water can propel by vibrating their wings, often making it to shore. In the second part of this thesis, the honeybee's propulsion mechanisms at the air-water interface is studied. The result shows that the bees can achieve three body-lengths per second propulsion speed. High-speed video of their wing motion shows that honeybee's propulsion involves pulling blobs of water with the underside of the wing, while pushing on a surface wave with its trailing edge. This propulsion mechanism resembles surfing on a self-generated capillary wave. Moreover, their wing vibration generates complicated surface waves and flows, below which the deeper water flow shows a single jet stream. From the wave and flow field measurements, the average force imparted to the surrounding fluid is estimated and compared to the average force calculated from the bee's body motion. The resulting average forces are of the same order of magnitude, which means that generating wave and flow are both important for the bee's propulsion." (Author)] Address: not stated

in damselflies. *Ecol Evol.* 2017; 11pp. <https://doi.org/10.1002/ece3.3083>: 11 pp. (in English) ["Genetic polymorphisms are powerful model systems to study the maintenance of diversity in nature. In some systems, polymorphisms are limited to female coloration; these are thought to have arisen as a consequence of reducing male mating harassment, commonly resulting in negative frequency-dependent selection on female color morphs. One example is the damselfly *Ischnura elegans*, which shows three female color morphs and strong sexual conflict over mating rates. Here, we present research integrating male tactics, and female evolutionary strategies (female mating behavior and morph-specific female fecundity) in populations with different morph-specific mating frequencies, to obtain an understanding of mating rates in nature that goes beyond the mere measure of color frequencies. We found that female morph behavior differed significantly among but not within morphs (i.e., female morph behavior was fixed). In contrast, male tactics were strongly affected by the female morph frequency in the population. Laboratory work comparing morph-specific female fecundity revealed that androchrome females have lower fecundity than both of the gynochrome female morphs in the short term (3-days), but over a 10-day period one of the gynochrome female morphs became more fecund than either of the other morphs. In summary, our study found sex-specific dynamics in response to different morph frequencies and also highlights the importance of studying morph-specific fecundities across different time frames to gain a better understanding of the role of alternative reproductive strategies in the maintenance of female-limited color polymorphism" (Authors)] Address: Sánchez-Guillén, Rosa, Depto de Ecología e Biología Animal, E. **19981.** Seidu, I.; Danquah, E.; Nsor, C.A.; Kwarteng, D.A.; Lancaster, L. (2017): Odonata community structure and patterns of land use in the Atewa Range Forest Reserve, Eastern Region (Ghana). *International Journal of Odonatology* 20(3/4): 173-189. (in English) ["Recent studies have indicated that frequent anthropogenic disturbances in tropical developing countries are primary drivers of reduction in community diversity and local extinction of many arthropods, including dragonflies. We assessed the impact of anthropogenic disturbances on odonate assemblages across

three different land use types, in a biodiverse nature reserve in Ghana. A total of 37 transects (100 x 10 m) were used to survey odonate species over two seasons and three rivers which pass through agricultural, matured forest and forest margin habitats. A total of 6940 individuals, belonging to 53 species (23 Zygoptera and 30 Anisoptera) in eight families, were recorded. *Sapho ciliata* (15% relative abundance) was the most abundant zygopteran, whereas *Orthetrum julia* (4.8% Relative abundance) was the dominant anisopteran. Rarer species like *Umma cincta*, *Chlorocnemis* sp. and *Elatoneura* sp. were represented by < 50 individuals. The effective number of species was affected by the surrounding terrestrial habitat type and this most strongly reflected the difference between agricultural habitats (8.09 ± s.e. 0.41) and matured forests (5.0 ± s.e. 0.24). A canonical correspondence analysis revealed that turbidity, surface water temperature, canopy cover and channel width were the key factors that influenced odonate assemblages. Degraded habitats were dominated by generalist and heliophilic dragonflies, while matured forest habitat included more stenotopic damselflies and dragonflies. These findings improve our understanding of the drivers of odonata distributions and diversity and will help river managers use odonates to monitor riverine health, as part of conservation activities." **19982.** Setyawati, S.M.; Purwowidodo; Huda, M.M.; Dewi, B.A. (2017): The diversity of the dragonfly of *Orthetrum* genus in protected area of Mount Prau, Central Java Indonesia. *J. Nat. Scien. & Math. Res.* 3(1): 228-235. (in English) ["Dragonfly of the genus *Orthetrum* is a dragonfly of the Libellulidae family. This dragonfly has a variety of types of morphological structure, body color, distribution and habitat. Habitat dragonfly of the genus *Orthetrum* is quite extensive, especially around lowland to upland waters. Protected Forest Mount Prau Central Java, is a rainforest that has a water flow appropriate for life dragonflies. It allows the Dragonflies of all kinds to live and thrive in the environment, including *Orthetrum*. This research was conducted to find out the types of *Orthetrum* that can be found in Protected Forest Area of Mount Prau, Central Java. Determination of sampling is done along the river flow at 3 stations with total sub plot of sample as much as 12 point, starting from near settlement flow up to 2100 m toward waterfall source. The results of the sample analysis showed morphological variations in the structure of the thorax and abdomen as well as the color variations and patterns on the thorax, abdomen, and wings. Identification of the dragonfly obtained four types of dragonfly *Orthetrum* with variations on the sex, the male and female sabina *Orthetrum*, *Orthetrum cafferum* males. *Orthetrum testaceum* male, male and female *pruinatum* *Orthetrum*, and *Orthetrum* male and female *glaucum*. ©2017 JNSMR UIN Walisongo. **19983.** Shkëmbi, E.; Qirinxhi, X.; Misja, K.; Papparisto, A. (2017): Contribution to the knowledge of Odonata in Shkodra Lake, Albania. 1-st International Conference on Social and Natural Sciences Proceedings Vienna, 8-9 April: 231-236. ["Shkodra Lake is located in the northwest part of Albania. It lies on the border of Albania and Montenegro, approximately two-third (229 km<sup>2</sup>) of its surface belongs to

Montenegro and about one-third (142 km<sup>2</sup>) belongs to Albania. The aim of our research is to complete the list of Odonata for Albania. In term of its Odonata fauna, the Albanian part of Shkodra Lake, is insufficiently known, with some sporadic data. Expeditions were conducted along the coast of the Albanian part of the lake, during spring-summer 2015 and 2016. 94 specimens have been classified into 16 species, 6 of them are Zygoptera and 10 are Anisoptera. *Erythromma lindenii* is reported for the first time in this area while *Lindenia tetraphylla* is mentioned as Vulnerable on the European Red List (Kalkman et al., 2010). Discussions on the need for further research and possible future additions to the fauna of Shkodra lake are still in progress." **19984.** Silva Filho, E. (2017): Efficiency of dragonfly nymphs (Odonata) as potential predators of *Aedes aegypti* larvae, under laboratory conditions in São Cristóvão, Sergipe. *Trabalho de Conclusão de Curso (Graduação de Tecnólogo em Agroecologia) - Instituto Federal de Sergipe, São Cristóvão: 24 pp.* (in Portuguese, with English summary) ["Studies to combat the *A. aegypti* vector are important to reduce the incidence of Dengue, Zika, Chikungunya and yellow fever, responsible for thousands of deaths worldwide. The objective of this work is to evaluate the efficiency of Odonatas nymphs as predators of *Aedes aegypti* larvae under laboratory conditions. 30 Odonata nymphs, from different families, were collected with D network, in the Poxim Agu river stretch (IFS), then transported to the laboratory in thermal boxes. In this, the nymphs were individualized in 20 cm diameter plastic pots containing river water and kept at room temperature, totaling 30 trials. To verify the potential predation of *A. aegypti* larvae by the Odonata nymphs, 30 mosquito larvae were added to each pot. Predation was evaluated daily by counting the number of predated larvae. The Odonata nymphs had an average predation efficiency of 6.08 mosquito larvae per day and could predate about 2189 larvae in a year. The families Aeshnidae (9.28), Libellulidae (8.37) obtained the highest averages of predation per day. All odonata families predated 25 to 30 larvae in one day, except Cordulidae, with a maximum of 8 prey larvae. The conditions of this experiment resemble the conditions domiciled found in water storage containers. Therefore, odonata nymphs (Aeshnidae and Libellulidae) are effective for the reduction or even extinction of the *Aedes aegypti* population and should be used in all municipalities in Brazil to reduce and / or eradicate Zika, Dengue, Chikungunya and yellow fever." **19985.** Subramanian, K.A.; Babu, R. (2017): Checklist of Odonata (Insecta) of India. Version 3.0. *www.zsi.gov.in. Zoological Survey of India: 54 pp.* (in English) ["Odonata of India is represented by 487 species and 27 subspecies in 152 genera and 18 families. Zygoptera comprise of 210 species under 57 genera and 9 families; Anisozygoptera one species under one genera and one family; Anisoptera 276 species under 94 genera and 8 families. One species in Zygoptera is considered as incenae sedis. High diversity and endemism is found in the hill streams and rivers of Western Ghats and eastern Himalaya. The taxonomy of adult is well worked out. however the descriptions of larva and their ecology remains as a major gap area, especially for several elusive hill stream breeding species. Geographically, the central India, eastern ghats, eastern Himalaya and Andaman Nicobar islands remains under explored where new species and records are still awaiting formal scientific description. In the current checklist, with reference to Version 2.0 (2014),

there are 58 nomenclatural changes, 29 new additions, 10 deletions and 7 species are kept under doubtful status." **19987.** Tüzün, N.; Op de Beeck, L.; Brans, K.I.; Janssens, L.; Stoks R. (2017): Microgeographic differentiation in thermal performance curves between rural and urban populations of an aquatic insect. *Evolutionary Applications* 10(10): 1067-1075. (in English) ["The rapidly increasing rate of urbanization has a major impact on the ecology and evolution of species. While increased temperatures are a key aspect of urbanization ("urban heat islands"), we have very limited knowledge whether this generates differentiation in thermal responses between rural and urban populations. In a common garden experiment, we compared the thermal performance curves (TPCs) for growth rate and mortality in larvae of the damselfly *Coenagrion puella* from three urban and three rural populations. TPCs for growth rate shifted vertically, consistent with the faster-slower theoretical model whereby the cold-adapted rural larvae grew faster than the warm-adapted urban larvae across temperatures. In line with costs of rapid growth, rural larvae showed lower survival than urban larvae across temperatures. The relatively lower temperatures, hence expected shorter growing seasons in rural populations compared to the populations in the urban heat islands likely impose stronger time constraints to reach a certain developmental stage before winter, thereby selecting for faster growth rates. In addition, higher predation rates at higher temperature may have contributed to the growth rate differences between urban and rural ponds. A faster-slower differentiation in TPCs may be a widespread pattern along the urbanization gradient. The observed microgeographic differentiation in TPCs supports the view that urbanization may drive life history evolution. Moreover, because of the urban heat island effect, urban environments have the potential to aid in developing predictions on the impact of climate change on rural populations." **19989.** Wasscher, M. (2017): The surroundings of Zanderij, the best-studied area for the dragonflies of Suriname. *Agria* 29(1): 23-26. (in English) [A total of 188 odonate taxa is listed. The list includes 7 species with their type localities in Suriname. 75 species are rather rare. 21 rare and 7 very rare. The author concludes: "The Zanderij area has a very high number of Odonata species. On one hand, this is because the savannah creeks in the area seem to be different from many other creeks in the country, with a sandy bottom and sometimes rich water vegetation. On the other hand, the high number of species is to some extent due simply to the fact that the area has been visited very often over many years." ] Address: Wasscher, M., Minstraat 15bis, NL-3582 CA Utrecht, The Netherlands, E-mail: marcel.hilair@12move.nl

**19990.** Winfrey, C.; Fincke, O.M. (2017): Role of visual and non-visual cues in damselfly mate recognition. *International Journal of Odonatology* 20(1): 43-53. (in English) ["In many species of damselflies, sexual conflict in the form of male harassment is thought to explain the widespread existence of female-limited color polymorphisms. With a few exceptions, the majority of investigations into these mating systems have assumed that male damselflies primarily use visual cues to detect and recognize their mates. Recently, laboratory studies have demonstrated that damselflies orient to olfactory signals from prey and that males orient to chemical cues from conspecific females. However, to date there are no field experiments which explicitly test the role that chemical cues play in sex recognition. Here we used a field experiment on *Enallagma civile* damselflies to test if free flying males detect and recognize females in the absence of visual cues through the use of non-visual signals. In the absence of visual cues males did not exhibit positive responses toward female conspecifics, whereas when both visual and non-visual cues were present, males readily detected females and often tried to mate with them. Although it is possible that non-visual cues may be involved during close contact, our results emphasized that visual cues take center stage in damselfly mate recognition in the field environment. Because the field environment is the context in which selection acts on natural populations, results of this study have implications for our understanding of how selection on visual cues acts to maintain female-limited color polymorphism in damselflies whose males must search for potential mates." **19992.** Zimová, K. (2017): Dragonflies (Odonata) of selected ponds in the Zbiroh area. *Bakalářská Práce, Biologie se zaměřením na vzdělávání, Plzeň: IV + 56 pp.* (in Czech, with English summary) ["The inventory research was done from April to September 2016 in selected ponds near Kaøez village (four ponds) and near Jableèno village (two ponds) in the Zbiroh area. The main aim of the research was observation of species diversity. In total, 21 species of dragonflies was observed, of them 11 species of the suborder Anisoptera and 10 of the suborder Zygoptera. Thirteen genera was observed (number of species is in brackets): Calopteryx (2), Ischnura (1), Coenagrion (2), Pyrrhosoma (1), Enallagma (1), Platycnemis (1), Lestes (2), Cordulia (1), Aeshna (4), Anax (1), Libellula (2), Orthetrum (1), and Symptetrum (2). Detail illustration of observed species are presented. The result indicates that despite intensive economic exploitation of ponds, the dragonflies diversity is rather high. The presence of littoral vegetation is likely the important factor controlling diversity of dragonflies. This is a contribution to mapping of the dragonflies distribution in the territory of the Czech Republic." (Author)] Address: not stated

**19993.** Palacino-Rodríguez, F.; Altamiranda-Saavedra, M.; Palacino, D.A.; Penagos, A.C. (2020): Effects of seasonality and environmental change on an Andean damselfly *Mesamphiagrion laterale* (Odonata: Coenagrionidae). *Journal of Insect Conservation* 24: 499-511. (in English) ["Land use change, notably the conversion of natural habitats into agriculture, has strong negative effects on wild animal populations. Effects of disturbance and seasonality on demographic parameters of the damselfly *Mesamphiagrion laterale* Selys, 1876 were assessed to investigate how individual survival probability and over population size changed according to season and anthropogenic disturbance (agricultural habitat vs. forested habitat). For each habitat type, forest cover, area covered by vegetation, percentage of macrophytes and water physicochemical attributes were measured. Likewise, population parameters such as sex ratio, population size, life expectancy, survival and recapture rates were estimated using Cormack-Jolly-Seber (CJ-S) models. Life expectancy of the total population was lower during the rainy season, while population size and survival in males were lower in agricultural habitats during this same season. Human activities related to agriculture and livestock production in the Colombian Andes threaten the long-term viability of odonate populations through degradation of aquatic habitats. Contrary to our initially proposed hypotheses, these effects were more intense for males due to their closer association with riparian vegetation and thus greater exposure to aquatic pollutants." **19998.** IUCN (2021): The conservation status of species and habitat in freshwater Key Biodiversity Areas (KBAs) and key additional sites from the Sebou Basin. Project WAMAN (Water Management) Sebou Project, Málaga: 57 pages + annexes- (in English) ["This report presents the results of a broad assessment of the freshwater diversity in four Key Biodiversity Areas (KBAs) and some key additional sites in the Sebou river basin in Morocco. The Sebou river basin houses a large proportion of the Moroccan human population that depends on the river for their livelihood. The basin has important ecosystems for threatened species that are currently being recognized as Ramsar sites or national parks. Additionally, four sites have been identified as Key Biodiversity Areas (KBAs) for the persistence of freshwater biodiversity. Assessments were made on the effectiveness of the existing Key Biodiversity Areas (KBAs) in containing important populations of trigger species. During the summers of 2018 and 2019, biodiversity surveys of the taxa used to identify freshwater KBAs (fishes, molluscs, dragonflies and damselflies, crabs and aquatic plants) were undertaken by a team of experts in 39 sampling points, of which 29 were located in KBAs, and the remaining 10 were located in surrounding areas. A total of 192 species was recorded: 17 fish, 6 bivalve, 17 gastropod, 44 dragonfly and damselfly, 2 crayfish/crab species and 106 aquatic plant species. Twenty-one of these species are classified as threatened with extinction in the IUCN Red List of Threatened Species™ (7 aquatic plant species, 2 fish species, 1 damselfly species, 1 crayfish species, 4 bivalve species, and 6 gastropod species). The highest native freshwater biodiversity was recorded in the South and East of KBA Oued Imouzzar Kandar. Also, in the central-east of KBA Oued Tizguite & Oued Ouaslane a high number of native species were found, especially aquatic plants. On the other hand, the number of threatened species was especially high in the KBA Oued Bouhlou and the KBA Oued Tigrigra. KBA Oued Bouhlou and its surroundings hosted a high number of threatened fish and a total of 7 threatened molluscs, including the Critically Endangered *Pseudunio maroccanus* (assessed as *Margaritifera marocana* in the IUCN Red List) and *Unio foucauldianus*. Many threatened molluscs species were also found in the surroundings of the KBA Oued Tigrigra, as well as the Endangered damselfly species *Calopteryx exul* and several threatened aquatic plants. For the surrounding areas, high freshwater biodiversity was found in the main channel of Oued Sebou, especially a high number of fish and dragonfly species. A major threat to the survival of the freshwater biodiversity is the introduction of non-native species that might outcompete the native species. A

total of 11 non-native fish species were found in this study. High numbers of non-native fish were found in KBA Oued Tizguite & Oued Ouaslane and KBA Oued Tigrigra, as well as in the lakes' region (Dayat Iffer/ Dayat Yfrah/ Dayat Afourgah) and the sites in Aguelmam n'Tifounassine and Sidi Ali. Habitat Quality Assessments (HQA) produced high values for KBAs and surrounding areas, but the Habitat Modification scores (HMS) were neither clearly negative nor positive. The region around the KBA Oued Tizguite & Oued Ouaslane is especially affected by human activity, and management plans have to be implemented to properly protect the biodiversity in the area. Other important threats are the construction of dams that are hindering the environmental flow required by many threatened species, soil erosion and siltation of river substrate and wastewater/solid waste disposal in the rivers. The Sebou basin has a high socio-economic importance for the Moroccan population, and is extensively used both for agriculture and industry. The effluents from agricultural or industrial activities have caused high contamination levels, that are harmful to humans, their livestock and the biodiversity. Another issue is the water shortage due to the water extraction for agricultural and urban uses, causing extreme droughts in some sites, especially in KBA Imouzzar Kandar. This intensive water extraction causes soil saline extrusion and increased water conductivity, as has been witnessed in the sites Aguelmam n'Tifounassine & Sidi Ali. Lastly, many of the springs and lakes are becoming unsustainable tourism destinations and have been completely altered and polluted, with the risk of a complete destruction of the freshwater biodiversity in the near future. The inclusion of freshwater biodiversity into the management plan for the Sebou basin, with the involvement of local authorities and communities, is necessary in order to preserve these high valued freshwater ecosystems. In the river Bouhlou crossing the Tazekka natural park, one of the best recruiting populations of the freshwater mussel *Pseudunio maroccanus* (assessed as *Margaritifera marocana* in the IUCN Red List), one of the world's 100 most threatened species, was detected. In order to protect this precious freshwater biodiversity, several measures should be taken to adjust the agricultural and industrial sector: inclusion of freshwater biodiversity into the water management plans and the increase of riparian buffers, wastewater treatment plans, the prevention of cattle overgrazing and bank destruction by trampling near the river banks. Campaigns on the correct management of the channels and the control of recreational activities by local authorities, could aid to manage the environmental flow necessary for many native species. For the rivers/lakes suffering from droughts, it will be necessary to setup an aquifer management plan covering the catchment of the aquifer on which the rivers/lakes depend, and develop artificial reservoirs to enable the reduction of exploitation of ground water. Finally, measures should be taken to stop the active re-stocking of fish in order to avoid non-native species outcompeting the native species. Further studies should be conducted to have a better understanding on the freshwater biodiversity in the Sebou basin. It is necessary to re-evaluate some of the KBAs to assess the presence of their trigger species and other threatened species. Finally, many of the additional sites that were studied here could be included as extension of the KBA, or a new KBA should be created to help focusing conservation efforts and promoting management actions that allow the persistence of the biodiversity elements present in there." **19999.** Janra, M.N.; Herwina, H. (2021): How to reclaim

your dragons? A retrospective review on odonatology in West Sumatra, Indonesia. IOP Conference Series: Earth and Environmental Science, Volume 757 012086: 9 pp. (in English) ["Dragonflies and damselflies (Odonata) were not really popular subjects for biological studies at least until a decade ago in West Sumatra. In many scientific publications published by Lieftinck, a colonial era odonatologist, not many localities in West Sumatra mentioned as the origin of his Odonata specimens. In this study, we intend to review the extent of current odonatological works in West Sumatra to gain perspective on the ongoing scientific aspects of this taxon. We used literature study method to compile data from historical and recent bibliographies, published works and other resources regarding dragonflies in West Sumatra. As result, from around 294 odonate species ever recorded in Sumatra Island, 98 species have been recognized from within the borders of West Sumatra Province with more than half recently reobserved. Albeit most publications are taxonomical and inventorial in their nature, further survey works are still needed to gain thorough insight on West Sumatran odonates. Meanwhile, the current studies and researches indicate the possibilities that dragonflies can also be integrated into the wider aspects, such as ecotourism, pest management, landscaping, environmental impact assessment, aesthetic and many others. Hence, introducing odonates as fascinating study object to the new generation of biologists can help furthering the advance and diversification of odonatological study in West Sumatra." **20002.** Lang, X.; Song, B.; Yang, W. (2021): Numerical simulation of pitching motion effects on the aerodynamic performance of a dragonfly-like flapping wing. 32nd Congress of the International Council of the Aeronautical Sciences, September 6-10, 2021, Pudong Shangri-La, Shanghai, China: 9 pp. (in English) ["Dragonflies have remarkable flight skills and their excellent flight performance has attracted persistent attention. The multi-degree-of-freedom flapping kinematics and interaction of the tandem wings might account for their extraordinary flight skills. In this paper, the effects of pitching motion on the aerodynamic performance of a dragonfly-like flapping wing have been numerically studied. A transient numerical method based on the overset mesh technique is used to simulate the flapping

and pitching movements. Different pitching amplitudes have been evaluated as the forewing and hindwing flap in counter-stroking during the hovering process. It is found that the pitching motion has an obvious influence on the tandem wings' aerodynamic performance, and there is a reasonable pitching amplitude to make the hovering vertical force optimal. Additionally, the interaction of the tandem configuration will lead to an obvious fluctuation in the aerodynamic force. The research in this paper is helpful to understand the flight mechanism of dragonflies flight." **20003.** Membere, O.; Bawo, D.D.S.; Onwuteaka, J.; Ugbohome, A.P.; Nwosu, O.R. (2021): Abundance and diversity of insects associated with *Rhizophora* mangle and *Avicennia germinans* in Bundu-Ama mangrove ecosystem of the Niger Delta, Nigeria. *Scientific African* 14(7):e01058: 11 pp. (in English) ["Mangrove species diversity is well known for larger animals and plant, but little is known about mangrove insects and their significance and yet they perform important roles in the ecology of the habitat. The present study was conducted to determine the diversity of insects associated with *Rhizophora* mangle and *Avicennia germinans* in Bundu-Ama mangrove habitats, a tributary of the Bonny River in the Niger Delta. Two stations were established based on the abundance of the mangroves. A total of 18 mangrove trees (nine each) for both species were randomly selected and insect samples collected bi-weekly between 7 am and 11 am between April and June 2017, making a total of 108 trees within the study period. Each tree was sampled for 10 minutes using sweep net, hand net and handpicking methods. A total of 8 insect orders (Diptera, Coleoptera, Hymenoptera, Homoptera, Rhopalocera, Odonata [one species, 15 specimens; not identified], Phasmida and Heterocera), 20 families and 35 species were identified. Hymenoptera (49.1%) was the highest insect order recorded, followed by Diptera and Homoptera. *Avicennia* had more insect orders, families and species. Coleoptera, diptera and Hymenoptera were found on both plants while others were on *Avicennia* only. Formicidae was the most abundant family (37.1%) while Lagiidae was the least (0.2%). The most abundant species was *Camponotus acvapimenis*. The highest species diversity was observed in the Diptera with Shannon H' of 2.00 for *Avicennia* and 2.13 for *Rhizophora*. The richness index was 2.43 for *Avicennia* and 2.62 for *Rhizophora*, and the highest species evenness ( $E' = 0.40$ ) was observed in the Diptera indicating that the insects were not evenly distributed. Two insect associations were identified: a specialist group of 23 species on *Avicennia*, and 6 species on *Rhizophora*, while the second group were the generalist made up of 3 species *Anopheles squamosus*, *Musca domestica* and *Fannia* sp. Insect families (Muscidae, Calliphoridae, Syrphidae, Ceratopogonidae, Culicidae, Tabanidae) are of medical, veterinary and ecological importance as pollinators, bioindicators, predators, parasitoid, agricultural pest and detritivores. Insect diversity was found to be higher in *Avicennia* than in *Rhizophora*. This study has shown that the mangroves of Bundu-Ama have a vast array of insects which will contribute to their biodiversity data and subsequent conservation and management of ecosystem in the Niger Delta." **20006.** Petrovicová, K.; Langraf, V.; David, S.; Krumpálová, Z.; Schlarmanová, J. (2021): Distinct Odonata assemblage variations in lentic reservoirs in Slovakia (Central Europe). *Biologia* 76: 3727-3741. (in English) ["The effects of various aquatic habitats on the abundance, species richness, diversity and taxonomic distinctness of Odonata were studied. The impact of environmental factors and living conditions in lentic habitats were expressed by the composition of coenoses, on the evaluation we used the Dragonfly Biotic Index. The positive effects of habitat heterogeneity on biodiversity are well known, but it is not clear how the diversity of studied and ecologically important taxa, such as odonates, may vary in different water reservoirs. We investigated how Odonata community metrics (composition, abundance, diversity and environmental compatibility) differ in lentic water: ponds, fishponds, excavation of mineral material and in marshlands, where biodiversity plays an important role. Using an entomological mesh, we took samples in the southwestern part of Slovakia in six geo-morphological units at 54 study sites during four years. This study detected distinct odonates assemblage variations among habitats and heterogeneity among gradients. Wide ranges of microhabitats with different environmental properties create appropriate conditions for living span of them. Surprisingly, the highest species richness was recorded in the excavation of mineral materials habitats. Stagnicolous Odonata species correlated (CCA) with the habitats of excavation of mineral material and marshlands; showed links to the littoral vegetation and dense vegetation cover. While the euryecious species have been linked to the ponds and fishponds; and correlated with the water body size. It seems to be degraded habitats are not so much suitable for rare and endangered species, but to preserve the biological value of the environment and for the existence of the high abundance and species richness of odonates." **20010.** Rychla, A. (2021): New data on the abundance and phenology of the Broad Scarlet *Crocothemis erythraea* (BRULLÉ, 1832) (Odonata: Libellulidae) on example of a site at lake Plaw (Lubuskie district). *Odonatrix* 174 (2021): 8 pp. (in Polish, with English summary) ["*C. erythraea* is a Mediterranean dragonfly species, constantly expanding its range northwards. Although it is already widespread in Poland, little is known about its ecology in the country. Therefore, the purpose of this study was to provide new infor-

mation on the abundance and phenology of an autochthonous population inhabiting shallow, eutrophic lake Plaw in western Poland. During 20 visits, which lasted from April 29th to August 16th, 2020, all Anisoptera exuviae were collected from a 20-meter-long transect along shoreline of the lake. In total, 436 exuviae representing 13 Anisoptera species were collected. Out of it, 244 exuviae belonged to *C. erythraea*, which made 56 % of the entire sample and was evidence for absolute dominance of this species in the investigated odonatological community. First exuviae of *C. erythraea* were found on May 19th, 2020 and the last ones on August 1th, 2020. Thereby, the entire emergence period lasted for 74 days. The highest exuviae abundances were recorded from Mid-June to the beginning of July, thus indicating asynchronous emergence of one generation. The results show that *C. erythraea* has been much more abundant in the dragonfly community as assumed by now. However, it is not clear whether this is a long-term trend or an effect of high air temperatures in recent years. As the species may interact with other native species, more attention should be paid for gathering data on the quantitative status of *C. erythraea* in the whole community of Odonata in Poland." **20015.** Susanto, M.A.D; Zulaikha, S. (2021): Diversity and community structure of dragonfly and damselfly (Odonata) at the Selorejo waterfall area, Ponorogo Regency, East Java Indonesia. *Jurnal Riset Biologi dan Aplikasinya* 3(1): 30-37. (in English) ["Selorejo Waterfall is a natural tourism area that is quite far from downtown Ponorogo and directly adjacent to the Gunung Sigogor Nature Reserve. Hence, this area has the potential as a natural habitat for dragonfly and damselfly. The presence of dragonfly and damselfly species is determined by the type of habitat, canopy conditions, vegetation diversity, and the microclimate that exists in a location. This study aimed to determine the diversity of dragonfly and damselfly and to determine the community structure of dragonflies in Selorejo Waterfall. The sampling method was Visual Day Flying. The results of research conducted in two streams showed that there were 12 species from 6 families with a total of 230 individuals. The value of species diversity at this location is  $H' = 2.05$ . In the community structure at the Selorejo Waterfall dragonfly, there are differences in the number of species and individuals in the two streams in Selorejo Waterfall Area. The large stream, eight species from four families, 151 individuals in total. Meanwhile, in small stream, there were nine species from six families, 79 individuals in total. The differences in the number of species and individual dragonflies in the two streams at Selorejo Waterfall can be used to describe the diversity and structure of the Odonata community in the area." **20016.** Tamm, J.; Dressler, B. (2021): Nachweise des Bachwechselflers bei *Cordulegaster bidentata* und weitere Beobachtungen zu Raumnutzung und Verhalten bei einer Metapopulation im Taunus (Odonata: Cordulegasteridae). *Libellula* 40(1/2): 19-46. (in German, with English summary) ["Evidence of stream hopping and further observations on special performance and behaviour in a metapopulation of *C. bidentata* living at forest streams in Taunus mountains, Germany - At 8 small forest streams in the Taunus mountains, Hesse, Central Germany, the spatial performance of a metapopulation of *Cordulegaster bidentata* was studied by 7 observers using 16 colour marked adult males. After marking, 969 individuals passing above 7 streams were counted during 9 counting days, among them 47 marked ones (5 %). In spite of sparse appearance of marked males, 7 ones were observed again after marking. 4 of them did not appear

on the stream, where they had been marked, but on other streams in the surroundings. Maximum range between the places of marking and reobserving was 1,125 m. Most marked males only occurred sporadically at the streams. One can conclude that in general a remarkable part of male *C. bidentata* do not take part in patrolling flight activities along the streams regularly. Moreover, male *C. boltonii* were common along two streams together with *C. bidentata*. This uncommon phenomenon is described and discussed." (Authors)] Address: Tamm, J., 34131 Kassel, Germany. **20023.** Abbott, J.C.; Bota-Sierra, C.A.; Guralnick, R.; Kalkman, V.; González-Soriano, E.; Novelo-Gutiérrez, R.; Bybee, S.; Ware, J.; Belitz, M.W. (2022): Diversity of Nearctic dragonflies and damselflies (Odonata). *Diversity* 2022, 14, 575: 18 pp. (in English) ["Rarely have studies assessed Odonata diversity for the entire Nearctic realm by including Canada, USA, and Mexico. For the first time, we explored Odonata diversity in this region according to a definition of natural community assemblages and generated species distribution models (SDMs). Species occurrence data were assembled by reviewing databases of specimens held by significant Odonata repositories and through an extensive search of literature references. Species were categorized as forest-dependent or non-forest-dependent, as lentic or lotic-dependent, and according to conservation status. Predicted distributions were stacked for all species across their entire ranges, including areas outside of the Nearctic. Species richness and corrected weighted endemism (CWE) were then calculated for each grid cell. We found a pattern of greater species richness in the eastern portion of the Nearctic, which can be explained by the higher aquatic habitat diversity at micro and macroscales east of the Rocky Mountains, promoting niche partitioning and specialization. In the Nearctic region, the southeastern US has the highest number of endemic species of Odonata; this degree of endemism is likely due to glacial refuges providing a foundation for the evolution of a rich and unique biota." **20027.** Aguilera, E.; Busto, B.; Ramo, C. (2022): Diet and food resource partitioning among six Ibis species in the Venezuelan Llanos. *Ornitología Neotropical* 33: 124-132. (in English, with Spanish summary) ["This work is the first study to provide simultaneous information on the diet of all six ibis species inhabiting the Venezuelan Llanos, which was obtained by analyzing gizzard contents of birds collected in 1979-1982 (between 59 and 11 per species). The percentage of prey number for the ibis species was determined: for the Scarlet/White ibis (*Eudocimus ruber/E. albus*), the main prey were Coleoptera, Diptera, and Heteroptera in the dry season, and Coleoptera and Odonata ["Anisoptera"] in the wet season. For the Barefaced Ibis (*Phimosus infuscatus*), main prey included Coleoptera and Ephemeroptera in the dry season, and Oligochaeta, Ephemeroptera, and Coleoptera

in the wet season. For the Glossy Ibis (*Plegadis falcinellus*), Spinicaudata, Coleoptera, and plant material were the main items consumed in the dry season, and Coleoptera, Decapoda, Odonata, and Heteroptera in the wet season. For the Sharptailed Ibis (*Cercibis oxycerca*), Pisces, Lepidoptera, Coleoptera, and Orthoptera were mainly consumed in the dry season, and Coleoptera, Orthoptera, and Oligochaeta in the wet season. For the Buff-necked Ibis (*Theristicus caudatus*), main prey were Coleoptera, Orthoptera, Arachnida, and Lepidoptera in the dry season, and Coleoptera and Orthoptera in the wet season. Finally, for Green Ibis (*Mesimbrinibis cayennensis*), we found that Coleoptera, Gastropoda, and Orthoptera were the most consumed in the dry season, without data for the wet season. We also found that rainfall seasonality has a great influence on the prey eaten by the ibises: diet overlap between the dry and wet season varied between 0.07 and 0.45 (Schoener's index), depending on the species. Moreover, diet overlap between pairs of species showed extremely low to medium values (0.13-0.44 in the dry season, 0.03-0.60 in the wet season, according to Schoener's index), which suggests that the coexistence of these species is largely facilitated by food resource partitioning." (in English) ["The present survey has been carried out on Odonata of agricultural field, Satana (Baglan) Nashik district, Maharashtra because it is now clear that agricultural fields are unique ecosystem that provides several services to Odonates. So, the different Odonates depend on these fields and their diversity also signs of good health of agroecosystems. But now-a-days agricultural land are gradually decreasing due to the rapid growth of highways, housing and factories. So, Odonates of these fields are also under risk. This side of the agricultural area is less highlighted so the main aim of this

study to prepare a list of those odonates which use these fields. There is the study was carried out for a period of two years i.e. July 2019 to July 2021. There are total of 21 species of Odonates were recorded during the period of the study. Maximum of 9 species falls under family Libellulidae followed by 6 species falls under Coenagrionidae and followed by 4 species fall under Platycnemididae and Lestidae and Aeshnidae showed less species diversity and represented by only one species. There are the maximum species richness reported from Monsoon and post-Monsoon season." (Authors)] Address: Ahire, D.K., Dept of Zoology, P.V. P. **20030.** Alkhatay, F.A.; Ahmad, A.H.; Rahim, J.; Imran, M.; Sheikh, U.A.A. (2022): Distribution and diversity of aquatic insects in different water bodies of Qatar. *Brazilian Journal of Biology* 84, e255950: 10pp. (in English, with Portuguese summary) ["Aquatic insect fauna remains an important tool for bio indication of environmental disturbance, while maintaining a healthy aquatic system. The purpose of the study was to document and to identify the diversity and distribution patterns of aquatic insect, a highly ignored aspect from the Qatar. Following the standard procedures, the samples were collected from aquatic habitats during the period October 2015 to May 2017 on monthly basis. A total of 11,287 individuals, belonging to 6 orders were captured. Dipterans were the abundant with the percentages of 71.01 (n=8,015), while the lowest percentage was observed for Coleoptera 0.04 (n=05). Twelve insects families were identified, among these five were reported under Diptera, followed by Hemiptera (03), while Coleoptera, Trichoptera, Odonata [exclusively: Orthetrum sabina], and Ephemeroptera were represented by single families. Among the selected localities, Dipterans were collected from 10 stations, followed by Hemiptera (9), Coleoptera (4), Odonata (4), Ephemeroptera (3) and Trichoptera (1) respectively. Among the water bodies samples, streams were the most preferred habitats (n=2,767), while drinking water pools were the least (27). Moreover, the highest Simpson diversity index of 1.48 and lowest of 0.47 was recorded for flooded sewage pool and plastic containers respectively, while the low evenness values were observed for ponds, and less than 1 Margalef's diversity values were seen for all habitats. This study documents the patterns of the diversity and distribution of aquatic insects, and provides a baseline for the future studies from Qatar." **20033.** Anand, K.; Dash, S.M.M.; Armanini, S. (2022): A numerical study on three-dimensional flapping dragonfly wings with optimized input kinematics for hovering and forward flight. Bulletin of the American Physical Society, 75th Annual Meeting of the Division of Fluid Dynamics. Sunday–Tuesday, November 20–22, 2022; Indiana Convention Center, Indianapolis, Indiana. Session L04: Animal Flight: Flying Insects I. 8:00 AM–9:57 AM, Sunday, November 20, 2022. Room: 133: (in English) [Verbatim: Dragonflies are capable of hover, glide, forward flight, quick turning, etc., with substantial flight times. Previous studies found that dragonfly wings require distinctive input kinematics for different flight modes. For instance, in hovering/forward flight, the wings flap out-of-phase, whereas during quick maneuvers, the wings flap in-phase. In this study, we performed numerical simulation using a dynamic mesh to analyze the wake structure over a pair of tandem dragonfly wings and further optimized their aerodynamic performance with novel flapping kinematics. The wing geometries are based on structural studies. The input kinematics are selected as the mix of pure sinusoidal and periodic Eldredge functions. The design parameters are taken similar to those of Berman and Wang (2007) and Geherke et al. (2019). Our study found that both wings' combined vertical lift coefficient is 1.56 times more than their individual lift coefficients when summed up. Moreover, the hindwing experiences most of the enhancement in lift resulting from the vortex synergy interaction. It was found the downwash-upwash wake interactions are insignificant in the in-phase flapping, which agrees with the results of Lua et al. (2018). The detailed flow physics will be discussed in the presentation.] Address: Indian Institute of Technology Kharagpur, India

**20034.** Antol, A.; Labecka, A.M.; Larsson, R.; Sniegula, S. (2022): First record of Microsporidia infection in the damselfly *Ischnura elegans* larvae: Temperature and predator cue effects on the host's life. Diversity 2022, 14, 428. <https://doi.org/10.3390/d14060428>: 10 pp. (in English) ["Here, we report, for the first time, a microsporidian infection in laboratory-reared larvae of *I. elegans*. Infected larvae originated from field-collected adult females, which were caught in southern Poland in August 2020 (the second half of the flight season). Higher rearing temperatures and the presence of predator cues from the invasive alien signal crayfish (*Pacifastacus leniusculus*) increased the number of infected larvae. Infected larvae had distorted wing development, and all individuals died before emergence. Hence, microsporidian infection in *I. elegans* larvae impacted damselfly morphology and life history. We propose that warming temperature and stress caused by nonconsumptive effects triggered by invasive alien predators are possible factors that produce negative fitness consequences from microsporidian infection in a key amphibious ectotherm." **20035.** Arase, C. (2022): Design and Kinematics of a Dielectric Elastomer Actuated Micro Dragonfly Robot. BSc thesis, Mechanical Engineering, Massachusetts Institute of Technology: 32 pp. (in English) ["Dragonflies fly in a unique way compared to other hovering insects. Soft robotics are used to learn more about their flapping motion. An at-scale dragonfly robot is designed around Dielectric Elastomer Actuators that compress and expand 0.5mm. With this knowledge, MATLAB was used to predict the linkage sizes that control the wing stroke movement. Using the values calculated in MATLAB, Solidworks was used to design a soft robot that mimics a dragonfly's flight. Motion analysis was then used to map the movements of the robot. This analysis showed an angular wing displacement of 93° in the  $\phi$  direction. The wing hinge ( $f$  direction) moves 90° on the upstroke and is stopped by a limiting piece to 40° on the downstroke." (Author)] Address: Cathleen Arase; not stated

**20036.** Archibald, S.B.; Cannings, R.A. (2022): The first Odonata from the early Eocene Allenby Formation of the Okanagan Highlands, British Columbia, Canada (Anisoptera, Aeshnidae and cf. Cephalozygoptera, Dysagrionidae). The Canadian Entomologist 154, e29: 1-8. (in English) ["Fossil insects have been collected and described from the early Eocene Allenby Formation of southern British Columbia, Canada for over a century, but these have never included Odonata. We describe the first members of that order from the formation: *Allenbya holmesae*, new genus and species, most likely belonging to the Dysagrionidae (suborder Cephalozygoptera), and a torn, folded, and incomplete wing assigned to the Aeshnidae (suborder Anisoptera) that cannot be identified below family level. In other regional deposits of the early Eocene Okanagan Highlands series of lacustrine shales, the Dysagrionidae is by far the most common odonate family, followed by the Aeshnidae." **20037.** Arguel, L.; Denis, A.S.; Danflous, S.; Gouix, N.; Santoul, F.; Buisson, L.; Pelozuelo, L. (2022): Detection and monitoring of riverine dragonfly of community interest (Insecta: Odonata): Proposal for a standardised protocol based on exuviae collection. Diversity 2022, 14(9), 728; <https://doi.org/10.3390/d14090728>: 17 pp. (in English) ["Collecting quantitative data on insect species occurrence and abundance is a major concern to document population trends. This is especially the case to assess the conservation status of species listed in the European Habitats Directive and to assess the efficiency of mitigation measures with a view to achieve the "no net loss of biodiversity" goal for protected species. However, at present, populations of riverine dragonflies listed in the Habitats Directive and protected under French national law are poorly quantified and monitored. Exuviae collection could be used for such monitoring but a standardised protocol is lacking. We here proposed and tested such a protocol to monitor riverine dragonfly populations through exhaustive exuviae collection along river bank transects. To define the optimal transect size and number of visits, ninety-eight 100 m-long transects divided into 10 m-long plots were monitored on three rivers in southern France. Each transect was visited three times over the emergence period. In the course of each visit, all the exuviae along transects were collected and identified. From our results, we recommend collecting exuviae along 100 m of river bank in the course of two visits in order to both maximise the species detection and minimise the monitoring cost." **20038.** Assandri, G.; Bazzi, G. (2022): Natural and anthropogenic determinants of peatland dragonfly assemblages: Implications for management and conservation. *Biodiversity and Conservation* 31: 703-722. (in English) ["Peatlands are unique ecosystems of global importance for biodiversity, though are severely threatened by human activities. Dragonflies are valuable ecological indicators, but comprehensive studies on the species inhabiting peatlands are limited. To fill this knowledge gap, we investigated the determinants of peatland odonate assemblages in the Italian Alps along the bog-poor fen-rich fen series, a vegetation gradient influenced by pH. The ultimate goal was to distil management recommendations to inform peatland dragonfly conservation. Species richness, bog specialist richness, and community composition were assessed at both pristine and human-impacted sites and then related to environmental and anthropogenic drivers. We showed that bog and poor fen assemblages were significantly distinct from those of intermediate and rich fens, which, in turn, displayed the highest species richness, but the lowest number of specialists, whilst being also the most degraded. Excavated sites, compared to non-excavated ones, harboured a higher number of species, although this effect was not significant for bog specialists. Drainage and abandonment of mowing/ grazing practices determined reed and shrub/tree invasion, negatively impacting fen species. Water availability and heterogeneous spatial arrangements of water pools within the peatland positively affected most species, with bog specialists only favoured by the latter. Peatland dragonfly conservation should primarily rely on the preservation of pristine sites, as they harbour unique dragonfly assemblages. Impacted sites could benefit from restoration actions; specifically, reed control, and the creation of pools of different sizes and depths within the more terrestriated peatlands are likely the most effective measures to support peatland Odonata communities." **20039.** Astuti, A.; Nayasilana, I.N.; Sugiyarto; Budiharjo, A. (2022): Community structure of dragonflies (Odonata) in Gunung Bromo's Forest Area with Special Purpose (FASP), Karanganyar, Central Java, Indonesia. *Biodiversitas* 23(5): 2493-2501. (in English) ["Dragonflies are one component of biodiversity in Indonesia, which function both as predators and bioindicators of water quality. Dragonfly habitat is widespread ranging from highland forest areas, lowland forests, reservoirs, lakes, rivers, swamps, and rice fields to settlements. One location that becomes dragonfly habitat is in the Gunung Bromo's Forest Area with Special Purpose (FASP), Karanganyar, Central Java, Indonesia. This study aims to determine the community structure and habitat preferences of dragonflies in Gunung Bromo's FASP. Data resulting from this study is expected used as a database for Gunung Bromo's FASP managing. The study was conducted along the Bamban river which is located in the Gunung Bromofs FASP area, in June-July 2019. Dragonflies were collected in 14 observation stations. At each observation, station transects were 100 m in length and 10 m in width. Data collection included the dragonflies species, the individual numbers, and environmental factors both abiotic and biotic factors. Data analysis included the diversity, evenness, dominance and

similarity of dragonfly species. Principal Component Analysis (PCA) was applied to determine the dragonfly abundance pattern and Canonical Correspondence Analysis (CCA) was applied to determine the relationship between dragonflies and their environmental factors. The results showed there were 23 species of dragonflies in the Gunung Bromo's FASP with a diversity index of 1.96. PCA results indicate the abundance of dragonflies is not much different in each species. Meanwhile, CCA results show almost of the dragonflies in the Gunung Bromofs FASP are influenced by abiotic and biotic factors, except on *Orthetrum sabina* and *Copera marginipes*. They are assumed have unspecific habitat preferences." (Authors)] Address: Astuti, A., Biodiversitas Study Club, Dept of Biology, Fac. of Mathematic and Natural Science, Universitas Sebelas Maret. (2022): Antimicrobial peptides isolated from insects and their potential applications. *Journal of Asia-Pacific Entomology* 25(2), June 2022, 101892: (in English) ["Highlights: • The recent advances of antimicrobial peptides isolated from insects were reviewed. Characterization and mechanisms of AMPs from various insect Orders were summarized. The most studied insect Orders were Hymenoptera, followed by Diptera and Coleoptera. A list of AMPs, methods for characterization, and bacteria tested were catalogued. A pictorial summary of the procedures for AMPs extraction and isolation was provided. Abstract: Antimicrobial peptides (AMPs) in insects have the potential to be developed as chemotherapy agents against numerous microbial species. This article reviewed the existing knowledge of what have been focused so far on published materials related to AMPs isolated from insects. Previous studies were focused on peptide characterization and the mechanism pathways of different AMPs from a variety of insect Orders. Most studied insect Orders are as follows: Hymenoptera (50%), Diptera (17%), Coleoptera (13%), Lepidoptera (10%), Hemiptera (5%), Blattodea (3%) and Odonata (2%). Dozens of new AMPs have been extracted from insects recently. However, more studies in vivo and in vitro are necessary to fully understand their effect and the mechanisms of antimicrobial action to utilize their promising potential in cosmetic and pharmaceutical industries." **20041.** Basaula, R.; Prasad, H.; Sapkota, K. (2022): The invasion of Water Hyacinth and its impact on diversity of macro-invertebrates in the lake cluster of Pokhara valley, Nepal. *Prithvi Academic Journal* 5: 1-16. (in English) [oas 64a; "Invasion of Alien Invasive Plant species (IAPs) is one of the major drivers for the wetland ecosystem degradation and aquatic biodiversity loss. Among the wetland ecosystems, the freshwater habitats including lakes and streams are more susceptible to species extinction. In the Lake Cluster of Pokhara Valley (LCPV), many aquatic species have been threatened by an abundant occurrence of water hyacinth (*Eichhornia crassipes*). Thus, this study aims to identify an association of the water hyacinth with different water parameters, diversity and abundance of macro-invertebrates. Water hyacinth is not only correlated with depth, transparency, pH and dissolved oxygen negatively, it is also correlated with temperature and free carbon dioxide positively. A total of

29 species and 26 genera from 21 families and 15 orders of macro-invertebrates were recorded. Among the macro-invertebrates, haplotaxida and diptera were found to be less abundant in the water hyacinth presence (HP) habitat than the water hyacinth absence (HA) habitat. However, the macro-invertebrates were found more abundant and diverse in the HP habitat than the HA habitat (Ranged: HP: 177 to 666; HA: 46 to 483). The abundance of orders like ephemeroptera, odonata, coleoptera, sphaeriida and caenogastropoda was significantly higher in the HP habitats. The direct and indirect effect of water hyacinth on the occurrence of macro-invertebrates and abundance can change the faunal structure of LCPV. Therefore, it is recommended to develop a plan of LCPV to manage the water hyacinth." **20042.** Bae, S.-W.; Hwang, T.-W.; Yoon, C.-S.; Hong, S.-J.; Cheong, S.-W. (2022): Distribution characteristics of and ecological information on benthic macroinvertebrates in the Hwapocheon stream. *Journal of Environmental Science* 31(2): 149-169. (in Korean, with English summary) ["Hwapocheon stream is located in Gimhae-si, Gyeongsangnam-do, and a part was declared a protected wetland area in 2017. In 2020 and 2021, we investigated the community structure of benthic macroinvertebrates of the Hwapocheon stream to provide ecological information for the management of the wetland. As a result, 4 phyla, 6 classes, 20 orders, 51 families, 83 species, and 2,621 individuals of benthic macroinvertebrates were identified. The average indices of diversity, richness, and evenness were the highest in the midstream area, whereas the highest average index of dominance was observed upstream. Seven biological water quality evaluations based on the distribution of benthic macroinvertebrates showed that the Biological Monitoring Working Party was an extremely suitable method for environmental evaluation of the Hwapocheon stream. Regarding functional feeding groups, the number of species of predators and gathering-collectors was the highest, and considering habitual dwelling groups, the number of species of clingers and sprawlers was the highest. The species number of Odonata, Hemiptera, and Coleoptera increased toward the downstream area, whereas the community loss index was the highest upstream. We also investigated relative resistance and resilience based on the distribution of aquatic insects and found that community stability was the highest downstream, whereas the lowest upstream." **20043.** Barbosa Ribeiro, R.A.; Juen, L.; Brasil, L.S. (2022): Habitat conditions in streams influence Odonata larval assemblages in the eastern Amazon. *International Journal of Odonatology* 25: 22-30. (in English) ["The growth of agricultural and mining activities in the Amazon has impacted land-use and caused significant changes in the local environmental conditions of streams. In the face of these changes, our study aimed at assessing how environmental changes affect Odonata larval assemblages in streams in the eastern Amazon. We hypothesized that habitat conditions in streams are strong predictors of Odonata larval assemblages. We sampled 30 headwater streams (1st through 3rd order) in the eastern Amazon. We corroborated our hypothesis that regional- and local-scale environmental changes are important predictors of the Odonata larval assemblage

structure. These results indicate that environmental conditions within the stream channel are important to maintain Odonata larval assemblages, as they provide important resources for larval development. For new studies, we recommend the assessment of temporal dynamics to evaluate whether these patterns are stable across time. Finally, evaluating various environmental scales of the original impact is extremely relevant for preventing the deterioration of or recuperating aquatic assemblages in Amazonian streams, considering the ongoing rapid environmental changes and deforestation in the region. Here we demonstrate that in-stream environmental conditions are important to assemblage structure and this must be considered in environmental restoration plans." **20047.** Behr, H. (2022): Notizen zur Libellenfauna (2013-2021) einiger Seeufer im Stadtgebiet Schwerin (Mecklenburg-Vorpommern) (Odonata). *Virgo* 25: 3-10. (in German) ["In 726 records, a total of 5441 individuals were recorded from 2013 to 2021 at the lakes studied with their tributaries. On most of the lakeshores in the urban area, only relatively low numbers of species were observed, with 11 to 17 dragonfly species. At the more intensively studied, elongated and structurally rich Neumühler Lake 26 dragonfly species were recorded. In the small, structurally rich tributary waters studied, which are connected to the main waters (especially: Small lakes, bays were home to many other typical stillwater species. On all shores of the larger lakes, which were predominantly overgrown with reeds, these three large dragonfly species were found with high dominance values (eudominant and dominant) for their group: *Anax parthenope*, *Orthetrum cancellatum*, *Libellula fulva*. The damselfly reached the relatively highest dominance values within the above-mentioned group C "Anisoptera without Libellulidae" at almost all investigated lakeshore sections. Only at the southern outlet of the Schwerin Inner Lake into the Störkanal several records of the dominant *Gomphus vulgatissimus* have been found as visual evidence of imagines and exuviae on the largely reed-free shore. Among the damselfly species, these species with relatively high dominance values occurred more frequently on typical lake shores: *Erythromma najas*, *Ischnura elegans*) and *Enallagma cyathigerum*. Among the accompanying species, the hitherto unique finding of *Epitheca bimaculata* hatching on the Common Crucian Carp stands out in particular. *Leucorhinia caudalis* and *L. pectoralis*, which are strictly protected in the urban area, occur at 3-4 smaller pond-like, near-natural sites. Sightings of the fire dragonfly (*Crocothemis erythraea*) have become increasingly frequent in the recent past at a wide variety of stillwater habitats." (Author) Translated with [www.DeepL.com/Translator](http://www.DeepL.com/Translator) (free version)] Address: Behr, H., Herrengartenweg 57, 19061 Schwerin, Germany. EMail: hauke-behr@web.de

**20048.** Bernard, R.; Daraz, B. (2022): Rift valley-driven species richness, composition and phenology of Odonata in central Zambia. *International Dragonfly Fund - Report* 171: 1-71. (in English) ["One hundred and seven species of damselflies and dragonflies were recorded at 66 localities in central Zambia during three expeditions between 2013 and 2017, with 104 species at 62 localities in the main study area, in broad environs of Chingombe. The relatively great richness and composition of the odonate fauna in this small remote area was a consequence of the close proximity of

three quite different geomorphological units - the flat bottom of the rift valley, the steep mountainous slopes bordering it, and undulating uplands, with a combination of their climatic and hydrological conditions. An odonatalogical 'river-continuum' sequence was studied, from the upper and lower reaches of the mountain stream, through submontane streams and rivers down to the large river draining the rift valley. This spatial sequence was characterised by large-scale interpenetration of the odonate assemblages, with more specific fauna of the mountain stream and large river, and rich, but less specific that of submontane watercourses. Fluent replacement of some species with their related counterparts was recorded, i.e. more upland species of closed habitats by species related to semi-open lower-elevated watercourses. The range of species well adapted to temporary waters was rich, but differed between the small waters of the tropical savannah bottom of the rift valley and larger and longer existing water bodies in seasonally inundated dambos in more subtropical uplands. The phenological pattern was generally well-structured due to two distinct peaks, the first in the first phase of the wet season, both in the large river and temporary waters, and the second at the end of the wet season, in the latter. Phenology of odonate assemblages in the temporary waters was based on two consecutive aspects dominated respectively by adults reproductively active in the early-mid season and generals emerging at the end of it. At the beginning of the wet season, the reaction of adult odonates to first heavier rains was extremely rapid and even preceded the formation of the seasonal water body. In the large river, the phenological shift towards the early wet season with a low-water phase and favourable habitat conditions was clearly discernible. In turn, the odonate fauna in another low-water phase, at the end of the wet season and before a cool phase of the dry season, was dramatically poor. In the smaller permanent watercourses, phenology of the odonate assemblages during the wet season was generally less patterned, without a dramatic change of generations and with the emergence more dispersed in time, though centred on the first half of the season. As an effect of replacing individuals and the prolonged occurrence of many species, the odonate assemblages, while richer in the first half of the rainy season, appeared more stable and continuous than those of the temporary waters and the large river." **20050.** Bidy, A.R.; McIntyre, N.E. (2022): Parasitism of *Enallagma civile* Hagen in Selys, 1853 (Zygoptera: Coenagrionidae) by *Arrenurus* water mites. *International Journal of Odonatology* 25: 98-95. (in English) ["We compared the prevalence and intensity of *Arrenurus* sensu stricto water mite parasites on *E. civile* from 10 freshwater wetlands (playas) in two different land-cover contexts in western Texas from 2006-2007. Vulnerability to parasitism may be a consequence of disturbance, so we predicted that the more natural form of regional land cover (grasslands) surrounding playas should be associated with a lower water mite load than more disturbed land cover (tilled croplands). Additionally, we examined *Arrenurus* occurrence and intensity of infection by host sex. Overall prevalence was 38.46% of 130 damselflies sampled having mites; this varied by land-cover type but with opposite trends between years. Overall average parasite load was ~11 water mites per infected host (range: 1-40 mites); intensity was significantly higher in hosts from cropland playas in 2006, but there was no difference by surrounding land cover in 2007. Although there were consistent trends in both years of more males being parasitized than females, the highly uneven distribution of parasites on hosts and differences in average mite load between years generated variability that obscured any statistically significant patterns. Thus, land-cover context surrounding playas, but not host sex, had an impact on parasite load in one of the two years of our study. Future work is needed to identify the mechanisms by which land cover may affect water mite-odonate host-parasite relationships as well as the role of the odonate assemblage as a whole in dispersal of parasites in a temporally dynamic wetland network." **20051.** Bidy, A.R. (2022): Using species distribution models to predict genomic isolation: A case study with a high-altitude, stream-specialist damselfly (Odonata, Calopterygidae: *Hetaerina vulnerata* Hagen in Selys, 1853) in Arizona, New Mexico, and Utah. M.Sc. thesis, Texas Tech University, Austin: VII + 46 pp. (in English) ["Aquatic animals in high-elevation streams of the arid southwestern U.S. are potentially isolated by distance (IBD) or environment (IBE). *H. vulnerata* is an insect that inhabits mountain streams in the American southwest. Spatial separation of streams and limited dispersal capacity of *H. vulnerata* may cause population isolation and genomic structuring, and projected climate change may exacerbate isolation by restricting distribution and movement. MaxEnt was used to construct a species distribution model (SDM) based on environmental variables and occurrences of *H. vulnerata*; this model indicated seven potential population clusters isolated by intervening unsuitable habitat. Projecting to future climate conditions, an overall gain of suitable habitat (0.8% increase) was identified, but current suitable habitat in southern Utah and northern New Mexico was lost. I collected 124 *H. vulnerata* from eight localities at six of the seven clusters; DNA was extracted from 78 individuals for ddRADseq genotyping. A suite of population and landscape genomic analyses were used: Admixture, IBD, FST, and a genotype-environment association (GEA). Admixture analyses determined six sub-populations, partially corroborating the SDM. IBD was not significant; IBE was only significant when considering two ecological variables. FST values were low (< 0.07). GEA determined that 20 SNPs were locally adapted to tree canopy coverage. These results indicate that *H. vulnerata* populations are likely recently separated but undergoing genomic isolation and local adaptation. Integrating SDMs with

landscape genomics combines techniques to indicate populations that are separated by distance and unsuitable habitat, providing explanations for patterns in genomic structuring." (Author)] Address: not stated

**20052.** Borisov, S.N.; Kazenas, V.L.; Borisov, A.S. (2022): Dragonflies (Odonata) of the Syrdarya Karatau and the Arys River valley (southern Kazakhstan) with notes on seasonal latitudinal and altitudinal migrations. *Euroasian Entomological Journal* 22(1): 78-90. (in English, with Russian summary) ["45 dragonfly species are presented for Syrdarya Karatau Range and Arys River valley in Southern Kazakhstan, with 19 species newly registered, and *Somatochlora arctica* given on the basis of literature data. Doubtful registrations of *Calopteryx samarcandica* and *S. arctica* are discussed. Seasonal latitudinal migrations of the four species, *Anax ephippiger*, *A. parthenope*, *Pantala flavescens* and *Sympetrum fonscolombii* are determined from Chokpak Pass by means of ornithological traps. Seasonal altitudinal migrations are registered for seven species, *Aeshna mixta*, *Sympetrum arenicolor*, *S. meridionale*, *S. striolatum pallidum* Selys, 1887, *Sympecma fusca*, *S. gobica* and *S. paeidisca*. In mountainous biocenoses the immigrant dragonfly species flight from plains for aestivation are represented in high numbers." **20054.** Borkenstein, A.; Jödicke, R. (2022): Thermoregulatory behaviour of *Sympetrum striolatum* at low temperatures with special reference to the role of direct sunlight (Odonata: Libellulidae). *Odonatologica* 51(1-2): 83-109. (in English) ["The thermoregulatory behaviour of the autumnal *Sympetrum striolatum* was studied and analysed at the end of its flying season in November from 2011 to 2021. Only on days with intense solar radiation did it leave its roosting sites in the treetops and became active at and around breeding ponds. We describe the perch site selection and body posture for basking, avoiding wind, feeding, and reproductive activities after warm-up. Ectothermic thermoregulation enabled flight largely independent of air temperature; we saw a male flying at 3.7°C and a tandem ovipositing at 6.0°C. In the afternoon all individuals returned to their roosting sites. If they were too cold for immediate take-off, they wing-whirred and flew after 2-3 minutes. Wing-whirring was performed at ambient temperatures between 3.8 and 13.6°C.

We suppose that this behaviour is obligatory when insolation is insufficient, especially when the sun is blocked by clouds. The combination of ecto- and endothermic thermoregulation is considered the main key factor for this species' exceptionally effective adaptation to cold." **20056.** Bowler, D.; Eichenberg, D.; Conze, K.-J.; Suhling, F.; Baumann, K.; Benken, T.; Bönsel, A.; Bittner, T.; Drews, A.; Günther, A.; Isaac, N.; Petzold, F.; Seyring, M.; Spengler, T.; Trockur, B.; Vedder, D.; Willigalla, C.; Bruelheide, H.; Jansen, F.; Bonn, A. (2022): Gewinner und Verlierer in der Libellenfauna: Veränderung der Verbreitung in Deutschland zwischen 1980 und 2016. *Libellula* 41(1/2): 25-45. (in German, with English summary) ["Recent studies suggest insect declines in parts of Europe; however, the generality of these trends across different taxa and regions remains unclear. Standardized data are not available to assess large-scale, long-term changes for most insect groups but opportunistic citizen science data is widespread for some. Here, we took advantage of 'citizen science' data to investigate distributional changes of Odonata. We compiled over 1 million occurrence records from different regional databases. We used occupancy detection models to account for imperfect detection and estimate annual distributions for each species during 1980–2016 within 5 x 5 km quadrants. We also compiled data on species attributes that were hypothesized to affect species' sensitivity to different drivers and related them to the changes in species' distributions. We further developed a novel approach to cluster groups of species with similar patterns of distributional change to represent multi-species indicators. More species increased (45%) than decreased (29%) or remained stable (26%) in their distribution (i.e., number of occupied quadrants). Species showing increases were generally warm-adapted species and/or running water species, while species showing decreases were cold-adapted species using standing water habitats such as bogs. Time-series clustering defined five main patterns of change – each associated with a specific combination of species attributes, and confirming the key roles of species' temperature and habitat preferences. Trends in Odonata provide mixed news – improved water quality, coupled with positive impacts of climate change, could explain the positive

trends of many species. At the same time, declining species point to conservation challenges associated with habitat loss and degradation. Our study demonstrates the great value of 'citizen science' and the work of natural history societies for assessing large-scale distributional change." **20059.** Brockhaus, T. (2022): Ausbreitungsmechanismus der Federlibelle *Platycnemis pennipes* (Pallas) am Beispiel des Chemnitzflusses (Sachsen) (Insecta: Odonata: Zygoptera: Platycnemididae) und weitere Ausbreitungsformen bei Libellen. *Artenschutzreport* 46: 63-72. (in German, with English summary) ["Mechanism of expansion in *P. pennipes* using the example of the Chemnitz river (Saxony) and other forms of expansion in Odonata. – The reasons of the expansion of *P. pennipes* along the Chemnitz river since the early 1990s has been studied. After evaluating determined morphometric data (head width, total length, wing dimensions, mass, wing loading) of 109 males and 41 females on six places along the river valley and population dynamic processes (abundance estimates in this places), the dispersal behavior can be described by individually different fitness

of specimens. In a reproductive population, large adults emerge first, originating from a two-year development cycle. Subsequently, smaller imagines emerge over a longer period of time, which originate from a one-year larval development. If the number of individuals is high, displacement occurs, with the smaller specimens with less wing loading leaving the habitat. In this way, new habitats are gradually being settled, with the specimens orienting themselves on terrain markings in the river valley. In addition to intraspecific displacement, further expansion strategies such as those based on habitat selection in metapopulations and those based on large-scale migration are briefly described. It has been proven for a few species that they have an extremely low potential for expansion. In the context of species protection, these species, as well as those species that are strongly bound to specific habitats, must be given special attention." **20060.** Bruno, C.G.C.; Gonçalves, R.C.; dos Santos, A.; Facure, K.G.; Corbi, J.J.; Jacobucci, G.B. (2022): The relationship between sediment metal concentration and Odonata (Insecta) larvae assemblage structure in Cerrado streams. *Limnetica* 41(1): 27-41. (in English, with Portuguese summary) ["Metals can be incorporated into stream sediment affecting benthic invertebrate assemblages in different ways. Odonata larvae have variable tolerances to metals; sublethal levels accumulated in larval tissue can indirectly influence assemblage structure in environments with differences in types and concentrations of metals in the sediment. This research evaluated the relationship between Odonata larvae assemblages and sediment metal content in Cerrado streams. We evaluated genus composition, abundance, richness, Shannon-Wiener (H') diversity index and Pielou's evenness index (J') of the assemblages from 12 streams. Cluster analysis was used to identify groups of streams according to sediment concentrations of Cu (copper), Zn (zinc), Ni (nickel), Fe (iron) and Mn (manganese). Canonical Redundancy Analysis (RDA) and Canonical Correspondence Analysis (CCA) were performed to determine how metals influence Odonata assemblage metrics. Cluster analysis revealed three distinct groups of streams according to metal concentration in the sediment. RDA showed a negative relation between Pielou evenness (J') and the concentration of Ni, Cu, Zn and Mn, while abundance, genus richness and Shannon-Wiener diversity were positively related with Fe. CCA indicated that some taxa showed an opposite relation with metal concentration, but others were more abundant in streams subjected to high metal concentrations. Although the increase in iron concentration in streams can lead to an increase in the abundance of Odonata larvae, high concentrations of copper, zinc and manganese can lead to a reduction in taxon evenness." (Authors)] Address: Jacobucci, G.B., Instituto de Biologia, Universidade Federal de Uberlândia, Rua Ceara, 38400-902, Uberlândia, Minas Gerais, Brazil. E-mail: jacobucci@ufu.br

**20061.** Buczynski, P.; Walczyk, K.; Tanczuk, A.; Buczynska, E.; Bojar, P.; Góral, N. (2022): Structural and physical factors as predictors of the species distribution and diversity of dragonflies and damselflies (Odonata) in an upland storage reservoir. *Folia Biologica (Kraków)* 70(2): 67-78. (in English) ["The negative impact of storage reservoirs on the environment has been well documented, but it appears that under certain circumstances these reservoirs can also help to protect biodiversity. The distribution of adult dragonflies and damselflies was studied in relation to eight environmental

variables, in an upland storage reservoir and its feeder rivers located in South-East Poland (East-Central Europe). A total of 25 species were recorded, including 22 in the reservoir. Submerged and floating plants, width of the shallow littoral zone and the water movement/current were found to be the key drivers of the species distribution (pCCA, NMDS). Five species (*Ischnura elegans*, *Sympetrum sanguineum*, *Platycnemis pennipes*, *Calopteryx splendens* and *Erythromma viridulum*) were responsible for over 70% of the dissimilarities between the riverine and reservoir sites (SIMPER). In addition, *I. elegans*, *Orthetrum albistylum* and *Calopteryx virgo* were distinguished as the indicator species (IndVal analysis) for the upland river-reservoir hydrological system. Our results highlight some design features of reservoirs that may help to maintain the diversity of odonates, as well as many other groups of aquatic organisms, as the former are well-known indicators of general biodiversity." **20064.** Chandra, K.; Gupta, D. (2022): Biodiversity issues and challenges: Non-agricultural insects. Shalinder Kaur, D.R. Batish, H.P. Singh, Ravinder Kohli (Eds.): *Biodiversity in India: Status, Issues and Challenges*. Springer: 285-324. (in English) ["With more than one million named species, insects are the most diverse terrestrial creatures on the planet, representing around 75% of the global fauna. They

contribute to invaluable ecosystem functions such as nutrient cycling, pollination, and seed dispersals and serve as a significant food source, aid in biocontrol of other organisms (such as predators, parasites), and maintain soil structure and fertility. Meantime, they are profoundly beneficial as pollinators. They often compete with humans, as pests of agriculture and stored products and as vectors of life-threatening diseases. Owing to four of the globally recognised biodiversity hotspots—Himalaya, Indo Burma, Western Ghats and Sri Lanka, and Sundaland—India is represented by 67,111 insect species in four classes of subphylum Hexapoda: Collembola (345 species), Protura (20 species), Diplura (18 species), and Insecta (66,728 species), 64.8% of the overall faunal diversity of the country. Eight insect orders — Coleoptera, Lepidoptera, Hymenoptera, Diptera, Hemiptera, Orthoptera, Thysanoptera, and Odonata — form the majority (94%) of the insects in the country. This chapter further updates India's known insect diversity, emphasising its diversity in ecosystems (such as aquatic, mangroves, soil, and forests) and biogeographic zones (Himalaya, Trans-Himalaya, Desert, and Islands). Additionally, information has been provided on the potential of insects in food security, pollination, forest pests, and their significance to medical and veterinary in context with Indian fauna. The chapter also includes a list of 27 insect species identified as invasive aliens in India and reports 22 species as threatened in the IUCN Red List from India." (in English) ["A total of 131 individual odonates belonging to 22 species and three families were recorded from 78 observations. Odonate sightings showed a peak in the month of October. No odonate could be observed in the months of July, January, and February. While *Pantala flavescens* and *Rhyothemis variegata* were the most abundant species and could be observed in five months, 10 of the 22 species reported were seen only once during the study. Out of the 80 individuals that could be sexed, 50 were males and 30 females. Among the males, eight individuals could be identified as immature from their pigmentation. This included three individuals of *Orthetrum chrysis* and one individual each of *Diplacodes trivialis*, *Aethriamanta brevipennis*, *Pseudagrion malabaricum*, *Urothemis signata*, and *Brachydiplax sobrina*. *Bradinopyga geminata* was the only species that displayed sexual behaviour at the study site, a pair of which was seen mating and egg laying in one of the synthetic tanks during the month of April. Three exuviae and five nymphs were seen in the tank. The study recorded 12% of the total odonate species recorded from Kerala till date (Society for Odonate Studies 2020). It can be assumed that except for *Bradinopyga geminata* which was observed to complete its life cycle at the site, most other odonates visited the site in their pre-reproductive adult stage when their primary activity is foraging. Observations of males with incomplete adult pigmentation and absence of post-reproductive adults (old individuals with pruinescence/ broken wings) support to this assumption. Maximum number of individuals was detected in October. This is mostly due to the influx of large numbers of the migratory dragonfly, *Pantala flavescens* in this month. Number of species recorded was also maximum (10) in October, consistent with earlier studies that show detection of maximum number of odonate species in the post monsoon period (Kulkarni & Subramanian 2013). Since the behaviour of adult males and females differs greatly, it can be nearly impossible to obtain precise measures of sex ratio during the

adult stage. The excess number of males detected (62.5% of the sexed individuals) in this study could be because of variability in dispersal of the sexes or their differential detectability, most female odonates being cryptic and males more colourful. Although urban sites host an abundance of generalist species of odonates, there are some specialist species that can also find refuge in urban habitats. *Pseudagrion malabaricum* is a species known to breed in small lakes in submontane and montane areas (Fraser 1933). Sighting of such species deserves special mention as it highlights the importance of the freshwater-woodland matrices in urban areas in the conservation of odonates." **20066.** Cheng, S.; Lin, H.; Li, M.; Li Y. (2022): Study on the relationship between environmental changes and breeding sites of *Larus relictus* in Hongjiannao Lake. *Quaternary Sciences* 42(4): 1201-1212. (in Chinese, with English summary) ["Hongjiannao Lake(38°59'59"~39°10'01"N, 109°45'16"~109°59'58"E) is located at the main route of migrant birds in China and is the main spot for resting and reproduction of many types of rare waterfowl, such as *Larus relictus*, at the junction of Shenmu City, Shaanxi Province and Ordos City, Inner Mongolia Autonomous Region. In this study, in order to further improve the protection of *Larus relictus*, using the Modified Normalized Differential Water Index (MN-DWI), 20 Landsat remote sensing images during the breeding period between 1987 and 2006 were used to extract Hongjiannao Lake island area and water area. Secondly, in 2015, 2016, and 2020, we came to Shenmu City, Shaanxi Province Nature Reserve for field research and data collection, and we sampled the water quality and benthic animals in the lake center and lakeside, which the water quality monitoring indicators is including pH, total nitrogen, total phosphorus, permanganate index, total alkalinity, salinity, etc. This research analyzes the changes of the ecological environment of Hongjiannao Lake, breeding conditions, and the change of *Larus relictus* breeding sites in the past 30 years, and explores why *Larus relictus* choose Hongjiannao Lake as a breeding site since 2001. The results show that: (1) Since the 1980s, with the shrinkage of water surface area, the pH, salinity, total nitrogen and total phosphorus of Hongjiannao Lake have increased, continuously salinized and eutrophicated. The fish in the lake disappeared after 2003 and improved slightly with the increase of water surface area after 2016; (2) Since 2001, *Larus relictus* has taken Hongjiannao Lake as a new breeding ground, which is closely related to the sharp decline and gradual disappearance of fish production in Hongjiannao Lake, which has liberated the *Larus relictus* food such as *Ischnura heterosticta* larvae and *Chironomidae* larvae from the grazing pressure; (3) Hongjiannao Lake is located in the distribution area of *Larus relictus* in Ordos. The parent birds of *Larus relictus* first moved out and scattered in the distribution area of *Larus relictus* in late July, which is qualified for the discovery of Hongjiannao Lake; (4) Since 2001, Hongjiannao Lake has had the conditions for the reproduction and survival of *Larus relictus*, which can provide suitable lake-center island and main food source for the whole breeding season, so it has been selected as a breeding site. These studies can better explain the reasons why *Larus relictus* inhabits in desert saline-alkaline lakes, which can provide technical support for its habitat management, and are of great significance to further protect *Larus relictus*." (Authors)] Address: Cheng, S., School of Earth Science and Resources, Chang'an University, Xi'an 710054, Shaanxi, China

**20067.** Chovanec, A. (2022): Populationsdynamische Prozesse bei der Großen Heidelibelle *Sympetrum striolatum* (CHARPENTIER, 1840) an einem kleinen, schnell zuwachsenden Feuchtgebiet in Niederösterreich (Odonata: Libellulidae). Naturkundliche Mitteilungen aus den Landessammlungen Niederösterreich 32: 21–40. (in German, with English summary) ["Population dynamics in *S. striolatum* at a small, quickly becoming overgrown wetland in Lower Austria): A small permanent wetland, unintentionally created in 2014, was subject of a study on the succession of the Odonata fauna carried out from 2016 to 2021. In 2016, with approximately 150 individuals, *S. striolatum* was the most abundant anisopteran species within the odonate community. Teneral and/or exuviae of this species were detected from 2016 to 2020. The rapid development of dense helophyte stands led to the complete loss of open water areas and to a decline of the numbers of individuals of the Common Darter (maximum yearly numbers: 2017 – 25; 2018 – 25; 2019 – 20; 2020 – 13; 2021 – 6). Although occurring in significantly lower numbers of individuals, also in 2017–2020, *Sympetrum striolatum* was the most abundant anisopteran species. In the years 2020 and 2021, *S. striolatum* was present at the wetland during a shorter time compared to the years before and to the species-specific flight period: 2016 – 24 weeks; 2017 – 19.5 weeks.; 2018 – 19 weeks; 2019 – 17.5 weeks, 2020 – 10 weeks; 2021 – 4 weeks. In 2019 and 2020, a decline in the frequency of egg deposition behaviour following preceding copulation was obvious. In 2021, only pairing behaviour, but no egg deposition behaviour was observed. Key stimuli inducing and factors limiting egg deposition behaviour in *S. striolatum* are discussed." (Author)] Address: Chovanec, A., Krottenbachgasse 68, 2345 Brunn am Gebirge, Austria. **20068.** Crabot, J.; Mauchamp, A.; Bergerot, B.; Bonis, A.; Gore, O.; Rossignol, N.; Paillisson, J.-M. (2022): How hydrology and landscape shape Odonata assemblages in marshlands crossed by ditches. *Freshwater Biology* 67(7): 1228–1241. (in English) ["1. One of the major current ecological challenges is to understand how to reconcile human activities with biodiversity conservation concerns. This issue is particularly relevant in freshwater ecosystems where biodiversity is globally under severe threat. Artificial waterbodies, such as ditch networks, are part of the few remaining wetlands in agricultural landscapes and hence play a crucial role in maintaining aquatic biodiversity in these landscapes. 2. We investigated the responses of adult Odonata assemblages at different spatial scales in a marshland crossed by ditches to two factors expected to be pivotal influences on assemblages. At the local scale, this was mainly the water regime in ditches and, at a broader scale, the composition of the landscape. Both taxonomic alpha and beta diversity, and functional trait composition were considered as response variables. 3. Significant differences were found between the responses of the two Odonata suborders. We showed that Zygoptera species richness decreased and species turnover increased with the duration of drying episodes in ditches. Geographical distances between local assemblages as well as landscape characteristics, notably woodland cover, meadow cover and ditch network length, also significantly shaped the distribution of Zygoptera. For Anisoptera, species richness was not explained by environmental variables and beta diversity was associated only with local conditions; it increased with increasing dissimilarity in water quality and riparian vegetation. We also found evidence of functional trait syndromes (combinations of correlated traits) in Odonata assemblages, but without clear relationships to environmental gradients. 4. This study reveals

the structuring role of water regime for Odonata in ditch networks and demonstrates the need to jointly consider environmental variables at different spatial scales to properly understand the distribution of Odonata. 5. Our findings have important conservation implications as the water regime is heavily managed in such ecosystems. Even though the relationship between functional composition and environmental gradients was found to be of limited extent in this study, we discuss how it might provide new insights for Odonata assemblage structure and be useful, locally, for stakeholders and managers. Lastly, we call for further multiscale investigations considering both the taxonomic and functional responses of Odonata assemblages (functional analyses with multiple traits and several species being scarce in this taxonomic group) in other anthropogenic freshwater ecosystems to gather more lessons for their conservation." **20069.** Craves, J.A.; Cognato, A.I.; O'Brien, D.; Mahoney, M.J. (2022): A new locality and unexpected haplotypes of the federally-endangered Hine's Emerald dragonfly, *Somatochlora hineana* (Odonata: Corduliidae). *Bulletin of American Odonatology* 13(2): 7–17. (in English, with Spanish summary) ["In June 2021, two female *S. hineana* (Hines Emerald) were collected in Oceana County, Michigan, a location >100 km from the nearest known populations. This is a region apparently lacking sizable areas of characteristic *S. hineana* habitat: fens or similar calcareous wetlands with shallow soils over dolomite or limestone bedrock. Phylogenetic analyses of mitochondrial haplotypes confirmed species identity and revealed that each individual represented a different haplotype. Neither haplotype had been previously represented in Michigan, northern Wisconsin, or Ontario populations, and one was new. Our finding of these two haplotypes suggests a *S. hineana* population occurs in west-central Michigan which may genetically link southern and northern Great Lakes populations. Continued surveys for *S. hineana* are needed to confirm the presence of an established population in this region. If discovered, it will provide valuable data that will further our understanding of the genetic diversity and population dynamics of this species." **20070.** da Silva-Méndez, G.; Riso, S.; Lorenzo-Carballa, M.O.; Cordero-Rivera, A. (2022): Sampling larvae, exuviae or adults of Odonata for ecological studies: a test of methods in permanent rivers in the Iberian Peninsula. *Odonatologica* 51(1-2): 63–81. (in English) ["To assess the suitability of a habitat for breeding by odonates, the best strategy is to search for exuviae or final instar larvae. However, due to their low detectability and the difficulty of sampling these stages, most studies in applied ecological research have targeted adult odonates, even though adults may be found in places unsuitable for successful breeding. Here, we tested odonate sampling methods in permanent rivers in the north-western Iberian Peninsula, focusing on three main objectives: (i) to study the degree of concordance of species lists obtained from sampling larvae, exuviae and adults; (ii) to estimate how long exuviae are available for sampling and how this time affects the results; and (iii) to analyse potential observer biases, due to the different ability of researchers to detect exuviae. We found that the time exuviae remain in place varies with taxon but is generally short (7–8 days), which could lead to under-detection. We also found that adult odonates may be found in parts of the river that have

no suitable habitat for their larvae. Furthermore, we were able to find more species as exuviae than by sampling adults or larvae and some taxa, such as gomphids, were difficult to find as adults but exuviae were very commonly observed. We did not find significant differences between observers in their ability to detect and identify exuviae. Altogether, our results suggest that in some systems, recording only adults could lead to inaccurate survey results, making it essential to include exuviae to avoid sampling bias." **20075.** De Knijf, G.; Lambrechts, J.; Maes, D. (2022): A new Red List of the dragonflies and damselflies in Flanders. A dramatic decline of Odonata species of bogs and heathland ponds. *Natuurfocus* 21(2): 52-61. (in Dutch, with English summary) ["The IUCN Red List criteria are intended to be an easily and widely understood system for classifying species the extinction risk of species in a given region. Because many new data of Odonata in Flanders have become available and the status of several species has changed since the previous Red List from 2006, we assessed the current state of dragonflies according to the IUCN Red List criteria. Of the 59 evaluated species, 15 species are Threatened and 1 is Near Threatened in Flanders, 5 species are Regionally Extinct and 43 species are of Least Concern. Overall dragonflies and damselflies in Flanders are doing better than in previous decades. This is mainly due to species of nutrient-rich waterbodies that are doing markedly better as a result of habitat restoration, creation of new ponds (e.g. garden ponds) and waters in an urban or industrial context, and to southerly species that benefit from climate warming. However, species from nutrient-poor waterbodies (fens, peatbogs and other oligotrophic waters) continue to perform poorly and deserve special attention in nature policy and nature management. Populations of several species decreased dramatically in the last five years. They are negatively affected by very high nitrogen depositions, the presence of invasive fish species, increased warm weather and extreme drought events leading to (partial) desiccation of these kinds of waters, and in many cases from too intensive management of their terrestrial habitat, resulting in the cutting of shrubs and trees near their reproductive biotopes. The drawing up of one or more Species Action Plans is therefore more than urgently needed to prevent the extinction of these species in Flanders." **20076.** De Lisle, S.P.; Mäenpää, M.I.; Svensson, E.I. (2022): Phenotypic plasticity is aligned with phenological adaptation on both micro-and macroevolutionary timescales. *Ecology*

Letters 25(4): 790-801. (in English) ["In seasonally variable environments, phenotypic plasticity in phenology may be critical for adaptation to fluctuating environmental conditions. Using an 18-generation longitudinal dataset from natural damselfly populations, we show that phenology has strongly advanced. Individual fitness data suggest this is likely an adaptive response towards a temperature-dependent optimum. A laboratory experiment revealed that developmental plasticity qualitatively matches the temperature dependence of selection, partially explaining observed advance in phenology. Expanding our analysis to the macroevolutionary level, we use a database of over 1-million occurrence records and spatiotemporally matched temperature data from 49 Swedish Odonate species to infer macroevolutionary dynamics of phenology. Phenological plasticity was more closely aligned with adaptation for species that have recently colonised northern latitudes, but with higher phenological mismatch at lower latitudes. Our results show that phenological plasticity plays a key role in microevolutionary dynamics within a single species, and such plasticity may have facilitated post-Pleistocene range expansion in this insect clade." **20079.** del Palacio, A.; Lozano, F.; Ramos, L.S.; Navarro, M.; Muzón, J. (2022): Odonata from Iberá wetland system (Corrientes, Argentina) are regional biogeographic schemes useful to assess Odonata biodiversity and its conservation? *Diversity* 2022, 14(10), 842; <https://doi.org/10.3390/d141-00842>: 15 pp. (in English) ["Regionalization schemes reflect

different macroscale distribution patterns and show large areas characterized by a common natural history, resulting in similar associations of biotic and abiotic features. Freshwater biota and terrestrial biota do not respond in the same way to environmental variables. The Iberá Depression, one of the largest wetlands in South America, is recognized in many schemes either as a functional unit or as an area with an ecotonal character. We used the distributional data of 128 species of Odonata, from a total of 103 collection sites from Corrientes and Misiones provinces, to test if Iberá functions as an ecological and functional unit, based on the Odonata distribution patterns. In addition, we tested if their distribution patterns fit into the most widespread regionalization schemes (hydrological basins, biogeographical provinces and ecoregions) used in Argentina. The Iberá Depression was not recovered as a functional unit; its sub-basins are more related to external basins than to each other. Neither the ecoregion nor the biogeographical schemes are suitable to explain the distribution patterns of the Odonata. The Odonata seem to respond to the availability of particular wetlands (e.g., ponds, streams, rivers, swamps, etc.), or to specific physical characteristics, such as the type of sediment, the availability of oxygen, etc., instead of to biogeographical or ecoregional schemes." **20081.** Dey, A.; Dey, D. (2022): Odonata richness in RAMSAR site, Deepor Beel, Assam, India. *Bione* 20: 17 pp. (in English) ["The study was conducted in the Deepor beel wetland for 18 months from January 2015 to mid June 2016. The Deepor beel is a RAMSAR site located (longitude 91° 38' 35" E and latitude 26° 07' 30" N) in the Kamrup district of Assam and is owned by the State Fisheries Dept. Odonates are boon for the environment. They act as a biological indicator of a healthy aquatic ecosystem and also act as a bio-control agent, as adult odonates prey on flies and mosquitoes which are parasites and pests of men and animals. During the present study, eight Anisopteran (Family: Libellulidae) and three Zygopteran (Family: Coenagrionidae) species could be found in and around the Deepor beel wetland site. Shrub land found to be the most favourable habitat for the odonates. The present findings showed that the study area is biologically active to contain divergent species of odonate fauna. However, a detailed environmental study is necessary so that the habitat of the odonates could be protected and conserved in situ against the increasing level of pollution, as less number of divergent species were recorded in the present study compared to previous surveys." **20083.** Dijkstra, K.-D.B.; Tate, R.B.; Papazian, M. (2022): Chapter 14 Dragonflies and Damselflies (Odonata) of Príncipe, São Tomé, and Annobón. In: L.M. Pires Ceriaco et al. (eds.), Biodiversity of the Gulf of Guinea Oceanic Islands, [https://doi.org/10.1007/978-3-031-06153-0\\_14](https://doi.org/10.1007/978-3-031-06153-0_14). 371-381. (in English) ["The Odonata fauna of the oceanic islands of the Gulf of Guinea is impoverished, even compared to other Afrotropical archipelagoes, with a combined total of 22 species recorded with certainty on São Tomé, Príncipe, and Annobón. *Trithemis nigra* Longfield, 1936 from Príncipe is the only known endemic, although two reported but unidentified species may still prove to be endemic too. Most recorded species occur widely across and beyond Africa, and 27 equally widespread species are listed as potential additions. Several hypotheses for the fauna's impoverishment are briefly discussed." (Authors)] Address: Dijkstra, K.D., Netherlands Centre for Biodiversity Naturalis, P.O. Box 9517, NL-2300 RA, Leiden, The Netherlands. E-mail: kd.dijkstra@naturalis.nl

**20084.** Dinning, J.; Stockan, J.A.; Fielding, D.A.; Young, M.R. (2022): Habitat suitability for *Coenagrion hastulatum* (Charpentier) (Northern Damselfly) in North-east Scotland. *J. Br. Dragonfly Society* 38(1): 47-64. (in English) ["*C. hastulatum* is a widespread and abundant species in northern Eurasia but in Great Britain it is classed as Endangered with a distribution restricted to north-east Scotland. Even within north-east Scotland, populations remain small and scattered. There has been no long-term monitoring for *C. hastulatum* but there are concerns that it may have been lost from some historic locations. Similarly, there have been no quantitative studies into the habitat preferences of *C. hastulatum* in Great Britain. An extensive survey was made of ponds in Aberdeenshire in 2016 and the presence or absence of *C. hastulatum* was analysed in relation to a wide range of habitat variables. The results showed that *C. hastulatum* was associated with eight habitat variables: positively correlated with water and silt depth, *Juncus acutiflorus*, *Carex rostrata* and Sphagnum, and negatively correlated with *J. bulbosus* and floating and emergent vegetation cover. These results provide a preliminary indication of *C. hastulatum*'s preferences in north-east Scotland which will aid further investigations, including the current British Dragonfly Society project on *C. hastulatum* (British Dragonfly Society, 2019)." (Authors)] Address: Dinning, Juliette, 143 Gairn Terrace, Aberdeen AB10 6AY, 2 Ecological Sciences, James Hutton Institute, Craigiebuckler, Aberdeen AB15 8QH, 3 Meiklepark, Oldmeldrum, Aberdeenshire AB51 0DL

**20085.** Devi, M.; Walia, G.K. (2022): DNA barcoding based on mitochondrial COI gene on some species of family

Platycnemididae (Odonata: Zygoptera) from India. *International Journal of Multidisciplinary and Current Research* 10: 19-28. (in English) ["Taxonomically, family Platycnemididae comprises 455 species referable to 43 genera all over the world, while 52 species of 14 genera are present in India. COI gene analysis of 11 species under 6 genera of family Platycnemididae from the states of Himachal Pradesh, Jammu and Kashmir, Kerala, Maharashtra and Meghalaya (India) has been done. The overall data has been used to calculate the sequence divergence at different taxonomic levels in the family Platycnemididae, which shows the hierarchical increase in the K2P values. In the present study, maximum intraspecific distance has been observed as 1.7% in *C. marginipes*, while the only exception is *Coeliccia didyma*, which shows intraspecific distance of 5.2%. Minimum interspecific distance has been observed as 3.4% in *Coeliccia cyaneothorax* and *Coeliccia nemoricola*, while maximum average interspecific distance has been recorded as 18.6±0% in *Calicnemia chaseni* and *Calicnemia eximia*, the only exception with very less distance (0.4±0.1%) in *Coeliccia chromothorax* and *Coeliccia renifera*. Intergeneric divergence has been calculated for all the 6 genera based on K2P distances. The most distant genera have been found to be *Calicnemia* and *Disparoneura* with average K2P distance of 24.2±1.2%, while *Calicnemia* and *Coeliccia* are the closest genera with K2P distance of 17.5±3.5%." (Authors) *Calicnemia eximia*, *Coeliccia chromothorax*, *C. didyma*, *C. fraseri*, *C. renifera*, *Copera marginipes*, *C. vittata*, *Disparoneura quadrimaculata*, *Esmé cyaneovittata*, *E. longistyla*, *Prodasineura verticalis*} Address: Devi, Monika, Assistant Professor, Trinity College Jalandhar, Punjab-144009, India

**20086.** Dissanayaka, H.M.S. (2022): Geo-spatial Analysis about Habitat Preferences of Odonata within the Diyasaru Wetland Park, Sri Jayawardenepura Kotte, Sri Lanka. *Proceedings of the 26th International Forestry and Environment Symposium / Biodiversity Conservation and Management 26: 33-* (in English) [Verbatim: "The Odonata (dragonflies and damselflies) have both aquatic and terrestrial life cycle and are considered good bio indicators. Diyasaru Wetland Park was selected as the study site is located in Sri Jayawardenepura Kotte and the main objective of this study was to identify the distribution of Odonata habitats in the Diyasaru Wetland Park. It was determined to identify the best suitable parts of urbanized area to increase their habitats using the developed distribution map. Line transect surveys were used to encounter species within the sampling areas. All Odonata species observed directly were recorded. The data collection was carried out from 0600 h to 1200 h, 1500 h to 1800 h. Field work was conducted from 11th February 2020 to 20th January 2021. Endeavor ED binoculars (10.5×45), DSLR cameras (Canon EOS 155D/EFS 18-55 mm F/3.5-5.6), Garmin GPS etrex 10 machine were used for closure observations, spotting locations and obtaining photographs. Odonata habitats have been identified, analyzed to identify their distributions within the park premises from using Geographic Information system (ArcGIS 10.8), and Odonata checklist was developed. Hotspot analysis was used to determine the clustering of Odonata, Kernel Density was calculated to identify the density of Odonata's distribution, and Inverse Distance Weighted (IDW) was used to measure values surrounding the prediction locations maps within the park. According to the developed maps, high level distribution or favorable areas were near the bank sides and channels, but some individual species distributed in another areas within the premises as they prefer the most suitable habitat for their living activities. A total

of 33 Odonata species were recorded belong in to five (5) families. This number includes one (1) endemic species, two (2) endemic sub species, also one migratory species. The threatened are Endangered (EN) one (1) species, Vulnerable (VU) two (2) species and Near Threatened (NT) nine (9) species were observed in the area. The wandering glider (*Pantala flavescens*) which has both migratory and resident population has been recorded throughout the year. Indicating the presents of resident population. The findings of this study could be used as preliminary information for further developments and maintenance of the Diyasaru wetland park by Sri Lanka Land Development Corporation." (Author)] Address: Dissanayaka H.M.S., Dept of Geography, Univ. of Sri Jayewardenepura, Nugegoda, Sri Lanka

**20087.** Doucet, G.; Jacquot, P.; Gayet, P. (2022): *Lestes barbarus* en Bourgogne-Franche-Comté: dynamique spatio-temporelle de l'espèce entre 2001 et 2020 et premières mentions d'émergence. *Martinia* 36(3): 22-33. (in French, with English summary) ["*L. barbarus* in Bourgogne-Franche-Comté: spatio-temporal dynamics of the species between 2001 and 2020 and first records of emergence. Observations of *L. barbarus* are more and more numerous in Bourgogne-Franche-Comté with, on some stations, data recorded for several consecutive years which suggests that the species has settled down in the region. The observation of emergences and the collection of exuviae in two Depts (Saône-et-Loire and Côte-d'Or) reinforce the impression of a perennial installation of the species in this area." **20088.** Duffus, N.E.; Morimoto, J. (2022): Current conservation policies in the UK and Ireland overlook endangered insects and are taxonomically biased towards Lepidoptera. *Biological Conservation* 266: 11 pp. (in English) ["Highlights: • UK policies show biases toward Lepidoptera over other large insect orders. Policy protection of mammals shows greater uniformity between orders than insects. Policies in Ireland lack protection for any insect species. UK priority lists do not prioritise all insects assessed as at risk of extinction. Abstract: Insects provide key ecosystem services for our sustainable future, which rely upon effective conservation policies to protect insect biodiversity. To date, however, we still do not know how effective current conservation policies are for protecting insect biodiversity, opening up the possibility that policies are unfit-for-purpose. Given the considerable debate and public awareness on the potential global decline of insect species, it is important to understand whether or not current policies can protect insect biodiversity. Here, we used IUCN listing of species status and developed a quantitative framework to analyse the potential effectiveness and coverage of current conservation policies pertaining to insect biodiversity in the UK and Ireland. We contrasted this against coverage for a well-known group – mammals – as a benchmark, to find that while the vast majority of the UK mammalian species in the European IUCN red list are directly protected by current policies, insects remain largely unprotected. Moreover, for those insect species that are explicitly protected by current policies, there is a taxonomic bias whereby the majority (>50%) of insect species are Lepidopterans (moths and butterflies), while a minority are Coleopterans (beetles), and none are Hymenopterans (bees, ants, wasps). Similar trends were observed in the UK priority biodiversity lists. Based on our data, we conclude that current biodiversity policies in the UK and Ireland have significant gaps in their protection of insect biodiversity and, there is a taxonomic bias that may skew

some conservation efforts toward butterflies and moths. We anticipate that our findings are likely to occur worldwide, highlighting the need for more directive policies to manage and protect insect biodiversity for the sustainability of ecosystem services." **20089.** Dwita, U.R.; Ansori, I.; Rahman, A.; Jumiarni, D.; Ruyani, A. (2022): Pengembangan LKPD Berdasarkan Keragaman Capung Di Kawasan Danau Dendam Tak Sudah. *Diklabio: Jurnal Pendidikan dan Pembelajaran Biologi* 6(1): 1-6. (in Indonesian) ["This study aims to develop a valid LKPD for high school students based on the diversity of dragonflies in the Danau Dendam Tak Sudah area. This type of research is Research and Development which refers to the steps of research and development according to Sugiyono. The research steps are adjusted to the needs of researchers, namely potential and problems, data collection, product design, design validation, and design revision. Data collection techniques in this study were observation, questionnaire, and documentation. Data analysis techniques for dragonfly species diversity were analysed descriptively. LKPD validation test includes aspects of material, language, presentation and graphics. The results of the LKPD validation test by material experts 83.4%, media experts 90.6% and expert practitioners (biology teachers) 92.6%. Overall the average percentage of the three validators was 88.8% with the criteria "very valid". It is concluded that the design of the LKPD developed based on the diversity of dragonflies in the Dendam Tak Sudah Lake area, Bengkulu City is valid to be used as a learning resource." **20090.** El Bouhissi, M.; Chaib, S.; Houhamdi, M.; Khelifa, R. (2022): Checklist of Odonata of Sidi Bel Abbas, Northwest Algeria. *Hydrobiology* 1(4): 433-439. (in English) ["The odonates of Algeria have been studied for more than a century and a half, but the Northwestern part of the country has historically received little attention. A recent study in central North Algeria reported a species new to the country, suggesting that new investigations in unexplored areas are necessary to fully understand the local odonatofauna. We studied assemblages of odonates in 23 sites in Sidi Bel Abbas (Northwest Algeria) by bimonthly recording adults across a 200 m-transect from May to August of 2019–2022. Our sampling yielded 29 species (13 damselflies and 16 dragonflies) belonging to 19 genera and seven families. We recorded a new locality for the regionally endangered *Coenagrion mercuriale*, expanding the western range limit of the species in Algeria. We documented the occurrence of *Selysiotthemis nigra*, a species that has recently become more frequent in North Africa. *Ischnura pumilio* and *Onychogomphus forcipatus unguiculatus*, which are relatively rare in the region, were also recorded. The arid-dwelling *Trithemis kirbyi* and the Mediterranean endemic *Orthetrum nitidiverve* were quite common in the study area. This study fills an important gap of knowledge in our understanding of odonate geographic distribution in North Africa." **20092.** Elmelech, L. (2022): On the role of the ventilatory wave in dragonfly larvae. *Bulletin of the American Physical Society, 75th Annual Meeting of the Division of Fluid Dynamics. Sunday–Tuesday, November 20–22, 2022; Indiana Convention Center, Indianapolis, Indiana. Session J05: Biological Fluid Dynamics: General. 4:35 PM–7:11 PM, Sunday, November 20, 2022. Room: 132: [Verbatim: Aquatic dragonfly larvae have various methods of ventilation in their modified hindgut chamber. One of these ventilations is chewing ventilation, which is a wavelike motion of the chamber wall. While this mode has been reported by multiple studies, its role remains unclear. In this study, we correlate the chamber wall motion with the internal and external flow to understand the role of the anteriorly propagating chamber wave in the larvae of *Libellula* sp. The transparency of the species allowed optical access to the internal flow and chamber kinematics. The particulates in the pond water visualized the flow inside the breathing chamber. We observed that soon after the wave motion ends, particles deep within the hindgut rapidly accelerates. This suggests that the function of the anteriorly propagating wave might be to pressurize the back end of the chamber in order to create pressure gradient within. In conjunction with the transmural pressure generated by compression of the abdomen, the axial pressure gradient deep within the chamber might assist in cleaning particulates lodged deep within the breathing chamber.]*

**20093.** Engelhardt, E.K.; Biber, M.F.; Dolek, M.; Fartmann, T.; Hochkirch, A.; Leiding, J.; Löffler, F.; Pinkert, S.; Poniatowski, D.; Voith, J.; Winterholler, M.; Zeuss, D.; Bowler, D.E.; Hof, C. (2022): Consistent signals of a warming climate in occupancy changes of three insect taxa over 40 years in central Europe. *Global Change Biology* 28: 3998-4012. (in English, with German summary) ["Recent climate and land-use changes are having substantial impacts on biodiversity, including population declines, range shifts, and changes in community composition. However, few studies have compared these impacts among multiple taxa, particularly because of a lack of standardized time series data over long periods. Existing data sets are typically of low resolution or poor coverage, both spatially and temporally, thereby limiting the inferences that can be drawn from such studies. Here, we compare climate and land-use driven occupancy changes in butterflies, grasshoppers, and dragonflies using an extensive data set of highly heterogeneous observation data collected in the central European region of Bavaria (Germany) over a 40-year period. Using occupancy models, we find occupancies (the proportion of sites occupied by a species in each year) of 37% of species have decreased, 30% have increased and 33% showed no significant trend. Butterflies and grasshoppers show strongest declines with 41% of species each. By contrast, 52% of dragonfly species increased. Temperature preference and habitat specificity appear as significant drivers of species trends.

We show that cold-adapted species across all taxa have declined, whereas warm-adapted species have increased. In butterflies, habitat specialists have decreased, while generalists increased or remained stable. The trends of habitat generalists and specialists both in grasshoppers and semi-aquatic dragonflies, however did not differ. Our findings indicate strong and consistent effects of climate warming across insect taxa. The decrease of butterfly specialists could hint towards a threat from land-use change, as especially butterfly specialists' occurrence depends mostly on habitat quality and area. Our study not only illustrates how these taxa showed differing trends in the past but also provides hints on how we might mitigate the detrimental effects of human development on their diversity in the future." **20094.** Fabian, J.; Siwanowicz, I.; Uhrhan, M.; Maeda, M.; Bompfrey, R.J.; Lin, H.-T. (2022): Systematic characterization of wing mechanosensors that monitor airflow and wing deformations. *iScience* 25, 104150: 23 pp. (in English) ["Highlights: • Dragonfly wings are innervated by an extensive collection of sensory neurons. Mechanosensors are spread across the whole span of the wing with consistent patterns. The axons of wing sensory neurons are scaled to compensate for transmission latencies. Anatomically accurate models reveal wing strain fields that inform sensor distribution. Summary: Animal wings deform during flight in ways that can enhance lift, facilitate flight control, and mitigate damage. Monitoring the structural and aerodynamic state of the wing is challenging because deformations are passive, and the flow fields are unsteady; it requires distributed mechanosensors that respond to local airflow and strain on the wing. Without a complete map of the sensor arrays, it is impossible to model control strategies underpinned by them. Here, we present the first systematic characterization of mechanosensors on the dragonfly's wings: morphology, distribution, and wiring. By combining a cross-species survey of sensor distribution with quantitative neuroanatomy and a high-fidelity finite element analysis, we show that the mechanosensors are well placed to perceive features of the wing dynamics relevant to flight. This work describes the wing sensory apparatus in its entirety and advances our understanding of the sensorimotor loop that facilitates exquisite flight control in animals with highly deformable wings." **20097.** Fattorini, S. (2022): Odonate diversity patterns in Italy disclose intricate colonization pathways. *Biology* 2022, 11(6), 886; <https://doi.org/10.3390/biology11060886>: 17 pp. (in English) ["Simple Summary: During the last Ice Age, most European animals retreated into southern refuges (mainly the Iberian, Italian, and Balkan peninsulas) from which they recolonized central and northern countries after deglaciation. These medio-European territories may have subsequently acted as secondary centers of southward dispersion for many species. Acting both as a refuge and as an area of colonization from adjacent territories, Italy was the theater of complex biogeographical histories, as illustrated by current distributional patterns of odonates. These patterns are a result of historical factors and current ecological conditions. Odonates need freshwater for their development, and their richness in Italy decreases southwards, both because of a decrease in precipitation and because of increasing distance from the mainland (peninsula effect). Biogeographical composition of Italian regions is influenced by climate, geographical distances and historical factors. In particular, biogeographical similarities between Italian regions and adjacent areas revealed multiple colonization patterns. After serving as a glacial refuge from which odonates may have colonized medio-European areas, Italy was in turn subject to complex colonization processes, that made its fauna biogeographically very complex, albeit not particularly rich. Abstract: As a natural bridge between Europe and Africa, Italy occupies a prominent position to understand the biogeography of Europe. The influence of climatic, spatial, and historical factors on current patterns of species richness and turnover (i.e., inter-regional biogeographical differences) has been analyzed for 88 species occurring in 17 Italian natural regions. Use of multimodel inference showed that odonate richness decreased southwards in response to decreasing rainfall, as expected for animals that depend on freshwater for their development. Use of Mantel tests indicated that patterns of inter-regional similarities were influenced by both climate and geographical distances. These patterns, as highlighted using Non-Metric Multidimensional Scaling, indicate a role for historical factors. Biogeographical similarities between Italian regions and adjacent areas revealed multiple colonization pathways. These results, coupled with the overall southward decrease in species richness, suggest that, after serving as a Pleistocene refuge from which odonates may have colonized medio-European areas, Italy was in turn subject to colonization from north to south. This resulted in Italian odonate fauna being less species rich compared to faunas in the medio-European territories, but also being biogeographically very complex." (Author)] Address: Fattorini, Simone, Dept of Life, Health & Environ. Sciences, Univ. of L'Aquila, 67100 L'Aquila, Italy. Email: [simone.fattorini@univaq.it](mailto:simone.fattorini@univaq.it)

**20098.** Feindt, W.; Hardys, H. (2022): The damselfly genus *Megaloprepus* (Odonata: Pseudostigmatidae): Revalidation and delimitation of species-level taxa including the description of one new species. *Zootaxa* 5115(4): 487-510. (in English, with Spanish summary) ["As the longest-winged

odonate species of the extant world, *Megaloprepus caerulatus* (Drury, 1782) has received attention by many entomologists. While the behavior and ecology of this species has been subject of intense studies, biogeography and species status throughout its distributional range in old-growth Neotropical forests are less well known. For tropical forests, this information is a sine qua non when estimating the impact of degradation and climate change. Recent population genetic analyses, quantitative morphometric, and traditional taxonomic studies rediscovered a complex composed of cryptic species within the genus *Megaloprepus* Rambur, 1842—up until now still regarded as a monotypic genus. Here we introduce one new species *Megaloprepus diaboli* sp. nov. from the southern Pacific coast of Costa Rica and from the central Caribbean coast of Honduras and Guatemala. The holotype is from the Corcovado National Park, Costa Rica (N 8°28'55.62" W 83°35'13.92"), and was deposited at the National Museum of Costa Rica. Aside from *M. caerulatus*, two formerly described and later refused species within the genus were reevaluated and consequently raised to species status: *Megaloprepus latipennis* Selys, 1860 is found in the northeastern regions of Mesoamerica and *Megaloprepus brevistigma* Selys, 1860 in South America east of the Andes. Morphological descriptions of selected specimens (holotype of *M. diaboli*, lectotype of *M. latipennis*, and the mature males of *M. brevistigma* and *M. caerulatus*) are provided. Diagnostic features of the four species are illustrated, discussed, and summarized in a key to adult males." (Authors)] Address: Feindt, Wiebke, Univ. (in English) ["Two new species of Kennedyidae: *Kennedyia madygensis* sp. nov. and *K. ferganensis* sp. nov. are described from the Middle-Upper Triassic deposits of the Dzhayloucho (Madygen) locality in Kyrgyzstan based on new material collected in 2007 and 2009. *K. carpenteri* Pritykina, 1981 is redescribed and variation in its discoidal area and other vein structures is demonstrated. The structure and transformation of the nodus in Kennedyidae are discussed." (Author)] Address: Felker, A.S., Borissiak Paleontological Inst., Russian Academy of Sciences, 117647, Moscow, Russia

**20100.** Ferreira Aleixo, M.H.; Quirino, B.A.; Yofukujia, K.Y.; Cardozo, A.L.P.; Fugii, R. (2022): Macrophyte biomass mediates trophic relationships between congeneric fishes and invertebrate communities. *Limnologica* 93, March 2022, 125957: 12 pp. (in English) ["This study aimed to verify whether habitat complexity, assessed through macrophyte biomass, can mediate interactions between fish and invertebrate communities and help to explain the coexistence of congeneric fish species. Fish and invertebrates [including "Odonata"] were sampled in ten macrophyte stands of different biomass in the Upper Paraná River floodplain. The abundance and richness of invertebrates and the diet and trophic niche breadth of *Moenkhausia bonita* and *Moenkhausia forestii*, as well as the diet overlap between these two species, were evaluated. Invertebrate abundance increased with increased macrophyte biomass but richness was not significantly affected. The diet of both fish species differed between low and high biomass stands, with the main difference being a decrease in aquatic invertebrate consumption and an increase in plant consumption with increased macrophyte biomass. In addition, the consumption

of items relied on their profitability and accessibility in the environment. The trophic niche breadth of both fish species increased with increased macrophyte biomass, but there was no niche overlap. Our results indicate that even with an abundance of invertebrates, there was a decrease in the consumption of this resource, suggesting that more complex stands can be more effective refuges for aquatic invertebrates. These results highlight the role of habitat complexity in mediating interactions between fish and invertebrates and promoting their coexistence, which also helps to explain the coexistence of congeneric fish species." **20101.** Fleck, G.; Haber, W.A. (2022): *Paracordulia calcarulata*, new species from Ecuador and notes on the genus *Paracordulia* Martin, 1907 (Odonata: Anisoptera: Corduliidae s. str.). *Zootaxa* 5124(5): 551-564. (in English) ["Based on two males from Ecuador (Sucumbios Province), *Paracordulia calcarulata* sp. nov. is the second described species of the genus. This new species is compared to *P. sericea* (Selys, 1871). The different shape of the anal appendages easily allows separation of the two. Generic diagnosis based on adults and larvae is amended. *Paracordulia* Martin, 1907 is a poorly known genus of the Amazonian biome, and its apparent rarity or absence of records is probably due to its secretive habits; considering the different forms of known females, its specific diversity has likely been significantly underestimated. Some structures of the vesica spermalis are briefly discussed." (Authors)] Address: Haber, W.A., Research Associate, Instituto Nacional de Biodiversidad, Quito, Ecuador, Correos de Costa Rica 5655, Monteverde, Costa Rica. Email: bill.haber01@gmail.com

**20102.** Galbiati, M.; Manenti, R.; Forlani, M.; Barzaghi, B.; Melotto, A.; Ficetola, F.G.; Lapadula, S. (2022): The roles of landscape of fear and light in allowing the exploitation of spring habitats by subterranean amphipods: an experimental and field approach. *ARPHA Conference Abstracts* 5: e87144. <https://doi.org/10.3897/aca.5.e87144>: 2 pp. (in English) ["Verbatim: Border habitats such as interfaces and ecotones promise research targets from an evolutionary and zoological point of view. Springs are typical ecotones that border two strongly distinct environments: surface and underground. They are exploited by both subterranean and surface species for which they may provide specific environmental pressures promoting phenotypic plasticity and local adaptations. The aim of this study is to understand how the landscape of fear (LOF) and physical constraints, like light occurrence, affect springs' exploitation by both a subterranean (*Niphargus thuringius*) and a surface crustacean amphipod species (*Echinogammarus stammeri*). From March to May 2021, we surveyed 15 springs, divided into 25 plots according to their distance to the border, and both day and night, we recorded amphipods activity and LOF levels for them. In a subterranean laboratory, we also reared 80 *N. thuringius* and 80 *E. stammeri* in safe and risky conditions with constant darkness and diel light variation assessing their activity and survival for 30 days. Risky conditions were represented by meso-predators (four fire salamander larvae) alone or with a top-predator (*Cordulegaster boltonii*). While in field conditions, the activity of *N. thuringius* seemed negatively affected by the number of active predators, in laboratory experiments, the main role was played by the light treatment; activity was significantly higher in constant darkness conditions. *E. stammeri* activity in the field

was higher in surface plots, while in laboratory conditions was affected by LOF. Predation risk negatively affected the survival of both amphipods. Our findings reveal that while light conditions seem to shape activity patterns of stygobionts strongly, predators have a lower effect on activity, even though predators have negative effects on survival. Moreover, physical constraints, such as light exposure, can affect antipredator responses of subterranean organisms, thus representing selective pressures for the exploitation of surface environments.] Address: Galbiati, M., Dipartimento di Scienze e Politiche ambientali, Università degli Studi di Milano, Via Celoria, 10 20133, Milano, Italy

**20103.** Garcia Junior, M.D.N.; Damasceno, M.T. dos S.; Vilela, D.S.; Souto, R.N.P. (2022): The Brazilian Legal Amazon Odonatofauna: a perspective of diversity and knowledge gaps. *EntomoBrasilis*. 15, (Feb. 2022), e977: 18 pp. (in English) ["The Brazilian legal Amazon occupies approximately 61% of its territory, covering a large part of Brazil's biodiversity. This large territorial dimension generates huge gaps in the animal diversity understanding, for example, the poor knowledge regarding the Odonata order. Worldwide, Odonata has almost 6,500 described species, with approximately 1,800 being recorded for the Neotropical region. Data on the Odonata order in the legal Amazon is still scarce, mainly due to its particularities, and little is known about the diversity of dragonflies in some of Brazilian states. Thus, the objective of this study is to present a list of species occurring in the states that make up the Brazilian legal Amazon. The list was made from the analysis of approximately 165 scientific papers, in addition to occurrence records contained in the SiBBR and GBIF databases. 641 species were found, which is equivalent to approximately 69% of the odonotofauna in Brazil. The states with the greatest diversity were Amazonas (n=364), Pará (n=310) and Mato Grosso (n=285). The study also indicated a low level of knowledge of the Odonata order in the states of Tocantins and Maranhão, in addition to the area of the Guianas shields, especially in the states of Amapá and Roraima. Carrying out new inventories and building catalogs is essential for understanding the biodiversity in this region, especially in areas with greater need." **20106.** Geiger, M.; Koblmüller, S.; Assandri, G.; Chovanec, A.; Ekrem, T.; Fischer, I.; Galimberti, A.; Grabowski, M.; Har- ing, E.; Hausmann, A.; Hendrich, L.; Koch, S.; Mamos, T.; Rothe, U.; Rulik, B.; Rewicz, T.; Sittenthaler, M.; Stur, E.; Tonczyk, G.; Zangl, L.; Moriniere, J. (2022): Coverage and quality of DNA barcode references for Central and Northern European Odonata. *PeerJ* 9:e11192 DOI 10.7717/peerj.111922021: 31 pp. (in English) ["Background: Odo- nata are important components in biomonitoring due to their amphibiotic lifecycle and specific habitat requirements. They are charismatic and popular insects, but can be chal- lenging to identify despite large size and often distinct color- ation, especially the immature stages. DNA-based assess- ment tools rely on validated DNA barcode reference librar- ies evaluated in a supraregional context to minimize taxo- nomic incongruence and identification mismatches. Meth- ods: This study reports on findings from the analysis of the most comprehensive DNA barcode dataset for Central Eu- ropean Odonata to date, with 103 out of 145 recorded Eu- ropean species included and publicly deposited in the Bar- code of Life Data System (BOLD). The complete dataset includes 697 specimens (548 adults, 108 larvae) from 274 localities in 16 countries with a geographic emphasis on Central Europe. We used BOLD to generate sequence di- vergence metrics and to examine the taxonomic composi- tion of the DNA barcode clusters within the dataset and in comparison with all data on BOLD. Results: Over 88% of the species included can be readily identified using their DNA barcodes and the reference dataset provided. Consid- ering the complete European dataset, unambiguous identi- fication is hampered in 12 species due to weak mitochon- drial differentiation and partial haplotype sharing. However, considering the known species distributions only two groups of five species possibly co-occur, leading to an unambigu- ous identification of more than 95% of the analysed Odonata via DNA barcoding in real applications. The cases of small interspecific genetic distances and the observed deep intraspecific variation in *Cordulia aenea* (Linnaeus, 1758) are discussed in detail and the corresponding taxa in the public reference database are highlighted. They should be considered in future applications of DNA barcoding and metabarcoding and represent interesting evolutionary bio- logical questions, which call for in depth analyses of the in- volved taxa throughout their distribution ranges." **20107.** Gerull, S.; Apel, J. (2022): Stabilisierung der Helm- Azurjungferbestände *Coenagrion mercuriale* im Landkreis Sömmerda. *Landschaftspflege und Naturshchutz in Thür- ingen* 58(2): 79-83. (in German) ["In the course of the pro- ject, it became apparent that the habitat and population data on the Helmeted damselfly for the water bodies outside the FFH management planning and the state and federal moni- toring are outdated, especially in view of the precipitation deficit in recent years. In order to update this data, a total of 69 km of designated habitat stretches were examined for vegetation, structure and habitat suitability in 2018 as part of a project extension and the expansion of the project area to include the districts of Unstrut-Hainich-Kreis and Gotha. At water bodies without current population figures, the pop- ulations were recorded at the same time. These data were used to draw up habitat maps with proposals for manage- ment measures. The water bodies or water body sections

were divided into four categories: 1. habitat = currently col- onised area with relatively good quality, 2. potential habitat = not colonised, but of good quality, 3. with effort potential habitat = not colonised, intensive management measures necessary, 4. no habitat = not suitable for colonisation. The proportions of the corresponding categories can be found in Figure 6. These data formed the basis for another ENL pro- ject "Measures to secure and stabilise the populations of the Helm's Azure Damselfly in the Thuringian Basin", which runs from 2019 to 2022. In order to obtain further infor- mation on the Helm's Azure Damselfly habitats, 209 water samples were taken and analysed at 26 sites over a period of seven months. Relevant parameters for the analysis were water temperature, oxygen content, conductivity, pH- value as well as nitrate, phosphate and ammonium content. Figure 7 shows the positive influence of buffer strips and ri- parian strips on the chemical water quality classification (based on the LAWA quality classes, Länderarbeitsgemein- schaft Wasser 1998) and thus on the population of Helm- meted damselflies. The buffer strips were divided into three classes for this purpose. A buffer was rated as good if it was present on both sides of the watercourse, e.g. in the form of a green strip, copse border or path. A moderate buffer was only present on one side, or on both sides, but very narrow. The category "poor buffer" was assigned to water bodies where there was no buffer strip or only a narrow one on one side. As a result of the inventory carried out in 2018, it can be assumed that the measures implemented in the project in 2017 were successful. More individuals were recorded at all water bodies than in the reference year 2016 (PETZOLD 2018). As can be seen in Table 1, many times as many in- dividuals were recorded after the measures were imple- mented. However, some stretches of water, especially in the FFH area "Gräben im Großen Ried", partially dried out in the late summer months of 2018 and 2019. However, the species remained in other stretches of water and can mi- grate into these stretches again when conditions are more favourable. The goal of permanently maintaining the water bodies could not be achieved at all water body sections. Only one of the six water bodies continues to be maintained by a farm. In general, the farms have shown interest in con- tinued maintenance and have also willingly established 1.5 km of riparian strips, but were unable to offer gentle mainte- nance either technically or in terms of personnel. The mu- nicipalities also see the maintenance of water bodies as rel- evant for the conservation of the species, but here too the financial and personnel effort is not affordable." **20108.** Getnet, H.; Mengistou, S.; Warkineh, B. (2022): Macroinvertebrate community structure and diversity in re- lation to environmental factors in wetlands of the lower Gilgel Abay River catchment, Ethiopia. *African Journal of Aquatic Science* 47(1): 23 -35. (in English) ["The influence of environmental factors on the diversity of macroinverte- brates was studied in the wetlands of the Gilgel Abay River (GAR) catchment in Ethiopia. The study was done between September 2017 and March 2018, encompassing both wet and dry seasons. Six study wetlands from the GAR catch- ment were selected in a targeted manner based on the sur- rounding land use, exposure to anthropogenic disturbances and accessibility to conduct a quantitative study. The rela- tionships between biological and environmental variables were evaluated by using multivariate analyses. Altogether, 36 families of macroinvertebrates were identified. Macroin- vertebrate diversity indices were significantly higher at less

impaired sites, compared with more impaired sites. Several families of Ephemeroptera, Odonata and Trichoptera taxa, including Corduliidae, Calopterygidae, Baetidae, Aeshnidae, Polymitarcyidae, Hydropsychidae, Heptageniidae, Polycen-trapodidae, Hydroptilidae and Philopotamidae were negatively correlated with organic and inorganic pollutants and human disturbances and might be considered as potential indicators of less impaired sites. Conversely, the families Chironomidae, Hirudinidae and Libellulidae were positively correlated with biological oxygen demand, ammonium and human disturbance score and negatively correlated with dissolved oxygen. Generally, results of macroinvertebrate diversity and composition in this study indicate poor ecological condition of the wetlands, particularly those adjacent to agricultural and urban areas." **20110.** Glännman, J.; Töttrup, K.S. (2022): En inventering av bottenfauna i Trönningeån med tvåbiflöden. Examensarbete, Naturvård och artmångfald, Halmstad 2022-05-25: 29 pp. (in Swedish, with English summary) ["Benthic macroinvertebrates are usually small animals living in our lentic and lotic ecosystems, they have been used as indicators of water quality and biodiversity for a long time. Dam removals have become one of the "go-to" conservation methods for restoring connectivity in lotic ecosystems and thereby enabling passage upstream for migrating species. In Sweden, a large part of rivers and streams have dams present which act as migration barriers. Hushållningssällskapet Halland runs a project, LIFE-Goodstream in which a dam considered a migration barrier was removed in the stream Trönningeån. This report has three focus areas 1) the ecological effects of the dam removal while 2) considering the effect on the species composition of the orders Ephemeroptera, Plecoptera, Trichoptera and Odonata [*Cordulegaster boltonii*] in the stream Trönningeån with two tributaries and finally 3) suggest appropriate conservation methods for the future. By examining the benthic macroinvertebrate community our study showed that a small dam removal can have a clear positive effect on water quality, changing the water status classification from low water quality to high. Although there was no effect on the species diversity by the dam removal, a turnover in species composition became obvious after the examination. Moreover, we learned that Trichoptera was the most present order in two out of the three streams while Odonata was the least represented order. Also, bottom substrate, velocity and riparian

zone have larger impact on species composition than adjacent environments. Re-meandering streams to further increase biodiversity while also ensuring water quality, is an essential method for a thriving conservation work in the future." (Authors)] Address: not stated

**20112.** Golab, M.J.; Sniegula, S.; Brodin, T. (2022): Cross-latitude behavioural axis in an adult damselfly *Calopteryx splendens* (Harris, 1780). *Insects* 2022, 13(4), 342; <https://doi.org/10.3390/insects13040342>: 11pp. (in English) ["Simple Summary: Animals adapt to the environment they live in. If the environment changes, animals usually adapt behaviourally as a first response. By studying behavioural profiles across long distances, we can detect environmental change reflected in shifts in behavioural profiles. This study examined variation in three behavioural axes: activity, courtship and boldness, and the association between these behaviours, i.e., behavioural syndromes, across three damselfly populations along a latitudinal gradient (i.e., climatic gradient). Our study organism was the temperate damselfly *Calopteryx splendens*. We predicted that behavioural expressions would gradually increase from southern to northern regions. This is because northern animals should compensate behaviourally for a brief and cold breeding season (i.e., time constraint). Activity was the only behaviour feature positively associated with latitudinal gradient. Courtship effort was highest in the central region, whereas boldness values were highest in the north but did not differ between central and south. In the southern region, an activity–boldness and a courtship—boldness syndrome were present, and in the northern region, only an activity–boldness syndrome was found. Our results confirm that environmental variability in biotic and abiotic factors across studied latitudes generates regional differences in behavioural profiles, which do not always follow latitudinal gradient. Abstract: Behavioural variation is important for evolutionary and ecological processes, but can also be useful when predicting consequences of climate change and effects on species ranges. Latitudinal differences in behaviour have received relatively limited research interest when compared to morphological,

life history and physiological traits. This study examined differences in expression of three behavioural axes: activity, courtship and boldness, and their correlations, along a European latitudinal gradient spanning ca. 1500 km. The study organism was the temperate damselfly *Calopteryx splendens* (Harris). We predicted that the expression of both behavioural traits and behavioural syndromes would be positively correlated to latitude, with the lowest values in the southern populations, followed by central and the highest in the north, because animals usually compensate behaviourally for increasing time constraints and declining environmental conditions. We found that behavioural expression varied along the latitudinal cline, although not always in the predicted direction. Activity was the only behaviour that followed our prediction and gradually increased northward. Whereas no south-to-north gradient was seen in any of the behavioural syndromes. The results, particularly for activity, suggest that climatic differences across latitudes change behavioural profiles. However, for other traits such as courtship and boldness, local factors might invoke stronger selection pressures, disrupting the predicted latitudinal pattern." (2022): The use of highly diverse clades as a surrogate for habitat integrity analysis: *Argia* damselflies as a practical tool for rapid assessments. *Environmental Science and Pollution Research* 29(16): 24334-24347. (in English) ["Human activities have impacted many environments on earth, and thus several species are facing an increased risk of extinction. The environmental crisis requires rapid tools to assess the ecosystem health accurately. Studies have been conducted with visual indices that quantify habitat integrity by predicting species richness and diversity. However, whether a diverse clade can predict habitat integrity has not been used. The genus *Argia* (Rambur, 1842) is one of the most locally diverse groups in southeastern Mexico. In this context, we hypothesized that the occurrence, species richness, and diversity of adults *Argia* spp. could be a better predictor of the Visual-Based Habitat Assessment Score (VBHAS) than the other taxonomic levels or less diverse clades. We found that the richness and diversity of *Argia* spp. are positively correlated with VBHA scores, as same as taxonomic ratios. Simultaneously, VBHA scores increase to 23.51 times when *Argia* spp. diversity increases. We discuss the possible use of a diverse Odonata clade, as *Argia* spp. could surrogate habitat integrity for local long-term biomonitoring programs. This approach requires testing with other indices and verifying a reliable and consistent relationship between diverse clades and environmental assessment scores." **20116.** Guadalquiver, D.M.E.; Nuneza, O.M.; Villanueva, R.J.T. (2022): Odonatofauna in the freshwater system of Kibalabag, Malaybalay City, Bukidnon, Philippines. *Biodiversitas* 23: 1857-1863. (in English) ["Despite the critical importance of freshwater ecosystems to human populations and biodiversity, many anthropogenic practices continue to imperil such habitats. An excellent way to monitor the integrity of these ecosystems is through bioindicator organisms like insects of order Odonata, which are highly sensitive to environmental changes. In Malaybalay City, Philippines, the freshwater system in barangay Kibalabag is the primary source of potable water. Thus, to gain insight into its integrity and health, the present study seeks to determine adult Odonata species composition and diversity in the area. Opportunistic sampling using sweep netting and handpicking was conducted in four sampling sites. Twenty-five species were identified, comprising 230 individuals under nine families and 21 genera. Endemism of 65% (17 species) was recorded, with five species exclusive to Mindanao Island and three species classified as threatened. A high ratio of Zygopterans to Anisopterans, indicative of pristine conditions, was observed. Computation of biodiversity indices revealed that Site 2 (Wetland) is the most diverse ( $H_1$ : 2.582) due to habitat variability. Cluster analysis also showed that Sites 1 (Kibalabag falls) and 2 were most similar. Species assemblage in these sites and high richness in Site 1 demonstrated high habitat integrity and good water quality, whereas the species assemblage in Sites 3 and 4 connotes habitat disturbance. The high endemism and moderate diversity showed that the area is a healthy and suitable habitat for Odonata, emphasizing the need for its conservation and proper management." **20119.** Gwos, N.S.R.; Foto, M.S.; Nyame, M.D.-O.; Biram, A.N.E.B.; Balzani, L. (2022): Physicochemical characterization of the waters of the Lep'oo river in Mbanda (Bot-Makak) and structuring of the benthic macroinvertebrate community. *World Journal of Advanced Research and Reviews* 13(3): 1-12. (in English) ["A study on the characterisation of the Lep'oo stream waters in Mbanda (BotMakak) by physicochemical parameters and benthic macroinvertebrates community was conducted from February to July 2016. Physicochemical parameters were measured according to Rodier's recommendations, while benthic macroinvertebrates were collected using the multihabitat approach. The physicochemical analysis showed that the waters of the Lep'oo stream were well oxygenated (71.16%), slightly acidic (6.36 UC), with low values of nitrogen and orthophosphates reflecting litter decomposition. A total of 2019 benthic macroinvertebrates were collected, divided into 4 phyla, 7 classes, 15 orders, 40 families and over 60 genera. The phylum Arthropoda was the most abundant with 98.61% relative abundance, followed by Molluscs (0.99%) and Annelids (0.29%). The greatest number of organisms collected belonged to the class Hexapoda, which represented 56.76% of relative abundance, followed by Malacostraca (41.75%). Within the Hexapoda class, the order Hemiptera predominated with 18.22% relative abundance and in the Malacostraca class, the order Decapoda predominated with 41.75% relative abundance. These two orders were dominated by the families Atyidae, Libellulidae, Gerridae, Leptophlebiidae and Hydroptilidae. In the upper part of the Lep'oo stream, the families Libellulidae and Belostomatidae were dominant. The station Lep2 was most colonised by the families Atyidae, Libellulidae, Belostomatidae, Hydrometridae, and Gerridae, while station Lep3 was dominated by the families Atyidae, Hydroptilidae and Leptophlebiidae. The Shannon and Weaver (H') and Pielou equitability (J) index showed a greater diversity of taxa downstream of the stream at station Lep3, where conditions seem more favourable to the development of benthic macroinvertebrates as indicated by the physicochemical results. The NGBI index characterized water quality from mediocre to excellent. Finally, the Lep'oo watercourse had a poor and diversified population of benthic macroinvertebrates, showing a relative good ecological quality of water." Odonata are scattered in various types of habitats, especially those associated with freshwater ecosystems. The aim of this research is to study the diversity of odonata in various habitat types in Leuwiliang District, Bogor Regency. The study was conducted on 10 habitat types with a total of 1289 observation lines. In total found 23 species of odonatan from eight families and two sub-orders. The highest species richness was found in stream water habitats (22 species) and the lowest in field habitats (five species). The chi-square test for the number of species and the number of individuals differed significantly between habitat types. The species diversity index ranged from 1.23-2.24 and the similarity index ranged from 0.39-0.71. The highest community similarity index was between lakes habitats and field habitats. The results of the MDS analysis resulted in three groups of odonata communities according to their habitat type." (2022): Inventory and diversity of dragonflies (Odonata) at Kuningan Resort of Mount Ciremai National Park, West Java Province. *IOP Conference Series: Earth and Environmental Science* 959 (2022) 012019: 11 pp. (in English) ["The presence of dragonflies regarding the sensitivity of nymphs towards environmental changes is considered a bioindicator

that can indicate changes in water quality and the environment. The purpose of this study is to take inventory of the species and the diversity of dragonflies at the Kuningan Resort, Mount Ciremai National Park in several representative aquatic habitats. The dragonfly inventory technique used a modified line transect method with observation plots that are not limited by a certain distance or area but by a set time of 15 minutes for each plot observation. The results of the inventory obtained 24 species of dragonflies from 8 families, as many as 591 dragonflies consisting of 58.2% of common dragonflies including of suborder Anisoptera consists of Aeshnidae, Gomphidae, Libellulidae and 41.8% of needlet dragonflies including of suborder Zygoptera consist of Platystictidae, Calopterygidae, Chlorocyphidae, Euphaeidae, Coenagrionidae. The dragonfly diversity index ( $H' = 1.94 - 2.32$ ) (medium), the species richness index, or the values of Margalef's diversity index ( $D_{mg}$ ) ranged from 1.99 to 2.87 (low), the species evenness index ranges from 0.39 - 0.6 (low - medium)." **20124.** Hernandez, M.A.; Casanueva, P.; Nunes, L.; Santamaría, T.; Sánchez-Sastre, L.F.; Ferreras-Romero, M.; Campos, F. (2022): Geographical variation of prementum size in Iberian *Cordulegaster boltonii* (Odonata: Cordulegasteridae) populations. *International Journal of Odonatology* 25: 56-61. (in English) ["Within wide geographical areas, Odonata populations can show biometric differences as a consequence of both biotic (e.g., predation, competition) and abiotic factors (mainly temperature). These differences can occur in the larval stage, although reliable characters are needed to detect differences. We analyzed whether *C. boltonii* larvae from 18 Iberian populations differ regarding head width and prementum size (maximum width, minimum width, and maximum length), using measurements taken on final stage exuviae. Prementum length was greater in southern populations than in northern ones. Geographic latitude and temperature were the variables that best explained this variation in females, whereas latitude and altitude above sea level offered the best explanation among males." **20125.** Högrevé, J.; Suhling, F. (2022): Development of two common dragonfly species with diverging occupancy trends. *Journal of Insect Conservation* 26: 571-581. (in English) ["The two sibling and syntopic odonate species *Sympetrum striolatum* and *S. vulgatum* are common and widespread in Central Europe. While *S. striolatum* has strong positive population trends, declines of *S. vulgatum* are observed. The aim of this study was to identify possible drivers of these diverging trends. We presumed that differences in egg development may lead to differences in survival until hatching. First, eggs laid in non-permanent or shrinking waterbodies may suffer of increasing drought periods. Second, differences in development may cause increased size-mediated intraguild predation, a common cause of reduced survival in odonate larvae. Egg development time and hatching rates were recorded of eleven egg clutches of *S. vulgatum* and ten clutches of *S. striolatum* under simulated drought vs. water and direct vs. delayed development treatments. Hatching rates were reduced under drought conditions, and particularly so in *S. vulgatum*. We did not observe obligate winter diapause in any of the egg clutches. But, *S. vulgatum* varied widely in development between clutches, while the

eggs of *S. striolatum* developed much faster and hatched highly synchronously. This would provide *S. striolatum* with a temporal advantage that may lead to a size-advantage over most *S. vulgatum*. We also found that *S. vulgatum* grew faster. Faster larval growth would only compensate for those *S. vulgatum* with fast egg development. The current population trends may be partly attributed to lowered survival of *S. vulgatum* under drought and by phenological and, thus, size benefits of *S. striolatum*. Implications for insect conservation: Our results show that population dynamics of two closely related dragonfly species can be explained by climatically induced changes in their interactions. Understanding the causes and processes of behavioural changes resulting in differing population trends is fundamental for the protection of species." (Authors)] Address: Suhling F., Inst. **20127.** Holuša, O.; Holušová, K. (2022): Population density and abundance of the northernmost population of *Cordulegaster heros* (Anisoptera: Cordulegasteridae) in Europe (Czech Republic) with notes on its biogeographical range. *Diversity* 2022, 14, 854. <https://doi.org/10.3390/d14100854>: 16 pp. (in English) ["*C. heros* is a Balkan species with a disjunctive area extending into Central Europe. The population in the Chřibý Mts. in the southeastern Czech Republic is the northernmost population, and this population was intensively studied from 2010 to 2021 to establish basic data on its abundance. In the territory, the geomorphological characteristics of streams, characteristics of sediment in streams, habitat, emergence time, and period of flight were recorded, and population viability was evaluated. Larvae were recorded in 10 small forest streams (altitude of 235–426 m a.s.l.), with an average minimum width of 51.9 cm, an average maximum width of 177.7 cm, an average minimum depth of 6.5 cm, an average maximum depth (in pools) of 21 cm, and an average stream gradient of 1.9 grades. The sediments in each stream exhibited a grain size distribution with an average fraction less than 0.05 mm represented by 6.3%, a fraction of 0.05–0.1 mm represented by 21.1%, a fraction of 0.1–2 mm represented by 52.1%, a fraction of 2–5 mm represented by 12.1%, a fraction of 5–20 mm represented by 8%, and a fraction of 20+ mm represented by 0.3%. The larval abundance was 0.1–6.7 larvae per 1 m<sup>2</sup> of suitable sediment. The emergence period was recorded from 28 May to 1 July. The emergence site was categorized as larvae-dominated plant leave (57% of cases), plant stalks (21%), and tree trunks (17%). Exuviae occurred at an average of 154 cm at horizontal distance from the shore and

an average vertical height of 77 cm above the ground. The average total distance of larval movement was 205 cm. The flight period in 2021 was recorded from 15 June to 11 August with peak flight activity noted in the third week of June. The northernmost population of *C. heros* was evaluated as viable and stable." (Authors)] Address: Holuša, O., Mendel University in Brno, Fac. Regional Development & Intern. Studies, Tr. **20128.** Holzmann, K.L. (2022): Challenges in a changing climate: The effect of temperature variation on growth and competition in damselflies. MSc thesis, Uppsala University, Disciplinary Domain of Science and Technology, Biology, Biology Education Centre. (Animal Ecology): 30 pp. (in English) ["Climate change is affecting biodiversity on multiple levels all over the world. Concomitant with a higher mean temperature, an increased amplitude of temperature variation is predicted. These fluctuations might be even more challenging for organisms than average temperature increases, as they have been demonstrated to decrease survival and physiological performance. However, little attention has been paid to the effects of thermal variation on species interactions. Temperature-dependence of interacting species might affect abundance and population dynamics of species and should be better understood to apply effective conservation measures. I experimentally investigated the influence of thermal variation on growth, cannibalism, and intraguild predation in larvae of two damselfly species: *Enallagma cyathigerum*, which is a common species in Northern Europe, and *Ischnura elegans*, which is expanding to the north in Europe. The temperature treatment in the experiment included three different levels of amplitude between 20–26°C (average 23°C) and a constant temperature at 23°C. There was no difference between the temperature variation treatments and also no difference between the constant and the variation treatments in growth, cannibalism and intraguild predation. Hence, at the temperature variation used in this experiment, plastic mechanisms may allow individuals to adjust to temperature fluctuations, or short-term effects in the cold and warm-exposure periods cancel each other out. There was a significant positive correlation between cannibalism/predation and body size variation at the start of the experiment. *E. cyathigerum* had higher growth rates than *I. elegans*, but the latter showed higher survival in interspecific treatments. Interestingly, cannibalism was higher than intraguild predation. This study is an important contribution to our understanding of climate change impacts on biotic dynamics, and thus, our ability of making predictions on biodiversity changes in the future." (Authors)] Address: Holzmann, Kim Lea, Uppsala University, Disciplinary Domain of Science & Technology, Biology, Biology Education Centre. (Animal Ecology)

**20129.** Holzmann, K.L.; Charrier, C.; Johansson, F. (2022): Weak effects on growth and cannibalism under fluctuating temperatures in damselfly larvae. Scientific Reports volume 12, Article number: 12910: 10 pp. (in English) ["The Earth's climate is changing with a trend towards higher mean temperatures and increased temperature fluctuations. Little attention has been paid to the effects of thermal variation on competition within species. Understanding the temperature-dependence of competition is important since it might affect dynamics within and between populations. In a laboratory experiment we investigated the effects of thermal variation on growth and cannibalism in larvae of a damselfly. The temperature treatments included three amplitudes between 20 and 26 °C with an average of 23 °C, and a constant con-

trol at 23 °C. Larvae were also raised at five constant temperatures for an estimation of the thermal performance curve, which showed that the thermal optimum for growth was 26.9 °C. Cannibalism was significantly positively correlated with initial body size variance. There was neither a difference among the temperature variation treatments, nor between the constant and the variation treatments in growth and cannibalism. Hence, positive and negative effects of temperature variation within the linear range of a species thermal performance curve might cancel each other out. Since our study mimicked natural temperature conditions, we suggest that the increase in temperature variation predicted by climate models will not necessarily differ from the effects without an increase in variation." (2022): Bericht über das siebte ÖEG-Insektencamp: Die bunte Biodiversität des Nationalparks Thayatal (Niederösterreich). *Entomologica Austriaca* 29: 87-181. (in German) ["Report on the seventh "Insect Camp" of the Austrian Entomological Society: colourful biodiversity of the National Park Thayatal (Lower Austria, Austria). The seventh Insect Camp of the Austrian Entomological Society took place in the National Park Thayatal from 18 to 21 June 2021. 24 specialists of entomology, malacology and arachnology and 21 students attended the Insect Camp and/or supported the post-processing of specimens. During the camp time, the participants gained hands-on experience in field research, different trapping, identification and preparation methods. The Insect Camp also provided opportunities to network with specialist entomologists and gather knowledge on scientific work. The study area included 16 different localities in the National Park with different habitats, from water bodies to dry grassland. In total, 1429 species of 19 orders were recorded: 3 species of Dermaptera, 4 of Blattodea, 6 of Odonata, 96 of Heteroptera, 99 of Auchenorrhyncha, 11 of Neuroptera, 3 of Raphidioptera, 1 of Megaloptera 3 of Mecoptera, 67 of Diptera, 26 of Trichoptera, 412 of Lepidoptera, 133 of Hymenoptera, 489 of Coleoptera, 40 of Araneae, 6 of Opiliones, 8 of Pseudoscorpiones, 21 of Pulmonata and 1 of Venerida. In addition, 147 plant species were documented. Worth mentioning are nine new records of different

orders for Lower Austria, like *Mallota cimbiciformis* and *Stenus oscillator*, and one new carabid record for Austria, *Paroponus hirsutulus*." (Authors)] Huber, Elisabeth, Ökoteam-Institut für Tierökologie und Naturraumplanung, Bergmann-gasse 22, A-8010 Graz, Austria.

**20132.** Iorio, E.; Dusoulier, F.; Soldati, F.; Noël, F.; Guil-loton, J.A.; Doucet, G.; Ponel, P.; Dupont, P.; Krieg-Jacquier, R.; Chemin, S.; Tillier, P.; Touroult, J. (2022): Terrestrial arthropods in impact studies: current limitations and proposals for better consideration of conservation issues. *Naturae, Publications scientifiques du Muséum*, 2022.10.5852/naturae2022a4: 58 pp. (in French, with English summary) ["Environmental impact studies are a regulatory process to assess projects that may have significant environmental impacts. It includes a "natural environments" section, where an ecological diagnosis gives an initial status of the site to be assessed, including its wildlife, botanical and habitat concerns, based on bibliographical references and dedicated surveys. The result is the proposal for "ERC" measures (avoid, reduce, compensate) to preserve the environmental issues identified prior to the project. Arthropods are by far the most diverse phylum of the animal kingdom, and should therefore have an important place in an environmental impact study. However, only four orders have species listed in the current regulations, and the phylum of arthropods is poorly represented compared to vertebrates. The review of 50 impact studies shows that only three main groups are studied, relatively related to existing protections: butterflies (*Zygaena* included), dragonflies and Orthoptera, and some protected saprophagous wood-boring beetles. A 'closed-loop' effect occurs, likely inherent in the regulations and many of the associated actions, as these groups are the ones on which knowledge is most advanced and which are the subject of most Red List assessments. This imbalance between the groups covered in the impact studies and the actual diversity of continental arthropods, their specialisations and ecological functions, and their particular distributional characteristics, means that the issues at stake are assessed unequally depending on the habitats and geographical sectors concerned. Thus, butterflies and Orthoptera primarily highlight species and conservation issues for grassland environments, followed secondarily by moors, thickets and scrubland; dragonflies for freshwater environments. Butterflies and dragonflies also include a significant number of species of concern that are associated with peat bogs and marshes. These groups are generally good indicators of the issues affecting these habitats. The beetles that appear most regularly in impact studies highlight isolated trees, hedgerows, tree lines and forest edges. On the other hand, these groups are very few valuable to highlight conservation issues for arthropods of the coastal and closed forest environments. Butterflies and dragonflies are among the arthropods with the lowest rates of endemism in metropolitan France, which means that this conservation issue is under-represented in the impact studies. Functional guilds such as coprophagous, necrophagous or litter predators and decomposers are virtually almost forgotten in impact studies. This article proposes six groups for which knowledge has progressed well over the last 10 to 20 years and which would provide an ecological and taxonomic complement to the species currently used in regulatory studies: centipedes (Chilopoda), woodlice (Isopoda, Oniscidea), long-horned beetles (Cerambycidae and Vesperidae), Scarabaeoidea and Tenebrionidae, and shield-bugs (Heteroptera, Pentatomoidea). Most of the species of high concern in these six groups are found on beaches or dunes, forests or environments such as caves, cliffs or screes.

Centipedes, woodlice and Tenebrionidae beetles have a large number of endemics and a high national responsibility. Beaches and coastal environments, from the shore to the dunes, are the most striking example of under-representation in protected species and current impact studies, with dozens of specialised species at risk and no umbrella species to protect them. To a lesser extent, the same applies to closed forests. Caves appear to be of less concern. However, the often narrow distribution of the endemic arthropods they house means that the stakes are not to be underestimated. The protection lists therefore need to be completed with groups other than those taken into account so far, but in a manner appropriate to continental arthropods. Protection should prioritise habitats and not specimens, in correlation with the particularities of their study and their biology. For butterflies, dragonflies and Orthoptera, although a large number of regulated species remain relevant, the lists need to be revised. This study proposes a list of 135 species with high conservation concerns in nine arthropod groups. If this list was taken into account by environmental agencies, landscape planners and environmental authorities, it would reflect the challenges for continental arthropods in impact studies and thus enable measures to be taken that are better suited to their conservation." **20133.** Jakubiak, M.; Bojarski, B.; Bien, M.; Stonawski, B.; Oglecki, P. (2022): Influence of fish ponds on the benthic invertebrate composition in hydrological networks of selected fish farms in Southern Poland. *Folia Biologica (Kraków)* 70: 11-18. (in English) ["Fish production can generate high amounts of wastewater containing compounds such as suspended solids, nitrogen and phosphorus. On the other hand, fish ponds provide a range of ecological functions including biocenotic, physiocenotic, hydrological and microclimatic functions as well as landscape shaping. The aim of this study was to determine the taxonomic composition of the bottom invertebrate fauna in selected watercourses on chosen carp fish farms and to assess the influence of fish farming on the taxonomic composition of the zoobenthos of the watercourses associated with such ponds. The research was conducted in four channels on two semi-intensive aquaculture fish farms located in Zaborze and Kraków (Poland). Sampling of the benthic fauna was carried out once a month between May and September 2018. The results showed that the mean monthly number of zoobenthos families in the inflow canal in Zaborze was higher than those in the outflow canal. Moreover, a decrease of the BMWP-PL index in the aforementioned farm may indicate a deterioration of the water quality resulting from its flow through the ponds. It can therefore be concluded that semi-intensive carp farming may affect the diversity of benthic invertebrate fauna in the watercourses connected to these ponds." **20138.** Jödicke, R.; Borkenstein, A. (2022): *Sympetrum fonscolombii* in Niedersachsen: ein Modell zu Immigration

und Reproduktion am Nordrand des transalpinen Invasionsraums (Odonata: Libellulidae). *Libellula* 41(1/2): 1–24. ["*S. fonscolombii* in Lower Saxony, northwestern Germany: a model of immigration and reproduction at the northern edge of the transalpine invasion – Since the 1990s *S. fonscolombii* increasingly became a regular immigrant. It was annually present at many different places in Lower Saxony from 2005 onwards. A separation of the data into immigrants or their progeny was problematic because most observers did not report their data on imagines with a sufficient age specification. However, by means of special requests the following picture arose: Immigrants were on the wing from early May until August. They arrived in almost or completely mature colouration and oviposited from mid-May until mid-July. At one lake, in 2019, the immigrants stayed for at least 68 days. At many places the migrants' offspring emerged in the same year. The long emergence period started presumably in mid-July and continued until early November, demonstrating a short development cycle, even in the North. Emerged individuals left their breeding site in an immature stage. Six cases of spring emergence were documented. We therefore conclude that, in a proportion of the eggs laid, larvae were unable to develop and reach emergence within the same year. Those individuals hibernated in the larval stage and emerged between mid-May and early July in the subsequent year, thus representing a univoltine life cycle. Nothing is known about their destiny. The model presented here is based on the evidence-based assumption that immigrants establish only one subsequent generation, which predominantly emerges within the same year, but does not mature in the invasion area. Larvae which do not reach the ultimate stage until the autumn hibernate and emerge in the following spring, just in the period when the next immigrants appear. This model is broadly supported by further data from northwestern Europe, but there are controversial interpretations which are discussed. The contradictory issue could be solved if in future more observers pay attention to the age of imagines seen." (Authors)] Address: Jödicke, R., Am Liebfrauenbusch 3, 26655 Westerstede, Germany. **20142.** Jouault, C.; Tischlinger, H.; Henrotay, M.; Nel, A. (2022): Wing coloration patterns in the Early Jurassic dragonflies as potential indicator of increasing predation pressure from insectivorous reptiles. *Palaeoentomology* 5(4): 305-318. (in English) ["Wing coloration is a very ancient feature among insects. Even the wings of the oldest known Pterygota showed transverse colored bands involved in a putative disruptive function. However, no evidence of wing coloration in the representatives of the superorder Odonoptera is recorded before the latest Triassic. These were the only insect flying-predators until the pterosaurs began their diversification. Here we argue that the situation dramatically changed in the Early Jurassic, with the simultaneous appearance of Odonata with patterns of coloration in phylogenetically distant clades. It is especially the case in the Heterophlebiidae, a small family closely related to the Anisoptera, in which we could record no less than five different patterns of coloration in the same rather small area of North-Western Europe. At the same time and in the same area, small potentially insectivorous pterosaurs greatly diversified. The increase of the predation pressure on the Odonata is the most probable cause of the appearance of patterns of colored spots and bands on the dragonfly wings at that time. In the period between the Middle Jurassic to Early Cretaceous, the number of Odonata with spots and bands of color on wings dramatically increased, we assume in relation to the predation pressure due to an increasing diversification of insectivorous pterosaurs, but also small feathered dinosaurs and birds." **20146.** Karunarathna, D.S.; Gauder, S.I.; Rathnayake, R.R.M.U.N.B.; Dammini Premachandra, W.T.S. (2022): Diversity and abundance of odonates (Order: Odonata) in Gurudeniya, Kandy District, Sri Lanka. Vingnanam Research Conference, 21st of July 2022, Faculty of Science, University of Jaffna, Sri Lanka: 37- (in English) [Verbatim: The previously unexplored Gurudeniya region in Kandy district was surveyed for adult odonate diversity and abundance. Three habitats, i.e., along the "Thalathuoya" tributary, adjacent forest cover and a home garden, were selected for the study. Sampling was conducted twice a week, during 8 am - 9 am and 4 pm - 5 pm for three months from October to December 2021, along a 200 m × 4 m belt transect. Altogether, 1933 odonate individuals belonging to eight families and fourteen species were recorded and they represented 43 % of the suborder Anisoptera and 57 % of Zygoptera, respectively. We detected eight endemic, three endangered and four vulnerable species. The Libellulidae was found to be the most diverse family, comprised of four species inhabiting only the tributary area. Calopterygidae, Gomphidae and Platycnemididae had two species in each. *Vestalis apicalis nigrescens*, *Euphaea splendens* and *Ceylonosticta* bina, were recorded as common inhabitants at all the study sites. *Vestalis apicalis nigrescens* and *Trithemis festiva* were the dominant Zygopteran and Anisopteran species with 37 % and 30 % relative abundance, respectively. The tributary had the most diverse and abundant odonate community, comprising fourteen species and 70 % relative abundance with a Shannon-Wiener diversity index of 1.94. At all of the study sites, the family Calopterygidae was abundant in terms of tributary 44 %, woodland 78 % and residential garden 89 %, respectively. In the majority of the odonate species, males outnumbered females. The findings of this study elucidated the odonates at Gurudeniya within a short

period of time. An extensive study is underway to determine the larval and adult assemblages.] Address: Premachandra, Dammini, Dept of Zoology, Faculty of Science, University of Ruhuna, Sri Lanka. Email: dammini@zoo.ruh.ac.lk

**20149.** Koneri, R.; Nangoy, M.J.; Elfidasari, D. (2022): Odonata diversity in the Laine Waterfall Area, Sangihe Islands, North Sulawesi, Indonesia. *AACL Bioflux* 15(3): 1083-1095. (in English) ["In the ecosystem, Odonata functions as a biological control agent and an indicator of the freshwater environment. Therefore, this research aims to analyze Odonata diversity in the Laine Waterfall Area, Sangihe Islands, North Sulawesi, Indonesia. The sampling was carried out in 3 types of aquatic habitats, namely waterfalls, secondary forests, and agricultural land. In each habitat, 3 line transects with a length of 100 m were constructed around the river flow and the sampling was conducted along the transect using a sweep net. The results obtained a total of 5 families, which consists of 25 species and 928 individuals of dragonflies. Among the families, Libellulidae was dominant, while the species with the highest abundance was *Nososticta flavipennis*. Furthermore, the highest abundance, richness, and species diversity index were discovered in waterfall habitats. This showed that the research location is suitable for dragonfly activity due to several factors, namely temperature, humidity, and light intensity, which were normal for the species' activity." (Authors)] Address: Koneri, R., Dept Biol., Fac. Mathematics & Natural Sciences, Sam Ratulangi University, Manado, North Sulawesi, Indonesia. Email: ronicaniago@unsrat.ac.id

**20150.** Koneri, R.; Nangoy, M.J.; Siahaan, P. (2022): Species diversity of dragonflies on the Sangihe Islands, North Sulawesi, Indonesia. *Applied Ecology and Environmental Research* 20(2): 1763-1780. (in English) ["The diversity of dragonflies on an island is strongly influenced by habitat degradation, as well as the size and distance from the mainland. Therefore, this study aims to analyze the species diversity of dragonflies in the Sangihe Islands, North Sulawesi, Indonesia. It was carried out in five types of habitats

namely forests, waterfalls, dams, agricultural land, and settlements. In each habitat, four-line transects with a length of 100 m each were made and placed around the river. The results showed 6 families which included 32 species and 3020 individuals. Libellulidae is the family with the highest number of species. Furthermore, the dominant species in the suborders Anisoptera and Zygoptera were *Orthetrum prunosum* and *Rhinocypha frontalis*, respectively. Forests, waterfalls, and dams tend to have the highest species richness and diversity index compared to other habitats. Based on the results, the diversity of dragonflies at the observation site is strongly influenced by the complexity of the vegetation and environmental factors, including temperature and humidity. The presence of the families Chlorocyphidae, Calopterygidae, and Platycnemididae in each of the studied habitats indicates that the water quality is still very good and supports the life of dragonflies." (Authors)] Address: Koneri, R., Dept Biol., Fac. Mathematics & Natural Sciences, Sam Ratulangi University, Manado, North Sulawesi, Indonesia. Email: ronicaniago@unsrat.ac.id

**20151.** Kownacki, A.; Szarek-Gwiazda, E. (2022): The impact of pollution on diversity and density of benthic macroinvertebrates in mountain and upland rivers. *Water* 2022, 14(9), 1349; <https://doi.org/10.3390/w14091349>: 14 pp. (in English) ["This article summarizes the studies concerning the impact of pollutants on benthic macroinvertebrate communities in the mountain and upland rivers of southern Poland. The Carpathian Raba River, which in the 1960s retained its natural character and had good water quality, was considered as a reference in terms of benthic macroinvertebrate communities. The other two analyzed rivers were polluted to different degrees. The Carpathian Dunajec River was contaminated mainly by sewage from small towns and treatment plant, while the upland Vistula River mainly by sewage from the Upper Silesian Industrial Region and saline waters from coal mines. In studied ecosystems in response to pollutions, a rapid increase in density of fauna caused mainly by the massive development of *Oligochaeta* was found. In the mountain river, the impact of contamination on macroinvertebrate diversity was negligible. There, taxa considered as indicators of clean water (Ephemeroptera, Plecoptera, and Trichoptera) were abundant and their diversity was similar to that of an uncontaminated river. In the heavily polluted upland Vistula River, the sites with a muddy bottom were dominated by *Oligochaeta* (99.4–99.9%), while at sites with stony bottoms, apart from *Oligochaeta*, there were also Chironomidae, Gastropoda, and Hirudinea. In comparison to the 1950s, all Ephemeroptera, Plecoptera, Odonata, Trichoptera, and Megaloptera were extinct." (Authors)] Address: Szarek-Gwiazda, Ewa, Institute of Nature Conservation PAS, av. Mickiewicza 33, 31-120 Kraków, Poland. E-mail: szarek@iop.krakow.pl

**20152.** Kumar, C.S.; George, B.S.; Anooj, S.S. (2022): Range extension and high altitudinal record of *Sympetrum meridionale* (Selys) (Odonata: Libellulidae). *Indian Journal of Entomology*, Online published Ref. No. e20353; <https://doi.org/10.55446/IJE.2021.301>: 4 pp. (in English) ["*S. meridionale* (Selys, 1841) occurs throughout Asia Minor to Persia and Kashmir. The earlier Indian records of *S. meridionale* are from Yusimarg, 2286 m, and from below Gulmarg, 2438 m, Kashmir valley. Herein, the range extension and high altitudinal record of this species is reported from the Indus riverine, Leh, Ladakh Union territory of India at an elevation of 3500 m. A note on the habitat, which is entirely different from that of Kashmir valley, its originally known habitat, is provided. Study of museum specimens reveals

the eastern most record of the species, from Sikkim and an additional new record from Srinagar. The species diagnosis including comparison of male genitalia, along with the need to validate the previous records from Rajasthan and further surveys along Himalaya and lower latitudes are discussed." (2022): Odonata diversity at the Mount Permisan Natural Tourism Park South Bangka regency, Bangka Belitung. *Bi-Link: Jurnal Biologi Lingkungan, Industri dan Kesehatan* 9(1): 66-75. (in English) ["Mount Permisan Natural Tourism Park, South Bangka regency is a conservation area that contains flora and fauna. The diversity of fauna in conservation areas is important to note because fauna can maintain the balance of natural ecosystems. This study aims to analyze the diversity of species and the effect of habitat characteristics on the Odonata population. Odonata sampling was carried out using an insect net randomly at a predetermined point in the left and right directions of the 100 m transect line. Identification was carried out at the Entomology Laboratory, Agricultural Quarantine Center Pangkalpinang, and compared with a comparison sample at the Zoology Laboratory, Biology Dept, Universitas Bangka Belitung. Based on the research that has been done, found 14 species of Odonata from the sub-order Anisoptera and 11 species of damselfishes from the sub-order Zygoptera. The species diversity at that location was classified as moderate because H' was 1.56 to 2.05. The evenness value is high with a value of 0.62 to 0.90. The species of wealth (Margalef) is in the range of values from 2.55 to 2.75 which indicates the species richness of dragonflies in the Mount Permisan Natural Tourism Park index is classified as moderate." This is a new locality of this species in the Janowskie Forests." (Author)] Address: Kuziora, P.; Email: pawelkuziora1@gmail.com

**20157.** Lancer, B.H.; Evans, B.J.E.; Fabian, J.M.; O'Carroll, D.C.; Wiederman, S.D. (2022): Preattentive facilitation of target trajectories in a dragonfly visual neuron. *Communications Biology* 5(829): 13 pp. (in English) ["The ability to pursue targets in visually cluttered and distraction-rich environments is critical for predators such as dragonflies. Previously, we identified Centrifugal Small-Target Motion Detector 1 (CSTMD1), a dragonfly visual neuron likely involved in such target-tracking behaviour. CSTMD1 exhibits facilitated responses to targets moving along a continuous trajectory. Moreover, CSTMD1 competitively selects a single target out of a pair. Here, we conducted in vivo, intracellular recordings from CSTMD1 to examine the interplay between facilitation and selection, in response to the presentation of paired targets. We find that neuronal responses to both individual trajectories of simultaneous, paired targets are facilitated, rather than being constrained to the single, selected target. Additionally, switches in selection elicit suppression which is likely an important attribute underlying target pursuit. However, binocular experiments reveal these results are constrained to paired targets within the same visual hemifield, while selection of a target in one visual hemifield establishes ocular dominance that prevents facilitation or response to contralaterally presented targets. These results reveal that the dragonfly brain preattentively represents more than one target trajectory, to balance between attentional flexibility and resistance against distraction." **20159.** Lemke, M.; Hryniuk, P. (2022): First record of the dragonfly biting midge *Forcipomyia paludis* (Diptera: Ceratopogonidae) in Ukraine. *Ukrainska Entomofaunistyka* 13(1): 7-10. (in English, with Ukrainian summary) ["Based on unnoticed photograph of immature adult male *Cordulia aenea* with three females of the dragonfly biting midge *Forcipomyia* (*Pterobosca*) *paludis* (Macfie, 1936) parasitizing on it in the National Nature Park "Northern Podillya", Lviv Region, western Ukraine, the latter species is recorded from Ukraine for the first time. The photo was uploaded in the open natural history online database of the Ukrainian Biodiversity Information Network (UkrBIN) and was later discovered there. This record extends the known range of *F. paludis* to Eastern Europe." (Authors)] Address: Lemke, M., Am Grüneberg 37, 66557 Illingen, Germany. Email: malemke@gmx.de

**20160.** Li, Z.; Sun, L.; Wang, Z.; Zhao, S.; Duo, L. (2022): The Critically Endangered dragonfly *Libellula angelina* is losing its habitat to urbanization in East Asia. *Oryx* 56(2): 172- (in English) ["The Critically Endangered dragonfly *Libellula angelina*, known as the bekko tombo, of central and northern China, Japan, western South Korea, and North Korea, was common before 1970 but has declined dramatically as a result of habitat loss caused by urbanization. In China, natural ponds and wetland parks have facilitated the survival of this species in megacities such as Beijing and Tianjin, but habitat degeneration in some cities appears to be resulting in further decline of the species. The natural ponds around the Chentai Bridge in Beichen district, Tianjin, one of the historical habitats of the bekko tombo, suffered a severe drought from excessive pumping for irrigation in spring 2020, followed by excessive water supplementation that increased the original water level in autumn 2020. In Tianjin Water Park, another habitat of the bekko tombo, sediment was dredged and reeds mowed, destroying habitat for the species' nymphs and imagoes, respectively, in 2020. During 15 April–15 May 2021, we surveyed for the bekko tombo in these two habitats on 18 occasions, concentrating on their preferred microhabitats in reeds and open grassland, but failed to find the species. Prior to this, the bekko tombo was commonly seen in these two areas in spring. The prime habitat for the bekko tombo is unmodified, stable

and organic-rich ponds with open water and moderate growth of emergent plants. Urbanization and habitat degradation, accompanied by reclamation, drought, contamination, sediment dredging, mowing of reeds and shrinkage of wetlands, are driving the collapse of the remaining populations of the bekko tombo. Measures are required to maintain the integrity of the species' habitat by protecting wetlands from urbanization and anthropogenic modification, with a halt to inappropriate dredging and mowing." (Authors)] Address: Li, Z., College of Life Sciences, Tianjin Normal University, Tianjin, China, and Tianjin Key Laboratory of Animal and Plant Resistance, Tianjin, China duolian\_tjnu@163.com

**20161.** Liao, J.; Wang, H.; Xiao, S.; Guan, Z.; Zhang, H.; Dumont, H.J.; Han, B.-P. (2022): Modeling and prediction of the species' range of *Neurobasis chinensis* (Linnaeus, 1758) under climate change. *Biology* 2022, 11(6), 868; <https://doi.org/10.3390/biology11060868>: 14 pp. (in English) ["Simple Summary: Global climate change is accelerating and modifying the distribution of many extant species. Dragonflies, as a group, inhabit aquatic as well as terrestrial environments and are considered sensitive climate change indicators. In this study, we model and predict the range of a large, tropical damselfly *Neurobasis chinensis* L. under the last glacial maximum (LGM), the current, and four future warming scenarios. The models show that the species mainly occupies forest ecosystems below 1200 m (preferring 500 to 1200 m) and had two historic core distribution areas in LGM, one of which survived, namely south-central Vietnam. The future scenarios show that the core distribution, high suitable habitats, and even the whole species range of *N. chinensis* will extend northwards. Abstract: *Neurobasis chinensis* is widely distributed in eastern tropical Asia. Its only congener in China, the *N. anderssoni*, has not been observed for decades. To protect *N. chinensis*, it is necessary to understand the ecological properties of its habitats and species' range shift under climate change. In the present study, we modeled its potential distribution under one historical, current, and four future scenarios. We evaluated the importance of the factors that shape its distribution and habitats and predicted the historical and current core spatial distributions and their shifting in the future. Two historical core distribution areas were identified: the inland region of the Bay of Bengal and south-central Vietnam. The current potential distribution includes south China, Vietnam, Laos, Thailand, Myanmar, Luzon of Philippines, Malaysia, southwest and northeast India, Sri Lanka, Indonesia (Java, Sumatra), Bangladesh, Nepal, Bhutan, and foothills of the Himalayas, in total, ca.  $3.59 \times 10^6$  km<sup>2</sup>. Only one core distribution remained, concentrated in south-central Vietnam. In a warming future, the core distribution, high suitable habitats, and even the whole range of *N. chinensis* will expand and shift northwards. Currently, *N. chinensis* mainly resides in forest ecosystems below 1200 m above sea level (preferred 500 m to 1200 m a.s.l.). Annual precipitation, mean temperature of driest quarter, and seasonality of precipitation are important factors shaping the species distribution. Our study provides systematic information on habitats and geographical distribution, which is useful for the conservation of *N. chinensis*." **20162.** Liu, H.; Jiang, F.; Wang, S.; Wang, H.; Wang, A.; Zhao, H.; Xu, D.; Yang, B.; Fan, W. (2022): Chromosome-level genome of the globe skimmer dragonfly (*Pantala flavescens*). *GigaScience* 11(1): 1-8. (in English) ["Background:

The globe skimmer dragonfly (*Pantala flavescens*) is a notable Odonata insect distributed in nature fields and farmlands worldwide, and it is commonly recognized as a natural enemy because it preys on agricultural pests and health pests. As one of the sister groups of winged insects, odonatan species are key to understanding the evolution of insect wings. Findings: We present a high-quality reference genome of *P. flavescens*, which is the first chromosome-level genome in the Palaeoptera (Odonata and Ephemeroptera). The assembled genome size was 662 Mb, with a contig N50 of 16.2 Mb. Via Hi-C scaffolding, 648 Mb (97.9%) of contig sequences were clustered, ordered, and assembled into 12 large scaffolds, each corresponding to a natural chromosome. The X chromosome was identified by sequence coverage depth. The repetitive sequences and gene density of the X chromosome are similar to those of autosomal sequences, but the X chromosome shows a much lower degree of heterozygosity. Our analysis shows that the effective population size experienced 3 declining events, which may have been caused by climate change and environmental pollution. Conclusions: The genome of *P. flavescens* provides more information on the biology and evolution of insects and will help for the use of this species in pest control." DOI: <https://doi.org/10.2436/10.8080.03.4>: 18 pp. (in Catalan, with English summary) ["Fieldwork and a literature review enabled a catalogue of the damselflies and dragonflies of La Moixina (Olot, Catalonia), and Parc Nou (Olot) to be compiled. In all, 40 species have been detected in this area, of which 19 are only occasional visitors. The remaining 21 species breed or are observed regularly in the area's three main habitats, the canals, the ponds and in the meadows and on woodland edges. Using an index of vulnerability for Catalan dragonflies (IVOC), it becomes clear that the most threatened species are all linked to the canals, of which *Calopteryx virgo* and *Boyeria irene* are good examples. By contrast, the species that breed in the ponds Basses d'en Broc are much more generalist and are not threatened." English) [Democratic Republic of the Congo; "The preliminary study of the structure of the macroinvertebrate stands of Lake Mai Ndombe in the DRC was carried out in February 2020. Six hundred and ten (610) aquatic macroinvertebrates were captured, divided into 7 orders and 28 families. The family of Corduliidae was the most abundant with 17.7% of the total specimens, it was followed by the Dystiscidae (14.1%), Naucoridae (12.7%), Limnebiidae (11.3%), Atyidae (7.7%), Coenagrionidae (6.5%) and Libellulidae (6.4%). The other families were poorly represented. The diversity indices calculated for the different stations varied between 1.67 (Ndom IV) and 2.8 (Ndom I) and the fairness between 0.93 (Ndom III and Ndom IV) and 0.96 (Ndom II). The IBGN calculation revealed that the biological and ecological quality of the waters of this lake ranges from fair quality with Polycentropodidae as the indicator group to poor quality with the oligochaetes as the indicator group." **20167.** Macgregor, C.J.; Bunting, J.; Deutz, P.; Bourn, N.A.D.; Roy, D.B.; Mayes, W.M. (2022): Brownfield sites promote biodiversity at a landscape scale. Science of The Total Environment Volume 804, 15 January 2022, 150162: (in English) ["Highlights: • Species richness of birds, plants and insects is higher in landscapes containing ex-landfill sites. Birds also have higher assemblage rarity in landscapes containing ex-landfill sites. For birds, plants and insects, species richness increases with increasing area of ex-landfill sites. For birds and insects, species richness declines over time after landfill site closure. For plants, species richness increases over time after landfill site closure. Abstract: Repurposing of brownfield sites is often promoted, because it is perceived that protecting the "green belt" limits damage to biodiversity; yet brownfield sites provide scarce habitats with limited disturbance, so conversely are also perceived to be ecologically valuable. Combining data from three national-scale UK biological monitoring schemes with location data on historical landfill sites, we show that species richness is positively associated with both the presence and increasing area of ex-landfill sites for birds, plants and several insect taxa. Assemblage rarity of birds is also positively associated with presence of ex-landfill sites. Species richness

associated with ex-landfill sites declined over time for birds and insects but increased over time for plants. These findings suggest that development of brownfield sites may have unintended negative consequences for biodiversity, and imply that to minimise loss of biodiversity, brownfield site repurposing could be targeted towards smaller sites, or sites in areas with a high density of other brownfield sites." **20169.** Maldonado-Benitez, N.; Mariani-Ríos, A.; Ramírez, A. (2022): Effects of urbanization on Odonata assemblages in tropical island streams in San Juan, Puerto Rico. *International Journal of Odonatology* 25: 31-42. (in English) ["Urbanization has considerable impacts on stream ecosystems. Streams in urban settings are affected by multiple stressors such as flow modifications and loss of riparian vegetation. The richness and abundance of aquatic insects, such as odonates, directly reflect these alterations and can be used to assess urban impacts on streams. The effects of urbanization on odonate richness and abundance on tropical islands is as yet poorly understood. The objective of this study is to identify the effects of urbanization on stream habitat quality and associated odonate assemblages in Puerto Rico. We sampled 16 streams along a rural to urban gradient in the San Juan Metropolitan Area, where each stream was characterized using the Stream Visual Assessment Protocol (SVAP) for Puerto Rico and by analyzing their surrounding land cover. A 100-m segment of each stream was surveyed to assess adult odonate richness and abundance during the rainy and dry seasons. Adults were identified visually, and their abundance was recorded. Favorable local scale factors, like improved habitat quality, as measured with the SVAP, resulted in higher abundances of odonates. However, regional factors such as percent urban cover did not appear to significantly affect richness and abundances of odonates. Overall, our study indicates that odonate assemblages are affected by the loss of habitat integrity, and conservation of tropical odonates may benefit from focusing on local scale factors." **20170.** Mariani-Ríos, A.; Maldonado-Benitez, N.; Ramírez, A. (2022): Natural history of Odonata assemblages in tropical streams in Puerto Rico. *Neotropical Biodiversity* 8(1): 112-123. (in English) ["Freshwater macroinvertebrates play an important role in maintaining stream food webs. Odonata are important top predators in these communities and serve as indicators of stream health. Our understanding of odonate

assemblages is limited in the Caribbean and the natural history of most odonate species in the region remains unknown. The focus of this research is to study the natural history of odonate species in headwater montane streams following major hurricane impacts in Puerto Rico. We monitored assemblages from August 2018 to July 2019 in two headwater streams within El Yunque National Forest, Puerto Rico. The study streams drain a protected forest, with aseasonal precipitation patterns, relatively constant water temperature, and flashy hydrographs that quickly respond to rain events. We sampled 226 adults and 550 larvae, dominated by three Caribbean endemics: *Scapanea frontalis*, *Macrothemis celeno*, and *Telebasis vulnerata*. Only *S. frontalis* and *M. celeno* were abundant enough to assess the temporal patterns and their natural history. Larval density fluctuated throughout the year with short peaks in abundance during different times of the year, according to the species. Small individuals (=10 mm body length) were more abundant than the large ones. However, all size classes were present during the year. The dominant species, *S. frontalis* and *M. celeno*, had continuous development patterns, without identifiable size classes and multiple overlapping generations. The exception was the last stadium that formed a separate group in the body length vs head width plots. Species had clear habitat preferences; *S. frontalis* was abundant in riffles and preferred areas with high amounts of cobble. *Macrothemis celeno* prefers pool habitats with fine substrates. While we found trends for negative relations between abundance and discharge, canopy cover, water temperature, and rainfall, none was statistically significant. Observed patterns suggest a lack of strong temporal seasonality in the natural history of Odonata, which coincides with the aseasonal environment of streams draining our study area. Overall, our study is the first to assess temporal variability of Odonata assemblages in montane streams of Puerto Rico and provides information on Caribbean endemic species." **20171.** Marinov, M. (2022): On two unjustified rankings of Pacific Odonata (Insecta). *Faunistic Studies in Southeast Asian and Pacific Island Odonata* 38: 1-10. (in English) ["Modifications of nomina proposed for two Pacific Odonata taxa are found to be unsubstantiated. Each has been proposed without the support of taxonomic studies. Herein, it is demonstrated that the raising of the subgenus *Adversaeschna* Watson, 1992 to genus rank and subsuming the genus *Amorphostigma* Fraser, 1925 to *Ischnura* Charpentier, 1840 are not justified. The first, *Adversaeschna*, was a mistake introduced and multiplied widely in nomenclature lists adopted by online databases and other studies. The second, *Amorphostigma*, was based on premature information to propose a plausible taxonomy of a diverse Pacific clade which most likely consists of several taxa deserving of separate generic ranks, supported by preliminary phylogenetic work. Therefore, these nomina should be reverted to reflect current taxonomic revisions. *Adversaeschna* should be considered as a subgenus of *Aeshna* Fabricius, 1775 and *Amorphostigma* as a nomen of generic rank." **20173.** Medeiros Chaviel, B.; Silveira Mascarenhas, C.; Corrêa, F.; Costa Silveira, E.; Afonso Coimbra, M.A.; Müller, G. (2022): Diet of *Acanthochelys spixii* and *Hydromedusa tectifera* (Chelidae) in the southern Brazil. *Caldasia* 44(1): 178-183. (in English, with Spanish summary) ["Data about the diet of the freshwater turtles *Acanthochelys spixii* and *Hydromedusa tectifera* from southern Brazil populations remain little known. In this context, the digestive tract of 21 *A. spixii* and 20 of *H. tectifera* individuals from three municipalities in the state of Rio Grande do Sul, Brazil were examined. The food items were identified at the lowest possible taxonomic level, quantified, and conserved in ethanol 70°GL. The frequency of occurrence (F %) and volume percentage (V %) were estimated, as well as the food importance index (IAi %). The range of the trophic niche and the feeding strategy of both species were analyzed. The diet of *A. spixii* and *H. tectifera* was compared through the Mann-Whitney test ( $P < 0.05$ ). Both species presented a generalist food strategy, consuming mainly insects, represented by Hemiptera, Odonata, Coleoptera, and Diptera. There was no significant difference in the volume of items consumed by both species (Mann-Whitney test,  $z = -0.387$ ,  $P = 0.69$ ). Concerning the trophic niche range, we observed low values for both species, it was of 0.41 for *A. spixii* and 0.39 for *H. tectifera* suggesting a more restricted diet with uniformity in food consumption, however, we highlight that a more restricted diet does not suggest a trophic specialization, because the availability of food items have variation in time and space. The study contributed information on the diet of species in the region, generating data that can be used in programs for the conservation of species and their habitats."] (Authors)] Address: Medeiros Chaviel, Bruna, Laboratório de Parasitologia de Animais Silvestres, Instituto de Biologia, Depto de Microbiologia e Parasitologia, Universidade Federal de Pelotas, Caixa Postal: 354, CEP 96010-900, Pelotas, RS, Brazil. brunachaviel@gmail.com

**20174.** Medina-Espinoza, E.F. (2022): Abundance of Odonata in different microhabitats at an oxbow lake in the Peruvian Amazon. *Acta Amazonica* 52(3): 236-240. (in English, with Spanish summary) ["The relationship between Odonata and vegetation in Amazonia has been studied primarily in streams. In this study, I examined the abundance of adult Odonata in two vegetation types (shrubs and herbs) surrounding an oxbow lake in the Peruvian Amazon. Daytime visual samplings of Odonata were carried out in time blocks along transects in each habitat. Thirteen taxa were identified. Five species were similarly abundant in both habitats, three used mainly herbs, and one mainly shrubs, with no variation among time blocks. The results suggest that most Anisoptera and Zygoptera are adapted to unshaded areas of the lake. Some Odonata also were observed during sunless days with light rainfall, suggesting they are adapted to rainy conditions in tropical climate."] (Author)] Address: Medina-Espinoza, Emmy Fiorella, Univ. **20177.** Merchant, M.; McClure, M.R. (2022): Phenoloxidase and melanization innate immune activities in Green Darner dragonfly nymphs (*Anax junius*). *Advances in Biological Chemistry* 12(4): 130-141. (in English) ["Odonata are highly subject to infection by gregarine parasites. However, despite the important ecological roles that insects play in every ecosystem in which they exist, little research has been devoted to the description of insect immunity. Insects rely heavily on the rapid actions of innate immune mechanisms to prevent infection. We characterized the melanization response in the hemolymph of *A. junius* nymphs. Incubation of chymotrypsin-activated hemolymph with L-DOPA resulted in volume- and time-dependent production of dopaquinone via the phenoloxidase (PO) enzyme, with biphasic accumulation of product. The PO activity was temperature-dependent, with a stepwise increase from 20° - 35° and maximum activity measured at 35° - 40°. The formation of product was also inhibited in a concentration-dependent manner by diethylcarbonate, a specific inhibitor of PO activity, which indicated that the observed activity was due to the presence of PO enzyme. The rate of formation and quantity of melanin was dependent on exposure to different titers of bacteria. This is the first characterization of both PO activity and melanization response in *A. junius*."] (Authors)] Address:

**20178.** Min, J.-K.; Lee, H.; Kong, D. (2022): Development of a benthic macroinvertebrate predictive model based on the physical and chemical variables of rivers in the Republic of Korea. *Journal of Freshwater Ecology* 37(1): 425-453. (in English) ["Predictive models for the benthic macroinvertebrate community based on environmental variables facilitate the identification of the organisms expected to inhabit an area according to the target environmental conditions when restoring rivers. In this investigation, a biotic community predictive model was developed using benthic macroinvertebrate and environmental variable data collected from 1,210 sites in the Republic of Korea from 2010 to 2020. The sites were classified into six groups according to Two Way Indicator Species Analysis (TWINSpan) and based on their individual abundance/m<sup>2</sup> of benthic macroinvertebrates. The TWINSpan groups were related to 14 variables by stepwise multi-discriminant analysis. The relative importance of the environmental variables that classified each TWINSpan group was in the order of mean diameter of particle size, catchment area, altitude, velocity, total phosphorus, latitude, pH, longitude, conductivity, water depth, suspended solids, biochemical oxygen demand, stream order, and total nitrogen. Discriminant functions 1–4 showed statistically significant and a predictive model was developed using functions 1 and 2 based on Wilks' lambda values. The fit of the derived model was confirmed using Sørensen similarity (number of taxa) and Bray–Curtis dissimilarity (individual abundance/m<sup>2</sup>) analyses between the predicted organisms and those observed at the sites. The distributions of similarity and dissimilarity that were confirmed by stream type ranged from 0.60 to 0.72 and 0.46–0.56, respectively, based on the mean. Based on the predicted and observed values, the ratio of shredders and scrapers to collectors showed similar results overall for each stream type. The predictive model derived using nationally managed available data is expected to be applicable to stream and river restorations in the future, as it provides a statistical assessment of the biotic communities that are expected to inhabit a given environment." (Authors) (Odonate) taxa are treated at the family level.] Address: Kong, D., Dept of Life Science, Kyonggi University, Suwon-si, 16227, Gyeonggi-do Province, Republic of Korea. **20180.** Mogali, S.M.; Shanbhag, B.A.; Saidapur, S.K. (2022): Predatory influence of dragonfly larvae and water scorpions on eggs and tadpoles of *Indosylvirana temporalis* (Anura: Ranidae). *Phyllomedusa* 21(1): 51-57. (in English, with Portuguese summary) ["We assessed in the laboratory the vulnerability of Bronzed frog (*Indosylvirana temporalis*) eggs and tadpoles to two potential sit-and-wait insect predators, larvae of *Pantala flavescens* and adult water scorpions (*Laccotrephes* sp.; Hemiptera: Nepidae). We exposed a series of different developmental stages of *I. temporalis* (from eggs to metamorphic climax stage) to these two predators. The results of this study showed that larvae of *P. flavescens* preyed on eggs and tadpoles of *I. temporalis* but only to stage 36. *Laccotrephes* sp. did not prey on eggs of *I. temporalis* but on tadpoles of all stages (22 to 42). This difference in predation rate was likely due to the gape size of the predators. The larvae of *P. flavescens* are gape-limited and cannot prey on larger tadpoles (above stage 36). Adults *Laccotrephes* sp. are non-gape-limited predators, using a segmented beak to pierce *I. temporalis* and suck the body fluids. They captured small to large tadpoles by quickly grabbing and immobilizing them using the front pair of raptorial legs. The present study shows that both predatory insects are a threat to *I. temporalis* at early and later stages of larval development." (Authors)] Address: Mogali, S.M., Dept Zool., Karnatak Univ., Dharwad-580 003, Karnataka State, India. E-mail: santoshmogali@rediffmail.com.

**20181.** Mohammed, I.; Wondie, A.; Mengist, M. (2022): The environmental quality and macroinvertebrate community structures of wetlands found in the Lake Tana Watershed, Ethiopia. *Journal of the Cameroon Academy of Sciences* 17(3): 183-203. (in English, with French summary) ["The present study was conducted to assess the environmental quality status and macroinvertebrate community structures of wetlands using macroinvertebrates as bioindicators. A multimetric biotic index approach was used for the study. The findings revealed 3,367 macroinvertebrates belonging to 37 families. The percentages of Ephemeroptera, Odonata, and Trichoptera (%EOT), percent Diptera, percent filterercollectors, the ratio of Ephemeroptera, Plecoptera, and Trichoptera to Chironomid (EPT/C), the Biological Monitoring Working Party Score, and the Shannon–Wiener diversity index were all significantly related to human disturbance and could be used to assess water quality. Based on the macroinvertebrate index, human disturbance had a significant impact on Shesher wetland, a relatively lower impact on Avaji and Yitamot, and a moderate impact on Chimba, while Dena and Wonjeta had good habitat quality. Their water quality was very poor, poor, moderate, and very good, in that order. Farming, leather tanning, waste dumping, and effluent discharges were responsible for the poor habitat quality of impacted wetlands. Therefore, unless managed properly, human disturbance activities in the wetlands

catchment were threatening macroinvertebrates and the wetlands ecosystem. Hence, implementation of catchment-based management together with continuous health status monitoring and a standalone wetland policy should be established." **20182.** Mohammed, S.H.; Eltaly, R.I.; Salem, H.H. (2022): Toxicological and biochemical studies for chlorpyrifos insecticide on some mosquito larvae and their associated predators. *Egyptian Journal of Basic and Applied Sciences* 9(1): 254-263. (in English) ["Use of chemical insecticide with natural enemies could be more effective in mosquito control strategy. This study examined the toxicity of chlorpyrifos insecticide against three field-collected mosquito species, *Culex pipiens*, *Anopheles pharoensis* and *Ochlerotatus caspius* and their associated predators (*Pantala flavescens*) and mayfly (*Caenis stephens*) naiads as non-target insect for chlorpyrifos. The predation potential of *Pa. flavescens* and *Ca. stephens* against tested mosquito larvae was also investigated. Additional biochemical assays were carried out to detect the effect of chlorpyrifos on some detoxifying enzymes of tested mosquito larvae and their associated predators. The results showed that (*Pa. flavescens*) have higher predation potential than (*Ca. stephens*). The toxicological results recorded high toxic effect of chlorpyrifos on *Ca. stephens* followed by *An. pharoensis* and *Oc. caspius* with percent mortality 100, 90 and 85% respectively, while *Pa. flavescens* exhibited high resistance followed by *Cx. pipiens* with percent mortality 20 and 40% respectively. Moreover, Acetylcholinesterase and glutathione S-transferase were significantly increased only in *Cx. pipiens* and *Pa. flavescens*. It could be concluded that, chlorpyrifos have different toxicological effect on the tested mosquito larvae and associated predators. So, the side effect of chlorpyrifos must be taken in consideration before using it in control programs." **20183.** Monnerat, C.; Juillerat, L. (2022): The Antoine Senglet collection: a major contribution to the knowledge of the odonates of Morocco from the 1960s (Odonata). *Odonatologica* 51(1-2): 41-62. (in English) ["Odonata collected by Antoine Senglet in Morocco from 12.vi. to 13.vii.1967 in 28 localities are deposited in the Muséum d'histoire naturelle in Geneva (MHNG, Switzerland). The collection includes 453 imagines of 46 species and 326 exuviae of 24 species, corresponding to 73 % of the presently known Moroccan Odonata fauna. It is one of the largest collections of Odonata ever made in Morocco and includes the first known evidence for *Erythromma viridulum*, *Orthetrum brunneum*, *O. cancellatum*, *Selysiotthemis nigra*, and *Sympetrum sinaiticum* for Morocco. Reproduction is proven by the presence of exuviae for all these species except *E. viridulum*. The collection, which has remained undocumented for more than half a century, is comparable in scope to the contributions presented by the first two syntheses on the dragonflies of Morocco published by Lieftinck (1966) and Dumont (1972). A chronological check-list of the odonate fauna of Morocco details the increase in knowledge from 1850 to the present day." jewski, D.J. (2022): Inter- and intraspecific trait compensation of behavioural and morphological defences in a damselfly genus. *Front. Ecol. Evol.* 10:874276. doi: 10.3389/fevo.2022.874276: 10 pp. (in English) ["Predation is a key driver of phenotypic diversification with prey having evolved sets of correlated anti-predator traits. Changes in anti-predator traits can be studied on an evolutionary as well as on a developmental timescale. Using a common garden setup, we studied inter- and intraspecific correlations of behavioural and morphological defences in four damselfly species that either occur in habitats dominated by predatory fish (fish habitats) or fishless habitats by raising larvae either with predatory fish or in a control treatment. We found inter- as well as intraspecific trait compensation (negative correlations) between behavioural and morphological defences. Compared to fishless habitat species, fish habitat species invested more in behavioural defences and less in morphological defences. This was mirrored by fish habitat species investing more in behavioural defences and less in morphological defences when reared with predatory fish whereas fishless habitat species invested less in morphological defences only. Our results emphasise the role of context-specific combinations of defensive traits to avoid predation. We suggest, considering changes in multiple correlated traits on different timescales when studying the evolution of anti-predator traits." **20185.** Mukherjee, A.; Sardar, S.; Mandal, B.; Chandra Saha, N.; Mitra, B. (2022): First insect faunal inventory from the recently declared Raimona National Park, Assam, India. *International Journal of Entomology Research* 7(3): 26-30. (in English) ["Protected areas which are essential for biodiversity conservation often provide habitat and protection from other anthropogenic activities threatened to the pristine wildlife. Therefore, establishment of new protected areas like sanctuaries, biosphere reserve and national parks relieve the wildlife a lot from risk. Before starting conservation and management of the protected areas, one need to know which species are endangered or threatened and what we must conserve. Raimona National Park was declared as the National Park by the Government of Assam on the World Environment Day, 2021. A visit of six days to this national park enumerates 62 species of insects. These includes 41 species of butterflies and 5 species of moths, 3 species of dragonflies, 7 species of grasshoppers and crickets, 3 species of bugs and 3 species of bees and wasps. Only 4 species of butterflies are found here under WPAACT (1972). This paper presents the first insect inventory from the 6th national park of Assam and the last declared national parks in India." (Authors) Three Odonata species are checklisted: *Crocothemis servilia*, *Orthetrum sabina*, *Potamarcha congener*.] Address: Mandal, B., Dept of Zoology, Jogesh Chandra Chaudhuri College, Kolkata, West Bengal, India. **20186.** Mzungu, E.; Yakub, S.; Anyimba, E.S: (2022): Macroinvertebrates as bio-indicators of water quality in Omubira Stream, in Kakamega County, Kenya. *International Journal of Fisheries and Aquatic Studies* 10(4): 70-77. (in English) ["Human-induced environmental stress can impair freshwater ecosystems by destroying them or altering them in negativeways. Laws and ordinances that stress Kenya's water resources' correct management and utilization were prompted by worries about the management of freshwater bodies. Therefore, understanding of the health status of aquatic environments, particularly their biodiversity, is crucial in order to comprehend the status of water

quality and limit the rate of pollution in our streams and rivers. Several well-known biological markers of water quality can be used for this. Bio-indicators are species or groups of species that can quickly reveal the abiotic or biotic condition of an environment, show how environmental change has affected a habitat or ecosystem. In many industrialized nations, including those in Europe and North America, macroinvertebrates are widely utilized as bio-indicators and are part of their national and technical standards for water quality monitoring. Their use is still relatively restricted in developing nations like Kenya. Furthermore, the use of aquatic macroinvertebrates as bio-indicators of water quality to assess the condition of aquatic ecosystems is not stressed by Kenyan environmental laws and regulatory bodies. This can be because the nation doesn't have a well-known and established biomonitoring system. However, only a small number of studies have begun utilizing macroinvertebrate species as bio-indicators at this time. A greater comprehension of the macroinvertebrate variety of the Omubira River could help in the stream management due to continued municipal and agricultural activities along this river. As a result, this study examined the use of macroinvertebrates as bio-indicators of river water quality and determined how they reacted to water quality in the various region of the stream. Macroinvertebrates and selected physicochemical variables were sampled monthly in four sites for a period of four months. On each sampling sites at every sampling episode physicochemical variables including temperature, conductivity, salinity, turbidity, pH, dissolved oxygen and percentage saturation oxygen were measured using a Hydrolab Quanta Multi-Probe Meter. A Surber sampler of an area 1200 cm<sup>2</sup> and corer sampler were used with catching area of 20.83 cm<sup>2</sup> to capture macroinvertebrates. There was a general decrease of Temperature, turbidity, salinity, conductivity and pH from the town area to the forested area. However, dissolved oxygen increased from the town area to forested area. A general variation of macroinvertebrates species from municipal area to forested area in the river was observed. The highest abundance of Belostomatidae (16.87), Chironomidae (16.77), Naididae (14.07) and Gomphidae (18.67) were found in the municipal reach of the river. The highest abundance of Elmidae (20.49) and Notonectidae (19.87) were found in the agricultural reach while the highest abundance of Gerridae (10.53), Hydropsychidae (28.65) and Perlidae (33.92) were found at the forested reach. From the diverse makeup of the macroinvertebrates, Omubira stream's water quality can be described as moderately clean. This could be harmful to aquatic life and communities living along, which depends on highly clean water to exist. This study therefore recommends continuous monitoring and proper management of pollution sources into the stream by the pertinent authorities as well as embracing bio-indicators." **20194.** Oldak, K. (2022): Dragonflies (Odonata) of retention ponds situated near the Mińsk Mazowiecki motorway bypass (east-central Poland). *Odonatrix* 183 (2022): 17 pp. (in Polish, with English summary) ["The aim of this study was to determine the species composition of Odonata of 8 motorway retention ponds situated in the Mińsk Mazowiecki district (Province of Mazovia). A total of 36 species were found (48.6% of the Polish odonate fauna), 24 of which were classified as autochthonous or probably autochthonous. The most abundant species in the ponds were *Coenagrion puella*, *Erythromma viridulum* and *Ischnura elegans*. Two species protected in Poland were recorded – *Leucorhinia albifrons* and *Sympecma paedisca*. The records of *Sympetrum depressiusculum*, *S. meridionale* and *Crocothemis erythraea* were the first from the Mińsk Mazowiecki district. The ponds exhibited a considerable qualitative faunistic similarity. As the odonate fauna of the individual ponds was qualitatively poor, these offered suitable habitats for only a small number of dragonfly species. This was due, among other things, to the small surface areas of the ponds and the inappropriate management of the plant succession in them. As the species found were mostly eurytopes and

common ones, the ponds are unlikely to enhance the regional dragonfly diversity. To date, there have been no published records of the odonate fauna of motorway retention ponds in Poland, so the present paper provides a comparative background for further research in this field. In addition, these results add to our knowledge of the dragonfly fauna of both the Mińsk Mazowiecki district and two hitherto poorly studied UTM squares (EC38, EC48), within which many species were found for the first time." (Author)] Address: Oldak, K., Ziemowita 14, 05-300 Mińsk Mazowiecki, Poland. Email: krystian.adam.oldak@gmail.com

**20195.** Oldak, K.A. (2022): Dragonflies (Odonata) in spider webs – cases from motorway retention ponds in the Mińsk Mazowiecki district (east-central Poland). *Odonatrix* 184 (2022): 6 pp. (in Polish, with English summary) ["Instances of dragonflies (Odonata) caught in spider webs were documented as part of a study of the odonate fauna of motorway retention ponds conducted in 2020. Identification of the dragonfly and spider (Araneae) species was based on photographs taken in the field. 46 cases of dragonflies caught in spider webs were recorded. Zygopterans made up 87.0% of all these prey items. In 46.7% of the cases where the dragonfly species was identifiable, the prey was *Ischnura elegans*. This was most likely due to the ubiquity and abundance of this species on these retention ponds. The quite characteristic appearance of the terminal abdominal segments of *I. elegans* sometimes enabled identification of this species even if the victim had been partially consumed. Fourteen spiders from two families – Araneidae and Tetragnathidae – were recorded, the former being somewhat more abundant (57.1%). Water bodies are the typical habitat for three of the five identified spider species – *Tetragnatha extensa*, *T. striata* and *Larinioides cornutus*; the other two – *Argiope bruennichi* and *Araneus quadratus* – inhabit more diverse habitats. *T. extensa* was the spider species found in the greatest number of cases." (Author)] Address: Oldak, K.A., Ziemowita 14, 05-300 Mińsk Mazowiecki, Poland. Email: krystian.adam.oldak@gmail.com

**20196.** Olsen, K.; Svenning, J.-C.; Balslev, H. (2022): Niche breadth predicts geographical range size and northern range shift in European dragonfly species (Odonata). *Diversity* 2022, 14(9), 719; <https://doi.org/10.3390/d14090719>: 14 pp. (in English) ["We studied how range sizes and shifts in species ranges depend on niche breadth in European dragonflies. We measured range sizes and shifts over a 22-year period (1988–2010) and grouped species into those reproducing in permanent running (perennial lotic) water, permanent standing (perennial lentic) water, and temporary (running or standing) water. Running water species are more specialized and have narrower niches with a more fixed niche position than standing water species. Temporary water species are more generalist and have broader niches without a fixed niche position as clear as permanent water species because they may utilize both temporary and permanent habitats. Running water species have smaller ranges, and some of them have contracted their ranges more than species reproducing in standing or temporary waters; that is, they are especially at risk of habitat loss and climate change because of the joint effects of their narrow niches and small range sizes. Temporary water species track climate changes better than permanent water species. This suggests that ecological specialization may cause contemporary range shifts to lag behind changes in climate and resources. Furthermore, it indicates that recent changes in climate and human land use cause biotic homogenization,

where specialists are outperformed and replaced by generalists." (Authors)] Address: Olsen, K., Research and Collections, Natural History Museum Aarhus, Wilhelm Meyers Allé 10, DK-8000 Aarhus, Denmark. Email: kent@nathist.dk

**20197.** Onah, I.E.; Ajanwachukwu, O.J.; Ubachukwu, P.O. (2022): Comparison of physico-chemical parameters with macroinvertebrate and vertebrate fauna of Lake Ogelube and Lake Ojii, Opi-Agu, south-eastern Nigeria. *African Journal of Aquatic Science*: (in English) ["The physico-chemical parameters of water provide crucial information on the condition of a waterbody at a point in time. Physico-chemical parameters determine the primary and secondary productivity of an aquatic ecosystem. Data on water temperature, pH, turbidity, water depth, total dissolved solids, total hardness, biochemical oxygen demand, dissolved oxygen, chloride, nitrate and phosphate, together with information on the aquatic macroinvertebrate and vertebrate species composition and abundance were collected for two Nigerian lakes, Lake Ogelube and Lake Ojii at Opi-Agu. The physico-chemical parameters were analysed using standard methods. Macroinvertebrate and vertebrate (Actinopterygii and Amphibia) species composition and abundance in the lakes were correlated with the physico-chemical parameters. Temperature, depth, biochemical oxygen demand and phosphate were significantly higher in Lake Ojii than in Lake Ogelube, while pH, turbidity and nitrate were significantly higher in Lake Ogelube ( $p < 0.05$ ). In total, 1 442 animals were collected from the lakes of which 1 101 were macroinvertebrates and 341 vertebrates. The family Libellulidae (Order: Odonata) and the species *Coptodon zillii* (synonym: *Tilapia zillii*) (Gervais, 1848) (Perciformes: Cichlidae) were the most abundant macroinvertebrate and vertebrate taxa, respectively. Libellulidae were negatively associated with biochemical oxygen demand, temperature, turbidity, phosphate and chloride and *Coptodon zillii* was positively associated with dissolved oxygen." (Authors)] Address: Onah, I.E., Dept of Zoology and Environmental Biology, University of Nigeria. Email: ikechukwu.onah@unn.edu.ng

**20198.** Onishko, V.V.; Koterin, O.E. (2022): *Ischnura elegans malikovae* subspecies nova (Odonata, Coenagrionidae) from the Far East of Eurasia, with discussion of other possible subspecies. *Zootaxa* 5120(4): 573-585. (in English) ["*Ischnura elegans malikovae* ssp. n. is described from the southern Far East of Russia (type locality: Russia, Primorskiy Krai, Pozharskiy District, Luchegorsk Town, the Luchegorsk Reservoir). Reconsideration of literature suggested it to broadly range in East Asia including Korea, Japan (Hokkaido and northernmost Honshu), north and north-east China and to be hitherto mistaken for *Ischnura elegans elegans* (Vander Linden, 1820) in Japan. The main difference of the new subspecies from *I. e. elegans* is the male paraprocts that are about 1.5 times shorter and scarcely diverging in dorsal view and directed obliquely upward in lateral view. *Ischnura elegans ebneri* Schmidt, 1938 is reconsidered as the presumably Anterior Asian subspecies characterised by scarcely or not diverging male paraprocts in dorsal view, versus strongly diverging in *I. e. elegans*. Based on scarce information in the literature, *I. elegans marquardtii* Schmidt, 1938 is supposed to be a junior synonym of *I. elegans ordosi* Bartenev, 1912 stat. rev., which is suggested to be an eastern Central Asian subspecies characterised by an incised prothoracic process in males." (Authors)] Address: Kosterin, O.E., Institute of Cytology and Genetics, Siberian Branch, Russian Academy of Sciences, Lavrentiev Ave 10, RUS-630090 Novosibirsk, Russia. **20199.** Onishko, V.V.; Kosterin, O.E.; Blinov, A.G.; Sukhikh, I.S.; Ogunleye, A.T.; Schröter, A. (2022): *Aeshna soneharai* Asahina, 1988, stat. rev., bona species – an overlooked member of the European fauna? (Odonata: Aeshnidae). *Odonatologica* 51(1-2): 111-145. (in English) ["Specimens and observations of *Aeshna mixta* Latreille, 1805, obtained in 2021 from Moscow and Moscow Province, Russia, lead us to the conclusion that what used to be regarded as this well-known Palaearctic species in fact represented two species. They differ in details of the abdominal maculation, including the conspicuous dorsal mark on the second segment, the relative length of the male epiproct, and some other characters. In addition, they also differ in the mitochondrial COI and COII gene sequences (with one odd specimen of *A. mixta* from Balkan Peninsula), but not in the ITS2 sequence. A potential hybrid male was observed. Analysis of photographic observations on the website "iNaturalist.org" suggests that the true *A. mixta* ranges in North Africa, Europe, the Caucasus, and West Asia, and extends north-east to South Ural and south-eastern Kazakhstan and east to Kashmir. The name available for the second species is *Aeshna soneharai* Asahina, 1988 stat. rev., bona species, described from Japan in subspecies rank. This species ranges in East Europe west to the longitude of Moscow and Voronezh, in Ural, Kazakhstan, Siberia, West China, Mongolia, the Far East including Russia, Northeast China, Korea, and Japan. Both species co-occur in Russia between the Don River and South Ural, in Kyrgyzstan and in south-eastern Kazakhstan. The iNaturalist photographs suggest that outside their contact zone, both species (especially *A. mixta* in southern Europe) exhibit some variation with respect to almost all characters that are diagnostic in Moscow Province but, on the other hand, are still identifiable using most of these characters. *Aeshna soneharai* seems not to share the swarming behaviour and the migratory abilities of *A. mixta*. The enigmatic *Aeshna lucia* Needham, 1930, is reconsidered a doubtful species rather than a synonym of *A. mixta*." (Authors)] Address: Kosterin, O.E., Institute of Cytology and Genetics, Siberian Branch, Russian Academy of Sciences, Lavrentiev Ave 10, RUS-630090 Novosibirsk, Russia. **20200.** Orłowska, A.B. (2022): Study of biocompatibility of nanostructured materials on in vitro and in vivo models. PhD thesis, Departament de Química Física i Inorgànica, Universitat Rovira i Virgili, Tarragona: 361 pp. (in English) ["Biomaterials play a substantial role in the health care industry. Each year, the number of medical devices used in humans is estimated to be around 1.5 million individual devices, according to the World Health Organization, with about 10 000 types of generic device groups available worldwide. As new devices emerge, the topic of the biocompatibility of these materials becomes more relevant. This thesis studies biocompatibility of biomaterials and their interaction with tissues and cells combining in vitro and in vivo models. The studied biomaterials are classified in synthetic (polymers, silicon, titanium, and alloys) and nature-derived biomaterials, which in turn, classify in xenogenic, derived from natural materials but foreign for the organism and autologous biomaterials, derived from the tissues of the same organism. In the case of synthetic materials, it was shown how different functionalization strategies of surfaces (in particular, the effect of protein coating and surface topography) affect mammalian cell response. Autologous biomaterials were represented by platelet rich fibrin (PRF), derived from the blood of the patient. Their potential as implantable system was studied in vitro and in vivo. PRF matrixes were characterized by growth factors storage capacity and release as

well as their cellular retention. In regard to xenogenic biomaterials, cell permeation and liquid absorption into different collagen membranes were studied *in vitro*, while evaluation of the host's tissue response was studied with *in vivo* implantation model. Results show that all tested collagen membranes were biocompatible, showcasing the formation of new blood vessels regardless of the presence of multinucleated giant cells." (Author) The study includes references to Odonata.] Address: Orłowska, Anna Barbara, Departament de Química Física i Inorgànica, C/ Marcel·lí Domingo s/n, Edifici N4, 43007 Tarragona, Spain

**20201.** Orr, A.G.; Pricexy, B.W. (2022): A description of the larva of *Matronoides cyaneipennis* Förster, 1897 from northern Borneo (Odonata: Calopterygidae). *Odonatologica* 51(1-2): 157-165. (in English) ["We describe the larva of *Matronoides cyaneipennis* Förster, 1897, based on an incomplete, dried F0 specimen collected at Mt Kinabalu, Sabah, in 1964, and held at the Natural History Museum, London. Since its collection nearly 60 years ago no other specimen has come to light despite considerable searching of its habitat. Identification is by supposition, but given its provenance the identity of the specimen is not in doubt. All diagnostic features remain intact. The larva is compared with those of the related genus *Neurobasis*, especially the potentially syntopic *N. longipes* from which it differs markedly." **20202.** Pacioglu, O.; Dutu, L.; Dutu, F.; Pavel, A.B. (2022): Habitat preferences and trophic interactions of the benthic invertebrate communities inhabiting depositional and erosional banks of a meander from Danube Delta (Romania). *Global Ecology and Conservation* 38 e02213: 15 pp. (in English) ["River restoration and biodiversity conservation programs require an in-depth knowledge of the influence that sediment composition and hydraulic stress have on invertebrate fauna composition and spatial distribution, as well as on nutrients cycling and food webs structure and functionality. Compared to low-order streams, the traditional focus of river ecology, the knowledge of these ecosystem properties of the meanders developed along large, lowland watercourses, is currently insufficient. The present study assessed the ecological preferences and the trophic interactions of the benthic invertebrate communities inhabiting erosional and depositional banks developed within a meander of the River Danube flowing through its delta (Danube Delta, Romania). The invertebrates from two mesohabitats, the concave (i.e. erosional) and convex (i.e. depositional) banks developed in the apex region of the meander were sampled quantitatively and qualitatively, along with sediment samples for assessing the grain-size characteristics and hydrodynamic parameters (i.e., critical shear stress, the Reynolds number, the critical velocity and Shields parameter). For assessing their mesohabitat preferences, quantitative samples were taken from both banks, whereas for inferring the trophic interactions, stable isotopes of  $\delta^{15}\text{N}$  and  $\delta^{13}\text{C}$  were measured from qualitative samples, comprising both invertebrates and basal resources. The results showed that increased siltation with fine sediments in the depositional bank led to a community dominated by chironomids, oligochaetes and bivalves, whereas the opposite bank comprised crayfish, caddis fly larvae and amphipods with a preference for coarser sediments. The  $\delta^{13}\text{C}$  of most consumers revealed that the dominant forms of carbon entries in the analysed food webs were photosynthetic based, whereas certain snails, chironomids and basal resources from the

depositional bank were  $\delta^{13}\text{C}$  depleted ( $\delta^{13}\text{C}$ : -35 to -39 ‰). Such low ratios for  $\delta^{13}\text{C}$  (mean  $<-35$  ‰) reflected the potential of carbon entry through the base of depositional food web as a result of methane oxidation at sediment-water interface (i.e. chemosynthesis), induced by the fine sediments deposition that could have favoured the methane production. Grazing methaneoxidising bacteria in the depositional meander bank could have provided the primary consumers with up to 50 % and the omnivores and predatory invertebrates with up to 30 % of their carbon, which could represent an important subsidy from an additional, chemosynthetic source. The impact of a supplementary carbon input was further reflected in increasing depositional food web basal niche diversity, which led to distinct trophic niches and lower interspecific competition of consumers compared to the erosional bank of the meander." Padilla-Morales, B.; Comejo-Páramo, P.; García-Miranda, O.; Carrillo Muñoz, A.I.; Lopez, A.N.; Castillo-Morales, D.L.; Barragán, G.W.; Urrutia, A.O.; Serrano-Meneses, M.A. (2022): Fast species diversification among dragonflies (Anisoptera: Odonata: Insecta) inhabiting lentic environments regardless of wing pigmentation. *Ecological Entomology* 47(3): 314-322. (in English) ["1. In dragonflies, species richness shows a marked variation between lineages. Species diversification in this lineage has been linked with habitat variation, but the role of other factors, such as wing pigmentation, arguably one of the most conspicuous traits in dragonflies, have not yet been explored. 2. In this study, using novel methodology that takes into account state-dependent speciation, extinction models, and ancestral reconstruction, we investigate the role of wing pigmentation (present/absent) in conjunction with habitat variation (lentic/lotic), to unveil the drivers of species diversification in dragonflies. 3. We found that wing pigmentation is associated with a marginal increase in diversification compared to unpigmented lineages. Inhabiting a lentic habitat is associated with higher diversification rates. When considering both factors in a single model, lentic environments are associated with higher diversification compared to lotic habitats regardless of pigmentation status. In contrast with results across the whole tree, in lotic environments, wing pigmentation is associated with marginally higher diversification rates compared to non-pigmented species. Ancestral state reconstruction revealed that the last common ancestor of dragonflies was most likely non-pigmented and lived in lotic habitats. 4. Our study provides evidence that wing pigmentation in conjunction with habitat has an important influence on dragonfly species diversification, with habitat being a better differentiator than wing pigmentation." **20207.** Peng, L.; Pan, T.; Zheng, M.; Song, S.; Su, G.; Li,

Q. (2022): Kinematics and aerodynamics of dragonflies (*Pantala flavescens*, Libellulidae) in climbing flight. *Frontiers in Bioengineering and Biotechnology* 10:795063. doi: 10.3389/fbioe.2022.795063: 14 pp. (in English) ["This study presents a detailed analysis of dragonflies' climbing flight by integrating highspeed photogrammetry, three-dimensional reconstruction, and computational fluid dynamics. In this study, a dragonfly's climbing flight is captured by two high-speed cameras with orthogonal optical axes. Through feature point matching and threedimensional reconstruction, the body kinematics and wing kinematics of 22 dragonflies in climbing flight are accurately captured. Experimental results show that the climbing angles ( $\zeta$ ) are distributed from 10° to 80° and are concentrated within two ranges, 60°–70° (36%) and 20°–30° (32%), which are defined as large angle climb (LAC) and small angle climb (SAC), respectively. In order to study the aerodynamic mechanism of the climbing flight based on the biological observation results, the kinematic parameters of the dragonfly during LAC and SAC are selected for analysis and numerical simulation. The results show that the climbing angle  $\zeta$  and wing kinematics are related. There are considerable differences in wing kinematics during climbing with different  $\zeta$ , while the wing kinematics are unchanged during climbing with similar  $\zeta$ . With the increase in  $\zeta$ , the phase difference ( $\dot{\epsilon}$ ) between the forewing and the hind wing decreases and the amplitude of the positional angle ( $\epsilon_{\text{mean}}$ ) of the hind wing increases, while  $\epsilon_{\text{mean}}$  of the forewing remains almost unchanged. Through numerical simulation of LAC and SAC, it can be found that during the climb with different  $\zeta$ , the different wing kinematics have a significant influence on aerodynamic performance. During SAC, the increase in  $\dot{\epsilon}$  and the decrease in  $\epsilon_{\text{mean}}$  of the hind wing weaken the aerodynamic disturbance of the forewing by the vortex wing of the hind wing, thus improving the flight efficiency." **20212.** Pires, M.M.; Sahlén, G.; Périco, E. (2022): Agricultural land use affects the heterogeneity of Odonata communities in the Brazilian Pampa. Journal of Insect Conservation 26: 503-514. (in English) ["Farming expansion has negative impacts on freshwater biodiversity. However, the effects of agricultural land use are not similar across taxa and depend on local context. For instance, the impacts of agricultural expansion are understudied in the Neotropics (one of the leading regions in cropland expansion). Knowledge of the effects of agricultural land use on aquatic insects from South American subtropical grasslands (Pampa) is even more incipient. We tested whether landscape modification related to increased agricultural land use was associated with taxonomic homogenization in odonate communities in waterbodies in the Brazilian Pampa. Odonates were collected in waterbodies differing in the main land-use class in their surroundings (cropland or grassland). Cropland and grassland sites differed with respect to their abiotic conditions (water chemistry) and species composition of Odonata. Additionally, we found higher variation in the composition of Odonata (and suborders Anisoptera and Zygoptera separately) in grassland than cropland sites. We found an

interplay between agricultural and grassland land uses and the variation in the composition of odonate communities in the Brazilian Pampa. Specifically, landscape modification by agriculture modified the abiotic conditions in the waterbodies, which may have favored species able to establish as larvae under harsher environmental conditions. Implications for insect conservation: We suggest that the maintenance of mixed-grassland and cropland land uses in the fields adjacent to waterbodies can limit the negative effects of agricultural encroachment on Odonata communities with respect to biotic homogenization in the Brazilian Pampa." **20214.** Priyadarshana, T.S.; Lee, M.-B.; Ascher, J.S.; Qiu, L.; Goodale, E. (2022): Crop heterogeneity is positively associated with beneficial insect diversity in subtropical farmlands. Journal of Applied ecology 58(12): 2747-2759. (in English) ["1. Increasing crop configurational heterogeneity – smaller crop fields with more field margins – has been repeatedly found to support farmland biodiversity. But research on compositional crop heterogeneity – the number and evenness of crop types – has usually shown only weak effects. However, much of this research has been conducted in large-scale temperate agroecosystems. 2. We examined smallholder subtropical agroecosystems in southern China to assess the effects of crop heterogeneity on beneficial insect biodiversity. In addition to pollinators (bees, apid and vespid wasps, butterflies), we studied dung beetles and dragonflies/damselflies, which are not usually considered in cropland heterogeneity studies, but are abundant in these multi-functional agroecosystems. We sampled these taxa in 468 transects placed inside 52 farms across

three seasons (summer, spring, winter), collecting data on 27,245 insects belonging to 160 species. 3. We found a strong positive effect of crop compositional heterogeneity (measured by Shannon-Wiener index) on dung beetle and dragonfly/damselfly diversity. Bees/wasps and butterflies, conversely, were positively affected by crop configurational heterogeneity (measured by cumulative field margin length). 4. Field margin type, categorized by the structure of the dominant crop types, was consistently an important explanatory variable, with weedy margins having high insect diversity. The presence of a vegetable crop on one side of the field margin, compared to non-vegetable monocultures on both sides, increased diversity in 3/4 taxon-season comparisons made for rice, and 6/9 comparisons made for sugarcane or corn. 5. Synthesis and applications. We demonstrate that crop compositional heterogeneity can support insects that respond to differences among crop types, including taxa that play a key role in nutrient cycling (dung beetles) and natural pest control (dragonflies/damselflies). Incorporating structurally diverse crops into monoculture Asian agroecosystems can reduce the adverse effects these intensive systems have on beneficial insects, and increase crucial ecosystem services." **20216.** Raczynski, M.; Stoks, R.; Johansson, F.; Barton, K.; Sniegula, S. (2022): Phenological shifts in a warming world affect physiology and life history in a damselfly. *Insects* 2022, 13, 622. <https://doi.org/10.3390/insects13070622>: 13 pp. (in English) ["Simple Summary: Climate warming affects phenological events of cold-blooded organisms. In this analysis we studied, in laboratory conditions, the impact of warming and hatching dates on key life history and physiological traits in a cannibalistic damselfly, *Ischnura elegans*. Larvae were reared in groups from hatching to emergence through one or two growth seasons, depending on the voltinism. Larvae were equally divided by hatching dates (early and late) and temperature treatment (current and warming). Early and late hatched groups were not mixed. Despite no difference in cannibalism rate between different hatching dates and temperatures, early hatched larvae reared under warming had elevated immune function

measured as phenoloxidase (PO) activity. This increased PO activity was not traded off with life history traits. Instead, age and mass at emergence, and growth rate were mainly affected by temperature and voltinism. Our results confirm the importance of phenological shifts in a warming world for shaping physiology and life history in a freshwater insect. Abstract: Under climate warming, temperate ectotherms are expected to hatch earlier and grow faster, increase the number of generations per season, i.e., voltinism. Here, we studied, under laboratory conditions, the impact of artificial warming and manipulated hatching dates on life history (voltinism, age and mass at emergence and growth rate) and physiological traits (phenoloxidase (PO) activity at emergence, as an indicator of investment in immune function) and larval survival rate in high-latitude populations of the damselfly *Ischnura elegans*. Larvae were divided into four groups based on crossing two treatments: early versus late hatching dates and warmer versus control rearing temperature. Damselflies were reared in groups over the course of one (univoltine) or two (semivoltine) growth seasons, depending on the voltinism. Warming temperature did not affect survival rate. However, warming increased the number of univoltine larvae compared to semivoltine larvae. There was no effect of hatching phenology on voltinism. Early hatched larvae reared under warming had elevated PO activity, regardless of their voltinism, indicating increased investment in immune function against pathogens. Increased PO activity was not associated with effects on age or mass at emergence or growth rate. Instead, life history traits were mainly affected by temperature and voltinism. Warming decreased development time and increased growth rate in univoltine females, yet decreased growth rate in univoltine males. This indicates a stronger direct impact of warming and voltinism compared to impacts of hatching phenology on life history traits. The results strengthen the evidence that phenological shifts in a warming world may affect physiology and life history in freshwater insects." **20217.** Raczyński, M.; Stoks, R.; Sniegula, S. (2022): Warming and predation risk only weakly shape size-mediated priority effects in a cannibalistic damselfly. *Scientific Reports* 12(17324): 12 pp. (in English) ["1. Differences in hatching dates can shape intraspecific interactions through size-mediated priority effects (SMPE), a phenomenon where bigger, early hatched individuals gain advantage over smaller, late hatched ones. While SMPE may be important for population dynamics, to what extent and how these are affected by key environmental factors such as warming and predation risk imposed by top predators remains unclear. 2. In a laboratory experiment, we studied effects of warming (low and high temperature) and predation risk (presence and absence of predator cues of perch) on SMPE in life history and physiological traits in the cannibalistic damselfly *Ischnura elegans*. We induced SMPE by manipulating hatching dates, thereby creating four groups: non-mixed phenology early (E) and late (L) hatchers, and mixed phenology early (E+L) and late (L+E) hatchers. 3. We found strong SMPE for survival and emergence success, with the highest values in E+L larvae and the lowest values in L+E larvae. Neither temperature nor predator cues affected SMPE for these two life history traits. The other life history traits (development rate and mass at emergence) did not show SMPE, but were affected by temperature and predator cues. 4. SMPE was found for protein content, but only in the high temperature treatment. The other physiological

traits (immune function measured as phenoloxidase activity and fat content) showed fixed expressions across treatments, indicating decoupling between physiology and life history. 5. The results underline that SMPEs are trait-dependent, and only weakly affected by temperature and predation risk." (Authors)] Address: Sniegula, S., Inst. Ochrony Przyrody Polskiej Akademii Nauk, al. SAARC Journal of Agriculture 20(1): 171-183. (in English) ["Pesticide application against insect pest infestation is environmentally unsafe and costly. An attempt was taken to evaluate the solar light trap as ecofriendly and cost-effective approach in Transplanted Aman rice (BRRI dhan32) field at Barhatta Upazila (Sub-district) in Netrokona district of Bangladesh. It was found that rice pest like Rice yellow stem borer, Rice leaf roller, Green leaf hopper, Brown plant hopper, Rice leaf miner, Rice gall midge, White leafhopper, Rice bug, Rice ear cutting caterpillar, White-backed planthopper, Rice caseworm, Grasshopper, Rice skipper and Rice beetle were the major insects that captured under the solar light traps. Some beneficial insects were also attracted by the trap these were Ladybird beetle, Water scavenger, Giant water bug, Ground beetle, Rove beetle, Damselfly. All the harmful and the beneficial insects were belonging the order of Lepidoptera, Hemiptera, Orthoptera, Coleoptera, Diptera and Odonata ["*Nehalennia gracilis*"]. Though the mean yield of rice was statistically insignificant in both fields, the light trap installed fields required the less frequency of pesticides than the control fields which ultimately rendered the low pesticides cost in a great extent. On an average 1,034 BDT was reduced in per hectare." (Authors)] Address: Mondal, M.F., Dept of Agricultural Extension, Ministry of Agriculture, Bangladesh. Email: mondalmf.entom@sau.ac.bd

**20220.** Rengifo-Correa, L.; Rocha-Ortega, M.; Córdoba-Aguilar, A. (2022): Modeling mosquitoes and their potential odonate predators under different land uses. EcoHealth 19(3): 417-426. (in English) ["To efficiently face the accelerated landscape transformation and its consequences in restructuring biotic communities and ecosystem services, one

first question is which regional systems deserve prioritization for empirical assessments and interventive strategies. For the particular case of vector-borne disease control, we should consider generalist predators exhibiting differential responses to land-use change, as is the case of odonate insects. Thus, our aim was to infer land uses in Mexico where odonates (i.e., damselflies and dragonflies) might have some potential to predate mosquitoes of medical relevance. The study area included the hydrological basins of central Mexico. We modelled 167 species of odonates, four species of mosquitoes, and 51 land-use categories. Inferring spatial co-occurrence patterns from data mining and complex networks, we identified: (1) the ecological network of odonates and mosquitoes and (2) the land uses shared by these two groups. We inferred that 34% of odonate species co-occur with mosquitoes of medical relevance mainly in some preserved—mountain mesophyll cloud forest, high evergreen rainforest, and low tropical dry forest—but also in highly modified—human settlements, irrigation-based and pastures crop fields—land uses with strong human presence. Our findings highlight the relevance of community-regional studies for understanding the public health consequences of landscape change." **20221.** Renner, S.; Périco, E.; Schmidt Dalzochio, M.; Sahlén, G. (2022): The balance of common vs. rare: a study of dragonfly (Insecta: Odonata) assemblages in the Brazilian Pampa biome. Neotropical Biodiversity 8(1): 188-199. (in English) ["We surveyed dragonflies (Odonata) at 87 sites in the anthropologically modified Pampa biome of southern Brazil to evaluate how regionally rare and common species form species assemblages in habitats with different water physiochemistry, habitat structures, and other environmental variables. We classified 9 out of the 90 species encountered as regionally common and 59 as regionally rare. A discriminant analysis confirmed that localities with only a few common species were characteristic in the set of rare species present, while localities housing more common species showed no clear pattern. A PCA revealed that a subset of the common species were strongly positively associated with water temperature, turbidity, dissolved O<sub>2</sub> and pH but negatively associated with desertification. In contrast, rare species were positively associated with grassland habitat, but negatively with agriculture, salinity, and conductivity. In general, the associations of the rare species were weaker than those of common species. Finally, a correlation suggested that sites with six or more common species present had a reduced number of rare species compared to sites with fewer common species. It is possible that common species reduce the available niche space for weaker competitors among the rare species. We conclude that the original species assemblages in the biome may have been species poor with few regionally common species. Current anthropogenic change has increased the number of common species, which in turn has negative effects on the survival possibilities of rare species." **20225.** Rodríguez-Tapia, G.; Prieto-Amparán, J.A.; Córdoba-Aguilar, A. (2022): Linking potential habitats of Odonata (Insecta) with changes in land use/land cover in Mexico. *Eur. J. Entomol.* 119: 272-284. (in English) ["Land use/land cover change (LULCC) is a major threat that affects the viability of insect populations worldwide yet our estimates of such effects are usually poor. We analysed how LULCC affected the distribution of 49 species of dragonflies and damselflies in the south-central zone in Mexico during the period 2006-2012. For this, we mapped the potential species richness using ecological niche models in order to analyse predicted future changes and determined the effect of LULCC on the current and future habitats of Odonata. We also estimated current incidence of deforestation and projected its effect to 2050 using the Dinamica-EGO program. Having predicted the level of deforestation in the year 2050, we then compared current vs. expected species richness and the factors that determine it. First, roads and urban areas turned out to be the most important drivers of LULCC in our analysis. Second, deterioration occurred at all sites, but species richness remained high despite considerable habitat fragmentation. Third, there is likely to be a high species turnover rate (i.e. a high species richness, but composed of different species) even in areas where there are significant changes in the vegetation. Our work illustrates both a resilience of Odonata to LULCC and provides a useful method for measuring the effects of LULCC on insects." **20226.** Ryu, S.; Zhang, H.; Salcedo, M.K.; Socha, J.J.; Pass, G. (2022): Transient perfusion through a microfluidic dragonfly wing vein model. *Bulletin of the American Physical Society*, 75th Annual Meeting of the Division of Fluid Dynamics. Sunday–Tuesday, November 20–22, 2022; Indiana

Convention Center, Indianapolis, Indiana. Session L04: Animal Flight: Flying Insects II. 8:00 AM–9:57 AM, Monday, November 21, 2022. Room: 131: (in English) [Verbatim: Insect wings include a network of tubular veins through which hemolymph (blood) flows to provide the sensory organs and other tissues with water and nutrients and to remove waste products. Thus, hemolymph flow through veins is important for stability and functionality of the fragile wing blade. However, the perfusion through wing venation has been poorly studied because tracing hemocytes (blood cells) in veins of living specimen provides limited information about flow patterns. To characterize transient perfusion through complex wing venation, we created a microfluidic wing vein model of the dragonfly, *Anax junius*. Hemolymph flow was simulated by injecting red dye into the device filled with water at a range of flow rates. Visualized perfusion patterns suggested that the perfused area in the device logarithmically increased with time. When water was injected into the device filled with the dye, perfusion occurred slower with different patterns, and the time dependence of the perfused area was not logarithmic. The observed difference suggests that perfusion does not occur uniformly throughout the wing vein network.] Address: not stated

**20227.** Sadasivan, K.; Nair, V.P.; Samuel, K.A. (2022): The dragonflies and damselflies (Insecta: Odonata) of Shendurney Wildlife Sanctuary, southern Western Ghats, India. *Journal of Threatened Taxa* 14(6): 21213-21226. (in English) ["The odonate diversity of Shendurney Wildlife Sanctuary, southern Western Ghats (WG) of Kerala state, is discussed in this paper. A total of 181 species belonging to 87 genera and 14 families have been compiled for Kerala and this includes 68 Western Ghats endemics. A total of 116 species of odonates including 33 endemics were recorded for the region. A total of 41 damselflies (Zygoptera) and 75 dragonflies (Anisoptera) were recorded for the sanctuary. Shendurney thus harbours 56.04 % of WG and 64.08 % of the odonate diversity of Kerala. In addition, this includes 48.52% of Kerala and 41.25 % of endemic odonates of Western Ghats. About 29% of all the species recorded for the Shendurney are endemic to WG. With respect to IUCN Red List of Threatened Species, one species is 'Endangered', three 'Vulnerable', two 'Near Threatened', 84 'Least Concern', 20 'Data Deficient', and six species whose IUCN Red List status was not assessed. Family Libellulidae (41 species) dominated the odonate diversity, followed by Coenagrionidae (15 species) and Gomphidae (13 species). Regarding the occurrence status, we found that 11 species were Very Common, 42 species were found to be Common, 34 species Not Rare, 10 species were Rare, and 19 species were Very Rare inside the sanctuary. None of the species listed is protected under the Indian Wildlife Protection Act 1972." **20229.** Sadler, D.; Chelmick, D. (2022): Observations on a new colony of *Ischnura pumilio* (Charpentier) (Scarce Blue-tailed Damselfly): the first record for West Sussex. *Journal of the British Dragonfly Society* 38(1): 65-83. (in English) ["In June 2020 *Ischnura pumilio* (Scarce Blue-tailed Damselfly) was recorded for the first time in West Sussex. This was not an isolated record; a colony had become established on a recently cleared wetland habitat near Sompting. This paper describes the find and provides observations of the colony over the summers of 2020 and 2021. The habitat has been shown to have exceptionally high mid-day water temperatures compared to surrounding habitat. The management regime for the habitat has meant that the area has proved to be transitional for the species. Particular features of this transitional population are: The population appears to have two generations. The female numbers are much lower than in permanent sites especially in the second year, 2021. The androchrome female, which is rare in Europe, has been observed frequently. Males appear to be much more loyal to the site and remain even when the females have mostly disappeared. Males can be individually recognised by the patterning on the tailight. Is this a factor in sexual attraction? There was one Observation of oviposition underwater, which is extremely rare in this genus." (Authors)] Address: Sadler, D., 135 Gordon Road, Shoreham-by-Sea, West Sussex BN43 6WF, UK. **20233.** Sandall, E.L.; Pinkert, S.; Jetz, W. (2022): Country-level checklists and occurrences for the world's Odonata (dragonflies and damselflies). *Journal of Biogeography* 49(8): 1586-1598. (in English) ["Aim: Biogeographical inference and assessments of species' threat status and trends depend on comprehensive information on the current geographical distribution of species. Even country-level presences remain poorly known for many insect species and consistent global overviews for those species are missing. Here we integrate information from literature checklists, point occurrences, and identify potential species range gaps to provide a database of country-level checklists of dragonfly and damselfly species and a useful baseline for global biogeographical assessment and for assessing remaining gaps in taxonomic and spatial knowledge. Location: Global. Taxon: Odonata (damselflies and dragonflies). Methods: Our database of checklist information contains country-level species distribution information from 491 literature sources, with a focus on checklist data from 1990 to 2021 to reflect the present taxonomic and country boundaries. Additionally, we apply a novel method to interpolate potential species-country combinations missing from the literature and point data by generating a list of species present in >50% of the surrounding countries. Results: Of the 6,322 globally recognized odonate species, taxonomically harmonized literature checklist records and quality-controlled point occurrence data address 6,076 and 4,170 species, respectively. Our compilation provides a total of 31,569 unique species-country combinations, with 23,239 uniquely provided by

literature checklist and 2,031 point occurrence data, respectively. Main Conclusions: This odonate country checklist dataset provides a resource for scientists and conservation practitioners to examine questions related to baseline odonate species richness, distributions, regional conservation, and gaps in taxonomic and spatial data coverage. The combined literature and point occurrence country-level information provide the most comprehensive data available to date on the global distribution of Odonata. Our results show that checklist and point occurrences are concordant in well-studied regions and that literature data are of complementary value in tropical and species-rich countries." **20234.** Santos, L.R.; Rodrigues, M.E. (2022): Land uses for pasture and cacao cultivation modify the Odonata assemblages in Atlantic Forest Areas. *Diversity* 2022, 14, 672. <https://doi.org/10.3390/d14080672>: 14 pp. (in English) ["Tropical forests such as the Atlantic Forest are under constant threats from the impact of human activities, mostly being caused by the loss of native forest areas for other land uses. This study aimed to evaluate the effect of changes in land use for pasture and cacao cultivation on the richness and composition of Odonata assemblages in comparison to native forest areas. We also evaluated the species as possible indicators of these different land uses. In total, 64 streams were sampled in southern Bahia, Brazil. A total of 84 species were recorded. The results indicated that changes in land use modify the richness and composition of Odonata assemblages. Regarding composition, our results indicated a difference among the assemblages in the three land use areas and that the native areas maintain more stable assemblages. According to the indicator species analysis, 13 species were recorded as possible bioindicators for different land uses. Changes in aquatic ecosystems and their surroundings caused by different land uses a select group of different species groups, modifying Odonata diversity among these areas. Notably, land uses that maintain a certain integrity of the environment, as in the case of cacao cultivation, are the best alternatives for conserving Odonata biodiversity in comparison with pasture." **20235.** Saul, A. (2022): Effects of PFOS on the behavior, growth, emergence, and predation susceptibility of larval mosquitoes (*Culex quinquefasciatus*). M.Sc. thesis, Bowling Green State University, Biological Sciences: 60 pp. (in English) ["Perfluorooctanesulfonic acid (PFOS) is a member of a group of synthetic chemicals called PFAS, or per-/polyfluoroalkyl substances. These chemicals are commonly used in the creation of non-stick cookware, fire-extinguishing foams, and waterproof coatings due to their heat, water, and oil resistance. PFAS chemicals are very persistent in the environment, but not much is known about their direct effects on aquatic invertebrates and their ecosystems. In this thesis, I examined the survival, behavior, development, and predation susceptibility of mosquito larvae *Culex quinquefasciatus* exposed to various concentrations of PFOS, ranging from 0 to 600 µg/L. PFOS exposure resulted in reduced larval survival, with 50% larval death in 48 hours occurring at a concentration of 310 µg/L PFOS. Mosquito larvae exposed to PFOS experienced significantly reduced developmental success and reached adulthood at a

slower rate compared to control larvae. Exposure to PFOS over time also resulted in delays in reaction to prodding stimuli, which were meant to simulate a predator attack. The durations of the subsequent reactions were significantly longer in mosquito larvae exposed to PFOS over time. Larvae exposed to PFOS also spent more time at the bottom of the water column, rather than at the surface where respiration takes place. Exposing mosquito larvae to PFOS prior to immersion with predators did not result in any differences in larval predation by unexposed damselfly naiads (genus *Ischnura*). Overall, PFOS does impact mosquito larvae survival, behavior, and development. This could be the case for other aquatic invertebrates as well, leading to significant food web implications." (Author)] Address: not stated

**20236.** Schifani, E. (2022): First report of underwater oviposition by the island bluetail damselfly, *Ischnura genei* (Zygoptera, Coenagrionidae). *Natural History Sciences, Milano*: 73-75. (in English) ["Among odonates that exhibit endophytic oviposition, a few, mostly damselflies, are known to be able to perform underwater oviposition. Among them, just a few species do so very frequently. Here I report the first observation of underwater oviposition for the damselfly *Ischnura genei*, which becomes the eighth species of its genus known to adopt this strategy after *I. asiatica*, *I. aurora*, *I. elegans*, *I. graellsii*, *I. hastata*, *I. nursei*, and *I. verticalis*. The reasons why these species or other odonates choose this particular mode of oviposition on rare occasions are not yet known, although a number of possible costs and benefits have been proposed." **20237.** Sedvall, E.; Fick, J.; Pettersson, C.; Hedeland, M. (2022): Pharmaceuticals are identified in insects in River Fyris – A study with both tandem quadrupole and quadrupole-time-of-flight mass spectrometry. *Environmental Advances* 8, July 2022, 100194: 8 pp. (in English) ["Highlights: • 33 different pharmaceuticals were detected in insects in River Fyris, Uppsala, Sweden. The most common drug classes were antidepressants, psycholeptics and antihistamines. The determined internal concentrations were up to 260 ng/g. Both UHPLC-tandem quadrupole MS/MS and UHPLC-qToF-MS/MS were used. Abstract: The internal concentrations of active pharmaceutical compounds in insects/macrobenthos in River Fyris, Uppsala, Sweden, have for the first time been investigated. Specimen of backswimmer, caddisfly larva, damselfly larva, mayfly larva and water louse were caught in the river downstream a wastewater treatment plant. After homogenization and extraction, analysis was carried out with Ultra-High Performance Liquid Chromatography – Electrospray – Tandem Mass Spectrometry (UHPLC-ESI-MS/MS) using both a tandem quadrupole (QqQ) and a quadrupole-time-of-flight (qToF) mass spectrometer. A combined qualitative/quantitative screening method for 89 pharmaceutical compounds in the selective reaction monitoring mode was applied to the samples using the QqQ instrument. Thirty-three different drugs were detected and quantified in the macroinvertebrate samples, covering a wide range of pharmacological classes, the most common being antidepressants, psycholeptics and antihistamines. Drug concentrations up to 260 ng/g (for tetracycline) were determined. A subset of thirteen compounds were selected for a complementary qualitative UHPLC-qToF-MS/MS analysis. This way, the confidence in the substance identifications was significantly strengthened by the availability of full scan high-resolution spectra and accurate

mass measurements. This is the first study demonstrating the uptake of pharmaceuticals in water-living macroinvertebrates in Sweden. Since these organisms are in the lower part of the food chain, pharmaceuticals might accumulate in predators leading to ecotoxicological effect at higher trophic levels. Macroinvertebrates might be promising indicator organisms for pharmaceutical pollution. ...The invertebrates collected were backswimmers (*Notonecta* sp.), damselfly larvae (*Zygoptera* sp.), caddisfly larvae (*Trichoptera* sp.), mayfly larvae (*Ephemeroptera* sp.) and water louse (*Asellus* sp.)." Shapoval (nazaret@bk.ru)

**20239.** Shela, S.; Athiyya, N.A.A.; Ratih, K.A.; Yaquta, M.J.; Dwi, A.R. (2022): Diversity and abundance of dragonflies (Odonata: Anisoptera) at Watu Gajah Tuban Field. *Bio Sains Jurnal Ilmiah Biologi* 1(2): 1-11. (in Indonesian, with English summary) ["Odonata is an order with the highest level of diversity and abundance among others Arthropoda phyla, but have not been identified. Dragonflies like green open area habitats, especially grass. This research aimed to analyze the diversity and abundance of dragonfly insects (Odonata: Anisoptera) in Watu Gajah Field, Semanding District, Tuban Regency. Watu Gajah Field is a green open space that supports the survival of insects, one of them is dragonflies. The climatic conditions of Watu Gajah Field with an average temperature of 29°C, an altitude of 40 meters above sea level, wind speed of 13 km/h, rainfall of 1.9 mm, humidity of 70.33%, and luminous intensity of 4259.33 lux. This research using the jelajah method (cruising methods) using insect nets and hand sampling technique at 3 point areas. Based on the research results were obtained 6 species of dragonflies. Data analysis was performed using the relative abundance formula, the Shannon-Winner diversity index, and the Simpson dominance index. The results of the calculation of the dragonfly diversity index are classified as low, namely 1.57 and the dominance index of 0.226 is included in the medium category. Watu Gajah Field is an ideal habitat suitable for the survival of dragonflies (Odonata: Anisoptera)." **20240.** Shipley, R.; Twining, C.W.; Mathieu-Resuge, M.; Parmar P.T.; Kainz, M.; Martin-Creuzburg, D.; Weber, C.; Winkler, D.W.; Graham, C.H.; Matthews, B. (2022): Climate

change shifts the timing of nutritional flux from aquatic insects. *Current Biology* 32(6): 1342-1349. (in English) [oas 64a; "Highlights: • Aquatic insect emergence is advancing much more rapidly than bird breeding timing. • Aquatic insects have more n-3 LCPUFAs than terrestrial insects. • The seasonal availability of key fatty acids is thus shifting with climate change. • Birds are increasingly at risk of experiencing nutritional phenological mismatch. Summary: Climate change can decouple resource supply from consumer demand, with the potential to create phenological mismatches driving negative consequences on fitness. However, the underlying ecological mechanisms of phenological mismatches between consumers and their resources have not been fully explored. Here, we use long-term records of aquatic and terrestrial insect biomass and egg-hatching times of several co-occurring insectivorous species to investigate temporal mismatches between the availability of and demand for nutrients that are essential for offspring development. We found that insects with aquatic larvae reach peak biomass earlier in the season than those with terrestrial larvae and that the relative availability of omega-3 long-chain polyunsaturated fatty acids (n-3 LCPUFAs) to consumers is almost entirely dependent on the phenology of aquatic insect emergence. This is due to the 4- to 34-fold greater n-3 LCPUFA concentration difference in insects emerging from aquatic as opposed to terrestrial habitats. From a long-sampled site (25 years) undergoing minimal land use conversion, we found that both aquatic and terrestrial insect phenologies have advanced substantially faster than those of insectivorous birds, shifting the timing of peak availability of n-3 LCPUFAs for birds during reproduction. For species that require n-3 LCPUFAs directly from diet, highly nutritious aquatic insects cannot simply be replaced by terrestrial insects, creating nutritional phenological mismatches. Our research findings reveal and highlight the increasing necessity of specifically investigating how nutritional phenology, rather than only overall resource availability, is changing for consumers in response to climate change." **20241.** Silva, G. (2022): Species diversity and barcoding of macroinvertebrates from the San Antonio River. *Student Research Symposium 2022*. 1. <https://digitalcommons.tamusa.edu/srs2022/1>: 19 pp. (in English) ["Macroinvertebrates are important biological indicators of health and ecological change within aquatic ecosystems. Macroinvertebrate diversity of the San Antonio (SA) River Watershed (Texas), which traverses rural and urban regions (Bexar County, TX), remains understudied compared to vertebrate counterparts of economic and conservation importance. The SA River hosts a diversity of crustaceans (crayfish), insects (beetles, dragonflies), annelids (leeches), and unidentified larvae at intermediate developmental stages. To improve ecological records of the SA River, an integrative approach is used to establish a reference macroinvertebrate species inventory and a genetic barcoding database (mitochondrial COI and/or 16S rRNA) for the SA River Mission Reach restored site. These data will improve the identification of (i) species of varying developmental stages to adult forms; (ii) cryptic species; and (iii) key biological indicators. Establishing baseline data will also facilitate the identification of not easily detectable changes in macroinvertebrate diversity potentially attributed to urban disturbance or climate change." **20242.** Silva-Hurtado, J.S.; Márquez, J. (2022): Colección

de odonatos (Insecta: Odonata) del Centro de Investigaciones Biológicas de la Universidad Autónoma del Estado de Hidalgo, México (COD-UAEH). Dugesiana 29(2): 163-169. (in Spanish, with English summary) ["Odonates constitute an order of paleopteran insects important to ecosystems because their role as generalist predators and some of their species are considered bioindicators of the environmental quality. The establishment, maintenance and growth of scientific collections that include this group may encourage their research. To this end, we are making public the creation of the odonates collection (COD-UAEH) of the Biological Research Center of the Autonomous University of the State of Hidalgo is announced. This collection contains 1,180 adult individuals belonging to ten families, 43 genera and 104 species collected in different states of the country, but mainly in the states of Hidalgo and Puebla. The incorporation of immature states has not been undertaken yet. 54% of the specimens belong to the Anisoptera suborder, which is represented by the families Aeshnidae, Cordulegastridae, Gomphidae and Libellulidae, for 26 genera and 56 species. The remaining 46% belong to the suborder Zygoptera, which includes the families Calopterygidae, Coenagrionidae, Heteragrionidae, Lestidae, Thaumatonereidae and Platystictidae, with 17 genera and 48 species. Every specimen included in the collection has been identified to the taxonomic level of species. It is worth mentioning that the collection contains the record of a female belonging to the *Megaloprepus caerulatus* (Drury, 1782) species, as well as a montage in cardboard of the extended wings build to make an easier photograph taking and the wing venation comparison required for the identification of genera." **20243.** Singh, A.; Chandra, G. (2022): Larvicidal, pupicidal, repellence and smoke toxic efficacies of *Nicotiana plumbaginifolia* leaves against *Culex vishnui* mosquito. International Journal of Tropical Insect Science 42: 1187-1195. (in English) ["Objectives of the study was to evaluate larvicidal, pupicidal, repellence activities of *Nicotiana plumbaginifolia* leaf extracts (crude and solvents) and toxicity of smoke originated from dry leaves against rice field mosquito, *Culex vishnui*, vector of Japanese encephalitis. Larvicidal property of most effective extract was evaluated against third instar *Cx. vishnui* larvae under simulated semi-field condition. Crude extract of leaves exhibited remarkable larvicidal property. Amongst three used solvent extractives of leaves, ethyl acetate extractive showed best result in larvicidal test. In larvicidal bioassay, ethyl acetate extractive exhibited lowest LC50 and LC90 values, which were 7.237 ppm and 18.964 ppm respectively against the 1st instar larvae after 72 h of exposure. In pupicidal bioassay, LC50 and LC90 values were 111.20 ppm and 176.96 ppm respectively after 24 h of exposure. Remarkable (99.33%) repellency was found in 6% concentration of ethyl acetate extractive after 150 min of exposure. Smoke of *N. plumbaginifolia* dry leaves exhibited significant toxicity. Results of semi-field condition depicted that ethyl acetate extract was also highly effective under semi-field condition having highest mortality rate of  $95.33 \pm 0.33\%$  at 500 ppm concentration against third instar *Cx. vishnui* larvae after 72 h exposure. The name of the isolated bioactive compound was "1-hexyl-2-nitrocyclohexane". However, the non-target organisms like, Damselfly nymph (*Ischnura* spp.: Odonata) and nymph of

Hemipteran bug, *Diplonychus* spp. were found to be least toxic to the extracts. *N. plumbaginifolia* leaf has remarkable larvicidal, pupicidal, repellency and smoke toxic potentialities against *Cx. vishnui*." **20244.** Singh, D. (2022): Field Guide to the Dragonflies & Damselflies of Northwest India. Messrs Bishen Singh Mahendra Pal Singh, Publishers & Distributors of Scientific Books, 23 A Connaught Place, Dehra Dun 248001(Uttarakhand), India. Email: <bsmpsbooks@gmail.com>: x, 518 pp- ["The book is a first of its kind, lavishly illustrated, and beautifully designed field guide which provides the first comprehensive overview of Odonata of the northwestern part of India, comprising two main geographic regions: the Himalayan range and the Gangetic Plain, as well as the west the arid zones of the Great Indian Desert or the Thar Desert. This Field Guide covers the states of Jammu-Kashmir, Himachal Pradesh, Punjab, Uttarakhand, Haryana, Delhi, Uttar Pradesh, and Rajasthan. 162 species of damselflies (Zygoptera) and dragonflies (Anisoptera) are, described and illustrated in this Field Guide. The book includes in-depth details of general knowledge of dragonflies like anatomy, life history, behavior, habitat, and an outline of the geography, ecology, and biogeography of Northwest India. An illustrated identification key to the species has been provided and is kept as simple as possible to help find the right family, genus, and species, supported by numerous drawings to show the meaning of the technical terms mentioned in the text. The description of each family provides an introduction giving brief information about the worldwide distribution, and the status of that family within present Indian borders, followed by a basic overview of the general characteristics. The species account provides a general statement of a first impression of a species at a glance in the field, field characters; sometimes hand characters (illustrated in the identification keys), habits and behavior, and habitat followed by a distribution (range, India, Northwest India), status and flight period. Distribution maps are shown for all species based on studied literature and authors' field observations. Photographs show a male, female, and variations for most species and point out the main numbered characters to observe in the field. Illustrated throughout in color over 500 colorful photos are neatly placed in this book. Common English names for families and species and scientific names have been provided. Threats and Conservation of Indian Odonata have been addressed in detail, Dragonfly watching tips, an extensive Glossary, Literature, a Checklist of damselflies and dragonflies of Northwest India and an index to English and scientific names have also been provided in the field guide. This book is comprehensive yet easy to use by beginners and experts alike. The book would surely help in raising local awareness about this group of freshwater species and will contribute to better protection and management of freshwater ecosystems: x, 518 pp (with over 500 colorful photos), ISBN: 978-81-943323-2-9, Abhimanyu Gahlot" (Publisher)] Address: Messrs Bishen Singh Mahendra Pal Singh, Publishers & Distributors of Scientific Books, 23 A Connaught Place, Dehra Dun 248001(Uttarakhand), India. **20248.** Späth, J. (2022): Damsel in distress – metabolomics as a novel tool to investigate the effects of wastewater

exposure on damselfly larvae. Doctoral thesis, Umeå University: 52 pp. (in English, with Swedish summary) [oas 64a; "Aquatic organisms, such as aquatic invertebrates, are exposed to anthropogenic pollutants through their environment. These pollutants, despite their low levels, can adversely affect exposed individuals or even entire ecosystems, especially when present in complex mixtures. The aim of this thesis was to assess the effects of a specific group of complex mixtures of pollutants, wastewater effluent, on damselfly larvae, a common, ecologically relevant invertebrate species. Metabolomics, i.e., the comprehensive analysis of an organism's metabolites, was explored as a tool to show the sub-lethal effects of wastewater effluent exposure. A set of multi-platform mass spectrometry-based metabolomics methods was developed. These methods were used to measure and identify which damselfly metabolites are responsive to wastewater exposure and thus could potentially be used as early warning tools for anthropogenic pollution. In addition, key behavioural traits of damselfly larvae were assessed after wastewater exposure to investigate whether a change of metabolites would also be reflected at a higher level of biological organisation. The effects of wastewater effluents treated with different treatment methods on the fatty acid metabolites (oxylipins) of exposed damselfly larvae were assessed (paper I). Oxylipins were affected by wastewater exposure and these effects depended on the degree of wastewater treatment. Using a similar set-up, the effect-based removal of a conventional wastewater treatment plant and an additional ozonation step was evaluated on-site at a wastewater treatment facility (paper II). Oxylipins were affected by the exposure in this study, however fewer effects were observed when compared to the previous paper. In a separate series of experiments, damselflies were lab-reared to different developmental stages and a subset of the larvae were exposed to wastewater effluent. In these larvae, oxylipins (paper III) as well as other metabolites (paper IV) were measured to establish metabolite baseline levels and developmental variations as well as variation in their responses to the exposure. Metabolite variations as well as the metabolites affected by the exposure depended greatly on the life stage of the damselflies. In another study, damselfly larvae were exposed to dilutions of conventionally treated effluent and behavioural alterations and metabolite profiles were investigated in the larvae (paper V). Individual metabolites as well as behavioural traits important for damselfly survival and reproduction were altered by exposure to undiluted effluent; however, few effects were observed in the diluted effluents. In conclusion, both metabolomic endpoints and behavioural traits measured on the damselfly larvae were responsive to wastewater effluent exposure. The metabolites affected by exposure mainly play a role in fatty acid metabolism, including oxylipins, and in amino acid metabolism. The individual metabolites that were affected differed across the studies. These observed variations might be due to differences in exposure conditions or differences in larval stages across the studies. The studies presented in this thesis pave the way for metabolomics to be used as a novel tool to monitor sub-lethal effects of anthropogenic pollution in the environment. However, more research is needed on, for example, the ecological implications of the affected metabolites for both the individual and the population before it can be implemented in environmental risk assessments." (Author)] Address: Späth, Jana, Department of Chemistry, Umeå University, KB.C6, Linnaeus väg 10, 90187 Umeå, Sweden. Email: jana.spath@umu.se

**20249.** Späth, J.; Brodin, T.; Falås, P.; Niinipuu, M.; Lindberg, R.; Fick, J.-; Nording, M. (2022): Effects of conventionally treated and ozonated wastewater on the damselfly larva oxylipidome in response to on-site exposure. *Chemosphere* 309(1): 7 pp. (in English) ["Highlights: • Average ozonation removal efficiency of 67% at an ozone dose of 0.49 g O<sub>3</sub>/g DOC. Oxylipins 12(13)-EpODE and 15(16)-EpODE were reduced in larvae exposed to conventionally treated wastewater. 5(16)-EpODE was also reduced in larvae exposed to ozonated wastewater. Abstract: Pharmaceutical residues discharged through insufficiently treated or untreated wastewater enter aquatic environments, where they may adversely impact organisms such as aquatic invertebrates. Ozonation, an advanced wastewater treatment technique, has been successfully implemented to enhance the removal of a broad range of pharmaceuticals, however diverse byproducts and transformation products that are formed during the ozonation process make it difficult to predict how ozonated wastewater may affect aquatic biota. The aim of this study was to investigate effects on fatty acid metabolites, oxylipins, in a common invertebrate species, damselfly larvae, after on-site exposure to conventional wastewater treatment plant (WWTP) effluent and additionally ozonated effluent at a full-scale WWTP. Subsequent ozonation of the conventionally treated wastewater was assessed in terms of i) removal of pharmaceuticals and ii) potential sublethal effects on the oxylipidome. Northern damselfly (*Coenagrion hastulatum*) larvae were exposed for six days in the treatment plant facility to either conventional WWTP effluent or ozonated effluent and the effects on pharmaceutical levels and oxylipin levels were compared with those from tap water control exposure. Ozonation removed pharmaceuticals at an average removal efficiency of 67% (ozone dose of 0.49 g O<sub>3</sub>/g DOC). Of 38 pharmaceuticals detected in the effluent, 16 were removed to levels below the limit of quantification by ozonation. Levels of two oxylipins, 12(13)-EpODE and 15(16)-EpODE, were reduced in larvae exposed to the conventionally treated wastewater in comparison to the tap water control. 15(16)-EpODE was reduced in the larvae exposed to ozonated effluent in comparison to the tap water control. One oxylipin, 8-HETE, was significantly lower in larvae exposed to conventional WWTP effluent compared to ozonated effluent. In conclusion, the study provides proof-of-principle that damselfly larvae can be used on-site to test the impact of differentially treated wastewater." **20250.** Spigolonía, Z.A.; Bernardy, J.V.; Brasil, L.S.; Dias-Silva, K.; Vieira, T.B.; De Marco, P. (2022): Odonata Concordance amongst aquatic taxa in Brazilian savanna streams. *International Journal of Odonatology* 25: 80-88. (in English) ["Environmental management is one of the most important activities in ecological conservation at present. Faced with various socioeconomic impacts (e.g., urbanization, agriculture, and logging), practical and effective ways to analyze and determine how biodiversity is affected by these anthropogenic activities are essential. Utilizing niche theory helps to understand how similar groups of organisms respond to environmental changes based on the assumption that organisms with some niche overlap (i.e., similar resources) will respond similarly to these changes. Members of the order Odonata are frequently used as biological indicators due to their low survey costs, relatively easy taxonomic identification, and sensibility to environmental changes. In this study, using the PROTEST method, we analyze the cross-taxon congruence between Odonata and two

aquatic organisms in Brazilian savanna streams: Gerromorpha and fishes. Although congruence was found between aquatic insects (~ 45%), this result changed when we only considered the species' genera: no congruence for the aquatic insects was found, but instead we found a congruence between Odonata and fishes (~ 44%). Since Odonata showed congruence with the other groups in different taxonomical resolutions and it is a relatively easy and cheap group to collect and identify, we suggest that Odonata could be used as an indicator of disturbance for this set of organisms and hence serve as an alternative method to traditional environmental management techniques." (Authors)] Address: Brasil, L.S., Instituto de Ciências Biológicas e da Saúde, Universidade Federal de Mato Grosso, Postal Code 78.698-000 – Pontal do Araguaia, Mato Grosso, Brazil. Email: leandro.brasil@ufmt.br

**20251.** Srayko, S.H. (2022): Seasonal migration of water boatmen (Hemiptera: Corixidae) as a wetland-river ecosystem linkage. Ph.D. thesis, Dept of Biology, University of Saskatchewan, Saskatoon: XVI + 187 pp. (in English) ["Organisms that undertake seasonal migrations can act as important ecosystem linkages by subsidizing food webs. Such transfers of material mean that even food webs which seem isolated may be closely connected. One such linkage that has largely gone unstudied is the seasonal migration of a family of aquatic insects, water boatmen, or corixids (Hemiptera: Corixidae) that fly from geographically isolated wetlands into large rivers in the Prairie Pothole Region (PPR) of North America every fall, to overwinter. This thesis provides further documentation of the phenomenon of corixid migration in the North American prairies, while also investigating the ecological importance and drivers of this movement across the landscape. First, I quantified and recorded the shifts in abundance and species composition of corixids in wetland and river ecosystems in different seasons. I found that these migrations can lead to drastically increased riverine corixid densities as high as ~3,000 individuals/m<sup>2</sup> within areas of standing or slow-moving water, with ~500 g of corixid material entering every meter of water immediately adjacent to the banks of rivers, where landings are concentrated. This movement shifts the corixid species assemblage in rivers to one dominated by wetland-breeding species, namely *Callicorixa audeni*, *Sigara bicoloripennis*, and *Sigara decoratella*. Stomach content analyses of riverine fishes revealed that goldeye (*Hiodon alosoides*), moon-eye (*Hiodon tergisus*), longnose sucker (*Catostomus commersoni*), and white sucker (*Catostomus commersoni*) make heavy use of this forage subsidy, with corixids occurring in 97% to 100% of these fishes and accounting for 38% to 97% of stomach contents by weight during the corixid migration period in fall. This could have implications for the productivity and overwintering survival of corixid feeding fish, with the potential for cascading effects in riverine food webs. Across the landscape, I estimated that seasonal migrations could result in ~1500 metric tons of corixids entering the North and South Saskatchewan rivers (~12,000 river km) within Saskatchewan, and ~12,000 tons of biomass moving between wetlands and rivers across the entire PPR. Next, by studying changing patterns in abundance and evidence of flight into rivers, I designated different corixid species from my study area as being predominantly migratory (62% of encountered species), acting as cyclic colonizers between wetlands and rivers, or non-migratory residents of either habitat type (27% of encountered species). This information allows for the identification of the corixid assemblage that is driving the seasonal flux between the two habitat types, and helps to fill a knowledge gap which exists on

the migratory abilities of corixids at the species level. Third, I examined the use of the stable isotope ratio of sulfur,  $\delta^{34}\text{S}$ , as a tracer of corixid movement and the incorporation of these insects as a dietary subsidy by riverine fish. I found that both corixids and other invertebrate taxa originating from wetland ecosystems exhibited lower  $\delta^{34}\text{S}$  values, with wetland taxa averaging  $-10.5 \pm 5.8\text{‰}$  overall, as opposed to riverine taxa at  $-4.1 \pm 4.1\text{‰}$ , allowing the use of  $\delta^{34}\text{S}$  as a tracer of insects out of wetlands. Specifically,  $\delta^{34}\text{S}$  values of invertebrates from the South Saskatchewan River ( $-5.1 \pm 4.1\text{‰}$ ) were more  $\delta^{34}\text{S}$  depleted than those from the North Saskatchewan River ( $-1.4 \pm 2.8\text{‰}$ ). In the fall season, the corixid-feeding fish species goldeye, mooneye, and longnose sucker exhibited lower  $\delta^{34}\text{S}$  values in fast-turnover liver tissue than non-corixid feeding species, shorthead redhorse, northern pike, and walleye, with mixing models indicating that ~17 to 94% of liver tissue may be derived from wetland sources during this season. However, goldeye was the only species to exhibit a significant seasonal reduction in liver  $\delta^{34}\text{S}$  values in fall compared to summer. These findings indicate that  $\delta^{34}\text{S}$  has utility in tracing flows of energy between wetland and riverine food webs. Finally, I examined the overwintering strategy of corixids that do not migrate to rivers in the fall, documenting the little understood ability of these insects to survive in wetlands that freeze solid. I found that while multiple corixid species were present in wetlands at ice-over, those embedded within the ice were almost entirely composed of two non-migratory species, *Cymatia americana* and *Dasycorixa hybrida*, of which only the former revived after thawing. These findings indicate that migratory species are likely incapable of survival within the ice, driving the need to leave shallow waters in fall. The percent of *C. americana* that revived after being experimentally thawed out from the ice ranged from 4% to 10% in both winters of this study. The majority of corixids were grouped together within air pockets, which could enable them to limit direct contact with the surrounding ice. Other invertebrate taxa were also found overwintering within the ice, including adults and larvae of crawling water beetles (Coleoptera: Haliplidae) and adults of predaceous diving beetles (Dytiscidae) within air pockets alongside the corixids or on their own, as well as damselfly nymphs (Odonata: Coenagrionidae), caddisfly larvae (Trichoptera: Phryganeidae, Leptoceridae), midge larvae (Diptera: Chironomidae), and snails (Gastropoda: Physidae, Planorbidae) that appeared to be encased in solid ice. Taken together, this thesis has demonstrated an extensive cross-boundary flux that occurs between spatially separated wetland and river ecosystems, highlighting a need for conservation to ensure that this connection is maintained. By examining migratory patterns, I have identified which species drive this flux, which may allow for increased protection of habitats that these corixids require.  $\delta^{34}\text{S}$  was shown to have the potential to trace insect movement and consumer use between isotopically distinct freshwater systems in the prairies. The study of corixids overwintering in ice represents a little understood survival mechanism of aquatic invertebrates in shallow wetlands, knowledge of which could help predict how the abundance of these organisms might change in the face of altered overwintering conditions due to global warming. The seasonal flights of corixids between wetlands and rivers may represent one of the world's great insect migrations, which has largely gone unnoticed, but could have important implications for ecosystem functioning and conservation in the North American prairies." **20252.** Stih, A.; Koren, T. (2022): Dragonfly fauna (Insecta:

Odonata) of the Brijuni National Park, Croatia. *Natura Croatica* 31(1): 19-30. (in English, with Croatian summary) ["The first systematic survey of the dragonfly fauna of the Brijuni National Park was carried out during the late spring and summer of 2016. A total of 13 species was recorded at two localities on the island of Veliki Brijun, 11 of them for the first time in the area. From the literature, one additional species was documented for the Park, amounting to a total of 14 Odonata species. The most common species was *Symptetrum meridionale* while the rarest was *Anax parthenope*. Zoogeographical analysis showed the domination of the Holo-Mediterranean zoogeographical element. Four recorded species are listed in the Red book of Croatian Dragonflies, indicating the conservation value of the investigated habitats. Both of the wetland habitats surveyed, Brijuni Pond, and the saline lakes, proved to be very important habitats for the island's Odonata. Therefore, it is essential to protect those habitats and their biota by planning and conducting restoration activities in the near future." **20253.** Suárez, B.; Barrios, M.; Teixeira de Mello, F. (2022): Macroinvertebrates' response to different land use in lowland streams from Uruguay: use of artificial substrates for biomonitoring. *Neotropical Biodiversity* 8(1): 136-146. (in English) ["The use of macroinvertebrates as indicators of water quality is an effective and low-cost tool, which is widely implemented in biomonitoring programmes. Certain taxa are characteristic of impaired watercourses (e.g. Oligochaeta, Chironomidae and Amphipoda), while others are characteristic of good-quality watercourses (e.g. Ephemeroptera, Plecoptera and Trichoptera; EPT). In this work, we evaluated the response of the macroinvertebrate assemblages to different land uses. For this purpose, artificial substrate colonization experiments were conducted in streams including urban (U, n = 3), intensive agriculture and dairy production (AD, n = 4) and extensive cattle ranching (CR, n = 4) land uses. Because in Uruguay pristine ecosystems are practically non-existent and streams of low order streams associated with extensive cattle production represent the lowest deterioration water quality condition, CR sites were used as control reference streams. Physicochemical water parameters were measured. For macroinvertebrate sampling, 10 artificial substrates were installed in each stream. A total of 110 artificial substrates were analysed. Each sample/site consisted of a plastic mesh bag of 1.2 cm opening, which were filled with 160 cm<sup>3</sup> (including 73.3 ± 5.8 cm<sup>3</sup> interstitial water) of stones sieved between 1.3 and 1.5 cm. During the summer of 2018 (February), devices were left in streams for 15 days for communities to colonize them. U and AD land use represented the stressors with the highest impact on the attributes and composition of the macroinvertebrate communities. Abundance of EPT was higher in CR, meanwhile Caenogastropoda dominated in AD, and Amphipoda in U sites. Macroinvertebrate groups to order level classification were able to effectively discriminate between different land uses. The use of artificial substrate also demonstrated to be efficient method for monitoring macroinvertebrate community. We did not find a correlation between the physicochemical water parameters and the macroinvertebrate community. In this context, we propose a rapid and cost-effective biomonitoring approach, capable of estimating the degree of impact of different land uses." (Authors)] Address: Teixeira de Mello, F. **20254.** Suárez-Tovar, C.M.; Guillermo-Ferreira, R.; Cooper, I.A.; Cezário, R.R.; Córdoba-Aguilar, A. (2022): Dragon colors: the nature and function of Odonata (dragonfly and damselfly) coloration. *Journal of Zoology* 317(1): 1-9. (in English) ["Adult odonates (dragonflies and damselflies) exhibit a great diversity of colors which vary remarkably between species, between individuals within species, and throughout the individual's lifetime in some species. Here, we provide a summary of what is known about color recognition, and production of color including pigmentary absorption, structural reflectance, and fluorescence, in odonates. We also review the current understanding of the function of color in adult odonates, such as in signals during mate choice, in species recognition, and in predator avoidance, as well as in physiological adaptations to abiotic conditions. Finally, we provide some directions for future research: eye and pterostigma color, coloration at different life stages, UV color, phylogenetic analysis of color evolution, color and hot climate patterns, and standardization of color recordings. Given how easily they can be marked and tracked, odonates are exemplary animals for field and laboratory research. Therefore, unraveling the physiology, evolution, and ecology of odonate color can provide significant advances, in general, to understand insect color." **20255.** Suárez-Tovar, C.M.; Castillo-Pérez, U.; Sandoval-García, I.A.; Schondube, J.; Cano-Santana, Z.; Córdoba-Aguilar, A. (2022): Resilient dragons: Exploring Odonata communities in an urbanization gradient. *Ecological Indicators* 141, August 2022, 109134: 11 pp. (in English) ["Highlights: • Cities are novel ecosystems that generate selective pressure on living organisms. Dragonflies and damselflies inhabit cities all over the world. We studied dragonfly and damselfly communities along an urbanization gradient in Central Mexico. Damselfly species richness and abundance are affected by urbanization. Dragonflies seem resilient to urban conditions. Abstract: Cities function as ecological systems composed of a geosphere, a biosphere and an anthroposphere, interacting with each other and generating various selection pressures on urban organisms. Odonates (damselflies and dragonflies) are frequent inhabitants of urban areas, showing no clear or unique responses to urbanization. Thus, we defined an urbanization gradient using a habitat integrity index (HII) calculated for 19 sites in central Mexico, and investigated: a) changes in species richness and abundance along the urbanization gradient; and, b) the relationship between presence of waste of anthropic origin, chemical conditions of water, macrophyte cover, and odonate species richness, abundance and community composition. We analyzed the data for the whole odonate community, as well as for dragonfly and damselfly communities separately in each site. We found higher damselfly species richness and abundance in sites with low urbanization than in sites with high urbanization, and no differences in dragonfly communities along the gradient. We found a positive relationship between dragonfly species richness and abundance and waste percentage and macrophyte cover, and a negative relationship with dissolved solids in water. Our results indicated that odonate communities were fairly tolerant to urbanization and dragonflies were less affected than damselflies. However, we suggest that during design and restructuring of cities, the care and conservation of water bodies and all the life forms that inhabit there, be considered." **20256.** Suhonen, J.; Ilvonen, J.J.; Korkeamäki, E.; Nokkala, C.; Salmela, J. (2022): Using functional traits and phylogeny to understand local extinction risk in dragonflies and damselflies (Odonata). *Ecology & Evolution* 12(3) e8648: 12 pp. (in English) ["Understanding the risk of local extinction of a species is vital in conservation biology, especially now when anthropogenic disturbances and global warming are severely changing natural habitats. Local extinction risk depends on species traits, such as its geographical range size, fresh body mass, dispersal ability, length of flying period, life history variation, and how specialized it is regarding its breeding habitat. We used a phylogenetic approach because closely related species are not independent observations in the statistical tests. Our field data contained the local extinction risk of 31 odonate species from Central Finland. Species relatedness (i.e., phylogenetic signal) did not affect local extinction risk, length of flying period, nor the geographical range size of a species. However, we found that closely related species were similar in hind wing length, length of larval period, and habitat of larvae. Both phylogenetically corrected (PGLS) and uncorrected (GLM) analysis indicated that the geographical range size of species was negatively related to local extinction risk. Contrary to expectations, habitat specialist species did not have higher local extinction rates than habitat generalist species nor was it affected by the relatedness of species. As predicted, species' long larval period increased, and long wings decreased the local extinction risk when evolutionary relatedness was controlled. Our results suggest that a relatively narrow geographical range size is an accurate estimate for a local extinction risk of an odonate species, but the species with long life history and large habitat niche width of adults increased local extinction risk. Because the results were so similar between PGLS and GLM methods, it seems that using a phylogenetic approach does not improve predicting local extinctions." **20257.** Suhonen, J.; Paasivirta, L.; Rantala, M.J.; Jukka, S.; Suutari, E. (2022): Macroinvertebrate species occupancy frequency distribution patterns in eutrophic lakes. *Aquatic Ecology* 56: 201-212. (in English) ["Metacommunity models describe species occupancy frequency distribution (hereinafter 'SOFD'). Our goal is to present how the differences in eight macroinvertebrate orders dispersal ability affect SOFD patterns. A total of 293 species from eight macroinvertebrate orders were observed in 14 eutrophic lakes in southern Finland. Species occupancy ranged from 1 to 14. About 30% (89 out of 293) of the species were found in only one lake, yielding a surprisingly high number of rare species. So, there were few widely distributed common species and numerous rare species with a restricted distribution. Combined data from eight macroinvertebrate orders supported the bimodal truncated SOFD pattern. Similarly, the low dispersal ability orders, watermites and mayflies, fitted the bimodal truncated SOFD pattern. However, bimodal symmetric SOFD pattern also fitted relatively well to Odonata with high dispersal ability. It seems that differences in dispersal ability among different macroinvertebrate orders may partly explain observed differences. Moreover, our results supported slightly more a niche-based model rather than a metapopulation dynamics model in eutrophic lakes littoral macroinvertebrate metacommunities. Our results highlight that the dispersal ability is important trait for

species conservation in patchily distributed habitat." (Authors)] Address: Suhonen, J., Dept of Biology, University of Turku, 20014 Turku, Finland. E-mail: juksuh@utu.fi

**20258.** Sumanapala, A.; Ranasinghe, T. (2022): First record of *Lestes concinnus* (Zygoptera: Lestidae) from Sri Lanka with observations on its natural history. *Travaux du Muséum National d'Histoire Naturelle "Grigore Antipa"* 65 (1): 129-139. (in English) ["*Lestes concinnus* is a widespread species in tropical Asia and Oceania. It is a species known to have variable colour patterns ranging between pale and dark phenotypes which have earlier been recognized as distinct species. *Lestes concinnus* has never been known from Sri Lanka before. We report observations of both phenotypes of the species and intermediate morphs of *Lestes concinnus* from coastal habitats with dry reed patches in the northern part of the country, adding it to the Odonata fauna of Sri Lanka. With multiple field observations examined, we also provide comments on its identification and natural history in the country." **20262.** Szabó, L.J.; Vajda, C.; Szalay, P.E.; Kis, O.; Miskolczi, M.; Dévai, G. (2022): Change of morphometric and allometric patterns on wings of banded demoiselle (*Calopteryx splendens*) males in case of ecologically different watercourse types. *Acta Zoologica Academiae Scientiarum Hungaricae* 68(1): 99-118. (in English) ["In the nature, larvae living in watercourses are exposed to a complex system of environmental influences. It is known that different watercourse types (creeks, brooks, streams, little rivers and medial rivers) provide different conditions for larval development (water depth, flow rate, temperature, oxygen content, substrate type, nutrient supply, etc.). These conditions can vary significantly between watercourse types, but be very similar within types. In this work, we examined the body sizes and wing morphometric characteristics of males of *Calopteryx splendens* reared from different watercourse types (brook, stream, creek, little river, medial river). Although there were no significant differences in body size among watercourse types, we found significant differences in the wing features. We found the most differences between the individuals reared from streams and creeks and between the individuals reared from stream and medial river. Our results show that the individuals reared from different watercourse types were clearly separated on the two wings. The results also suggest that there are significant differences in the number and pattern of allometric features on the wings of individuals reared from different watercourse types." **20264.** Tamm, J. (2022): Weitere Beobachtungen zum Bachwechsel und Verhalten von *Cordulegaster bidentata* im Vordertaunus (Odonata: Cordulegastridae). *Libellen in Hessen* 15: 59-78. (in German, with English summary) ["Further observations on stream hopping and behaviour in a population of *C. bidentata* living at forest streams in Taunus mountains, Germany.- At 15 small forest streams in the Taunus mountains, Hesse, Central Germany, the spatial performance of a population of *C. bidentata* was studied in 2021 using 53 colour marked adult males. 711 males passing above 12 of these streams were counted during 9 counting days, among them 93 marked ones (13 %). In spite of sparse reappearance of marked males, 15 ones were observed again after marking (28 %). Five of them appeared on streams in the surroundings, where they had not been marked. Maximum range between the places of marking and reobserving was 635 m. Altogether 6 cases of stream hopping show that this behaviour may be regular in *C. bidentata* males. A considerable part of marked males only occurred sporadically at the streams. One can conclude that in general a remarkable share of male *C. bidentata* does not take part in patrolling flight activities along the streams regularly. Moreover, remarkable changes in abundance of the species were found at 3 streams compared to previous studies in the area." (Author)] Address: Tamm, J., 34131 Kassel, Germany. **20265.** ten Thoren, S.; Holtkamp, M.; ten Thoren, B. (2022): Faunistische Erfassung auf Schloss Ippenburg 2021 Avifauna, Libellen, Tagfalter. Auftraggeber: Freifrau Viktoria von dem Bussche, Schloss Ippenburg, Schlossstr. 1, 49152 Bad Essen: 62 pp. (in German) ["With 18 dragonfly species, a comparable number of species as in 2018 were recorded in the study area. The presence of 10 species on the ground is considered very probable. It is striking that only a small number of pairs were observed in 2021 (approx. 25) compared to the number of dragonfly pairs observed in 2018 (approx. 200). The reasons are mainly assumed to be changed, suboptimal weather conditions. The species spectrum reflects a richly structured water landscape, which presented itself in optimal "dragonfly" conditions in the study year. However, these are almost exclusively ubiquitous species, species that do not make any special demands on their habitat and can inhabit a wide variety of aquatic landscapes. Nevertheless, it remains to be said that there is a high diversity of species that colonise the water mosaic around Ippenburg Castle in particular. The diversity of dragonflies enriches the structurally rich habitat and as such is also dependent on it. Preserving this interplay should be one of the goals of conservation measures. Recommendations for stabilising the populations are given." (Authors/DeepL)] Address: BioConsult, Dulings Breite 6-10, 49191 Belm, Germany

**20266.** Theischinger, G.; Polhemus, D.A.; Richards, S.J. (2022): *Nososticta digimu* sp. nov., a new damselfly from Papua New Guinea (Odonata: Platycnemididae). *Odonatologica* 51(1-2): 167-174. (in English) ["*Nososticta digimu* sp. nov., is described from Southern Highlands Province, Papua New Guinea, and its affinities are discussed. It belongs to a group of *Nososticta* in which the male synthorax exhibits discrete patches of blue, and the tip of the male abdomen is blue. The new species differs from its congeners exhibiting these characters either by lacking a transverse blue frontal bar from eye to eye or by its much larger blue ante-

humeral patch that extends anterior to the mesokatepisternum. *Nososticta digimu* sp. nov. represents the 85th species of the genus and is currently known only from a single location in the Digimu River catchment. The supra-specific term *Nososticta conifera* complex is introduced." (Authors)] Address: Theischinger G., 2A Hammerley Road, Grays Point, NSW 2232, Australia. **20271.** Tituskin, J.R.; Waddell, S.M.; Mabry, K.E. (2022): Species-specific responses to warming alter community composition. *Ecological Entomology* 47(3): 284-295. (in English) ["1. Species are responding to global climate change in varied and nuanced ways. However, how species-specific responses to climate change= affect interactions among species remains poorly understood. It is important to understand species interactions under potential climate change scenarios because those interactions can in turn alter community dynamics. 2. In this study, we conducted two complementary experiments to examine how simulated warming might alter larval intraguild predation (IGP) rates and resulting adult assemblage composition in three species of North American dragonflies: *Pachydiplax longipennis*, *Plathemis lydia* and *Libellula luctuosa*. 3. First, using both *P. longipennis* and *L. luctuosa*, we isolated interspecific and intraspecific pairs of larval dragonflies of different size differentials to determine how the size and species identity might influence IGP rates. 4. In tandem, we conducted a year-long mesocosm experiment with all three species to assess how simulated warming and heat waves influenced the resulting adult dragonfly assemblages. 5. IGP trials revealed that *P. longipennis* individuals were much more likely to engage in IGP than *L. luctuosa*, regardless of size differential. In the mesocosm experiment, emerging adult assemblages were dominated by *P. longipennis* individuals, a pattern that was most pronounced in the control treatment. 6. Our results indicate that while *P. longipennis* may be the competitively dominant species under current ambient conditions, warming may alter this dynamic and lessen the dominance of this species on the resulting assemblage composition." **20272.** Trapero Quintana, A.D.; Torres Cambas, Y.; Reyes Tur, B.; Cordero Rivera, A. (2022): Diversidad de las libélulas de Cuba. *Anales de la Academia de Ciencias de Cuba* 12(2): 5 pp. (in ASpanish, with English summary) ["Dragonflies are hemimetabolous predatory insects, which belong to the order Odonata with approximately 6,000 species, grouped into two suborders. The objectives of this study were to characterize and update the systematics of the order Odonata, its geographical and temporary distribution; to characterize, besides, their genetic diversity, ecology of populations, and both adult and larvae assemblies, emergency pattern from exuvias, as well as to describe aspects

of their reproductive ecology, in diverse habitats of the Cuban archipelago for conservation purposes. Specimens and data were collected in 50 locations in Cuba, from 1995 to the present with aerial and aquatic nets. Four sites in Santiago de Cuba were selected to study the larvae, exuviae and the emergency pattern. The climate variables were recorded during the low-rain and rainy periods. The specimens were processed in the laboratories of the universities of Havana and Oriente; the extraction of DNA was completed in Vigo. Tests of normality, Pearson correlation, principal components, Maximum Likelihood and estimation of ecological niche were used. The Cuban fauna of odonates includes 88 species, in six families, 41 genera and six of them are endemic. The larvae of three species are described and dichotomous keys were elaborated for larvae and adults from Cuba and the Antilles. The geographical distribution of dragonflies in Cuba was updated and, by using genetic data and population ecology, a proposal for conservation strategies for *Hypolestes* is presented. Permanent rivers and lagoons favor dragonfly assemblies with high equitability. To record the maximum number of species, it was estimated that 30 weekly samples of exuvia collection are needed. Five groups of larvae were created using morphology and functional attributes, and it was found that the emergence pattern was broad and unsynchronized, due to the presence of accidental and multivoltine species. The phylogenetic analyses revealed four Antillean lineages for *Hypolestes*, with inferences of the effect of climate change, flight period, longevity and environmental assessment as bioindicators of aquatic ecosystems." **20273.** Trapero Quintana, A.D.; Soto Borrero, M. (2022): Odonatos de la colección del Museo de Historia Natural Charles Ramsden de la Torre. *Revista Cubana de Ciencias Biológicas* 10(1): 1-9. (in Spanish, with English summary) ["Odonates are hemimetabolous insects that play an important role in aquatic ecosystems. They are an indispensable group in entomological collections, such as those of the Charles Ramsden de la Torre Museum of Natural History at the Universidad de Oriente. The objective of this work is to inventory the Cuban specimens of the Odonata order deposited in the collection of the Charles Ramsden Museum of Natural History, through the quantification and review of the total number of dragonfly individuals and the data on their labels. With this information, tables and graphs were made that illustrate the richness of said collection, which has a total of 530 specimens, belonging to 57 species of 33 genera and seven families of the Anisoptera and Zygoptera suborders. Libellulidae was the best represented family followed by Coenagrionidae, in correspondence with the diversity and abundance that they exhibit worldwide. Four of the six Cuban endemics are present. Pastor Alayo was the entomologist with the greatest contribution to the group's collection, being appointed curator of the museum and an active collector of all orders of insects in localities of the eastern region, fundamentally. The state of conservation of the collection is optimal and with a promising future." (Authors)] Address: Trapero Quintana, A., Depto de Biología de la Universidad de Oriente, Patricio s/n, Santiago, Cuba, CP 90500, Cuba. E-mail: atrapero@cnt.uo.edu.cu

**20274.** Trisna, P.A.W.; Watiniasih, N.L.; Ginantra, I.K. (2022): Diversity of dragonflies around the Ayung River. *Simbiosis X* (1): 64-74. (in Indonesian, with English summary) ["This research was conducted from february to April

2020 in three different areas, including in Penikit Village, Petang, Sayan Village, Ubud, and in Padang Galak Village, Sanur using sweeping techniques. This study aims to determine the diversity of dragonflies along the Ayung river. The analyzes carried out include analyzing the Shannon-Wiener diversity index ( $H'$ ), evenness index ( $E$ ), dominance index ( $D$ ) sympons, frequency of presence and water quality of the Ayung River. The results showed as many as 11 species of dragonflies. The most common individuals found were *Orthetrum Sabina* (23 individuals), while the lowest individuals were from the Libellulidae family as many as 5 individuals. Most species and individuals were found at the Sayan location with 11 species with a total of 124 individuals ( $H'=2.24$ ,  $E=0.93$ ,  $D=0.19$ ), followed by 6 species in the Petang location with a total of 27 individuals ( $H' =1.60$ ,  $E=0.89$ ,  $D=0.30$ ), while the lowest was the Sanur location with 4 species with a total of 15 individuals ( $H'=0.94$ ,  $E=0.69$ ,  $D=0.67$ ). Diversity of dragonflies in the Ayung River is classified as moderate ( $H'=2.36$ ), the evenness index of species at the Petang and Sayan locations is in the almost evenly distributed category. Petang (0.89) and Sayan (0.93), while the Sanur location was in the fairly even category (0.69). The highest frequency of presence in *Orthetrum sabina* species was 89% with frequent or absolute presence categories. The BOD and DO values in the Ayung River do not meet the requirements of water quality standards, while COD meets the requirements based on PP No. 82 of 2001." **20276.** Verma, P.; Thakkar, N.; Andrew, R. (2022): Hatching in Coromandel Marsh Dart Damselfly *Ceragrion coromandelianum* (Fabricius) (Zygoptera: Coenagrionidae): process and influence of the oviposition substrate. *Journal of Threatened Taxa* 14(4): 20840-20847. (in English) ["Coromandel Marsh Dart Damselfly *Ceragrion coromandelianum* (Fabricius) breeds in stagnant pools, small garden tanks and ornamental cement ponds containing submerged and/or floating vegetation. Eggs were collected to observe two aspects of larval development: (1) The hatching rate of eggs deposited in different vegetation (*Nymphaea nouchali*, *Lemna paucicostata*, *Hydrilla verticillata*). Although *C. coromandelianum* prefers to oviposit in the broad leaves of *N. nouchali*, the highest rate of hatching was found in *H. verticillata* (95.8%) followed by *N. nouchali* (87.6%) and *L. paucicostata* (81.3%). Hatching commenced on Day 5 and was completed by Day 9. Maximum hatching (56%) was recorded on the sixth day of oviposition followed by the seventh day (20%) in all three substrates. (2) To document the process of hatching as follows: Around three minutes prior to hatching, the embryo exhibits cyclic pumping and pushing movements of the head (caused by the peristaltic movement of the mid- and hind- gut) of low intensity followed by high intensity and long pumping movements interspaced with smaller pulsating movements. Swelling of the head forces the apical chorion to split along the micropylar chute and like a lid, the apical tip topples over as a conical cap. This allows the prolarva to exit the egg. As it does so, it twists and the thorax swells breaking the prolarval sheath and releasing the first instar larva." (Authors)] Address:

**20280.** Vilenica, M.; Rebrina, F.; Ružanovic, L.; Gulin, V.; Brigic, A. (2022): Odonata assemblages as a tool to assess the conservation value of intermittent rivers in the Mediterranean. *Insects* 2022, 13, 584. <https://doi.org/10.3390/insects13070584>: 16 pp. (in English) ["Simple Summary: Intermittent rivers and are an important source of water in arid regions such as the Mediterranean. Water resources and riparian habitats in the Mediterranean regions are under diverse anthropogenic pressures, including the land-use change. We studied Odonata adults at four intermittent Mediterranean rivers in the Dinaric Western Balkans ecoregion, with the aim of inspecting the conservation value of

these habitats based on Odonata assemblages and in the context of the surrounding land-cover heterogeneity. We analyzed several diversity and conservation indices and recorded significant differences in Odonata species richness and Croatian Conservation Odonatological index among the studied rivers. Our findings showed that land use, as a long-term moderate anthropogenic impact, can enhance land-cover heterogeneity and in some cases even lead to increased Odonata diversity in the intermittent rivers in the Mediterranean. Abstract: Intermittent rivers, lotic habitats that cease to flow during the dry periods of the year, make up a large proportion of the world's inland waters and are an important source of water in arid regions such as the Mediterranean. Yet, water resources and riparian habitats in the Mediterranean regions are under diverse anthropogenic pressures, including land-use change. Odonata are widely used as a valuable tool for assessing freshwater ecosystems. Hence, with the aim of inspecting the conservation value of intermittent rivers in the Mediterranean based on the assemblages they support, we studied Odonata adults at four intermittent Mediterranean rivers in the Dinaric Western Balkans ecoregion with respect to the surrounding land-cover heterogeneity. We analyzed several diversity and conservation indices and recorded significant differences in Odonata species richness and Croatian Conservation Odonatological index among the studied rivers. Our findings showed that land use, as a long-term moderate anthropogenic impact, can enhance land-cover heterogeneity and in some cases even lead to increased Odonata diversity in intermittent rivers in the Mediterranean. Intermittent rivers provide habitat for several threatened Odonata species, suggesting the importance of Odonata in planning the conservation activities in these vulnerable ecosystems." **20281.** Vinko, D.; Šalamun, A.; Bedjanic, M. (2022): On the odonates, odonatology and odonatologists in Slovenia. 6th European Congress on Odonatology, 27-30th June 2022, Kamnik, Slovenia, Book of Abstracts: 9-22. (in English) ["brief overview of odonatological research in Slovenia from its origins in the second half of the 17th century to the present is provided. The importance of pioneer odonatological activities by Prof. Boštjan Kiauta and his mentorship as well as support to the work by younger Slovene odonatologists are highlighted. A checklist of 73 recorded dragonfly species for the country is given, together with their common Slovenian names. Diversity of dragonflies and their habitats in Slovenia is presented, with an overview map of 8,605 localities with dragonfly records, map of number of recorded Odonata species per 5x5 km squares and examples of currently known distributions of *Cordulegaster heros* Theischinger, 1979 and *Somatochlora meridionalis* Nielsen, 1935. Scope and activities of the Slovene Dragonfly Society, founded in 1992 with the aim to increase popularity of dragonflies and to connect dragonfly enthusiasts in Slovenia, are also presented, highlighting the importance of the national odonatological database, which contains over 61,500 faunistic data and is maintained jointly by the Slovene Dragonfly Society and the Centre for Cartography of Fauna and Flora. Although the protection of threatened dragonfly species in Slovenia is satisfactorily covered in legislative terms, some species experience, in reality, serious decline and ongoing encroachment upon their habitats, while systematic, state funded monitoring is not carried out. The beginning of the 6th European Congress on Odonatology (ECOO 2022), to be held between June 27th and 30th

June 2022 in Kamnik, Central Slovenia, is announced." (Authors)] Address: Vinko, D., Slovene Dragonfly Society, Verovškova 56, 1000 Ljubljana, SLOVENIA. Email: damjan.vinko@gmail.com

(2022): Distribution and species richness of a dult Odonata in urban wetlands in Tagum City, Mindanao, Philippines. *Philippine Journal of Science* 151(6A): 2173-2182. (in English) ["Several studies on Philippine Odonata have focused mainly on the protected landscapes and forest reserves; however, little ecological research has been done in an urban setting. Species distribution, abundance, and diversity of Odonata in Tagum were conducted, where no previous records were available. Field sampling was conducted from July–October 2018 among various locations in Tagum City, Davao del Norte. Results showed a total of 1,239 individuals of identified Odonata composing nine species of Family Libellulidae and three species of Family Coenagrionidae. The dominant and most abundant species were *Pantala flavescens*, *Diplacodes trivialis*, and *Orthetrum sabina*. A relatively high Margalef's Index of species richness ( $R = 2.148$ ) and moderate species diversity ( $H' = 1.935$ ) were recorded in Botanical Park and a less even distribution was observed in all sites. Canonical correspondence analysis indicated that both temperature and humidity can affect the abundance of certain species within the community." **20283.** Vliegthart, A. (2022): *Opmerkelijk. Vlinders 1/2022: 32-* (in Dutch) [*Coenagrion scitulum* on its way to the Wadden Islands: After the forked damselfly became established in 2007, the species has been expanding since 2010. By now, the species is widespread below and even above the major rivers. Via the dunes, *C. scitulum* now seems to be spreading (quickly?) to the north. How long will it take before it arrives in Den Helder? And will the transfer to Texel succeed?]

**20284.** Walia, G.K.; Singh, H. (2022): The Journal of Basic and Applied Zoology 83:47. A review on intraspecific karyomorphological variations of m chromosomes in family Libellulidae (Anisoptera: Odonata): 11 pp. (in English) ["Background: Family Libellulidae is one of the largest families of suborder Anisoptera (Odonata) including 1035 species of 144 genera throughout the world. Libellulids are distributed all around the globe, while some are cosmopolitan and some are endemic. Cytogenetic data pertains to 258 libellulid species and chromosome number varies from  $2n = 6.47$ . Majority of the species possess  $2n$  (male) = 25, which is the modal number of the family. The m chromosomes are considered as the fragments of autosomes and are present in 78% of studied libellulid species. Main body: Presently, 29 libellulid species have been catalogued based on various research articles related to cytogenetic studies regarding intraspecific chromosomal variations especially due to the m chromosomes within the same or different geographical populations of the species. Conclusions: Odonata possess holokinetic chromosomes and m chromosomes are the fragments of autosome. The break can occur at any time, at any place, which is responsible for variations in the size of m chromosomes. These variations also depend on the geographical distribution of the species which persists over generations by the action of natural selection and also play role in speciation." **20285.** Wang, Z.J.; Melfi Jr., J.; Leonardo, A. (2022): Recovery mechanisms in the dragonfly righting reflex. *Science* 376(6594): 754-758. (in English) ["Following formidable flyers: Flying involves complicated maneuvers, not the least of which is the process of returning to an upright flying position after being flipped over in midair. Wang et al. used a combination of experiments and biophysical models to understand this process in dragonflies, which are adept insect flyers. The authors reveal that righting involves a series of signals beginning with the visual system through to wing pitch muscles. This approach revealed connections between neural signals and physical processes that could be used to study flight mechanics across species. —SNV. Abstract: Insects have evolved sophisticated reflexes to right themselves in mid-air. Their recovery mechanisms involve complex interactions among the physical senses, muscles, body, and wings, and they must obey the laws of flight. We sought to understand the key mechanisms involved in dragonfly righting reflexes and to develop physics-based models for understanding the control strategies of flight maneuvers. Using kinematic analyses, physical modeling, and three-dimensional flight simulations, we found that a dragonfly uses left-right wing pitch asymmetry to roll its body 180 degrees to recover from falling upside down in ~200 milliseconds. Experiments of dragonflies with blocked vision further revealed that this rolling maneuver is initiated by their ocelli and compound eyes. These results suggest a pathway from the dragonfly's visual system to the muscles regulating wing pitch that underly the recovery. The methods developed here offer quantitative tools for inferring insects' internal actions from their acrobatics, and are applicable to a broad class of natural and robotic flying systems." (2022): Evidence for widespread gene flow and migration in the Globe Skimmer dragonfly *Pantala flavescens*. *International Journal of Odonatology* 25: 43-55. (in English) ["The global population structure and dispersal patterns of *P. flavescens* are evaluated using a geographically extensive mitochondrial DNA dataset, a more limited samples of nuclear markers, wing isotopic ( $d^2H$ ) data and a literature review. No spatial or temporal haplotype structure was recovered between the samples. Isotope data suggest that most samples were immigrants at the collection locations. A literature review of migration events for the species confirms regular inter-and intra-continental migrations occur (the majority reported from Asia, Africa and Australasia), with individuals and swarms dispersing thousands of kilometers over land and oceans. Migrations coincide with prevailing winds and seasonal rains, which points to a mechanism we name the "pantropical *Pantala* conveyor belt", suggesting widespread gene flow is possible for an aquatic insect with excellent flying ability linked to rapid larval development." **20288.** Wilk, T. (2022): Scarce Chaser *Libellula fulva* (Odonata: Libellulidae): second record from the Polish part of the Carpathian Mountains. *Odonatrix* 1811: 3 pp. (in Polish, with English summary) [oas 64: "*L. fulva* is a moderately frequent species in Poland, its distribution being largely confined to the post-glacial landscape of northern Poland and the Lublin region. It becomes much scarcer and more localised towards the south and has hitherto been found just once in the mountainous regions of southern Poland. This paper discusses the second record of this species in the Polish part of the Carpathian Mountains: one general individual was observed in a gravel pit near the village of Podrzeczce in the Dunajec Valley. The record greatly extends the Scarce Chaser's known range in Poland, indicating that this may be slowly shifting southwards. Its presence in the mountainous areas of southern Poland could be linked with new artificial waterbodies that have formed in abandoned gravel or sand pits along Carpathian rivers." **20289.** Wilkinson (2022): Perching and roosting postures in adult *Pyrrhosoma nymphula* (Sulzer) (Large Red Damselfly). *Journal of the British Dragonfly Society* 38(1): 84-99. (in English) ["Although generally considered to be a species that rests with its wings held over its abdomen in a closedwing posture, the author has observed *Pyrrhosoma nymphula* with a diurnal propensity to rest with its wings spread in more half-open wing postures. Furthermore, in contrast to its daytime perching behaviour, late evening observations of roosting *P. nymphula* around a small urban garden pond have consistently revealed that adults habitually adopt 'openwing' roosting postures, either half-open or fully open. Forewings may be pulled forwards up to 110° and may be depressed to approximately 5° above the horizontal plane (Fig. 1); hindwings pulled forwards to between 70° and 130° and depressed by as much as 15° below the horizontal plane. When first settling to roost for the night both sexes may settle with a typically 'closedwing' posture or one of a range of commonly utilised daytime half-open postures. However, a significant number subsequently adjust their position and open their wings to orientations approximately at right angles to the body. There is some evidence that the half-open wing posture orientations are adopted in both males and females earlier in the year, when temperatures are lower; later in the year, as temperatures rise, their behavioural repertoire expands to include more fully open roosting postures. The various hypotheses that have been proposed to explain the significance and function of closedwing versus openwing behaviour are discussed." **20292.** Xu, F.; Wang, J.; Hua, L. (2022): Multi-objective biomimetic optimization design of stiffeners for automotive door based on vein unit of dragonfly wing. *Proceedings of the Institution of Mechanical Engineers, Part C: Journal of Mechanical Engineering Science* 236(9): 4551-4564. (in English) [oas 64a; "In this paper, a biomimetic optimizing design of the stiffeners layout of the automotive inner door panels is proposed based on vein unit of dragonfly wing. The distributions features of the dragonfly veins and similarity as stiffeners are analyzed, and then the excellent structural features of mechanical properties of the dragonfly veins are extracted to work as a biomimetic design. In order to research the distribution of the reinforced areas in the interior door panels under various operating conditions, the finite element model is established firstly. Secondly, gray relation theory combined with analytic hierarchy analysis are imposed to determine the weight value of each condition in multi-objective topology optimization to fully consider both objective and subjective factors, and topological optimization results indicate that the stiffeners of the inner door panel are biconically designed. Finally, the original finite element

results of the inner door panels are compared with that after optimized with biomimetic stiffeners under the same operating conditions, and the result of the comparison verify the effectiveness of the biomimetic topology design. Specifically, for the dent-resistant and sinking condition, the strength of new door increases by 20.2% and 14.3%, respectively. Therefore, doors with biomimetic stiffeners have an increased resistance to deformation and vibration, while the mass is reduced by 2.7%. The results can provide valuable new ideas for the optimal biomimetic design of automotive door inner panel stiffeners." (2022): Descriptions of the larvae of *Huosoma Guan*, Dumont, Yu, Han & Vierstraete, 2013 from China (Odonata: Coenagrionidae). *Zootaxa* 5134(3): 426-434. (in English) ["The final stadium larvae of *Huosoma latiloba* (Yu, Yang & Bu, 2008) and *Huosoma tinctipenne* (McLachlan, 1894) from Yunnan Province, China are described and illustrated for the first time, with diagnostic differences between the two species identified. While no morphological characters separating the adults of this genus, and the closely related western Palaeartic *Pyrrhosoma* Charpentier, 1840 have been found, the larvae of these two genera do show differences which are

discussed here." (Authors)] Address: Orr, A.G., Cooperative Research Centre for Tropical Rainforest Ecology and Management, Environmental Sciences, Griffith University, Nathan, Q 4111, Australia. E-mail: agorr@universal.net.au

**20296.** Zaini, A.; Bunda, H.; Utami, N.H. (2022): Validitas dan keterbacaan booklet capung untuk mahasiswa pada mata kuliah zoologi invertebrata. *Jurnal Pendidikan dan Ilmu Sosial* 1(2): 63-73. (in Indonesian) ["The validity and readability of dragonfly booklets for students in invertebrate zoology course: Dragonfly is one type of insect which is a bioindicator in the environment. Insects can be found in rice fields, so that rice fields are one of the habitats for dragonflies to be found, so the presence of dragonflies in rice fields can increase an interesting learning resource for students to improve understanding of the diversity of the Odonatan order in invertebrate zoology courses. The aims of this study were (1) to analyze the diversity of dragonflies of the order Odonata found in the rice fields of Beringin Kencana village, Tabunganan sub-district. (2) Describe the validity of the booklet compiled from data on the diversity of dragonflies in the Beringin Kencana rice field area, Tabunganan Subdistrict as teaching material for invertebrate zoology courses. (3) Describe the readability test of a booklet compiled from data on the diversity of dragonflies in the Beringin Kencana rice field area, Tabunganan District as an invertebrate zoological enrichment. This research method uses the R&D model developed by Borg and Gall with the stages of development research using the steps, namely research and information collecting, planning, developing preliminary form of product, preliminary field testing, main product revision. Based on the research results, it is known that (1) there are 7 species of dragonflies, namely *Orthetrum sabina*, *Neurothemis fluctuans*, *Brachytemis contaminata*, *Agriocnemis pygmaea*, *Ceriagrion cerinorubellum*, *Tholymis tilarga*, and *Ischnura senegalensis*. (2) Based on the validity test the developed booklet was declared very valid by three expert lecturers with a validity score on the content aspect, namely 88.89%, in the language aspect, 88.89%, and in the presentation aspect, namely 94.44%. (3) The readability test by 6 students got a score of 86.76% so that the Booklet got very good criteria." **20298.** Zhang, V.M.; Martin, R.L.; Murray, R.L. (2022): Chronic road salt exposure across life stages and the interactive effects of warming and salinity in a semiaquatic in-

sect. *Environmental Entomology* 51(2): 313-321. (in English) ["The salinization of freshwater habitats from winter road salt application is a growing concern. Understanding how taxa exposed to road salt run-off respond to this salinity exposure across life history transitions will be important for predicting the impacts of increasing salinity. We show that *Leucorrhinia intacta* dragonflies are robust to environmentally relevant levels of salt pollution across intrinsically stressful life history transitions (hatching, growth, and metamorphosis). Additionally, we observed no carry-over effects into adult dragonfly morphology. However, in a multiple-stressor setting, we see negative interactive effects of warming and salinity on activity, and we found that chronically warmed dragonfly larvae consumed fewer mosquitoes. Despite showing relatively high tolerance to salinity individually, we expect that decreased dragonfly performance in multiple-stressor environments could limit dragonflies' contribution to ecosystem services such as mosquito pest control in urban freshwater environments." **20299.** Zulhariadi, M.; Irawan, R.D.; Zulfaeda, A.; Hidayani, N. (2022): Dragonflies diversity and land cover changes in the Batubolong River, West Lombok District. *Biotropica* 29(2): 112-123. (in English) ["West Lombok District is the second largest district in Lombok Islands. The diversity of dragonflies (Order Odonata) as a bioindicator of environmental quality has not been widely studied in the West Lombok region. This study aimed to determine the species diversity of dragonflies (Order Odonata) found in Batubolong River, West Lombok District and its relation to the occurring land cover changes. This study was carried out by using a descriptive explorative method, where the sampling technique was done by means of line transects. Maps of study and sampling locations as well as land cover changes were made using ArcGIS 10.4.1 software based on primary and secondary data. The results showed that there were 11 species of dragonflies with a Shannon-Wiener diversity index value ( $H'$ ) of 2.212 (medium diversity), a population density index ( $C$ ) of 0.126 (low dominance), and a species evenness index ( $E$ ) of 0.923 (high uniformity). Our study also found two rare species of dragonfly in Lombok Island i.e., 3 individuals of *Nososticta emphylla* (Lieftinck, 1936) with 9% relative abundance and 1 individual of *Drepanosticta berlandi* (Lieftinck, 1939) with 3% relative abundance. The discovery of *D. berlandi* in Lombok is the third time after the findings in 1896 and the 19th century. Analysis of satellite data around the sampling area within the period 2013-2020 showed that there has been an increase in land cover of 6,149.29 m<sup>2</sup>. The increase in land cover changes may have caused the disappearance of several Odonata species in the sampling location." **20300.** Carron, G. (2008): Espèces particulièrement menacées de la région genevoise. Plans d'actions pour la conservation (phase 3). Agrion de Mercure *Coenagrion mercuriale* (Odonata: Coenagrionidae). Etat de Genève, Domaine Nature & Paysage: 55 pp. (in French) [*C. mercuriale* is the 8th insect species considered particularly threatened in the Geneva region (Switzerland) and is the subject of a specific regional action plan. Discovered only in 2006, after several decades of absence in the canton, this dragonfly has its only population on the Creuson, in the Geneva and especially the Vaud sectors, on both sides of the border. Doubts remain as to whether this is a recent colonisation or whether the species has gone unnoticed. There is no other known population within a 40 km radius, there is no other population in the canton of Vaud. *C. mercuriale* is threatened with extinction throughout the country and is protected at the Swiss and European levels. The agrionis requires very sunny and well oxygenated running water and is therefore very sensitive to organic pollution. The present study shows that the population (daily maximum of 700-800 individuals over 3 km) is concentrated in the Vaud sector of the Creuson, between the Bois des Dailles and the Bois de Portes. The Creuson is located in an open landscape, in a sunny situation, and the pollution is marked but not excessive since it is located upstream of the outlet of the Chavannes-Bois WWTP. The optimal habitat is composed of a clear runoff bordered by water cress (*Nasturtium officinale*) and beccabunga speedwell (*Veronica beccabunga*), plants in which the female agrion lays her eggs. The actions must be based on good information / consultation of the different services concerned (as well as the partners involved in the management of the site), on both sides of the border. This will involve limiting the arrival of chemical pollutants (nitrates and biocides from agriculture; copper, organic matter, etc. from the WWTP), modifying the maintenance of the grassy banks, and increasing the amount of sunlight in certain heavily overgrown sections." **20301.** Cheung, K.-w. (2008): Spatial and seasonal variations of freshwater macroinvertebrates, Odonata and waterbirds in Luk Keng marshland, Hong Kong. MSc. thesis, The Univ. of Hong Kong (Pokfulam, Hong Kong): V + 125 pp. (in English) [<sup>1</sup>The temporal and spatial distribution of macroinvertebrates, adult odonates and waterbirds in 26-ha Luk Keng marsh, the largest freshwater wetland in Hong Kong, were investigated between February 2005 and April 2006 to

provide information relevant to management of the marsh for biodiversity conservation. 2. A salinity gradient has been created in Luk Keng as a result of the presence of a sluice gate which allows sea water to intrude the marsh. Ten habitat zones were identified: a stand of mangroves (*Kandelia obovata*: Rhizophoraceae; M) on the seaward side, and – progressing landward – a reed bed (*Phragmites australis*: Poaceae) situated towards the western (WP) and north-eastern side (NEP) of Luk Keng; a tidal mudflat area on the western (WMudflat) and southern side (SMudflat) of Luk Keng; a portion of the marsh (W) dominated by water chestnut (*Eleocharis dulcis* and *E. spiralis*: Cyperaceae); two grass-dominated freshwater marshland zones (SS and ST); a stream flowing into Luk Keng with an associated marshy area (Ri); and, the junction between the stream and the marsh (H). 3. A total of 75 aquatic macroinvertebrate taxa in 38 families were recorded in 112 samples collected during the dry and wet seasons in the two freshwater marshland zones SS and ST, and is the highest thus far reported from such habitats in Hong Kong. Assemblage composition and richness at SS and ST were broadly similar. Diptera dominated in terms of richness and relative abundance, although Coleoptera and larval odonates were also important. In terms of functional organization, macroinvertebrate assemblages were dominated by predators while collector-gatherers were also numerous. 4. Significant seasonal variation of macroinvertebrate assemblage structure was detected in both SS and ST with odonates more abundant in the wet season and oligochaetes more numerous during the dry season. The proportion of predators was the highest during the wet season when similarity between areas was the greatest. Seasonal variations were more marked at SS due to the greater range of salinity recorded in that area. 5. Forty-two odonate species (15 Zygoptera and 27 Anisoptera) representing 38% of odonate species in Hong Kong, including the globally-vulnerable *Mortonagrion hirosei* and 10 species of local conservation concern, were recorded in M, WP, W, SS, ST and H during biweekly transect counts. The odonate assemblage was dominated by Libellulidae and Coenagrionidae, and *Agriocnemis femina*, *Ceragrion auranticum* and *Orthetrum luzonicum* were the most common species. 6. There was an obvious seasonal change in abundance and species richness of odonates with an increase from March until July then a decline through August to October and followed by a dry-season low. 7. Species richness of adult odonates decreased from the freshwater zones to the mangrove zone, although *M. hirosei* was mainly confined to reed bed, and salinity appeared to have an important influence on odonate assemblage structures, possibly by way of an effect on vegetation structure. 8. Thirty waterbird species, mainly Scolopacidae and Ardeidae were recorded in M, WP, NEP, WMudflat, SMudflat, W, SS, ST and Ri during monthly

point counts and transect counts. [...] 10. It is recommended that populations of globally-vulnerable *Mortonagrion hirosei* be monitored in Luk Keng each year by the Agriculture, Fisheries and Conservation Dept using line transects in reed beds; censuses should be made from April to June. Biweekly odonate surveys during the wet season, especially in July and August, are also recommended to monitor the ecological conditions at Luk Keng. Biweekly point counts should also be undertaken to record the abundance of globally-endangered Black-faced Spoonbills from November to May. Counts of Common Snipe, Pintail Snipe, Swinhoe's Snipe and Greater Painted Snipe which are threatened by the degradation of wet agricultural lands in Hong Kong should also be made. 11. A sluice gate which can be closed during spring tides should be built by the Home Affairs Dept to replace the present faulty gate so as to manage salinity levels in the marsh and prevent excessive saline intrusion. While some intrusion will be needed to maintain the reed bed and mangroves as habitats for *M. hirosei* and the Black-faced Spoonbill, investigation of the consequences of salinity intrusion should be initiated by AFCD. Designation of Luk Keng marsh as a Country Park or Special Area to protect the biodiversity it supports should be undertaken as a matter of urgency." (Author)] Address: not stated

**20302.** Cremona, F. (2008): Transfert de méthylmercure et structure des réseaux trophiques chez les macroinvertébrés littoraux. Thèse universitaire, Université du Québec à Montréal: XIV + 159 pp. (in French or English) ["In the context of the COMERN St. Lawrence River case study, the overall objective of the thesis was to determine the role of littoral macroinvertebrates in the transfer of methylmercury (MeHg) in the Lake St. Pierre ecosystem. The first chapter was devoted to the quantitative contribution of non-consumptive invertebrates ("trophic impasses") to the transfer of MeHg to fish. For this purpose, total mercury (THg) and MeHg concentrations in four functional groups of littoral macroinvertebrates (grazers, detritivores, consumable predators, non-consumable predators) were measured. The results showed that non-consumptive predators had the highest THg, MeHg and MeHg/THg concentrations of all functional groups. The MeHg load (concentration x biomass) of non-consumptive predators represented 10-36% of the MeHg pool of phytophilic invertebrates. This high proportion of MeHg sequestered in trophic impasses could help explain the low Hg concentrations measured in fish in Lake St Pierre. Our results show that non-consumptive organisms must be taken into account in predictive models of Hg contamination of ecosystems in order to avoid overestimating the quantities of MeHg bioavailable to fish. In the second chapter, the objective was to determine the links between the source of organic matter (OM) and MeHg contamination in primary consuming littoral macroinvertebrates. An isotope approach was applied to meet this objective. Indigenous sources (epiphytes and macrophytes) dominated the OM assimilated by primary consumers, with a lower proportion of allochthonous OM (suspended particulate matter in particular). MeHg/THg in macroinvertebrates was positively correlated with epiphyte proportions, whereas the latter were negatively correlated with the inorganic Hg fraction. This finding may suggest that the main pathway of MeHg into nearshore food webs is through epiphytes. Primary consumers could then modulate the transfer of MeHg to higher trophic levels depending on whether they feed on OM sources with high or low MeHg concentrations. The third chapter dealt with the influence of functional group (grazer, collector, fragmenter, omnivore, predator, predator-haematophagous, biting-sucking) and spatiotemporal variables

(year, month, sampling station) on the  $\delta^{15}\text{N}$  signature of littoral macroinvertebrates in Lake St Pierre. Station was the most important factor in explaining  $\delta^{15}\text{N}$  variations, followed by sampling month and functional group. Organisms from the south shore, which is heavily influenced by agricultural inorganic nitrogen inputs, had higher  $\delta^{15}\text{N}$  values than those from the north shore which receives inputs from the Canadian Shield. The  $\delta^{15}\text{N}$  signature of the organisms increased by about 3‰ during the sampling period from May to September, equivalent to one trophic level. The enrichment of  $\delta^{15}\text{N}$  from herbivores to predators averaged 1.6‰, which is lower than the 3.4‰ generally considered in pelagic organisms. Since isotopic fractionation is not homogeneous throughout the food web, we recommend using fractionation values specific to the trophic levels considered, in order to better reconstruct nearshore food webs. In the last chapter, the roles of macrophyte habitat and architecture on the biomass and abundance of phytophilic invertebrates were investigated. We also calculated a lake-wide estimate of the macroinvertebrate biomass associated with different macrophytic habitat types in order to estimate the quantitative effects of vegetation changes on macroinvertebrate communities. Biomass, abundance and richness of invertebrate communities were higher in submerged macrophyte habitats than in floating and emergent macrophyte habitats. Macrophytes with complex architecture did not harbour significantly more macroinvertebrate biomass than those with simpler architecture. In the case of a decrease in water level in Lake St. Pierre we predicted that the total biomass of phytophilic invertebrates would decrease by 16% at the lake scale. In nearshore food webs, it appears that energy and MeHg flows are not perfectly superimposed. Firstly, the lower trophic levels constituted by primary consumer macroinvertebrates are capable of modulating MeHg fluxes according to the nature of their OM sources. Secondly, among secondary consumers a significant proportion of the MeHg pool will be available for transfer to fish only to a limited extent or not at all. The small difference in  $\delta^{15}\text{N}$  between primary and secondary consumers makes us doubt the usefulness of this tool as a tracer of the trophic level of an organism in the littoral zone compared to  $\delta^{13}\text{C}$ ." **20307.** van der Tol, M. (2011): Onderzoek naar de geschiktheid voor libellen van de duinpoelen Zuid-Kennemerland en de invloed van grote grazers hierop - [Study of the suitability for dragonflies of dune pools South-Kennemerland and the influence of large grazers on this]. BSc. thesis, Bos- en Natuurbeheer, Hogeschool Van Hall - Larenstein: 91 pp. (in Dutch) ["Zuid-kennemerland contains a large number of dune pools. The area is integrally grazed by Scottish Highlanders, Shetland ponies and Konik horses, in order to prevent grassification and encroachment and to

promote varied vegetation structures. The dune pools provide grazing and drinking opportunities for these animals. They are also important breeding grounds for dragonflies, among other things. Management company PWN wants to monitor the effect of the large grazers on the pools in general and on the dragonfly fauna in particular. The aim is to adapt the management for the benefit of the dragonflies if necessary. The assignment was carried out within the graduation phase of the course Forestry and Nature Management, Nature and Landscape Technology at the Van Hall - Larenstein Univ. of Applied Sciences in Velp (Gelderland). The research question is as follows: What is the suitability for the dragonfly fauna of the dune pools in South-Kennemerland, and what is the influence of the large grazers on this? Existing inventory data of various dune pool characteristics and of dragonflies were used for the analysis and converted into a usable dataset. The data were statistically processed with SPSS. The inventory data are not complete; important data of both dune pool characteristics and dragonflies are missing. This fact and the very limited time available for the research have led to research results that partially answer the research question. Moreover, the reliability of the results is limited. In the analysis, relationships between large grazers, dune pools and dragonflies were sought by determining Pearson correlations and by means of the Mann-Whitney U test, a distribution-free significance test. A negative relationship between the use of the pools by large grazers and the total number of reproducing species was found, but it is not a strong relationship. One species, the Flat-bellied Dragon, has been shown to benefit from trampled banks. The most important key factor for dragonfly reproduction in general in the dune pools is the presence of flab in summer. Further research, improvement and extension of inventory methods for dragonflies and dune pool characteristics are necessary in order to arrive at reliable results and useful management advice." ## 2012

**20308.** Hilfert-Rüppell, D.; Rüppell, G. (2012): Blaue Luftkrobaten: Prachtlibellen als Modellorganismen für Verhaltensbeobachtungen. *PdN Biologie in der Schule* 61(6): 8-12. (in German) ["Behavioural observation; Secondary school I; Secondary school II; Courtship; Biology lessons; Flowing water; Wing beat; Dragonfly; Mating; Territorial behaviour; Animal behaviour; Germany. Abstract: Damselflies (*Calopteryx*) are typical inhabitants of flowing water. The blue males are immediately noticeable when they flutter around each other or approach the camouflaged females in buzzing flight. After only a short observation of the animals, it becomes clear that the males occupy certain areas, so-called territories, and drive other males out of them. They do this with very different flights: They fly side by side or behind each other in arcs up and down or back and forth. They circle each other or chase each other at top speed. The winner gets the reward later, usually in the midday and afternoon hours, mating with females. However, when a lot of males gather on the shore, chaos breaks out. Now the males can no longer defend territories and they all pounce on rivals and females. Pupils are given instructions on how to observe, but also how to film with a slow-motion camera to see the behaviour in detail. In doing so, they get to know the animals and their behaviour and thus gain the ability to independently draw conclusions about the order of behaviour, adaptation and evolution. The topic offers both material and content at entry level as well as for more demanding

processing in secondary school. It is possible to advance into modern areas such as genecology, female choice or integrative models by combining physiological (e.g. dual function of flight), ecological (e.g. qualities of the habitat) and evolutionary (e.g. sexual conflict) elements. The behaviour of damselflies is one of the model systems for the study of animal communication." (Authors)] Address: Hilfert-Rüppell, Dagmar, Technische Universität Braunschweig, Institut für Fachdidaktik der Naturwissenschaften, Abteilung Biologie & Biologiedidaktik, Bienroder Weg 82, 38106 Braunschweig, E-Mail: d.hilfert-ruempel@tu-bs.de

## 2016

**20310.** Kaelin, K.; Altermatt, F. (2016): Landscape-level predictions of diversity in river networks reveal opposing patterns for different groups of macroinvertebrates. *Aquatic Ecology* 50(2): 283-295. (in English) ["Aquatic biodiversity in rivers and streams is threatened in many regions worldwide. As biodiversity loss has severe consequences on ecosystem functioning, it is important to understand the causes of decline and to predict biodiversity in space and time. In order to achieve this, the identification of the driving factors and the appropriate choice of indicator groups are needed. We developed a spatially explicit habitat distribution model for aquatic macroinvertebrates in Swiss watercourse networks using national biodiversity monitoring data from 410 randomly selected sampling sites. We specifically looked at two worldwide frequently used macroinvertebrate indicator groups. Using generalized linear models, we related firstly species richness of mayfly, stonefly and caddisfly (Ephemeroptera, Plecoptera, Trichoptera; EPT) and secondly richness of all macroinvertebrate families and higher-order taxa (macroinvertebrate family richness) to 38 nationwide available environmental variables. We then predicted richness of both indicator groups at the landscape scale, providing the first nationwide prediction of EPT species and macroinvertebrate family richness. Consistent with previous work, we found that variables describing land use and topology were most important for explaining richness at the landscape level. However, the two indicator groups showed opposing patterns of richness and a different sensitivity to land-use variables. This indicates that the sole use of one of these groups may be misleading with respect to water quality assessments and to the identification of overall diversity hotspots. We conclude that commonly used richness patterns derived from aggregated groups, such as

family-level macroinvertebrate richness, may be less appropriate for conservation strategies." (Authors)] Address: Altermatt, F., Dept of Aquatic Ecology, Eawag, Swiss Federal Inst. of Aquatic Science & Technology, Überlandstr. 133, 8600, Dübendorf, Switzerland. Email: Florian.Altermatt@eawag.ch

**20311.** Liebhold, A.M.; Yamanaka, T.; Roques, A.; Augustin, S.; Chown, S.L.; Brockerhoff, E.G.; Pysek, P. (2016): Global compositional variation among native and non-native regional insect assemblages emphasizes the importance of pathways. *Biological Invasions* 18: 893-905. (in English) ["Insects are among the world's most ecologically and economically important invasive species. Here we assemble inventories of native and non-native species from 20 world regions and contrast relative numbers among these species assemblages. Multivariate ordination indicates that the distribution of species among insect orders is completely different between native and non-native assemblages. Some orders, such as the Psocoptera, Dictyoptera, Siphonaptera, Thysanoptera, and Hemiptera, are always over-represented in the non-native compared to native assemblages. Other orders, such as the Plecoptera, Trichoptera, Ephemeroptera, Odonata, Mecoptera and Microcoryphila, are consistently under-represented in non-native assemblages. These patterns most likely arise both as a result of variation among taxa in their association with invasion pathways responsible for transporting species among world regions, as well as variation in life-history traits that affect establishment potential. However, our results indicate that species compositions associated with invasiveness are fundamentally different from compositions related to insularity, indicating that colonization of islands selects for a different group of insect taxa than does selection for successful invaders. Native and non-native assemblage compositions were also related, to a lesser extent, to latitude of the region sampled. Together, these results illustrate the dominant role of invasion pathways in shaping the composition of non-native insect assemblages. They also emphasize the difference between natural background colonization of islands and anthropogenic colonization events, and imply that biological invasions are not a simple subset of a long-standing ecological process." **20313.** Amundrud, S.L.; Videla, M.; Srivastava, D.S. (2018): Dispersal barriers and climate determine the geographic distribution of the helicopter damselfly *Mecistogaster modesta*. *Freshwater Biology* 63(2): 214-223. (in English) ["1. Species' ranges are typically constrained by the interplay of physical barriers to dispersal, environmental requirements such as suitable climatic conditions and biotic constraints such as from predation or competition. However, teasing apart the relative importance of these constraints in determining species distributions still represents a major challenge for ecologists. 2. The Neotropical damselfly *M. modesta* inhabits wet and moist forests in mainland Central America and north-western South America. This habitat specialist spends its larval development exclusively in tank bromeliads, where it acts as a keystone predator within the aquatic food web. Although tank-forming bromeliads occur from the southern United States throughout most of South America, *M. modesta* is absent from the Caribbean islands and South America south-east of the Andes mountain chain. 3. We employed species distribution models to explore the relative importance of physical barriers (Andes mountain range and oceanic barriers), climate (mean annual temperature and annual precipitation) and biotic interactions (competition from other bromeliad-dwelling odonates) in limiting the geographic distribution of *M. modesta*. 4. We found that dispersal barriers strongly limit the geographic distribution of *M. modesta*. In addition, its range is restricted by low temperatures and low precipitation. Competition from other bromeliad-dwelling odonates was not important in limiting the damselfly's range. Because of the physical barriers to dispersal, *M. modesta* does not occupy its full potential geographic range. Specifically, our model predicted suitable habitat on the Caribbean islands and throughout most of South America, where the species is currently absent. 5. These findings have important conservation implications, particularly as the aridification of rainforests and subsequent localised extinctions due to climate change continue. On the other hand, the species may respond to warming temperatures by tracking climate to higher elevations, with subsequent effects on naïve high-elevation bromeliad food webs. An upwards migration could also increase the probability of *M. modesta* overcoming the dispersal barrier presented by the Andes, enabling the damselfly to invade large areas of suitable habitat in South America." **20314.** Andrew, R.J.; Thomas, S. (2018): Egg chorion of *Paragomphus lineatus* (Odonata: Gomphidae). *Odonatologica* 47(1/2): 133-144. (in English) ["The egg chorion of the exophytic dragonfly *Paragomphus lineatus* was examined using light and scanning electron microscopy. The egg is sub-spherical and possesses a very large conical but flat-top micropylar apparatus. The outer surface of the chorion is uniformly sculptured with strong hexagonal reticulations formed by the fusion of tiny low nodules on the chorion (3–4µm). The area lying inside the hexagonal reticulation is filled with 7–10 nodules. The chorion is formed of a uniformly thin endochorion and a multi-layered exochorion. The micropylar apparatus is composed of a central, tubular micropylar projection which terminates as a flat circular disc. This plate bears a central elevated knob around which 6–7 micropylar orifices are arranged in a circle. The micropylar projection is surrounded by a thick mass of sticky jelly. Development of the micropylar apparatus takes place during the late vitellogenic and choriogenic stages of egg maturation. The jelly mass is exochorionic in origin and is deposited

by the follicular epithelial cells of the oocyte. The micropylar projection is formed by the evagination and morphogenetic movement of the endochorion. The egg chorionic architecture of *P. lineatus* is discussed with respect to phylogeny and oviposition behaviour of the female." **20315.** Aziz, M.A.A.; Mohamed, M.; Tokiman, M.L. (2018): Faunistic studies of odonates (Insecta: Odonata) in Johor, Peninsular Malaysia. *Serangga* 23(2): 14-35. (in English, with Malay summary) ["The purpose of this research is to study the diversity and distribution of odonates in Johor, Peninsular Malaysia. The method used for odonate sampling was manual collection along 1 km line transect using aerial net. Overall, a total of 2222 individuals under 84 species from 13 families and 58 genera were recorded. Family Libellulidae was the most well-represented family. Shannon Diversity Index (H') and Evenness Index (E) were highest in Endau-Rompin Johor National Park (H'= 3.155; E= 0.733) and lowest in Soga Perdana Recreational Forest (H'= 2.444; E= 0.501). To determine the site with highest conservation priority, the ecological data and entomotourism criteria was further analyzed using grid analysis. The site with highest priority was Endau-Rompin Johor National Park with a score value of 52 while the lowest priority was recorded in Sungai Sayong with a score value of 35. All these data will be helpful in assisting towards a better management of the conservation areas in Johor." **20316.** Bäumlér, F.; Gorb, S.N.; Büsse, S. (2018): Comparative morphology of the thorax musculature of adult Anisoptera (Insecta: Odonata): Functional aspects of the flight apparatus. *Arthropod Structure & Development* 47(4): 430-441. (in English) ["Due to their unique flight mechanism including a direct flight musculature, Odonata show impressive flight skills. Several publications addressed the details of this flight apparatus like: sclerites, wings, musculature, and flight aerodynamics. However, 3D-analysis of the thorax musculature of adult dragonflies was not studied before and this paper allows for a detailed insight. We therefore, focused on the thorax musculature of adult Anisoptera using micro-computed tomography. Herewith, we present a comparative morphological approach to identify differences within Anisoptera: Aeshnidae, Corduliidae, Gomphidae, and Libellulidae. In total, 54 muscles were identified: 16 prothoracic, 19 mesothoracic, and 19 metathoracic. Recorded differences were for example, the reduction of muscle Idlm4 and an additional muscle Ildm1 in *Aeshna cyanea*, previously described as rudimentary or missing. Muscle Iscm1, which was previously reported missing in all Odonata, was found in all investigated species. The attachment of muscle Ipcm2 in *Pantala flavescens* is interpreted as a probable adaptation to its long-distance migration behaviour. Furthermore, we present a review of functions of the odonatan flight muscles, considering previous publications. The data herein set a basis for functional and biomechanical studies of the flight apparatus and will therefore lay the foundation for a better understanding of the odonatan flight. ] Address: Bäumlér, F., Dept of Functional Morphology and Biomechanics Institute of Zoology, Kiel Univ., Am Botanischen Garten 9, 24118, Kiel, Germany

**20317.** Barnard, A. (2018): The role of divergent genital morphologies in reproductive isolation. PhD. thesis, Univ. of Oklahoma: XV + 145 pp. (in English) ["How a single ancestral species can give rise to new, separate species remains a major outstanding question in evolutionary biology. Understanding speciation requires identifying how reproductive isolation (RI) is initiated and maintained in the early stages of population divergence. External male reproductive structures have received considerable attention as an early-acting cause of RI, because the morphology of these structures often evolves rapidly between populations. My dissertation research used a pair of recently diverged damselfly species in the genus *Enallagma* (Odonata: Coenagrionidae) to understand the role of divergent genital morphologies in causing RI at early stages of the speciation process. Specifically, I investigated the mechanisms by which species-specific morphologies limit gene flow between species, and then explored the relationships between morphological differentiation and overall genomic differentiation between species. My research focused on *Enallagma anna* and *E. carunculatum*, two damselfly species that diverged within the past ~250,000 years and differ conspicuously in their reproductive structure morphology, yet currently hybridize in at least one sympatric region. In chapter 1, I tested the importance of mechanical and tactile incompatibilities in RI between *E. anna* and *E. carunculatum* by quantifying 19 potential prezygotic and postzygotic RI barriers, using both naturally occurring and lab-reared damselflies. I found that mechanical incompatibilities between heterospecific male and female reproductive structures limit but do not completely prevent heterospecific mating attempts. However, females were significantly less likely to mate with hybrid or heterospecific males compared to conspecific males, which suggests that tactile incompatibility between male and female morphologies forms an additional mechanism to limit gene flow between these species. Postmating RI barriers appeared weak or nonexistent, which indicates that premating isolation, mediated by divergence in genital morphologies, was the first type of reproductive barrier to evolve in this group. These results highlight the potential for rapidly evolving genitalia to cause RI via tactile mechanisms, which may be a more widespread RI mechanism than we are currently aware of. In chapter 2, I more closely examined the female structures presumed to be important in evaluating male tactile signals during premating contact and influencing *Enallagma* female mating decisions. I quantified and compared several mechanosensory sensilla phenotypes on the female thorax among multiple sympatric and allopatric populations to test for evidence of reproductive character displacement, which would indicate that sensilla phenotypes are important in species recognition. My results suggest that species-specific placement of female mechanoreceptors is sufficient for species recognition, but mechanosensor variation among females within species may be important for mate choice within species. This hypothesis requires additional study to test the relationships between female sensilla phenotypes and behavior. This experiment reveals *Enallagma*'s potential as a study system for elucidating the neurobiological basis of female mating decisions. In chapter 3, I explored the relationships between morphological divergence and genomic differentiation during speciation. Persistent gene flow between species as they diverge can homogenize some regions of the genome and make differentiated regions stand out in comparison. Some of these highly divergent loci are predicted to harbor genes responsible for reproductive isolation. However, patterns of genome diversification at this stage remain poorly understood, such as how such loci are arranged across the ge-

nome and whether such loci commonly contribute to reproductive isolation or are simply less subject to recombination. I generated a set of genome-wide variant loci in a large collection of samples from multiple populations, including both natural and lab-reared hybrids. I used these loci to quantify introgression patterns in nature, identify divergent loci, and test for associations between genomic ancestry and species-specific phenotypic variation. The results suggest ongoing gene flow between *E. anna* and *E. carunculatum* in nature, but also demonstrate the challenge of differentiating shared ancestral polymorphism from recent admixture when studying young species. Additionally, the results revealed that estimated ancestry proportions in hybrids were a reliable predictor of hybrid reproductive structure phenotype in most cases – but some individuals appeared to have a genome that mostly resembled one parental species, yet morphology more similar to that of the other parental species. Clarifying the relationships between genotypes and phenotypes will likely require more fine-scale genomic sequencing efforts than this study obtained. My dissertation research integrated behavioral studies in the field and lab with quantitative trait comparisons and genomics to investigate the importance of rapid evolution of reproductive structures in reproductive isolation. This work enhances our understanding of how morphological divergence affects mating behavior to cause RI, and in turn how RI and behavior shape differentiation of genomes. Together, these experiments contribute to our understanding of how biodiversity is generated and strengthen the role of damselflies as models for understanding evolution." **20318.** Benchalel, W.; Bouziane, A.; Bouslama, Z.; Ramdani, M.; Elmsellem, H.; Flower, R.; Ramdani, M. (2018): Odonata of Wadi Bouarroug (northeastern Algeria) and environmental determinants of their distribution. Moroccan Journal of Chemistry 6(1): 78-91. (in English, with French summary) ["The present paper describes odonates recorded over an extended period at wadi Bouarroug, south of lake Mellah, in the national reserve of Brabtia (North-east Algeria). In all, 42 weekly visits were made to four stations at wadi Bouarroug between March 2015 and February 2016. 19 species of odonates comprising seven families was recorded. Among the 19 species, autochthonous status was confirmed for 12 species. Two Maghrebian endemics species, *Platycnemis subdilata*, *Gomphus lucasi* ("Data Deficient" species in the Mediterranean IUCN Red-List) were recorded. In the latest check-list of the odonates fauna of wadi Bouarroug, 11 species were reported, during 1993 and 1994. Eight species have been recently added of which *Paragomphus genei* was recorded for the first time in the reserve of Brabtia in 2014 and its autochthonous status is confirmed at wadi Bouarroug from June 2015. Species richness along the wadi Bouarroug is positively correlated with density of riverine vegetation and with weak to moderate water flow during all the year. By contrast, species richness varies negatively with habitat fragmentation and the destruction caused by urbanization and pollution. As a result of this study, we do not propose any change of the "Red List of the IUCN" classification of the recorded species recorded at wadi Bouarroug. However, the presence of some taxa like *Calopteryx haemorrhoidalis* and *Paragomphus genei* at wadi Bouarroug, testifies to the persistence of high-quality natural environments, which are able to still support an important diversity of aquatic species." (Authors) A total of 1810 individuals was counted during the sampling period. The total number of species was 19, assigned to nine families : Calopterygidae (*Calopteryx haemorrhoidalis*), Lestidae

(*Lestes virens*, *L. viridis*), Platycnemidae (*Platycnemis subdilatata*), Coenagrionidae (*Ischnura graellsii*, *Coenagrion puella*, *Erythromma lindinii*, *E. viridulum* and *Ceriagrion tenellum*), Aeshnidae (*Anax imperator*, *Boyeria irene*), Gomphidae (*Gomphus lucasii*, *Paragomphus geneii*, and *Onychogomphus uncatatus*), Libellulidae (*Orthetrum cancellatum anceps*, *Sympetrum striolatum*, *Crocothemis erythraea*, *Trithemis arteriosa* and *T. annulata*). Nine species belong to the suborder of willing zygoptera and 10 in Anisoptera. Autochthony is confirmed for 12 species out of the 19 inventoried species (*Calopteryx haemorrhoidalis*, *Lestes viridis*, *Platycnemis subdilatata*, *Ischnura graellsii*, *Coenagrion puella*, *Ceriagrion tenellum*, *Anax imperator*, *Boyeria irene*, *Gomphus lucasii*, *Paragomphus geneii*, *Onychogomphus uncatatus* and *Orthetrum cancellatum*) (Tab. II).] Address: Elmsellem, H., Lab. de chimie analytique appliquée, matériaux et environnement (LC2AME), Faculté des Sciences, B.P. 717, 60000 Oujda, Morocco. E-mail: h.elmsellem@gmail.com

**20319.** Berenbaum, M. (2018): Damsel flies in Distress? *American Entomologist* 64(1): 3-6. (in English) ["Whatever its other shortcomings might have been, 2017 was certainly a year for female empowerment—from the Women's March on Washington in January to "the Silence Breakers" as Time Magazine's People of the Year in December, it was a year of upending norms in interactions between the sexes. Although sexual harassment may have finally received long-overdue public attention in just about every dimension of human endeavor, it has been a focus for entomological research for decades, and the entomological literature in 2017 illustrated the point nicely. A Web of Science search revealed 484 citations in 2017 for articles with "insect" and "sexual harassment" as topics. That number is 484 times higher than the number of citations in 1965, the first year for publication of any articles on those topics ("Sexual aggressiveness of male...") **20320.** Bergsten, J.; Göthberg, A.; Johansson, K.; Pettersson, A.; Burkart, W.; Burkart G. (2018): Entomologmötet på Gotland 2017: temaexkursion med fokus på vattenlevande skalbaggar, skinnbaggar och trollsländor i Åskåkersvät. [Entomology meeting on Gotland 2017: thematic excursion on aquatic beetles, bugs and dragonflies to the locality Åskåkersvät.]. *Entomologisk Tidskrift* 139(1): 39-49. (in Swedish, with English summary) ["The yearly Swedish entomology meeting 2017 was organized by the local entomology society of Gotland, on the northern part of the Baltic island Gotland near Bunge, 4-6 August. One thematic excursion was focused on aquatic insects, especially aquatic beetles, bugs and dragonflies. A shallow pond, Åskåkersvät, with Characeae in an open grazed landscape with high natural values was studied. Åskåkersvät lies just adjacent to the larger area around Lake Bästeträsk which is the focus of a pilot study evaluating its potential as a future national park. The pilot study is undertaken by Gotland County Administrative Board, the Swedish Environmental Protection Agency, Region Gotland and the Swedish Agency for Marine and Water Management. Here we give an annotated report of the 103 species found: 69 species of water beetles (out of which 34 were Dytiscidae), 20 species of aquatic or semiaquatic bugs (out of which 10 were Corixidae), and 14 species of dragonflies. [*Lestes sponsa*, *L. virens*, *Sympecma fusca*, *Enallagma cyathigerum*, *Coenagrion pulchellum*, *C. hastulatum*, *Ischnura elegans*, *Orthetrum cancellatum*, *Sympetrum sanguineum*, *Libellula quadrimaculata*, *Cordulia aenea*, *Anax imperator*, *Aeshna isosceles*, *A. sp.*] These

include *Hydrophilus piceus* and *H. aterrimus* redlisted in Sweden (both as NT), and *Dytiscus latissimus*, globally redlisted (VU). We also noted the noble crayfish, *Astacus astacus* (redlisted as CR in Sweden) and the European medicinal leech *Hirudo medicinalis* (redlisted as NT globally). *Anax imperator* was noted, a species first recorded from Gotland in 2002 and we present a graph on its increase and spreading on the island since. The number of species found in spite of a relatively modest collecting effort at a suboptimal time when many species may be in pupal stage out of water as witnessed by many general individuals, indicates a species rich locality with high natural value. The stoneworts (Characeae) vegetation certainly contributes to this, for instance vouched for by the occurrence of specialists as *Halipilus confinis* and *H. obliquus* whose larvae feed on stoneworts." **20322.** Blanke, A.; Pinheiro, M.; Watson, P.J.; Fagan, M.J. (2018): A biomechanical analysis of prognathous and orthognathous insect head capsules: Evidence for a many to one mapping of ridge strain to head strain. *Evolutionary Biology* 31(5): 665-674. (in English) ["Insect head shapes are remarkably variable but the influences of these changes on biomechanical performance are unclear. Among "basal" winged insects, such as dragonflies, mayflies, earwigs, and stoneflies, some of the most prominent anatomical changes are the general mouthpart orientation, eye size and the connection of the endoskeleton to the head. Here, we assess these variations as well as differing ridge and sclerite configurations using modern engineering methods including multibody dynamics modelling and finite element analysis in order to quantify and compare the influence of anatomical changes on strain in particular head regions and the whole head. We show that a range of peculiar structures such as the genal/subgenal, epistomal, and circumocular areas are consistently highly loaded in all species, despite drastically differing morphologies in species with forward projecting

(prognathous) and downwards projecting (orthognathous) mouthparts. Sensitivity analyses show that the presence of eyes has a negligible influence on head capsule strain if a circumocular ridge is present. In contrast, the connection of the dorsal endoskeletal arms to the head capsule especially affects overall head loading in species with downward projecting mouthparts. Analysis of the relative strains between species for each head region reveals that concerted changes in head substructures such as the subgenal area, the endoskeleton and the epistomal area lead to a consistent relative loading for the whole head capsule and vulnerable structures such as the eyes in prognathous and orthognathous insects. It appears that biting-chewing loads are managed by a system of strengthening ridges on the head capsule irrespective of the general mouthpart and head orientation. Concerted changes in ridge and endoskeleton configuration allow for more radical anatomical changes such as the general mouthpart orientation which could be an explanation for the variability of this trait among insects. In an evolutionary context, many to one mapping of strain patterns onto a relatively similar overall head loading indeed could have fostered the dynamic diversification processes seen in insects." **20323.** Boda, P.; Móra, A.; Várbiro, G.; Csabai, Z. (2018): Livin' on the edge: the importance of adjacent intermittent habitats in maintaining macroinvertebrate diversity of permanent freshwater marsh systems. *Inland Waters* 8(3): 312-321. (in English) ["Taxonomic and functional patterns of macroinvertebrate communities were investigated to reveal the importance of different habitat units within a marsh system in maintaining its macroinvertebrate diversity. Hydrogeomorphic units based on their functional characteristics were used to distinguish 3 types of aquatic habitats within the marsh system: (1) Core Unit (CU), a permanent inundation of a wetland in the central position of a marsh system; (2) Transitional Unit (TU), a seasonal to intermittent inundation of a wetland, with seasonal saturation; and (3) Satellite Unit (SU), seasonal depression wetlands with ephemeral to intermittent saturation. We hypothesized that communities in each Unit would have specific taxonomic and functional features. Species richness was highest in the TU, with unique community composition in the SU, and moderately high species richness characterized by a stable community with high taxonomic distinctness in the CU. The meta-community of the entire marsh was nearly random with a substantial equilibrium between beta-diversity features: replacement and dissimilarity. Our results suggest that the combination of directly connected or isolated waterbodies in close proximity to a large core waterbody is likely to maintain the highest level of diversity. Each Unit has unique characteristics and provides habitats for species with different ecological traits; thus, different aquatic habitats of a marsh system should be considered together as one meaningful ecological entity." **20325.** Boucenna, N.; Kahalerras, A.; Boukhemza-Zemmouri, N.; Houhamdi, M.; Khelifa, R. (2018): Niche partitioning at emergence of two sympatric top-predator dragonflies, *Anax imperator* and *A. parthenope* (Odonata: Aeshnidae). *Annales de la Société entomologique de France* (N.S.) 54(2): 1-8. (in English) ["In natural communities, closely related species are phenotypically similar but usually spatially and/or temporally isolated. In odonates, interspecific competition occurs not only at the larval or adult stage but also during emergence. We investigated the emergence of two sympatric *Anax* species, focusing on the temporal pattern, vertical stratification, and body size trend over time. *Anax imperator* started to emerge two weeks earlier than *A. parthenope* but most of the emergence season overlapped. Both species showed an asynchronous emergence and the median emergence date was 10.3 days earlier in *A. imperator*. Sex ratio at emergence was not significantly different from 1:1. Body size of both species increased significantly over time, which contrasts many previous studies. The height of exuvia fixation was not significantly different between species but the larger species *A. parthenope* selected longer supports." (Authors)] Address: Khelifa, R., Biodiversity Res. Center, Univ. British Columbia, 2212 Main Mall, Vancouver, B.C. V6T1Z4, Canada. Email: rassimkhalifa@gmail.com

**20326.** Bray, J.P.; Reich, J.; Nichols, S.J.; King, G.K.K.; Mac Nally, R.; Thompson, R.; O'Reilly-Nugent, A.; Kefford, B.J. (2018): Biological interactions mediate context and species-specific sensitivities to salinity. *Phil. Trans. R. Soc. B* 374: 20180020. <http://dx.doi.org/10.1098/rstb.2018.0020>: 10 pp. (in English) ["Toxicants have both sub-lethal and lethal effects on aquatic biota, influencing organism fitness and community composition. However, toxicant effects within ecosystems may be altered by interactions with abiotic and biotic ecosystem components, including biological interactions. Collectively, this generates the potential for toxicant sensitivity to be highly context dependent, with significantly different outcomes in ecosystems than laboratory toxicity tests predict. We experimentally manipulated stream macroinvertebrate communities in 32 mesocosms to examine how communities from a low-salinity site were influenced by interactions with those from a high-salinity site along a gradient of salinity. Relative to those from the low-salinity site, organisms from the high-salinity site were expected to have greater tolerance and fitness at higher salinities. This created the potential for both salinity and tolerant-sensitive organism interactions to influence communities. We found that community composition was influenced by both direct toxicity and tolerant-sensitive organism interactions. Taxon and context-dependent responses included: (i) direct toxicity effects, irrespective of biotic interactions; (ii)

effects that were owing to the addition of tolerant taxa, irrespective of salinity; (iii) toxicity dependent on sensitive-tolerant taxa interactions; and (iv) toxic effects that were increased by interactions. Our results reinforce that ecological processes require consideration when examining toxicant effects within ecosystems." **20327.** Brito, G.G.; Martins, R.T.; Oliveira, V.C.; Hamada, N.; Nessimian, J.L.; Hughes, R.M.; Ferraz, S.F.B.; de Paula, F.R. (2018): Biological indicators of diversity in tropical streams: Congruence in the similarity of invertebrate assemblages. *Ecological Indicators* 85: 85-92. (in English) ["Highlights: •Trichoptera, EPT or families are surrogates for Amazon stream macroinvertebrate assemblage. •Functional and taxonomic groups congruence was lower than among only taxonomic groups. •Macroinvertebrate groups responded similarly to riparian forest loss and channel substrate. Abstract: Surrogate indicators are important alternatives to overcome the shortage of total biodiversity data for planning and implementing conservation measures. The most important premise of this approach is congruence among surrogate candidates and among different assemblages. The aim of this study was to evaluate abundance and incidence congruence between invertebrate assemblages at two taxonomic resolutions (genus and family), and between invertebrate assemblage (genus) and three groups of taxa (EPT, Odonata, and Trichoptera). We also evaluated the congruence between functional groups of EPT and the taxonomic groups listed above. Data were collected from 51 stream sites distributed along a disturbance gradient in the rural area of the Paragominas municipality of the state of Pará, Brazil. We used Procrustes analysis to test congruence between invertebrate assemblages at the multiple taxonomic resolutions listed previously. Family taxonomic level was a good substitute for similarity patterns measured at the genera level. EPT genus also were highly congruent with whole invertebrate assemblage (genus level) variation. Trichoptera had greater congruence with all macroinvertebrate genera than did Odonata. The congruence between EPT functional groups and groups of taxa was greater than  $r = 0.70$ . In general, taxonomic and functional metrics responded similarly to environmental conditions (water quality, channel morphology, substrate, riparian vegetation cover). Trichoptera (abundance), EPT (genera and functional groups), or invertebrate families appear to be reasonable surrogates for Amazon stream invertebrate assemblage as biological indicators for assessing and conserving streams influenced by agriculture." **20328.** Brydegaard, M.; Jansson, S.; Schulz, M.; Runemark, A. (2018): Can the narrow red bands of dragonflies be used to perceive wing interference patterns?. *Ecology and Evolution* 8: 5369-5384. (in English) ["Despite numerous studies of selection on position and number of spectral vision bands, explanations to the function of narrow spectral bands are lacking. We investigate dragonflies (Odonata), which have the narrowest spectral bands reported, in order to investigate what features these narrow spectral bands may be used to perceive. We address whether it is likely that narrow red bands can be used to identify conspecifics by the optical signature from wing interference patterns (WIPs). We investigate the optical signatures of Odonata

wings using hyperspectral imaging, laser profiling, ellipsometry, polarimetric modulation spectroscopy, and laser radar experiments. Based on results, we estimate the prospects for Odonata perception of WIPs to identify conspecifics in the spectral, spatial, intensity, polarization, angular, and temporal domains. We find six lines of evidence consistent with an ability to perceive WIPs. First, the wing membrane thickness of the studied Odonata is 2.3  $\mu\text{m}$ , coinciding with the maximal thickness perceivable by the reported bandwidth. Second, flat wings imply that WIPs persist from whole wings, which can be seen at a distance. Third, WIPs constitute a major brightness in the visual environment only second after the solar disk. Fourth, WIPs exhibit high degree of polarization and polarization vision coincides with frontal narrow red bands in Odonata. Fifth, the angular light incidence on the Odonata composite eye provides all prerequisites for direct assessment of the refractive index which is associated with age. Sixth, WIPs from conspecifics in flight make a significant contribution even to the fundamental wingbeat frequency within the flicker fusion bandwidth of Odonata vision. We conclude that it is likely that WIPs can be perceived by the narrow red bands found in some Odonata species and propose future behavioral and electrophysiological tests of this hypothesis." **20329.** Buden, D.W. (2018): Dragonflies and damselflies (Insecta: Odonata) of the Republic of the Marshall Islands. *Pacific Science* 72(3): 373-387. (in English) ["Seven species of Odonata are recorded from among the numerous atolls and mid-ocean reef islands that make up the Republic of the Marshall Islands (RMI). They include two Zygoptera (*Tanymecosticta* sp. and *Ischnura aurora*) and five Anisoptera (*Anax guttatus*, *Diplacodes bipunctata*, *Pantala flavescens*, *Tholymis tillarga*, and *Tamea transmarina*). *Tanymecosticta* sp. is known only from a single WW II-era extralimital record reported here for the first time. Breeding is confirmed for the six other species, which are widely distributed in the Pacific and often further afield. The frequently cited record of *Pantala flavescens* as being the first odonate and one of the first insects to colonize Bikini Atoll after cessation of nuclear testing requires verification. Additional surveys on many of the Marshall Islands not yet sampled for odonates will doubtless result in many new locality records. However, small island size, limited habitat diversity and water resources for breeding, and large distances from potential source populations contribute to an impoverished odonate fauna, and few, if any, species are likely to be added to the list. The six species known to inhabit the Marshall Islands make up the entire known odonate faunas of many other low, coralline islands in the west-central Pacific." (Author)] Address: Buden, D.W.; E-mail: don\_buden@comfsm.fm

**20330.** Cai, Y.; Ng, C.Y.; Ngiam, R.W.J. (2018): Diversity, distribution and habitat characteristics of dragonflies in Nee Soon freshwater swamp forest, Singapore. *Gardens' Bulletin Singapore* 70 (Suppl. 1): 123-153. (in English) ["Biodiversity baselines were established for dragonflies of Nee Soon freshwater swamp forest based on quantitative sampling across the eight sub-catchments. Surveys were conducted from December 2014 to April 2016. Hydrological, physiochemical parameters and habitats were analysed to identify the main drivers structuring the dragonfly community. A total of 1706 odonate specimens were recorded, comprising 49 species of 34 genera in 11 families. The species diversity in each sub-catchment was compared using the Shannon-Wiener Index ( $H'$ ). Hierarchical clustering and Detrended

Correspondence Analysis (DCA) indicated that three main groupings of sites existed, each with a distinct community of associated species. Further analysis by Canonical Correspondence Analysis (CCA) with 12 significant environmental variables showed that these groups were significantly associated with respective environmental variables. Principal Components Analysis (PCA) was performed to analyse the full 23 environmental variables. The first four principal components of the PCA explained 63% of the variation in all the environmental variables. These four axes were input as independent variables into an Ordinary Least Square (OLS) model to test the significance of the link between habitat characteristics and diversity of the dragonfly community. Threats to the odonate fauna of the freshwater swamp forest are identified and conservation management measures are discussed." (Authors)] Address: Cai, Y., Nat. Biodiversity Centre, National Parks Board, 1 Cluny Road, 259569 Singapore. E-mail: cai\_yixiong@nparks.gov.sg

**20331.** Carter, S.K.; Vodopich, D.; Crumrine, P.W. (2018): Heterogeneity in body size and habitat complexity influence community structure. *Journal of Freshwater Ecology* 33(1): 239-249. (in English) ["Food web studies commonly ignore individual variation within a population and variation in the environment and assume these factors have insignificant effects on community dynamics relative to interspecific interactions. However, variation in body sizes within a population (size structure) and the physical structure of habitats (habitat complexity) can both affect interspecific interactions independently, with possible interactive effects. Using experimental mesocosms, we examined effects of predator size structure and habitat complexity on predation by two common predators in fishless ponds: larval aquatic beetles (*Cybister fimbriolatus*) and larval dragonflies (*Anax junius*). Cannibalism, intraguild predation, and predation on shared prey were measured at two levels of habitat complexity crossed with six size-structured pairs of predators. We found that highly complex habitats sustain a higher prey density because prey can take refuge from predators. Additionally, size structure had direct (size better predicted predation rate than did species identity) and indirect (IGP and cannibalism lowered predation rates) effects on consumptive interactions, which changed the composition and density of the predator guild. The identified size- and habitat-mediated mechanisms can change the frequencies of intra-guild vs. interguild predation (a balance important in determining top-down control of predators), and therefore we argue that these sources of heterogeneity should be included in community ecology studies where possible." **20332.** Chung, A.Y.C. (2018): A note on insect diversity of northern Gunung Rara forest in Sabah, with special reference to some Bornean endemic and iconic species. *Sabah Society Journal* 34: 39-54. (in English) ["An insect diversity survey was carried out from 9th to 14th of March, 2015 in the Northern Gunung Rara-Sustainable Forest Management (NGR-SFM) project area in south central Sabah. As there is no insect survey in the past in the NGRSFM project area, this pioneer data will serve as baseline information for other research work in future. Insect data recorded during the survey provides salient information to enhance the biodiversity conservation and for formulation of the forest management plan of this area. At least 12 Bornean endemic species were recorded from NGR during this survey. The endemics include beetle, moth, cicada, odonate species.

This information provides input towards recommendations on High Conservation Value Forest (HCVF) of the area. A few iconic and rare species were also recorded. The nocturnal insect species richness and abundance were moderate. This is not surprising because NGR was logged in the past and some of the surveyed sites were degraded. On average, 58 species and 70 individuals were recorded within a one-square-metre. The mean Shannon Index was 3.94 while Simpson Index was 128.81 and Fisher Alpha Index was 191.70. Monitoring, as well as enforcement according to the management plan in this area at a regular basis is important in ensuring that this project area is protected and conserved accordingly.... At least 20 Odonata species were recorded during the survey. Four damselfly and one dragonfly species are endemic to Borneo. There could be more because some of the damselflies were only identified up to the genus level, e.g. *Vestalis*. Most of the Odonata species were sampled along Sg. Imbok, Sg. Lanap, Sg. Katak in PSP1 and a river adjacent to the Batu Timbang F.R." (Authors) The following species are figured: *Heliocypha biseriata*, *Rhinocypha cucullata*, *R. aurofulgens*, *Rhinagrion elopuriae*, *Macromia corycia*.] Address: Chung, A.Y.C., Forest Research Centre, Sabah Forestry Dept, P.O. **20333.** Claeson, S.M.; Crisafulli, C.M.; Gerth, W.J. (2018): Diversity of large-bodied macroinvertebrates in ponds created on the Debris-Avalanche Deposit following the 1980 eruption of Mount St. Helens. *Ecological Responses at Mount St. Helens: Revisited 35 years after the 1980 Eruption*: 235-249. (in English) ["The numerous ponds formed in the weeks following the 1980 eruption of Mount St. Helens provided a unique opportunity to investigate macroinvertebrate communities in young (23- to 25-year-old) fishless ponds following a large natural disturbance. Over a 3-year period, Large-bodied macroinvertebrates were sampled from 97 ponds with a range of hydroperiods and biophysical characteristics. Macroinvertebrate communities from these ponds were spatially and temporally variable in spite of their close geographical proximity, shared regional species pool, and similar creation history. We identified 110 taxa, many of which were observed at only one pond or in only one year. Community differences appeared to be influenced more by pond size and riparian tree development rather than by hydroperiod alone, and stochastic colonization events were likely an important factor determining community composition." **20334.** Cordero Rivera, A.; Zhang, H. (2018): Ethological uniqueness of a damselfly with no near relatives: the relevance of behaviour as part of biodiversity. *Animal biodiversity and conservation* 41(1): 161-174. (in English) ["Taxonomically isolated species may contribute unique characters to biological diversity, particularly at the level of ethodiversity. To test this idea, we analysed the territorial and reproductive behaviour of *Pseudolestes mirabilis* (Zygoptera, Pseudolestidae), an endemic damselfly from Hainan Island, China, and the only representative of its family. Our hypothesis was that the uniqueness of this taxon would be evident

in its behaviour. We found that the agonistic encounters between males were usually very short (less than 2 min) and consisted of a face-to-face display with both males maintaining a close distance while flying using only the forewings. No other odonate flies with only two wings in territorial contests. Furthermore, a small proportion of fights were escalated and lasted about one hour, with clear exhibition of the coloured hindwings. Males also confronted wasps (*Eustenogaster nigra*) that used the same microhabitat in a similar way, albeit for short time. Females were found in low numbers. This limited copulatory frequency and most males did not mate in the whole day. Unexpectedly for a damselfly with coloured wings, precopulatory courtship was almost absent, suggesting that intrasexual selection is behind the evolution of coloured wings in this species. Copulation lasted an average of seven minutes, with a first stage of rivals' sperm removal (64% of sperm removed) and a second stage of insemination. In agreement with our initial hypothesis, copulatory behaviour was unique: males did not translocate sperm to their vesicle before each mating but translocated sperm after copulation, a behaviour that cannot be easily explained. These exclusive characteristics point to the relevance of this species as an exceptional taxon that merits high conservation priority." **20336.** Dann, T.J. (2018): Fast versus slow: differing life history strategies of two New Zealand damselfly (Odonata: Zygoptera) species. Thesis, Master of Science, Univ. of Otago: XIII, 86pp. (in English) ["Life history strategies are important for all organisms and are studied in large part to understand how an individual, population or species reacts to/lives in/survives in its environment and how it/they adapt to changes within that environment. No single strategy is optimal because environmental, morphological and physiological constraints lead to trade-offs between different traits, and how a species responds to these constraints determines their life history. Two variations of life history strategies are slow and fast, which are characterised by differences in activity, development, metabolism, behaviour and their environment. These differences can result in species divergent preference for different habitats, influencing species distribution. Around 90% of New Zealand's insects are endemic and most are not well represented in the literature. Their life histories often lack synchronicity, seasonality, and winter diapause, when compared to their Northern Hemisphere counterparts, traits which are often associated with a mild, maritime climate. Odonata are model insects for life history studies but their diversity in New Zealand is low. Two

species of damselfly are present in the South Island: *Austrolestes colenisonis* and *Xanthocnemis zealandica*. Both of these species were selected to study because they are easy to locate, abundant and widely distributed. They are well described, taxonomically distinct, and are easy to collect, and maintain in the lab. These two species also permit the study of two closely related, cohabitating, predator species that potentially differ in their life history strategies. The primary objective of this thesis was to determine if a fast-slow life history strategy dichotomy exists between *A. colenisonis* and *X. zealandica* by investigating aspects of their life history and distribution. A long term (two year) field study was used to investigate differences in life history characteristics between both species in six different populations over an altitudinal gradient. A survey of the lower half of the country was conducted to create a distribution map for each species and investigate any species-specific habitat preferences. Laboratory studies were conducted to investigate differences in metabolism, by measuring movement behaviour and ability to withstand starvation, as well as the likelihood of winter diapause occurring. *A. colenisonis* naiads were found to grow larger, move more, have a decreased starvation tolerance, and a preference for lower altitude. These characteristics are consistent with a life history at the fast end of the continuum. *X. zealandica*, on the other hand, display characteristics more in alignment with a slow life history, because naiads of this species are smaller, move less, and can survive longer periods of starvation. *X. zealandica* require permanent habitats; however, they can take advantage of low quality habitats, particularly those at high altitudes, which don't suit *A. colenisonis*. Therefore, a fast/slow life history strategy dichotomy is confirmed to be present and may influence how these species interact with the environment and each other. Additionally, like many other endemic New Zealand invertebrates, *A. colenisonis* and *X. zealandica* undergo quiescence rather than diapause when overwintering. This allows these species to opportunistically take advantage of a mild changeable climate and hence the periods when suitable conditions for growth prevail." **20337.** Davidovich, H.; Ribak, G. (2018): Loaded flight in male *Ischnura elegans* and its relationship to copulatory flight. *Journal of Insect Physiology* 110: 44-56. (in English) ["Copulation in *Ischnura elegans* can last several hours, during which the pair may fly together in the 'wheel position' with both insects flapping their wings. Previous studies have suggested that during flight in copula, the male increases its power output while the female decreases it. Consequently, the male must support some of the female's body weight in the air. We tested the hypothesis that female body mass places a biomechanical constraint on the ability of smaller males to mate with larger females by attaching weights to male damselflies and analyzing their wing motion and force exerted using high-speed cameras. Males flying with an added load exerted extra forces equivalent to 157% of their body weight. Males flying in the mating wheel position with females whose wings were clipped bore a similar weight and were barely able to fly. To fly with an added load, males increased their wing-flapping frequency and amplitude, reaching values of mean wing tip flapping speed that were 1.9-fold higher than that in solitary flight. Our experiments indicate that although males would be able to fly briefly with the added weight of a non-responsive female, the flight performance of the pair would be severely compromised without the female contributing effort to the joint flight." **20339.** Deacon, C.; Samways, M.J.; Pryke, J.S. (2018): Artificial reservoirs complement natural ponds to improve pondscape resilience in conservation corridors in a biodiversity hotspot. *PLoS ONE* 13(9): e0204148. <https://doi.org/10.1371/journal.pone.0204148>: 17 pp. (in English) ["Natural ponds are rich in biodiversity, contributing greatly to regional aquatic biodiversity. Artificial reservoirs used for irrigation can be significant additional features of the landscape. They infill the local natural pondscape, and are attractors for aquatic insects. Here, we determine the extent to which artificial reservoirs represent the local natural pond biota, and how they contribute to the pondscape in conservation corridors used to mitigate the impact of plantation forestry in a global biodiversity hotspot. We did this by: 1) identifying the environmental factors, including plants, that drive dragonfly, water beetle, and water bug species richness, diversity and composition, and 2) determining the value of natural ponds vs. artificial reservoirs for maintaining the population size and expanding the area of occupancy for dragonflies, beetles and bugs in conservation corridors. While vegetation cover was central for maintaining species richness and composition of the assemblages in general, many other environmental variables are necessary to encourage the full suite of local diversity. Artificial reservoirs are attractive habitats to many species, overall increasing area of occupancy for 75% of them (ranging from 62–84% for different taxa). These reservoirs provide complementary alternative habitats to natural ponds, leading to improved ecological resilience across the pondscape. We conclude that maintaining a diverse and heterogeneous pondscape is important for conserving local aquatic insect diversity, and that artificial reservoirs increase the local area of occupancy for a range of pond insects in conservation corridors, and improve the biodiversity value of these pondscapes." **20343.** Frances, D.N.; McCauley, S.J. (2018): Warming drives higher rates of prey consumption and increases rates of intraguild predation. *Oecologia* 187(3): 585-596. (in English) ["Warming due to climate change is expected to alter species interactions. These interactions are shaped by components of individual behavior, particularly foraging behaviors. However, few studies consider species' behavioral responses to warming to predict how species interactions will be affected by warming. We chose two complementary approaches to examine how climate warming may affect the behavior and interactions of aquatic intraguild predators. First, we measured behavioral responses to warming in six larval dragonfly species, expecting that feeding rate and activity would increase with temperature. Secondly, we conducted intraguild predation (IGP) trials with three species to understand how temperature affects IGP, and if species' behavioral responses to warming are indicative of the outcome of IGP interactions. Warming increased feeding rates by 42% on average across species but had no effect on activity rate. The magnitude of change in feeding rate was positively correlated with the maximum temperatures species experience across their ranges. Lastly, warming increased rates of IGP twofold, however, species' behavioral responses alone were not predictive of their susceptibility to become IG prey of other larvae at warmer temperatures. Our results provide evidence that IGP interactions may be greatly affected by future increases in temperature; however, activity responses to warming alone are weak predictors of the outcomes of these interactions. Future studies should consider other species' traits when forecasting the effects of climate change on species interactions.... We used the following species in our experiments: *Erythemis simplicicollis*, *Epitheca canis*, *Libellula pulchella*, *Sympetrum vicinum*, *Leucorrhinia intacta*, and *Plathemis lydia*." (Authors)] Address: Frances, Dachin, Dept of Biology, Univ. of Toronto Mississauga, 3359 Mississauga Road, Mississauga, ON, L5L 1C6, Canada. dachin.frances@mail.utoronto.ca

**20344.** Goldyn, R.; Szapkowska, B.; Swierk, D.; Domek, P.; Buxakowski, J.; Dondajewska, R.; Baralkiewicz, D.; Sajnog, A. (2018): Influence of stormwater runoff on macroinvertebrates in a small urban river and a reservoir. *Science of the Total Environment* 625: 743-751. (in English) ["Highlights: • Stormwater caused marked transformation of benthic macroinvertebrates composition. • Abundance and biomass of benthic organisms were also strongly influenced. • Particularly sensitive were Ephemeroptera, Trichoptera and Mollusca. • Impact on macroinvertebrates in the reservoir was more pronounced than in the river. • Reservoirs improve water quality and composition of organisms in outflowing river. The impact of stormwater on benthic macroinvertebrates was studied in two annual cycles. Five small catchments drained by stormwater sewers to a small urban river and a small and shallow reservoir situated in its course were selected. These catchments were located in residential areas with single-family houses or blocks of flats as well as industrial areas, i.e., a car factory, a glassworks and showroom as well as the parking lots of a car dealer and servicing company. In addition to the five stations situated in the vicinity of the stormwater outlets, three stations not directly influenced

by stormwater were also established. Macroinvertebrates were sampled in every season, four times per year. Both abundance and biomass were assessed. Stormwater from industrial areas associated with cars, whose catchments showed a high percentage of impervious areas, had the greatest impact on benthic macroinvertebrates. This was due to a large amount of stormwater and its contamination, including heavy metals. Stormwater outflow from residential multi-family houses exerted the least influence. Macroinvertebrates in the water reservoir were found to undergo more extensive changes than those in the river. The cascade of four reservoirs resulted in a marked improvement of water quality in the river, which was confirmed by species composition, abundance and biomass of macroinvertebrates and indicators calculated on their basis for the stations below the cascade in comparison to the stations above and in the first reservoir. These reservoirs replaced constructed wetlands or other measures, which should be undertaken for stormwater management prior to its discharge into urban rivers and other water bodies. ... High concentrations of Zn, Ni and Al in water contributed to an increase in the biomass of Odonata (Fig. 5C)." **20345.** Guillemot, A.; Krieg-Jacquier, R. (2018): *Aeshna caerulea* en France, une espèce en limite d'aire et menacée par le changement climatique (Odonata: Aeshnidae). *Bourgogne-Franche-Comté Nature* 27: 265-272. (in French, with English summary) ["Extremely rare in France, *Aeshna caerulea* is a boreo-alpine species which trend is considered decreasing in Europe and is currently known from only 10 sites between 1,600 and 2,300 meters high in Haute-Savoie. Since its discovery in 1994, very little attention was paid to the species in the Dept. Its inclusion in the National plan of action on Odonates has encouraged the *Sympetrum* Group to carry out annual research since 2015 on propitious sites. No new breeding locations have been identified and autochthony has only been found on three wetlands of the surveyed area. The natural evolution of environments, human activities and climate change are the most obvious threats to French populations. The species is found on very small wetlands which increases the threat due to the lack of inventory on these environments and the lack of protection status of *A. caerulea* in France." (Authors)] Address: Guillemot, A., Asters, Conservatoire d'espaces naturels de Haute-Savoie / Groupe de recherches et de protection des libellules *Sympetrum*, 150 route de Chez Diannay - 74570 Groisy - alexandre.guillemot@asters.asso.fr

**20346.** Harisha, M.N.; Hosetti, B.B. (2018): Species richness, diversity and conservation threats of odonates in Dyamannana Lake (Kere), Bhadravathi Taluk, Shivamogga district, Karnataka, India. *International Journal of Zoology Studies* 3(1): 197-200. (in English) ["The study was conducted to find out the status, diversity and conservation threats of Odonata at Dyamannana Lake, Shivamogga District during October 2015 to September 2016. Sampling was done by direct counts method and collected data were statistically analyzed to work out the magnitude of Odonate diversity. A total of 470 individuals of odonates belonging to 41 species in 29 genera under 6 families were recorded. The order- Anisoptera was found to be the most dominant with 76% (n=31) species, belonging to 3 families, followed by order- Zygoptera with 24% (n=10) species, under 3 families respectively. Among the order- Anisoptera, the family wise, abundance, richness, diversity and evenness indices was found to be maximum in Libellulidae (340, 4.1, 2.9,

0.72) followed by the Aeshnidae (38, 0.8, 1.3, 0.93) and minimum in Gomphidae (26, 0.3, 0.7, 1.0) respectively (Table 2). Similarly, among the order: Zygoptera, it was found to be maximum in Coenagrionidae (42, 1.6, 1.9, 0.92) and minimum in Platynemididae (12, 0.5, 0.6, 0.94), however, it was least in Lestidae (12, but showed no significant indices value with only single species) respectively. The study revealed that, odonates and their habitats were under threat due to intensive anthropogenic activities, which are attributed to encroachment and loss of habitat. Also, addition of fertilizers and insecticides from the surrounding arecanut plantation lead to pollution and eutrophication of the lake, which not only affect the assemblage of Odonata population but also cause local extinctions." **20347.** Herrmann, A.; Schnabler, A.; Martens, A. (2018): Phenology of overland dispersal in the invasive crayfish *Faxonius immunis* (Hagen) at the Upper Rhine River area. *Knowledge and Management of Aquatic Ecosystems* 2018, 419, 30: 6 pp. (in English, with French summary) ["The non-indigenous crayfish *Faxonius immunis* (Hagen) is the dominant crayfish species at the Upper Rhine River system since his detection in 1993. As an invasive alien species, it is one of the biggest threats to aquatic biodiversity in the area. By dispersing over land, the species has a high potential to colonize small ponds created for threatened amphibians and dragonflies. Shortly after invasion, the fast growing population of *F. immunis* is changing the habitat drastically. In June 2016, our team started a local information campaign including citizen science project where the local people south of Karlsruhe, Baden-Wuerttemberg, Germany, could contact us when they spot a crayfish migrating over land to assess the activity of overland dispersal on a regional scale. Until January 2018, we got a total of 98 responses. Thirty-nine include suitable information including 33 records of overland dispersal of *F. immunis*. The species was recorded on land throughout the year, except February and July. Additionally, single observations of overland dispersal of other invasive crayfish species, naming *Procambarus clarkii* (Girard), *Pacifastacus leniusculus* (Dana), *Procambarus virginalis* (Lyko) and *Faxonius limosus* (Rafinesque), were recorded." (2018): A simple developmental model recapitulates complex insect wing venation patterns. *PNAS* published ahead of print September 17, 2018 <https://doi.org/10.1073/pnas.1721248115>: 6 pp, App. 42 pp. (in English) ["Significance: The wing veins of the fruit fly *Drosophila melanogaster* have long been studied as an example of how signaling gradients in a growing tissue can generate precise, reproducible patterns. However, fruit fly wings represent only a small slice of wing diversity. In many insect species, wings are like human fingerprints: even the left and right wings of the same individual have unique vein patterns. We analyze wing geometry in many species and then present a minimal developmental model for how vein patterns can be formed. This model will serve as a hypothesis for future empirical work. Abstract: Insect wings are typically supported by thickened struts called veins. These veins form diverse geometric patterns across insects. For many insect species, even the left and right wings from the same

individual have veins with unique topological arrangements, and little is known about how these patterns form. We present a large-scale quantitative study of the fingerprint-like "secondary veins." We compile a dataset of wings from 232 species and 17 families from the order Odonata, a group with particularly elaborate vein patterns. We characterize the geometric arrangements of veins and develop a simple model of secondary vein patterning. We show that our model is capable of recapitulating the vein geometries of species from other, distantly related winged insect clades." **20351.** Ilvonen, J.J. (2018): A comparative study of parasitism in insects: why some Odonata species have parasites and others do not? *Annales Universitatis Turkuensis Ser. A. II*, 344: 34 pp. (in English, with Finnish summary) ["Parasites are one of the most diverse groups of animals, capable of infecting virtually all other organisms on the planet. They are a strong evolutionary force, influencing genetic diversity and thereby affecting individuals, populations and entire species. Studies of host-parasite interactions have frequently examined how host individuals and their parasites interact,

but this focus on the host individual offers a very narrow perspective on the general dynamics of hosts and their parasites. To understand the dynamics of hosts and their parasites on an evolutionary scale, examination has to be moved beyond the individual, to include multiple host species, multiple parasites, and various host species traits. To this end, I decided to expand our knowledge by studying the host-parasite interactions of a large number of damselfly and dragonfly species and their endo- and ectoparasites. I evaluated specific physical, behavioral and distributional traits of the host species along with their parasitism in order to understand what traits affect parasitism. In addition, I examined these associations using the known evolutionary tree of the different damselfly and dragonfly hosts. Using this method I was able to get a deeper understanding on the co-evolution between Odonata and their endo- and ectoparasites. In paper I, I confirmed that there is huge variation in endo- and ectoparasitism between different damselfly and dragonfly species. I also found that damselfly females had more ectoparasites than males did, but there was no difference between sexes in dragonflies. In paper II, I found that there is significant variation between different damselfly and dragonfly species in their strength of immune response and body mass. Using the evolutionary tree of these host species I also discovered that closely related species are more similar in their parasitism and in their two evaluated traits than would be expected if the species were drawn at random. In paper III, I discovered that both endo- and ectoparasites tend to infect the same host species which are relative small, live in high density and are common. Paper IV continued my investigation and I found that territorial or large species have fewer ectoparasites than non-territorial or small species and I also found that northern species have more ectoparasites than southern ones. It seems that the larger size of odonate species lowers their susceptibility to parasitism. However, whether this is the cause of the host's physical traits or due to the infection mechanism and/or preference of the parasite, remains unknown. Further studies are required to understand how the size of the host influences other traits and subsequently co-evolution between damselflies, dragonflies and their endo- and ectoparasites." **20352.** Jaffe, B.D.; Ketterer, M.E.; Smith, D.S. (2018): An arsenic hyperaccumulating fern, *Pteris vittata* L. (Pteridaceae) broadly affects terrestrial invertebrate abundance. *Ecological Entomology* 43: 76-84. (in English) [Florida, USA "1. The Chinese brake fern (*Pteris vittata* L.; Pteridaceae) can accumulate up to 27 000 mg kg<sup>-1</sup> dry wt. of arsenic (As) from the soil into its above-ground biomass. They may use this As to deter invertebrate threats. 2. This study explored how As concentrations [As] in the fern, and in soil associated with the fern, influenced the abundance and composition of various invertebrates. 3. Populations of *P. vittata* were identified in the field. Soils from the base of the fern and from 3 m away of each plant were collected and pitfall traps were installed. Soil and fern arsenic concentrations ([As]) were measured via inductively coupled plasma mass spectrometry and invertebrates were identified to order and classified by feeding guild. 4. Increased [As] did not affect all feeding guilds and orders equally. For example, individual herbivore abundance did not decrease as [As] increased, but predator abundance did. In many cases, the impact of soil [As] on invertebrates depended on the distance from the fern. Fern [As] also influenced components of the community, but only at 3 m away from the fern. Furthermore, the abundances of many invertebrate groups

were higher beneath the fern, where [As] was higher. 5. These results suggest that hyperaccumulated As can impact the invertebrate community, but the defensive benefits of hyperaccumulation are more complex than have been previously described. The authors advocate that future studies examining the potential defensive benefits of hyperaccumulation should do so in a natural setting that incorporates this complexity and invertebrate richness." **20354.** Janssens, L.; Verberk, W.; Stoks, R. (2018): A widespread morphological antipredator mechanism reduces the sensitivity to pesticides and increases the susceptibility to warming. *Science of the Total Environment* 626: 1230-1235. (in English) ["Pollution and predation are two omnipresent stressors in aquatic systems that can interact in multiple ways, thereby challenging accurate assessment of the effects of pollutants in natural systems. Despite the widespread occurrence of morphological antipredator mechanisms, no studies have tested how these can affect the sensitivity of prey to pesticides. Sensitivity to pesticides is typically measured via reductions in growth rates and survival, but also reductions in heat tolerance are to be expected and are becoming increasingly important in a warming world. We investigated how autotomy, a widespread morphological antipredator mechanism where animals sacrifice a body part (here the caudal lamellae) to escape when attacked by a predator, modified the sensitivity to the insecticide chlorpyrifos in larvae of *Coenagrion puella*. Exposure to chlorpyrifos reduced the growth rate and heat tolerance (measured as CTmax). A key finding was that the pesticide had a greater impact on growth rates of intact animals, i.e. those that retained their lamellae. This reduced sensitivity to chlorpyrifos in animals without lamellae can be explained by the reduced outer surface area which is expected to result in a lower uptake of the pesticide. Larvae that underwent autotomy exhibited a lower heat tolerance, which may also be explained by the reduced surface area and the associated reduction in oxygen uptake. There is a wide diversity

of morphological antipredator mechanisms, suggesting that there will be more examples where these mechanisms affect the vulnerability to pollutants. Given the importance of pollution and predation as structuring forces in aquatic food webs, exploring the potential interactions between morphological antipredator mechanisms and sensitivity to pollutants will be crucial for risk assessment of pollutants in aquatic systems." **20355.** Janssens, L.; Stoks, R. (2018): Rapid larval development under time stress reduces adult life span through increasing oxidative damage. *Functional Ecology* 32(4): 1036-1045. (in English) ["1. While a trade-off between larval development and adult life span is key to understand why not all animals develop at their maximum rate and why life histories align along a fast-slow continuum, it has been rarely studied. More general, the physiological mechanisms underlying life-history trade-offs are poorly understood and there is ongoing debate about the mediatory role of oxidative stress. 2. We explicitly investigated the role of oxidative stress in mediating the trade-off between larval development and adult life span in the damselfly *Lestes viridis*. We exposed larvae to time stress (by manipulating photoperiods) and manipulated oxidative stress levels using the mitochondrial uncoupler 2,4-dinitrophenol (DNP) that causes a reduced production of reactive oxygen species. In addition, we considered other costs of an accelerated development in terms of reductions in immune function (the activity of phenoloxidase [PO]) and energy storage (fat content). 3. Larvae accelerated their development but not growth under time stress, allowing to identify costs of rapid development without confounding effects of rapid growth. Rapid development came at the cost of a much shorter life span, which was associated with an increase in oxidative damage to lipids, proteins and DNA. Other costs in the adult stage of a rapid larval development included a lower body mass and reduced immune function, while the fat and protein contents were not reduced. 4. Time-stressed animals exposed to DNP developed even faster and did not show the increase in oxidative damage. Notably, they did not suffer the costs of rapid development: they had no shorter life span, lower body mass or reduced PO activity. 5. Our results provide strong experimental support for a trade-off between rapid development and life span and for the mediatory role of oxidative stress in shaping this life-history trade-off. Our study highlights that manipulation of mitochondrial uncoupling may be a powerful method to study the mechanistic underpinnings of life-history trade-offs." (Authors)] Address: Stoks, R., Lab. voor Aquatische Ecologie, K.U.Leuven, De Beriotstraat 32, 3000 Leuven, Belgium. E-mail: [robby.stoks@bio.kuleuven.ac.be](mailto:robby.stoks@bio.kuleuven.ac.be)

**20356.** Jiang, B.; Mikolajewski, D.J. (2018): Shift in predation regime mediates diversification of foraging behaviour in a dragonfly genus. *Ecological Entomology* 43: 525-533. (in English) ["1. Behavioural adaptations to avoid and evade predators are common. Many studies have investigated population divergence in response to changes in predation regime within species, but studies exploring interspecific patterns are scant. Studies on interspecific divergence can infer common outcomes from evolutionary processes and highlight the role of environmental constraints in shaping species traits. 2. Species of the dragonfly genus *Leucorrhinia* underwent well-studied shifts from habitats being dominated by predatory fish (fish lakes) to habitat being dominated by predatory invertebrates (dragonfly lakes).

This change in top predators resulted in a set of adaptive trait modifications in response to the different hunting styles of both predator types: whereas predatory fish actively search and pursue prey, invertebrate predator follow a sit-and-wait strategy, not pursuing prey. 3. Here it is shown that the habitat shift-related change in selection regime on larval *Leucorrhinia* caused species in dragonfly lakes to evolve increased larval foraging and activity, and results suggest that they lost the ability to recognise predatory fish. 4. The results of the present study highlight the impact of predators on behavioural trait diversification with habitat-specific predation regimes selecting for distinct behavioural expression." **20358.** Kalkman, V.J.; Dijkstra, K.-D.B.; Dow, R.A.; Stokvis, F.R.; van Tol, J. (2018): Out of Australia: the Argiolestidae reveal the Melanesian Arc System and East Papua Composite Terrane as possible ancient dispersal routes to the Indo-Australian Archipelago (Odonata: Argiolestidae)? *International Journal of Odonatology* 21(1): 1-14. (in English) ["Information on the origin of distribution patterns shown by freshwater invertebrates in the Indo-Australian Archipelago is poor. Here we present a molecular based hypothesis of the phylogenetic relationships of Argiolestidae, a family of damselflies found throughout the tropical parts of the Eastern Hemisphere. We use this to address the following questions: (1) did Argiolestidae colonize Wallacea and the Philippines from the Eurasian or from the Australian continent? (2) Is the presence of Argiolestidae in New Guinea the result of a single colonization event, i.e. are the Argiolestidae found in New Guinea monophyletic? The results show that clades occurring in the Philippines, Wallacea and New Guinea all originate from Australian ancestors. Representatives in Sundaland are most closely related to African genera and failed to reach the Philippines and Wallacea. The presence of Argiolestidae north of Australia is the result of at least

three colonization events from Australia to areas that presently compose New Guinea and probably a fourth from Australia to Sulawesi. The two most diverse lineages found north of Australia show different distribution patterns. One reaching north as far as Luzon, presumably facilitated by Late Oligocene to Miocene islands arcs (Melanesian Arc System). The other clade shows a diversification of two genera and numerous species in the eastern tail of New Guinea, an area largely corresponding with the East Papuan Composite Terrane (EPCT) followed by the expansion of one genus into the rest of New Guinea. The EPCT's importance as source area for the New Guinean fauna has been suggested on the basis of distribution patterns, but we present the first evidence based on phylogeny reconstruction of strong diversification on this formerly isolated landmass." **20363.** Kosewska, O.; Buczynski, P. (2018): New record of an autochthonic population of *Sympetrum depressiusculum* (SELYS, 1841) (Odonata: Libellulidae) in the north-eastern Poland. *Odonatrix* 149: 6 pp. (in Polish, with English summary) ["The autochthonic population of *Sympetrum depressiusculum* was found in the Che<sup>3</sup>mno-Dobrzyń Lake District in north-eastern Poland, in fish ponds in the village of Koszelewy near Lidzbark (53°19'N, 19°57'E, UTM: DE30). Juvenile imagines were caught here on July 2 and July 4, 2018. The new site, together with other sites in northern Poland located to a maximum of 54°18'N, form the northernmost belt in Central and Eastern Europe, where the regular development of this species is found, which determines the limits of the generative range. They are also probably the source of individuals colonizing the Baltic countries. The authors also discuss the vegetative range of the species, now reaching Latvia, and point to the role of the area of Poland as a refugium of *S. depressiusculum* in Central and Eastern Europe: in most neighbouring countries this species is endangered and in the regression, also in the whole Europe and the EU it was classified as VU threat category, while in Poland it is not threatened and in the southern regions and locally in central regions it is widespread. The habitats occupied by the species are varied in Poland, however, in the northern part of the country fish ponds are still predominant, whose change in management methods is one of the main factors threatening the species in other countries." **20364.** Le Gall, M.; Fournier, M.; Chaput-Bardy, A.; Husté, A. (2018): Determinant landscape-scale factors on pond odonate assemblages. *Freshwater Biology* 63(3): 306-317. (in English) ["1. Species assemblages are related to environmental factors acting at different landscape scales. Local habitat heterogeneity also contributes to maintain the regional species pool. Understanding factors determining species presence is therefore crucial for formulation of successful conservation and management strategies. 2. Odonates can reveal much about patterns of species assemblages since their presence at a site reflects both their dispersal ability and life cycle constraints. Odonate assemblages were studied at 31 ponds located in three different landscapes: forest, urban and field. The impact of pond geographical distribution and their local characteristics (i.e., vegetation, suspended matter, freshwater macroinvertebrates, pond area and temporariness) on odonate composition, species richness and larval presence were studied. 3. According to their

intrinsic requirements, Odonata presence on ponds depended on local characteristics. Some species of the two orders were only detected in field or forest ponds. Moreover, some species were never detected in urban ponds. Differences in odonate assemblages were mainly related to vegetation, freshwater macroinvertebrates and pond area. Species richness was related to predator abundance and pond area, especially for dragonflies. The presence and abundance of odonate larvae were both related to aquatic vegetation, and to contrasted aquatic variables of ponds. Therefore, this study confirms that vegetation within and around ponds determines odonate presence. Interestingly, in a pond, species detected at the adult stage were not always detected at the larval stage, highlighting the need to really consider both parts of the lifecycle when studying odonate assemblages. 4. Diversity of local habitats within and around ponds depends strongly on the surrounding landscape and influences the assembly of odonates. Forest and field ponds presented particularly dissimilar species assemblages. Urban ponds had no specific environmental habitats compared to the other contexts. Species present on these ponds are rather generalist and able to support human disturbances. Overall, this study confirms that pond heterogeneity may be a key factor in maintaining the regional pool of odonate species." (in French) ["Three years of inventories (from 2011 to 2013) have made it possible to draw up an ecological assessment of most of the aquatic ecosystems present on the Salève massif [Département Haute-Savoie, France]. Alpine pasture or forest ponds, marshes or even forest streams were investigated in order to record the diversity of odonates [n=21 species] and macrophytes present in these particular biotopes. This work has made it possible to identify remarkable species for the Salève; some ecosystems even host species that are almost absent from the Geneva basin. These inventories have also made it possible to highlight the ecological challenges and threats facing these fragile ecosystems. Conservation measures were thus proposed in order to maintain or restore them. A hierarchy of interventions was also proposed in order to intervene in the most degraded environments. Finally, only regular monitoring of the restored environments will make it possible to assess the positive or negative effects of the various works carried out in recent years and thus to review the management guidelines if necessary." Volume 151, 2018: 4 pp. (in English) ["Gliding flight is a common mode of flight for dragonfly, the objective of the current research is to use numerical simulations to explore whether the corrugations have positive effect on aerodynamic performance of the dragonfly wings in gliding flight. In order to compare aerodynamic performance of the dragonfly wing and flat plate, a three-dimensional model of the dragonfly forewing and a three-dimensional flat plate with the same shape of the dragonfly forewing are established. The flow fields around three-dimensional dragonfly forewing and flat plate are simulated for  $Re=10000$  and angles of attack changing from  $0^\circ$  to  $25^\circ$  (with an interval of  $5^\circ$ ), numerical simulation indicate that aerodynamic performance of the dragonfly wing is slightly better than the flat plate over the entire range of parameters tested, especially the effect of the corrugations on the flow is more evident at large angle of attack." Biodiversity Observations 9.13: 1-10. (in English) ["This paper reports progress with OdonataMAP, the Atlas of Dragonflies and Damselflies of Africa, for the two-year period 1 July 2016 to 30 June 2018. During the two-year review period, the database for the project grew by 30,423 records to 52,257, starting from 22,809 records collected between 2010 and June 2016. Submissions were made from 25 African countries. In six of the nine provinces of South Africa, the number of OdonataMAP records for the province more than doubled. The provinces in which the number of records were not doubled were Gauteng (44% of records made during reporting period), Free State and North West (both 46%). Five observers contributed more than 1000 records over the two-year period, and a further 10 between 500 and 999 records. The total number of observers for the two-year period was 529, compared with 295 in the 2010–16 period. One of the important success of OdonataMAP during the review period was to increase the number of observers, and to reduce the project's dependence on a small number of citizen scientists." (2018): Dragonfly wings-inspired deployable structures. *Bulletin of the American Physical Society Abstract: APS March Meeting 2018, Monday–Friday, March 5–9, 2018; Los Angeles, California H47.00005*: (in English) [Verbatim: Maintaining the overall shape of a flat structure while increasing its surface area is a nontrivial challenge when designing soft structures. When the wing of an emerging dragonfly deploys in a couple of minutes, the expansion is guided by a network of veins, in which hemolymph is injected and subsequently solidifies to generate rigidity. During the deployment stage, the looping patterns of the edge of the wings are characteristic of differential growth. Inspired by this insect, we build a model experiment of the inflatable deployable structure composed of a tubular network of the veins. We first characterize the response of a unique looping tubular structure under pressure. We then characterize the in-plane expansion of the structure and study its correlation to the network geometry and the pressure applied in the system. A systematic variation of the geometric and elastic parameters allows us to search for an optimal design and operational conditions for maximal extension, while minimizing the input pressure.] Address: not stated

**20371.** Mashkova, I.V.; Krupnova, T.G.; Kostryukova, A.M.; Vlasov, N.E. (2018): Distribution of dragonflies (Odonata: Insecta) in South Ural lakes, Russia. *Biodiversitas* 19: 202-207. (in English) ["This paper studies the diversity and distribution of Odonata (Insecta) in the South Urals region lakes such as Lake Large Miassovo, Lake Small Miassovo, Lake Ilmenskoe, Lake Savelkul and Lake Baraus. We revised dragonflies in five lakes during May–September 2014–2016. Dragonflies and larvae were identified up to the species. As results, 36 species (12 Zygoptera and 22 Anisoptera) belonging to 15 genera were recorded. To compare the similarities of dragonfly communities of different lakes we used the Canonical Correspondence Analysis (CCA) according the Jaccard index. Comparing the number of records of odonate species for selected lakes in our study, we found that the small richness of species was typical for lakes Savelkul and Baraus (22% and 25% of the total number of species, respectively) and the large values of the species richness was obtained for lakes Small Miassovo, Ilmenskoe and Large Miassovo (50%, 72% and 80% of the total number of species, respectively)." **20372.** Masterson, R. (2018): A survey of microplastics in invertebrates in the Lake Champlain basin. Poster; <https://soar.suny.edu/handle/20.500.12648/847>: (in English) ["The goal of this research was to determine whether microplastics (MP) were ingested by aquatic macroinvertebrates resident to Lake Champlain. We did so by quantifying and characterizing (e.g., fragment, fiber, film, foam, pellet) microplastic particulate. In more recent samples, we have dried and weighed invertebrates to better assess uptake. Preliminary wet peroxide oxidation digests were performed on aquatic invertebrates (n = 301). Invertebrate specimens were collected across two classes (Insecta, Malacostr)

and 7 orders including Coleoptera, Ephemeroptera, Hemiptera, Odonata, Trichoptera, Mysida, and Amphipodae. These representative organisms are an important part of the lake food web, serving as preferred food for higher vertebrates including fish and waterfowl. Aquatic macroinvertebrates in our sample possess unique feeding methods, such as filter feeding, scraping, piercing, shredding, scavenging, collecting/gathering, and predation. Our research indicated that fibers were the most common microplastic type uptaken by invertebrates. Preliminary results suggest that, *Hydropsyche*, a filter-feeding insect digested, the greatest mean number of MP's (n=3). Lake Champlain macroinvertebrates contained on average 0.36 microplastic particles. There are limited reports of microplastics uptaken in aquatic invertebrates and this research provides baseline information for a guild that will be involved in trophic transfer. Results from this research serve to inform residents of the Lake Champlain watershed, anglers, non-profit lake organizations, as well as public health and government officials of the risks microplastics pose to aquatic biota and ultimately humans." **20374.** McDevitt-Galles, T.; Calhoun, D.M.; Johnson, P.T.J. (2018): Parasite richness and abundance within aquatic macroinvertebrates: testing the roles of host- and habitat-level factors. *Ecosphere* 9(4): 1-16. (in English) ["The importance of parasites as both members of biological communities and structuring agents of host communities has been increasingly emphasized. Yet parasites of aquatic macroinvertebrates and the environmental factors regulating their richness and abundance remain poorly studied. Here, we quantified parasite richness and abundance within 12 genera of odonate naiads and opportunistically sampled four additional orders of aquatic macroinvertebrates from 35 freshwater ponds in the San Francisco Bay Area of California, U.S.A. We also tested the relative contributions of host- and habitat-level factors in driving patterns of infection abundance for the most commonly encountered parasite (the trematode *Haematoloechus* sp.) in nymphal damselflies and dragonflies using hierarchical generalized linear mixed models. Over the course of two years, we quantified the presence and intensity of parasites from 1612 individuals. We identified six parasite taxa: two digenetic trematodes, one larval nematode, one larval acanthocephalan, one gregarine, and a mite, for which the highest infection prevalence (39%) occurred in the damselfly genus, *Ischnura* sp. Based on the hierarchical analysis of *Haematoloechus* sp. occurrence, infection prevalence and abundance were associated predominantly with site-level factors, including definitive host (frog) presence, nymphal odonate

density, water pH, and conductivity. In addition, host suborder interacted with the presence of fishes, such that damselflies had higher infection rates in sites with fish relative to those without, whereas the opposite was true for dragonfly nymphs. These findings offer insights into the potential interaction between host- and site-level factors in shaping parasite populations within macroinvertebrate taxa." **20375.** Melendez Quinto, J.M. (2018): Odonatofauna larval de ríos, humedales y otros sistemas acuáticos en Lima Metropolitana, Perú. Tesis para optar el título profesional de biólogo, Universidad Nacional Agraria la Molina, Facultad de Ciencias, Lima – Perú: X + 174 pp. (in Spanish, with English summary) ["Odonata (dragonflies and damselflies) is a little known taxon in South America, especially its larvae. I set out to complete this information for the Lima metropolitan area because the species level offers advantages in ecology. Larvae (almost always close to the last instar) were caught in the Lurin, Rimac and Chillón rivers, the Villa and Ventanilla wetlands, and in the UNALM. I reared these specimens to obtain imago and nominate their exuviae. I also checked the museum material from the main collections in Lima. Twenty-one species were recorded in the study area, six of them for the first time (two new species), three ones only as imago and two others known just by literature. I deleted three species (*Argia fissa*, *Ischnura ramburii* and *Phyllocyba unifirma*) from the record. I made identification keys for 20 species of all recorded ones (*Argia* spec. nov. larva is hitherto unknown) and for their mandibles. Here was included figures (illustrations and photographs) of all species too. In the taxonomic treatment, I described each species the most detailly possible and, as the case may be, I did comments about the differences among their phylogenetically closest congeneric ones in America and their conspecific ones which were described in other countries of the New World. In addition I included information regard to their bionomics (aquatic habitat and emergence time), distribution and conservation status. For all taxa, I put a diagnosis to local (species) and national (supraspecific taxa) scale. *Argia inculta*, l. aff. *ramburii*, *Rhionaeschna brevifrons* and *Erythrodiplax cleopatra* have been described for the first time; while my description of *Progomphus joergenseni* was noticeably different from the same species in Argentina." **20376.** Mellal, M.K.; Zebba, R.; Bensouilah, M.; Houhamdi, M.; Khelifa, R. (2018): Aspects of the emergence ecology of the regionally endangered *Coenagrion mercuriale* (Odonata: Coenagrionidae) in Northeast Algeria. *Zoology and Ecology* 28(3): 224-230. (in English) ["Emergence is a critical phase in the life cycle of odonates because then they are highly susceptible to predation and damage. Thus the ecological understanding of this phenomenon is crucial, particularly for the conservation and management of threatened species. We studied the emergence ecology of the regionally endangered *C. mercuriale* in Northeast Algeria where the species produces two generations per year (spring and autumnal), focusing on the temporal emergence pattern, body size and vertical stratification of exuviae of the autumnal population. Emergence was synchronous with 50% of the population emerging within eight days. Sex ratio at emergence was slightly female biased. A seasonal decline

was observed in the body size of the autumnal population like in that of the spring population. Vertical stratification of exuviae at ecdysis depended on the height of the support and vegetation density. These data are expected to be important for the management and conservation of this threatened species in Northeast Algeria and elsewhere within the distribution range." **20377.** Michelson, C.I.; Clark, R.G.; Morrissey, C.A. (2018): Agricultural land cover does not affect the diet of Tree Swallows in wetland-dominated habitats. *The Condor* 120(4): 751-764. (in English) ["Agricultural practices have intensified during the past 50 yr, increasing crop production and altering the Canadian prairie landscape by removing or degrading uncropped habitats, including wetlands. We predicted that agricultural practices would alter invertebrate communities and the diets of consumers such as insectivorous birds. Using stable isotope analysis ( $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$ ), we tested for differences in the assimilated diets and isotopic niche widths of adult and nestling Tree Swallows (*Tachycineta bicolor*) in grassland and cropland sites with similar wetland densities in Saskatchewan, Canada. We also assessed relationships between swallow diet and body size, mass, and condition. Dietary composition and niche width differed between years and age classes but were not consistently related to agricultural land cover. Aquatic insect prey (Diptera and Odonata) made up 75% of all swallow diets, but nestlings consumed a larger proportion of terrestrial Diptera, resulting in broader isotopic niche widths compared with adults. Age-specific dietary differences could have been related to temporal shifts in the insect community or distinct foraging by adults when feeding nestlings. The body mass and condition of adult and nestling swallows were unrelated to diet, but were higher on average in grassland than cropland habitat. Overall, Tree Swallows specialized in feeding on aquatic insects, regardless of agricultural land cover, at least in wetland-dominated habitats. Food resources originating from wetlands may play a critical role in supporting insectivorous bird populations in agricultural landscapes." (2018): Influence of acid mine drainage, and its remediation, on lakewater quality and benthic invertebrate communities. *Water, Air, & Soil Pollution* 229(2), <https://doi.org/10.1007/s11270-017-3671-3>: (in English) ["The abandoned Aldermac Mine in Québec, Canada, has been a source of acid mine drainage to Lake Arnoux since 1946. Restoration of the site was undertaken in 2008 and completed in 2010. We compared lakewater chemistry and benthic invertebrate communities in the spring of 2010, prior to complete restoration, and in spring 2011, when acid mine drainage was no longer entering the lake. Between these years, lakewater pH increased by about one unit and the concentrations of many trace metals declined substantially. In 2010, benthic taxonomic richness increased significantly with distance from the source of contamination, whereas after restoration, there was no longer a clear trend. Communities in highly contaminated stations tended to be dominated by burrowing taxa such as larvae of *Chironomus* (Chironomidae) and *Oligochaeta*, whereas less contaminated stations had taxonomic and functional communities that were more diverse. In the year following recovery, some new taxa appeared (Trichoptera, Odonata,

and the Ceratopogonidae Bezzia), whereas the populations of an acid-tolerant Chironomus species declined. However, only larger individuals exhibited a significant response to pH and metal contamination." **20379.** Mor, J.-R.; Ruhí, A.; Tornés, E.; Valcárcel, H.; Muñoz, I.; Sabater, S. (2018): Dam regulation and riverine food-web structure in a Mediterranean river. *Science of the Total Environment* 625: 301-310. (in English) ["Highlights: • Flow regulation increased flow stability in a highly-variable Mediterranean river. • The detritus-based food web shifted into an algae-based food web. • Changes in consumers and their interactions widened and lengthened the food chain. • Flow regime alteration may impact river food webs beyond their individual components. Flow regimes are a major driver of community composition and structure in riverine ecosystems, and flow regulation by dams often induces artificially-stable flow regimes downstream. This represents a major source of hydrological alteration, particularly in regions where biota is adapted to strong seasonal and interannual flow variability. We hypothesized that dam-induced hydrological stability should increase the availability of autochthonous resources at the base of the food web. This, in turn, should favour herbivorous over detritivorous strategies, increasing the diversity of primary consumers, and the food-web width and length. We tested this hypothesis by studying the longitudinal variation in food-web structure in a highly-seasonal Mediterranean river affected by an irrigation dam. We compared an unregulated reach to several reaches downstream of the dam. Hydrological and sedimentological stability increased downstream of the dam, and altered the type and quantity of available resources downstream, prompting a change from a detritus-based to an algae-based food web. The fraction of links between top and intermediate species also increased, and the food web became longer and wider at the intermediate trophic levels. Food-web structure did not recover 14 km downstream of the dam, despite a partial restitution of the flow regime. Our results advance the notion that hydrologic alteration affects riverine food webs via additions/deletions of taxa and variation in the strength and distribution of food-web interactions. Thus, flow regulation by dams may not only impact individual facets of biodiversity, but also food-web level properties across river networks." **20380.** Muktitama, S.R.; Hari prayogo, Yulianti indrayani (2018): Species diversity of dragonflies in Univ. campus area of Tanjungpura in Pontianak. *Jurnal Hutan Lestari* 6(4): 752-764. ["Dragonfly is an indicator to environment and ecosystem in a particular area. It is also known as a balancing predator to another insects' population. Various types of dragonfly are affected by some factors such as habitat conditions and the foods. Various types of dragonfly can be found in swamland, rice fields, flooded area, and also some locations around Universitas Tanjungpura. This research aims to convey information about various types of dragonfly in the area of universitas tanjungpura and also to define the index of variety of dragonfly types (H), equalization index (e), domination index (D), and species similarity (IS). This research took two weeks of fieldwork by applying purposive

sampling, which was started from 5th – 15 th April, 2018. Where the researcher is free to down each location seen from the large number of dragonflies are found. Then each location specified each plot with a distance of 15 meters each point of view of forming a circle pattern diameter 30 meters. The researcher found that 16 type of dragonfly consist of 13 type categorized as Subordo Anisoptera and 3 type categorized as Subordo Zygoptera. The 13 Anisoptera consist of 12 in Libellulidae family and 1 in Gomphidae family. The other 3 Zygoptera are in the the category of Coenagrionidae. This research shows that the role of dragonfly as a bioindicator and the predator of particular environment. Ecologically, Universitas Tanjungpura is indicated to have deficient environment in terms of the population growth of dragonfly in ecological ecosystem." (2018): Effects of the adipokinetic hormone/red pigment-concentrating hormone (AKH/RPCH) family of peptides on MK-801-induced schizophrenia models. *Fundamental and Clinical Pharmacology* 32(6): 589-602. (in English) ["The adipokinetic and red pigment-concentrating hormone (AKH/RPCH) family of peptides controls fat, carbohydrate and protein metabolism in insects. In our previous study, we showed that AKH possesses antidepressant, anxiolytic, and analgesic effects, causes hyperlocomotion and exerts neuroprotective effects and increased brain neurotrophic factors in mice. The aim of this study is to investigate the effects of Anax imperator AKH (Ani-AKH), Libellula auripennis AKH (Lia-AKH) and Phormia-Terra hypertrehalosemic hormone (Pht-HrTH) on MK-801-induced memory deterioration in the active allothetic place avoidance test (AAPA) and MK-801-induced sensorimotor gating deficit in the prepulse inhibition test (PPI). In the AAPA task, Long Evans rats were treated with Ani-AKH (2 mg/kg), Lia-AKH (2 mg/kg), Pht-HrTH (2 mg/kg), MK-801 (0.15 mg/kg) and the combination of MK-801 with the hormones subchronically. In the prepulse inhibition test, Wistar-albino rats were treated with Ani-AKH (1 mg/kg), Lia-AKH (1 mg/kg), Pht-HrTH (1 mg/kg), MK-801 (0.1 mg/kg) or the combination of MK-801 with hormones acutely before the test. In our study, Ani-AKH (2 mg/kg), Lia-AKH (2 mg/kg) and Pht-HrTH (2 mg/kg) reversed MK-801 (0.15 mg/kg)-induced cognitive memory impairment effects in the AAPA task. Lia-AKH (1 mg/kg) significantly potentiated the MK-801-induced PPI disruption, while Ani-AKH (1 mg/kg) partially potentiated the impairment caused by MK-801, and Pht-HrTH did not modify the effect of MK-801. In conclusion, AKH had no effect in sensorimotor gating deficits in the PPI test in schizophrenia model while AKH improved memory in the schizophrenia model of MK-801." **20382.** Nasiruddin, M.; Barua, A. (2018): Odonate abundance and diversity in four selective spots of Chittagong Univ. campus. *J. biodivers. conserv. bioresour. manag.* 4(1): 55-62. (in English) ["The abundance and diversity of odonate fauna were studied in four selective spots of Chittagong Univ. Campus, Chittagong, Bangladesh from August 2016 to July 2017. A total of 928 individuals of odonates under three families was collected during the study period from the four sampling sites. Out of 25 species identified one belonged to Gomphidae, 13 belonged to Libellulidae and 11

belonged to Coenagriidae. The abundance of odonate species was highest in July'17 (13.04%) and was lowest in December'16 (4.96%). Spot 2 was a hotspot for odonates as highest number (370) was collected from this spot. A total of 196, 188 and 174 individuals were collected from Spot 4, Spot 3 and Spot 1, respectively. The members of Libellulidae (472) were dominant followed by Coenagrionidae (406) and lastly Gomphidae (50). Highest species richness (SR), species diversity (H') and species evenness (J') values were observed in the months of May'17 (1.56±0.08), May'17 (1.29±0.08) and December'16 (0.96±0.03), respectively. But lowest such values were observed in December'16 (0.96±0.05), November'16 (0.90±0.02) and May'17 (0.81±0.05), respectively. Amongst the spots, highest SR, H' and J', values were observed in Spot 4 (1.40±0.10), Spot 2 (1.22±0.05) and Spot 1 (0.93±0.02), respectively, whereas, lowest such values were observed in Spot 1 (1.02±0.08), Spot 1 (1.01±0.04) and Spot 4 (0.82±0.02), respectively. Ecological conditions and seasonal fluctuation had great impact on the abundance and diversity of odonates." **20383.** Neto, M.V.B.; Campos Júnior, O.; Rodrigues, G.G. (2018): Influence of the reproductive behavior of *Neoneura sylvatica* (Odonata: Protoneuridae) on spermatid morphology. *MOJ Anat & Physiol.* 5(3): 192-193. (in English) ["The present study aimed to verify the behavioral effects on the spermatid morphology of *Neoneura sylvatica* Hagen in Selys, 1886. For this, males were analyzed behaviorally for intra-sexual competition and for morphology of spermatozoa. With the observation of the five labelled individuals it was possible to observe agonistic relationships between resident males and intruders. When an intruding male attempted to invade the territory of the resident male, there were aggressive contacts. In the reproductive behavior it was possible to observe mating and oviposition with guard after copula in all the couples and attempts of interruption of oviposition by the male intruder. Through the histological analysis individual spermatozoa were observed and not found in bundles. Spermatozoa dimorphism was found for *N. sylvatica* being the first record for Odonata. This dimorphism is presented as follows: morphotype 1 has a total length of 99µm, undifferentiated head of the flagellum, spiral body. Morphotype 2 has a total length of 118µm, and it is possible to differentiate the head (31µm) from the flagellum (86µm). The head showed a shape of hook and ripples in the flagellum. We conclude that the behavioral attributes of male intra-sexual competition of *N. sylvatica* can influence the morphological characteristics of spermatozoa generating dimorphism." **20384.** Nilén, S. (2018): Effects of frequency-dependence in maintaining diversity in coexisting ecologically similar species. BSc. thesis, Dept of Biology, Lund Univ.: (in English) ["Niche theory predicts that cooccurring species must differ in their use of environments in order to coexist, thereby diversity can be maintained in a community. However, ecologically similar species do frequently occur in nature, hence species inhabit similar physical environs and share single underlying resources. In coexisting species with a similar niche, ecological drift is thought to eventually cause all but one species to go extinct, assuming drift acts alone. As drift is likely to be present in a community, contracting forces are expected to be found. One of those forces could be selec-

tion where frequency-dependence that can maintain diversity through e.g. rare species advantages and is thus capable of maintaining stable coexistence. Here we investigate mechanisms that can maintain diversity in ecologically similar but evolutionary separated species *I. elegans* and *E. cyathigerum*. We regulated frequencies of both species in mesocosm experiments and mating trials and were able to experimentally demonstrate the importance of negative frequency-dependence (rare-species advantages) in maintaining diversity in ecologically similar species. The maintenance of diversity in a community have long been explained by how species differ in their use of their environment. However, there are many examples in nature where similar species do cooccur in nature. For example, in Barro Colorado Island approximately 300 tree species were found in only 50 ha. This inevitably raises the question: How can so many closely related species coexist? Interestingly, closely related species of damselflies inhabit similar physical environments and often share single underlying resources. The minor differences of damselflies challenge traditional models of species coexistence. Methods: We wanted to know how closely related species can be maintained in a community without outcompeting each other. As study organisms we used the two, co-occurring species of damselflies: *Ischnura elegans* and *Enallagma cyathigerum*. The two species were kept in big outdoor cages simulating natural conditions where we wanted to understand how survival were affected by interference competition within and between species. We also used smaller cages where we looked at how mating affected both species. In both experiments we manipulated the frequencies of both species in experiments in three frequencies, (Rare: 25 %, Common: 75 % and Allopatric: 100 %) for the Blue-tailed damselfly and the common blue damselfly. Results: We found that the Blue-tailed damselfly survived longer in all treatments compared to the common blue damselfly. As this species does better in all the treatments one would expect that this species will outcompete the common blue damselfly in their natural community. However, we also found that the Blue-tailed damselfly regulates its own abundance. When common the Blue-tailed damselfly will interact with itself more through interference competition which decreases its survival. When rare this species both survives longer and have a higher proportion of matings, which can affect population growth. I suggest that the combination of interference competition that can regulate the species abundance and through rare-species advantages, diversity can be maintained, even if differences between species are small." **20385.** Noorhidayah, M. (2018): Bio-ecological studies of Malaysian odonates and an integrated taxonomic study on the genus *Rhinocypha*. PhD thesis, Faculty of Science, Univ. of Malaya: XXIII + 218 pp. (in English) ["Studies on Odonata have gained worldwide attention as well as here, locally in Malaysia. Although there is a wealth of data available to be utilized for solving taxonomic problems but ecological and behavioural research areas are more favoured in contrast to taxonomy and systematics. Thus, there are existing confusions for correct identifications in closely related and sympatric species, especially in female odonates. One such example is in the genus *Rhinocypha*, in which one of the objectives of this study is to fill in this gap. Consequently, the research aims and study techniques were; to illuminate the nationwide distribution and diversity of Odonata from Peninsular Malaysia forest reserves and relate these to the environmental parameters. Secondly, applying the molecular technique to elucidate the phyloge-

graphic pattern of *Rhinocypha fenestrella* which a predominant species in this study. Thirdly, a focused taxonomic work was conducted on *Rhinocypha*, employing multi-approaches, in the form of morphological procedures (Field Emission Scanning Electron Microscope, FESEM and geometric morphometric analysis); bio-material property investigations by using Laser Scanning Confocal Microscopy (LSCM), Scanning Electron Microscopy (SEM) and Atomic Force Microscopy (AFM). Overall, 1193 individuals from 70 species were collected from the 22 sampling localities. Chlorocyphidae was the dominant family and *R. fenestrella*, *R. biforata*, and *Euphaea ochracea* were the most abundant species. The PCA analysis confirmed that higher species richness was associated with the lower water chemical characteristics (compositions of sulphate, ammonia, iron and nitrite). The genetic diversity, expressed by CO1 and 16S rRNA genes for *R. fenestrella* was high, with 26 and 10 unique haplotypes, while 33 haplotypes were recovered by both combined datasets. The TCS analysis revealed the common ancestor of *R. fenestrella* was from the state of Negeri Sembilan. For the taxonomic study, 17 morphological characteristics were created to differentiate between the females of *Rhinocypha* spp. The FESEM on the female's ovipositor was done to focus on the anal appendages and sheathing valve (V3). Also, the phylogenetic patterns and canonical variate analysis for the wing geomorphometry revealed three clusters that supported the distinction of the *Rhinocypha* group. Exploration on bio-material, illustrate a general widespread distribution of resilin patches and cuticular spikes along the longitudinal veins of the wings. A novel technique applied in this study, was on nanoindentation (AFM) clarified the presence of varying size of nanostructures for all sample sections (membranes, mobile and immobile joints), and the elasticity values differed between sections. In summary, this study had effectively developed an integrated approach of classic morphological and trendy molecular as well as biomaterial studies, combined with different microscopy techniques, LSCM, SEM and AFM which provided corroborative evidence in resolving taxonomic uncertainties." **20386.** Ohba, S.-y.; Honki, K. (2018): Note on odonates in artificial ponds around the Faculty of Education, Nagasaki Univ.. Bulletin of Faculty of Education, Nagasaki Univ. 4: 19-26. [In addition to the odonates reported previously, we have newly identified two aeshnids, one macromiid, and three libellulids, in the vicinity of the Faculty of Education building at Nagasaki Univ.. Of these, *Rhyothemis fuliginosa* is placed in the 'Red List' of Nagasaki City in Nagasaki Prefecture. Students who attended a Biological Experiment I program from ,Q,O,P,R to ,Q,O,P,V evaluated the abundance of damselfly nymphs among three ponds. As a result, the abundance of damselfly nymphs in the artificial pond situated between the Faculty of Environmental Science and Faculty of Education buildings was found to be the least among the three ponds evaluated. The mosquitofish, *Gambusia affinis*, in the pond feeds on all kinds of Odonata nymphs. These results confirm the presence of invasive species in our Univ. ponds, and managing the invasive species is important for conservation of the odonates." (Authors)] Address: Ohba, S.-y., Fac. Education, Biology Education, Nagasaki Univ., Japan

**20387.** Ousterhout, B.H.; Graham, S.R.; Hasik, A.Z.; Serano, M.; Siepielski, A.M. (2018): Past selection impacts the strength of an aquatic trophic cascade. Functional Ecology 32: 1554-1562. (in English) [1. In complex food webs, in-

teractions among species in different trophic levels can generate cascading indirect effects that couple top predators with primary producers, thereby affecting ecosystem functioning. Natural selection imposed by top predators on intermediate predators may play a role in shaping the strength of these trophic cascades, but this conjecture remains largely untested. 2. To determine the effects of natural selection on the strength of trophic cascades, we conducted a two-part experiment in a four-level aquatic trophic system involving a top predator (fish), an intermediate predator (damselflies [*Enallagma* sp.]), herbivores (zooplankton) and primary producers (algae). We first quantified how predation by fish generated selection on damselfly activity levels after controlling for phenotypic plasticity. We then measured the indirect effects of this selection on primary production (phytoplankton biomass). In both experiments, we varied the density of predators, allowing us to elucidate both trait-mediated and density-mediated indirect effects. 3. We found that as fish density increased, damselfly survivorship declined, which generated natural selection favouring less active damselflies. These results are robust after taking into account latent effects of plasticity in response to fish predator cues. The surviving damselflies likely foraged less, freeing herbivores from predation, which in turn reduced primary production. This selection-driven trait-mediated indirect effect was only apparent at low damselfly densities, because the consumptive effect of damselflies at high densities overwhelmed the effects of past selection. 4. These results demonstrate how the past action of natural selection imposed by predators affects the phenotypes of prey that consume herbivores, which ultimately influences primary productivity—a selective trophic cascade. Natural selection can therefore act as a mechanism coupling ecological dynamics across trophic levels, which ultimately influences ecosystem functioning." **20388.** Pander, J.; Mueller, M.; Geist, J. (2018): Habitat diversity and connectivity govern the conservation value of restored aquatic floodplain habitats. Biological Conservation 217: 1-10. (in English) [Floodplains have been strongly altered by human activities such as channelization and other river regulations. Globally, there is a growing interest in their restoration because of an increasing understanding of the ecological importance of these habitats for feeding, spawning, nursery or overwintering of aquatic species. In this study, a large floodplain restoration project of the upper Danube River was used to investigate colonization and succession patterns of fish, macroinvertebrates, macrophytes and periphyton in relation to abiotic habitat variables that can be restored through ecosystem management. Highest species diversity was detected near the contact zones of the floodplain channel to the main stem of the Danube, and in the transition zones of river sections (RS) and oxbow lakes (OS). The highest proportions of all taxa (82%) and of distinctive species (22%) were detected in RS, followed by OS (66% of all taxa, 8% distinctive species) and floodplain ponds (FP, 47% of all taxa, 5% distinctive species). The habitat types RS, OS and FP significantly differed in overall community composition and their colonization processes comprising fast colonization of current-adapted specialists in RS, and mostly generalist species in OS and FP. Our results indicate that restoration of floodplain habitats should not only consider the re-establishment of maximum connectivity, but also provide a mosaic of distinct habitat types with different degrees of connectivity and disturbance. Each habitat type in the floodplain supported a unique assemblage

of species, which suggests that such habitat mosaics can facilitate exceptionally diverse ecosystems." **20390.** Phillips, P.; Swanson, B.J. (2018): A genetic analysis of dragonfly population structure. *Ecology and Evolution* 8: 7206-7215. (in English) ["Dragonflies reside in both aquatic and terrestrial environments, depending on their life stage, necessitating the conservation of drastically different habitats; however, little is understood about how nymph and adult dragonflies function as metapopulations within connected habitat. We used genetic techniques to examine nymphs and adults within a single metapopulation both spatially and temporally to better understand metapopulation structure and the processes that might influence said structure. We sampled 97 nymphs and 149 adult *Sympetrum obtrusum* from eight locations, four aquatic, and four terrestrial, at the Pierce Cedar Creek Institute in Southwest Michigan over two summers. We performed AFLP genetic analysis and used the Bayesian analysis program STRUCTURE to detect genetic clusters from sampled individuals. STRUCTURE detected  $k = 4$  populations, in which nymphs and adults from the same locations collected in different years did not necessarily fall into the same clusters. We also evaluated grouping using the statistical clustering analyses NMDS and MRPP. The results of these confirmed findings from STRUCTURE and emphasized differences between adults collected in 2012 and all other generations. These results suggest that both dispersal and a temporal cycle of emergence of nymphs from unique clusters every other year could be influential in structuring dragonfly populations, although our methods were not able to fully distinguish the influences of either force. This study provides a better understanding of local dragonfly metapopulation structure and provides a starting point for future studies to investigate the spatial and temporal mechanisms controlling metapopulation structure. The results of the study should prove informative for managers working to preserve genetic diversity in connected dragonfly metapopulations, especially in the face of increasing anthropogenic landscape changes." **20391.** Pirela Pérez, R.E. (2018): Libélulas (Insecta) como indicadores da qualidade do habitat de riachos de lavrado em Roraima, Brasil. Programa de Pós-Graduação em Recursos Naturais, Universidade Federal de Roraima, Boa Vista, R.R., Brazil: 43 pp. (in Portuguese, with English summary) ["Human activities can cause great changes in the

Landscape, affecting hydrological cycles and causing habitat degradation, which results in habitat homogenization. Bioindicator species can be used to assess change in ecosystems biological integrity, as they vary their composition and incidence on disturbed aquatic ecosystems. This study aims to evaluate the environmental integrity of Lavrado streams in Roraima using Odonates, in which we stipulated the following hypothesis: Odonata richness and abundance are positively associated with the best rate of environmental stream quality because of their thermoregulatory capacity, their capacity of dispersal and habitat specialization. We sampled 10 Lavrado Streams in Roraima, Brazil, searching for the biggest variation across the savannahs of the region, in the months of October, November, and December of 2017, and March of 2018, the dry season. For each stream, we calculated the Habitat Integrity Index (HII), and we also determined adult Odonata richness, physicochemical variables, and the streamflow. In Lavrado areas there was no relation between the HII and Odonata richness. However, some species were nested in areas with intermediate values of integrity close to 0.5, and we believe that it is necessary to adapt the index, by including variables that can determinate the rate of disturbance of riparian savannah ecosystems. Zygoptera richness and stream's environmental temperature were related negatively. This response in Zygoptera is explained by the fact that they are species with a low capacity of dispersal due to their small size, and therefore are specialists." (Author)] Address: not stated

**20392.** Pires, M.M.; Stenert, C.; Maltchik, L. (2018): Effects of wetland hydroperiod length on the functional structure of assemblages of Odonata. *Austral Entomology* 58(2): 354-360. (in English) ["The role of hydroperiod as an environmental filter in structuring wetland assemblages is usually associated with trait selection in invertebrates. However, the effects of changes in the hydroperiod of non-permanent wetlands on invertebrate assemblages are still unclear, and few studies have assessed the functional structure of insect assemblages along the hydroperiod gradient. In this study, we investigated the effects of different hydroperiod lengths on the functional structure of Odonata assemblages in non-permanent wetlands (posteriorly classified as 'short-', 'medium-' and 'long-hydroperiod') in southern Brazil in 2013 and 2014. Biological traits related to life-history strategies in temporary waters were assessed according to seasonal patterns of occurrence of nymphal and adult stages of odonates. Following the rationale of an environmental filter produced by hydroperiod, we expected to find (1) higher functional diversity in longer hydroperiods and (2) trait-convergence patterns in odonate assemblages in shorter hydroperiods. Patterns of functional diversity were detected along the hydroperiod gradient. More specifically, higher functional dispersion was found in long-hydroperiod wetlands and trait-convergence patterns occurred in wetlands with shorter hydroperiods, supporting our general hypothesis. Odonate taxa with life-history traits associated with shorter life cycles predominated in medium- and short-hydroperiod wetlands. Our results thus suggest that more pronounced reductions in wetland hydroperiod length should produce odonate assemblages functionally more similar, and these results gain special importance as climate change scenarios indicate that the hydrology of wetlands will be affected by variation in rainfall regimes." (2018): Cyclicity of long-term population dynamics in dragonflies of the genus *Sympetrum* (Odonata, Anisoptera) in the basin of Lake Chany. *Contemporary Problems of Ecology* 11(6): 551-562. (in English) ["This work is directed at continuous studies of cyclicity of long-term (1980–2010) population dynamics of odonates in the basin of Lake Chany (in the south of Western Siberia). 4 sympatric species of the genus *Sympetrum* [*S. danae*, *S. flaveolum*, *S. sanguineum*, *S. vulgatum*) have been investigated by spectral analysis method. The cycle spectra of population dynamics have been constructed for each species; the basic parameters of these cycles (period, phase, and power) have been calculated. Special number cycles have been found for each species. Interspecies differences increased in the direction from high to low frequencies of the spectrum. In the cases of similar cycles, interspecies differences have been shown in the ratio of cycle powers and/or phases: identical phases can indicate the ability of species to increase their number synchronously with any of close species; different phases can indicate the possibility of a small-numbered species to reach its maximum number against the minimum number of numerous species. A comparison of sympatric species spectra of the genera *Coenagrion* and *Sympetrum* has led to the conclusion that, the more similarity there is in environmental standards among species inside a genus (as for *Sympetrum*), the more specific the species frequency spectra are. All species of the genus *Sympetrum* can synchronize their number fluctuations with 2- to 3 and 4- to 5-year fluctuations of the local climate. Also specific synchronization with important nature-climatic rhythms was found for each species: for *S. danae*, with an 18-year rhythm of the level of Lake Chany and with a 16-year rhythm of June temperatures; for *S. flaveolum*, with a 24-year Brickner cycle, with an 8-year cycle of rainfall, and with a 28-year cycle of April and May temperatures; for *S. vulgatum*, with a 40- to 42-year cycle of the level of Lake Chany, with 12-year cycle of rainfall, and with a 7-year cycle of April and June temperatures; and for *S. sanguineum*, with a 7-year cycle of April and June temperatures. Perhaps the adaptation mechanism of species to each other and to environments is enclosed in the cyclicity of long-term fluctuations of species number." **20395.** Pulok, M.K.H.; Chakravarty, U.K. (2018): Experimental analysis of aerodynamic performances of dragonfly

wings. *AIP Conference Proceedings* 1980(1), 10.1063/1.5044311: (in English) ["Nature-inspired flying robots are beneficial than other multi-rotor or fixed wing analogs, in many aspects. As wings play the key role on the hovering and maneuvering conditions of flying insects, structural functions and aerodynamic performances of the insect wings are needed to be analyzed for designing more effective wings for insect-sized flying robots. This study describes the method for experimental analysis of aerodynamic and vibration characteristics of dragonfly (*Erythemis simplicicollis*) forewings and hindwings. Vibration testing of the dragonfly wings has been conducted to obtain natural frequencies and mode shapes of the wings. The wings have also been examined in a suction wind tunnel having pistol-grip sting balance to illustrate the vibration and aerodynamic characteristics. The structural aerodynamic response of the wing has been determined at different freestream velocities and at different angles of attack. From the experimental results, the deformation response and the coefficients of drag and lift of the insect wings have been obtained for different Reynolds numbers and angles of attack. The coefficient of lift of the wings increases with the Reynolds number and angle of attack. The coefficient of drag of the wings also increases with the Reynolds number and angle of attack." **20396.** Quenta Herrera, E.; Casas, J.; Dangles, O.; Pincebourde, S. (2018): Temperature effects on ballistic prey capture by a dragonfly larva. *Ecology and Evolution* 8(8): 4303-4311. (in English) ["Understanding the effects of temperature on prey–predator interactions is a key issue to predict the response of natural communities to climate change. Higher temperatures are expected to induce an increase in predation rates. However, little is known on how temperature influences close-range encounter of prey–predator interactions, such as predator's attack velocities. Based on the speed–accuracy trade-off concept, we hypothesized that the increase in predator attack velocity by increasing temperature reduces the accuracy of the attack, leading to a lower probability of capture. We tested this hypothesis on the dragonfly larvae *Anax imperator* and the zooplankton prey *Daphnia magna*. The prey–predator encounters were video-recorded at high speed, and at three different temperatures. Overall, we found that (1) temperature had a strong effect on predator's attack velocities, (2) prey did not have the opportunity to move and/or escape due to the high velocity of the predator during the attack, and (3) neither velocity nor temperature had significant effects on the capture success. By contrast, the capture success mainly depended on the accuracy of the predator in capturing the prey. We found that (4) some 40% of mistakes were under-shooting and some 60% aimed below or above the target. No lateral mistake was observed. These results did not support the speed–accuracy trade-off hypothesis. Further studies on dragonfly larvae with different morphological labial masks and speeds of attacks, as well as on prey with different escape strategies, would provide new insights into the response to environmental changes in prey–predator interactions." **20397.** Raby, M.; Nowierski, M.; Perlov, D.; Zhao, X.; Hao, C.; Poirier, D.G.; Sibley, P.K. (2018): Acute toxicity of six neonicotinoid insecticides to freshwater invertebrates. *Environmental Toxicology and Chemistry* 37(5): 1430-1445. (in

English) ["Neonicotinoids are a group of insecticides commonly used in agriculture. Due to their high water solubility, neonicotinoids can be transported to surface waters and have the potential to be toxic to aquatic life. The present study assessed and compared the acute (48 or 96h) toxicity of 6 neonicotinoids (acetamiprid, clothianidin, dinotefuran, imidacloprid, thiacloprid, and thiamethoxam) to 21 laboratory-cultured and field-collected aquatic invertebrates spanning 10 aquatic arthropod orders. Test conditions mimicked species' habitat, with lentic taxa exposed under static conditions, and lotic taxa using recirculating exposure systems. Lethal (LC50) and effective (immobility, EC50) concentrations were calculated and used to construct separate lethal and immobilization-derived species sensitivity distributions (SSDs) for each neonicotinoid, from which 5th percentile hazard concentrations (HC5s) were calculated. Results showed the most sensitive invertebrates were insects from the orders Ephemeroptera (e.g. *Neocloeon triangulifer*) and Diptera (*Chironomus dilutus*), while cladocerans (e.g. *Daphnia magna*, *Ceriodaphnia dubia*) were the least sensitive. HC5s were compared to neonicotinoid environmental concentrations from Ontario monitoring studies. For all neonicotinoids except imidacloprid, the resulting hazard quotients indicated little to no hazard in terms of acute toxicity to aquatic communities in Ontario freshwater streams. For the neonicotinoid imidacloprid, a moderate hazard was found when only invertebrate immobilization, and not lethality, data was considered." (Authors) Test organisms include "Coenagrion sp.".] Address: Raby, Melanie, School of Environmental Sciences, Univ. of Guelph, Guelph, Ontario, Canada. Email: mraby@uoguelph.ca

**20398.** Ramadan, D.M.; Katbeh-Bader, A. (2018): Diversity of aquatic and semi-aquatic insects in Wadi Al-Walah in Jordan. *Zoology and Ecology* 28(2): 117-138. (in English) ["The aquatic and semi-aquatic insects of Wadi Al-Walah, Jordan were collected biweekly from five sites from August 2015 to August 2016. A total of 24,176 specimens of aquatic and semi-aquatic insects representing at least 75 identified or putative species of 33 families and seven insect orders were collected. The most abundant insect order was the Ephemeroptera of the family Caenidae. The Diptera was the most diverse (43 species in 13 families), followed by Coleoptera (10 species in 3 families), Hemiptera (7 species in 6 families), Odonata (7 species in 5 families), Ephemeroptera (4 species in 3 families) and Trichoptera (3 species in 2 families). A total of 22 species were recorded for the first time from Jordan; 8 were identified to the species level. Larvae of all collected species are briefly described and color images are provided illustrating morphological structures useful for future identification, especially for the Diptera. The results of our study indicated an urgent need for identification manuals for aquatic insects to support freshwater quality assessments in developing regions of Jordan and other eastern Mediterranean countries." **20399.** Reborá, M.; Frati, F.; Piersanti, S.; Salerno, G.; Selvaggini, R.; Fincke, O.M. (2018): Field tests of multiple sensory cues in sex recognition and harassment of a colour polymorphic damselfly. *Animal Behaviour* 136: 127-136. (in English) ["Highlights: •We examined whether free-flying male damselflies detect sex and morph via odour. •Male responses to nonvisual cues of live conspecifics and controls did not differ. •Males showed no preference for andromorphic or heteromorphic females. •Marked female morphs

were equally successful in resisting mating attempts. •Harassment responses of *Ischnura elegans* and *Enallagma* females appear similar. The use of multiple sensory modalities in mating decisions has prompted a reassessment of sexual selection in many species. Odonate males have long been assumed to use only visual cues in mate recognition. Using only airborne cues in the laboratory, a previous study of *Ischnura elegans* found that males discriminate between the sexes and exhibit an odour preference for male-like female colour morphs. In a field experiment that required free-flying males to detect and recognize potential mates, we scored nonsexual and sexual reactions of free-flying males to live conspecifics (andromorphic females, which mimic male body colour and pattern; heteromorphic females, which differ from males in body colour and pattern; and males) and empty control dowels positioned at ponds. 'Non-visual' treatments concealed under a muslin bag offered only olfactory cues, whereas the unbagged 'visual' treatments offered visual plus odour cues. Live conspecifics in the nonvisual treatments did not elicit more sexual reactions than control dowels. In contrast, live individuals in the visual treatment elicited more sexual responses than did controls, suggesting that odour alone was insufficient for detection of conspecifics. However, even with visual cues, males reacted sexually towards other males as often as they did towards either female morph, indicating a failure to discriminate between sex or morph. A second, more realistic visual treatment away from water, where 77% of the solitary mature individuals were males, produced similar results. Thus, we measured natural harassment rates of marked, free-flying females. Both female colour types used similar behaviours to evade males. We found no difference in harassment or mating rates between colour morphs. Our results suggest that visual cues of female *I. elegans* act similarly to the context-dependent signal apparency of *Enallagma* colour morphs, and emphasize the need for laboratory results to be validated by comparison of sensory abilities under natural conditions." **20400.** Renner, S.; Périco, E.; Schmidt Dalzochio, M.; Sahlén, G. (2018): Water body type and land cover shape the dragonfly communities (Odonata) in the Pampa biome, Rio Grande do Sul, Brazil. *Journal of Insect Conservation* 22(1): 113-125. (in English) ["The biogeographical region known as the Pampa biome in southern Brazil, was originally mainly covered with open fields or grassland, with areas of riparian forest surrounding the water bodies. Today this landscape appears highly fragmented due to agricultural activities such as rice cultivation, extensive cattle farming, and forest plantations. Studies have shown that the Pampa biome has high levels of biodiversity and endemism, but with regard to invertebrates, this biome is still one of the least known in Brazil. We therefore designed a study comparing the Odonata communities to environmental and landscape features in this area, measuring diversity by species richness, relative abundance and Shannon index. Our results showed that the Pampa is a biome very rich in odonates, and that the species communities are highly dependent on the environmental conditions of the area. Habitats such as Rivers/Streams, bordered by native grasslands and riparian forests, were shown to harbour communities that were ecologically more complex and sensitive than other habitat types. Man-made lakes and agricultural areas displayed lower levels of biodiversity and odonate communities dominated by generalist species. By combining data

on the communities of Odonata and other taxa, our analyses may be instrumental in determining priority areas for future conservation measures within the area." (Authors)] Address: Renner, S., Laboratório de Ecologia e Evolução, Univde do Vale do Taquari - UNIVATES, Lajeado, Brazil

**20401.** Rieckh, C.; Körner, A.; Holzinger, W.E. (2018): Die Libellenfauna des Laabachs im Grazer Feld. *Entomologica Austriaca* 25: 151- (in German) [Verbatim: In this study, the dragonfly fauna along the Laabach in the Graz field south of the Styrian capital was investigated. The stream, which is about 9.4 km long, runs partly through village and settlement areas, but mostly through agricultural land and is therefore mainly surrounded by fields. It was divided into 59 largely homogeneous sections from its source to its mouth in the Poniglach. Each section was walked at least four times during the flight season from May to September 2017 and the dragonfly fauna was recorded semi-quantitatively. In addition, data from random surveys in 2016 are available. In order to be able to record the influence of the habitat features of the surrounding area on the dragonfly fauna, the surrounding area was mapped up to a distance of 30 metres on both sides of the bank. A total of at least 25 species were recorded. While some sections of the stream were richly structured and had a high dragonfly diversity, other sections were heavily anthropogenically impaired (canalised) and/or temporarily dry. These sections were colonised by only a few species in low densities. Particularly noteworthy from a nature conservation point of view are the occurrences of *Coenagrion ornatum*, *Somatochlora meridionalis* and *Lestes barbarus* on the Laabach."] Address: Rieckh, Christina, Institut für Zoologie der Karl-Franzens-Universität Graz, Universitätsplatz 2, 8010 Graz, Austria. **20402.** Rodrigues, A.C.M.; Bordalo, M.D.; Golovko, O.; Koba, O.; Barata, C.; Soares, A.M.V.M.; Pestana, J.L.T. (2018): Combined effects of insecticide exposure and predation risk on freshwater detritivores. *Ecotoxicology* 27: 794-802. (in English) ["Insecticides usually present in low concentrations in streams are known to impair behaviour and development of non-target freshwater invertebrates. Moreover, there is growing awareness that the presence of natural stressors, such as predation risk may magnify the negative effects of pesticides. This is because perception of predation risk can by itself lead to changes on behaviour and physiology of prey species. To evaluate the potential combined effects of both stressors on freshwater detritivores we studied the behavioural and developmental responses of *Chironomus riparius* to chlorantraniliprole (CAP) exposure under predation risk. Also, we tested whether the presence of a shredder species would alter collector responses under stress. Trials were conducted using a simplified trophic chain: *Alnus glutinosa* leaves as food resource, the shredder *Sericostoma vittatum* and the collector *C. riparius*. CAP toxicity was thus tested under two conditions, presence/absence of the predator *Cordulegaster boltonii*. CAP exposure decreased leaf decomposition. Despite the lack of significance for interactive effects, predation risk marginally modified shredder effect on leaf decomposition, decreasing this ecosystem process. Shredders presence increased leaf decomposition, but impaired chironomids performance, suggesting interspecific competition rather than facilitation. *C. riparius* growth rate was decreased independently by CAP exposure, presence of predator and shredder species. A marginal interaction between CAP and predation risk was observed regarding chironomids development. To better un-

derstand the effects of chemical pollution to natural freshwater populations, natural stressors and species interactions must be taken into consideration, since both vertical and horizontal species interactions play their role on response to stress." **20404.** Schlemmer, L. (2018): Padrões de diversidade e suas implicações para a conservação de Odonata (Insecta) em igarapés amazônicos. Belém,: X + 144 pp. (in Portuguese, with English summary) ["The distribution of species within a landscape and the mechanisms that determine this distribution are fundamental questions for the understanding of the ecology of biological communities. The understanding of these phenomena is essential for the management of ecosystems and decision-making on the conservation of biodiversity, environmental conditions, and ecosystem resources. In this dissertation, we focused on the communities of Zygoptera, found in streams in the Brazilian Amazon region to investigate their alpha diversity (Chapter 1), beta diversity (Chapter 2), and the elements that structure metacommunities (Chapters 3), as well as the spatial priorities for the conservation of Amazonian odonates (Chapter 4). We used environmental, biogeographic, and spatial predictors to investigate the mechanisms that structure the distribution of the communities analyzed in this dissertation. In the case of alpha diversity (Chapter 1), environmental heterogeneity (climate) and primary productivity were the most important determinants of zygopteran species richness. For beta diversity (Chapter 2), turnover was the most important component of changes in species composition within the landscape, together with the spatial distance between sites, and the biogeographic region (centers of endemism), which were the most important predictors of zygopteran beta diversity. In our analysis of metacommunity patterns (Chapter 3), we found a Clementsian pattern in well-preserved streams, with a major change in the configuration of the communities in streams with environmental alterations, which represented subsets of the better preserved areas. In Chapter 4, we show that the spatial distribution of the conservation units in the Amazon region is relatively ineffective for the conservation of most of the beta diversity of the region's odonates. As the priority areas are located predominantly in southern Amazonia, and most of these areas have already been deforested, given that they lie within the arc of deforestation, the priority areas were displaced toward the

forested environments located nearer the center of the Amazon region. Based on this analysis, we suggest the creation of new conservation units or the implementation of incentives for the establishment of activities that cause reduced environmental impacts in more central, priority areas, which are still forested, as well as the restoration of priority areas that have already been deforested. One possibility here would be the implementation of programs that pay for ecosystem services, such as carbon credits obtained through reforestation and/or the development of activities with a reduced impact on biodiversity, such as agroforestry. This study also makes a major contribution to the reduction of the Wallacean and Hutchinsonian shortfalls on the zygoptera of the Brazilian Amazon region." **20406.** Schneider, T.; Ikemeyer, D.; Müller, O.; Dumont, H.J. (2018): Checklist of the dragonflies (Odonata) of Iran with new records and notes on distribution and taxonomy. *Zootaxa* 4394(1): 1-40. (in English) ["Iran has a complex dragonfly fauna influenced by contacts and overlaps of different geographical zones. Its fauna is dominated by Eurosiberian taxa. However, the SE Province Sistân-va-Baluchestân is rich in oriental species, many of which having their western distribution limit in Iran. In NE-Iran, Irano-Turanian elements live and in the S- and SW-Iran African species are found. The Iranian Odonata fauna seems well studied, however, a closer look reveals many uncertainties and confusion, some records coming clearly from misidentification whereas other, which were missing proofs of correct identification remains to be confirmed. Even today, every new collecting trip reveals species new for Iran whereas species new for science are still detected, although rarely. In this checklist we include seven taxa new for Iran: *Stylurus ubadschii* (although a male of uncertain origin is recorded in Schmidt (1954)), *Ischnura senegalensis* (although two uncertain records were published by Martin (1912) and Schmidt (1954)), *Coenagrion ponticum*, *C. lunulatum*, *C. pulchellum*, *Lestes macrostigma*, and *Calopteryx splendens tschaldirica*. We critically checked all available data, including all published records. Fourteen taxa have been rejected, or placed in the category for need of confirmation. Till the end of 2017, 100 autochthonous taxa of dragonflies and two migratory species could be confirmed to be or have been present in Iran. We provide distribution maps, created after evaluation of published data and containing our own data from 12 trips to Iran, travelling over 35000 km in the country. Over 200 new localities are integrated. Taxonomic confusion is reduced by

rejecting the following taxa for Iran: *C. splendens mingrellica*, *C. hyalina*, *Erythromma najas*, *Aeshna cyanea*, *Gomphus davidi*, and *Sympetrum sinaiticum*. We regard the taxa *Gomphus amseli* and *G. schneiderii transcaspicus* as synonyms of *G. schneiderii*, and *Onychogomphus forcipatus lucidostriatus* as a synonym of *O. f. albotibialis*." **20409.** Shumway, N.; Gabryszuk, M.; Laurence, S.J. (2018): Flapping tandem-wing aerodynamics: dragonflies in steady forward flight. 2018 AIAA Aerospace Sciences Meeting, AIAA SciTech Forum, (AIAA 2018-1290): 15 pp. (in English) ["The study of tandem flapping wing aerodynamics of dragonflies in steady forward flight is presented here.

CFD simulations of one forewing-hindwing pair are run using wing kinematics measured in experiments with free flying dragonflies. Wing kinematics were acquired from tests of dragonflies flying through a confined space using multiple high speed cameras, placed such that they could record the dragonfly's motion. The test results contain videos of dragonflies flying inverted as well as upright, and wing kinematics have been extracted for three inverted and two upright flights. In the inverted flights the upstroke is longer than the downstroke and the pitch angle of the forewing is lower during the downstroke than similar upright flights. Three simulations were run based on this kinematic information: one simulating upright flight, one simulating inverted flight, and one looking at the effect of changing relative downstroke duration. The simulation results indicate that the dragonflies are controlling the orientation of their wing such that they have a similar orientation relative to their velocity during the halfstroke when the wing is flapping down in the lab reference frame. In addition, decreasing relative downstroke duration increases peak and average lift, making it unclear why dragonflies use a longer downstroke than upstroke while flying upright." **20410.** Simon, S.; Blanke, A.; Meusemann, K. (2018): Re-analyzing the Palaeoptera problem - The origin of insect flight remains obscure. *Arthropod Structure & Development* 47(4): 328-338. ["The phylogenetic relationships of the winged insect lineages - mayflies (Ephemeroptera), damselflies and dragonflies (Odonata), and all other winged insects (Neoptera) - are still controversial, with three hypotheses supported by different datasets: Palaeoptera, Metapterygota and Chiasmomyaria. Here, we reanalyze available phylogenomic data with a focus on detecting confounding and alternative signal. In this context, we provide a framework to quantitatively evaluate and assess incongruent molecular phylogenetic signal inherent in phylogenomic datasets. Despite overall support for the Palaeoptera hypothesis, we also found considerable signal for Chiasmomyaria, which is not easily detectable by standardized tree inference approaches. Analyses of the accumulation of signal across gene partitions showed that signal accumulates gradually. However, even in case signal only slightly supported one over the other hypothesis, topologies inferred from large datasets switch from statistically strongly supported Palaeoptera to strongly supported Chiasmomyaria. From a morphological point of view, Palaeoptera currently appears to be the best-supported hypothesis, however, recent analyses were restricted to head characters. Phylogenetic approaches covering all organ systems including analyses of potential functional or developmental convergence are still pending so that the Palaeoptera problem has to be considered an open question in insect systematics." (Authors)] Address: Email: [ablanke@evolution.uni-bonn.de](mailto:ablanke@evolution.uni-bonn.de)

**20411.** Smith, D.R. (2018): The aquatic ecology of Lake Rotokare. M.Sc. thesis, The Univ. of Waikato, Hamilton, New Zealand: 220 pp. (in English) ["The biology of three endemic and one exotic species of fish (banded kokopu, *Galaxias fasciatus*; shortfin eel, *Anguilla australis*; longfin eel, *Anguilla dieffenbachii*; and the European perch, *Perca fluviatilis*) was investigated in Lake Rotokare. Little is currently known regarding the local ecology of the lake. This study improves the understanding of the biological processes in Lake Rotokare and investigates the characteristics of the lake's water quality. Fish sampling occurred in the lake using a combination of boat electrofishing, gill netting, and fyke netting. The tributary was sampled using night time spotlighting. Fish

taken from the lake were used to determine length-weight relationships, size frequencies, CPUE, abundance estimations, fish biomass, stable isotope analyses, trophic levels, and perch diet. Water quality sampling was also undertaken to further build upon data from previous studies. The majority of fish sampled in Lake Rotokare were perch, with a mixture of size classes, but dominated by a large juvenile size class. Perch density was high (16.55 fish 100 m<sup>2</sup>). Longfin eels showed a cohort of large individuals with no evidence of recruitment occurring; while shortfin eels exhibited a distribution of size ranges with evidence of juvenile recruitment occurring. Electrofishing showed evidence of banded kokopu inhabiting the lake, even at distance from the tributary outlet, suggesting the possibility of a lake fringe population of kokopu. Spotlight sampling in June and December revealed a stable kokopu and koura population residing in the lakes' main tributary. Water quality data showed an overall decrease in total nitrogen and phosphorous loads within the lake since 1979. However, the lake has shown strong thermal stratification over summer over multiple years (1977, 2013, February 2017 and December 2017), and remains in poor condition, with a eutrophic TLI 4 rating of 4.1. Frequent cyanobacterial blooms continue to occur during the summer season, resulting in closure of the lake for contact recreation. Both dietary and stable isotope analyses showed indications that chironomid larvae and *Daphnia* sp. constituted the bulk of the primary production of the food web [also including "Odonata"]; juvenile perch were found to be the predominant food source of the three resident fish species. A three-end member mixing model was created to duplicate the theoretical food-web within the lake with chironomid larvae, dragonfly larvae, and juvenile perch at the base. Lipid treatment techniques were examined in this study for eel fin and muscle tissue. The results indicate that lipid treatment is needed for 13C isotope values for both longfin and shortfin muscle, and longfin fin tissue for accurate results. Mathematical equations were constructed to correct untreated fin tissue values into treated muscle values for 13C and 15N; avoiding the necessity for future lethal sampling methods." (Author)] Address: not stated

**20412.** Staentzel, C.; Arnaud, F.; Combroux, I.; Schmitt, L.; Tremolieres, M.; Grac, C.; Piegay, H.; Barillier, A.; Chardon, V.; Beisel, J.-N. (2018): How do instream flow increase and gravel augmentation impact biological communities in large rivers: A case study on the Upper Rhine River. *River Research and Applications* 34(2): 153-164. (in English) ["Actions are being developed to address the adverse consequences of engineering works on large European rivers by developing and implementing restoration activities in order to enhance the functionality and biodiversity of fluvial hydrosystems. However, as has frequently been mentioned in the scientific literature, quantitative and qualitative evaluation of the project benefits, if any, and their sustainability are hindered by the difficulty in assessing the responses of aquatic and riparian communities to the methods employed. A case study was conducted on a by-passed section of the Upper Rhine River (France and Germany) to investigate the effects of instream flow increase and gravel augmentation on selected aquatic and riparian communities (macroinvertebrates, macrophytes, and riparian plants). This paper presents the results of a 6-year interdisciplinary, before-after control-impact design monitoring study. The complexity of the study lies in carrying out a separate assessment of the cumulative effects on a site-based, project-specific basis. The results showed that (a) the instream flow increase resulted in greater richness of macrophyte species in the newly created backwaters, (b) the artificial gravel bar favoured the

recruitment of pioneer species, including invasive species, although gravel redistribution by floods prevented their development, and (c) gravel augmentation tended to promote the taxonomic richness of macroinvertebrate communities with the appearance of species adapted to the new substrate areas. These findings should help to fill the knowledge gaps in large-scale restoration and contribute key responses to the most frequently arising issues in this area, especially those concerning the efficiency and sustainability of river restoration projects." (2018): Structure and chemical organization in damselfly *Calopteryx haemorrhoidalis* wings: A spatially resolved FTIR and XRF analysis with Synchrotron Radiation. *Scientific Reports* 8, Article number: 8413: 9 pp. (in English) ["Insects represent the majority of known animal species and exploit a variety of fascinating nanotechnological concepts. We investigated the wings of the damselfly *Calopteryx haemorrhoidalis*, whose males have dark pigmented wings and females have slightly pigmented wings. We used scanning electron microscopy (SEM) and nanoscale synchrotron X-ray fluorescence (XRF) microscopy analysis for characterizing the nanostructure and the elemental distribution of the wings, respectively. The spatially resolved distribution of the organic constituents was examined by synchrotron Fourier transform infrared (s-FTIR) microspectroscopy and subsequently analyzed using hierarchical cluster analysis. The chemical distribution across the wing was rather uniform with no evidence of melanin in female wings, but with a high content of melanin in male wings. Our data revealed a fiber-like structure of the hairs and confirmed the presence of voids close to its base connecting the hairs to the damselfly wings. Within these voids, all detected elements were found to be locally depleted. Structure and elemental contents varied between wing membranes, hairs and veins. The elemental distribution across the membrane was rather uniform, with higher Ca, Cu and Zn levels in the male damselfly wing membranes." (2018): Zur Populationsökologie und Ethologie von *Cordulegaster bidentata* an einem Bach im Kaufunger Wald - eine Fallstudie (Odonata: Cordulegastridae). *Libellula* 37(3/4): 23-54. (in German, with English summary) ["About population ecology and ethology of *C. bidentata* living on a forest stream in Kaufunger Wald, Germany - A small forest stream in Kaufunger Wald, Central Germany, on Bunter Sandstone Substrate was populated by imagines of *C. bidentata* four months after removing a long solid layer of branch waste. One year after this removal 17 males were colour marked and both marked and unmarked individuals were counted during several days when passing the counting Station. Moreover, two unmarked males were observed simultaneously. Females were present too. Forty exuviae found in 2018 verified that the indigenous population is on this scale. In contrast to this result, only five larvae of *C. bidentata* could be found in this stream. In the surrounding forests no streams were found where other

large populations occurred. Individual flight behaviour of marked males was recorded both during season and days. One half of males could not be observed after marking any more. Among the other males few individuals dominated, others only occurred sporadically. One male belonging to the sporadic group occurred twice, in both cases just when a female was present along the stream. It happened to copulate in both cases. These copulations have been the only ones observed during this counting season." (Author)] Address: Tamm, J., Elgershäuser Straße 12, D-34131 Kassel, Germany. E-mail: jochen.tamm@t-online.de

**20415.** Torralba-Burrial, A. (2018): Comunidad Virtual de Aprendizaje (CVA) informal sobre los odonatos ibéricos: análisis de la lista de correo Odo-GIO (Odonata). *Boln. S.E.A.* 63: 357-361. (in Spanish, with English summary) ["The informal Virtual Learning Community (VLC) on Iberian Odonata: an analysis of the Odo-GIO mailing list Abstract: Virtual Learning Communities (VLC) are a reference for informal learning. The Odo-GIO mailing list, hosted by Rediris and linked to the Grupo Ibérico de Odonatología (GIO), is analysed according to the subject and aims of the messages shared by its members. Virtual learning community members' perceptions are evaluated through a questionnaire on both past and future developments of the mailing list. Community members who responded to the questionnaire manifested a high interest in dragonflies, and commented on positive learning experiences within the virtual community. The evaluation of its potential as a learning tool, issues related to odonate distribution, conservation or behaviour were highlighted." **20416.** Tsui, M.T.; Adams, E.M.; Jackson, A.K.; Evers, D.C.; Blum, J.D.; Balog, S.J. (2018): Understanding sources of Methylmercury in songbirds with stable mercury isotopes: Challenges and future directions. *Environmental Toxicology and Chemistry* 37(1): 166-174. (in English) ["Mercury (Hg) stable isotope analysis is an emerging technique that has contributed to a better understanding of many aspects of the biogeochemical cycling of Hg in the environment. However, no study has yet evaluated its usefulness in elucidating the sources of methylmercury (MeHg) in songbird species, a common organism for biomonitoring of Hg in forested ecosystems. In the present pilot study, we examined stable mercury isotope ratios in blood of 4 species of songbirds and the invertebrates they are likely foraging on in multiple habitats in a small watershed of mixed forest and wetlands in Acadia National Park in Maine (USA). We found distinct isotopic signatures of MeHg in invertebrates (both mass-dependent fractionation [as  $\delta^{202}\text{Hg}$ ] and mass-independent fractionation [as  $\Delta^{199}\text{Hg}$ ]) among 3 interconnected aquatic habitats. It appears that the Hg isotopic compositions in bird blood cannot be fully accounted for by the isotopic compositions of MeHg in lower trophic levels in each of the habitats examined. Furthermore, the bird blood isotope results cannot be simply explained by an isotopic offset as a result of metabolic fractionation of  $\delta^{202}\text{Hg}$  (e.g., internal demethylation). Our results suggest that many of the birds sampled obtain MeHg from sources outside the habitat they were captured in. Our findings also indicate that mass-independent fractionation is a more reliable and conservative tracer than mass-dependent fractionation for identifying sources of MeHg in bird blood. The results demonstrate the feasibility of Hg isotope studies of songbirds but suggest that larger numbers of samples and an expanded

geographic area of study may be required for conclusive interpretation." (Authors)] Address: Tsui, M., Dept of Biology, Univ. of North Carolina at Greensboro, Greensboro, North Carolina, USA

**20417.** Tüzün, N.; Stoks, R. (2018): Pathways to fitness: carry-over effects of late hatching and urbanisation on lifetime mating success. *Oikos* 127(7): 949-959. (in English) ["Life history theory and most empirical studies assume carry-over effects of larval conditions to shape adult fitness through their impact on metamorphic traits (age and mass at metamorphosis). Yet, very few formal tests of this connection across metamorphosis exist, because this entails longitudinal studies from the egg stage and requires measuring fitness in (semi)natural conditions. In a longitudinal one-year common-garden rearing experiment consisting of an outdoor microcosm part for the larval stage and a large outdoor insectary part for the adult stage, we studied the effects of two factors related to time constraints in the larval stage (egg hatching period and urbanisation) on life history traits and lifetime mating success in the males of the damselfly *Coenagrion puella*. We reared early- and late-hatched larvae from each of three rural and three urban populations from the egg stage throughout their adult life. Key findings were that both the hatching period and urbanisation shaped adult fitness, yet through different pathways. As expected, the more time-constrained late-hatched individuals accelerated their larval life history and this was associated with a lower lifetime mating success. A path analysis revealed this carry-over effect was mediated by the changes in the two metamorphic traits (reduced age and lower mass at emergence). Notably, urban males had a 50% lower lifetime mating success, which was not mediated by age and mass at emergence, and possibly driven by their shorter lifespan. Our results point to long-term carry-over effects of the usually ignored natural variation in egg hatching dates, and further contribute to the limited evidence showing fitness costs of adjusting to an urban lifestyle." **20419.** Turra, B.L.; Raimundi, E.R.; de Souza-Franco, G.M. (2018): Influência de variáveis ambientais em ambientes lóticos de Mata de Araucária sobre a taxocenose de Odonata. *Revista Ibero-Americana de Ciências Ambientais* 9(3): 289-305. (in Portuguese, with English summary) ["Influence of environmental variables in Araucaria Forest lotic environments on taxocenosis of Odonata - The size of the water bodies can be considered the main controller of the physical and chemical characteristics of the lotic environments. Therefore, the substrate type, river flow, organic and inorganic composition, and habitat heterogeneity are directly related to the size of the lotic environment. In turn,

these characteristics are determinant in the distribution and diversity of the immature fauna of Odonata. In this context, we test the hypothesis that different dimensions of lotic environments support similar diversity of Odonata immatures, however, differ in their composition. Thus, we evaluated the influence of water body size on abiotic factors and Odonata immature body taxocenosis. We carried out five seasonal samplings between 2011 and 2012, in the Araucarias National Park, Santa Catarina, in eight environments, through quantitative and qualitative methods. There were 520 Odonata individuals, distributed in eight families and 41 genera. The environments were evidently separated by the classification of the rivers. The highest values of diversity, richness and equitability were recorded in small streams, environments with greater habitat heterogeneity, higher percentage of organic matter and protected by ciliary forest. It was confirmed by this study that the high habitat heterogeneity in low order lotic environments influences the diversity, the abundance and the richness of the Odonata fauna. Another determining factor for the high indexes was the integrity of the study site, favoring the protection and cycling of nutrients in water bodies." (in Chinese, with English summary) ["Some dragonflies are nutrient-rich edible insects with the value of health care. Currently, there are 12 species of edible dragonflies in the domestic market (*Crocothemis servilia*, *Orthetrum albistylum*, *O. triangulare melania*, *Pantala flavescens*, *Sympetrum uniforme*, *O. pruinatum neglectum*, *Epophthalmia elegans*, *Icetinogomphus rapax*, *Sinictinogomphus clavatus*, *Anax parthenope julius*, *Gomphus cuneatus*, *Lestes praemorsa*). We found a smaller species of edible dragonfly nymphs at Daping Township, Yuanyang County, Honghe State in Yunnan Province. This species of dragonfly does not belong to the

above 12 species based on the morphological characteristics. This edible dragonfly was identified with DNA barcoding method as *Sympetrum speciosum*." (Authors)] Address: Wang, C.; Email: cywang11@126.com

**20422.** Wang, J.; Han, P.; Zhu, R.; Liu, C.; Deng, X.; Dong, H. (2018): Wake capture and aerodynamics of passively pitching tandem flapping plates. 2018 Fluid Dynamics Conference. DOI: 10.2514/6.2018-3236: 13 pp. (in English) ["The passive pitching mechanism of insect wings during unsteady flapping flight is commonly observed in nature and has been extensively studied using single wing models. However, passive pitching in ipsilateral wings, which will be inevitably affected by the wing-wing interactions, remains unexplored. In this paper, the wake capture and aerodynamic performances of two passively pitching tandem flapping plates ( $AR = 3.0$ ) is numerically investigated with a torsional spring model. The computations are conducted using an immersed boundary method (IBM) based direct numerical simulation (DNS) solver. A constant incoming flow is introduced to model the flow condition of dragonfly takeoff flight. A parametric study on the phase difference ( $A\langle p$ ) between the downstream and upstream plate is performed at  $Aq\rangle$  between  $-90^\circ$  and  $+90^\circ$ . The simulation results show significant changes in the passive pitching of both plates, especially the plate in downstream, due to wing-wing interactions. Significant wake capture by the leading edge of the downstream plate is found at positive  $A\langle p$ , which helps the downstream plate maintain high passive pitching angle and results in high lift force generation. Wake capture by the trailing edge of the downstream plate is found at negative  $A\langle p$ , which suppresses the passive pitching of the downstream plate and leads to deterioration of its aerodynamic performance." **20423.** Wang, M.; Shi, G.; Zhu, Y.; Wang, Y.; Ma, W. (2018): Au-decorated dragonfly wing bioscaffold arrays as flexible Surface-Enhanced Raman Scattering (SERS) substrate for simultaneous determination of pesticide residues. *Nanomaterials* 2018, 8, 289: 14 pp. (in English) ["Rapid sampling and multicomponent analysis are vital in pesticide residue detection. In this work, we proposed a SERS platform to detect three kinds of pesticides on apple peels simultaneously by a straightforward "press and peel off" method. The flexible Au/dragonfly wing (Au/DW) substrate was obtained from sputtering Au nanoislands on DW bioscaffold arrays by a simple direct current (DC) magnetron sputtering system. The high-performance substrate exhibited a low limit of detection (LOD) to 4-aminothiophenol (4-ATP) ( $10.9 \text{ M}$ ), outstanding reproducibility (less than 12.15%), good stability and suitability in multifold pesticide residues detection. Considering its excellent sample collection efficiency, the Au/DW substrate was employed to solve critical pesticide residue problems for detection of acephate (APT), cypermethrin (CPT), tsumacide (MTMC) and their multiple components on apple peels. The results show that the LOD was  $10.3 \text{ ng/cm}^2$  for APT obtained on the apple surface with a calculation equation of  $y = 0.26x + 6.68$  and a determination coefficient ( $R^2$ ) of 0.970. Additionally, the LOD values for CPT and MTMC were  $10.3 \text{ ng/cm}^2$  and  $10.4 \text{ ng/cm}^2$ , respectively. The finding in this work may provide a promising biomimetic SERS platform for on-spot detection of other organic pollutants in the food industry and environmental protection." **20424.** Wellenreuther, M.; Muñoz, J.; Chávez-Ríos, J.R.; Hansson, B.; Cordero-Rivera, A.; Sánchez-Guillén, R.A. (2018): Molecular and ecological signatures of an expanding hybrid zone. *Ecology and Evolution* 8(10): 4793-4806. (in English) ["Many species are currently changing their distributions and subsequently form sympatric zones with hybridization between formerly allopatric species as one possible consequence. The damselfly *Ischnura elegans* has recently expanded south into the range of its ecologically and morphologically similar sister species *Ischnura graellsii*. Molecular work shows ongoing introgression between these species, but the extent to which this species mixing is modulated by ecological niche use is not known. Here, we (1) conduct a detailed population genetic analysis based on molecular markers and (2) model the ecological niche use of both species in allopatric and sympatric regions. Population genetic analyses showed chronic introgression between *I. elegans* and *I. graellsii* across a wide part of Spain, and admixture analysis corroborated this, showing that the majority of *I. elegans* from the sympatric zone could not be assigned to either the *I. elegans* or *I. graellsii* species cluster. Niche modeling demonstrated that *I. elegans* has modified its environmental niche following hybridization and genetic introgression with *I. graellsii*, making niche space of introgressed *I. elegans* populations more similar to *I. graellsii*. Taken together, this corroborates the view that adaptive introgression has moved genes from *I. graellsii* into *I. elegans* and that this process is enabling Spanish *I. elegans* to occupy a novel niche, further facilitating its expansion. Our results add to the growing evidence that hybridization can play an important and creative role in the adaptive evolution of animals." **20425.** Wiczorek, M.V.; Bakanov, N.; Bilancia, D.; Szöcs, E.; Stehle, S.; Bundschuh, M.; Schulz, R. (2018): Structural and functional effects of a short-term pyrethroid pulse exposure on invertebrates in outdoor stream mesocosms. *Science of the Total Environment* 610–611: 810-819. (in English) ["Agricultural land-use frequently results in short pulse exposures of insecticides such as pyrethroids in river systems, adversely affecting local invertebrate communities. In order to assess insecticide-induced effects, stream mesocosms are used within higher tier aquatic risk assessment. Regulatory acceptable concentrations (RACs) derived from those studies are often higher compared with tier 1 RACs. Hence, the present mesocosm study evaluates this aspect using a pulse exposure scenario typical for streams and the pyrethroid insecticide etofenprox. A 6-h pulse exposure with measured concentrations of  $0.04$ ,  $0.3$  and  $5.3 \mu\text{g L}^{-1}$  etofenprox was used. We considered abundance, drift and emergence of invertebrates as structural endpoints and the in situ-measured feeding rates of the isopod *Asellus aquaticus* as functional endpoint. Most prominent effects were visible at  $5.3 \mu\text{g L}^{-1}$  etofenprox which caused adverse effects of up to 100% at the individual and population level, as well as community structure alterations. Transient effects were observed for invertebrate drift (effect duration .24 h) and for the invertebrate community (9 days after exposure) at  $0.3 \mu\text{g L}^{-1}$  etofenprox. Furthermore,  $0.04 \mu\text{g L}^{-1}$  etofenprox affected the abundance of the mayfly *Cloeon simile* (decrease by 66%) and the feeding rate of *A. aquaticus* (decrease by 44%). Thus, implications for the functional endpoint leaf litter breakdown in heterotrophic ecosystems may be expected. A hypothetical RAC derived from the present mesocosm study ( $0.004 \mu\text{g L}^{-1}$ ) is in line with the official tier 1 RAC ( $0.0044 \mu\text{g L}^{-1}$ ) and thus shows that the

present mesocosm study did not result in a higher RAC." (Authors)] Address: Wieczorek, M., Inst. Environmental Sciences, Univ. of Koblenz-Landau, Fortstr. 7, 76829 Landau, Germany. Email: wieczorekm@uni-landau.de

**20426.** Wolfe, J.D.; Lane, O.P.; Brigham, R.M.; Hall, B.D. (2018): Mercury exposure to red-winged blackbirds (*Agelaius phoeniceus*) and dragonfly (Odonata: Aeshnidae) nymphs in Prairie Pothole wetlands. *FACETS* 3: 174-191. (in English) ["The Prairie Pothole Region (PPR) in the northern Great Plains is an area of ecological significance, serving as an important breeding site for avian wildlife. However, organisms feeding within the PPR may be at risk of mercury (Hg) exposure due to deposition of anthropogenic emissions and the high Hg methylation potential of PPR wetlands. We quantified Hg concentrations in red-winged blackbirds'; RWBLs) blood, feathers, and eggs in the spring and summer breeding season and compared our values with those from RWBLs sampled from ecoregions across North America. Hg concentrations in whole water, aeshnid dragonfly nymphs, and RWBL tissues varied by wetland and were below those considered to elicit acute effects in wildlife, and egg total Hg (THg) concentrations were significantly related to spring whole water methylmercury concentrations. Only RWBL blood THg concentrations showed a clear increase in summer compared with spring, resulting in decoupling of summer blood and feather THg concentrations. Moreover, blood THg concentrations varied by ecoregion, with those impacted by an industrial point source exhibiting high Hg levels. Our study emphasizes that tissue renewal time as well as ecological factors such as competition and diet shifts are important considerations when using RWBLs to assess biological Hg exposure." **20427.** Zia, Z.; Amad-Ud-Din; Azam, I.; Munir, A.; Afsheen, S. (2018): Effect of salinity gradients on species composition of Odonata naiads. *Arthropods* 7(1): 11-25. (in English) ["In present study the relationship between salinity gradients of various water bodies and inhabiting Odonata naiads was studied. Naiads, being a popular group of water pollution indicators, were studied. Totally 35 sites were surveyed for collection of naiads and water samples were taken from each positive site. Eight factors viz. Electrical Conductivity (Ec), Calcium +Magnesium (Ca+Mg), Sodium (Na+), Carbonates (Carb), Bicarbonates (Bc), Sodium Absorption Ratio (SAR) and Residual Sodium Carbonate (RSC) were studied for each water sample. Interesting results were obtained both for Anisoptera and Zygoptera species. Among dragonflies, genus *Crocothemis* of family Libellulidae appeared to be resistant while Genus *Gomphidia* and *Sympetrum* of families Gomphidae and Libellulidae were observed to be affected by variations in salinity gradients of waters of different sites. However in case of damselflies Genus *Ischnura* of family Ceonagrionidae and genus *Pseudagrion* of family Ceonagrionidae were observed to be adaptive followed by genus *Ceriagrion* of same family. As an overall conclusion, Anisopterous naiads were found more susceptible to salinity gradients than Zygoptera and thus can be better used in water salinity diagnoses studies." **20428.** Zsoldos, A. (2018): Study on biomass in semiaquatic insects (Odonata) over a 20-year period in central, Sweden. B.Sc. thesis, Halmstad Univ., School of Business,

Engineering and Science: 11 pp. (in English) ["This study is about how biomass of dragonfly insects have changed over the past 20-years in a forested area of central Sweden. This was done by analysing previously collected Odonata larvae stored in ethanol where sampling effort corrects the weight per locality. The results display a small but significant biomass increase over past decades, going against the recently observed trend of biomass decline in insects. However, this biomass gain was not even between the families, the ones that increased the most was Aeshnidae and Libellulidae. The reasons for the observed increase are discussed, some possible suggestions are less disturbance in their environments and their ability to adapt due to their long evolution giving them a phenotypical advantage." **20429.** Šigutová, H.; Šigut, M.; Dolný, A. (2018): Phenotypic plasticity in specialists: How long-spined larval *Sympetrum depressiusculum* (Odonata: Libellulidae) responds to combined predator cues. *PLoS ONE* 13(8): e0201406: 15 pp. (in English) ["Phenotypic plasticity is a common defensive strategy in species experiencing variable predation risk, such as habitat generalists. Larvae of generalist dragonflies can elongate their abdominal spines in environments with fish, but long spines render larvae susceptible to invertebrate predators. Long-spined specialists adapted to fish-heavy habitats are not expected to have phenotypic plasticity in this defence trait, but no empirical studies have been undertaken. Moreover, in comparison to prey responding to multiple predators that induce similar phenotypes, relatively little is known regarding how species react to combinations of predators that favour opposing traits. We examined plasticity of larval dragonfly *Sympetrum depressiusculum*, a long-spined habitat specialist. In a rearing experiment, larvae were exposed to four environments: (i) no predator control, (ii) fish cues (*Carassius auratus*), (iii) invertebrate cues (*Anax imperator*), as well as (iv) a combination of (ii) and (iii). Compared with the control, fish but not invertebrate cues resulted in longer spines for two (one lateral, one dorsal) of the six spines measured. Interestingly, the combined-cue treatment led to the elongation of all four dorsal spines compared with the fish treatment alone, whereas lateral spines showed no response. Our experiment provided evidence of morphological plasticity in a long-spined specialist dragonfly. We showed that nearly all spines can elongate, but also react differently under specific predator settings. Therefore, while spine plasticity evolved in direct response to a single predator type (fish), plasticity was maintained against invertebrate predators as long as fish were also present. Selective spine induction under the combined condition suggests that *S. depressiusculum* can successfully survive in environments with both predators. Therefore, phenotypic plasticity may be an effective strategy for habitat generalists and specialists. Although more studies are necessary to fully understand how selection shapes the evolution of phenotypic plasticity, we demonstrated that in dragonflies, presence or absence of a specific predator is not the only factor that determines plastic defence responses] Address: Šigutová, Hana, Institute of Environmental Technologies, Faculty of Science, Univ. of Ostrava, Ostrava, Czech Republic. **20432.** Adu, B.W.; Oyeniyi, E.A. (2019): Water quality parameters and aquatic insect diversity in Aahoo stream, southwestern Nigeria. *The Journal of Basic and Applied Zoology* (2019) 80:15. <https://doi.org/10.1186/s41936-019-0085-3>: 9 pp. (in English) ["Background: The role of water in the maintenance of an aquatic ecosystem is indispensable. In this study, aquatic insect biodiversity and the physico-chemical parameters of Aahoo stream, in southwestern Nigeria, were investigated from March to August 2017. Seven physico-chemical parameters were examined in six study sites. Results: There were significant effects ( $p < 0.0001$ ) of flow rate (F5, 12 = 2221.9), electrical conductivity (F5, 12 = 276.3), air temperature (F5, 12 = 110.3), water temperature (F5, 12 = 55.5) and pH (F5, 12 = 31.45) on the quantity of aquatic insects at the study sites in Aahoo stream. Dissolved oxygen (F2, 12 = 7.82) also had a significant impact ( $p = 0.002$ ) on the quantity of aquatic insects at the stream. Three aquatic insect orders, Diptera (most dominant), Odonata (median dominant) and Hemiptera (least dominant), nine families and 12 genera were found occurring in the stream. Chironomus sp. (Chironomidae, 55.29%), *Brachythemis* sp. and *Orthetrum* sp. (Libellulidae, 21.84%) which are usually associated with polluted water showed the highest occurrence in the stream. Low values of diversity indices were observed across the six study sites, which suggest that the six sites were in unstable conditions. Site 5 has the richest (Simpson 1-D 0.77, Shannon H 1.81, Margalef 1.91) and best taxa distribution (Equitability J: 0.73), while site 3 was the poorest (Simpson 1-D 0.52 and Shannon H 1.31) and the least in taxa distribution (Equitability J 0.55). Conclusion: This study has provided information on the assemblage and copiousness of various aquatic insects as well as the physico-chemical parameters of Aahoo stream. It could therefore be concluded that the stream could be somewhat polluted and unsafe for human consumption without being properly treated." **20433.** Amari, H.; Zebsa, R.; Lazli, A.; Bensouilah, S.; Melal, M.K.; Mahdjoub, H.; Houhamdi, M.; Khelifa, R. (2019): Differential elevational cline in the phenology and demography of two temporally isolated populations of a damselfly: Not two but one taxon? *Ecological Entomology* 44(1): 93-104. (in English) ["1. Temporal isolation by cohort splitting is a life-history mechanism that has been reported in many temperate insects, including those inhabiting freshwater habitats. Although the cohorts seem to maintain separate temporal niches in a specific location, the temporal isolation may be disrupted across a geographic gradient due to constraints imposed by seasonality. 2. This prediction was tested on two temporally isolated populations of the obligatory univoltine *Lestes virens* in north-east Algeria. Although the two cohorts emerge at the same time in spring, one cohort reproduces in summer, while the second cohort estivates in summer and reproduces in autumn. A survey assessing the phenology and abundance was conducted on eight ponds across an elevational gradient (5–1012 m a.s.l.) using capture–mark–recapture and adult density sampling. 3. In all sites from low to high elevation, the species showed cohort splitting. The phenology of reproduction of both cohorts showed a delay with elevation, but the cline was 2.2 days for the summer cohort and 0.7 days for the autumn cohort per 100 m of elevation. Moreover, the density of adults in the autumn cohort was higher than that of summer cohort across the entire elevational range, and the difference increased with elevation. 4. These findings regarding the differential elevational cline in the phenology show that the temporal isolation of the two cohorts becomes narrower at high elevation, suggesting potential inter-cohort temporal overlap at higher elevations. 5. The claim that the two cohorts of *L. virens* are true temporally isolated species needs further investigation." **20434.** Anjos-Santos, D. (2019): Colecciones científicas en Latinoamérica: Brasil La odonatología brasileña después del incendio del Museo Nacional. ¿Quiénes son y dónde están los odonatólogos de Brasil? *Hetaerina* 1(2): 8-11. (in Spanish) ["In 2018, Brazilian odontology suffered the loss of its most illustrious collection, which was housed in the Dept of Entomology of the National Museum of the Federal Univ. of Rio de Janeiro (MNRJ). This fateful fire also consumed other important collections, as well as historical holdings and exhibitions open to the general public. At present, the National Museum is carrying out an arduous search of the debris in search of pieces that may have survived the tragedy. The Odonata Collection of the MNRJ was the legacy of Dr. Newton Dias dos Santos (1916-1989). Many of the specimens were the fruit of his innumerable campaigns throughout Brazil and South America. Other researchers contemporary to Santos and after him also contributed to the growth of the collection. Of the thousands of specimens deposited in the collection, there were, in addition to the primary types, specimens from various Brazilian regions, which had not even been studied and which, perhaps, will never be found in the wild again. The few specimens of Odonata that escaped the fire were outside the institution and will be returned to the Museum as soon as possible. The good news is that, in recent months, the MNRJ's Entomology Dept has been receiving donations of insects of different orders and its researchers continue to work in the unaffected areas of the Museum. In addition to the MNRJ, there are other collections in Brazil (described below) that contain specimens of Odonata, mainly from the

Neotropics, and some even have primary types. In recent years, Brazilian odonatology has been growing and a new generation of researchers is focusing on the study of neotropical odonates, with collaborations in taxonomy, phylogeny, behaviour and ecology. To aid interaction between Latin American researchers, the following is a list of contact and basic data for the main research groups and collections in the country. The information was provided by their leaders or by members of the laboratories (Table 1)." **20435.** Ansari, M.I.; Siddique, M.H.; Samad, A.; Anwer, S.F. (2019): On the optimal morphology and performance of a modeled dragonfly airfoil in gliding mode. *Physics of Fluids* 31(5): 23 pp. (in English) ["Numerical investigation on the effect of wing morphology of the dragonfly *Aeshna cyanea* is carried out to understand its influence on the aerodynamic performance. The two-dimensional wing section has corrugation all over the surface along the chord length on both upper (suction side) and lower (pressure side) surfaces. By considering each corrugation separately on different airfoils at their different positions, 10 single corrugated airfoils were generated. Simulations are performed on these different airfoils to determine the effect of each corrugation on aerodynamic performance. The flow is modelled as incompressible, Newtonian, homogeneous, and unsteady. The angle of attack was varied from 0° to 20°, and the Reynolds number (Re) was varied from 150 to 10 000. The optimum morphology and angle of attack were predicted by using the surrogate-based optimization technique for a maximum gliding ratio at different Re. A fully corrugated pressure side gives the best performance at angles of attack of 9.79° and 14.83° at low Re. At high Re, corrugations on the pressure side which are in the middle and those near the trailing edge give a maximum gliding ratio at angles of attack 9.22° and 5.276°. The spatiotemporal dynamics indicate that corrugations near the leading edge on the upper surface and corrugations near the trailing edge for the lower surface and which are in the middle are beneficial. It is also found that shear drag due to corrugation decreases but pressure drag increases; therefore, the overall drag coefficient for a fully corrugated airfoil increases. Corrugations on the suction side have little influence, while those on the pressure side causes lift enhancement." **20436.** Aromaa, S.; Ilvonen, J.J.; Suhonen, J. (2019): Body mass and territorial defence strategy affect the territory size of odonate species. *Proc. R. Soc. B* 286: 20192398: 8 pp. (in English) ["The territory is a distinct mating place that a male defends against intruding conspecific males. The size of a territory varies between species and most of the variation between species has been found to scale allometrically with body mass. The variation that could not be explained by body mass has been explained with several variables such as habitat productivity, trophic level, locomotion strategy and thermoregulation. All previous interspecific comparative studies have been done on vertebrate species such as birds, mammals, reptiles and fishes, meaning that studies using invertebrate species are missing. Here, we studied the relationship of a species's territory size with its fresh body mass (FBM) in addition to other ecologically relevant traits using 86 Odonata species. We found that territory size is strongly

affected by species FBM, following an allometric relationship similar to vertebrates. We also found that the territory size of a species was affected by its territorial defence strategy, constantly flying species having larger territories than species that mostly perch. Breeding habitat or the presence of sexual characters did not affect territory sizes, but lotic species and species without wing spots had steeper allometric slopes. It seems that an increase in a species's body mass increases its territory size and may force the species to shift its territory defence strategy from a perch to a flier." **20437.** Bach, A.E.T. (2019): Estudio de los Odonata (Insecta) de los edoststemas altoandinos de la región del Cusco. MSc thesis, Facultad de Ciencias, Escuela Profesional de Biología, Universidad Nacional de San Antonio Abad del Cusco: 152 pp. (in Spanish) ["Odonates from the high Andean ecosystems of the Cusco region were studied. Material previously collected and deposited in the Entomology Laboratory of the National Univ. of San Antonio Abad del Cusco and the Museum of Natural History of the Universidad Nacional Mayor de San Marcos was reviewed. Additionally, between January 2017 and October 2018, collections were made in 12 provinces of the Cusco Region, prioritising provincial capitals and localities where water bodies such as rivers, streams and lakes above 2800 m above sea level are found. The high Andean ecosystems are located from 3700 m above sea level and form a zoogeographic district located within the biogeographic province of the Yungas. In the high Andean ecosystems of the Cusco region, 6 species were identified: *Rhionaeschna fassifrons*, *R. machali*, *R. peralta*, *R. absoluta*, *Sympetrum gilvum* and *Protallagma titicacae*. In the Yungas biogeographic province, the species *Rhionaeschna obscura*, *R. diffinis* and *R. cornigera* were recorded. Finally, the highest species richness was found between the provinces of Calca, Urubamba and Cusco." (Author/DeepL)] Address: not stated

**20438.** Bäumlér, F.; Büsse, S. (2019): Resilin in the flight apparatus of Odonata (Insecta) — cap tendons and their biomechanical importance for flight. *Biol. Lett.* 15: 201901-27. <http://dx.doi.org/10.1098/rsbl.2019.0127>: 7 pp. (in English) ["In Odonata, a direct flight mechanism with specialized tendons evolved. One particular adaptation, the implementation of the rubber-like protein resilin in these cap tendons, might be of major importance. Although resilin was first described in one tendon of Odonata, to our knowledge no comprehensive study about the presence of resilin in the thorax exists yet. We investigated various species of Odonata, using  $\mu$ CT, dissection and fluorescence microscopy. Here we show a complete mapping of the odonatan pterothorax, regarding the presence of tendons and their properties. Thus, 20–21 cap tendons in the pterothorax of Odonata show the presence of resilin. While performing outstanding and often-aggressive flight manoeuvres, resilin can provide shock absorption against mechanical damage from strong impacts. It may further improve the wear and fatigue resistance owing to resilin's damping behaviour. Additionally, resilin in tendons can absorb and return kinetic energy to restore muscles to their original shape after contracting and help in maintaining self-oscillation of the flight muscles. Here, the material distribution within the direct flight system of Odonata and the biomechanical importance and possible function of resilin are discussed. These results are an important step towards the understanding of the complex form–material–function interplay of the insect cuticle." (Authors)] Adult Odonata studied: *Sympetrum striolatum*, *Anax*

(2019): Odonata of the state of Maranhão, Brazil: Wallacean shortfall and priority areas for faunistic inventories. - Odonata do estado do Maranhão, Brasil: Déficit wallaceano e áreas prioritárias para inventários faunísticos. *Biota Neotropica* 19(4): e20190734. <http://dx.doi.org/10.1590/1676-0611-BN-2019-0734>: 11 pp. (in English, with Portuguese summary) ["Environmental changes are worrying in a scenario with large knowledge gaps on species diversity and distribution. Many species may become extinct before they are known to science. Considering this scenario, the present study aims to evaluate the known distribution of the species recorded for Maranhão state in Brazilian northeast region and discuss knowledge gaps about Odonata indicating the priority areas for faunistic inventories. Using primary and secondary data together, we present convex minimum polygons of the distribution of all the species registered for the state. In addition, we created maps with the richness of species and number of records of Odonata in the Maranhão state. In primary data sample 269 specimens, represented by 17 genera and 30 species were collected. Of the 30 species collected, 17 are new records for the state of Maranhão; of these, 35.29% are geographically widespread species, occurring in practically all regions of Brazil. Considering the records in the literature, there was a 68% increase in the number of Odonata species known for Maranhão. The most unexplored region is the Cerrado of the state of Maranhão. Furthermore, the transition regions between Cerrado and Amazônia and between Cerrado and Caatinga are also unknown. All these areas are a priority for faunistic inventories." **20442.** Bergmann, T. (2019): Character-based barcoding, a symbiosis and potential successor of traditional taxonomy

and modern DNA barcoding. Dissertation, Naturwissenschaftlichen Fakultät der Gottfried Wilhelm Leibniz Universität Hannover: VII + 155 pp. (in English) ["Classic taxonomy is a powerful tool for identifying animals based on morphology but has shown to be problematic on similar looking, cryptic species. A solution to this problem has been found within the bauplan of life, the DNA (deoxyribonucleic acid). DNA is used to create and regulate proteins. The structure of DNA has highly unique sections that are conserved within species, but diverse between species. One particular section, a 648 bp long fragment of the mitochondrial cytochrome c oxidase subunit 1 (CO1) gene, has become a popular barcode for species identification. Here, a new barcoding technique, character-based barcoding more similar to traditional approaches is tested. This thesis investigates whether CO1 is suitable as a single marker (a) or should be complemented by others (b). Performance of distance- and character-based barcoding (c) is evaluated and it is tested whether character-based barcoding can be used to identify cryptic species (d). In the first manuscript, CO1 sequences of endangered turtle species are compared (a). Having a reliable tool for species identification is an important asset in species protection surveillance. Variability within the barcode region is assessed and the utility of both distance- and character-based methods for species identification are evaluated (c). Odonata is an old order rich in species. As many species have evolved in a short time, it was observed that intra- and interspecific variety is overlapping in some sister groups. This observation made Odonata the ideal candidate for testing CO1 (a), ND1 (b), as well as distance- and character-based barcoding (c) in the second manuscript. Ants are prime examples for high degrees of cryptic biodiversity due to complex population differentiation, hybridization and speciation processes. As combinations of multiple marker regions seemed to be a better approach to barcoding, three markers (CO1, 28S rDNA, rhodopsin) are tested (b) in the third manuscript. A combined, layered approach to character-based barcoding is evaluated and unique diagnostics specific to geolocations are identified (d). The results of all three studies show that combining multiple markers improves identification success. The character-based approach provides better identification in the tested animal groups. This method can be used to estimate presence, absence or frequency of cryptic species." (Author)] Address: Bergmann, T., Untere Hauptallee 3, 31812 Bad Pyrmont, Germany

**20443.** Bernard, R.; Felska, M.; Makol, J. (2019): Erythraeid larvae parasitizing dragonflies in Zambia—description of *Leptus* (*Leptus*) *chingombensis* sp. nov. with data on biology and ecology of host-parasite interactions. *Systematic & Applied Acarology* 24(5): 790-813. (in English) ["A survey of odonate fauna in Zambia (Central Province, Luano District) resulted in discovery of ectoparasitic larvae of *Leptus* (*L.*) *chingombensis* sp. nov. (Trombidiformes: Parasitengona, Erythraeidae) on four species of dragonflies (Odonata) representing four different families assigned to Zygoptera and Anisoptera. The morphological characteristics of the new species is supported with DNA barcode sequence. Despite some intra-group variation related to relatively large sample, the morphological and genetic consistence confirm the common specific identity of the material. A brief comparison of *Leptus* spp. hitherto known from the Afrotropic as larvae is given. Supplementary data to the descriptions of *Leptus* (*L.*) *bicristatus* Fain et Elsen, 1987, *Leptus* (*L.*) *aldonae* Haitlinger, 1987 and *Leptus* (*L.*) *soddagus* Haitlinger, 1990, based on examination of type material, are provided. In the case of *L.* (*L.*) *chingombensis* sp. nov., the parasite load

reached high, previously not recorded for Odonata–terrestrial Parasitengona association values, attaining at 44 and 49 larvae. Clear topic preferences towards the ventral side of the host's body were recorded, with an additional tendency to distal parts of synthorax and the ventral depression of the abdomen. We hypothesize that the infestation did not take place synchronously at dragonflies emergence, but consisted in repeated infestation events during the recurrent appearance of dragonflies in the contact microhabitat occupied by *Leptus*. The very local character of the finding along with the regular appearance of larvae parasitizing dragonflies, obviously favoured by specific habitat conditions, no doubts confirms the non-accidental nature of the phenomenon." **20444.** Berquier, C.; Andrei-Ruiz, M.-C. (2019): Synthèse des connaissances et évaluation de l'état de conservation de *Lestes macrostigma* en Corse (Odonata: Lestidae). *Martinia* 34(1-2): 1-16. (in French, with English summary) ["State of knowledge and assessment of the conservation status of *L. macrostigma* in Corsica – Corsica hosts in France a large number of reproductive stations for *L. macrostigma*. During these last decades, the number of studies and data concerning this damselfly in the island has considerably increased. They allow a completion and an update of the knowledge provided in 2004 in the atlas of Odonata from Corsica. The purpose of our study was to do so focusing on *L. macrostigma* regional population in order to assess its conservation status and to identify the regional conservation management issues in relation to this species, as recommended by the National Action Plan for Odonata. The gathered data were analysed using baseline methodology, especially recommended by the European Habitats directive. Today, *L. macrostigma* appears widely distributed all along the island coastline, especially in the natural protected and managed sites network. In Corsica, *L. macrostigma* larvae can develop every year in different types of temporary waters ranging from brackish to fresh and mainly of natural origin. Among the types of wetlands in which reproduction is successful, the Mediterranean freshwater temporary ponds appear to be unusual for the species. In this strong conservation value habitat, the monitoring which has been carried out since 2014 highlights the great inter-annual variability in the phenology and the abundance of the species. Our assessment reveals an "Unfavourable-inadequate" conservation status for the species in Corsica, mostly because of the recent destruction of reproduction stations close to main island conurbations. Our analysis also demonstrates that the island has a major heritage responsibility for this specie relative to the national territory. Hence, with respect to these challenges, we strongly encourage to carry out ambitious regional conservation and management policies." **20445.** Bried, J.T.; Siepielski, A.M. (2019): Predator driven niches vary spatially among co-occurring damselfly species. *Evolutionary Ecology* 33(2): 243-256. (in English) ["Determining how niche differences contribute to local species coexistence is a vexing problem. Previous work has shown that the ecological and evolutionary processes shaping niche

differentiation can vary among populations, suggesting that the strength of niche differences among species should likewise vary geographically. Most tests of this idea compare different species in different locations, not the same species in different locations. Thus, it is unclear whether niche differences vary spatially because of variation in community composition or because populations of the same species experience differences in the strength of niche effects. To test this latter hypothesis, we used field experiments to manipulate the relative abundances of the same pair of *Enallagma* damselfly species at two lakes. Manipulating relative abundances allowed us to quantify the demographic signature of niche differences that could stabilize coexistence, because if species are niche differentiated, they should experience lower mortality in response to their shared fish predator, and higher growth in the face of resource competition, when rare. We found that both species experienced lower mortality when rare in one location but not the other. No differences in growth were detected, indicating that competition for prey resources may not be a key factor affecting coexistence. These results suggest the species are ecologically differentiated among populations in ways shaping survivorship in response to a shared predator, which should promote their coexistence. We discuss several factors that could contribute to the differences we observed, focusing on the ideas that either (1) niche differentiation between species evolves locally, or that (2) spatial variation in environmental factors affects the manifestation of species niche differences. We therefore argue that the problem of 'species coexistence' is not a problem of species, but rather is one of understanding if species' populations coexist. Such results imply a role for microevolutionary processes in structuring communities." (Authors)] Address: Bried, J.T., Dept of Biological Sciences, Univ. of Arkansas, Fayetteville, USA

**20446.** Brown, T.A.; Fraker, M.E.; Ludsins, S.A. (2019): Space use of predatory larval dragonflies and tadpole prey in response to chemical cues of predation. *The American Midland Naturalist* 181(1): 53-62. (in English) ["Chemical cues are frequently a key source of information to aquatic organisms. Both predators (kairomones digestive metabolites) and prey (alarm and damage-released cues) may generate chemical cues during their interactions, and different cue types can have different informational values. How predators and prey use the information from chemical cues to make spatial movement decisions influences both their direct interaction rates and their interactions with other species. We measured the spatial response of predatory larval *Anax junius* and predator-naïve green frog (*Lithobates clamitans*) tadpoles exposed to several types of chemical cues using experimental mesocosms. We found tadpoles only responded with spatial avoidance when exposed to both *Anax* kairomones and conspecific alarm cues together, whereas *Anax* did not exhibit consistent spatial responses to any cue type. Our results suggest tadpole prey selectively respond to environmental information from chemical cues (possibly to minimize costly antipredator behavior due to responding to insufficient information or reflecting a need for associative learning). They also show predatory dragonflies may use nonchemical information to make space use decisions (possibly due to inability to detect the same chemical cues as tadpoles)." **20448.** Cavallaro, M.S.; Main, A.R.; Liber, K.; Phillips, I.D.; Headley, J.V.; Peru, K.,M.; Morrissey, C.A. (2019): Neonicotinoids and agricultural stressors collectively modify aquatic insect communities. *Chemosphere* 226: 945-955. (in English) ["Highlights: • Few field studies investigate how neonicotinoids interact with agricultural stressors. • Wetlands and aquatic insect emergence were monitored over 2 growing seasons. • Community affected by neonicotinoids, turbidity, vegetative variables. • Neonicotinoids associated with lower abundance and more tolerant insect taxa. • Intensive agricultural practices collectively degrade insect communities and abundance. Abstract; Threats to wetland water quality and aquatic insect secondary production in agricultural landscapes are multifaceted and are known to vary spatially and temporally. We designed this study with the aim to disentangle the effects of multiple stressors on emerging aquatic insects from wetlands impacted by intensive agricultural practices and receiving runoff from neonicotinoid-treated canola. In 2013, 2015, 22 semi-permanent wetlands were monitored over two growing seasons (11 different wetlands per year) in central Saskatchewan, Canada. Over the two sampling years, dipterans from the families Chironomidae (60–67%), Muscidae (13–15%) and Ceratopogonidae (7–13%) made up the majority of emergent taxa, representing 80–95% of the total emergence. Multivariate ordination analyses of eight water quality and nine wetland habitat variables revealed that neonicotinoid concentration, turbidity, vegetation disturbance, and continuity of a vegetative grass buffer zone were significant factors influencing the aquatic insect taxa composition. Generalized linear mixed effects models indicated that total insect emergence over time was significantly predicted by neonicotinoid concentrations (imidacloprid toxic equivalency, TEQ) and vegetation disturbance. Higher neonicotinoid concentrations negatively affected insect emergence over time, whereas vegetation disturbance increased total emergence, likely due to the abundance of taxa tolerant to habitat disturbance. Overall, we observed community-level responses driven by multiple indicators of wetland degradation (insecticides, turbidity, and vegetation disturbance). Collectively, these multivariate field data provide an in-depth understanding of how agricultural management practices, including neonicotinoid use, interact to shape wetland aquatic insect communities." **20450.** Chance, F.S. (2019): Dragonfly-inspired algorithms for intercept trajectory planning. SANDIA Report SAND-2019-11695: 28 pp. (in English) ["Autonomous real-time trajectory calculations "inside the basket", or within "sight" of the target, remain a critical but unsolved problem. This LDRD was performed in support of the Autonomy for Hypersonics Mission Campaign, specifically to address challenges associated with engagements involving high-speed, highly-maneuverable vehicles with limited sensing capabilities. Algorithms that can dynamically and autonomously adjust intercept trajectories in response to a maneuvering target are critically needed to support our national security missions. Current state-of-the-art solutions rely upon proportional navigation, which requires an overmatch of speed and maneuverability to ensure success. The objective of this project was to develop a model of dragonfly interception, testing a specific hypothesis of how dragonflies use visual information to implement proportional navigation, with the longer-term goal of developing a novel neural-inspired interception algorithm that would decrease or eliminate the required overmatch for successful interception. Dragonflies are known to be highly successful hunters (achieving 90-95% success rate in nature) that implement a guidance law like proportional navigation to intercept their prey. This project tested the hypothesis that dragonflies implement proportional navigation using prey-image translation across their eyes. The model dragonfly presented here calculates changes in pitch and yaw to maintain the prey's image at a designated location (the fovea) on a two-dimensional screen (the model's eyes). When the model also uses self-knowledge of its own maneuvers as an error signal to correct the fovea's location, the resulting interception trajectory becomes guided by proportional navigation (verified using range vector correlation as a metric of proportional navigation). The fovea-adjustment and resulting modifications to interception trajectory can be performed in realtime and in response to prey maneuvers. While further work is required to evaluate the viability of this model for implementation on a manmade system, my results provide a proof-of-concept demonstration of the potential of using the dragonfly nervous system to design a robust interception algorithm for implementation on a manmade system." **20451.** Cheeseman, S.; Truong, V.K.; Walter, V.; Thalmann,

F.; Marques, C.M.; Hanssen, E.; Vongsvivut, J.; Tobin, M.; Baulin, V.A.; Juodkazis, S.; MacLaughlin, S.; Bryant, G.; Crawford, R.J.; Ivanova, E.P. (2019): The interaction of Giant Unilamellar Vesicles (GUVs) with the surface nanostructures on dragonfly wings. *Langmuir* 35(6): 2422-2430. (in English) ["The waxy epicuticle of dragonfly wings contains a unique nanostructured pattern that exhibits bactericidal properties. In light of emerging concerns of antibiotic resistance, these mechano-bactericidal surfaces represent a particularly novel solution by which bacterial colonization and the formation of biofilms on biomedical devices can be prevented. Pathogenic bacterial biofilms on medical implant surfaces cause a significant number of human deaths every year. The proposed mechanism of bactericidal activity is through mechanical cell rupture, however this is not yet well understood and has not been well characterized. In this study we used giant unilamellar vesicles (GUVs) as a simplified cell membrane model to investigate the nature of their interaction with the surface of the wings of two dragonfly species, *Austrothemis nigrescens* and *Trithemis annulata*, sourced from Victoria, Australia and the Baix Ebre and Terra Alta regions of Catalonia, Spain. Confocal laser scanning microscopy (CLSM) and cryo-scanning electron microscopy (Cryo-SEM) techniques were used to visualize the interactions between the GUVs and the wing surfaces. When exposed to both natural and gold-coated wing surfaces, the GUVs adsorbed on the surface, exhibiting significant deformation, in the process of membrane rupture. Differences between the tensile rupture limit of GUVs composed of DOPC and the isotropic tension generated from the internal osmotic pressure, were used to indirectly determine the membrane tensions, generated by the nanostructures present on the wing surfaces. These were estimated as being in excess of 6.75 mN m<sup>-1</sup>, the first experimental estimate of such mechano-bactericidal surfaces. This simple model provides a convenient bottom-up approach towards understanding and characterizing the bactericidal properties of nanostructured surfaces." **20452.** Cunningham-Minnick, M.J.; Meyer, T.B.; Crist, T.O. (2019): Shifts in dragonfly community structure across aquatic ecotones. *International Journal of Odonatology* 22(2): 121-133. (in English) ["Anisoptera are often used as indicators of habitat type and quality due to their varied use of aquatic and terrestrial habitats. Species differ in their preferences for lotic and lentic waters, but community changes across ecotones, or transitional zones between distinct habitats (e.g. lotic and lentic), are not well understood. We quantified dragonfly species richness, abundance, and composition along a gradient of habitat types, including streams, stream mouths (ecotones), and open waters (lakes and ponds). We tested if dragonfly assemblages in aquatic ecotones differ from adjacent stream and open water habitats, and how species respond to riparian forest cover across these habitat types. Adult dragonflies were sampled in all habitat types at four sites in southwest Ohio during the summer of 2016. Riparian canopy cover and relative densities of algal mats and emergent vegetation were recorded. We sampled 157 individuals of 12 dragonfly species [*Pachydiplax longipennis*, *Libellula luctuosa*, *Plathemis lydia*, *Perithemis tenera*, *Epi-theca princeps*, *Dromogomphus spoliatus*, *Libellula pulchella*, *Pantala flavescens*, *Tamea lacerata*, *Anax longipes*, *Anax junius*] and found significant differences in community composition between stream and ecotone habitats, both forming subsets of the open water community. Canopy

cover explained 55% and 75% of abundance and species richness variance across habitat types, respectively, but these relationships were strongest at ecotones. Finally, the Odonata Index of Wetland Integrity (OIWI), which uses sensitivities of adult odonates to habitat disturbances to evaluate wetland conditions, showed that species composition at ecotones uniquely represents the ecological integrity of the entire wetland system. Thus, transition zones may provide an effective and more efficient alternative to rapidly assess wetland quality for conservation monitoring than sampling the entire wetland." (Authors)] Address: Cunningham-Minnick, M.J., Dept of Biology, Miami Univ., Oxford, OH, USA. Email: minnicmj@miamiOH.edu

**20453.** Dewan, S.; Darnal, N.; Acharya, B.K.; Subramanian, K.A.; Chettri, B.; Jins, V.J. (2019): Effectiveness of organic terrace rice cultivation in conservation of odonates in Sikkim, Eastern Himalaya, India. *International Journal of Odonatology* 22(3-4): 207-222. (in English) ["Conversion of natural habitat into agricultural landscape has been identified as one of the major drivers of habitat loss. Human-modified ecosystems, such as agricultural land, have gained significant attention in terms of the conservation of their native biodiversity. We studied the effectiveness of organic agroecosystems in conserving odonate diversity by comparing organic terrace rice cultivation with a nearby natural forest system with streams in Sikkim, Eastern Himalaya, India. We sampled adult odonates using a transect count method (laying six permanent transects) covering two villages (Lingmoo in South Sikkim and Dzongu in North Sikkim), making a total of 48 transect counts. A total of 881 individual odonates representing 31 species under two suborders (16 Anisoptera and 15 Zygoptera) and seven families were recorded during this study. Of these, 20 species representing three families and 18 species representing seven families were observed in terrace rice cultivation and the natural forest system, respectively. Beta diversity estimates showed that the community composition of the odonates differed qualitatively (incidence measure) and quantitatively (abundance measure) between the two land use types. Turnover component (abundance balance in case of abundance based beta diversity measure) had higher contribution in the overall beta diversity, suggesting that one assemblage of species is being replaced by another due to environmental sorting. The variation in community composition between the two habitats was statistically significant. Our results suggest that organic wetland habitats are important for conservation of odonates and associated biodiversity (especially herpetofauna) in the Himalaya and require urgent conservation attention." (in English) ["Knowing the biodiversity of a given site is the first step in establishing strategies for its conservation, monitoring and sustainable use. The objective of the present study was to catalogue the Odonata community of two ponds in the Cerrado-Pantanal ecotone area. Collections were carried out between October 2012 and September 2013, encompassing different hydrological seasons. This study presents the first systematized survey of Odonata for lentic environments in the region. A total of 347 individuals were recorded, distributed in 41 species, 22 genera and three families. The suborder Zygoptera was represented by the Coenagrionidae and Lestidae families,
