while the suborder Anisoptera was represented by the Libellulidae family. The Acanthagrion, Erythemis and Erythrodiplax genera were the most representative. The results indicate that there is seasonality in the occurrence of the species. The wide diversity found in lentic environments emphasizes the importance of long-term monitoring of these ecosystems, in order to understand the effect of seasonality and of anthropic alterations to the surrounding environment on the Odonata community." **20456.** Frantz, B. (2019): Haematoleochus lung flukes in American Bullfrogs: Prevalence and associations of infection. Univ. Honors Theses. Paper 716. <https://pdxscholar.library.pdx.edu/honorstheses/716>: 25 pp. (in English) ["The prevalence and intensity of infection by lung flukes (Haematoleochus sp.) was examined by dissecting 1,590 American bullfrogs (Rana catesbeiana) collected between 2013 and 2018, from Conboy Lake National Wildlife Refuge, Washington. Overall infection, across all age classes, was 59.7% (n=1,580) and mean intensity was 17 (n=169; SD=19.3, range=1-166). A logistic regression model showed a significant relationship between infection and frog snout-to-vent length, gape, and collection year. Sex had a significant relationship to infection ( $\chi^2=7.31$ , df=1, P=0.007). Presence of odonates in the stomach was also significantly related to infection ( $\chi^2=22.49$ , df=1, P<0.001). This study expands on the current breadth of knowledge on this taxon in anurans into a previously unstudied region of the USA and emphasizes the use of odonates as secondary intermediate hosts....The aquatic cercariae are shed from the snail and proceed to enter the second intermediate host: principally Odonata." **20457.** Friesen, O.C.; Goellner, S.; Poulin, R.; Lagrue, C. (2019): Parasite infection reduces predation risk by dragonfly larvae in crustacean prey. Hydrobiologia 835: 63-70. (in English) [New Zealand, "Parasites can modify the phenotype of their hosts, altering host vulnerability to predation. Tropically-transmitted parasites often use host manipulation to increase their probability of transmission to the next host or reduce their chances of being consumed by the wrong species. However, phenotypic changes may actually increase the host's vulnerability to other predators that are 'dead-ends' for the parasite, reducing parasite fitness while

potentially impacting host populations. The isopod Austrodotea annectens serves as intermediate host to Maritrema poulini (trematode) and display behavioural changes when infected that may increase parasite transmission. We tested the role of parasite infection on predation risk of isopods by a dragonfly nymph [Hemicordulia australiae (Rambur 1842)], a 'dead-end' parasite host. Size-matched isopod pairs were exposed to nymphs and observed until one was captured; subsequently isopod parasite abundance was determined. Isopods with lower parasite abundance were significantly more likely to be caught. Several mechanisms may explain this; behavioural modification by the parasites may be altering isopod behaviour to avoid predation by dead-end hosts, or, alternatively, increased activity may allow heavily infected isopods to avoid predation by sit and wait predators. Assessing the effects of parasites on their host's ability to avoid predation is crucial in understanding how parasites may affect ecosystem dynamics and structure." **20458.** Fuentes, A. (2019): Effects of pH, dissolved O<sub>2</sub> and temperature of pond water on the richness of odonates at Indiana Dunes National Lakeshore. <https://opus.govst.edu/researchday/2019/posters/12/>: (in not stated) ["Odonates are valuable indicators for assessing impacts of human activities on aquatic habitats. The few studies that have examined the relationship between water quality and Odonate diversity have demonstrated a positive linear relationship between richness and the three water quality parameters: pH, dissolved oxygen and temperature. Previous research has mostly excluded the Odonate nymphs, which according to our hypothesis should be impacted the most by the water quality. To conduct this survey, DNA barcoding and sequence alignments were used to identify samples of nymph and adult Odonates from six different ponds at Indiana Dunes National Lakeshore. After the samples were identified, the total species richness for each location was correlated with three water quality parameters, pH, dissolved oxygen and temperature. Out of the 48 nymph samples identified, there were 16 unique species. The preliminary results show a positive linear relationship between pH, temperature, dissolved O<sub>2</sub> and adult richness, but no significant relationships have been found between any of these water quality variables and nymph richness. The sample size was small for the nymphs compared to the adults because only half of the nymph samples of that year have been identified so far. If further laboratory analysis demonstrates that there is a relationship between nymph richness and the water quality measures above, species indices could provide a more efficient means to determine the presence of particular species as well as overall species richness. This information could then be used to assess the overall health of aquatic habitats." (Authors)] Address: Governors State Univ.

**20459.** Gallardo, L.I.; Coronel, J.M.; Guadalupe Poi, A.S. (2019): Urban rain-fed lakes: macro-invertebrate assemblages associated with Egeria najas as indicators of biological integrity in wetlands of Corrientes Province (Argentina). Biodiversity and Conservation 28: 1549-1568. (in English) ["In northeast Corrientes Province, there are more than 50,000 semi-rounded shallow rain-fed lakes. Several lakes have been disturbed mainly because urbanization causes eutrophication due to the illegal discharge of wastewater. We compared 22 metrics based on the structural attributes of macro-invertebrates associated with Egeria najas across seasons between five lakes with different human disturbance levels. Sixty-six samples of E. najas and associated

invertebrates were collected seasonally using a net with an area of 962 cm<sup>2</sup>. A total of 17,737 macro-invertebrates of eight major groups, 35 families and 30 genera were recorded. The total macro-invertebrate abundance (number of individuals per plant dry weight) and the family richness were significantly higher in less disturbed lakes than those under human disturbance, but the differences between seasons were not significant. Non-metric multidimensional scaling analysis differentiated the macro-invertebrate abundances between the more and less disturbed lakes; instead, the diversity indices were not useful for measuring the changes in the studied lakes. Besides, total number of taxa, number of EOT (Ephemeroptera, Odonata, Trichoptera) taxa, abundance and proportion of Trichoptera and abundance of Chironomidae reflected significant differences between the more and less disturbed lakes. Our results suggest that 7 invertebrate metrics respond to urbanization, and they could be used to assess biological integrity of the studied lakes in complement of chemical monitoring of water quality. Management efforts should focus on the maintenance of macrophyte stands that provide high invertebrate diversity, which serve as food for a wide variety of fish." **20460.** Garcia Junior, M.D.N.; Rakes, M.; Pazini, J.; Pasini, R.A.; Garcia, F.R.M.; Grützmacher, A.D. (2019): The diversity of Odonata adults's at Pampa Biome from Brazil. *Revista de Biología Tropical* 67(1): 107-117. (in English) ["The growth of humankind has brought with it several environmental problems that have worsened over time, including the loss of insect biodiversity. The Odonata order have been indicated by several authors as relevant bioindicators for assessing and monitoring environmental conditions of specific locations. The main objective of this study was to conduct an inventory of the Odonata diversity in the Pampa Biome, of the Southern region of the state of Rio Grande do Sul, Brazil. The species survey was conducted between November 2014 and October 2015. Adult insects were collected in Capão do Leão, Pelotas and Rio Grande cities. Each location was visited nine times, totalizing 54 samplings. Entomological nets were used for capturing adult insects, which were then kept in entomological envelopes. The identification of the specimens was carried out with taxonomic keys of Lencioni and Heckman. In addition, Chao-1, the Shannon-Wiener and Jackknife indexes were associated with the sampling areas. During the species survey a total of 2 680 Odonata specimens were collected, representing 45 species encompassed in 22 genera and six families. The Libellulidae and Coenagrionidae families were registered in 60 and 30 % of the specimens sampled, followed of the Aeshnidae, Calopterygidae, Gomphidae and Lestidae, of reduced occurrence. The genera Erythrodiplax, Micrathyria and Ischnura were found at least once in all the visited sites. The study resulted in the registration for the first time of the following species: Progomphus complicatus Selys, Lestes minutus Selys, Homeoura ambigua Ris, and Tauriphila xiphea Ris. These species were not previously reported in any Odonata study of the Brazilian state of Rio Grande do Sul. In regard to Odonata diversity in the Southern region of Rio Grande do Sul, Libellulidae and Coenagrionidae are the families more abundants. Erythrodiplax and Micrathyria are the most common genera. Miathyria marcella represented 9.6 % of all collected libellulidae and was the most abundant specie. Capão do Leão has the largest species diversity (wealth), the largest number of collected specimens and more diversity than Pelotas and Rio Grande.

However, the results showed that the Odonatofauna in the State are still little known, and new studies are needed to better describe this group in other regions." **20461.** Guan, D.-L.; Qian, Z.-Q.; Ma, L.-B.; Bai, Y.; Xu, S.-Q. (2019): Different mitogenomic codon usage patterns between damselflies and dragonflies and nine complete mitogenomes for odonates. *Scientific Reports* 9, Article number: 678: 9 pp. (in English) ["Odonata have distinct body plans and predatory abilities. Knowledge of their various evolutionary histories will allow for an understanding of the genetic and phenotypic evolution of insects. Mitogenomes are suitable materials to elucidate this, but the mitogenome of only a few odonates have been annotated. Herein, we report the complete mitogenome of nine odonates, including seven dragonflies and two damselflies, and a comprehensive analysis of the codon usage in 31 Odonata mitogenomes with the aim to estimate their evolutionary characteristics. Overall, a weak codon bias exists among odonate mitogenomes, although this favours AT-ending codons. Damselflies have a weaker codon usage bias than dragonflies, and 37 codons have significantly different usages. Both directional mutation and purifying selection shape damselfly and dragonfly mitogenomes. Although inevitable, directional mutation bias plays a minor role, whereas purifying selection pressure is the dominant evolutionary force. A higher selection pressure is observed in dragonflies than in damselflies, but it mainly acts on codon usage patterns rather than amino acid translation. Our findings suggest that dragonflies might have more efficient mitochondrial gene expression levels than damselflies, producing more proteins that support their locomotion and predatory abilities.... In the present study, we examined the mitogenome of nine odonates by next-generation sequencing. Furthermore, we reconstructed the complete mitogenome of seven Anisoptera dragonflies (*Tramea virginia*, *Orthetrum testaceum*, *O. sabinia*, *O. melania*, *Deielia phaon*, *Acisoma panorpoides*, *Trigomphus carus*, *Atrocalopteryx atratum* and *Platycnemis foliacea*. The mitogenome features of these two species have been described. The codon usage bias in protein coding genes within the mitogenome of dragonflies and damselflies was examined to reveal the evolutionary forces that contributed the most in shaping the mitogenomes and their codon usage patterns in dragonflies and damselflies." **20462.** Hidayat, S.; Husnia, F.; Rohmah, E.; Mukhlisoh, S. (2019): Study on diversity of dragonfly (Odonata) as a bio-indicator of water quality in Mount Muria area, Central Java. *J. Nat. Scien. & Math. Res.* 5(2): 53-61. (in English) ["Water in the Mount Muria area is needed by the surrounding community to fulfill life. An indicator is needed to determine water quality. Dragonfly (Odonata) is one of the organisms as ecosystem controllers and bioindicators. This study aims to determine the diversity of dragonflies, determine water quality and describe the role of dragonflies as a bioindicator of water quality in the Mount Muria area. This type of research is descriptive quantitative research. The data collection technique used direct observation at 3 stations, namely the Colo Flower River, the Monthe Waterfall River and the River in the Rejenu Area. The results showed that there were 10 species of dragonflies consisting of 6 suborders

Anisoptera and 4 suborders Zygoptera with the highest abundance value being *Euphaea variegata* (51.39%), *Enallagma signatum* (28.47%), *Trithemis festiva* (6.94%), *Orthetrum glaucum* (5.56%), *O. chrysis* (2.78%), *O. pruinatum* (2.08%), *O. testaceum* (0.69%), *O. sabina* (0.69%), *Prodasineura autumnalis* (0.69%), and *Drepanosticta fontinalis* (0.69%). Based on water quality analysis and according to government regulation no. 82 of 2001, the water in the Muria river belongs to category 2. According to the analysis of the family biotic index, it can be seen that the FBI value of the river in the Muria area is 5.60 which means the condition of the river is fair with moderate pollution levels." **20463.** Jacmenev, V. (2019): Importance of UV perception for dragonflies (Odonata). Faculty of Science, Ecological and Evolutionary Biology, Dept of Ecology, Karlova Univ., Praha: 24 pp. (in Czech, with English summary) ["It has long been known that some animals are able to perceive radiation at other wavelengths than perceive we humans. In dragonflies, UV sensitivity has been demonstrated in the 1974, however a recent study has unveiled an extraordinary diversity of genes of specific photoreceptor proteins known as opsins, including UV-sensitive opsin. In addition some dragonflies have coloration on their body and wings, which can reflect UV radiation at unchanged wavelength – UV reflectance. Very little is known about the use of UV in dragonfly life. My thesis summarizes the current knowledge of the importance of UV for dragonflies, focusing on interspecific and intraspecific communication." (Author)] Address: not stated

**20464.** Jäger, N. (2019): *Coenagrion mercuriale* am nordöstlichen Arealrand bei Leipzig, Sachsen (Odonata: Coenagrionidae). *Libellula* 38(3/4): 179-203. (in German, with English summary) ["Between May and September 2017, ten sections of streams and ditches west of Leipzig were studied on the abundance of *C. mercuriale* as well as the syntopic odonatan species. Furthermore, various habitat parameters were recorded and a mark-recapture study on *C. mercuriale* was carried out on four days. With the exception of one population, the study sections cover the sites with the highest abundance of all known occurrences in Saxony. The study sections correspond in many ways to the habitat spectrum known from literature. These are mostly perennial streams and ditches, which are narrow, shallow, sunny, do not freeze in winter and show occurrence of marsh plants (helophytes). Submerged herbs that are characteristic of the habitats of *C. mercuriale* are found in only one of the ten study sections with significant coverage. The hydrology seems to be less influenced by groundwater than by diverse discharges. This results in comparatively low water quality, with which the species apparently copes in many places. During the study, a total of 3,427 specimens of *C. mercuriale* were recorded. The highest abundance was 156.9 adults per 100 meters. The longest documented flight period lasted twelve weeks. During the mark-recapture study, a total of 372 specimens were marked at eleven sections. The median of the recapture rate was 18.0% (0.0–40.0%) two days after the markings, and 2.0% (0.0–11.1%) after five days. Outside the study sections no marked specimen were detected. The frequencies determined by the Petersen method are 2.5 to 50.0 times, on average 10.0 times higher than the number of adults counted." **20465.** Jiang, B.; Johansson, F.; Stoks, R.; Mauersberger, R.; Mikolajewski, D.J. (2019): Predator species related adaptive changes in larval growth and digestive physiology. *Journal of Insect Physiology* 114: 23-29. (in English) ["Prey species are often non-randomly distributed along predator gradients but according to how they trade off growth against predation risk. The foraging-mediated growth/predation risk trade-off is well established, with increased foraging accelerating growth but also increasing predator induced mortality. While adaptations in digestive physiology may partly modify the relationship between foraging and growth in response to predation risk, studies exploring the impact of digestive physiology on growth in prey subjected to predation risk are still scarce. Larvae of the dragonfly genus *Leucorrhinia* segregate at the species level between lakes either being dominated by predatory fish (fish-lakes) or predatory invertebrates (dragonfly-lakes). Predators of these two lake types differ dramatically in their hunting style like searching and pursuing mode causing different selection pressure on prey traits including foraging. In a laboratory experiment we estimated growth rate, digestive physiology (ingested food, growth efficiency, assimilation efficiency, conversion efficiency) and metabolic rate (oxygen consumption) in the presence and absence of predator cues. Whereas fish-lake and dragonfly-lake *Leucorrhinia* species did not differ in growth rate, they evolved different pathways of digestive physiology to achieve similar growth rate. Because fish-lake species expressed a higher metabolic rate than dragonfly-lake species, we assume energy to be differently allocated and used for metabolic demands between species of both predator environments. Further, growth rate, but not digestive physiology was plastic in response to the presence of predator cues. Our results highlight the impact of digestive physiology in shaping the foraging-mediated growth/predation risk trade-off, with digestive physiology contributing to species distribution patterns along predator gradients." **20466.** Kemalok, J.; Mohamed, M.; Rahman, A.A.A.; Ashikin Ismail, N. (2019): Biodiversity across boundary: Ethnoentomology among the Jakun of Kampung Peta, Mersing and the Malay, Chinese and Indian of Kahang, Kluang, Johor. *IOP Conference Series: Earth and Environmental Science* 269 012024: 9 pp. (in English) ["An ethnoentomological survey was carried out on the usage of insects in the culture of several ethnics: Orang Asli Jakun in Kampung Peta, Mersing; the Malay, Chinese and Indian in Kahang, Kluang. Responses from these four communities were compared to understand the uses of insects in their life as well as gauged their views on ethnoentomology. Insects were either part of their spiritual beliefs or used as food, medicine, and entertainment. Four groups of insects were considered, namely Lepidoptera, Homoptera, Odonata and Orthoptera. For example, *Dundubia vaginata* is used by Orang Asli as a source of food, by Malay as entertainment, by Chinese as medicine and by Indian as part of their beliefs. In terms of percentage of insect recognized per ethnicity, Orang Asli accounts for 44.44%, Malay 22.22%, Chinese 16.67% and Indian 16.67%. It was discovered that among the four communities, Orang Asli Jakun were more knowledgeable and open about using insects traditionally. Many insects were integrated in their folklore and myths. Orang Asli Jakun also had more variety of uses for insects in their day to day life compared to the other three communities. Based on this study, it indicated that much of the Malaysian diversity are known and familiar to Orang Asli. Throughout history, Orang

Asli plays important roles in maintaining and managing natural resources through traditional systems. The frequency of human interaction with insects has created a close culture between humans and insects." (Authors)] Address: Mohamed, M., Centre of Res. Sustainable Uses of Nat. Resources, Fac. Applied Sciences & Technology, Univ. Tun Hussein Onn Malaysia, Kampus Pagoh, Jalan Panchor, 84000, Muar, Johor, Malaysia. E-mail: maryati@uthm.edu.my

**20467.** La Porta, G.; Goretti, E. (2019): Investigation on the declining Southern Damselfly (*Coenagrion mercuriale*, Odonata) in a Mediterranean population: survival rate and population size. *Journal of Insect Conservation* 23: 667-675. (in English) [*C. mercuriale* classified as 'Near Threatened' by the Global IUCN Red List and as 'Endangered' in some parts of its range. The species is characterized by fragmented and declining populations with their core in the western Mediterranean and parts of western Europe. This study reported the first estimates of survival rate and population size for a southern European population of *C. mercuriale* living in central Italy. Surveys were carried out in 2017 in the peak of the flight period applying capture-recapture models. More than 1200 specimens were captured on 11 occasions and the sex ratio observed was male-biased (2.8:1). Daily survival probabilities ranged from  $0.662 \pm 0.059$  to  $0.868 \pm 0.045$ . Maximum longevity was 14 days for males. The maximum number of estimated individuals on any day was  $507.2 \pm 49.6$  for males, and  $219.8 \pm 27.7$  for females in mid-June. The estimate of the cumulative population size was about 4000 specimens, with a mean density of 1.2 individuals/m<sup>2</sup> at the breeding site. Our results pointed out that population ecology of *C. mercuriale* in central Italy is similar to that of the populations living in the northern limit of its range. The present study also indicated that monitoring plans, with seven marking occasions at least, can provide consistent estimations of population size, useful for evaluating the viability of populations and for assessing the species conservation status." (Authors) The species considered is *Coenagrion castellani* Robert, 1948 and not *C. mercuriale*.] Address: Goretti, E., Dipartimento di Chimica, Biologia e Biotecnologie, Università degli Studi di Perugia, Perugia, Italy

**20468.** Lee, D.J.; Matthews, P.G.D. (2019): Quantifying the acid-base status of dragonflies across their transition from breathing water to breathing air. *Journal of Experimental Biology* 222, jeb210294. doi:10.1242/jeb.210294: 9 pp. (in English) [*Amphibiotic* dragonflies show a significant increase in hemolymph total CO<sub>2</sub> (T<sub>CO2</sub>) as they transition from water-breathing to air-breathing. This study examines the hemolymph acid-base status of dragonflies from two families [*Anax junius*, *Rhionaeschna multicolor*, *Libellula forensis*, *L. quadrimaculata*] as they transition from water to air. CO<sub>2</sub> solubility (aCO<sub>2</sub>) and the apparent carbonic acid dissociation constant (pK<sub>app</sub>) were determined in vitro, and pH/bicarbonate [HCO<sub>3</sub><sup>-</sup>] plots were produced by equilibrating hemolymph samples with P<sub>CO2</sub> between 0.5-5 kPa in custom-built rotating microtonometers. Hemolymph aCO<sub>2</sub> varied little between families and across development (mean  $0.355 \pm 0.005$  mmol l<sup>-1</sup> kPa<sup>-1</sup>) while the pK<sub>app</sub> was between 6.23 to 6.27, similar to values determined for grasshopper hemolymph. However, the non-HCO<sub>3</sub><sup>-</sup> buffer capacity for dragonfly hemolymph was uniformly low relative to other insects (3.6 to 5.4 mmol l<sup>-1</sup> pH<sup>-1</sup>). While aeshnid dragonflies maintained this level as bimodally-breathing late-final instars and air-breathing adults, the buffer capacity of bimodally-breathing late-final instar *Libellula* nymphs increased substantially to 9.9 mmol l<sup>-1</sup> pH<sup>-1</sup>. Using the pH/[HCO<sub>3</sub><sup>-</sup>] plots and in vivo measurements of TCO<sub>2</sub> and PCO<sub>2</sub> from early-

final instar nymphs, it was calculated that the in vivo hemolymph pH was 7.8 for an aeshnid nymph and 7.9 for a libellulid nymph, respectively. The pH/[HCO<sub>3</sub><sup>-</sup>] plots show that the changes in acid-base status experienced by dragonflies across their development are more moderate than those seen in vertebrate amphibians. Whether these differences are due to dragonflies being secondarily aquatic, or arise from intrinsic differences between insect and vertebrate gas exchange and acid-base regulatory mechanisms, remains an open question." (Authors)] Address: Lee, D.J., Dept of Zoology, Univ. of British Columbia, Vancouver, BC, Canada V6T 1Z4. Email: danlee@zoology.ubc.ca

**20469.** Marinho, R.; Barbosa de Oliveira Junior, J.M.; Silva da Rocha, T.; Cruz da Silva, E.; Souza, L. (2019): Efeito da integridade ambiental sobre a abundância e riqueza de espécies de Zygoptera (Insecta: Odonata) em Igarapés no município de Santarém, Pará, Brasil. *Debate e Reflexão das Novas Tendências da Biologia*. Atena Editora: 1-8. (in Portuguese, with English summary) [*Effect of environmental integrity on the abundance and wealth of Zygoptera species (Insecta: Odonata) in Igarapés in the municipality of Santarém, Pará, Brasil. The monitoring of aquatic ecosystems with the use of dragonflies is indicated by the fact that these organisms inhabit all types of aquatic habitats; the stage larval of each species is specific, able to tolerate environmental disturbances; the males mature they are easily notable while patrolling near the habitat larval, thus facilitating their collection and observation in the field. The suborder Zygoptera is constituted by species that tend to be more sensitive to environmental changes and with it, suffer negative effects on their communities. About addition, this study aims to perform a survey of the diversity of Zygoptera in small creeks preserved and changed in the municipality of Santarém-PA, and to compare the abundance and richness of species of Zygoptera between creeks, preserved and changed. The study was developed in eight creeks in the municipality of Santarém, state of Pará, Brazil, being four located in urban area and four in the preserved areas. Were collected 606 specimens of Zygoptera, distributed in six families, 11 genera and 22 species. The streams classified as preserved were the environments with the greatest richness estimated species of Zygoptera, as this suborder is associated with the most integrity, with riparian vegetation preserved due to the biological requirements more specific. The creeks changed showed a lower species richness of Zygoptera. An explanation for the lower species richness of Zygoptera in environments that have changed is due to changes in riparian forests that have allowed greater entry of light and heat in the systems." (Authors)] Address: Souza, L., Univ. de Fed. do Oeste do Pará, Santarém – Pará, Brasil*

**20470.** Masbou, A.; Goret, T. (2019): Etude de la qualité de l'habitat et monitoring de la population d'Agrion de Mercure (*Coenagrion mercuriale*) dans la plaine de Focant (Beaurain) entre 2013 et 2019. *Natagora*: 32pp. (in French) [*General conclusion: C. mercuriale* is a critically endangered species in Wallonia. In the Focant plain, the population decreased from 696 to 357 individuals between 2013 and 2018. For conservation purposes, it was necessary to confirm our knowledge of the biological requirements of the species. At the end of this study, we can conclude that the abundance of *C. mercuriale* is positively correlated to the presence of headlands and the cover of the ditch by herbaceous vegetation (especially when the latter is higher than 80%). Conversely, factors such as the presence of continuous hedges and the covering of watercourses by bushes are unfavourable factors for the presence of the species. The summer of 2019 was

particularly hot: the average temperature for the months of June, July and August was 19.1°C compared to the normal seasonal temperature of 17.5°C\*. Although there was a surplus in June, the average rainfall was lower in quantity and frequency than the seasonal norms (33 days of rainfall instead of 43.8). Drought is therefore a factor to be taken into account in the results, particularly for the habitat quality maps. Finally, as the data were collected over several years and by multiple operators, it is preferable to remain cautious with regard to our results, particularly for comparative analyses. Management advice in favour of *C. mercuriale*: The management of watercourses and ditches on the Focant plain is a delicate issue. LIFE Bocageous Meadows can only make recommendations to the regional and communal authorities (Beauraing) who are in charge of the management of this biotope: 1) To fight against eutrophication by developing agricultural practices using a minimum of inputs (in particular: fertilisers and pesticides) as well as by restructuring the wastewater treatment system from the surrounding villages. 2) Removing the various logjams that impede the proper flow of water (Annex 6). 3) Planting of alders or other trees should be avoided along the drains, ditches and watercourses in the Focant Valley. Established plantations should ideally be thinned to limit shading of the stream bed. 4) Carry out light dredging in small sections and in rotation over several years as part of a new action plan to avoid the risk of destroying all larval populations of Mercury's Agrion. 5) Do not mow the edges of ditches between 1 April and 31 July. 6) Inform farmers about the Agro-environmental and Climatic Methods, in particular the MAEC "grassed headland", which provides a subsidy of €24 per 20 m long section (12 m wide), i.e. €1,000/ha. 7) Continue to search for other populations in the most favourable regions (Fagne-Famenne and Lorraine)." **20471.** Messlinger, U.; Burbach, K.; Faltin, I.; Frobel, K.; Schloemer, S. (2019): Zum Einfluss des Europäischen Biber *Castor fiber* auf den Larvallebensraum von *Cordulegaster boltonii* (Odonata: Cordulegastridae). *Libellula* 38(3/4): 157-178. (in German, with English summary) ["In 2016 the effects of beaver activities on habitat quality of *C. boltonii* were studied in various regions of Bavaria and the northern Eifel. In almost all of the study sites the larvae of *C. boltonii* were found in sections influenced by beavers. The larvae also inhabited structures which only arise through beaver activities like dams; water filled cavities on the side and base of dams; beaver ponds and secondary streams with appropriate sandy sediments. In a fast-flowing stream in the Spessart region (Kalter Grund) every location with suitable sediments on a 200 m long stretch of the stream was surveyed. This study revealed, that well populated larval environments were principally provided by beaver damming activities. In stream sections influenced by beavers the density of *C. boltonii* larvae was more than six times higher as in sections not influenced by beavers. The results indicate that *C. boltonii* is both able to survive and benefit from the structures and micro-habitats that beavers typically provide. This applies particularly to streams which are anthropogenically poor in structures. The return of the beaver and the structures which result from their complex behavioural activity is of clear benefit to dragonflies which utilise running waters. It is apparent from our study that these species are from an evolutionary perspective well adapted to beavers and that beaver activities should where practicable be tolerated and supported in the habitat of *C. boltonii*. The prevention of beaver activity in these artificially modified water bodies is therefore a hindrance to their renaturation." (Authors)]

**20472.** Nattawut Sareein; Chitchol Phalaraksh; Panida Rahong; Chotiwiut Techakijve; Sangwoo Seok; Yeon Jae Bae (2019): Relationships between predatory aquatic insects and mosquito larvae in residential areas in northern Thailand. *Journal of Vector Ecology* 44(3): 223-232. (in English) ["In order to elucidate the poorly understood relationships between mosquito larvae and their predatory aquatic insects in urban and suburban areas of tropical Southeast Asia, where vector-borne diseases are prevalent, aquatic insects were sampled from 14 aquatic habitats in residential areas of Chiang Mai, northern Thailand, during the rainy season (July to November) in 2016. Correlations among biological variables, densities of major predatory aquatic insect groups (i.e., Odonata, Coleoptera, and Hemiptera: OCH group) in wetlands and artificial lentic habitats, and the density of mosquito larvae were analyzed. Among the sampled mosquito larvae, *Culex* spp. were the most abundant, and both OCH density and water quality were major determinants of *Culex* spp. density ( $r_s = -0.302$  and  $-0.396$ , respectively). Logistic regression analyses indicated that the probability of *Culex* spp. occurrence was significantly and negatively correlated with OCH density. Furthermore, high macrophyte abundance was associated with higher predator density, potentially reducing mosquito density. Hemipteran predators were most negatively correlated with *Culex* spp. density, regardless of whether macrophyte abundance was high or low ( $r_s = -0.547$  and  $-0.533$ , respectively). Therefore, hemipteran predators were the most important aquatic insect predators in the urban and suburban residential areas of Chiang Mai, Thailand, and OCH species, such as the hemipteran *Micronecta scutellaris*, could be used as biological control agents against mosquitoes in the region." **20473.** Nava-Bolaños, A.; Sánchez-Guillén, R.A.; Wellenreuther, M.; Muñoz, J.; Torres-Pachón, M.; Novelo-Gutiérrez, R.; Córdoba-Aguilar, A. (2019): Predicting hybridisation as a consequence of climate change in damselflies. *Insect Conservation and Diversity* 12: 427-436. (in English) ["(1) Climate change is a key stressor for species. Two major consequences of climate-induced range shifts are the formation of new areas of geographic overlap (i.e. sympatry) and an increased probability of hybridisation in the de novo created contact zones. (2) One method to effectively quantify the potential of hybridisation is to integrate ecological niche modelling and the propensity to hybridisation based on genetic divergence. In this paper, we have applied this methodology to predict hybridisation outcomes following different scenarios of climate change in 30 species of *Argia* damselflies. (3) We (i) investigated how climate change may affect species' distributions; (ii) quantified if changed distributions generate new areas of sympatry between species; (iii) calculated the propensity to hybridise based on genetic divergence between species; and (iv) integrated these data to predict the future potential of species to hybridise. (4) We found that the distribution of 29 of the 30 species was affected by a change in climate which led to a general increase in sympatric overlap among species. The degree of genetic divergence among the 108 species' combinations ranged from 0.06% to 0.36%. Based on the sympatric overlap and genetic divergence, it can be predicted that 97 of the species pairs are likely to hybridise in the future. (5) Our results are useful to forecast how highly diverse and closely

related groups, such as *Argia* damselflies, may respond to a change in climate and how this can impact the potential of species mixing under a scenario of increased global warming." **20474.** Nel, A.; Garrouste, R.; Schubnel, T. (2019): Response to Trueman and Rowe (2019) 'The wing venation of Odonata. International Journal of Odonatology'. International Journal of Odonatology 22(2): 115-119. (in English) ["Trueman & Rowe (2019) claimed that they have finally solved the wing venation homologies for the Odonoptera, refuting the previous models, and especially that of Riek & Kukalová-Peck (1984). Nevertheless, their proposal has several failures, viz. nature of the distal part of their "anal vein", nature of the "MA", and incongruence with recent results obtained by Jacquelin et al. (2018) on the morphology of the extreme wing base. Currently the only pattern of venation in total accordance with the known data is that of Riek & Kukalová-Peck (1984), as modified in Nel et al. (1993) and Jacquelin et al. (2018)."] (Authors)] Address: Nel, A., Lab. Ent. Mus. Natn. Hist. Nat., 45 rue Buffon, F-75005 Paris, France. E-mail: anel@mnhn.fr

**20475.** Nel, A. (2019): A glance at the deep past history of insects. *Comptes Rendus Biologies* 342(7-8): 253-254. (in English) [Verbatim: With more than 1,100,000 described species, the insects are the most diverse clade of extant animals, far before all other groups. Nevertheless, they undergo a drastic decrease of their populations, due to the sixth extinction of human origin. Thus it is important to define when and how they became so diverse and if they were impacted by the major crises of biodiversity in the deep past to estimate the importance of the current one. Insects are generally among the best preserved terrestrial fossil organisms, much more complete than the vertebrates. They are also much more frequent. Thousands can be found in Konservat-Lagerstätten since the Carboniferous. They are preserved either in lacustrine sediments as compression fossils, or embedded in amber (fossil resins) (Fig. 1). The Hexapoda (or six-legged arthropods, viz., wingless Collembola, Diplura, Protura; wingless and winged Insecta) are among the oldest known terrestrial organisms, with first records dated from the Middle Devonian of Rhynie in Scotland. Recent molecular phylogenetic dating suggests that they appeared during the Silurian or even the Ordovician, with the first terrestrial plants. The Devonian hexapodan record is very scarce and disappointing, with less than six described fossils, all wingless [1]. The early Carboniferous one is even worse, without any fossil insects. But at the very end of this period and during the late Carboniferous, the insect diversity exploded, with a 'sudden appearance' of winged insects with very diverse feeding resources, e.g., carnivorous, plant suckers, leaf eaters, detritivorous, gall-makers, etc. The wingless clades remained a minority and the high diversification of the Carboniferous Hexapoda clearly concerned the winged forms. Wings and flight were probably the first crucial structures and function that allowed the first burst of diversification of the insects. Flight allows them to escape predators, find new resources, sexual partners, and travel to new environments. The most popular fossil insects are the Paleozoic 'giant' dragonflies Meganeuridae. These flying insects with very large wingspans (ca. 70 cm wide) had large bodies but comparable to those of some extant beetles. In fact, the unique really giant Carboniferous terrestrial arthropod was *Arthropleura*, a myriapod that was more than 1 m long. It is supposed that the great increase of oxygen

proportion in the air during the Late Carboniferous favored the gigantism among the terrestrial arthropods, due to their breathing via trachea. The question is in fact more complex, because the winged insects knew a unique situation during the late Paleozoic, as they had no flying vertebrates as predators. As they were the only flying animals, they probably knew a phenomenon of parallel increases of sizes of predators (the Meganeuridae) and preys, the Palaeodictyoptera that also became larger and larger [2]. At the end of the middle Permian, both clades are very diverse, with still very large taxa, while the oxygen proportion began to decrease. The first gliding 'lizard-like' vertebrates are also recorded at the same time, and certainly began to predate these giant insects, which became rarer during the late Permian and no longer existed in the Triassic. The late Carboniferous was also the time of the oldest known holometabolous insects, with complete metamorphosis (wasps, beetles, scorpionflies), and of the oldest bugs (Hemiptera). These were discovered very recently because they were very small insects [3]. They are now the most diverse animal clades, with the 'big five' (Hemiptera, Hymenoptera, Diptera, Lepidoptera, and Coleoptera). But during all the Paleozoic, these insects were clearly very few. Holometaboly in itself was not 'sufficient' to cause their diversification and each of these orders 'separately' diversified during the last 220 Ma. The exact impact on the insects of the most important Permian–Triassic crisis of diversity remains difficult to estimate because there are very few latest Permian and earliest Triassic outcrops with insects. Thus if we know that the Triassic entomofaunas are very different from the Permian ones, we cannot establish that the great changes that occurred between the two periods happened during this crisis or before, during the late Permian or even at the end of the middle Permian. Nevertheless, the Palaeodictyoptera and the Meganisoptera are no longer present in the Triassic, while all the Triassic entomofaunas are clearly 'dominated' by the beetles and other Holometabola. Beetles were still minority during all the Permian in the fossil record. The 'true' flies (Diptera) and crown group of Hymenoptera are also dated from the Middle Triassic. At the end of this period, all the extant orders were present, except, maybe the parasite groups such as fleas (Siphonaptera), whose oldest fossils are middle Jurassic. The 'modern' entomofauna is thus much older than the extant mammal orders. During the Jurassic, the insects continued their diversification, with the first parasitoid wasps (there is no record of parasitoid insects before). The Cretaceous was the second crucial period for the insect (especially the Holometabola) diversification, with the oldest eusocial taxa (termites, wasps, bees, ants). The Albian–Cenomanian (ca. 100 Ma.) was the time of replacement of the gymnosperms by the angiosperms in all the terrestrial biotas, and the time of appearance of nearly all the extant insect families (even some extant genera have this age). It is also an important time of extinctions of several older Jurassic clades, replaced by extant taxa. Only the insects that adapted to the new environments related to flowering plants could diversify. The modern insect–plant relationships were established during the late Cretaceous. The recent new studies of the extraordinarily rich and diverse entomofauna of the 'mid' Cretaceous Burmese amber allowed one to discover that the Cretaceous insect world was as complex, rich and diverse as the extant one. The Cretaceous–Cenozoic (K–T) crisis had clearly a very weak impact on insect diversity, at least at the family level [4]. In fact, there were more extinctions and appearances of new families during the Paleocene–early Eocene than during the K–T crisis. These were periods of global warming followed by global cooling. The entomofaunas suffered the successive periods of cool-

ing of the Oligocene, Miocene, and the Pliocene–Pleistocene glaciations, causing the extinctions of numerous widespread families that survived in small areas (the Australian mastotermitid termites or the Tasmanian hairy cicadid Tetigarctidae are the most spectacular examples). The deep past history of insects is unique, with bursts of diversification ca. 330 Ma, 220 Ma, and 100 Ma ago. The causes of the first one remain poorly known, those of the second one are probably linked to the renewal of the ecosystems during the early Triassic, and the third one to the great floristic change. At least the K–T crisis did not affect much insect diversity. Thus the current crisis of biodiversity that begins to greatly affect the insect biomass, is extremely alarming. It may be more important than the K–T one.] Address: Nel, A., Lab. Ent. Mus. Natn. Hist. Nat., 45 rue Buffon, F-75005 Paris, France. E-mail: anel@cimr1.mnhn.fr

**20476.** Nur Hikmah, A.; Subchan, W.; Prihatin, J. (2019): Diversity of Odonata species in the Wonoasri resort Meru Betiri National Park. *International Journal of Advanced Research* 7(1): 1183-1188. (in English) ["Meru Betiri National Park is part of Blambangan Biosphere located in East Java Indonesia that consisting of several zone, including core zone, wilderness zone, marine protection zone, utilization zone, traditional zone, rehabilitation zone, and special zone. Wonoasri Resort area included into the rehabilitation zone which consist of a converting forest land to agricultural land. This change of land function will effect on biodiversity included dragonfly. The level of biodiversity of dragonfly, Odonata orders can be used as indicator of quality of the environment. This research needs to be done to know the diversity of dragonfly in the rehabilitation area of Meru Betiri National Park. The results of this research revealed that the order of Odonata consist of 9 species that has been found, which consist of 4 species from Libellulidae, 1 species from Aeshnidae, 1 species from Platycnemididae, 1 species from Euphaeidae, and 1 species from Calopterygidae. The result of the research are expected to be preliminary data for the conservation of biodiversity in Meru Betiri National Park." **20477.** Pelli, A.; Pimenta, P.C. (2019): The life of dragonflies: order Odonata. *Ciencia e Natura*, Santa Maria 41, e43: 1-7. (in English) ["The Odonata Order has a wide geographical distribution. The life cycle is complex, with stage of aquatic nymph, the naiad and winged adults. The research was carried out in peer-reviewed journals at the PubMed and Capes databases, with the keyword Odonata "and" ecology, when the text was complete and available. The used books were researched with insects theme, entomology, available in the collection of the library of the Federal Univ. of the Triângulo Mineiro or private collection. The theoretical framework deals with biology, life cycle, sexual behavior and biodiversity. The Odonata order needs preserved places to reproduce and develop. Some authors mention that certain species of dragonflies can be considered good bioindicators of preserved environment, since they are sensitive to environmental changes. Finally, there is a need for further studies on taxonomy, physiology, and ethology to use this group as a bioindicator in quick works." **20478.** Pimenta, A.L.A.; Pinto, A.P.; Takiya, D.M. (2019): Integrative taxonomy and phylogeny of the damselfly genus *Forcepsioneura* Lencioni, 1999 (Odonata: Coenagrionidae: Protoneurinae) with description of two new species from the Brazilian Atlantic Forest. *Arthropod systematics & phylogeny* 77(3): 397-414. ["*Forcepsioneura* Lencioni, 1999 is a small genus of eight forest-dependent damselfly species endemic to the Brazilian Atlantic Forest domain. Some of its species are difficult to identify due to their strong morphological similarities. Thus, the use of DNA sequences for taxonomic purposes is warranted. This study examined the diversity among mitochondrial COI and 16S and nuclear PRMT markers in *Forcepsioneura*, identified discrete evolutionary units based on morphological and molecular characters, and described two new species using an integrative approach to propose species-level hypotheses. The first molecular phylogeny of *Forcepsioneura* species, including seven of the 10 valid species, is presented. *Forcepsioneura gabriela* sp.n. and *Forcepsioneura janeae* sp.n. are described and illustrated based on males. *Forcepsioneura gabriela* sp.n. is closely related to *F. garrisoni* Lencioni, 1999 and *F. regua* Pinto & Kompier, 2018 and was included in the light blue group, but was recovered with high K2P COI divergence values relative to *F. garrisoni*. PRMT and ribosomal 16S rDNA sequences were too conservative to distinguish this new species from others of the light blue group. Nevertheless, *F. gabriela* sp.n. can be distinguished from other *Forcepsioneura* by its coloration and shape and length of the ventrobasal process of cercus and MP vein. On the other hand, we were unable to get COI sequences for *F. janeae* sp.n., but morphological diagnostic characters, such as, coloration and shape of the posterior lobe of the prothorax and ventrobasal process of cercus supported its proposal as a new species. A concatenated Bayesian analysis of all markers supported the monophyly of both *Forcepsioneura* and the light blue group of species. This study affirmed the value of COI sequence variation for species-level studies but did not support the use of PRMT and 16S for this group of damselflies, as there was very little interspecific variation between some closely related species." **20479.** Ramamonjisoa, N.; Oiiire, C.; Zheng, X.J.; Kimura, S. (2019): Predation decreases cohort foraging activity and growth, yet increases individual size variation in prey. *Evolutionary Ecology* 33(2): 233-242. (in English) ["There is increasing evidence that size variability within a cohort can have important consequences on community ecology and evolution. It is commonly assumed that the threat of predation can influence cohort size variability by homogenizing foraging behavior among members. We combined predictions of growth–defense models with those from models of genesis of size variation to test the non-lethal effects of size-selective newt and gape-unconstrained aeshnid dragonfly larva predators [*Anax* sp.] on the size structure of *Rhacophorus arboreus* tadpoles in a controlled laboratory experiment. We hypothesized that the predators would induce differential growth and behavioral responses in the tadpoles, and would decrease cohort size variation. The tadpoles reduced activity levels in the presence of the predators, but the responses were generally stronger in the presence of dragonfly larvae. Growth costs were commensurate with the levels of behavioral defense investments in the tadpoles. Despite strong reductions in activity levels and growth, cohort size variation increased in the presence of predators,

contrasting current models on relationship between foraging rates, growth, and cohort size variation in prey. The underlying mechanisms are unclear, but it is possible that reduced rates of movement limited access to food for some cohort members or that predation risk enhanced the expression of behavioral variation among individuals." (Authors)] Address: Ramamonjisoa, N., Ecology Group, Graduate School of Environmental Studies, Nagoya Univ., Nagoya, Japan. Email: noelikanto@d.mbox.nagoya.u.ac.jp

**20480.** Renner, S.; Périco, E.; Dalzochio, M.S.; Sahlén, G. (2019): Ecoregions within the Brazilian Pampa biome reflected in Odonata species assemblies. *Austral Ecology* 44(3): 461-472. (in English) ["Based on vegetation composition, previous studies of the Pampa biome in southern Brazil have defined seven ecoregions within the area. Here, we test this ecoregion approach studying the semi-aquatic insect group Odonata in five of these regions, aiming at comparing the ecoregions to the more traditional environmental predictors of water quality and land cover. Based on a data set of occupancy comprising 99 species distributed between 131 localities, a one-way Permutational Multivariate Analysis of Variance was used to compare differences in the species composition between the ecoregions, followed by a Principal Component Analysis to visualize the variation. The composition varied significantly between all groups tested, and the ordination explained 61.8% of the variance. A partial redundancy analysis of ecoregions, land cover and water quality variables explained 71% of the variance in Odonata community structure. Ecoregion was the most important predictor, followed by water quality and land cover. Within these species assemblies, we could select certain species that were representative of a given ecoregion, to which their distribution within the Pampa biome was entirely or mainly confined. Of 24 representative species 41.7% were rare, while the rest were more abundant and, hence, easier to detect. We suspect that the differences found between the Pampa ecoregions might be due to geology, as such factors may be strong determinants of biodiversity. Specific ecological requirements at the family and genus levels also seemed to act selectively on the species compositions within the ecoregions. Today, the Pampa is highly fragmented due to agricultural activities such as rice cultivation, extensive cattle farming and forest plantations. We suggest that an ecoregion-based approach to the implementation of conservation measures may be the best way to help these distinct species assemblies survive." **20483.** Russell, S. (2019): Variations in the dragonfly microbiome through life stages and its ability to harbor antibiotic resistant bacteria. M.Sc. thesis, Biological Science, Univ. of Mississippi: V + 45 pp. (in English) ["Juvenile dragonflies (nymphs) may possess the ability to pass their microbiome to the adult life stage through metamorphosis. If this is so, the environment in which the nymph develops may have an effect on the adult microbiome. In this study, the gut microbiomes of 13 species of dragonfly were compared across life stages and when collected from environments at different levels of urbanization. The gut of each dragonfly was removed, DNA extracted, and a portion of the bacterial 16S rRNA gene amplified and sequenced. Gut suspensions were also plated on antibiotic amended plates to determine the potential for dragonflies to contain antibiotic resistant bacteria. Gut microbiomes of dragonflies mainly separated by life stage, with nymphs further separating by the environment from which they were collected from. Dragonfly species was not a significant factor in the separation of either nymph or adult microbiomes. The microbiomes of nymphs and adults differed in levels of their dominant bacterial phyla, with Proteobacteria being dominant in adults, while nymphs showed a higher proportion of Acidobacteria and Bacteroidetes compared to adults. Nymphs also contained bacteria phyla that were not present in the adult microbiome. Both life stages contained antibiotic resistant bacteria, with the guts of dragonfly adults having higher counts of resistant bacteria than nymphs. The environment from which the dragonflies were collected had a significant influence on the counts of resistant bacteria for multiple antibiotics, as did dragonfly species. These results suggest that the gut microbiomes of dragonfly nymphs and adults are fundamentally different, and that both life stages have the potential to contain antibiotic resistant bacteria. The local environment influences both the numbers of these antibiotic resistant bacteria and the composition of the gut microbiome in general." **20484.** Senn, P. (2019): New localities of southern darter *Sympetrum meridionale* (SELYS, 1841) and banded darter *S. pedemontanum* (MÜLLER in ALLIONI, 1766) (Odonata: Libellulidae) in northern Poland. *Odonatrix* 153: 6 pp. (in English, with Polish summary) [*Sympetrum meridionale*, 28.08.2018 at a pond in Gdynia Dabrowa (UTM: CF33) and two males and one female of *S. pedemontanum* from 14 to 29.09.2018 in three districts (and UTM squares: CF32, CF33, CF42) of Gdansk, Poland. *S. meridionale* is a Ponto-

Caspian/Ponto-Mediterranean species with a Palaearctic distribution extending from north-eastern China and Mongolia, across central Asia, and the Caspian and Black Seas, to Europe, where it is common in France, northern Italy, the Balkans and Greece (KALKMAN et al. 2015). There are increasing reports of sightings from Belgium and The Netherlands, where short-lived populations have been established: in 2018 nearly 400 individuals were sighted in Belgium (<https://waarnemingen.be>) and over 860 in The Netherlands (<https://waarneming.nl>). The species has been found in all of the German states except Schleswig-Holstein, Bremen and Berlin (ROLAND & STÜBING 2014). Although the southern darter is very likely to have reached the U.K. in the last few years, there have not yet been any definitive reports of it from there, probably because of the difficulty in distinguishing it in the field from other darter species (D. HEPPER (quoting from A. PARR), pers. comm.). In the eastern part of Europe, obviously migrating individuals of *S. meridionale* have been trapped on the Curonian Spit on the Baltic coast over a number of years (SHAPOVAL and SHAPOVAL 2017), but the species has not been found in the interior of the Kaliningrad region of Russia or in neighbouring Lithuania (GLIWA and ŠVITRA 2016) or Latvia (KALNINŠ 2017). In Poland, *S. meridionale* has a stable distribution in the south and south-east of the country (BERNARD et al. 2009), but this region lies at the northernmost edge of its known contiguous breeding range in eastern Europe. The species has been sighted in some numbers further north – in the province of Wielkopolska (URAWLEW et al. 2010, URAWLEW 2013) and in the province of Łódź (URAWLEW 2011). But further north still, on the Baltic coast, any southern darters encountered, like this one in Gdynia, must surely be vagrants or migrants, especially in the light of the data from the Curonian Spit (SHAPOVAL and SHAPOVAL 2017), which is only 160 km or so from Gdynia as the crow flies.] Address: Senn, P., ul. (2019): Abundance and diversity of insects on apple water tree during fruit season using different colours and different height placement of sticky trap. *Journal of Physics: Conference Series*, Volume 1217, conference 1: 5 pp. (in English) ["The objective of this research were to determine the abundance and diversity of insects on apple water tree and to measure the effectiveness of several colours and height placement of sticky trap on fruit flies and other insects on apple water tree during fruit season. Sampling of insects was conduct-

ing in an apple water field during fruit season in Demak Central Java Indonesia using sticky trap with methyl eugenol attractant. There were three different sticky trap colours i.e., yellow, white, and blue; and two height of trap placement i.e., one meter and three meter, were used. Parameters observed included the number of fruit flies in each colour, height placement of sticky trap, and the taxon of insects. The data was analysed into Shannon-Wiener diversity and abundances of insects on each colours and height placement of sticky traps. The results showed that the insects found consist of 5 orders (Diptera, Hymenoptera, Coleoptera, Lepidoptera, and Odonata), and 21 families. Most families are found in the order Diptera (8 families), Hymenoptera (4 families), and Coleoptera (3 families). The Diptera family consists of Tephritidae, Culicidae, Agromyzidae, Muscidae, Asilidae, Mycetophyllide, Drosophyllidae, Bombyllidae. In short, the insects on apple water tree were more abundant in 3 meter height and they tend to be attracted on yellow sticky trap." (Authors) Four Calopterygidae were captured at blue sticky traps at a height of three meters.] Address: Rahadian, R., Dept of Biology, Fac. of Sciences & Mathematics, Diponegoro Univ., Jl. **20488.** Taybi, A.F.; Mabrouki, Y.; Berrahou, A.; Sbaa, M.; Brochard, C. (2019): New data on the dragonfly fauna (Odonata) of the Moulouya River Basin and the Oriental Region, Morocco. *Arxius de Miscel·lània Zoològica* 17: 85–108. (in English, with Spanish and Portuguese summaries) ["New data on the dragonfly fauna (Odonata) of the Moulouya River Basin and the Oriental Region, Morocco. We present new faunistic and distributional data on dragonflies (Odonata) from the east of Morocco, comprising the administrative Oriental Region and the Moulouya River Basin and covering an area of 119,268 km<sup>2</sup>. A checklist of 47 species belonging to 19 genera and 7 families is provided. *Pseudagrion s. sublacteum* (Coenagrionidae), *Aeshna mixta* (Aeshnidae), *Sympetrum sinaicum* and *S. meridionale* (Libellulidae) are new for Eastern Morocco, while *Paragomphus genei* (Gomphidae) is new for the Moulouya watershed. Our surveys yield evidence of breeding of *Zygonyx torridus* in the Moulouya River, of *Sympetrum sinaicum* in the Oriental province, and also of *Boyeria Irene*, which remained unrecorded for more than three decades. We confirm the occurrence of *Brachythemis impartita* in the study area, by providing new sightings. Our results also revealed the range expansion of several other species whereas some previously known species in the region were not found. We found a clear dominance of the Palearctic elements, mainly Mediterranean, with a high proportion of Ibero–Maghrebian endemic species. This chorotype pattern is similar to patterns observed for other macroinvertebrate groups in the same study area." (Authors)] Address: Brochard, C., Marsstraat 77, 9742EL Groningen, The Netherlands. **20490.** Wrynn, T.E.; Gall, B.G. (2019): Palatability and defense of Eastern Newt (*Notophthalmus viridescens*) larvae and metamorphic juveniles against predatory dragonfly nymphs. *Northeastern Naturalist* 26(4): 849-857. (in English) ["We examined the predator-prey relationship between nymphs of the predatory dragonfly *Anax junius* (Common Green Darner) and larval and metamorphic *Notophthalmus viridescens* (Eastern Newt), some of which may contain the potent neurotoxin, tetrodotoxin. First, we conducted a palatability study to determine which life-history stages were palatable to dragonflies. We also tested the metamorphosis and survival rates of larval newts when exposed to predatory dragonflies in small microcosms. Finally, we tested the predator avoidance behavior of larval newts in response to chemical cues from a control, food stimulus, and predatory dragonflies. All life-history stages (small and large larvae, and recent metamorphs) were palatable to dragonflies. In microcosm trials, we found that newt larvae had a lower chance of surviving and transforming when dragonflies were present compared to a control. Finally, newt larvae decreased movement significantly when exposed to predatory dragonfly stimulus compared to either a control or food stimulus. These results suggest dragonflies are effective predators of newts from hatching through metamorphosis. However, the larvae do possess behavioral avoidance mechanisms that likely reduce the risk of predation by dragonflies." (Authors)] Address: Gall, B.G., Hanover College, Hanover, IN 47243, USA

**20491.** Yamada, S.; Tsujino, R.; Takemon, Y.; Urabe, J. (2019): The role of spatial and temporal variations in habitat uses and food habits of larvae in persistent occurrence of multiple odonate species in Mizorogaike Pond, Kyoto, Japan. *Limnology* 20: 181-190. (in English) ["Larvae of many odonate species commonly appear within the same freshwater ecosystem. However, it remains unknown whether there is a dietary separation among the larvae of different species. In this study, we collected different species of odonate larvae in different seasons at various sites on the floating mat of Mizorogaike Pond in Kyoto, Japan, and examined the abundance and gut contents of the dominant species. Our analyses showed that habitat and seasonal abundance of the odonate larvae did not significantly overlap between most pairs of the dominant species. Moreover, the degree of dietary overlap was not related to larval biomass in microhabitats. These results suggest that, although larval food habits were similar among species, the existence of various vegetation types on the floating mat allowed many odonate species to inhabit Mizorogaike Pond." **20492.** Zenteno Clemente, L.; Makoto Nakagaki, J.; Lima-Junior, S.E. (2019): Benthic macroinvertebrates as bioindicators of environmental quality in three streams of the Amambai River basin, Upper Paraná River, Brazil. *Oecologia Australis* 23(4): 951-960. (in English) ["The objective of this study was to evaluate the environmental integrity of three streams (along 13 sampling sites) of the Upper Paraná River Basin using the benthic macroinvertebrate fauna as bioindicators and to answer the following question: Is there spatial variation, related to environmental quality, in the composition of these taxa in the streams? The invertebrates were sampled with a surber collector and for habitat analysis were determined characteristics as stream depth and width, water velocity, dissolved oxygen, pH, temperature, turbidity, and electrical conductivity. The environmental variables were analyzed by Principal Component Analysis in order to synthesize the data and identify the most important variables for ordering the collection sites. For biological analysis, the BMWP index was used. A Canonical Correlation Analysis of the environmental and biotic data was also performed in order to identify correlations between these two sets of variables. The collected macroinvertebrates belonged to four phyla (Nematoda, Annelida, Mollusca and Arthropoda), with Arthropoda being the most representative (54.93%), with the predominance of the order Diptera (30.29%). The most sensitive orders (Ephemeroptera, Plecoptera and Trichoptera) occurred in four sampling sites, corresponding to less impacted ones. Tolerant organisms, mainly chironomids, were found in all streams, including the most impacted places. These results indicate a spatial variation in the composition of the macroinvertebrates taxa in the streams, in response to variation of environmental quality." **20493.** Zhang, S.; Ochiai, M.; Sunami, Y.; Hashimoto, H. (2019): Influence of microstructures on aerodynamic characteristics for dragonfly wing in gliding flight. *Journal of Biomechanical Engineering* 16(3): 423-431. (in English) ["In this paper, the functionalities of microstructures for dragonfly wing during gliding flight are investigated. Three dragonfly-mimic airfoil-shaped wings with hybrid structures were designed and fabricated as: flat wing, zigzag-edged wing and zigzag-edged wing with pillar structure. Based on the wind tunnel experiments, the zigzag-edged wing structure significantly reduces the drag force in the gliding flight. Moreover, the drag reduction is more effective on the combination of the surface pillar and zigzag-edged structure. In addition, the zigzag-edged wing structure has less influence of Karman vortex street, and the surface pillars reduce the frictional drag and stabilized the streamline in the lower vortex region. Overall, the microstructure of the dragonfly wing is an important element in the aerodynamic study. These findings can enhance the knowledge of insect-mimic wing structure and facilitate the application of Micro Air Vehicle (MAV) in the gliding flight." **20494.** Šigutová, H.; Šipoš, J.; Dolný, A. (2019): A novel approach involving the use of Odonata as indicators of tropical forest degradation: When family matters. *Ecological Indicators* 104: 229-236. (in English) ["Highlights: •Odonata can be effective and cost-efficient indicators of habitat status. • Coenagrionidae and Libellulidae as indicator groups. • Odonata adult-based bioassessment method is reliable. • The method may be easily applied in any tropical forest habitat worldwide. Abstract: Odonata have proven to be good indicators of freshwater as well as terrestrial habitat conditions. Several studies have shown changes in odonate species richness and/or community composition in response to deforestation, suggesting their potential as bioassessment tools in the tropics. However, former approaches using Odonata as an indicator group required comparative samples from differently disturbed sites and/or knowledge of the focal species environmental specificity. Here, we tested a robust, adult-based bioassessment method assuming that the level of tropical forest degradation reflects the proportional representation of the taxa above species. Based on Web of Science, ScienceDirect, and Scopus databases, we used data from previously published studies linking odonate assemblages to human-mediated disturbances in tropical forests. We hypothesized that along a disturbance gradient (from primary forest to non-forest), (i) the proportion of the suborder Zygoptera (mostly habitat specialists sensitive to deforestation) will decrease in favor of the suborder Anisoptera (high proportion of generalists); and (ii) the proportions of largely generalist families Coenagrionidae and Libellulidae will increase at the expense of other Zygoptera and Anisoptera, respectively. Our results revealed that a ratio of Zygoptera/Anisoptera is a poor indicator of tropical forest conditions, probably because of ecological diversity within these groups. However, the proportions of Coenagrionidae/other Zygoptera and Libellulidae/other Anisoptera significantly increased along a disturbance gradient, suggesting their potential to be a good indicator of well-preserved, altered, and heavily degraded forest habitats. Therefore, our results are in line with studies presenting the usefulness of adult Odonata as versatile indicators for assessing human-mediated changes in tropical forest environments, supporting the practical use of this group in biological monitoring." **20495.** Adu, B.W.; Ogbogu, S.S. (2020): Odonata assemblages in Akure Forest Reserve, southwestern Nigeria. *Agrion* 24(3): 202-207. (in English) ["A survey of adult dragonflies and damselflies of Rivers Alatori, Aponmu and Owena in Akure Forest Reserve was undertaken with the aim of determining the species assemblage patterns in them. A total of 517 individuals of dragonflies (339) and damselflies (178) was collected, representing 48 species in three families of dragonfly and five families of damselfly. *Trithemis arteriosa* was the dominant dragonfly and well represented in the rivers. *Chlorocypha curta* dominated the damselflies with 21 individuals. Species diversity in River Owena was the richest (Margalef index  $d = 6.267$ , Simpson's dominance index  $— 0.7419$ , and Shannon Wiener IF  $— 2.446$ ). The distribution of species was best in River Alatori (Evenness  $E = 0.3511$  and Equitability  $= 0.6787$ ). Simpson diversity t-test indicated that there was no significant difference in the species diversity among the three rivers studied in Akure Forest Reserve at  $p < 0.05$  (P1: p-value 0.89592, P 2: p-value 0.89497, P 3: p-value 0.99972). Although the forest is under considerable human disturbance the ecosystem is

still conducive for a fairly large number of species of Odonata. Species of some interesting genera such as *Gynacantha*, *Sapho*, *Umma* and *Chlorocypha* were also encountered in the forest. However, a large percentage of species sampled at the forest are ubiquitous, indicating the effect of disturbed environment with altered ecosystem integrity." **20497.** Buczynski, P.; Karasek, T. (2020): Dragonflies (Odonata) of the peat bog Wielkie Bloto (Eastern Poland). *Rocznik Muzeum Górnoskalskiego w bytomiu Przyroda* 26: 1-13. (in Polish, with English summary) ["In 2009 and 2011, the Wielkie Błoto high and transitional peat bog in Zawieprzycze Kolonia was researched (51°22'26"N, 22°47'10"E, UTM: FB29, 13.5 km NE of Lublin). The peat bog with an area of 25.9 ha lies in a depression surrounded mainly by arable fields and buildings of the village of Zawieprzycze Kolonia. There are about 30 peat excavations on it, some of which are used as fish ponds or for fishing. 12 sites representing undisturbed peat bog and peat excavations of various types of usage were examined. 31 dragonfly species were found, including a number of peat bog specialists, some of which were very numerous (*Lestes virens*, *Coenagrion hastulatum*, *Nehalennia speciosa*, *Sympetrum danae*, *Leucorrhinia pectoralis*). Of key importance for their occurrence were: water reaction, its mineralization, water body morphology, the distance between the site and the peat bog border and the occurrence of some plant structures. The immediate vicinity of agrocenoses and the lack of a buffer zone caused that the outer part of the bog had partially transformed fauna, but the central part was well preserved. Particular attention was paid to the occurrence of *Nehalennia speciosa*, which was found in 9 sites. Its number on them was estimated at about 1000 individuals in general and on the entire peat bog – several thousand. The Wielkie Błoto marks the western border of a distribution island of this species, which includes mainly the Łęczna-Włodawa Plain. It is isolated (50-100 km from the nearest sites). At least four populations in this area are very large (several thousand individuals)." **20498.** Burwell, C.J.; Hobson, R.G.; Hines, H.B.; Jefferies, M.G.; Power, N.P.; White, D. (2020): Dragonflies and damselflies (Odonata) of the Granite Belt Region, South-Eastern Queensland, Australia. *Australian Entomologist* 47(1): 1-24. (in English) ["Records of species of dragonflies and damselflies were collated from the Granite Belt region (more or less equivalent to the IBRA subregion of the Stant-horpe Plateau) in southeastern Queensland. The Granite Belt is the most northerly extent of the New England Tablelands bioregion and is an elevated region (mostly above

800 m) characterised by adamellite domes and tors. Records of odonate species were collated from our own observations, photographs and collecting activities, specimens in the Queensland Museum, and specimens from other Australian museum collections and observational records from the Atlas of Living Australia. To date, a total of 58 species of Odonata have been recorded from the Granite Belt, 19 species of damselflies from seven families and 39 species of dragonflies from six families. The odonate fauna of the Granite Belt has strong southern affinities with almost all of the region's species occurring in the southern half of the continent. In terms of their distributions in Queensland, a little over half the species recorded from the Granite Belt are widespread extending north into the tropics. Most of the remaining species are restricted to south-eastern Queensland with 13 species potentially restricted within Queensland to the Granite Belt which is the northernmost extent of their national ranges. Some of these restricted species are associated with riverine habitats but more are associated with swamps and wet heaths in the south-eastern parts of Girraween National Park. The long-term persistence of these species in Queensland is at risk due to rising temperatures, more severe and prolonged droughts and more severe and frequent fires due to climate change." (Authors)] Address: Burwell, C.J., Biodiversity Program, Queensland Museum, P.O. Box 3300, South Brisbane, Queensland 4101, Australia. **20499.** Cheri, C.R. (2020): Dragonflies and damselflies (Insecta: Odonata) as indicators for riparian condition in Ozark Spring Streams. M.Sc. thesis, Missouri State Univ.: 97 pp. (in English) ["Odonata are often ineffectively sampled during standard stream bioassessments in North America. Subsequently, odonates are not frequently regarded as informative taxa for stream assessment, particularly when monitoring the ecological impacts of organic pollution. I hypothesized that stream-dwelling odonates should be more useful bioindicators for the assessment of riparian conditions surrounding streams because vegetation associated with streams is used for oviposition, roosting and to establish breeding territories. I selected 12 Ozark spring streams that satisfied a broad array of riparian conditions for study. I sampled each stream's odonate and total benthic community along with both instream and vegetation-specific environmental variables. Odonate and total benthic communities were compared across study sites to identify differences in community structure and identify sensitivity to different environmental variables. Odonate community structure alone was highly correlated with riparian-specific vegetation variables. Meanwhile, standard water-quality assessment metrics used by the Missouri Dept of Natural Resources were not useful to indicate riparian habitat condition, based on the total benthic community. I developed tolerance values for use in an odonate-oriented biotic index as a more appropriate metric for assessment of Ozark spring stream riparian conditions. I additionally examined two abundant damselfly species using occupancy modeling associated with riparian habitat. The two species showed different occupancy patterns in relation with the level of riparian impactedness around study sites. Overall, odonates showed greater sensitivity to riparian conditions than did total benthic communities, supporting the idea that this taxon alone is useful for biomonitoring associated with riparian structure around Ozark spring streams. The sensitivity of odonates to riparian conditions in stream ecosystems found in other Nearctic regions should be further studied to identify regional and species differences. Future studies can help land managers make informed decisions concerning riparian conservation

efforts around streams by employing biomonitoring practices that incorporate this apparently riparian-sensitive taxon." (2020): Habitat preferences and trophic position of *Brachydiplax chalybea flavovittata* Ris, 1911 (Insecta: Odonata) larvae in Yeongsan River wetlands of South Korea. *Insects* 2020, 11, 273; doi:10.3390/insects11050273: 18 pp. (in English) ["In freshwater ecosystems, habitat heterogeneity supports high invertebrate density and diversity, and it contributes to the introduction and settlement of non-native species. In the present study, we identified the habitat preferences and trophic level of *Brachydiplax chalybea flavovittata* larvae, which were distributed in four of the 17 wetlands we examined in the Yeongsan River basin, South Korea. Larval density varied across four microhabitat types: open water area, and microhabitats dominated by *Myriophyllum aquaticum*, *Paspalum distichum*, and *Zizania latifolia*. Microhabitats dominated by *M. aquaticum* had the highest larval density, followed by those dominated by *P. distichum*. The larvae were more prevalent in silt sediments than in plant debris or sand. Stable isotope analysis showed that *B. chalybea flavovittata* is likely to consume, as a food source, other species of Odonata larvae. We conclude that successful settlement of *B. chalybea flavovittata* can be attributed to their habitat preferences. As temperature increases due to climate change, the likelihood of *B. chalybea flavovittata* spreading throughout South Korea increases. We, therefore, recommend continued monitoring of the spread and ecological impacts of *B. chalybea flavovittata*." **20503.** Cudera, R.B.; Razon, B.C.; Millondaga, K.J.I. (2020): Cultural and ecological significance of Odonata (Insecta) to the T'boli of Lake Sebu, Mindanao, Philippines. *Biodiversitas* 21: 2536-2554. (in English) ["Lake Sebu in Mindanao, Philippines, covered by the Allah Valley Protected Landscape, is home to the T'boli ethnolinguistic group. This study focuses on the cultural and ecological significance of the Odonata (insect order of dragonflies and damselflies) to the T'boli people who are known to have a close connection to their natural environment. According to the T'boli who participated in-depth interviews and focus group discussions, the Odonate larvae of Family Libellulidae and Aeshnidae known as Kmimi and Ogong El respectively are handpicked by the village members as a food source shared in the community when resources are scarce. The Odonata larvae are also used to cure illnesses and are locally believed to be important components for a love potion. In agriculture, T'boli farmers utilize the adult form of Odonata known as Klowong as natural biocontrol agents. Moreover, the Odonata larvae are prominent images in T'boli oral literature, specifically folklore and lullabies, teaching the children the importance of maintaining a harmonious relationship with nature. The results show that the presence of endemic species of Odonata indicates a healthy freshwater environment in the area; thus, studies on the sustainable use and conservation measures of the Odonata should be conducted." **20504.** Deacon, C. (2020): Abiotic and biotic drivers of African aquatic insect distribution. PhD thesis, Stellenbosch Univ.: XIII, 170 pp. (in English, with Dutch summary) ["Freshwater habitats are disproportionately rich in biodiversity, and are among the most threatened, yet poorly protected ecosystems. Aquatic insects make up much of the total freshwater fauna and contribute greatly to ecosystem functioning. At the broad-scale, aquatic insect distribution is driven by combinations of traits, as well as regional climate gradients and historical landscape context. Locally, both aquatic insect species richness and diversity are driven by various aspects related to vegetation and to physiochemical environments. Effective conservation requires thorough understanding of species distribution patterns at various spatial scales. My overall aim here is to combine broad-scale, theoretical biogeography, and local-scale empirical ecology to investigate drivers of aquatic insect distribution across Africa. Species are often binarily classified as 'widespread generalists' or 'narrow-range specialists' based on their ecological traits. Results in Chapter 2 show that ecological and biological traits are highly interactive among dragonflies, and inferring geographical range size based on ecological preference and/or biotope specialization alone should be

approached with caution. Biological traits related to phenology and mobility were also strong drivers of dragonfly range size, indicating that conservation efforts should include multiple species across all habitat types. Regional climates show considerable variation across latitudinal and longitudinal gradients, and determine areas of high species richness and diversity. In Chapter 3, I show strong latitudinal and longitudinal gradients for South-African dragonfly species richness and endemism. Dragonfly assemblage-turnover boundaries coincided with significant geographical features and/or areas where contemporary climate changed from one condition to another. However, these dragonfly assemblage turnover-boundaries were gradual rather than discrete throughout South Africa. At the local scale, natural and artificial ponds contribute greatly to overall biodiversity, especially when they are of high quality and occur in networks across the landscape. I show that ponds characterized by high heterogeneity support diverse aquatic insect assemblages (Chapters 4 and 5). Chapter 4 showed artificial reservoirs, occurring alongside natural ponds in ecological networks, to expand the area of occupancy for most widespread dragonflies, aquatic beetles and true bugs. Some species with specific habitat requirements were confined to natural ponds, suggesting the significance of natural ponds for conserving the full range of insects. Dragonflies, aquatic beetles and true bugs occupy low-quality artificial reservoirs at low abundance to survive the adverse effects of drought (Chapter 5). However, many insects exclusively occupied natural ponds, emphasizing the overall importance of naturalness, and suggests that there is merit in improving artificial reservoirs. This would most likely be by having macrophytes and vegetated banks similar to those of natural ponds. Investigating aquatic insect distribution patterns is important for conservation, and here, I demonstrate the value of dragonflies as model organisms for investigating the drivers of broad-scale distribution patterns. Studying other taxa is also appropriate, as I have demonstrated at the local scale, but not always possible due to limited distribution knowledge. I recommend broad-scale investigations of other complementary taxa to determine their added value for elucidating the drivers of overall insect distribution patterns, and so address our current shortfalls to improve insect conservation." **20506.** Dorji, T.; Nidup, T. (2020): Study of nymphs of Odonata (Anisoptera & Zygoptera) as a bio-indicator for aquatic ecosystem: A case study in Trashigang District. *Sherub Doenme: The Research Journal of Sherubtse College* 13(1): 16 pp. (in English) ["Nymphs of Odonata are useful indicator of ecosystem functioning and environmental impact in the aquatic system. In this study a total of 222 nymphs belonging to seven Odonata families were collected from four (2 lentic and 2 lotic) study sites. Family Coenagrionidae, Libellulidae and Lestidae were associated with lentic, while Gomphidae, Euphaeidae and Epiophlebiidae were associated with lotic habitat. Aeshnidae is found in both lentic and

lotic habitat but showed strong affinity to lentic habitat. Diversity (H), abundance and richness were compared between and within lentic and lotic habitats. Yonphula Lake is heavily affected by anthropogenic activity and had less abundance and diversity of Odonata Family. Bray-Curtis cluster dendrogram of four study sites based on physicochemical parameters grouped Yonphula Lake, Chiya Lake and two lotic streams (Bamridrang and Gomchu) in separate clades. PCA scatter plot revealed conductivity, total dissolved solids and turbidity as the three physicochemical parameters that characterized Yonphula Lake. A high abundance of Lestidae nymph were found in Yonphula Lake. Aeshnidae, Coenagrionidae and Libellulidae were found in Chiya Lake. Epiophlebia laidlawi and Euphaeidae were found in Gomchu and Bamridrang respectively. Gomphidae was found in both streams. Presence of Epiophlebia laidlawi, Euphaeidae and Gomphidae indicates that they are restricted to pristine streams. As revealed by this study the need for protection and conservation of Lakes and streams to prevent the global decline of Odonata fauna is highlighted." **20510.** Hefler, C.; Noda, R.; Qiu, H.H.; Shyy, W. (2020): Aerodynamic performance of a free-flying dragonfly — A span-resolved investigation featured. *Physics of Fluids* 32(4): 18 pp. (in English) ["We present a quantitative characterization of the unsteady aerodynamic features of a live, free-flying dragonfly under a well-established flight condition. In particular, our investigations cover the span-wise

features of vortex interactions between the fore- and hind-pairs of wings that could be a distinctive feature of a high aspect ratio tandem flapping wing pair. Flapping kinematics and dynamic wing-shape deformation of a dragonfly were measured by tracking painted landmarks on the wings. Using it as the input, computational fluid dynamics analyses were conducted, complemented with time-resolved particle image velocimetry flow measurements to better understand the aerodynamics associated with a dragonfly. The results show that the flow structures around hindwing's inner region are influenced by forewing's leading edge vortex, while those around hindwing's outer region are more influenced by forewing's shed trailing edge vortex. Using a span-resolved approach, we found that the forewing-hindwing interactions affect the horizontal force (thrust) generation of the hindwing most prominently and the modulation of the force generation is distributed evenly around the midspan. Compared to operating in isolation, the thrust of the hindwing is largely increased during upstroke, albeit the drag is also slightly increased during the downstroke. The vertical force generation is moderately affected by the forewing-hindwing interactions and the modulation takes place in the outer 40% of the hindwing span during the downstroke and in the inner 60% of the span during the upstroke." **20515.** Johansson, F.; Berger, D.; Höglund, J.; Meyer-Lucht, Y.; Rödin-Mörch, P.; Sniegula, S.; Watts, P.C. (2020): High variation in last male sperm precedence and genital morphology in the emerald damselfly, *Lestes sponsa*. *Biological Journal of the Linnean Society* 130(3): 497-506. (in English) ["In organisms in which individuals mate multiply, knowledge of the proportion of offspring sired by the last male to mate (P2) under field conditions is important for a thorough understanding of how sexual selection works in nature. In many insect groups, pronounced intraspecific variation in P2 is commonplace. Interestingly, however, in stark contrast to these observations, compilation of P2 data in dragonflies and damselflies (Odonata) indicates that a high P2, seldom below 0.95, is a feature of this taxon. Here we used double digest restriction-site associated DNA sequencing to generate a panel of single nucleotide polymorphisms (SNPs) with which we could determine paternity and estimate values of P2 in the offspring of 19 field-collected pairs of the emerald damselfly *Lestes sponsa*. We also estimated the relationship between P2 and male genital shape of 16 males using geometric morphometric analysis. P2 was variable (range = 0.0–1.0; mean = 0.5), and there was a marginally non-significant ( $P = 0.069$ ) relationship between genital shape and P2, suggesting that males with a high P2 had an aedeagus with a broader tip. We suggest that the high P2-values reported in past studies in Odonata are partly due to the methods used to infer paternity. Use of SNPs to determine patterns of paternity and P2 in odonates is needed for a better appraisal of fitness in odonates, and would open many future avenues for use of odonates as models of sexual selection." (Odonata: Aeshnidae). *Libellula* 39(1/2): 63-78. (in German, with English summary) ["The summer dragonfly *A. viridis* – emergence patterns in northwestern Germany – Collecting exuviae from breeding sites is an important method of quantifying emergence patterns, the sex ratio and the approximate population size. In this study the emergence patterns of *A. viridis* in northwestern Germany are described for the three years 2011, 2012 and 2013. *A. viridis* is proved to be a typical summer species with an emergence beginning in the last ten days of June and peaking between the beginning and middle of July. The emergence period lasted six to nine weeks. Differences in the start of emergence between males and females were not detected, but EM50 (the time, when 50% of the population emerged) was not in the same week in 2012 and in 2013. Furthermore, it was possible to determine protandry. The detected sex ratio of *A. viridis* was significantly biased towards the female in all three years. Overall, our results matched existing data for *A. viridis* from other regions in the western distribution area." **20517.** Kohli, M.K. (2020): Insect micro- and macroevolution through space and time. Rutgers, The State Univ. of New Jersey: VIII + 162 pp. (in English) ["This dissertation uses computational molecular phylogenetic methods to study macro- and micro-evolutionary processes that give rise to biodiversity. Insects, the most diverse group of organisms on earth, are an excellent group for studying and testing various evolutionary hypothesis. I used molecular phylogenetic methods to study the population structure of the northern most Arctic dragonfly species *Somatochlora sahlbergi*. Our results show that this species doesn't follow a common trend seen in evolutionary biology that is, large geographic distances and geographic barriers lead to increased genetic variation. Not only does *S. sahlbergi* appears to interbreed across its entire Holarctic range, there also seems to be almost no variation among European and North American populations in their COI gene fragment (the barcode gene), which is usually extremely variable. These findings seem to be unique to this particular species as none other Arctic dragonflies show such genetic patterns. Upon examining four other distantly related dragonfly species, *Aeshna juncea*, *A. subarctica*, *Sympetrum danae* and *Libellula quadrimaculata*, that have similar Holarctic distribution as *S. sahlbergi*, we find that these species indeed show a geographic structure across their range unlike *S. sahlbergi*. We find that North American and European populations show clear genetic distinction, and this split occurred ~ 400,000 ago, during the Quaternary Period. Lastly, I use the popular divergence time estimation methodology to study the evolutionary past of the Insects and explore how our use of fossil record can influence the outcome of such methods. The results show that fossils can be extremely influential depending on the age of the node (i.e. origin to two lineages). Deep nodes, that represent very old relationships in the evolutionary history, tend to be heavily impacted by the fossil calibrations compared to younger nodes. Older nodes suffer more in their age estimates and the precision around these age estimates in the absence of a fossil. Further, we find that certain groups of insects like flies and butterflies evolve at a much faster rate than most of the other groups of insects." **20518.** Kruger, A.; Morin, P.J. (2020): Predators induce morphological changes in tadpoles of *Hyla andersonii*. *Copeia* 108(2): 316-325. (in English) ["Predators can affect the development, fitness, and behavior of prey species in myriad ways. In response to the threat of predation, tadpoles can alter growth rate, morphology, and foraging behavior. Changes to tadpole development have the potential to alter life history characteristics and are therefore of interest in species of conservation concern. Using experimental mesocosms, we explored how non-lethal predators affected the larval development of the Pine Barrens Treefrog, *Hyla andersonii*, a near-threatened species in the United States. We found that caged dragonflies (*Anax junius*) induced darker tail coloration and deeper tail fins in tadpoles of *H. andersonii*, but the dragonflies did not affect tadpole behavior, survival, or size at metamorphosis. Non-lethal predator presence also induced greater within population variation in the tail color trait compared to populations without predators. This result suggests that there may be underlying genetic variation in the ability to express phenotypically plastic traits, a concept that should be explored further because it has implications for the evolution of inducible defenses. These findings support the existence of an adaptive syndrome among hylid tadpoles, where tadpoles develop conspicuous tail morphology in response to larval dragonfly predators." **20519.** Kumar, D.; Shandilya, S.; Khare, V.; Kamle, S.; Chiang, C.-H. (2020): Insect-inspired micro air vehicle with nanocomposite flapping wings and flexure joints. *Proceedings of the SPIE* 11376, id. 1137616: 14 pp.- (in English) ["The biomimicking and understanding of the dynamics of insect flyers is important in developing agile and efficient MAVs. The present study is based on the development of dragonfly inspired MAV and investigation of its motion characteristics. Initially, a tethered two-winged MAV model is constructed, composing of two flapping wings, a flapping mechanism, a chassis, and an external power supply with a function generator. The wings are fabricated with composite stiffeners and membrane. The material of the wings consists of carbon nanotubes (CNTs)/polypropylene (PP) nanocomposite and low density polyethylene (LDPE). The wings are thus lightweight, thin, flexible, and can generate large amplitude bending-twisting motion. The flapping mechanism is constructed with a cantilever type piezoelectric actuator, a mediator mechanism having CNTs/PP nanocomposite flexure joints, and carbon fiber/epoxy composite linkages. The assembled two-winged MAV model has a total mass, body length, wingspan, and aspect ratio of 0.61g, 60.46mm, 90.14mm, and 10.06, respectively. The characteristic flapping frequency of the model is 20Hz, as compared to the wingbeats (or characteristic frequency) of 27.53Hz of an actual dragonfly species, i.e., the *Anax Parthenope Julius*. Measured via digital image correlation (DIC) technique, the fabricated wings exhibit a bending dominated motion during downstroke as well as upstroke. The combined design of flapping wings and flexure joint mechanism is also computationally studied for their structural dynamic characteristics (performed using ANSYS). The first resonance mode or the characteristic frequency, at which the wings have highest deflections, is 17.25Hz. The flexure mechanism is able to generate very large wing deflections (maximum deflection 22.7mm at wing tip) with a sinusoidal heaving input excitation of very small amplitude (0.1mm given at the actuator attachment location). This is useful to

generate higher aerodynamic forces and improve efficiency. The maximum stresses and strains are found at flexure-rigid link and wing stiffener attachment, respectively. Finally, a dragonfly-inspired four-winged MAV is developed. It consists of two pairs of nanocomposite wings with independently actuated flapping mechanisms. Like a natural dragonfly, the forewing and hindwing pairs can be controlled independently and operated at different characteristic frequencies as well as relative phase angles." **20522.** Palacino-Rodríguez, F. (2020): Larval development and foraging behavior of *Erythrodiplax abjecta* (Rambur) (Anisoptera: Libellulidae) in captivity. *Journal of Asia-Pacific Entomology* 23(4): 1030-1040. (in English) ["Highlights: • *Erythrodiplax abjecta* is univoltine and has a slow lifestyle. • Head width, metathoracic leg length, and total length serve to separate instars. • Total development time was 316 (SD  $\pm$ 6.6) days, with 13 instars. • Foraging behavior of this species includes active and sit-and-wait strategies. • Foraging strategies were not affected by time of the day or detritus cover. Abstract: Understanding the life cycle of Neotropical odonate species is essential given our scant knowledge of this region. In this paper, we examine growth ratio between instars, development patterns, and active/passive feeding behavior of the Andean dragonfly *Erythrodiplax abjecta* (Rambur, 1842). Larvae were obtained from eggs laid by two females in the laboratory and were maintained at 12–34 °C in individual containers until either their emergence or their death. Larvae hatched 26–57 days after laying, and

the total development time was determined as being 316 (SD  $\pm 6.6$ ) days, including 13 instars. Larval instars were characterized using six morphometric variables. The foraging behavior was analyzed considering the time of day and the percentage of the background covered by detritus. The growth ratios between successive instars averaged 1.9 for FW pad length, 1.6 for HW pad length and 1.2 for head width, head length, metathoracic leg length, and total length. Neither the active foraging nor the sit-and-wait foraging behavior were affected by either time of the day or the percentage of background covered by detritus. *Erythrodiplax abjecta* is univoltine and has a slow lifestyle associated with lentic perennial waters, where larval development and growth rates are low. We provide an equation to estimate the *E. abjecta* larval instars from field specimens." (in German) ["In autumn 2020, *S. fusca* was observed near Heidelberg (Germany, Baden-Württemberg). Two females exhibited unusual behavior. A female sitting on a bent stem flexed its abdomen so that it followed the course of the stem. Another female sunbathing on a beech trunk, lifted and lowered single legs alternately. Possible reasons for this behaviour are discussed." (Author)] Address: Post, M., Baden-Badener Str. 5, 69126 Heidelberg, Germany. Email: mjphd@posteo.de

**20526.** Rocha-Ortega, M.; Rodríguez, P.; Bried, J.; Abbott, J.; Córdoba-Aguilar, A. (2020): Why do bugs perish? Range size and local vulnerability traits as surrogates of Odonata extinction risk. *Proc. R. Soc. B* 287: 20192645. <http://dx.doi.org/10.1098/rspb.2019.2645>: 9 pp. (in English) ["Despite claims of an insect decline worldwide, our understanding of extinction risk in insects is incomplete. Using bionomic data of all odonate (603 dragonflies and damselflies) North American species, we assessed (i) regional extinction risk and whether this is related to local extirpation; (ii) whether these two patterns are similar altitudinally and latitudinally;

and (iii) the areas of conservation concern. We used geographic range size as a predictor of regional extinction risk and body size, thermal limits and habitat association as predictors of local extirpation. We found that (i) greater regional extinction risk is related to narrow thermal limits, lotic habitat use and large body size (this in damselflies but not dragonflies); (ii) southern species are more climate tolerant but with more limited geographic range size than northern species; and (iii) two priority areas for odonate conservation are the cold temperate to sub-boreal northeastern USA and the transversal neo-volcanic system. Our approach can be used to estimate insect extinction risk as it compensates for the lack of abundance data." **20528.** Tamm, J.; Dressler, B. (2020): Zur Populationsökologie und Ethologie der Imagines von *Cordulegaster bidentata* an einem Waldbach im Taunus (Odonata: Cordulegastriidae). *Libellula* 39(1/2): 1-25. (in German, with English summary) ["At a small forest stream in the Taunus mountains, Hesse, Central Germany, 16 adult males of *Cordulegaster bidentata* were colour marked and both marked and unmarked individuals were counted during five days when passing the counting station. 69% of the marked males were observed again after the day of capture. Appearing males – marked and unmarked ones – carried out 193 passing flights along the stream, 27% of them were done by marked individuals. One can conclude that the population size was remarkable for this tiny stream. Flight activities were strongest in late morning and late afternoon. Among the patrolling males few individuals were frequently observed, others only occurred sporadically. On the nearby forest streams some more populations of *C. bidentata* were present, but no marked individuals could be found there. Single males of *C. boltonii* occurred along the flight way of *C. bidentata*. This uncommon phenomenon is described and discussed. Moreover, methodological questions of marking and population size calculation are discussed." (Authors)] Address: Tamm, J., 34131 Kassel, Germany. E-Mail: jochen.tamm@t-online.de

**20529.** Tung, T.T.; Dung, L.T. (2020): Food components of the *Brachytarsophrys feae* (Boulenger, 1887) and *Megophrys major* (Boulenger, 1908) in Xuan Son National Park, Phu Tho province. *TNU Journal of Science and Technology* 225(08): 286-291. ["*B. feae* and *M. major* are two useful amphibian species in terrestrial and aquatic ecosystems. However, information on the nutritional characteristics of this

species in Vietnam is currently limited. We have used the method of gastric lavage to collect food samples from 62 stomachs, while simultaneously describing the morphological characteristics of these 2 species. The results showed that the snout-vent length (SVL) of the mature individual *Brachytarsophrys feae* (83 – 89 mm), *Megophrys major* (67.5 – 81 mm), the new distributional records of *Brachytarsophrys feae*. We have identified 18 types of food, in which *Brachytarsophrys feae* has 14 types, accounting for 77.77%; *Megophrys major* has 16 categories, accounting for 88.88%. The most important prey species of *Brachytarsophrys feae* include 5 types of food: (18.48%) of the Phasmatodea; Araneae (17.64%); Insect larvae (15.96%); Coleoptera (12.60%); Hemiptera (10.08%). *Megophrys major* has 4 types of food: Hemiptera (17.21%); Hymenoptera (15.89%); Opiliones (14.56%); Odonata (11.25%). In which, the halfwing set Hemiptera is used by both species." (Authors)] Address: Tung, T.T., Vinh Phuc College, Vietnam. Email: tungbiology3@gmail.com

**20533.** Basel, A.M.; Simaika, J.P.; Samways, M.J.; Midgeley, G.F.; MacFadyen, S.; Hui, C. (2021): Assemblage reorganization of South African dragonflies due to climate change. *Diversity and Distributions* 27(12): 2542-2558. (in English) ["Aim: Climate change is expected to cause large shifts in species assemblages such as Odonata. Here, we assess the influence of environmental drivers of turnover on Odonata assemblages. Secondly, we map the predicted spatial variation in species composition, first as a gradient of assemblage similarity, and then as discrete bioregions delineating major areas of odonate endemism. Finally, we map the magnitude of expected change in species turnover in response to climate change under two emission scenarios. Location: South Africa. Methods: We used a spatial database comprising of 164 species of odonates and 20 covariates, to explore changes in compositional turnover using generalized dissimilarity models. Bioregions were compiled through various clustering techniques. Results: Present-day odonate bioregions correspond to climatic zones and are clearly separated by transitional zones with rapid spatial turnover. Present odonate bioregions are projected to undergo extensive reorganization by 2050 and 2070. Temporal turnover in species composition is expected to reach up to 80% in the large arid interior and 64% along the coast. Half of all South Africa's protected areas are likely to experience climate induced changes to dragonfly bioregions in the near future. Main conclusions: Species assemblages are rapidly changing. This work highlights future shifts in climate will result in complex and nonlinear responses in Odonata communities. With ongoing climate change, current odonate bioregions are predicted to expand while others will contract considerably in size within the next 30 years. The current demarcated protected areas may be inadequate to protect dragonflies as climates change. Odonata can be used to track forefronts of climate change, which will likely affect a larger array of taxa as well." (Authors)] Address: Basel, Ashleigh, Biodiversity Informatics Unit, Dept Mathematical Sciences, Stellenbosch Univ., Matieland 7602, South Africa. Email: A.Basel@cgiar.org

**20534.** Bastos, R.C.; Brasil, L.S.; Oliveira-Junior, J.M.B.; Carvalho, F.G.; Lennox, D.D.; Barlow, J.; Juen, L. (2021): Morphological and phylogenetic factors structure the distribution of damselfly and dragonfly species (Odonata) along an environmental gradient in Amazonian streams. *Ecological Indicators* 122, March 2021, 107257: 13 pp. (in English) [oas 65: "Highlights: • Odonata order contains distinct species groups that share similar responses to environmental change. • Response patterns were related to phylogeny structure and morphology similarity. • The mentioned above

relationship appears to be complex and no clear. • We believe that other factors as land use historical can effect these Odonata. • Despite this the response patterns had presented some differences between the areas. Abstract: A range of factors may determine the structure of ecological communities in time and space, in particular niches, dispersal limits, and the evolutionary history of the species. In the last decades, the traditional focus of community ecology on species diversity and composition have been supplemented by approaches incorporating functional traits and phylogeny. Following this perspective, we evaluated the response pattern of adult damselflies and dragonflies (Odonata) along a gradient of environmental disturbance in Brazilian Amazonia, with the objective of identifying subgroups of species that respond in a similar manner to environmental filters. The study tested the hypothesis that the subgroups of species with similar responses to the environmental gradient are structured phylogenetically and will be morphologically more similar to one another than they are to the other species. Adult odonates were sampled in 98 Amazonian streams, 48 in the region of Santarém and Belterra and 50 in the municipality of Paragominas, both located in the Brazilian state of Pará. The study was based on an ecological niche modeling approach and statistical significance testing methods to identify groups of species. These species groups (latent classes) were then associated with their morphological characteristics (Abdomen Length and Thorax Length) and phylogenetic relationships. Four latent classes, containing 34 species, were generated for each region. The latent classes of the Odonata formed along the gradient of anthropogenic impact had effects of phylogenetic proximity and the species' morphological similarity. Therefore, species belonging to the same latent class are more morphologically similar and have greater similarities in evolutionary history. It seems likely, however, that other processes may be important for the understanding of the structuring of the latent classes, such as intra- and interspecific relationships, environmental plasticity, and the history of land use. Both morphology and phylogeny are important for understanding species' responses to environmental gradients." **20535.** Beaune, D.; Sellier, Y. (2021): Stream restorations with meanders increase dragonfly and damselfly diversity and abundance, including an endangered species. Journal

for Nature Conservation 60 (2021) 125950: 10 pp. (in English) ["Highlights: • Many streams were artificially linearized for human usage, but with probable negative effect on biodiversity. • Two streams were restored with meanders and diggings allowing water to run again. • On both restored streams, diversity and abundance of Odonata (dragonflies & damselflies) significantly increased. • The endangered southern damselfly (*Coenagrion mercuriale*) colonized both streams after restorations. Abstract: This study presents examples of successful restoration projects for biodiversity conservation. In West France, the Pinail National Nature Reserve is a protected wetland interspersed with more than 6000 ponds. This wetland is inhabited by 50 species of Odonata and thus is a key biodiversity area for damselflies and dragonflies conservation. In the past, when the limestone was exploited, the streams of the plateau were artificially channeled rectilinearly, running to the Vienne River. Eventually streams were blocked by biomass and sediments resulting in water flowing mainly underground. In 2011, two restoration projects dug and recreated lost habitats such as running streams and meanders by openly reconnecting bodies of standing water (two sites: Rivau (207m) and Hutte (400m) streams). The Odonata species diversity and abundance are annually monitored following transect inventories since 1995 and still ongoing. Diversity and abundance were compared before and after the restoration. The abundance and species diversity increased at both sites due to the addition of lotic habitats and consequently additional new species. The number of observed species almost doubled on the Rivau (from 5.4 observed species to 9.9 spp). By extrapolation the total species number on site increased from 15-18 spp to 29-37 spp. The abundance also greatly increased with 770% more individuals on the Rivau. Similarly, on the 400m Hutte stream, the extrapolated diversity increased from 31-38 spp to 35-43 spp; as well as the abundance with 475% more individuals. These restoration projects created new habitats leading to local biodiversity enrichment and conservation success. More specifically, *Coenagrion mercuriale* (Odonata: Zygoptera), one of Europe's most threatened damselflies and listed in the European Habitats directive, successfully recolonized the Rivau stream and colonized the Hutte stream." **20536.** Bekkouche, B. (2021): The neural mechanisms of selective attention. Investigation of insect selective attention during visual object tracking using neurophysiology, neuroanatomy, computational modelling. PhD thesis, Faculty Science, Lund Univ., Sweden: 101 pp. (in English) ["The brain simulates the world around us using sensory information and provides an estimation of reality in which actions can be executed. This estimation of reality is controlled by attention which decides which information is accepted, further processed and ignored. The process of attending a certain part of the sensory information while ignoring other parts is called selective attention. I have studied visual selective attention on a neuronal level in hoverflies and dragonflies. These insects are highly skilled at object tracking in behaviors related to defending territories, mating or hunting prey. They have very small brains with few neurons compared to mammals and yet execute object tracking tasks with impressive accuracy. In Paper 1 we compare insect brain tissue preparation techniques for optimizing the amount of neuronal morphology details that can be captured during microscopy imaging. We then use these techniques to acquire a highly detailed neuron morphology and further apply

the techniques in the other papers. In Paper 2 we captured the morphology of a hoverfly target-tracking neuron using techniques from Paper 1. I measured a type of short-term memory called response facilitation in a population of these hoverfly target-tracking neurons. This was measured by comparing the response of long (primed) versus short (unprimed) target traveling paths. In the next experiment I measured the neuronal response while distracting the neuron with another target moving outside the part of the visual field in which that neuron responds. Both primed and unprimed distractors reduced the response, indicating that the attention was sometimes moved to the distractor. This phenomenon could potentially be implemented using long range inhibition as part of an attention mechanism. Paper 3 & 4 involved computational modeling of target tracking neurons using a neuronal morphology from the dragonfly. We show that a receptor (N-methyl-D-aspartate receptor), known for its involvement in short term memory processing, have some of the properties required to generate facilitation. Altogether, the results of this thesis have improved our knowledge and understanding of the neural mechanisms of selective attention in hoverflies and dragonflies. It has also paved the way for future studies to further expand on this knowledge and understanding." (Author)] Address: not stated

(2021): Impact of environmental changes on the behavioral diversity of the Odonata (Insecta) in the Amazon. *Scientific Reports* 11(1): 9742 (2021): 12 pp. (in English) ["The odonates are insects that have a wide range of reproductive, ritualized territorial, and aggressive behaviors. Changes in behavior are the first response of most odonate species to environmental alterations. In this con-

text, the primary objective of the present study was to assess the effects of environmental alterations resulting from shifts in land use on different aspects of the behavioral diversity of adult odonates. Fieldwork was conducted at 92 low-order streams in two different regions of the Brazilian Amazon. To address our main objective, we measured 29 abiotic variables at each stream, together with five morphological and five behavioral traits of the resident odonates. The results indicate a loss of behaviors at sites impacted by anthropogenic changes, as well as variation in some morphological/behavioral traits under specific environmental conditions. We highlight the importance of considering behavioral traits in the development of conservation strategies, given that species with a unique behavioral repertoire may suffer specific types of extinction pressure." **20545.** Dirisu, R.; El Surtasi, E.I. (2021): Bioindicators of lotic and lentic ecosystems in Agbede wetlands (Southern Nigeria), using macroinvertebrate tools. *Scientific African* 14, November 2021, e01000: 15 pp. (in English) ["Macroinvertebrates are globally acclaimed as essential tools for biological monitoring in freshwater ecosystems. The essence of this study was to establish bioindicators for Agbede wetlands located in Edo- North in southern Nigeria. Both lotic (stations 1 to 3) and lentic (stations 4 to 7) water bodies were sampled between December, 2012 and May, 2014. Standard methods were applied for macroinvertebrates collection from the littoral habitats. The results of physicochemical parameters indicated that; flow velocity influenced the lotic environments, while temperature, electrical conductivity and turbidity mostly influenced the lentic water bodies. Three major pollution indicator groups were realised across the ecotypes and they are; the pollution sensitive (Ephemeroptera, Coleoptera and Trichoptera), the facultative (Anisoptera, Zygoptera and Decapoda) and the pollution tolerant groups (aquatic snail, Oligochaete and Leech). Pollution tolerant group was preponderance across the study stations but was significantly predominant in the lentic stations, especially during the dry seasons (November to March). The performance of pollution tolerance index (PTI) model, biodiversity indices and Multivariate analyses; all showed high taxa abundance, species composition and diversity across the stations. Similarly, PTI model revealed moderate water quality particularly in the lentic stations (values between 17 and 18) indicating healthy ecosystems, which was also proven by the biodiversity indices. The implication of this work is that, it will remain a comprehensive guide on biomonitoring programmes of the water bodies and the catchment areas as the water bodies are not in a bad quality." (Authors) All odonate taxa are misidentified because they represent European or American taxa.] Address: Dirisu, R. ## 2004

**20546.** Suh, A.N. (2004): Dragonfly assemblage dynamics and conservation at small reservoirs in KwaZulu-Natal, South Africa. PhD thesis, School of Botany and Zoology, Faculty of Science and Agriculture, Univ. of KwaZulu-Natal, Pietermaritzburg: XX + 178 pp. (in English) ["A study of the odonate fauna was carried out at the edge of a major escarpment, in eastern South Africa, using the same methodology as has been used in the temperate regions to obtain a sub-tropical perspective. The study used the macroecology approach to compare patterns and responses of these animals (at the developmental stages of larva, teneral and adults) to seasonal, topographical and anthropogenic disturbances. The habitats used were small, but well-established reservoirs located at five elevational gradients: Stainbank Nature Reserve (100 m), Krantzklouf Nature Reserve (450 m), National Botanical Gardens Pietermaritzburg (790 m) Cedara (1050 m) and Mondi Goodhope Estate (1350 m). Although this is essentially a local component of a larger macroecological study, it is shown that even though species and identities differ between temperate, tropical and sub-tropical ecoregions, the general pattern of community response to these variables is similar. Odonate species phenologies in this sub-tropical study showed great similarity to their tropical counterparts by reason of their adults being highly elevation-tolerant, with long flight periods and overlapping generations. Yet they also show temperate characteristics by over-wintering principally as larvae and eggs. The Libellulidae, followed by the Coenagrionidae were the most abundant, elevation-tolerant families, with national endemics constituting only 6.5% of the total species sampled. Classification and ordination methods identified and characterised sub-sites to ecologically meaningful biotopes for odonates. This also allowed inferences as to how the various landscape disturbances at the five elevations affect species richness and abundance. Species that responded to these impacts were potential indicator groups that can assist in the planning and management of the landscape for conservation of biodiversity. Some management recommendations for these landscapes are given. Individual odonate species developmental stages and their environmental relations were investigated using both univariate and multivariate analyses. The solutions to these analyses were then used to describe how odonate species are distributed along major environmental gradients. It was shown that regional processes e.g. elevation and insolation alongside local variables e.g. pH, marginal grasses, percentage shade, exposed rock, marginal forest, marsh and flow greatly accounted for adult (aerial stage) assemblage variation and distribution. Turbidity, floating/submerged vegetation and water depth (also influenced by regional factors), highly explained larval (aquatic stage) variation. Elevation has therefore, an indirect effect in that it determines climate, which in turn, determines soil and vegetation types which then determine

species presence and absence. Also, although these artificial water bodies do not increase the 'extent of species occurrence', they are important in increasing their 'area of occupancy'. Dragonflies play a major role in conservation. The Japanese culture has strongly illustrated how dragonflies feature in everyday life more than any other country in the world. While many parks and Botanical Gardens feature dragonfly trails in their nature trails in Britain, this does not necessarily cater for threatened species. Conservation of invertebrates in urban environments in South Africa for example by ecological landscaping designed to encourage dragonflies has been particularly rewarding. A core of regularly occurring odonate species occupied the dragonfly trail at the National Botanical Gardens in Pietermaritzburg, while other species visited the study site at irregular periods. This is likely to be the case for a longer term, say ten years or more. Also, the trail, with updated information on species phenologies, variability and habitat preferences continues to play a valuable role in sensitising an increasingly urbanised population to biodiversity and conservation issues. Odonates remain a major component when assessing ecological components of aquatic biotopes, with the assemblage composition at anyone locality capable of changing over time. This has been extensively illustrated in the northern hemisphere. Medium to longer term changes in odonate population at established reservoirs as demonstrated in this study at the National Botanical Gardens in Pietermaritzburg, South Africa, makes it possible to determine whether a species in a conservation area is being given enough protection from local anthropogenic impacts and effects of unpredictable weather conditions. This in turn enables one to understand how concepts of residency and succession underpin conservation management decisions. In conclusion, this study has addressed some salient aspects of species inventory, monitoring and conservation practice at a local scale that also play a central role in conventional biodiversity conservation practice of a global nature. Information on species phenologies enhances their awareness-raising in addition to providing valuable insights into their population dynamics and conservation, especially for those under threat. In addition, baseline data from this study and similar ones is useful in conserving biodiversity (as subjects) or in multi-taxa studies (as tools) in conserving ecosystems and/or landscapes. Finally, the macroecological approach employed in this study has great potential for teasing apart local effects from regional and/or global ones, and can contribute to the conservation of biodiversity at both small and large scales." ## 2005

**20547.** Chakona, A. (2005): The macroinvertebrate communities of two upland streams in eastern Zimbabwe with reference to the impact of forestry. M.Sc. thesis, Tropical Hydrobiology & Fisheries, Biological Sciences Dept, Univ. of

Zimbabwe, Harare: VIII, 49 pp. (in English) ["Benthic macroinvertebrates and physico-chemical parameters of the water were examined from two fast flowing streams, the Nyahode River which drains a pine monoculture catchment and the Haruni River which drains an undisturbed deciduous forest catchment in the Chimanimani Mountains, Eastern Zimbabwe. Benthic samples and environmental data were collected in October 2004, December 2004 and January 2005. The water quality was similar in many respects but turbidity was significantly higher ( $p < 0.05$ ) in the Nyahode River compared to the Haruni River (mean 17.1 NTU and 6.0 NTU respectively). Conductivity was almost three times higher in the Nyahode ( $66 \mu\text{S cm}^{-1}$ ) than the Haruni ( $24 \mu\text{S cm}^{-1}$ ). The impact of forestry on faunal composition was evident on Ephemeroptera (Euthraulus, Afronurus and Diceromyzon), Plecoptera (Neoperla spio) and Trichoptera (Macrostemum capense) (EPT) richness. Absence of shredders from both streams is a result of the low retention of Course Particulate Organic Matter (CPOM) in the streams due to the rapid flows whilst dominance of filterers suggests that the retention of organic material seems to be limited to Fine Particulate Organic Matter (FPOM). These results indicate that unless reference conditions are established first, results from biotic indices could be completely misleading because absence of some taxa could not be due to human impact but is just a natural phenomenon. Many of the taxa collected from both rivers were sensitive to water quality change (ASPT, 5.6 to 7.8) indicating good water quality which is attributable to the currently underdeveloped nature of the catchment." **20548.** Chovanec, A.; Waringer, J. (2005): Dragonflies (Insecta: Odonata) as indicators of the ecological health of wetland ecosystems. *Verh. Internat. Verein. Limnol.* 29: 422-425. (in English) ["Dragonflies play an essential role in the assessment of the ecological integrity of aquatic systems. They are reliable indicators of habitat heterogeneity, connectivity aspects and the ecological quality of the land-water interface. The key factors for understanding this indicator potential are highly specific sets of habitat requirements reflected by distinct patterns of niche differentiation. Bioindication by dragonfly surveys has been broadly discussed (SCHMIDT 1985, 1989, SAMWAYS 1993, CUOVANEC & WARINGER 2001). The aim of this paper is to describe a scheme for assessing the ecological status of river/floodplain systems by analysing dragonfly communities, a method that meets the requirements of the EU Water Framework Directive (WFD). The "Odonata Habitat Index", a key element of this approach, is designed to assess characteristic features of a river/floodplain system, such as connectivity aspects, flow dynamics and terrestrialisation processes. Application examples are presented." (Authors)] Address: Chovanec, A., c/o Umweltbundesamt, Spittelauer Lände 5, A-1090 Wien, Austria. E-mail: chovanec@ubavie.gv.at

**20549.** Chovanec, A.; Strait, M.; Waidbacher, H.; Schiemer, F.; Cabela, A.; Raab, R. (2005): Rehabilitation of an impounded section of the Danube in Vienna (Austria) - evaluation of inshore structures and habitat diversity. *Large Rivers* 15(1-4), *Arch. Hydrobiol. Suppl.* 155/1-4: 211-224. (in English) ["River regulation, urban development and the construction of a hydroelectric power plant have considerably changed the ecological condition of the Danube section in Vienna. In 1997. The previously straight shoreline of the Danube in this area was reconstructed by creating shallow water areas,

coves, gravel banks and side channels. These inshore structures were created to increase habitat diversity in this area and to establish, together with existing ponds, a system of stepping stone biotopes, which serve as migration linkage through the municipal area of Vienna. A monitoring programme (1998-2001) was established to assess the functional integrity of these structures. A multi-species-approach using odonates, amphibians and fish was developed to cover aquatic, amphibious and terrestrial habitat components. As demonstrated in this study, rehabilitation of heavily altered systems may play an important role in improving ecologically degraded areas and in reconnecting isolated lands-cape patches. A new metric (Floodplain Index) was applied for defining an ecological management objective, for characterizing the newly created structures and for assessing habitat heterogeneity." (Authors)] Address: Chovanec, A., c/o Umweltbundesamt, Spittelauer Lände 5, 1090 Wien, Austria. E-mail: chovanec@ubavie.gv.at

**20550.** Chovanec, A.; Waringer, J.; Strait, M.; Graf, W.; Reckendorfer, W.; Waringer-Loschenko, A.; Waidbacher, H.; Schultz, H. (2005): The Floodplain Index - a new approach for assessing the ecological status of river/floodplain-systems according to the EU Water Framework Directive. *Large Rivers* 15(1-4), *Arch. Hydrobiol. Suppl.* 155/1-4: 169-185. (in English) ["A new method was developed to assess the ecological status of river/floodplain-systems. The approach is based on the requirements of biological assessment laid down in the EU Water Framework Directive, and, therefore, focuses on water bodies and their environs while neglecting truly terrestrial floodplain sections. The following indicator groups have been integrated: molluscs, caddisflies, dragonflies, amphibians, and fish. These groups were chosen to describe species associations representative of all types of floodplain waters along the gradient of hydrological connectivity. Key element of the procedure is the Floodplain Index, which is calculated for each site investigated on the basis of species-specific habitat values expressing the species' habitat preferences. Since species compositions vary according to the hydrological conditions, the water bodies of an investigation area can be characterized according to the index values. The distribution of the index values shows if and to which extent the degree of lateral connectivity is disturbed in the floodplain area. The assessment of the ecological status is based on a comparison between a river-type-specific reference condition and the status quo. The method is presented with an example from a Danube floodplain area in the north of Vienna (Austria)." (Authors)] Address: Chovanec, A., Umweltbundesamt, Spittelauer Lände 5, 1090 Wien, Austria. ## 2008

**20554.** Preiß, B. (2008): Die Gestreifte Quelljungfer *Cordulegaster bidentata* und der Feuersalamander *Salamandra salamandra* als Leitarten an ausgewählten Kalksinterquellen und -bächen im Naturpark Eichsfeld-Hainich-Werratal. Bachelorarbeit. Hochschule Anhalt (FH): 83 pp. (in German) [Thüringen, Germany; "For the preparation of this work, eight calcareous sinter springs in the Obereichsfeld (Eichsfeld-Hainich-Werratal Nature Park) were regularly visited between April and August 2007. Here, important structures and parameters of the respective spring run were recorded and described. A targeted search was carried out for exuviae of the striped damselfly *C. bidentata*, which were collected. Furthermore, flying striped damselflies were observed. The larvae of the Fire Salamander *Salamandra salamandra* were observed in the calm areas of the water bodies. The aim of the surveys was to record the ground population and population density of the two flagship species. The evaluation focused on the distribution of the species in the stream system and their seasonal behaviour. Furthermore, the influence of the water structures and parameters on the occurrence of the species was in the foreground." (Author/DeepL)] Address: not stated

**20555.** Torralba Burrial, A. (2008): Medidas de conservación para los Odonatos. I jornadas sobre la conservación de los artrópodos en Extremadura. Fondos LIFE-Proyecto LIFE 2003/NAT/E/000057 "Conservación de Artrópodos Amenazados de Extremadura", Junta de Extremadura.

Consejería de Industria, Energía y Medio Ambiente: 91-102. (in Spanish) ["Dragonflies, with its conspicuous color, size and habits have left their mark on many fields of human activity, being a fundamental part of the European natural heritage its scientific values, educational, cultural and intrinsic values. However, their role as predators agencies associated aquatic ecosystems affects the conservation problems they present, and that suitable habitats for dragonflies are being lost or degraded at all critically the world. Of the nearly 5600 known species worldwide, 176 have been included in any category of threat in the IUCN Red List 2006. In this paper we review various measures to improve the conservation status of communities of dragonflies. These can be structured according to four courses of action, all necessary and complementary development of lists red, including figures of legal protection measures for the effective protection of the media living and outreach and environmental awareness. Importantly, the synergies given to addressing the problem from the four paths, and that effective protection of the media, that is the way that ensures preservation depend heavily on the existence of a desire or need for society to protect biodiversity in general and dragonflies in particular, need on which attention is drawn to the development of red lists, which increased with the disclosure the magnitude of the problem and knowledge of the species affected and structured by the legal protections. Dragonflies, with its conspicuous color, size and habits have left their mark on many fields of human activity as the mythology, superstition, literature, music, painting, philately and personal adornment (Lucas, 2002). Although the major influences on humans are aesthetic and scientific, interact with them in various ways (Corbet, 1999). Indeed, they are a fundamental part of the European natural heritage for its scientific, educational, cultural, recreational, aesthetic and intrinsic (Council of Europe, 1987). However, the role of organisms associated predators affect aquatic ecosystems to the conservation problems they present, as the habitats Odonata suitable for being lost or degraded worldwide critically, and at an accelerated rate (Corbet, 1999). In addition to increasing knowledge about the biology and habitat of each species, the measures aimed at seeking the conservation of dragonflies can be structured according to four-way of action, all necessary and complementary development of red lists, including figures of legal protection measures for the effective protection of living resources and activities outreach and environmental awareness. The following are examples of conservation measures following each Odonata of these pathways." ## 2009

**20556.** Duan, X.-h.; Wang, Z.-y. (2009): Experimental study on the effect of habitat isolation on river ecology. *Advances in Water Science* 20(1): 86-91. (in Chinese, with English summary) ["The field investigations and an experiment were conducted in the Juma river in the suburbs of Beijing to study the effect of habitat fragmentation on river ecology, using benthic macro-invertebrates as indicator species. Three experimental plots were isolated from a relatively undisturbed stream habitat with sheet iron. The benthic assemblages and water parameters were measured by sampling periodically. The results indicate that the abundance, taxa richness and bio-diversity of invertebrates significantly decrease in the experimental plots owing to the habitat isolation. The smaller the experimental habitat plot, the more significantly these biotic indices decrease. The

contents of the dissolved oxygen in the studied plots present the inconsistent variations. The comparison of the benthic communities shows that the relative abundances of Ephemeroptera and Diptera reduces significantly in the isolated plots, and that of the Odonata and Lamellibranchia increase significantly. It is also found that the benthic communities need some time to stabilize after isolation, and then present apparent variation over time. There is a relatively high degree of taxa turnover between isolated plots and the non-isolated reach, which can be attributed to the flight and dispersal of many aquatic insects in their adult stage. However, the benthic communities in isolated plots are not nested subsets in the natural non-isolated stream. This paper also gives some suggestions of the river restoration and the preservation of river ecological integrity based on the study and the present status of the rivers in China." **20559.** Wellenreuther, M.; Tynkynen, K.; Svensson, E.I. (2010): Simulating range expansion: Male species recognition and loss of premating isolation in damselflies. *Evolution* 64(1): 242-252. (in English) ["Prolonged periods of allopatry might result in loss of the ability to discriminate against other formerly sympatric species, and can lead to heterospecific matings and hybridization upon secondary contact. Loss of premating isolation during prolonged allopatry can operate in the opposite direction of reinforcement, but has until now been little explored. We investigated how premating isolation between two closely related damselfly species, *Calopteryx splendens* and *C. virgo*, might be affected by the expected future northward range expansion of *C. splendens*

into the allopatric zone of *G. virgo* in northern Scandinavia. We simulated the expected secondary contact by presenting *C. splendens* females to *C. virgo* males in the northern allopatric populations in Finland. Premating isolation toward *C. splendens* in northern allopatric populations was compared to sympatric populations in southern Finland and southern Sweden. Male courtship responses of *G. virgo* toward conspecific females showed limited geographic variation, however, courtship attempts toward heterospecific *C. splendens* females increased significantly from sympatry to allopatry. Our results suggest that allopatric *C. virgo* males have partly lost their ability to discriminate against heterospecific females. Reduced premating isolation in allopatry might lead to increased heterospecific matings between taxa that are currently expanding and shifting their ranges in response to climate change." **20562.** Nicoli Aldini, R.; Tabarroni, A. (2011): Contributo allo studio della distribuzione degli Odonati nel Piacentino. Abstract de XXIII Congresso Nazionale Italiano di Entomologia,

(Genova, 2011-06-13 -2011-06-16), erredi grafiche editoriali, Genova 2011: 72. (in Italian) ["The territory of Piacenza, the extreme western edge of Emilia bordered to the north by the course of the P river and to the south by the northern Apennine ridge, includes the catchment basins of a number of right-hand Padana tributaries (Tidone, Trebbia, Nure, Chiavenna, Arda). Among the wetlands, the riparian environments of the Po with the mouths of the aforementioned tributaries and, in the Po agricultural area, the network of irrigation canals stand out. In the hills and mountains there are also artificial basins (Lake Trebecco, Lake Mignano) and, higher up, other smaller lakes. In view of this hydrographic variety, which is undoubtedly important for research on amphibiotic entomofauna, it can be stated that current knowledge on the distribution of Odonates in the province of Piacenza is relatively scarce when compared with that available for some other provinces in the region or in neighbouring regions. In view of the importance of Odonates as bio-indicators and in order to obtain a more in-depth knowledge of their distribution in the territory and of any variations in the same over time, we identified the unpublished material from the Piacenza area kept in the collections of the Entomology Institute of the Catholic Univ.. The collection period of the approximately 200 specimens examined covers the last thirty years; there are about sixty localities, located mainly in the lowland and hilly areas of the province. The original geoneimical data concern the following 38 species: Calopteryx haemorrhoidalis, C. splendens, C. virgo, Sympecma fusca, Lestes dryas, L. sponsa, L. viridis, Platycnemis pennipes, Pyrrhosoma nymphula, Ischnura elegans, I. pumilio, Enallagma cyathigerum, Coenagrion puella, Ceriagrion tenellum, Aeshna affinis, A. cyanea, A. isosceles, A. mixta, Anax imperator, Hemianax ephippiger, Gomphus flavipes, G. vulgatissimus, Onychogomphus forcipatus, Somatochlora metallica, Libellula depressa, L. fulva, L. quadrimaculata, Orthetrum albistylum, O. brunneum, O. cancellatum, O. coerulescens, Crocothemis erythraea, Sympetrum depressiusculum, S. fonscolombii, S. meridionale, S. pedemontanum, S. sanguineum, S. striolatum. Some of these species had been reported several times for the area under study, while for others citations in the literature are very scarce or absent. For the Piacenza area, further bibliographic data exist for less than a dozen other species. It is probable that especially the mountainous Apennine environments, which have been less investigated, may provide other findings of some faunistic interest." **20563.** Resende, D.C.; Meira, A.Q.; Campos, L.A.O.; Lino - Neto, J. (2011): Hipóteses evolutivas sobre a morfologia das asas de Libellulidae (Insecta, Odonata). X Congresso de Ecologia do Brasil, 16 a 22 de Setembro de 2011, Sao Lourenço - MG: 2 pp. (in Portuguese) ["The Continuous evaluates the evolution of a characteristic through three parameters, named,  $\delta$  e and  $\epsilon$  o. Of these, the parameter  $\delta$  is responsible for evaluating whether the shared evolutionary history (the  $\delta$ -logeny) explains the variability observed in the data ( $\delta=1$ ). The result of the comparative analyses showed that the features of interest in this work do not present a  $\delta$ -lognetic  $\delta$ -signal ( $\delta=0$ ), suggesting that traditional statistical analyses can be used. The PCA analysis, performed from the pairwise comparison data between the forewings and hindwings of the species, originated a main axis with 48.7% of the explained variance, which separated the species *T. binotata*, *P. avescens* and *M. marcela* from the other species

analyzed. The multiple regression showed that the differences between forewings and hindwings increase with the increase in body size of the species ( $R^2=0.88$ ;  $b= - 3.75$ ;  $t(8)= - 4.46$ ;  $p<0.01$ ). The change in wing shape also correlated with an increase in the anal area of the hind wing ( $b= - 3.75$ ;  $t(8)= - 4.46$ ;  $p<0.01$ ), a characteristic that Corbet (1962) suggested as important for flying species, facilitating the maintenance of a flight with less energy expenditure (gliding). Larger species, in fact, remained longer in flight during reproductive activities ( $R^2=0.48$ ;  $b=1.42$ ;  $t(7)=2.45$ ;  $p<0.05$ ). However, the change in shape between wings ( $R^2=0.48$ ;  $b=1.03$ ;  $t(7)=1.96$ ;  $p=0.09$ ) and the anal area of the hind wing ( $R^2=0.48$ ;  $b=1.05$ ;  $t(7)=2.22$ ;  $p=0.06$ ) did not correlate with the flight time of the species, reinforcing the idea that the dichotomy between fliers and landers seems, in fact, to exist, but would involve other flight activities than those related to reproductive behavior, as already argued by Corbet & May (2008). Conclusion: The morphological and behavioral characteristics of interest showed no  $\delta$ -lognetic signal, reinforcing the idea that Libellulidae may have undergone rapid adaptive radiation. The differences in wing shape are correlated with the body size of the species, but do not influence the flight time during reproductive activities. **20564.** Sundermann, A.; Stoll, S.; Haase, P. (2011): River restoration success depends on the species pool of the immediate surroundings. *Ecological Applications* 21(6): 1962-1971. (in English) ["Previous studies evaluating the success of river restorations have rarely found any consistent effects on benthic invertebrate assemblages. In this study, we analyzed data from 24 river restoration projects in Germany dating back 1 to 12 years and 1231 data sets from adjacent river reaches that lie within 0-5, 5-10, and 10-15 km rings centered on the restored sites. We calculated restoration success and recolonization potential of adjacent river reaches based on stream-type-specific subsets of taxa indicative for good or bad habitat quality. On average, the restorations did not improve the benthic invertebrate community quality. However, we show that restoration success depends on the presence of source populations of desired taxa in the surrounding of restored sites. Only where source populations of additional desired taxa existed within a 0-5 km ring around the restored sites were benthic invertebrate assemblages improved by the restoration. Beyond the 5-km rings, this recolonization effect was no longer detected. We present here the first field results to support the debated argument that a lack of source populations in the areas surrounding restored sites may play an important role in the failure to establish desired invertebrate communities by the means of river restorations. In contrast, long-range dispersal of invertebrates seems to play a subordinate role in the recolonization of restored sites. However, because the surroundings of the restored sites were far from good ecological quality, the potential for improvement of restored sites was limited." (Authors)] Address: Stoll, S., Res. Inst. ### 2013

**20566.** Buczyński, P. (2013): Two forgotten papers about dragonflies (Odonata) of Poland. *Odonatrix* 9(2): 65-71. (in Polish, with English summary) ["The author discusses two Russian papers with data from the vicinity of Pu.awy (eastern Poland) which have been omitted in odonatological literature so far including "A distribution atlas of dragonflies (Odonata) in Poland" (Bernard et al. 2009). Zaitsev (1908) gave on the margins of the paper about interesting insects of the vicinities of Pu.awy the information about the recording of *Caraphractus cinctus* (Hymenoptera: Mymaridae). Then it was wrongly regarded as a specialized parasite of the eggs of *Calopteryx virgo* therefore its presence was treated as an evidence for the occurrence of this dragonfly species (Kolosov 1916; Zaitsev 1908). However, *C. cinctus* parasitizes mainly *Dytiscidae* (Coleoptera), it is also found in the eggs of *Notonecta* spp. (Hemiptera: Heteroptera). Therefore this reasoning is unauthorized and the paper of Zaitsev (1908) should be excluded as a source of data on dragonflies of Poland. Kolosov was known as the author of the paper about the mass migration of *Libellula quadrimaculata* through Pu.awy (Kolosov 1915). His collection was partially preserved in the Museum and Institute of Zoology of the Polish Academy of Sciences (MIZ PAS). This data has been used by Bernard et al. (2009) and discussed in details by Buczynski (2012) who considered it in most as unpublished. However, it was published in *Zapiski Nowo-Aleksandriyskago Instituta Selskago Khozyaistva i Lesovodstva* (Memoires de Institute Agronomique et Forester a Nowo-Alexandriach) (Kolosov 1916) although this work has never been cited, not only in Poland but also in Russia and the Soviet Union. This probably resulted from a chain of unfortunate events. The paper was published during the war when the publishing institute was evacuated from Pu.awy to Kharkov where it stayed. Therefore this paper was absent in Polish libraries. However, for Russian authors the discussed paper was not interesting then for it was local and referred to a different country. Kolosov (1916) gave 41 dragonfly species: 40 from Pu.awy and its vicinity as well as 5 from fragmentary studied sites in other areas of Poland. At the same time *Orthetrum cancellatum* was wrongly recorded: the provided picture of copulatory apparatus of a male indicates *O. albistylum*. The analysis of data and the comparison with the preserved material (Buczyński 2012) show that the specimens in MIZ PAS were re-labelled which resulted in the loss of the detailed data about the sites: new unformed labels provided general site. *Novaya Aleksandriyach* (=Pu.awy). Moreover, the collection of MIZ PAS contains the species which were not given by Kolosov (1916): *Lestes virens*, *Enallagma cyathigerum*, *Anax imperator* and *A. parthenope*. Taking into consideration all of the data, in the

area of Pu.awy ca. 100 years ago 44 dragonfly species were recorded. That number was impressive in the light of contemporary standards of faunistic studies and such a small area. This shows the very high natural values of the valley of the middle River Vistula at that time. This data show the unique, almost complete picture of dragonfly assemblages of the valley of large lowland river in Central Europe during the period when such areas were still transformed in small degree by man." ISBN 978-609-95323-1-8: 164-198. (in German, with English and Lithuanian summaries) ["Odonata of two nature reserve boglands in Lithuania: *Praviršulis* and *Didysis Tyrulis*. While *Didysis Tyrulis* has been largely destroyed due to peat cutting, *Praviršulis* remained healthy, however, with disorders of natural hydrological conditions in a large part. As a result *Praviršulis* contains still two natural lakes and plenty of raised bog and fen. By contrast, at *Didysis Tyrulis* one finds no natural water bodies at all but lots of secondary „lakes“ in the digged pools together with a dense set of ditches. *Praviršulis* is well researched in terms of dragonflies, 45 species have been recorded. Among them some species strongly specialized in bogland, e.g. *Nehalennia speciosa*, *Somatochlora arctica*. Due to still started research, only 27 species have been recorded at *Didysis Tyrulis*, among them rare species as *Coenagrion armatum* and *Coenagrion lunulatum*. As a surprise, a large of population of *N. speciosa* could be observed as well. This is the first report of this species in a renaturating habitat. Really large populations were recorded for *Leucorrhinia rubicunda* and *L. pectoralis* in 2012.] Address: Gliwa, B., Lithuanian Entomological Society, Akademijos 2, LT-08412 Vilnius, Lithuania. **20574.** Omondi, R.; Yasindi A.W.; Magana A. M. (2013): Food and feeding habits of three main fish species in Lake Baringo, Kenya. *Journal of Ecology and the Natural Environment* 5(9): 224-230. (in English) ["The diets of three fish species of commercial importance in Lake Baringo, *Protopterus aethiopicus*, *Clarias gariepinus* and *Oreochromis niloticus*, were determined using frequency of occurrence and volumetric methods between April 2008 and March 2010. Seine and gill nets were used to catch a total of 430 fish specimens. The diet of *P. aethiopicus* was 94.3% molluscs with a frequency of occurrence of 98.6% of stomachs with food. Adult *C. gariepinus* fed mainly on fish with 75% of the stomachs with food containing fish remains and mean of 49.2% contribution by volume. *C. gariepinus* also fed on zooplankton, especially the cladoceran *Daphnia barbata*. The food items in the stomachs of *O. niloticus* consisted mainly of algae, detritus and zooplankton. Algae was consumed by *O. niloticus* of all length classes in proportions ranging from 26.5 to 88.1%. The importance of zooplankton as food for *O. niloticus* decreased with size of fish. The study reveals the importance of zooplankton as food for *O. niloticus* and *C. gariepinus* in Lake Baringo. There is need to rehabilitate the catchment of Lake Baringo so as to improve the water quality thus improve productivity." (Authors) The diet of *P. aethiopicus* included very few odonate specimens.] Address: Omondi, R., Kenya Marine & Fisheries Res. Inst., P O Box 31 Kisumu, Kenya. ail: reubenomondi@yahoo.com.

**20575.** Piper, M. (2013): Some Odonata Notes from Samos. *Atropos* 49: 91-93. (in English) ["During June 2010

with the help of Bower's *The Dragonflies of Lesbos* (2008) and *Field Guide to the Dragonflies of Britain and Europe* (Dijkstra & Lewington, 2006) I managed to find and identify a number of interesting dragonflies on Lesbos. The combination of sunshine, good food and abundant wildlife proved a big hit for me and my long suffering wife so we decided to try a different Aegean island in 2011. We settled upon Samos, some 125km to the south of Lesbos. I couldn't find any recent English references on the Odonata of this island (unlike birds, why are there so few trip lists for dragonflies and butterflies?). However, its close proximity to Turkey meant there must be some interesting species to see there and the lack of information was in some ways part of the appeal. What would I find there? The area of the island is 478km<sup>2</sup> and it is separated from Anatolia by the approximately 1.6km wide Mycale Strait. While largely mountainous, Samos has several relatively large and fertile plains. So during early June 2012, armed with a map (Samos 1: 50.000 Skai Map Hiking Terrain Cartography Group, map 331) I set forth, exploring the relatively few wetlands on the Island. We stayed in Pythagorio on the south-eastern coast, which proved a great base for getting around and had plenty of hotels and restaurants. The most interesting sites and species encountered are described briefly here. Alyki Wetlands (near Psili Ammos in the south-east) is a large shallow lake that dries out in the summer. A single visit here produced approximately 20 *Lestes macrostigma*. These were located on the seaward side of the lake, close to the ruined building. Very few other species were seen, perhaps not surprising given the extreme conditions of the site. Glyfada Wetlands (just west of Pythagorio by the Potokaki turnoff) consisted of two very small pools—one very artificial with concrete banks and one shallow and brackish. Only the brackish pool produced anything of note. Dark Spreadwing were seen on all three visits but only in small numbers of up to 10. A single *Orthetrum sabina* was the only one seen during the holiday. The reservoir near Ormos Marathokambou is a small stone-banked reservoir, approximately 2km north-east of the village on the south-west coast. Surrounded by high fencing, on inspection the padlock on the entrance gates was not locked and so I gained entry. How I love Greece! Good numbers of *Selysiothemis nigra* were seen along tracks around this site. The reservoir itself held very little, although *Trithemis annulata* was here in good numbers. The wonderfully named Valley of the Nightingales (the road to Vourliotes from the north coast main road) hosted a tumbling mountain stream running through woodland. The best species here were several *Cordulegaster insignis*, which were seen from the road along the most shaded sections of the river; they were very skittish and never settled. Quite often they left the stream area and flew along the road and into adjacent woodland. Other species seen here were typical Aegean fast-flowing stream species, such as *Caliaeschna microstigma* and *Epallage fatime*. Walking along the track from Vourliotes to Mandates I chanced across a *Gomphus schneiderii* perched on the ground and then in nearby trees. The River Imvressos in the south of the Island proved productive. The shadier upper stretches of the river between Myli and Agios Georghios again had the typical Aegean fast-flowing water species, *C. microstigma* and *E. fatime*. *Aeshna affinis* were observed feeding over nearby clearings. Where the river slowed near Myli Bridge typical species were *Orthetrum coerulescens* ssp. *anceps*, *Orthetrum brunneum* and *Onychogomphus forcipatus*. And south of here as the river trickled into the sea at Ireon, *Aeshna isosceles* were seen skirmishing with *Anax parthenope*. During the two weeks I found 26 species of dragonfly without trying too hard. So if you fancy the idea of sitting by the beach, cold Mythos in hand, a sparkling Aegean Sea, a content partner,

and a notebook and camera brimming full of dragonfly encounters you could do a lot worse than Samos." (Author)] Address: Piper, M., 83 Logan Street, Market Harborough, LE16 9AW, UK. E-mail: Mark.Piper@mercedes-amg-hpp.com

**20576.** Sanches, R.D.; Ribeiro, C. (2013): *Variação Lexical para Libélula no Atlas Linguístico do Amapá*. Web-Revista SOCIODIALETO • www.sociodialeto.com.br; Bacharelado e Licenciatura em Letras • UEMS/Campo Grande; Mestrado em Letras • UEMS / Campo Grande. ISSN: 2178-1486 • Volume 4 • Número 11 • Novembro 2013 : 435-449. (in Portuguese, with English summary) ["This article includes a sample of lexical research, leaving the focus on the study of the lexicon which currently has been a topic quite widespread in the variational-based studies. This study was based on data from the Linguistic Atlas of Amapá (ALAP), however, will address only those municipalities that have already been made all collections of data, in this case, we highlight the following municipalities: Amapá, Calçoene, Tartarugalzinho, Laranjal do Jari, Mazagão, Oiapoque Porto Grande, Pedra Branca do Amapari and Santana. The research is based on the theoretical and methodological assumptions adopted by the ALAP project. Therefore, we analyze the semantic field of fauna and flora of the lexical-semantic questionnaire in order to verify the uses made in this region for the lexical item dragonfly. It is noteworthy that the observed variation of this item considering the spatial and social, as recommended by the linguistic geography in a multidimensional perspective. Thus, it was found that the variants found in the state of Amapá were: libélula, jacinta, jacinto, cigarra, cigana, cinza, caba and gafanhoto. However, the most frequent variant is jacinta, since this term dictionaries. Data analysis also reports that the people who use this term are the municipality of Amapá. In relation to gender are the men of the second age group, from all points of inquiry, they have 100% occurrence of the term jacinta instead of dragonfly." (Authors)] Address: Romário Duarte Sanches (UNIFAP/UEPA). Email: duarte.romrio@gmail.com

**20577.** Shetty, S.; Sreepada, K.S. (2013): *Prey and nutritional analysis of Megaderma lyra Guano from the west coast of Karnataka, India*. *Advances in Bioresearch* 4(3): 1-7. (in English) ["Microchiropteran bats play a vital role in the ecosystem. They consume large volumes of insects many of which are agricultural pests and their droppings (guano) contain large amount of partly digested insect parts that form the resource base for other diverse form of consumers in the food chain including diverse microbes. These together make guano the best organic fertilizers. However, food habits of different species of bats vary depending on the species, locality, season and the ability of the bat to detect certain types of insects using morphological characteristics. Hence, an attempt is made in the present study to analyze the seasonal variations in the food habit of a microchiropteran bat, *Megaderma lyra*, so as to determine the insects on which they feed and also to do a nutritional analysis that include the moisture, carbohydrate, protein, lipid, ash, nitrogen, phosphorus and potassium content of their guano. The study was carried out during November 2009 to October 2010 in a maternity colony in an abandoned house which is mainly surrounded by coconut plantations and paddy fields. It is located at Karkala in D.K. district of Karnataka. To determine their insect prey, insect parts present in the bat guano were identified to ordinal level. The percent volume and percent frequency of food items present were also determined and were classified as basic food (>20%), constant food (5-20%), supplementary food (1-5%) and chance food (<1%). During the sampling period insects belonging

to 15 orders were identified. The scales of fishes, legs of frogs and hair, tooth and legs of rats recorded during pre monsoon, monsoon and post monsoon were all included under Vertebrates. Of the total insect orders identified, Coleopterans formed the major food items in all the three seasons (Premonsoon, monsoon and postmonsoon) and Vertebrates alongwith Coleopterans formed major food items during monsoon and postmonsoon. Whereas Hemipterans formed the constant food in all the three seasons and Lepidopterans formed the constant food along with Hemipterans during monsoon and postmonsoon. Other insect orders quantified included Dictyoptera, Trichoptera, Orthoptera, Diptera, Hymenoptera, Odonata, Ephemeroptera, Isoptera, Neuroptera, Dermaptera, Thysanoptera and spiders. The insect orders represented in the faecal pellets though not all indirectly reflect the occurrence of agricultural pests since their presence coincides with the type of vegetation surrounding the roosting site. Nutritional analysis of the guano revealed that the guano contained maximum carbohydrate (2.8%) during pre monsoon, lipid content (9.3%) during post monsoon and protein during pre monsoon and post monsoon (8.9%) period. N-P-K analysis revealed that guano is rich in phosphorus. Also phosphorus content was recorded highest in all the seasons (6-11%) and potassium during monsoon (1.3%) and post monsoon (1.2%). However, no significant variation in the nitrogen content was recorded. Therefore, the present study indicates that the Indian false vampire bat preys substantially on several insects injurious to crops, gardens and lawns and also on rodents. Further study is needed on the potential impacts of this and other insectivorous bats on these economic pests and also on organic enrichment of bat guano in the study area." **20581.** Hefler, C.; Qiu, H.; Shyy, W. (2014): The interaction of wings in different flight modes of a dragonfly. 17th International Symposium on Application of Laser Techniques to Fluid Mechanics, Lisbon, Portugal, July 07 – 10, 2014: 4.5.2. (in English) [Verbatim: considered in the targeted size region for Micro Air Vehicles MAVs. In a low Reynolds number region, where MAVs and natural flyers operate, viscous forces and unsteady aerodynamics must be considered and account for a number of unique phenomena. At such conditions traditional designs are disadvantaged over a flexible flapping wing which can extract additional aerodynamic forces through unsteady flow mechanisms (Shyy et al., 2008; Shyy et al., 2010). Bio inspired designs offer a viable solution to design MAVs. Among natural flyers dragonflies are unique. They possess 2 pairs of wings which they can move separately. The interaction between the fore and hind wing is a particularly interesting topic. Phase difference highly affect the force production of tandem configuration, and while highest force peaks achieved when wings flapping in phase, the efficiency increases if the hind wing leads with a certain phase difference (Lian et al., 2013). Downwash generated by the forewing as well as shed vortexes greatly affect hind wing performance, however this effect is depend on the studied flight mode as well as geometrical and environmental conditions (Maybury & Lehmann, 2004; Sun & Huang, 2007; Rival et al. 2011;). Our aim is to characterize the flow field around the wings of a tethered dragonfly. We have measured the flow field with PIV; expanded with high speed video recording and a novel smoke visualization experiment. All three experiments were executed in still air, so the recorded flow field and vortex shedding wasn't affected by a free stream velocity like in case of wind tunnel studies (Thomas et al., 2004; Tsuyuki et al., 2006). It is in our interest to see whether downwash and vortex shedding is a prominent feature of wing wake interaction of a living dragonfly under near hovering conditions. According to the generated flow stream, we identified three flight modes: vertical take off, emerging flight and forward flight. The dragonfly executed these flight modes with two different flapping modes; in phase flapping and out of phase flapping. The occurrences

of flapping modes for the distinguished flight modes shows that out of phase flapping can be generally used by the dragonfly for takeoff, cruising or emerging flight. The number of occurrences shows that it is not preferred mode for vertical takeoff. In phase flapping wasn't found for forward flight mode. In case of in phase flapping, the wings seemingly functions as one large wing, with no prominent interaction. In case of out of phase flapping hind wing TEV and forewing LEV formation were observed on most of the recorded cases. The position of the shed TEV was above the top side of the hind wing, and in every recorded case only one could be identified. Forewing TEV could not be identified clearly on any of the recorded cases, neither do forewing shed LEV appeared near to the hind wing. It seems that forewing wake and hind wing interaction for these conditions is limited to the downwash effect. The dragonfly is capable of generating two separate flow stream, in an out of phase flapping mode (Fig. 1). This supposedly adds extra stability for the dragonfly when it changes from taking off to forward flight] Address: Hefler, C., Dept Mechanical & Aerospace Engineering, Hong Kong Univ. of Science & Tech., Hong Kong SAR, China. **20582.** Horváth, G.; Kriska, G.; Robertson, B. (2014): Polarized light and polarization vision in animal sciences. *Springer Series in Vision Research* Volume 2: 443-513. (in English) ["In the last decade it has been recognized that the artificial polarization of light can have uniquely disruptive effects on animals capable of seeing it and has led to the identification of polarized light pollution (PLP) as a new kind of ecological photopollution. In this chapter we review some typical examples for PLP and the resulting polarized ecological traps. All such polarized-light-polluting artificial surfaces are characterized by strongly and horizontally polarized reflected light attracting positively polarotactic aquatic insects, the larvae of which develop in water or mud, such as aquatic beetles (Coleoptera), water bugs (Heteroptera), dragonflies, mayflies (Ephemeroptera), caddisflies (Trichoptera), stoneflies (Plecoptera) and tabanid flies (Tabanidae), for example. We survey here the PLP of asphalt surfaces, solar panels, agricultural black plastic sheets, glass surfaces, black gravestones and the paintwork of black-, red- and dark-coloured cars. We show how the maladaptive attractiveness (PLP) of certain artificial surfaces to polarotactic insects can be reduced or eliminated. We consider how birds, spiders and bats exploit polarotactic insects trapped by different sources of PLP. We deal with the phenomenon that the vertically polarized mirror image of bridges seen at the river surface can deceive swarming polarotactic mayflies, which is an atypical kind of PLP. We explain why strongly polarizing black burnt-up stubble fields do not attract aquatic insects, which is an example for a horizontal, black polarizing surface that does not induce PLP and thus is an exception proving the rule. Finally, we show that phototaxis and polarotaxis together have a more harmful effect on the dispersal flight of night-active aquatic insects than they would have separately. This provides experimental evidence for the synergistic interaction of phototaxis and polarotaxis in these insects." (Authors)] Address: Horváth, G., Environmental Optics Laboratory, Dept. Biological Physics, Eötvös Univ., Pázmány sétány 1, 1117, Budapest, Hungary. E-mail: gh@arago.elte.hu

**20583.** Kalniņš, M. (2014): *Resnvedera purvuspares* Leucorrhinia caudalis (Charpentier, 1840) sugas aizsardzības plans. Approved by the Minister for the Environment and Regional Development of the Minister of the Environment and Regional Development of 16 January 2015, Order No

15. Biedriba "Zala upe", Sigulda: 71 pp. (in Latvian, with English summary) ["*Leucorrhinia caudalis* is one of the species of dragonflies occurring in Latvia, which is considered to be endangered and is included in the regulatory enactments of different levels of conservation of the species. In accordance with the report of Article 17 [Article 17 – A report to the European Commission on the status of conservation measures of habitats and species in Latvia (assessment of the period 2007-2012).] the conservation status assessment of *L. caudalis* is adverse; and a negative trend of the conservation status has been found. The assessment of a number of parameters included in the report is based on the grounds of an opinion of an expert or there is no data at all (e.g. as to the hydro-chemical parameters of the micro-habitats and habitats of the species). The natural data management system "OZOLS" of Nature Conservation Agency contains only a few, including inaccurate entries on the fields of the species; therefore it is not possible to plan and carry out appropriate conservation of the fields of the species. When planning the measures of freshwater habitat management, the coastal habitat needs are not assessed in connection of the conservation of *L. caudalis* (and other specially protected species of dragonflies). *L. caudalis* most commonly is found in eutrophic lakes, less often in diseutrophic lakes and old riverbeds in Latvia. The vegetation in the fields of *L. caudalis* in eutrophic lakes and old riverbeds are usually visually moderately abundant to abundant, diverse and rich in species. Typically all zones of aquatic plants – the surface, floating-leaf and submerged – are well-developed. Currently *L. caudalis* is found throughout the territory of Latvia. Comparing the historical and contemporary data of the distribution of the species it can be concluded that the number of observations of the species has decreased, which could indicate the decrease of the population of the species in Latvia. The uneven distribution of the species is more referable to the uneven level of research than to the actual distribution of the species. The influencing factors of the population of *L. caudalis* are the following: their natural enemies and non-native species, collecting, extreme weather conditions, toxic substances in the environment and the minimum size of the population. However, all these factors hold an unknown or low to medium risk. The non-native species and the minimum size of the populations can be a high risk factor too. The loss of a habitat of the species is a medium risk factor, because it has been established only in some specific places. The fragmentation of habitats (isolation of fields), habitat management (cleaning of water bodies) and mismanagement of habitats of coastal zone (overgrowing) are assessed similarly. However, the combination of these factors can have a major impact on the status of the species' population in Latvia. The protection plan of the species contains a description of the conservation measures of *L. caudalis* in the following areas: legislation and conservation planning, conservation of the species and habitats of it, research and monitoring, as well as information and education. A part of the described measures are attributable to the protection of invertebrates or even species and habitats as a whole." ## 2015

**20584.** Sivasankaran, P.N. (2015): Development of an optimal dragonfly-like flapping wing structure for use in biomimetic micro air vehicles. PhD thesis, Faculty of Engineering, Univ. of Malaya: XX, 118 pp. (in English, with Malaysian summary) ["Biomimetic Micro Air Vehicles (BMAV) are unmanned,

micro-scaled aircrafts that are bioinspired from flying organisms to achieve lift and thrust by flapping their wings. Micro Air Vehicles (MAV) are a relatively new and rapidly growing area of aerospace research. They were first defined by the US Defense Advanced Research Projects Agency (DARPA) in 1997 as unmanned aircraft that are less than 15 cm in any dimension. This allows BMAV to potentially be smaller and more lightweight than the other two types. These characteristics make BMAV ideally suited for flight missions in confined areas (e.g. around power lines, narrow streets, indoors, etc.). Therefore, BMAV structural components must be ultra-lightweight, compact, and flexible. Most past MAV research has focused on fixed wings, which are essentially scaled-down versions of wings on conventional fixed wing aircraft. These wings are unsuitable for BMAV due to their lack of flexibility. So a new type of structural wing design is required for BMAV. In this work, a dragonfly wing structure is mimicked to construct a new BMAV wing design. A dragonfly (Odonata) was selected for biomimicry, because they are highly maneuverable flyers, capable of hovering, rapid forward flight, or reverse flight. Therefore, structurally analyzing these wings could yield results that inspire the design of more effective wings for BMAVs. The overall objective of this research is to develop a simplified wing model for a BMAV, bioinspired from actual dragonfly wings. A simplified model was created using spatial network analysis, a topological optimization method. These simplified wing frame models were then fabricated using seven different types of materials. Stainless steel type 321, balsa wood, red pre-impregnated fiberglass, black graphite carbon fiber, polyvinyl acid, acrylic and acrylo-nitrile butadiene styrene. These wing frame structures were fabricated using laser cutting machine and a 3D printer. These wing frames were then immersed in a chitin-chitosan membrane by a casting method. These wing frames were subjected to mechanical testing's such as bending and tensile to study its suitability for use in a BMAV. A flapping mechanism was also created and used to produce flapping motion on these BMAV wings and an actual dragonfly wing (for comparison). The aero elastic properties of both the BMAV and actual dragonfly wings were examined using two high speed frame camera. The bending angle, displaced distance or deflection, wing tip angle, and the wing tip rotational twist speed were analyzed at the flapping frequencies of 10, 20, 30 Hz, 60 Hz and 120 Hz." **20585.** Arrowsmith, J. (2016): Acidity gradients shape the phylogenetic structure of odonate communities across three biomes. M.Sc. thesis, Faculty of Arts and Science, Biology, Concordia Univ.: 58 pp. (in English) ["Environmental filtering and competitive exclusion can act simultaneously to shape the structure of communities, but disentangling them has proved difficult. Specifically, environmental filtering may restrict establishment at a site to a set of species sharing particular traits permitting local persistence. Mutual exclusion of ecologically similar or phylogenetically related species can also dictate community composition. Patterns of phylogenetic structure allow assessment of the relative influence of these processes. Using phylogenetic patterns of community structure, this study aims to assess the predominant processes structuring odonate communities along a broad-scale environmental gradient in Quebec. Phylogenetic analyses of forty lentic (i.e. lake) odonate communities revealed that co-occurring species in temperate regions were more related than expected by chance, suggesting a predominant role of environmental filtering. Site-to-site variation

in phylogenetic structure was related to pH. That is, the most alkaline lakes, found in temperate regions, were the most phylogenetically clustered, suggesting that pH acts as a main environmental filter of odonate communities. However, environmental filtering may not be the only important process. One alternative explanation is that temperate communities are phylogenetically clustered because damselflies are disproportionately diverse relative to dragonflies in this region. Specifically, the recent radiation of damselflies in temperate regions could have increased the diversity of this group in the temperate species pool, which could then shape local communities in that region. Nevertheless, further analyses suggested that environmental filtering along a pH gradient, rather than the evolutionary history of the species pool, shapes odonate communities in Quebec." **20586.** Arslan, N.; Salur, A.; Kalyoncu, H.; Mercan, D.; Barisik, B.; Odabasi, D.A. (2016): The use of BMWP and ASPT indices for evaluation of water quality according to macroinvertebrates in Küçük Menderes River (Turkey). *Biologia* 71(1): 49-57. (in English) ["This study was carried out in the Küçük Menderes River basin in order to determine the water quality and investigate the environmental quality and the applicability of both the Biological Monitoring Working Party (BMWP) and Average Score Per Taxon (ASPT). Monitoring took place in May, July and September 2014 at 10 stations (7 rivers and 3 lakes) according to the method of Intercalibration Common Metrics. Some metrics (BMWP, ASPT, Family Biotic Index, Simpson Diversity Index, Shannon-Wiener Diversity Index, Margalef Diversity Index, dominance, frequency and existence of sensitive species) were calculated. In total, 69 taxa comprising 5,814 individuals were detected. The taxa having the highest frequency rate were *Limnodrilus hoffmeisteri* (70%), *Chironomus (Camptochironomus) tentans* (70%), *Psammoryctides albicola* (60%), *Physella acuta* (60%), *Nais elinguis* (60%) and *Stylaria lacustris* (50%), which are alpha mesosaprobic and polysaprobic species, respectively. The presence and high dominance and frequency rate of these species have indicated basin pollution. Positive indicator species for water quality are *Gomphus schneideri*, *Trithemis annulata*, *Lindenia tetraphylla*, *Orthetrum cancellatum*, *Hydropsyche angustipennis*, *Cricotopus (Cricotopus) fuscus* and *Cricotopus (Cricotopus) annulator*, while negative indicator species are *Culex pipiens*, *Chironomus (Camptoch.) tentans*, *Chironomus thummi*, *Stylaria lacustris* and *Eristalis tenax*. Habitat quality of the Küçük Menderes River basin was not high (it was found to be heavily polluted/polluted/slightly polluted according to the physicochemical data, BMWP and ASPT) due to physical habitat degradation, urban waste waters, touristic, seasonal dwelling and agricultural activities." **20588.** Calvao, L.B.; Nogueira, D.S.; Montag, L.F.; Lopes, M.A.; Juen, L. (2016): Are Odonata communities impacted by conventional or reduced impact logging? *Forest Ecology and Management* 382: 143-150. (in English) ["Timber harvest is a prevailing economic activity in Amazonia, which contributes to forest degradation and biodiversity loss. However, Reduced-impact logging has been used to mitigate the loss of environmental integrity and biodiversity, since it has been assumed to be less detrimental than conventional logging practices. The objective of this study was to evaluate if environmental conditions, streams and Odonata communities in reduced-impact logging areas (RIL) are similar to those of unlogged areas (CONTROL), whilst all are modified in conventional logging areas (CL), as a consequence of vegetation removal from the margins of water bodies. Forty-nine streams in areas that differ in timber harvest practices were sampled in eastern Amazonia. As expected, aquatic systems in RIL areas showed environmental conditions and Odonata species composition similar to CONTROL areas while CL streams differed both from CONTROL and RIL. Odonata richness and abundance were not different between CONTROL, RIL and CL treatments, however. Despite the fact that species richness and abundance changes may be masked by the presence of remaining riparian vegetation in CL areas, the use of reduced-impact logging minimizes changes in Odonata species composition and environmental conditions, that remain similar to that of unlogged areas. This is possible due to the planning to reduce environmental impacts in RIL. Unlike RIL, most canopy cover in the proximity of the water bodies (<10 m distance) is lost in CL areas due to logging activities." **20590.** Ghani, W.M. H. W. A.; Rawi, C.S.M.; Hamid, S.A.; Al-Shami, S.A. (2016): Efficiency of different sampling tools for aquatic macroinvertebrate collections in Malaysian streams. *Tropical Life Sciences Research* 27(1): 115-133.

(in English, with Malaysian summary) ["This study analyses the sampling performance of three benthic sampling tools commonly used to collect freshwater macroinvertebrates. Efficiency of qualitative D-frame and square aquatic nets were compared to a quantitative Surber sampler in tropical Malaysian streams. The abundance and diversity of macroinvertebrates collected using each tool evaluated along with their relative variations (RVs). Each tool was used to sample macroinvertebrates from three streams draining different areas: a vegetable farm, a tea plantation and a forest reserve. High macroinvertebrate diversities were recorded using the square net and Surber sampler at the forested stream site; however, very low species abundance was recorded by the Surber sampler. Relatively large variations in the Surber sampler collections (RVs of 36% and 28%) were observed for the vegetable farm and tea plantation streams, respectively. Of the three sampling methods, the square net was the most efficient, collecting a greater diversity of macroinvertebrate taxa and a greater number of specimens (i.e., abundance) overall, particularly from the vegetable farm and the tea plantation streams (RV<25%). Fewer square net sample passes (<8 samples) were sufficient to perform a biological assessment of water quality, but each sample required a slightly longer processing time ( $\pm 20$  min) compared with those gathered via the other samplers. In conclusion, all three apparatuses were suitable for macroinvertebrate collection in Malaysian streams and gathered assemblages that resulted in the determination of similar biological water quality classes using the Family Biotic Index (FBI) and the Biological Monitoring Working Party (BMWP). However, despite a slightly longer processing time, the square net was more efficient (lowest RV) at collecting samples and more suitable for the collection of macroinvertebrates from deep, fast flowing, wadeable streams with coarse substrates." **20592.** Grup d'Estudis dels Odonats de Catalunya (2016): *Les Libèl·lules de Catalunya*. Brau Edicions S L: 208 pp- ["The result of ten years field work - a compilation of current information on the dragonflies and damselflies of Catalonia. Introduction to the biology of the group, followed by 70 species accounts, each including a distribution map for Catalonia, detailed morphological description to aid identification, information on habitat, ecology, behaviour and conservation status. A chart for habitat type and phenology is also included for each species." (Publisher) "OXYGASTRA, Grup d'Estudi dels Odonats de Catalunya was born in 2003 and joined the Catalan Institute of Natural History, as a working group, in January 2005. From the moment of its constitution, the group propose two priority lines of work: to expand the knowledge of the odonatofauna of Catalonia and to bring the world of dragonflies closer to all those interested in the knowledge and observation of nature. With these objectives

in mind, the Oxygastra group set out to create the first monograph on odonates in Catalonia. Fieldwork began in 2003 and ended in 2012. To carry out this work, 348 grids of 10x10Km in the Catalan territory have been surveyed and almost 30,500 records of observations have been obtained. This, added to the bibliographic records, has made it possible to obtain more than 34,400 useful records. The book is structured in four sections. The first sets out the historical antecedents in the study of odonates in Catalonia, contains an introduction to the biology of the group and details the methodology used in the preparation of this work. The second part contains the files of the seventy cataloged species, which include distribution maps, morphological details to facilitate their identification and graphics illustrating the habitats, ecology and phenology of each species. The third part presents the distribution patterns of odontoids in Catalonia, the main areas of odontological interest and the state of conservation of the species. The last section contains a glossary with the terminology used in the book, a basic bibliography and a systematic list of taxa. It should be noted that this work has been possible thanks to the selfless work of the members of the Oxygastra group, who for more than ten years have spared no effort to finally see the publication *Les libèl·lules de Catalunya* see the light of day. We must also thank the support received throughout this long process by the Institut d'Estudis Catalans and by the Dept of Territory and Sustainability, the Mascort Foundation and other private sponsors when it comes to publishing the results of the work done. The book *les libèl·lules de Catalunya* has been published by Brau edicions." (<http://www.oxygastra.org/2017/03/les-libellules-de-catalunya.html>)

**20593.** Harabis, F. (2016): The value of terrestrial ecotones as refuges for winter damselflies (Odonata: Lestidae). *Journal of Insect Conservation* 20: 971-977. (in English) ["Habitat requirements of many species may vary significantly throughout the lifecycle. Species are often forced to exchange their habitats to meet requirements of different life stages. Due to the effect of human activities, however, there is a loss of habitat complexity and a consequent disappearance of species associated with multiple habitat types. This also applies to freshwater invertebrates occurring in temporary habitats. However, it appears that many species are able to meet their habitat requirements even in a human-altered landscape. The aim of this study was to analyze the habitat preferences of the damselfly *Sympecma fusca* in an area significantly influenced by human interventions. According to the results of a capture-mark-recapture study and generalized additive models, I found that, during a pre-reproductive period (in the autumn), imagoes utilize predominantly insolated ecotones, which constitute only a small fraction of the available terrestrial habitat. During the reproductive period (in spring), however, imagoes completely change their priorities in favour of reproductive success. At this time, males use ecotones only in adverse weather conditions. Ecotones allow the species to survive a long pre-reproductive period. However, suitable habitat conditions may be lost because of inappropriate interventions (e.g., mowing). These small-scale interventions often resemble natural disturbances and may not necessarily lead to the extinction of an entire population. Imagoes are able to move on to different habitat patches, but only if they have alternative habitats. This outcome indicates that maintaining a high heterogeneity of keystone structures is crucial for maintaining high levels of biodiversity." **20594.** Hefler, C.; Qiu, H.; Shyy, W. (2016): Dragonflies utilize flapping wings phasing and spanwise characteristics to achieve aerodynamic performance. arXiv:1612.05353v1 [physics.flu-dyn: 15 pp. (in English)] ["While dragonflies are highly agile flyers, some key aerodynamic mechanisms responsible for their flight performance remain inadequately understood. Based on forward flight conditions, we investigate dragonflies spanwise aerodynamic behaviors associated with flapping wings phasing relationship. Overall, the leading edge vortex (LEV) on the forewing forms without the influence of the hindwing. For hindwing, the wing root region prominently displays a trailing edge vortex (TEV). In the inner span region, the vortical flow structures around the hindwing is influenced by the forewings LEV when both wings are in close proximity and move in opposite directions. In the mid-span region, downwash following the forewing suppresses LEV formation on the hindwing. Finally the outer span region of the hindwing develops its LEV by wake capture at the end of a stroke cycle. In the inner region, the timing of shedding on both fore- and hind-wings is synchronized, which is not the case elsewhere. These varied flow structures suggest that the fore- and hind-wings, along their spanwise directions, play different roles in force generation." (in Indonesian, with English summary) ["Dragonflies have an important role for the stability of the ecosystem that is as predator and prey at the same time. The availability of food resources and optimal environmental conditions affect the species richness of dragonflies in the habitats. Research on dragonfly community structure aims to find out the differences of community structure in each habitat type in the region of Curug Lawe Benowo. The research was conducted in 4 different stations which focus on species of dragonfly, amount of an individual species, habitats, environmental conditions, and the correlation between the variables. The method used is point count. The results showed that there are 19 dragonfly species which came from 7 different families. The total number of individuals encountered from 4 stations is 205. The common species that can be found in all of the stations is *Euphaea variegata*. The level of diversity are medium, the level of evenness is fairly even. Similarity of species in any habitat types indicate that the habitats has a three kind of similarity levels that is fairly equal, less equal and not equal. Data analysis shows that there is a correlations between environmental conditions, and dragonfly species, affecting abundance and distributions of a dragonfly in the habitats, and can be used to describe dragonflies community structure in the region." **20596.** Khelifa, R.; Zebba, R.; Amari, H.; Mellal, M.K.; Mahdjoub, H.; Kahalerras, A. (2016): A hotspot for threatened Mediterranean odonates in the Seybouse River (Northeast Algeria): are IUCN population sizes drastically underestimated? International Journal of Odonatology 19(1-2): 1-11. (in English) ["Several odonate species are threatened in the Mediterranean basin and some of them show alarming decreasing trends. The distribution and population estimations provided by the IUCN are based on occasional field sampling

or non-rigorous methodologies and could be erroneous and misleading. To obtain reliable estimations of the population size and distribution of three threatened species, *Calopteryx exul*, *Coenagrion mercuriale*, and *Gomphus lucasii*, we first conducted capture-mark-recapture in a natural population during one flight season, and second we carried out intensive sampling of adults, larvae and exuviae in the Seybouse watershed, Northeast Algeria. In addition, a revision of odonate occurrence and distribution in the watershed was done by pooling information collected over six years (2010–2015). Our results show that population estimations of the three species are much higher than what the IUCN presents; that is, 2208 individuals of *C. exul* (22.08% of the estimated global population), 1765 individuals of *C. mercuriale*, and 11,204 individuals of *Gomphus lucasii* (about 4.5 times as large as the estimated global population). Moreover, a total of 42 species were recorded in the study site, of which seven are new. The mean number of localities per species increased by a factor of 2.47, e.g. from six to 12 in *C. exul*, two to 12 in *Coenagrion mercuriale* and five to 14 in *Gomphus lucasii*. Our results suggest that the Seybouse watershed is one of the most important areas in North Africa and the Mediterranean basin for these three threatened species and requires particular attention and an urgent conservation plan to reduce anthropogenic effects and maintain populations." **20597.** Nava-Bolaños, A.; Sánchez-Guillén, R.A.; Munguía-Steyer, R.; Córdoba-Aguilar, A. (2016): Isolation barriers and genetic divergence in non-territorial *Argia* damselflies. Biological Journal of the Linnean Society 120(4): 804-817. (in English) ["Isolation barriers work at different instances during the mating process in odonate insects. In territorial damselflies, heterospecific interactions are mainly precluded by sexual (visual) isolation, while in non-territorial damselflies, heterospecific interactions are mostly precluded by mechanical isolation and sexual (tactile) isolation. In this study we investigated the strength of three premating barriers (visual, mechanical and tactile), genetic divergence and degree of sympatry (on their entire distribution) between four non-territorial *Argia* damselflies (*A. anceps*, *A. extranea*, *A. oenea* and *A. tezpi*). Our results are explained in the light of learned mating preferences and Kaneshiro's hypothesis. We detected a strong reproductive isolation between all pairs of species by the joint action of the three studied barriers [visual (90.6%), mechanical (8.7%) and tactile (0.7%)]. Sexual (visual) isolation was the most important barrier, perhaps driven by learning mating preferences. One of the studied species, *A. extranea*, which is the most derived of the studied species, showed a highly asymmetric isolation in reciprocal crosses, which is consistent with Kaneshiro's hypothesis. Moreover, we detected a negligible ecological niche differentiation between the studied species (70% of shared distribution). Our results suggest that sexual (visual) selection may be an important force driving speciation in non-territorial species." **20598.** Outomuro, D.; Söderquist, L.; Nilsson-Örtman, V.; Cortázar-Chinarro, M.; Lundgren, C.; Johansson, F. (2016): Antagonistic natural and sexual selection on wing shape in a scrambling damselfly. Evolution 70(7): 1582-1595. (in English) ["Wings are a key trait underlying the evolutionary

success of birds, bats and insects. For over a century, researchers have studied the form and function of wings to understand the determinants of flight performance. However, to understand the evolution of flight, we must comprehend not only how morphology affects performance, but how morphology and performance affects fitness. Natural and sexual selection can either reinforce or oppose each other, but their role in flight evolution remains poorly understood. Here we show that wing shape is under antagonistic selection with regard to sexual and natural selection in a scrambling damselfly. In a field setting, natural selection (survival) favored individuals with long and slender forewings and short and broad hindwings. In contrast, sexual selection (mating success) favored individuals with short and broad forewings and narrow-based hindwings. Both types of selection favored individuals of intermediate size. These results suggest that individuals face a trade-off between flight energetics and maneuverability and demonstrate how natural and sexual selection can operate in similar directions for some wing traits, i.e. wing size, but antagonistically for others, i.e. wing shape. Furthermore, they highlight the need to study flight evolution within the context of species' mating systems and mating behaviors." **20599.** Romero, G.Q.; Piccoli, G.C.O.; de Omena, P.M.; Gonçalves-Souza, T. (2016): Food web structure shaped by habitat size and climate across a latitudinal gradient. *Ecology* 97(10): 2705-2715. (in English) ["Habitat size and climate are known to affect the trophic structure and dynamics of communities, but their interactive effects are poorly understood. Organisms from different trophic levels vary in terms of metabolic requirements and heat dissipation. Indeed, larger species, such as keystone predators, require more stable climatic conditions than their prey. Likewise, habitat size disproportionately affects large-sized predators, which require larger home ranges, thus being restricted to larger habitats. Therefore, food web structure in patchy ecosystems is expected to be shaped by habitat size and climate variations. Here we investigate this prediction using natural aquatic microcosm (bromeliad phytotelmata) food webs comprised of litter resources (mainly detritus), detritivores, mesopredators, and top predators (damselflies). We surveyed 240 bromeliads of varying sizes (water retention capacity) across 12 open restingas in SE Brazil spread across a wide range of tropical latitudes (-12.6° to -27.6°, ca. 2.000 km) and climates ( $\Delta$  mean annual temperature = 5.3°C). We found a strong increase in predator-to-detritivore mass ratio with habitat size, representative of a typical inverted trophic pyramid in larger ecosystems. However, this relationship was contingent among the restingas; slopes of linear models were steeper in more stable and favorable climates, leading to inverted trophic pyramids (and top-down control) being more pronounced in environments with more favorable climatic conditions. By contrast, detritivore-resource and mesopredator-detritivore mass ratios were not affected by habitat size or climate variations across latitudes. Our results highlight that the combined effects of habitat size, climate and predator composition are pivotal to understanding the impacts of multiple environmental factors on food web structure and dynamics." **20601.** Stigge, H.A.; Bolek, M.G. (2016): Evaluating the biological and ecological factors influencing transmission of larval digenetic trematodes: A test of second intermediate host specificity of two North American *Haliipegus* species. *Journal of Parasitology* 102(6): 613-621. (in English) ["Host specificity of parasites is a basic principle in parasitology; however, it is not easily measured. Previously, host specificity was calculated as the number of species that a parasite infected, but this is not an accurate description of host usage because some species are capable of being infected but do not contribute to the completion of the life cycle. Instead, measures of host specificity should take into consideration interactions between a parasite and a potential host species as well as interactions between current and subsequent hosts in the life cycle. The objectives of this study were to track the development of 2 trematode species, *Haliipegus eccentricus* and *Haliipegus occidialis*, in 3 phylogenetically and ecologically distinct microcrustacean second intermediate hosts, and then, evaluate the extent to which each of these hosts contributed to transmission of each *Haliipegus* species to the next odonate host in the life cycle. All 3 microcrustacean species exposed became infected with both species of *Haliipegus*. The patterns of growth of *H. eccentricus* and *H. occidialis* were similar, but there were consistent differences in the rates of growth among the microcrustacean species in both *Haliipegus* species. Regardless of host species infected, all individuals of both species were considered to be developmentally infective to the next host in the life cycle by 19 days post exposure (DPE) when they lost their excretory bladder. Worms of varying sizes were capable of surviving without this structure suggesting that there is not a strong relationship between the rate of growth of the metacercariae and the development of their osmoregulatory system. Although *Haliipegus* species were capable of living without an excretory bladder at 19 DPE, there were differences in their size and rates in which the 3 microcrustaceans contributed to transmission of the parasites to subsequent odonate hosts. Collectively, under controlled laboratory conditions, there was an approximately 2-fold difference in the average percent of worms that established in odonates from the ostracod, *Cypridopsis* sp., than from the harpacticoid copepod, *Phyllognathopus* sp., and the difference was nearly 3-fold between *Cypridopsis* sp. and the cyclopoid copepod, *Thermocyclops* sp. Therefore, Powered by Editorial Manager® and ProduXion Manager® from Aries Systems Corporation despite all 3 microcrustacean species becoming infected, not all species were equally suited for

transmission and completion of the life cycle. Differences among the 3 microcrustacean species in cercaria ingestion, metacercarial growth and development, and odonate predation rates on infected microcrustacean species were important factors in determining transmission of the 2 *Halipegus* species to odonate hosts.] Address: Stigge, Heather, Dept of Integrative Biology, Oklahoma State Univ., Stillwater, Oklahoma 74078, USA

**20602.** Viyapuri, R. (2016): Development of chitosan based nanocomposite film for the wing membrane of biomimetic micro air vehicles (BMAV). PhD thesis, Faculty of Engineering, Univ. of Malaya: XXII, 135 pp. (in English) ["Biomimetic Micro Air Vehicles (BMAV) are unmanned, micro-scaled aircraft that are bioinspired from flying organisms to achieve lift and thrust by flapping their wings. There are still many technological challenges involved with the designing BMAV. One of these is designing ultra-lightweight materials and structures for the wings that have the mechanical strength to withstand continuous flapping at high frequencies (e.g. 30 Hz for a dragonfly). Insects achieve this by using chitin-based, wing frame structures that encompass a thin, film membrane. The overall objective of this research is to develop an innovative wing membrane for a BMAV, bioinspired from actual dragonfly wings. Chitosan was used as a polymer matrix. Chitin nanowhiskers (CNW) and nanocrystalline cellulose (NCC) were prepared in laboratory and used as reinforcement fillers in the design of two types of nanocomposite membranes. In each type, tannic acid was used as crosslinker for the chitosan matrix. Film samples with different ratios of nanomaterials and crosslinking agent were prepared. The chemical changes, structural properties, and mechanical performance of each sample was measured, analyzed, and compared. Following these initial studies, heat treatment was also investigated to assess its potential for improving the chitosan nanocomposite film. Transmission electron microscopy (TEM) and scanning electron microscope (SEM) confirms the nano-scaled size of nanomaterial produced and reveals the dispersion level of the nanomaterials in the chitosan matrix. Fourier-transform-infrared spectroscopy (FTIR) was used to investigate the molecular interaction of film. X-ray diffraction (XRD) results indicated that the nanocomposite films have a rigid structure. Performance analysis using a universal testing machine (UTM) and nanoindentation machine indicates that, the tensile strength and modulus increase significantly for the crosslinker nanocomposite films. Wettability, moisture content and solubility tests show that the film exhibits elevated water resistant when the additives and heat treatment are introduced. A dragonfly wing frame structure iv was also bio-mimicked and fabricated using a 3D printer. The membrane was applied to these BMAV wing frames by a casting method. A flapping generator was used to produce static, flapping motion on these BMAV wings and an actual dragonfly wing (for comparison). The aeroelastic properties of both the BMAV and actual dragonfly wings were examined using two high speed frame camera. Bending angle, wing tip deflection and wing tip twist angle were analyzed at the flapping frequencies of 30 Hz, 60 Hz and 120 Hz." (Author)] Address: not stated

**20603.** Wesner, J.S. (2016): Contrasting effects of fish predation on benthic versus emerging prey: a meta-analysis. *Oecologia* 180(4): 1205-1211. (in English) ["Predator-prey interactions are often studied entirely within the ecosystem of the predator. However, many prey transition between ecosystems during development, expanding the effects of predators across ecosystems. Prey are often vulnerable to

predation during this transition, facing a predator gauntlet as they leave their source ecosystem. As a result of predation during this transition, predators may have stronger effects on prey fluxes to the neighboring ecosystem than on prey densities in the predator's own ecosystem. I used meta-analysis of predator (fish) and prey (invertebrate) interactions in freshwater ecosystems to test the hypothesis that fish have stronger effects on prey flux to the terrestrial ecosystem, by reducing insect emergence biomass, than on prey densities in the aquatic ecosystem, by reducing benthic insect/invertebrate biomass. Fish reduced insect emergence by 39 % on average, more than twice as strong as their reductions of benthic prey (16 % reduction; averages are variance-weighted). In fact, fish effects on benthic prey were not significantly different from zero, but were significant for emergence. These results indicate that predator effects can not only cascade from one ecosystem to another but also that effects can be stronger outside than within the ecosystem of the predator. Failure to account for this may underestimate the effects of predators on prey." (Author)] Address: Wesner, J.S., Dept of Biology, Univ. of South Dakota, Vermillion, SD, USA. Waikoloa, Hawaii, USA, July 30–August 3, 2017, Conference Sponsors: Fluids Engineering Division.

ISBN: 978-0-7918-5806-6: 10 pp. (in English) ["Bioinspired designs offer a viable solution to the design challenges of micro air vehicles (MAVs) desired to operate in the same size region under similar conditions as flying vertebrates and insects. Inspired by our previous studies of tethered live dragonflies, here, a quantitative characterization of the unsteady aerodynamic features of a live, freely flying dragonfly under well-established level flight condition will be presented. In particular with regard of the span-wise features of vortex interactions between the fore- and hind-pairs of wings, that highly contributes to the flight agility and efficiency of dragonflies. Flow fields of free flying dragonflies in still air have been measured by time-resolved stereo particle image velocimetry (TRS\_PIV). A specifically designed dark flight chamber has been built, where hand hold dragonflies (*Pantala flavescens*) were released and made to fly nearly parallel to the measurement plane toward a guiding light. Realistic kinematics of the dragonfly wings in free flight were measured by filming with 2 synchronized high-speed video cameras. Using the recorded images, several dozens of landmarks on the fore- and hind-wing surfaces and several landmarks on the body were traced with high precision and the three-dimensional coordinates were then reconstructed with a direct linear transformation (DLT) method. Using the reconstructed wing-body model, Navier-Stokes-based computational fluid dynamics (CFD) analyses, with wing shapes prescribed based on the experimental measurement, dynamically moving multi blocked, and an over-set-grid system were conducted. The numerical results are in overall agreement with the PIV data, and the combined numerical and experimental approach offers valuable insight into aerodynamic analyses. The results show that the interaction with the forewing leading edge vortex (LEV) strongly influences the flow structures around the inner spanwise region of the hindwing, while aerodynamic enhancement via vortex capture in the outer span is observed. The interaction depends not solely on wing phasing, geometrical arrangement, but also the flight mission." **20610.** Volz, D. (2017): Biodiversity of larval and adult dragonflies and damselflies (Odonata) of interdunal wetlands at Saugatuck Harbor Natural Area. Honors Theses. 2924, Western Michigan Univ.: 34 pp. (in English) ["The effects of climate change on insects in the United States have yet to be fully understood. Research on the insect populations of Lake Michigan's interdunal wetlands has been particularly limited. As these vibrant habitats are already at risk of destruction due to increased development, it is vital to have a working knowledge of the species that are living in the habitat. However, to date, there have been no studies on assemblages of interdunal wetlands in Michigan. Examining community compositions is critical to understanding the ecological problems that could occur in the future. This study is the first to look at Odonata diversity in an interdunal wetland in Michigan. The research, done at Saugatuck Harbor Natural Area on populations of Odonate species, provides a base-level of awareness about which species are living and breeding in this wetland habitat. The written record of the specific species observed in the area as adult odonates contributes to the Michigan Odonata Survey. This survey helps scientists better understand what odonates are living in and migrating to Michigan. Species with complex life cycles, such as Odonata, are important to both aquatic and terrestrial habitats. As these populations experience changes in the future, this research will provide crucial data on which species change their habitats. Examining the richness, diversity, and evenness of adult and larval Odonata provides a better view of the species living in wetland habitats. Odonates are an important food source for many other species living in these wetlands. Alterations to the complex food web within a wetland can have cascading effects on many species that live in the habitat. Incorporating the information gained from this study into future studies of the same wetland area will increase awareness about the effects of climate change on interdunal wetlands in the Great Lakes region." (Author)] Address: Volz, D., Western Michigan Univ., [devonvolz@gmail.com](mailto:devonvolz@gmail.com)

**20611.** Zeyghami, S.; Bode-Oke, A.; Dong, H. (2017): Quantification of wing and body kinematics in connection to torque generation during damselfly yaw turn. *Science China Physics, Mechanics & Astronomy* volume 60, Article number: 014711: 13 pp. (in English) ["This study provides accurate measurements of the wing and body kinematics of three different species of damselflies in free yaw turn flights. The yaw turn is characterized by a short acceleration phase which is immediately followed by an elongated deceleration phase. Most of the heading change takes place during the latter stage of the flight. Our observations showed that yaw turns are executed via drastic rather than subtle changes in the kinematics of all four wings. The motion of the inner and the outer wings were found to be strongly linked through their orientation as well as their velocities with the inner wings moving faster than the outer wings. By controlling the pitch angle and wing velocity, a damselfly adjusts the angle of attack. The wing angle of attack exerted the strongest influence on the yaw torque, followed by the flapping and deviation velocities of the wings. Moreover, no evidence of active generation of counter torque was found in the flight data implying that deceleration and stopping of the maneuver is dominated by passive damping. The systematic analysis carried out on the free flight data advances our understanding of the mechanisms by which these insects achieve their observed maneuverability. In addition, the inspiration drawn from this study can be employed in the design of low frequency flapping wing Micro Air Vehicles (MAV's)." **20612.** Al Basheer, A.; Parshad, R.D.; Quansah, E.; Yu, S.; Upadhyay, R.K. (2018): Exploring the dynamics of a Holling–Tanner model with cannibalism in both predator and prey population. *Int. J. Biomath.* 11, 1850010 (2018): 29 pp. (in English) ["Cannibalism is an intriguing life history trait, that has been considered primarily in the predator, in predator–prey population models. Recent experimental evidence shows that prey cannibalism can have a significant impact on predator–prey population dynamics in natural communities. Motivated by these experimental results, we investigate a ratio-dependent Holling–Tanner model, where cannibalism occurs simultaneously in both the predator and prey species. We show that depending on parameters, whilst prey or predator cannibalism acting alone leads to instability, their joint effect can actually stabilize the unstable interior equilibrium. Furthermore, in the spatially explicit model, we find that depending on parameters, prey and predator cannibalism acting jointly can cause spatial patterns to form, while not so acting individually. We discuss ecological consequences of these findings in light of food chain dynamics, invasive species control and climate change. [...] A dragonfly-larvae system consisting of *Anax junius* and *Plathemis lydia* (which are the prey for other predators such as tadpoles in a pond setting) is used to understand the effects of prey cannibalism on predator–prey interactions" (Authors)] Address: Al Basheer, A., Mathematics Dept, The Univ. of Georgia, 240A Riverbend Rd, Athens GA 30602, USA

**20613.** Beolens, R. (2018): *The Eponym Dictionary of Odonata*. Whittles Publishing: 352 pp. (in English) ["The Eponym Dictionary of Odonata is a comprehensive listing of all people after whom damselflies and dragonflies have been named in scientific or common names. Each entry provides details of the species and a brief biography of the person. It

is also cross-referenced so that the relationships between scientific authors, entomologists and others can be followed. Many entries have been contributed by the people so honoured who are not necessarily odonatologists, entomologists, zoologists or even great men of science. Many damselflies and dragonflies are named for the author's family members, friends and those who collected the species holotypes, while others are figures from myth or history. In fact, it could be anything from the author's mother to a favourite musician. Because entries may include details of dates, places, educational and work institutions, it is possible to discover information about each person and for a picture to be built of how the science sometimes follows groupings of colleagues or those significantly influenced by charismatic teachers. The Dictionary includes other names which might, at a glance, be thought to be eponyms yet are not in the truest sense. These may be species named after characteristics embodied in characters from literature, whole peoples, acronyms or toponyms, etc. To some extent it can read like a canon of the great women and men of science over the last several centuries. Interestingly there are species named after as many as three generations of the same family, veiled references to old lovers, sycophantic homage, financial patronage, etc., as well as all the more 'legitimate' reasons for naming species. Not surprisingly, odonatologists exhibit a range of opinion on the practice, from naming all species after people, to wanting all eponyms banned; they can be totally humourless and pedantic or full of fun and irreverence. Like all of us they have as many reasons for their namings as ordinary folk have for naming their children or pets. Underlying all this, however, is the value of Eponym Dictionary of Odonata in cataloguing this fascinating aspect of science for all users, whether scientists or interested lay readers." Guillemot, A.; Krieg-Jacquier, R.; Bal, B.; Lamouille-Hébert, M. (2018): A la recherche d'*Aeshna caerulea* sur la réserve naturelle nationale de Passy (Odonata: Aeschnidae). Document non publié (<http://files.biolovision.net/haute-savoie.-lpo.fr/userfiles/larecherchedAeshnacaeruleasurlarservenaturellenationaledPassy.pdf>): 13 pp. (in French) ["Within the framework of survey weekends and in association with the manager of the Passy national nature reserve (Asters), the Sympetrum group carried out a survey weekend on 6 and 7 August 2016 to search for *Aeshna caerulea* (Ström, 1783), a rare and threatened species discovered in 1994 in the vicinity of France. Thus, after having identified several wetlands favourable to the presence of the species in 2015, twelve people were gathered to search for this emblematic taxon of boreo-alpine ecosystems. Following these surveys, *A. caerulea* was not observed, despite the presence of the range of species generally associated with it. It is necessary to continue the surveys to refine the distribution of the species in the Dept and to identify possible connections between the different populations in Haute-Savoie." **20614.** Gumpinger, C.; Höfler, S.; Pichler-Scheder, C.; Chovanec, A. (2018): *Ökologische Aufwertungsmaßnahmen in oberösterreichischen Gewässern. Planung, Umsetzung, Erfolge, Probleme.* Im Auftrag des Amtes der Oberösterreichischen Landesregierung Direktion Umwelt und Wasserwirtschaft, Abteilung Wasserwirtschaft, Wels: 109 pp. (in German) ["The identified success factors on the way

from technically completely over-formed water bodies to ecologically upgraded - in the best case renatured - water bodies are summarised again in Fig. 82. In summary, it can be stated that these conclusions do not contain any fundamentally new findings, but that the authors are in line with international literature. The measures implemented in Upper Austria show the same deficits and problems that occur again and again - at least throughout Europe - and are accordingly more or less of high ecological quality - in the majority of cases, however, they can only be assessed to a limited extent on the basis of analogies with other measures or other water bodies, because no monitoring was carried out. In the future, in order to implement measures as successfully as possible, it will be important to learn to understand watercourses as overall systems, and accordingly to align planning and implementation as closely as possible to the guiding principles, and in this way ultimately to actually renaturalise watercourses. Where this is not possible due to limited framework conditions, the focus should be on habitat diversity, the best possible connection to the surrounding area and a design that enables or even initiates dynamic processes. Special attention must be paid to the water ecological functionality of created or initiated structures. Sufficiently generous dimensioning plays a major role here, as these initial measures create the preconditions for the long-term self-development of the streams and rivers. A particular challenge in the future will be to bring the sediment balance of the water bodies closer to its natural state. With regard to the monitoring of success, a standardised integrative medium- to long-term monitoring approach of hydromorphology (incl. sediment) and aquatic and terrestrial ecology is desirable with regard to the overall system of water bodies including the surrounding area. If the monitoring results do not document the hoped-for effects, remedial work - if at all possible even several adaptation loops consisting of remedial work and monitoring - is urgently recommended. This is particularly important because even small mistakes can lead to bottleneck effects that can prevent or at least delay the achievement of the set goals in the long term. If watercourse restoration projects are planned and carried out in the future with these crucial points in mind, technicians and ecologists - provided they have the necessary will and vision - will be able to learn together how flowing waters function and what really matters in restoration projects. Ultimately, there is also justified hope that more intact watercourse habitats will develop again and thus not only will the objectives of the Water Framework Directive be achieved in the long term and permanently, but also that the population will be able to benefit from the added value of intact watercourse habitats." **20615.** Janssen, A.; Hunger, H.; Konold, W.; Pufal, G.; Staab, M. (2018): Simple pond restoration measures increase dragonfly (Insecta: Odonata) diversity. *Biodiversity and Conservation* 27: 2311-2328. (in English) ["Ponds are home to a diverse community of specialized plants and animals and are hence of great conservation concern. Through land-use changes, ponds have been disappearing rapidly and remaining ponds are often threatened by contamination and eutrophication, with negative consequences for pond-dependent taxa like amphibians or dragonflies (Odonata: Anisoptera and Zygoptera). Increasingly, restoration measures such as removal of shading terrestrial vegetation or submerged organic matter are implemented to counteract current threats, but how these measures affect the target taxa is rarely assessed. We tested if and how simple pond

restoration measures affectionate diversity. We propose that pond restoration influences the light regime, which promotes aquatic and riparian vegetation important for different dragonfly life stages, thus increasing their diversity. Additionally, we assume that this changes dragonfly species composition between restored and unrestored ponds. We surveyed exuviae in the riparian and aquatic vegetation along the shore of 29 (12 restored, 17 unrestored) man-made ponds in southwest Germany and assessed environmental variables known to affect dragonfly diversity. We identified the cover of tall sedges and submerged macrophytes as the driving biotic variables for dragonfly diversity and species composition, with restoration measures affecting submerged macrophyte cover directly but tall sedges indirectly via available sunlight. This study demonstrates that simple restoration measures not only have a positive effect on overall dragonfly diversity, but also increase habitat suitability for several species that would otherwise be absent. We therefore propose dragonflies as a suitable flagship group for pond conservation." **20616.** Mamat-Noorhidayah; Yazawa, K.; Numata, K.; Norma-Rashid, Y. (2018): Morphological and mechanical properties of flexible resilin joints on damselfly wings (*Rhincocypha* spp.). *PLoS One*. 2018 Mar 7;13(3):e0193147. doi: 10.1371/journal.pone.0193147. eCollection 2018: 17 pp. (in English) ["Resilin functions as an elastic spring that demonstrates extraordinary extensibility and elasticity. Here we use combined techniques, laser scanning confocal microscopy (LSCM) and scanning electron microscopy (SEM) to illuminate the structure and study the function of wing flexibility in damselflies, focusing on the genus *Rhincocypha*. Morphological studies using LSCM and SEM revealed that resilin patches and cuticular spikes were widespread along the longitudinal veins on both dorsal and ventral wing surfaces. Nanoindentation was performed by using atomic force microscopy (AFM), where the wing samples were divided into three sections (membrane of the wing, mobile and immobile joints). The resulting topographic images revealed the presence of various sizes of nanostructures for all sample sections. The elasticity range values were: membrane (0.04 to 0.16 GPa), mobile joint (1.1 to 2.0 GPa) and immobile joint (1.8 to 6.0 GPa). The elastomeric and glycine-rich biopolymer, resilin was shown to be an important protein responsible for the elasticity and wing flexibility." **20619.** Moore, M.P.; Lis, C.; Martin, R.A. (2018): Larval body condition regulates predator-induced life-history variation in a dragonfly. *Ecology* 99(1): 224-230. (in English) ["Organisms with complex life cycles commonly exhibit adaptive plasticity in the timing of transitions between life stages. While the threat of predation is predicted to induce earlier transitions, empirical support has been equivocal. When predation risk affects both the propensity to transition to the next life stage and the ability to reach the energetic thresholds necessary to complete the transition, only those individuals in the best physiological condition may be able to accelerate development and emerge earlier. To test this hypothesis, we followed uniquely marked dragonfly larvae (*Pachydiplax longipennis*) through emergence in pools where we factorially manipulated the presence of a large heterospecific predator (*Anax junius*) and cannibalism risk via conspecific size variation. Consistent with our hypothesis, high-condition larvae were more likely to emerge in the presence of the heterospecific predator than in its absence, and low-condition larvae were more likely to emerge in its absence than in its presence. Moreover, high-condition larvae emerged earlier when cannibalism risk was high than when it was low. Predation risk therefore has condition-dependent effects on emergence. As predation risk frequently affects resource accumulation, similar mechanisms across taxa could commonly underlie the incongruence between empirical results and theoretical expectations for predator-induced life-history variation." **20620.** Moreno-Benítez, J.M.; Ripoll, J. (2018): Dragonflies along the Málaga Great Path and in the Province. IDENTIFICATION GUIDE. Diputación de Málaga, 29004 Málaga, Spain: 188 pp. (in English) [The Identification Guide to the Dragonflies along the Great Málaga Path and in the Province' forms part of the above actions, and brings us nearer to these metallic coloured beautiful creatures, which make our river and lakes more colourful. This publication follows the one about 'The Birds along the Great Path' and 'The Identification Guide to the Diurnal Butterflies along the Great Málaga Path', which has recently been published. However,

their identification was not the only purpose of this edition. We also aim to present this fascinating world and participate in research into them and its protection. Dragonflies are real survivors as they existed in the same time as dinosaurs, but contrary to them, they survived the massive extinction of the great part of life on Earth from that period. Here they are, hundreds of millions of years later, with slight changes in their basic physical form and biological features. These winged insects achieved to adapt to all kinds of water, even with certain level of salinity and contamination. Dragonflies are rather necessary in the ecosystems where they live and of great importance for humans. What would happened to us if dragonflies did not exist? Well, no doubt, we would not be fine. While larvae in water and as adult insects, they feed on many insects which, among other negative aspects, can be harmful for humans. For instance, these are mosquitoes. Moreover, they are part of food chains in water ecosystems, together with other animals which live there like fish, amphibians, and birds. In the province of Málaga, 54 different species of the Odonata have been spotted. This is 69% of all the Odonata in the Iberian Peninsula (79 species) or 7 out of 10." (Authors)] Address: Diputación de Málaga (Málaga county council), great Málaga path team, Pacifico 54, Edificio A (Building A), 29004 Málaga, Spain. <https://www.grandesdemalaga.es/en/7346/dragonflies-along-great-malaga-path-province-identification-guide>

**20621.** Moyo, S.; Richoux, N.B. (2018): Fatty acids reveal the importance of autochthonous non-vascular plant inputs to an austral river food web. *Hydrobiologia* 806: 139-156. (in English) ["We hypothesised that the dominant organic source supporting macroinvertebrate consumers in a South African river is autochthonously produced non-vascular algae (regardless of season), and that the prevalence of autochthony increases with increasing distance from the headwaters. Fatty acid profiles of macroinvertebrates from six sites and four sample times were assessed to characterise the consumer diets and estimate the relative assimilation of autochthonous versus allochthonous-based sources in the food web. Fatty acid markers, ordination analyses and mixing models confirmed that the ultimate nutritional source for the invertebrate assemblages was autochthonous-produced carbon, with some contributions occurring from vascular plants (potentially of allochthonous and autochthonous origin, as some vascular plants were aquatic macrophytes). However, contrary to our second hypothesis, the prevalence of autochthony did not change predictably along the river. Such an autochthonous-based food web is consistent with many large rivers in well-researched regions of the world, although the complexity and variability that we observed in the fatty acid profiles of macroinvertebrate consumers in a small South African river should help stimulate renewed interest in investigations of carbon flow within small rivers from less-studied regions (particularly in arid climates)." **20623.** Start, D. (2018): Ontogeny and consistent individual differences mediate trophic interactions. *The American Naturalist* 192(3): 301-310. (in English) ["Ecologists use species traits to predict responses to environmental change and, ultimately, to understand the composition of biological communities. However, this ignores known and substantial intraspecific variation that can have important consequences for species interactions and community composition. This within-species variation results from two distinct sources: ontogeny and consistent individual differences. Ontogeny and consistent differences interact to produce phenotypes, but the community-level consequences of this interaction have not been studied. Using larval dragonfly communities, I investigate patterns of intraguild predation by manipulating (1) consistent individual differences in activity rate and (2) the ontogeny of the focal and interacting species. I show that activity rate is a consistent individual trait but that the effect of activity rate on intraguild predation depends on the functional role of an organism in the community (predator or prey). An organism's functional role itself varies across ontogeny of both the focal and interacting individuals. I suggest that ontogeny and consistent individual differences interact to produce intraspecific variation, with consequences for species interactions, communities, and eco-evolutionary dynamics." **20624.** Tschol, M. (2018): Role of natural and sexual selection in the evolution of a sexual trait in an old insect order. M.Sc. thesis, Dept of Biology, Lund: (in English) ["Wing pigmentation in dragonflies and damselflies (odonates) functions as a secondary sexual trait with a role in courtship and antagonistic male-male interactions. Recently, a thermoregulatory function of wing pigmentation has also been suggested. This study aimed to elucidate how both sexual and natural selection have influenced the evolution and global distribution of wing pigmentation in odonates. I examined the role of wing patch colour in intra- and inter-sexual selection in the banded demoiselle (*Calopteryx splendens*) utilizing manipulation experiments. While no clear effect of wing patch colour on female preference was found, male *C. splendens* showed reduced aggression towards males with red manipulated wing patches, suggesting that colour mediates information that is used in territorial male conflicts. Additionally, I reconstructed the evolutionary history of this sexual trait and tested for a macroevolutionary association between latitude zone and wing pigmentation, with the expectation that thermoregulatory benefits promote wing pigmentation in temperate regions. I found wing pigmentation evolved several times in multiple lineages of dragonflies and damselflies and a high number of secondary trait loss is in agreement with the view that this sexual trait is costly. Pigmented species were found to be more prevalent in the tropics and evolutionary rates of wing pigment loss were higher in the temperate region. Together, my results do not support the view that a thermoregulatory benefit at temperate

regions has promoted the emergence and maintenance of this trait. Instead, other unknown selective pressures in the tropical regions may have shaped the evolutionary trajectory of wing pigmentation. There may be a more important role of this visually appealing sexual signal in intra- and inter-specific interactions in the tropics compared to the temperate regions. Popular Abstract: Evolution of a Sexual Signal in Dragonflies and Damselflies. Animals often use visual signals to choose mates or communicate fighting ability between rivals. Some dragonfly and damselfly species exhibit colourful pigmentation patterns on their wings which females use as a cue while selecting a mate and males to determine if they want to get into a fight with another competing male. I conducted field experiments to learn more about the role of wing pigmentation in one species of damselfly (*Calopteryx splendens*) and additionally used phylogenetic comparative methods to look at the evolution of this sexual signal across many dragonfly and damselfly species. To better understand how abiotic and biotic factors contribute to the diversity of life, we often select specific traits that we study more closely. One prominent biotic factor is the interaction between the sexes. Some traits that are important in this interaction function as sexual signals, like in the case of wing pigmentation in dragonflies and damselflies. I conducted two field experiments where I manipulated the wing patch colour of male *C. splendens* and recorded the reactions of either free ranging females or resident territorial males. It turns out, while females did not prefer or discriminate more between different colours, resident males showed less aggression towards individuals with red coloured wings. This suggests a possible role of the wing patch in signalling information towards other competing males. In an evolutionary perspective, this signalling role might get lost over time because of other forces acting against it. So could potentially increased predation on individuals with wing pigmentation lead to the loss of the trait in the whole species and its ancestors. In my between species phylogenetic comparative study I found a pattern that fits this prediction. Wing pigmentation evolved several times in different lineages of Odonata, and was subsequently lost three times more often. Interestingly, my analyses also indicate a difference in the evolutionary history of wing pigmentation between tropical and temperate species, possibly indicating different selective pressures acting on this trait in both regions. This will have to be investigated more closely in the future!" (Author)] Address: not stated

**20625.** Ul Islam, S.; Lin, W.; Wu, R.; Lin, C.; Islan, W.; Arif, M. (2018): Complete genome sequences of three novel cycloviruses identified in a dragonfly (Odonata: Anisoptera) from China. *Archives of Virology* 163: 2569-2573. ["Three cycloviruses (genus *Cyclovirus*, family *Circoviridae*) were recovered from a dragonfly (Odonata: Anisoptera) captured in Fuzhou, China. The three cycloviruses, named dragonfly associated cyclovirus 9, 10 and 11 (DfCyV-9, -10, -11), respectively, show 56.1-79.6% genome-wide identity to known cycloviruses and 61.6-65.1% among themselves. Thus, according to the current species demarcation criteria, they represent three novel cycloviruses. Notably, DfCyV-10 has a predicted replication-associated protein (Rep) that is most similar to that of bat associated cyclovirus 2 (BatACyV-2), a cyclovirus discovered in China, with 79.4% amino acid sequence identity, but a putative capsid protein (Cp) most similar to that of BatACyV-10, a cyclovirus discovered in Brazil, with 71.7% amino acid sequence identity. These data are useful for understanding the diversity and evolution of cycloviruses, especially those found in insects." (Authors)] Address: Du, Z., State Key Laboratory of Ecological Pest

**20626.** Vinko, D.; Tratnik, A.; Bahor, M.; Erbida, N.; Pirnat, A.; Šalamun, A. (2018): [An inventory of dragonflies (Odonata) in the area of the Ribniki Nature Reserve in the Draga Valley near Ig. Report. Client: Public Institution Landscape Park Ljubljansko barje, Inner Gorice. Slovenian Odonatological Society, Ljubljana, October 2018: 29 pp., 3 appendices- (in Slovenian) [Google translator: With 49 species of dragonflies recorded, the area of Ribniki Nature Reserve in the Draga valley near Ig is one of the richest areas in Slovenia. And yet, 15 species of dragonflies are rare here. The 17 species present here are rare in the rest of the Ljubljana Marshes, for 7 the nature reserve is the only known habitat on the Marshes. 17 species are endangered, 5 protected, two listed in the Annex to the Habitats Directive and one in the Annex to the Berne Convention. New localities of the *Cordulegaster heros* have been found in the area. This European protected species, listed in Annexes II and IV of the Habitats Directive, is relatively common in the nature reserve and rare in the rest of the Ljubljana Marshes due to the lack of suitable habitat for it. In 2017, the *Leucorrhinia pectoralis* was first recorded here and re-certified in 2018. The medium-sized pond where this internationally strictly protected species was listed in Annexes II and IV of the Habitats Directive and Appendix II of the Berne Convention, thus, it represents the only confirmed habitat of the species in central Slovenia today. Active conservation measures are urgently needed to improve the conservation status of the species, and are based on a thorough inventory of the current state of the field, and we therefore suggest that the species be investigated as soon as possible in the nature reserve area. Given that the species has been regularly present in the last two years, although in smaller numbers, and aquatic biotopes are subject to succession and management, it is important to identify sites of development as soon as possible. The requirements of the species and the findings of the research required must therefore be incorporated into further management plans for the site. Further monitoring of the state of the ecological situation and the population also needs to be made. We reaffirmed the presence of the *Lestes dryas*, which is only the second species of the reserve area, the first being from the 1950s. Similar is the case with the rare bush beast (*Lestes barbarus*) and the beast beast (*Lestes virens vestalis*), which were not recorded in the area between 1954 and 2017. Some of the area's most important natural resources include the *Coenagrion scitulum*, *Erythromma lindenii*, *Epiheca bimaiculata* and *Sympetrum meridionale*. In the nature reserve Ribniki in the Draga valley near Ig we find the richest water in Slovenia from the point of view of the fauna of dragonflies. Many species diversity is also achieved, for example. Mura river with 56 species (Šalamun et al., 2015), Vipava valley with 53 (Vinko, 2016), Bela krajina with 50 (Šalamun et al., 2012), Mirna valley with 47 (Bahor, 2017), all of which on the surface much larger than in this project task of the area under consideration. Since there are not many large standing waters in central Slovenia, the ponds in the Draga valley near Ig are all the more important in order to preserve the diversity of dragonflies, including the wider area. The entire Ljubljana Marshes, together with the finds over the past two years, boasts the appearance of 51 species of dragonflies. For comparison, 45 species of dragonflies are known for the nearby Ljubljana, Rožnik and Šišenski hrib Nature Parks (Šalamun, 2018); for the entire City of Ljubljana there are 52 species (Kiauta, 2014a, 2014b; Vrhovnik et al., 2015, 2016; Šalamun, 2018), but only 42 species have been listed

in the City of Ljubljana in recent years (Vrhovnik et al., 2016; Šalamun, 2018).] Address: Vinko, D., Slovenska 14, 1234 Mengeš, Slovenia; E-mail: damjan.vinko@gmail.com

**20630.** Bose C., N.; Kakkassery, F.K. (2019): Study on the diversity and abundance of odonates in three different geographic divisions in Kerala. *Biodiversity of Kerala after Deluge-Concerns, Implications and Conservation Strategies* 22-23 February 2019: 74-78. (in English) ["Like all living organisms, odonate diversity is also susceptible to environmental factors. The objective of the present study was to analyse how different geographical features affect the distribution and diversity of odonates. For the present survey, 12 different locations of Thrissur and Ernakulam districts were selected and they were categorised under three geographical divisions- the eastern highlands, the central midlands and the western coastal plains. The observation was

carried out for 1 year from August 2017 to July 2018. A total of 61 species were encountered during the survey. Maximum species richness was observed in the eastern highlands, followed by central midlands and western coastal plains. Similarly, maximum values of diversity indices were recorded from eastern highlands, followed by central midlands and western coastal plains. Our observations indicate that Marotichal, Athirampilly, Vazhani and Malayatoor in the eastern highlands has a diverse odonate fauna." **20631.** Csar, D.; Gumpinger, C.; Pichler-Scheder, C.; Höfler, S.; Chovanec, A. (2019): Sanierung der Morphologie kleiner und mittlerer Fließgewässer in Österreich Resultate und Erkenntnisse aus Best-Practice Projekten inkl. Empfehlungen für die Erfolgskontrolle. Im Auftrag des Bundesministeriums für Nachhaltigkeit und Tourismus. Forschungsprojekt Nr. 101291: 81 pp. (in German) ["As part of the implementation of the European Water Framework Directive (WFD), watercourses throughout Austria are being upgraded and renatured in order to achieve "good ecological status" or "good ecological potential". However, the effectiveness of the measures is often below the improvement that can be shown with the currently available assessment systems, the jump to a better ecological status class. If this jump in class does not occur after the implementation of a measure, the measure was not necessarily unsuccessful. In the present project, measures already completed throughout Austria to improve the ecological situation of water bodies were collected with accompanying monitoring studies and the data analysed in order to derive general recommendations for success monitoring. Since no such recommendations for the recording and evaluation of measure effects have been available so far, a methodological framework for effect documentation was developed, with which one can already present and evaluate small changes in the water ecological situation at measure level. The results of surveys of the quality elements in accordance with the guidelines of the EU Water Framework Directive, which can be supplemented as needed by various criteria that offer a higher resolution by considering additional aspects and thus enable improved interpretation of the results and the presentation of even small successes, essentially serve as the basis for monitoring the success of the measures. For data entry, calculation and presentation, the template of a calculation table was developed in the generally available software Microsoft Excel. The results are transferred to a summary data sheet, supplemented with characteristic data on the water body and the measure, and concluded with an expert assessment. This data sheet finally functions as a short report for the general documentation of the effect of the measure and guarantees the comparability of projects. In the coming years, this methodological framework will be tested, evaluated and further developed in practice." **20632.** Ferreira do Amaral, D.; Montalvão, M.F.; Mendes, B.; Araújo, A.P.; Rodrigues, A.S.; Malafaia, G. (2019): Sublethal effects induced by a mixture of different pharmaceutical drugs in predicted environmentally relevant concentrations on *Lithobates catesbeianus* (Shaw, 1802) (Anura, ranidae) tadpoles. *Environmental Science and Pollution Research* 26(1): 600-616. (in English) ["The increasing consumption of medications by humans has negative effects such as the increased disposal of these compounds in the

environment. Little is known about how the disposal of a "drug mix" (DM) in aquatic ecosystems can affect their biota. Thus, we evaluated whether the exposure of *Lithobates catesbeianus* tadpoles to a DM composed of different medication classes (antibiotic, anti-inflammatory, antidepressant, anxiolytic, analgesic, and antacid drugs)—at environmentally relevant concentrations—may change their oral morphology, trigger behavioral disorders, and have mutagenic effects on erythrocyte cells. Based on our data, animals exposed to the DM showed changes in mandibular sheath pigmentation, dentition, and swimming activity, as well as atypical behavior in the social aggregation test [with co-specific and interspecific (*Physalaemus cuvieri*) individuals] and antipredatory defensive response deficit (chemical stimulus from Odonata larvae), after 15 exposure days. The mutagenic analysis revealed higher frequency of nuclear abnormalities in the erythrocytes of tadpoles exposed to the DM (e.g., multilobulated, blebbed, kidney-shaped, notched nucleus, binuclear, and micronucleated erythrocytes). Given the chemical complexity of the DM, we assumed that several organic functions may have been affected, either by the isolated, synergistic, antagonistic, or additive action of DM compounds. Finally, our study confirms the toxicological potential of DM in *L. catesbeianus* tadpoles, with emphasis to impacts that can affect the fitness of individuals and their natural populations. Thus, we suggest that more attention should be given to the disposal of medications in the environment and reinforce the need of improving water and sewage treatment systems." **20633.** Fraixedas, S.; Galewski, T.; Ribeiro-Lopes, S.; Loh, J.; Blondel, J.; Fontès, H.; Grillas, P.; Lambret, P.; Nicolas, D.; Olivier, A.; Geijzendorffer, I.R. (2019): Estimating biodiversity changes in the Camargue wetlands: An expert knowledge approach. *PLoS ONE* 14(10): e0224235. <https://doi.org/10.1371/journal.pone.0224235>: 18 pp. (in English) ["Mediterranean wetlands are critical strongholds for biodiversity and the provision of ecosystem functions and services; yet, they are being severely degraded by a number of socio-economic drivers and pressures, including climate change. Moreover, we still lack comprehensive understanding of the extent to which biodiversity loss in Mediterranean wetlands will accelerate change in ecosystem processes. Here, we evaluate how changes in biodiversity can alter the ecosystem of the Camargue (southern France). We collected data on species presence/absence, trends and abundance over a 40-year period by combining observations from the scholarly literature with insights derived from expert knowledge. In total, we gathered more than 1500 estimates of presence/absence, over 1400 estimates of species abundance, and about 1400 estimates of species trends for eight taxonomic groups, i.e. amphibians, reptiles, breeding birds, fish, mammals, dragonflies (odonates), orthopterans and vascular plants. Furthermore, we used information on recently arrived species and invasive species to identify compositional changes across multiple taxa. Complementing targeted literature searches with expert knowledge allowed filling important gaps regarding the status and trends of biodiversity in the Camargue. Species trend data revealed sharp population declines in amphibians, odonates and orthopterans, while birds and plants experienced an average increase in abundance between the 1970s and the 2010s. The general increasing trends of novel and invasive species is suggested as an explanation for the changing abundance of birds and

plants. While the observed declines in certain taxa reflect the relative failure of the protection measures established in the Camargue, the increasing exposure to novel and invasive species reveal major changes in the community structure of the different taxonomic groups. This study is the first attempt to assess changes in biodiversity in the Camargue using an expert knowledge approach, and can help manage the uncertainties and complexities associated with rapid social-ecological change in other Mediterranean wetlands. ... To compile the species lists for odonates and orthopterans, we consulted the management plan of the Tour du Valat Regional Nature Reserve written by Cohez et al. [15] and the MSc thesis about odonates and orthopterans by Merlet [16]. This gave us information on species presence/absence and their status (e.g. abundance, distribution, nativeness). For odonates, we also looked for quantitative data (number of individuals) from the National Odonata data collection programme (Complément à l'inventaire des libellules de France) known as «CILLIF» (French Odonatological Society, Société française d'odonatologie – SfO) for the period 2014-2016 to help complementing the species list, as well as the doctoral thesis from Aguesse [17] and the revision of the species red list for the Provence-Alpes-Côte d'Azur region by Lambret et al. [18]. As for orthopterans, the list was further elaborated with the doctoral thesis of Bigot [19], one of Bigot's works [20], and the red list for the Mediterranean region from Sardet and Defaut [21]. Both lists were checked and supplemented by an expert from the Tour du Valat. Lack of literature for the 1970s made difficult to obtain qualitative information for both groups (also for many orthopteran species we could not find information for their present status). However, for some species qualitative information on the species abundance and distribution could be added to the surveys." **20636.** Kathan, B. (2019): Die Libellenfauna (Insecta: Odonata) des Spitzbergs bei Tübingen unter besonderer Berücksichtigung der Arten *Sympecma fusca* (Lestidae) und *Cordulegaster bidentata* (Cordulegasteridae). Bachelorarbeit der Mathematisch-Naturwissenschaftlichen Fakultät der Eberhard Karls Universität Tübingen: 106 pp. (in German) ["Holistic mapping of the order Odonata is in itself an exceptional case. In this work, this intensive type of recording was additionally provided with a three-part focus. The study was carried out over the course of a whole year on the Spitzberg near Tübingen, a study area with little water, but nevertheless promising in terms of dragonflies. In addition to all ground-dwelling species, species that are often neglected in routine mapping and occur purely temporarily for hunting and maturing purposes were also recorded with the same intensity in the entire area. At the same time, comprehensive surveys of the species *Sympecma fusca* and *Cordulegaster bidentata* flying on the Spitzberg were carried out between March 2018 and February 2019. Both species are highly specialised and particularly complex to record, which is why their complex biology has still not been fully deciphered in detail. With regard to *S. fusca*, we investigated which areas of the Spitzberg the imagines use during the maturation period in spring and autumn, whether they overwinter in the study area and to what extent the habitat structures used during this part of the life cycle overlap. Concerning *C. bidentata*, an intensive sampling of the larval habitats, i.e. all spring rivulets in the blades of the Spitzberg, was carried out. In addition to the distribution of the larvae, their degree of association within all microhabitats of a spring rivulet was investigated. In addition, the different size classes into which all recorded individuals were divided were checked for any significant differences in their distances to the main sources of the respective streams. 19 of the total of 33 dragonfly species recorded at Spitzberg in 2018 as part of this work subjected the study area to purely temporary use, 14 species were classified as native. *S. fusca* was recorded in high abundance, numerous habitats used in autumn, winter and spring overlapped. Reproduction of the species took place both on the Spitzberg itself and in the nearby surrounding area. *C. bidentata* was recorded in high abundance in the larval stage in several sections of spring rivulets, partly syntopically with *Cordulegaster boltonii* and *Aeshna cyanea*. The majority of individuals were found living solitarily in a microhabitat, but many larvae were also associated in small groups within a microhabitat at the time of discovery. The 4 different size classes did not differ significantly in their distances from the main source." (Author/DeepL) <https://www.researchgate.net/publication/33853->

**20637.** Kim, Y.j.; Kong, D.S. (2019): Benthic macroinvertebrates fauna of Mt. Chilbo. Korean J. Nat. Conserv. 18(1): 1-13. (in Korean, with English summary) ["Benthic macroinvertebrates fauna was investigated at the Mt. Chilbo, Gyeonggi-do, Korea, from June to October, 2019. 4 sites located around the Mt. Chilbo were selected for quantitative (surber net: 30×30cm, mesh size: 1mm) of benthic macroinvertebrates. Including qualitative sampling, total 39 species, 31 families, 12 orders, 6 classes in 4 phyla occurred. Insecta was composed of 6 species in Ephemeroptera, 4 species in Odonata [*Ischnura asiatica*, *Calopteryx atrata*, *Davidius lunatus*, *Sympetrum flaveolum*], 1 species in Hemiptera, 2 species in Coleoptera, 9 species in Diptera and 5 species in Trichoptera. Non-insecta was 12 species composed of 1 species in Platyhelminthes, 4 species in Mollusca and 2 species in Annelida 5 species in Crustacea. The dominant species and the subdominant species based on individual abundance were Chironomidae sp. and *Physa acuta* with 20.4% and 18.7% of dominance respectively. McNaughton's dominance indices, Shannon-Weaver's diversity indices, Margalef's species richness indices and Pileou's evenness indices, Kong's Benthic Macroinvertebrate indices of benthic macroinvertebrates (BMI) showed the range of 0.53~0.82, 1.27~2.76, 1.09~2.84, 0.68~0.81, and 26.6~57.9 respectively." **20638.** Koszalka, J.; Jablonska-Bama, I. (2019): Aquatic macroinvertebrate biodiversity in freshwaters in northeastern Poland. In: The Handbook of Environmental Chemistry book series (HEC, volume 87): Polish River Basins and Lakes – Part II: 103-125. (in English) ["Biodiversity is a significant element that describes the ecological state of waterbodies. Eutrophication is a widespread problem that has an impact on water habitats and leads to the succession of sensitive species. Habitat degradation results in significant, predictable decreases in taxonomic diversity. We assessed benthic macroinvertebrate community structure (mainly families) in 9 rivers, 9 ponds, and 23 lakes in northeastern Poland. Mollusca, Annelida, Arthropoda, and Nematelminthes were the 4 phyla represented, and 76 Insecta families, 5 taxa of Crustacea, and 12 Mollusca families were identified. A total of 91 taxa (mainly families) were recorded in all of the waterbodies studied. Diptera, Trichoptera, Ephemeroptera, and Gastropoda were the major components of the benthic macroinvertebrate communities in the aquatic habitats studied. The biodiversity values of the macroinvertebrate assemblages in the rivers and lakes studied were similar. This likely resulted from the similar number of habitats in both types of waters. Differences in biodiversity among the various waterbodies could be evidence of the moderate, diversified anthropogenic pressure to which they are subjected. The analysis of similarities indicated that in terms of the benthic macroinvertebrate communities, the waterbodies studied formed three groups, which, with just one exception, consisted separately of rivers, ponds, and lakes." **20639.** Liu, Y.; Wang, Y.; Zhang, Z.; Bu, Y.; Niu, H. (2019):

Roost selection and ecology of *Stoliczka's* trident bat, *Aselliscus stoliczkanus* (Hipposideridae, Chiroptera) in China. Mammalian Biology 95: 143-149. (in English) ["Bats choose their habitats based on microclimate, structure, environment, human disturbance and availability. Selection of suitable roosts by bats can have fitness benefits by providing shelter and a place to rear young. To clarify the mechanism of habitat selection by *Stoliczka's* trident bat (*Aselliscus stoliczkanus*), roost selection, ecology and diet of this species were studied from December 2013 to September 2017 in mainland China. Ninety-six potential roosts were investigated. Of these, 73 roosts were occupied by bats, and 20 of these roosts were used by *A. stoliczkanus*. Eighteen variables related to habitat characteristics were measured, and *A. stoliczkanus* habitat preferences were evaluated using independent-samples t-tests and Chi-square tests. The major environmental factors affecting selection of roosts were determined by principal component analysis (PCA). Roosts used by *A. stoliczkanus* were significantly smaller in size than those used by other bat species, with more and narrower entrances. Hibernation roosts of *A. stoliczkanus* had relatively longer roost length, as well as lower entrances. Breeding roosts of *A. stoliczkanus* were close to the nearest water source and had more entrances, with more area covered by water. Disturbance levels were significantly higher in non-breeding roosts than that in breeding roosts, and disturbance levels were lower in hibernation roosts than non-hibernation roosts. Entrances of breeding roosts were more commonly located on sunny slopes, while entrances of hibernation roosts were more commonly located on shady slopes. Our results are the first to describe roost characteristics and habitat selection of *A. stoliczkanus*, and increase our understanding of the ecology and habitat of this species. The diet of *A. stoliczkanus* mainly includes five orders of insects, namely, Lepidoptera, Coleoptera, Hemiptera, Odonata, and Diptera, and showed clear seasonal variation from summer to autumn." (Authors)] Address: Liu, Yingying, College Life Science, Henan Normal Univ., Xinxiang, 453007, China

**20640.** Lounis, K. (2019): Inventaire et écologie des macroinvertébrés dans les mares temporaires de la région d'Oum El-Bouaghi (Nord-Est algérien). Thèse Présentée en vue de l'obtention du doctorat LMD, Université Larbi Ben M'hidi Oum El Bouaghi, Faculté Des Sciences Exactes et des Sciences de la Nature et de la Vie, Département des Sciences de la Nature et de la Vie: 117 pp. (in French, with English summary) ["This work aims to conduct a systematic study of the macroinvertebrate species of seventeen temporary pools south of Oum El Bouaghi, in order to bring a contribution to the knowledge of the entomofauna of these ephemeral ecosystems which is not well known and analyze their waters for better characterize their environment where 18 physicochemical parameters were analyzed. Faunal samples were harvested using a surgeon net. Identification of organisms was done using the determination keys (Dejoux et al., 1981; Tachet et al., 2002) and digital keys. The results of the physicochemical analyzes carried out on the 17 stations revealed that the temperature of the water varies between 12.6 °C and 20.3 °C, with an average of 17.36 ± 2.13 °C, the pH of the waters varies between 6.45 and 8.48, with an average of 7.34 ± 0.54. The dissolved oxygen showed an average of 5.81 ± 0.66mg / l and the electrical conductivity of the waters of the region is large and varies between 966 and 1055 µS.cm<sup>-1</sup>, with an average value of 1012.1 ± 20.17 µS.cm<sup>-1</sup>. For pollution elements, only nitrates can present a serious contamination. Faunistic analysis has identified 11 orders, 31 families and 47 species

of which 39 are constant, 7 ubiquitous and only one accessory. The number of benthic population showed that Beetles are the largest numerically important ecological group (41.94%), followed by odonates with 9.68%, followed by orders from Amphipods and Basommatophores with 6.45%, while other orders represent only 3.22% each." (2019): Insects of Taman Negara Johor Tanjung Piai: A Ramsar site. *Journal of Wildlife and Parks* 34: 53-62. (in English) ["Tanjung Piai, located in Pontian district, forms the southernmost point of mainland Asia. This wetland area has been classified as one of six RAMSAR sites in Malaysia. This study was performed to record the number of insect fauna that can be found in the area. The focus was on three main insect groups: ants, butterflies, and odonates. The collection was conducted using general collection methods, namely baited traps and sweep netting. Overall, 36 species of insects from the three main groups were recorded. Formicidae recorded the highest number of species (21), followed by Odonata with nine species and butterflies with six. The low number of insects collected was due to the comparatively low diversity of vegetation and poor accessibility. The conditions of the waterlogged area limited the sampling collection process. Nevertheless, this is the first attempt to record insect species at Taman Negara Johor Tanjung Piai.... The present assemblage of odonate species sampled from Tanjung Piai shows common flowing stream species; they could be using freshwater bodies around the park as their breeding and foraging ground, as no species are known to live in salty or brackish water. As Tanjung Piai is open to the sea, with relatively few freshwater bodies, the diversity among odonates was also poor. The most common species found in this area were *Orthetrum sabina* and *Orthetrum chrysis*, while there were no signs of damselflies in the area during the survey." (2019): The efficacy of a generalized antipredator defense against a novel predator depends on the source of induction in prey. *Hydrobiologia* 836: 197-205. (in English) ["Ecological naiveté or the failure to recognize a novel enemy is often put forward as a cause of extirpation of biodiversity in newly invaded systems. We tested the efficacy of a generalized antipredator defense, namely reduced activity level, in the tadpoles of *Rhacophorus arboreus* to the threat of the invasive predator red swamp crayfish *Procambarus clarkii* in simplified laboratory environments. We first investigated the behavioral responses of the tadpoles in the presence of caged fed predators (native: dragonfly larvae and newts, and novel *P. clarkii*), and subsequently tested the vulnerability of predator-induced tadpoles to free-ranging predators. The tadpoles reduced activity level in the presence of the native predators but did not recognize the crayfish. Reducing activity level increased survival in the presence of native predators. This behavior was still effective in the presence of crayfish, but survivorship varied with the identity of the native predator from which the tadpoles received induction cues: tadpoles that were previously exposed to dragonfly larvae noticeably survived better than those previously induced by newts. Our findings suggest that naive prey may exploit information from native predators to better resist the threat of novel predators, but not all sources of induction confer the same benefit." **20645.** Rhainds, M. (2019): Ecology of female mating failure/lifelong virginity: a review of causal mechanisms in insects and arachnids. *Entomologia Experimentalis et Applicata* 167: 73-84. (in hermaphroditism, Lampyridae, mating cost, neoteny syndrome, population density effects, precopulatory cannibalism, scaling inversion, sex role reversal, Strepsiptera, wallflowers) ["Sexual reproduction implies binary outcomes of competitive interactions for access to male gametes: lifelong virgin females with null fitness vs. mated females with variable (generally nonzero) fitness. Female mating failure has long remained a dormant concept in sexual selection theory in part because it is acutely maladaptive (lifelong virgins that do not reproduce are strongly selected against) and also due to widespread acceptance of the Bateman–Trivers paradigm (anisogamy and correlated sex roles). Based on recent scientific output on lifelong virginity across multiple taxonomic groups in insects (Coleoptera, Diptera, Hemiptera, Lepidoptera, Odonata, Orthoptera, Strepsiptera), female mating failure has become a mainstay of sexual selection over the last decade. Lifelong virginity and senescence (death) are intertwined processes; old virgin females compensate for increased risk of lifelong virginity by becoming less choosy and increasing investment in mating-related activities. Low rates of female lifelong virginity (<5%) in most natural populations of insects indicate that sex generally 'works' due to selective pressures acting on both males and females to enhance lifetime fitness. Mating failures are most common in insects with female flightlessness; these pressures may lead in evolutionary time to transitional pathways from sexual reproduction to parthenogenesis. Female mating probability is affected by nonlinear density-dependent processes dependent upon the scale of observation (mate-encounter Allee effect at large spatial scales, mating interferences between females at small scales). Mate choice and sex role reversal (females being the active sexual partner) are ubiquitous in insects and arachnids with significant paternal investment, but consequences

in terms of female lifelong virginity remain unknown. Logistically, conceptual development of female mating failure in insects is most limited by the lack of broadly applicable methods to assess rates of lifetime virginity among flighted females." **20646.** Rodrigues, M.E.; Moura, E.B.; Roque, F.O. (2019): Dragonflies as indicators of the environmental conditions of veredas in a region of Central-Western Brazil. *Oecologia Australis* 23(4): 969-978. (in English) ["Veredas (palm swamps) play a critical role in maintaining the hydrological system and they are considered the cradle of the waters of the Brazilian Cerrado. Currently, veredas are suffering intense human pressure due to the conversion of native landscapes for other land uses as agriculture, pasture and urban environments. Few studies have evaluated the biodiversity of veredas and the current effects of human impact, especially on aquatic communities. Odonata have excelled as bioindicators of environmental quality and they are increasingly used in environmental monitoring programs. In this study, we evaluate whether loss of riparian vegetation around the vereda areas alters the communities of Odonata and whether the species can be considered bioindicators of these environmental conditions. Our hypothesis is that eco-physiological and behavioral characteristics, such as thermoregulation capacity and oviposition behavior, influence the persistence of species in communities in natural or altered environments. We sampled 25 veredas and classified them into two groups, namely "preserved riparian vegetation" (VRP), when the riparian vegetation surrounding the sampled stretch was 30 meters or more, and "altered riparian vegetation" (VRA), when the vegetation extended for less than 30 meters from at least one of the banks. Our results showed that the composition of the communities in areas classified as VRP was more similar to each other and different from the communities found in the areas classified as VRA. Of the 52 species observed, 11 species responded as indicators for preserved or altered riparian vegetation. Of these species, four were indicative of areas with preserved riparian vegetation and seven were indicative of veredas with altered riparian vegetation. Our results show that the composition of dragonflies and damselflies, and some taxa in particular may be potential indicators of the condition of veredas, and may, therefore, be included in vereda monitoring programs in Central-Western Brazil." **20647.** Sinaei, M.; Loghmani, M. (2019): Plankton and aquatic insect biodiversity in the Sarbaz River, Southeastern Iran. *Indian Journal of Geo Marine Sciences* 48(12): 1907-1915. (in English) ["Studying plankton community and determining the trends in river pollution are of great value and importance. In the present work, plankton and aquatic insect community were evaluated in 10 sites along the Sarbaz River in southeastern Iran. Among the species identified, *Navicula* has the highest incidence with five species. The highest frequency and density belongs to the ciliates group. Results indicate that the studied environment has a poor planktonic diversity and density. Results suggested that a decrease in plankton communities could be one of

the factors influencing reductions in mugger crocodile (*C. palustris*) hatchling survival. Moreover, it was found that dominant populations of aquatic insects are susceptible to organic pollutants with tolerating levels of 0 to 4 from Diptera, Ephemeroptera, Trichoptera, Ephemerehidae, Hemiptera, Odonata ["Aeshnidae, Calopterygidae"] orders. Moreover, an increase is noted in the Family Biotic Index (FBI) in downstream sites, suggesting a decrease in water quality compared with other sites." **20649.** Svensson, E.I. (2019): Eco-evolutionary dynamics of sexual selection and sexual conflict. *Functional Ecology* 33: 60-72. (in English) ["1. The research framework of eco-evolutionary dynamics is increasing in popularity, as revealed by a steady stream of review articles and a recent and influential book, but primary empirical research is lagging behind. Moreover, the few empirical case studies demonstrating eco-evolutionary dynamics might not be entirely representative. 2. Much current research on eco-evolutionary dynamics is focused on how ecological interactions lead to natural selection on phenotypic traits "eco-evo", and in turn how the evolutionary change in such traits feed back on ecological dynamics ("evo-eco"). A key feature of eco-evolutionary dynamics is thus a feedback loop between ecology (e.g., population dynamics) and evolution (i.e., genetic change). 3. In contrast to previous research on eco-evolutionary dynamics driven by natural selection, the role of eco-evolutionary feedbacks in sexual selection and sexual conflict is largely unknown. Here, I review theory and the limited empirical evidence in this area and identify some promising future lines of research. 4. I update a past review on contemporary evolution of secondary sexual traits in natural populations and formulate six explicit and rigorous criteria for contemporary evolution of secondary sexual traits by natural or sexual selection or sexual conflict. I then discuss the other key prediction of eco-evolutionary dynamics (i.e., evolution by sexual selection or sexual conflict shapes ecological dynamics). My overview reveals that our current knowledge in this area is limited and mainly come from theoretical models and laboratory experiments. 5. A major challenge in eco-evolutionary dynamics is therefore to link ecological and population dynamics with sexual selection and sexual conflict. This is not an easy task but might be possible with carefully chosen study systems and methods." **20651.** Weathered, J.; Hammill, E. (2019): Adaptation to agricultural pesticides may allow mosquitoes to avoid predators and colonize novel ecosystems. *Oecologia* 190(1): 219-227. (in English) ["Human activities such as the application of agrochemicals may detrimentally disturb natural ecosystems, generating novel selection pressures. Here we examine how pesticides may influence community composition using the aquatic communities within bromeliad phytotelmata, and how adaptive responses to pesticides may influence community-level patterns. We first quantified the composition of macroinvertebrate communities from pesticide-free and pesticide-exposed locations. Complementary manipulative experiments where bromeliads were transplanted between pesticide-free and pesticide-exposed sites were then performed. Finally, pesticide bioassays on the most common predators (*Mecistogaster modesta* damselflies) and prey (*Wyeomyia abebela* mosquitoes) assessed a potential evolutionary mechanism that may influence community compositional differences. Our field survey revealed differences in *W. abebela* and *M. modesta* abundances between pesticide-free and pesticide-exposed areas. Our transplant experiment suggested compositional differences were not due to physical differences between bromeliads from different locations. Pesticide bioassays revealed that *M. modesta* from pesticide-free locations had higher innate pesticide tolerances than *W. abebela* from pesticide-free areas, but *M. modesta* larvae showed no evidence of adapted resistance as none were found where pesticides were used. Conversely, *W. abebela* larvae from pesticide-exposed locations had higher pesticide tolerances than individuals from pesticide-free sites, suggesting an adaptive response. This evolved resistance to pesticides may, therefore, allow *W. abebela* to colonize habitats free of the dominant predator in the system, explaining the higher *W. abebela* abundances in pesticide-exposed areas than in pesticide-free locations. We suggest that the total effect of novel stressors is driven by interactions between ecological and evolutionary processes." (Authors)] Address: Hammill, E., Dept Watershed Scienc. & Ecol. **20652.** Zou, P.-Y.; Lai, Y.-H.; Yang, J.-T. (2019): Effect of phase lag on hovering flight of damselflies and dragonflies. *Physical Review E* 100, 063102: 14 pp. (in English) ["In this work we studied the differences in flight kinematics and aerodynamics that could relate to differences in wing morphologies of a dragonfly and a damselfly. The damselflies and dragonflies normally fly with the fore wing or hind wing in the lead, respectively. The wing of the damselfly is petiolate, which means that the wing root is narrower than that of the dragonfly. The influence of the biological morphology between the damselfly and the dragonfly on their hovering strategies is worthy of clarification. The flight motions of damselflies and dragonflies in hovering were recorded with two high-speed cameras; we analyzed the differences between their hovering motions using computational fluid dynamics. The distinct mechanisms of the hovering flight of damselflies (*Matrona cyanoptera*) and dragonflies (*Neurothemis ramburii*) with different phase lags between fore and hind wings

were deduced. The results of a comparison of the differences of wing phases in hovering showed that the rotational effect has an important role in the aerodynamics; the interactions between fore and hind wings greatly affect their vortex structure and flight performance. The wake of a damselfly sheds smoothly because of slender petiolation; a vertical force is generated steadily during the stage of wing translation. Damselflies hover with a longer translational phase and a larger flapping amplitude. In contrast, the root vortex of a dragonfly impedes the shedding of wake vortices in the upstroke, which results in the loss of a vertical force; the dragonfly hence hovers with a large amplitude of wing rotation. These species of Odonata insects developed varied hovering strategies to fit their distinct biological morphologies." **20653.** Aksenova, O.V.; Potapov, G.S.; Bepalaya, Y.V.; Kolosova, Y.S.; Vikhrev, I.V.; Kondakov, A.V.; Gofarov, M. Yu.; Bolotov, I.N. (2020): Dragonflies from hot springs in Russia with a country-level checklist of species known to occur in geothermal environments. *Ecologica Montenegrina* 34: 49-63. (in English) ["Geothermal springs are known to harbor unusual assemblages of Odonata worldwide. A review of original records and the body of available literature revealed that 27 Odonata species were recorded from hot springs in Russia so far and that the successful larval development in geothermal environments was discovered for 17 species. Among them, four species exclusively inhabit hot springs, i.e. *Mnais costalis*, *Anotogaster sieboldii*, *Orthetrum melania* (Kunashir Island), and *O. albistylum* (Eastern Siberia). In Russia, these southern species are unable to develop beyond geothermally heated water bodies due to cold climate, and they exist as local geothermal populations there. Here, we report on several novel records of Odonata species from geothermal springs in eastern Russia. Four species were recorded on the Kunashir Island (Kurile Archipelago): *Mnais costalis* (adults), *Anotogaster sieboldii* (adults and larvae), *Orthetrum melania* (adults), and *Symphetrum pedemontanum elatum* (adults and larvae). Two species were found in the Kamchatka Peninsula, i.e. *Libellula quadrimaculata* (freshly emerged imago and exuvia) and *Aeshna juncea* (larvae). To explain the origin of isolated geothermal populations of Odonata, three alternative hypotheses can be proposed as follows: (1) pre-glacial relicts; (2) mid-Holocene relicts (since the Holocene Climate Optimum); and (3) recent (late Holocene) populations founded by long-distance dispersal events. These scenarios are yet to be tested by means of a molecular approach." (Authors)] Address: Potapov, G.S., N. **20655.** Baeta, R.; (ANEPE CAUDALIS) (2020): Suivi diachronique des populations ligériennes de *Stylurus flavipes* et d'*Ophiogomphus cecilia* en région Centre Val-de-Loire (Saison 2019 – Cinquième année de suivi à l'échelle régionale). Association Naturaliste d'Étude et de Protection des Écosystèmes CAUDALIS / DREAL Centre Val de Loire: 17 pp. (in French) ["In 2019, the 43 grids surveyed are spread over more than 300 km of the Loire and correspond to a cumulative surveyed length, all sessions combined, of 35 km of banks. The regional database for the 2019 season thus contains information on 6,501 exuviae collected and identified, of which 6,496 concern three species (Fig. 2). On the scale of the grids *Onychogomphus forcipatus* was contacted on 42 of the 43 grids surveyed, *Ophiogomphus cecilia* on 36 and *Stylurus flavipes* on 6. The very sharp decline observed in this species in 2018 (Baeta, 2018) has therefore continued in 2019. At this stage, it is becoming relatively worrying. The differences between species are even more marked if we look at the transects. Thus, only 8 out of 521 transects (1.5%) were validated for *Stylurus flavipes*, whereas 126 were validated for *Ophiogomphus cecilia* (24%) and 340 for *Onychogomphus forcipatus* (65%). However, these relative abundances vary between Depts (Fig. 3) and depend on the upstream-downstream position of the surveyed grids (see maps in the appendix). A summary of the raw data collected by ANEPE Caudalis on the 8 grids monitored in Indre-et-Loire in 2019 is presented in the appendix in the form of 2 tables (Tab. SI & SII). All the data have been transferred in SINP format to the DREAL Centre Val de Loire." **20656.** Bogan, M.T.; Eppehimer, D.; Hamdhani, H.; Hollien, K. (2020): If you build it, they will come: rapid colonization by dragonflies in a new effluent-dependent river reach. PeerJ 8:e9856 <https://doi.org/10.7717/peerj.9856>: 19 pp. (in English) ["Background: Aquatic ecosystems are greatly altered by urban development, including the complete loss of natural habitat due to water diversions or channel burial. However, novel freshwater habitats also are created in cities, such as effluent-dependent streams that rely on treated wastewater for flow. It is unclear how diverse these novel ecosystems are, or how quickly aquatic species are able to colonize them. In this study, we (1) quantify odonate (Insecta, Odonata) colonization of a novel effluent-dependent river reach, (2) examine how drying events affect odonates in these novel habitats, and (3) explore whether effluent-dependent streams can support diverse odonate assemblages. Methods: We conducted monthly odonate surveys at three sites along the Santa Cruz River (Tucson, AZ, USA) between June 2019 and May 2020. One site was in a long-established effluent-dependent reach (flowing since the 1970s) that served as a reference site and two sites were in a newly-established reach that began flowing on June 24, 2019 (it was previously dry). We compared odonate species richness, assemblage composition, and colonization patterns across these reaches, and examined how these factors responded to flow cessation events in the new reach. Results: Seven odonate species were observed at the study sites in the new reach within hours of flow initiation, and species rapidly continued to arrive thereafter. Within 3

months, species richness and assemblage composition of adult odonates were indistinguishable in the new and reference reaches. However, drying events resulted in short-term and chronic reductions in species richness at one of the sites. Across all three sites, we found over 50 odonate species, which represent nearly 40% of species known from the state of Arizona. Discussion: Odonates were surprisingly diverse in the effluent-dependent Santa Cruz River and rapidly colonized a newly established reach. Richness levels remained high at study sites that did not experience drying events. These results suggest that consistent discharge of high-quality effluent into dry streambeds can be an important tool for promoting urban biodiversity. However, it remains to be seen how quickly and effectively less vagile taxa (e.g., mayflies, caddisflies) can colonize novel reaches. Effluent-dependent urban streams will always be highly managed systems, but collaboration between ecologists and urban planners could help to maximize aquatic biodiversity while still achieving goals of public safety and urban development." **20658.** Figueiró, R.; Silva dos Santos, S.; Docile, T.N.; Rodrigues da Costa, T.; Ferreira, C.; Gil-Azevedo, L.H. (2020): Preliminary observations on the patterns of co-occurrence of Black fly (Diptera: Simuliidae) larvae and some of their potential macroinvertebrate predators. Revista Brasileira de Entomologia 64(3) São Paulo 2020 Epub Sep 04, 2020: 6 pp. (in English) ["Biotic factors such as predation, although important drivers of the black fly community, are rarely investigated in the literature. This study aimed to test the hypothesis that the patterns of co-occurrence of black fly larvae and its potential predators is not random and that there is a correlation between its frequencies and Simuliidae larvae abundances. Larvae were sampled from two localities in the Pedra Branca State Park, Rio de Janeiro, Brazil, during the dry season in June 2018. We collected *Simulium pertinax* Kollar, 1832, *Simulium subpallidum* Lutz, 1910, *Simulium* (*Inaequalium*) sp., *Simulium* (*Psaroniocompsa*) sp. and *Simulium* (*Trichodagmia*) sp. The predators families present were Perlidae, Hydropsychidae, Leptoceridae, Libellulidae and Chironomidae. The null models showed that species co-occurred significantly more than expected by chance. The canonical correlation analyses for the Vargem Grande and Pau da Fome areas area showed a significant relationship between black fly abundances and predator abundances. In Vargem Grande the abundance of Chironomidae showed a highly significant positive correlation to *S.* (*Psaroniocompsa*) sp., while Hydropsychidae was significantly correlated to

Simulium sp. On the other hand, in Pau da Fome Libellulidae was significantly correlated to *S. (Psaroniocompsa)* sp. and Simulium sp. and Chironomidae correlated significantly to Simulium sp. The result is consistent with what would be expected of organisms that exercise mutual population regulation, although other factors than biotic interactions may be causing these patterns. However the lack of mechanistic evidences on the effect of biotic interactions on black fly populations pose a challenge on the understanding of these patterns." **20659.** Haring, E.; Fischer, I.; Sittenthaler, M.; Chovanec, A.; Szucsich, N.; Sattmann, H.; Wolf, P. (2020): Die Libellenfauna Wiens: Erhebungen und Erfassung mittels DNA-Barcoding unter besonderer Berücksichtigung der FFH-Arten Cordulegaster heros und Leucorrhinia pectoralis. Endbericht zum LE-Projekt: 63 pp. (in German) ["The subject of the project was the survey and recording of the dragonfly fauna in the rural areas of Vienna. Both traditional survey methods and molecular genetic methods (DNA barcoding, environmental DNA barcoding) were used. In the course of the surveys, a total of 95 sites at 42 water bodies were investigated. In the process, 48 dragonfly species were detected, which corresponds to 77% of the Viennese and 62% of the Austrian dragonfly fauna. Particularly noteworthy is the first record of *Leucorrhinia albifrons* for Vienna. The species is "threatened with extinction" in Austria and was detected in the Lobau. Of the 48 species, 26 are listed in endangerment categories according to the Austrian Red List. Five of the detected species are listed in the Annexes of the Habitats Directive. Special attention was paid to the two Habitats Directive species, *Cordulegaster heros* and *Leucorrhinia pectoralis*. *C. heros* was found at 15 of a total of 17 watercourses surveyed in the Lainzer Tiergarten and Wienerwald, *L. pectoralis* at three of 14 watercourses surveyed in the Lobau. In the course of the surveys, 198 individuals from 45 species were collected. Tissue samples of these animals were used to record species-specific gene segments, so-called DNA barcodes, for the creation of a DNA reference database. Based on this reference database, a molecular genetic identification method for dragonfly exuviae of all Central European dragonfly families was established within the framework of the project and tested with 85 exuviae. For 83 of them it was possible to determine them by means of species-specific DNA barcodes. For the eDNA pilot study, filtrates from 103 water samples served as DNA source. The method was established for the detection of a total of five dragonfly species (*C. heros*, *L. pectoralis*, *Calopteryx virgo*, *Erythromma viridulum* and *Sympetrum sanguineum*). At least one of the five species was detected via eDNA barcoding in 25 of 43 field samples processed in the project." **20662.** Janssens, L.; Stoks, R. (2020): Oxidative stress mediates rapid compensatory growth and its costs. *Functional Ecology* 34(10): 2087-2097. (in English) ["1. While oxidative stress has been hypothesized to function both as a constraint on and a cost of growth, its mediatory role in shaping life history is still highly debated. Empirical studies about the role of oxidative stress in shaping growth responses and the associated costs are scarce and the two hypotheses have never been combined in one study. 2. By directly manipulating oxidative stress we tested its role in determining compensatory growth responses and the associated costs in *Lestes viridis*. We reduced oxidative stress levels using the mitochondrial uncoupler 2,4-dinitrophenol (DNP). To induce a compensatory growth response, half of the larvae in each oxidant treatment was exposed to a transient starvation period, after which food was present ad libitum. 3. As expected, the transient starvation period induced a compensatory growth response, which was associated with increased oxidative damage and costs in terms of performance (reduced escape swimming speed) and physiology (reduced fat content). As expected, DNP exposure reduced oxidative stress and this resulted in the strongest compensatory growth response without any apparent costs and no increase in oxidative damage. 4. By directly downregulating oxidative stress, our results are consistent with the hypothesis that the level of oxidative stress predictably determines the degree of the compensatory growth response and its associated costs. Our data therefore suggest a mediatory role of oxidative stress in shaping life history." (Authors)] Address: Janssens, Lizanne, Debérotstraat 32, 3000 Leuven, Belgium. **20664.** Lamouille-Hébert, M. (2020): Impact du changement climatique sur la future distribution des espèces d'Odonates boréo-alpins: exemple dans la région de Chamonix (Haute-Savoie). Ministère de l'enseignement supérieur et de la recherche École Pratique des Hautes Études, Sciences de la Vie et de la Terre, Mémoire: 113 pp. (in French) ["In the context of the current biodiversity crisis, many species are threatened with extinction or have disappeared due to the degradation or disappearance of their habitats as a result of direct or indirect anthropogenic pressures (developments, discharges). The most vulnerable species are specialists whose habitats are rare and threatened. This is the case for stenothermic species in high altitude wetlands. Climate change is a threat to these isolated species, which, with the displacement of competing eurothermic species, see their habitats colonised by other species and do not always have the capacity to move or the possibility of finding habitats that are favourable to them at higher altitudes. To better understand, anticipate and mitigate the impacts of climate change on specialised mountain species, we studied between 2017 and 2019 in the Chamonix region, the current and future potential distributions of six boreo-alpine Odonata species: *Aeshna caerulea*, *Aeshna juncea*, *Somatochlora alpestris*, *Somatochlora arctica*, *Leucorrhinia dubia* and *Coenagrion hastulatum* in 125 wetlands above 1900 meters. Before studying these distributions, using this sample of wetlands representative of the study area, we demonstrated that only 79% of the high altitude wetlands are known in the area: small wetlands are often missing. Secondly, in order to maximise the probability of detection of species in this sample, we set up and compared different detection methods: three based on morphological identification of species (larva, adult, exuviae) and metabarcoding (environmental DNA analysis method). Combinations of methods have allowed for some species to reach detection probabilities higher than 0.9 or even equal to 1. Based on the detection probabilities and the distribution of known wetlands, we have built models to predict the current and future distributions of the species and to identify areas of conservation concern: the species have the upper limit of their distribution range which potentially rises by an average of 288 metres in altitude between 2020 and 2100 (3.6m/year). The results obtained demonstrate the need for better knowledge and protection of the habitats of rare and threatened specialist species, in order to propose courses of action and monitoring programmes adapted to the species and to high altitude wetlands. Deploying this research by taking into account this group, but also different groups of species that respond differently to environmental constraints, on a larger scale than the Chamonix region, would be necessary for the effective preservation of wetlands and biodiversity at altitude." **20665.** Min, J.-K.; Kong, D.-S. (2020): Distribution patterns of benthic macroinvertebrate communities based on multispacial-scale environmental variables in the river systems

of Republic of Korea. *Journal of Freshwater Ecology* 35(1): 323-347. (in English) ["Understanding the relationship between benthic macroinvertebrates and environmental variables is the first step toward establishing sustainable freshwater ecosystems in terms of biodiversity, and this knowledge can be applied in river management. We analyzed major environmental variables that affect biotic communities on the national scale in the Republic of Korea. To achieve this goal, 2647 sampling stream sites were surveyed from 2016 to 2018 to collect benthic macroinvertebrates and measure 14 environmental variables. We identified a total of 359 taxa, belonging to 32 orders in 9 classes of 5 phyla, most of which were aquatic insects including Ephemeroptera, Odonata, Plecoptera, Coleoptera, Diptera and Trichoptera. Two-way indicator species analysis (TWINSPAN) based on biotic communities divided the sampling sites into six groups. Discriminant analysis identified gradient, streambed substrates, velocity, biological oxygen demand (BOD) and altitude as the major environmental variables that distinguished each TWINSPAN group. In addition, stream order and stream width also influenced aquatic macroinvertebrate communities, but the influence was low. The indicator taxa in each group were gradually changed from sensitive organisms preferring high altitudes, fast velocities and coarse substrates to tolerant organisms preferring low altitudes, slow velocities and fine substrates in each group from one to six. Canonical correspondence analysis confirmed that the composition of benthic macroinvertebrate communities in the Republic of Korea was dependent on stream gradient, microhabitat, organic pollution and geographical feature rather than on stream size or other water quality variables. Our study identified variables affecting the overall distribution patterns of biotic communities on a national scale and provides useful information for conservation and management of stream ecosystems in the Asian monsoon region." **20666.** Nel, A.; Huang, D. (2020): A new genus and species of damsel-dragonfly from the Middle Jurassic of Inner Mongolia (Odonata: Campteroptelebiidae). *Palaeoentomology* 3(4): 357-360. (in English) ["The Campteroptelebiidae is the largest family of fossil damsel-dragonflies, containing more than 60 species described from Lower Jurassic–Lower Cretaceous strata of Europe and Asia. This group is especially diverse in the Middle–Late Jurassic strata in Inner Mongolia, northeastern China, with some very large species (Zhang et al., 2006, 2008, 2013; Nel et al., 2007, 2008, 2009; Petrulevicius et al., 2011; Li et al., 2013; Zhang et al., 2013; Zheng et al., 2016, 2017). Thus it is surprising that we found a new representative of these damsel-dragonflies, belonging to a group of genera characterized by a very particular shape of the forewing cubito-anal area. This fossil has a unique shape of the forewing median vein, allowing its attribution to a new genus and species. It increases our knowledge about the palaeobiodiversity of this impressive group of Odonata." (Authors)] Address: Nel, A., Lab. Ent. Mus. Natn. Hist. Nat., 45 rue Buffon, F-75005 Paris, France. **20667.** Pastorino, P.; Zaccaroni, A.; Doretto, A.; Falasco, E.; Silvi, M.; Dondo, A.; Elia, A.C.; Prearo, M.; Bona, F. (2020): Functional feeding groups of aquatic insects influence trace element accumulation: Findings for filterers, scrapers and predators from the Po basin. *Biology* 9(9), 288: 15 pp. (in English) ["For this study, we measured the concentrations of 23 trace elements (Al, As, Ba, Bi, Cd, Cr, Co, Cu, Fe, Ga, Hg, In, Li, Mn, Mo, Ni, Pb, Se, Sr, Ti, Tl, V, and Zn) in the

whole bodies of three functional feeding groups (FFG) (filterers—Hydropsychidae, scrapers—Heptageniidae, and predators—Odonata) of aquatic insects collected from two sites in the Po basin (Po Settimo and Malone Front, Northwest Italy) to determine: (a) how FFG influence trace element accumulations, (b) if scrapers accumulate higher elements compared to the other FFG, since they graze on periphyton, which represents one of the major sinks of metals, and (c) the potential use of macroinvertebrates to assess the bioavailability of trace elements in freshwater. The hierarchical clustering analysis generated three main groups based on trace element concentrations: the most abundant elements were Fe and Al, followed by Sr, In, Zn, V, Mo, and Cu. Ti was below the limit of detection (LOD) in all FFG. Ga was detected only in scrapers from both sites and Hg only in predators from Po Settimo. The principal component analysis showed that concentrations of Al, As, Bi, Cd, Co, Cr, Ga, Fe, In, Mn, Pb, Ni, and Sr were highest in scrapers, suggesting that trace elements accumulate from the ingestion of epilithic periphyton (biofilm). Odonata (predators) accumulate certain elements (Ba, Hg, Li, Se, V, Ti, and Zn) in higher concentrations by food ingestion composed of different aquatic organisms. Differently, Cu and Mo concentrations were the highest in filterers due to their bioavailability in the water column. Non-metric multidimensional scaling clearly differentiated the FFG based on their ability to accumulate trace elements. The findings from this study represent an important step toward the definition of an innovative approach based on trace element accumulation by macroinvertebrates." **20668.** Pena-Firme, P.; Guillermo-Ferreira, R. (2020): Females of the red damselfly *Mnesarete pudica* are attracted to more ornamented males and attract rival males. *Scientific Reports* 10(14320): 7 pp. (in English) ["Male calopterygid damselflies often exhibit colourful wings used during aggressive contests and courtship displays. Evidence suggests that male wing coloration is a secondary sexual character assessed by males and females to identify male quality. In some species, males adopt a lekking strategy, where females visit exhibition arenas and choose the best mate. Here, we addressed whether the behaviour of *Mnesarete pudica* males is influenced by female visitation when gathering in leks. We hypothesized that female visitation would increase male investment in courtship and fighting, while reducing patrolling flights and harassment attempts. Moreover, we tested the hypothesis that more ornamented males attract more females to the territory, following the hotshot model of lek evolution. Our results suggest that, indeed, males with more pigmented wings attract more visiting females, independently of male size. Our results also show that the number of females in a territory attracts more males and elicits male contest behaviour, reducing male harassment. We conclude that male ornament and male clustering is a good predictor of female visitation rates, suggesting that females may exert mate choice." **20669.** Ptatscheck, C.; Gansfort, B.; Majdi, N.; Traunspurger, W. (2020): The influence of environmental and spatial factors on benthic invertebrate metacommunities differing in size and dispersal mode. *Aquatic Ecology* 54: 447-461. (in English) ["Understanding the drivers of species distribution

is an important topic in conservation biology and ecology, pertaining to species traits like dispersal strategies and species–environment interactions. Here we examined the drivers of benthic species distribution at 20 sections of a second-order stream network. Environmental and spatial factors and the dispersal modes of the organisms were considered. We expected that species with aerial dispersal capabilities like insects would be less restrained by distance between sites and thus mostly affected by environmental factors. In contrast, we hypothesized that completely benthic species would mainly be affected by spatial factors due to limited dispersal. However, microscopic species like nematodes characterized by a high passive dispersal potential may be less limited by spatial factors. When using redundancy analyses and subsequent variance partitioning, the included variables explained 24% (insects), 24% (non-flying macrobenthos), and 32% (nematodes) of the variance in the respective community composition. Spatial factors mainly explained the species composition of all tested groups. In contrast with other larger species, nematodes were characterized by fine-scale patterns that might have been induced by random processes (e.g., random distribution and priority effects). Our study showed that dispersal processes are crucial in shaping benthic communities along streams albeit the relatively small sampling area (max. distance between sampling sites: 2 km). The demonstration of spatial factors as important drivers of the species distribution of passively dispersing benthic organismal groups highlights the role played by connectivity in determining species distribution patterns in river systems." **20670.** Potts, K.M. (2020): Survival and development of larval odonates (Anisoptera) and female oviposition site choice in response to predatory fish. MSc. thesis, Dept of Biology, Univ. of Mississippi: VII + 43pp. (in English) ["The reproductive success of many aquatic insects is highly dependent on where they deposit their eggs. Not all habitats are created equal. Some are more favorable than others for larval development. Therefore it would be evolutionarily advantageous for an ovipositing female to differentiate between them and choose the most suitable for her offspring's survival. Numerous studies have shown that many species with complex life-cycles representing a diverse array of taxonomic groups sort themselves non-randomly among habitat patches on the basis of perceived habitat quality. In the case of dragonflies, insufficient evidence exists to support the hypothesis that this group can assess relevant indicators of patch quality and use those cues to select habitat. I conducted a series of experiments to investigate what effects a predatory fish, the green sunfish (*Lepomis cyanellus*), had on larval dragonfly [*Erythemis simplicicollis*, *Pachydiplax longipennis*] performance and development and adult female habitat selection behavior. Developmental studies were performed to determine the degree of consumptive and non-consumptive effects of *L. cyanellus* and how they affect survival and other fitness correlates of larval dragonflies. I found that larval survival is significantly affected by the presence of uncaged *L. cyanellus*, but not affected by caged *L. cyanellus*. Caged *L. cyanellus* did not have an effect on fitness correlates, suggesting larvae are not capable of detecting fish. I examined whether female dragonflies actively avoid ovipositing in sites containing predatory fish which potentially inflict significant fitness costs via offspring predation. Results indicated that female adults of three common species of dragonflies did not discern between

habitat patches based on the presence or absence of fish predators. This suggests that members of this group either rely on a bet-hedging or risk-spreading strategy, utilize a form of philopatry, or the presence of fish predators may not be an important factor for odonates in oviposition site selection. There is a mismatch between the results of the oviposition and development experiments, suggesting there is much more to learn about how dragonflies select habitat for their offspring, how their decisions affect aquatic community assembly, and how these can be used to inform conservation efforts designed to protect threatened odonate species." (Author)] Address: not stated

**20671.** Senzaki, M.; Kadoya, T.; Francis, C.D. (2020): Direct and indirect effects of noise pollution alter biological communities in and near noise-exposed environments. *Proceedings of the Royal Society B Biological Sciences* 287(1923): 9 pp. (in English) ["Noise pollution is pervasive across every ecosystem on Earth. Although decades of research have documented a variety of negative impacts of noise to organisms, key gaps remain, such as how noise affects different taxa within a biological community and how effects of noise propagate across space. We experimentally applied traffic noise pollution to multiple roadless areas and quantified the impacts of noise on birds, grasshoppers and odonates. We show that acoustically oriented birds have reduced species richness and abundance and different community compositions in experimentally noise-exposed areas relative to comparable quiet locations. We also found both acoustically oriented grasshoppers and odonates without acoustic receptors to have reduced species richness and/or abundance in relatively quiet areas that about noise-exposed areas. These results suggest that noise pollution not only affects acoustically oriented animals, but that noise may reverberate through biological communities through indirect effects to those with no clear links to the acoustic realm, even in adjacent quiet environments." **20672.** Smith, B.D.; Patten, M. (2020): Dragonflies at a biogeographical crossroads. *The Odonata of Oklahoma and complexities beyond its borders*. eBook Published 15 June 2020, Pub. location Boca Raton, Imprint CRC Press: 748 pp. (in English) ["This lavishly illustrated book examines the distribution, ecology, conservation status, and biogeography of 176 species of dragonflies in the southern plains of the United States, where twelve ecoregions converge. The topics discussed, such as phenotypic variation and ecology, are applicable and of interest across the United States and much of north America, and will appeal to researchers and dragonfly enthusiasts alike. A series of maps, including a distributional map by specific locality of occurrence, indicate level of documentation and allow the reader to visualize the biogeographical associations of a given species. These maps also encourage citizen scientists to contribute documentation wherever they spend time in the field. Context-driven chapters, including one on the region's rich paleontological history, blend environmental history and biogeography, giving the book a fresh perspective on the natural world while providing a rich summary of the odonates. This book will be sought out by dragonfly researchers and enthusiasts, entomologists, amateur naturalists, paleontologists, conservation biologists, educators, regional historians, and those seeking to meld the disciplines of cultural and environmental history with biology. It will also be readily accessible to

the lay public. Dragonflies combine the visually stunning with acrobatic fireworks in ways no other insect can hope to combine. Table of contents: Introduction. History of Oklahoma Odonatology. Oklahoma Geography and Habitats. Biogeography of Oklahoma Odonata. The Odonata Fossil History of Oklahoma and the Region. Environmental History of Oklahoma. Conservation of Oklahoma Odonata. Seasonality of Oklahoma Odonata. Introduction to Species Accounts. Species Accounts. Zygoptera – Damselflies. Calopterygidae – Broad-winged Damsels. Lestidae – Spreadwings. Coenagrionidae – Pond Damsels. Anisoptera – Dragonflies. Petaluridae – Petaltails. Aeshnidae – Darners. Gomphidae – Clubtails. Cordulegastridae – Spiketails. Macromiidae – Cruisers. Corduliidae – Emeralds. Libellulidae – Skimmers. Appendices. A. Synonyms, Dubious Records, and Hypothetical Species. B. List of Specimen Collections, Data Sources, and Record Contributors. C. **20673.** Srivastava, D.S.; Ware, J.L.; Ngai, J.T.; Starzomski, N.M.; Amundrud, S.L. (2020): Habitat size thresholds for predators: Why damselflies only occur in large bromeliads. *Biotropica* 52(6): 1030-1040. (in English) ["Predators are often more sensitive to habitat size than their prey and frequently occur in only the largest habitats. Four explanations have been proposed for this pattern: (a) Small habitats do not have enough energy to support higher trophic levels; (b) small habitats are less likely to contain particular prey required by specialist predators; (c) small habitats are risky for predators with slow life histories or large body sizes; and (d) small habitats are numerically unlikely to be colonized by regionally rare species, such as predators. We critically examine these four hypotheses in relation to the predatory damselfly larva, *Mecistogaster modesta* Selys. (Pseudostigmatidae), which occurs almost exclusively in bromeliads > 100ml in capacity. We synthesize multiple years of survey data and three manipulative experiments from the Área de Conservación Guanacaste, Costa Rica, to conclude that damselflies do not occur in small bromeliads due to their higher risk of desiccation—not because of energetic limitation, trophic specialization, risk of terrestrial predation, or pure numerical effects. These results suggest that recent and predicted declines in precipitation in northwestern Costa Rica may further restrict bromeliad occupancy by damselflies, with cascading consequences for the rest of the aquatic food web." **20674.** Subramanian, K.A.; Babu, R. (2020): 3. Dragonflies and Damselflies. In: S Ramani, Prashanth Mohanraj, Yeshwanth HM (eds.): *Indian Insects: Diversity and Science*: 29-46. (in English) ["Order Odonata, popularly known as dragonflies and damselflies, are primarily associated with wetlands and surrounding landscape. Dragonflies lay broad and elliptical eggs either in flight or by perching on an overhanging vegetation or rock. In dragonflies, the inner surface of the rectum is foliate and richly supplied by tracheae. Dragonflies are very popular in folklore and stories from time immemorial in different Indian cultures. Adult dragonflies are aerial predators and catch small insects like mosquitoes, midges, small butterflies, moths, and bees on wing. Dragonflies

capture their prey by perching at a vantage point and making short sallying flights or by flying continuously. The last abdominal segments of the male have claspers, which are used to hold the female by the posterior side of head in the case of dragonflies and by prothorax in damselflies. Dragonflies found at undisturbed habitats with good riparian vegetation were specialists with narrow distribution." **20676.** Bancila, R.I.; Plaiasu, R.; Stanescu, F.; Schmidt, B.; Nae, I.; Denoël, M. (2021): Food level and light conditions affect the antipredator behavior in larvae of a stream-breeding amphibian. Behavioral Ecology and Sociobiology 75, Article number: 36 (2021): (in English) ["Understanding how long-term changes in environmental conditions influence the way that individuals cope with threats is essential in the context of behavioral adaptation to a rapidly changing world. However, little is known about the behavioral responses to predation risk for individuals that experienced different environmental conditions for extended periods of time, such as food levels and light conditions. In this experimental study, we tested whether previous long-term exposure to different food levels (low versus high) and light conditions (0-hour light versus 8-hour light) play a significant role in shaping the antipredator response (i.e., the probability of emerging from the refuge and the distance moved) to stimuli from caged larval dragonflies, in larvae of the fire salamander (*Salamandra salamandra*). Specifically, we quantified behavioral differences in the response to predation risk in larval salamanders that were reared in the laboratory for two months under controlled food and light conditions. The results of this study showed that the interaction between food level and light conditions affected the antipredator behavior of the larvae. Fire salamander larvae maintained at low food levels and in 8-hour light conditions emerged from the refuge with a higher probability (i.e., took more risk) than larvae maintained at high food levels and all other combinations of light conditions. Thus, our results highlight the complexity of antipredator responses, pointing attention to the fact that interactions among environmental factors are likely to determine the magnitude of antipredator response." **20677.** Batista, J.D.; Ferreira, V.R.S.; Cabette, H.S.R.; de

Castro, L.A.; De Marco, P.; Juen, L. (2021): Sampling efficiency of a protocol to measure Odonata diversity in tropical streams. PLoS ONE 16(3): e0248216. <https://doi.org/10.1371/journal.pone.0248216>: 18pp. (in English) ["Odonata can be sampled following different types of protocols. In Brazil, the most used protocol is the scanning in fixed areas method, where a 100-meter transect is delimited in one of the stream margins, subdivided into 20 segments measuring 5 meters. Despite being universally used, the methodological efficiency or limitations of this protocol for Odonata has never been tested. In this scenario, our objective was to assess the efficiency of the sampling protocol to measure the richness and composition of Odonata in three fundamental aspects: the time of sampling and sampling effort over time and space. We show that the best sampling efficiency was achieved in collections performed at noon, in transects measuring 100 meters, requiring at least two samplings in the same location, supporting the procedures traditionally adopted by many studies with the group. While comparing species composition, we did not see any implication between the different treatments on the capture of the local species pool. However, we highlight and discuss some possible methodological flaws when using this protocol to sample specific Odonata groups. We believe the results obtained are fundamental in the inventory of species and to conduct future studies, as well as to aid conservative measures that use the order Odonata as a tool for environmental monitoring." **20678.** Bizarro, G.L.; Périco, E.; Dalzochio, M.; Liberato da Silva, G.; Ferla, N.J. (2021): Aquatic larval of the genus *Arrenurus* (Trombidiformes: Parasitengonina: Arrenuridae) associated with Odonata species from Pampa Biome, Brazil. Biota Neotropica 21(2). e20201157: 7 pp. (in English, with Portuguese summary) ["Many studies have reported that the interaction between water mite larvae and their Odonata hosts affects mating success, flight, and longevity. Males and females of Odonata species collected in the steppes and coastal plains (Pampa Biome) of Rio Grande do Sul were analyzed. Mites were removed when present and the prevalence and intensity of parasites was calculated. The aim of this study was to search and report new Odonata hosts species that are parasitized by water mite larvae and also to evaluate the prevalence and intensity rates; the differences in mite occurrence and frequency between males and females, and between thorax and abdomen of the dragonflies and damselflies in the southern Pampa biome located in Rio Grande do Sul. A total of 162 larval mites were found associated to two Odonata families: Coenagrionidae (*Acanthagrion lancea* Selys, 1876, *Ischnura capreolus* Hagen, 1861 and *Ischnura fluviatilis* Selys, 1876) and Libellulidae (*Micrathyrina ocellata* Martin, 1897 and *Perithemis mooma* Kirby, 1889). All mites were identified as *Arrenurus* (*Arrenurus*) sp. (*Arrenuridae*) and showed high numbers when attached to *I. capreolus* (55.5%), *I. fluviatilis* (33.3%), followed by low numbers on *M. ocellata* (6.1%), *A. lancea* (3.7%), and *P. mooma* (1.2%). Mites were found on males and females of *I. capreolus* and *I. fluviatilis*, females of *A. lancea* and *P. mooma* and in *M. ocellata* only in males. As the parasitized Odonata species are generalist and abundant in all water body types, traits associated with mating and oviposition or larval behavior are believed to explain the frequency of parasitism in these species." **20680.** Brasil, L.S.; Ferreira, V.R.S.; Resende, B.O.; Juen, L.; Batista, J.D.; Castro, L.A.; Giehl, N.F.S. (2021): Dams change beta diversity of aquatic communities in the Veredas of the Brazilian Cerrado. *Front. Ecol. Evol.* 9:612642. doi: 10.3389/fevo.2021.612642: (in English) ["The veredas are wetland ecosystems responsible for supplying most of the water for rivers and streams in the Cerrado. The veredas' hydromorphic soils retain a large amount of rainwater, releasing it slowly during drier periods. Therefore, these habitats are often used to build dams for cattle raising. Here we assessed the environmental conditions and beta-diversity of Odonata and Heteroptera on veredas impacted by dams in the Brazilian Cerrado. We sampled biological communities and a set of environmental variables in 13 veredas, six with dams and seven without dams. One limnological variable [oxidation-reduction potential (ORP)] and one landscape metric (% of the altered area) differed among veredas with and without dams. These variables were important predictors of the beta-diversity of both Odonata ( $R^2 = 0.650$ ;  $p < 0.001$ ) and Heteroptera ( $R^2 = 0.740$ ;  $p < 0.001$ ). The veredas stand among the most sensitive wetland ecosystems of the Cerrado. In this study, we show, for the first time, that veredas with dams may lose environmental quality resulting in changes in biological communities, especially ecologically unique species. Because the Cerrado naturally goes through approximately 5 months of severe drought, the veredas are critical for the Cerrado's hydric safety. Therefore, we recommend that cattle-raising activities should rely on artificial water tanks instead of using dams for water storage since it affects ecologically unique species in this poorly known ecosystem." (Authors)] Address: Brasil, L.S., Laboratório de Ecologia e Conservação, Instituto de Ciências Biológicas, Universidade Federal do Pará, Belém, Brazil.

**20681.** Brito, J.P.; Carvalho, F.G.; Juen, L. (2021): Response of the zygopteran community (Odonata: Insecta) to change in environmental integrity driven by urbanization in eastern Amazonian streams. *Ecologies* 2021, 2(1): 150-163. ["The accelerated and disordered growth of large urban centers has caused a significant loss of biodiversity and the negative effects are more significant in aquatic environments. Thus, the objective of this study is to assess the effects of environmental change due to urbanization in the abundance and biomass patterns of species belonging to the Zygoptera suborder. We tested the hypothesis that, in altered streams, there will be a predominance of organisms with fast growth and small biomass (*r*-strategists), and intermediate streams will have an overlapping of *r* and *k*-strategists. In control streams, there will be a predominance of *k*-strategists, with

slow growth, decreased abundance, and high biomass. Urban expansion in Amazonian streams will cause loss of Zygoptera species richness. Streams draining urban areas will have higher air temperatures than control streams. Thus, small-sized and less abundant species will be favored. We sampled 15 streams in the metropolitan area of Belém. Sites were classified, using the index of physical habitat integrity, as control, intermediate and altered. Comparisons between biomass and abundance were analyzed using *W* Statistics. Our analyses showed that: the effects of urbanization cause loss of *k*-strategists and favors *r*-strategists, once abundance was placed above biomass; in intermediate environments, contrary to what we expected, there was no overlapping of strategies, once *r*-strategists were also placed above *k*-strategists; in control environments, biomass was placed above abundance, suggesting these environments have a predominance of *k*-strategist species, as we suggested; and we observed increased levels of temperature favor the most abundant species, the ones having generalist biological mechanisms; however, contrary to what we expected, there was no difference in richness. With these results, we reinforce the need for public policies to create or maintain the riparian forest along streams running through urban areas and create or maintain urban parks." **20683.** Castillo-Pérez, E.U.; Nava-Bolaños, A.; Rocha-Ortega, M.; Córdoba-Aguilar, A. (2021): Does heat tolerance explain female polymorphism in damselflies? *Journal of Insect Behavior* 34: 41-48. (in English) ["Morphological variation is widespread, and one case is that of female morphs in damselfly insects. Current knowledge indicates that these female morphs are maintained by a fitness balance whereby male-like, clear-colored females (i.e. andromorphs) are more likely to "escape" from male harassment given their male mimicking compared to dark females (i.e. gynomorph). However, males can learn to distinguish the more frequent morph, leading to a frequency-dependent selection. Alternative to frequency-dependent selection, we tested whether temperature plays a role in driving female morph activity and survival. We used *Ischnura denticollis* damselflies to test for differences between female morphs and males in: (a) daily activity; (b) time to resume activity following a chilling event (10°C); and, (c) survival at 30, 35 and 40°C. There was no difference in activity among groups after a chilling event. However, gynomorph females were more active early in the day (ca. 17°C) and less active by 1600 hrs (after reaching 32°C), and had lower thermal tolerance than andromorph females. Thus, high temperatures may act against gynomorph females. This implies a role for high temperatures in the maintenance of female polymorphism." **20688.** Deacon, C.; Samways, M.J. (2021): A review of the impacts and opportunities for African urban dragonflies. *Insects* 2021, 12(3), 190; <https://doi.org/10.3390/insects12-030190>: 15 pp. (in English) ["Simple Summary: The expansion of urban areas in combination with climate change places

great pressure on species found in freshwater habitats. Dragonflies are iconic freshwater organisms due to their large body sizes and striking coloration. They have been widely used to indicate the impacts of natural and human-mediated activities on freshwater communities, while also indicating the mitigation measures required to ensure their conservation. Here, we review the major threats to dragonflies in southern Africa, specifically those in urban areas. We also provide information on effective mitigation measures to protect dragonflies and other aquatic insects in urban spaces. Using three densely populated areas as case studies, we highlight some of the greatest challenges for dragonflies in South Africa. More importantly, we give a summary of current mitigation measures which have maintained dragonflies in urban spaces. In addition to these mitigation measures, public involvement and raising awareness contribute greatly to the common cause of protecting dragonflies around us. Abstract: Urban settlements range from small villages in rural areas to large metropolises with densely packed infrastructures. Urbanization presents many challenges to the maintenance of freshwater quality and conservation of freshwater biota, especially in Africa. There are many opportunities as well, particularly by fostering contributions from citizen scientists. We review the relationships between dragonflies and urbanization in southern Africa. Shifts in dragonfly assemblages indicate environmental change, as different species are variously sensitive to abiotic and biotic water and bank conditions. They are also conservation umbrellas for many other co-occurring species. Major threats to southern African dragonflies include increasing infrastructure densification, frequent droughts, habitat loss, pollution, and invasive alien vegetation. Mitigation measures include implementation of conservation corridors, maintenance of healthy permanent ponds, pollution reduction, and removal of invasive alien trees. Citizen science is now an important approach for supplementing and supporting professional scientific research." **20691.** Dudaniec, R.Y.; Carey, A.R.; Svensson, E.I.; Hansson, B.; Yong, C.J.; Lancaster, L.T. (2021): Latitudinal clines in sexual selection, sexual size dimorphism, and sex-specific genetic dispersal during a poleward range expansion. *Journal of Animal Ecology* 91(6): 1104-1118. (in English) ["1. Range expansions can be shaped by sex differences in behaviours and other phenotypic traits affecting dispersal and reproduction. 2. Here, we investigate sex differences in morphology, behaviour and genomic population differentiation along a climate-mediated range expansion in *Isochnura elegans* in northern Europe. 3. We sampled 65 sites along a 583 km gradient spanning the *I. elegans* range in Sweden and quantified latitudinal gradients in site relative abundance, sex ratio and sex-specific shifts in body size and mating status (a measure of sexual selection). Using single nucleotide polymorphism (SNP) data for 426 individuals from 25 sites, we further investigated sex-specific landscape and climatic effects on neutral genetic connectivity and migration patterns. 4. We found evidence for sex differences associated with the *I. elegans* range expansion, namely (1) increased male body size with latitude, but no latitudinal effect on female body size, resulting in reduced sexual dimorphism towards the range limit, (2) a steeper decline in male genetic similarity with increasing geographic distance than in females, (3) male-biased genetic migration propensity, and (4) a latitudinal cline in migration distance (increasing migratory distances towards the range margin), which was stronger in males. Cooler mean annual temperatures towards the range limit were associated with increased resistance to gene flow in both sexes. Sex ratios became increasingly male-biased towards the range limit, and there was evidence for a changed sexual selection regime shifting from favouring larger males in the south, to favouring smaller males in the north. 5. Our findings suggest sex-specific spatial phenotype sorting at the range limit, where larger males disperse more under higher landscape resistance associated with cooler climates. The combination of latitudinal gradients in sex-biased dispersal, increasing male body size, and (reduced) sexual size dimorphism should have emergent consequences for sexual selection dynamics and the mating system at the expanding range front. Our study illustrates the importance of considering sex differences in the study of range expansions driven by ongoing climate change." **20692.** Eh Rak, A.; Salam, M.A.; Omar, S.A.S.; Daliman, S.; Mat Nazari, N.N.I.; Azlan, A. (2021): Benthic macroinvertebrates diversity and composition at Lata Janggut Recreational Area, Kelantan, Malaysia. *Serangga* 26(4): 30-41. (in English) ["Lata Janggut is a public-focused recreational area with a high possibility of changes in biodiversity involving benthic macroinvertebrates, reflecting the water quality and health of Lata Janggut itself. Therefore, this study was carried out to determine the river health and water quality of Lata Janggut using benthic macroinvertebrates through common biotic indices. Benthic macroinvertebrates were collected monthly at nine points from three stations, i.e. three points at down-stream (ST1), middle-stream (ST2) and up-stream (ST3), respectively. The sampling protocols have followed Karr's Aquatic Insect Stream Sampling Protocol. The benthic macroinvertebrates were identified based on key identification published by Thorp and Covich, Gooderham and Tsyrlin Mekong River Commission (MRC). Biological Monitoring Working Party (BMWP) index, Family Biotic Index (FBI), and Ephemeroptera, Plecoptera and Tri-

choptera (EPT Index) were used as biotic indices, and Mann-Whitney U was also used as a comparison test of macroinvertebrates compositions. A total of 4037 macroinvertebrates, comprising eight orders, 32 families, and 31 genus, were recorded. These include the order of Ephemeroptera, Plecoptera, Trichoptera, Coleoptera, Diptera, Hemiptera and Odonata. It shows that ST2 (U=73, P=0.05) and ST 3(U=88.5, P=0.02) were significantly higher in compositions than ST1. Apart from that, the benthic macroinvertebrate composition during March was significantly higher than compositions during April to July (U.10, P<0.05). Biotic indices indicate that ST1 has recorded Moderate BMWP (21.0-58.0), Excellent FBI (1.43-3.61) and Fair EPT Index (4-12), while ST2 has recorded Clean BMWP (31-67), Excellent FBI (1.69-3.69) and Fair EPT Index (5-13). Thus, ST2 has recorded a better biotic index value as compared to ST1. Nonetheless, ST3 has recorded Moderate BMWP (31-56), Excellent FBI (1.79-3.53) and Fair EPT Index (5-8). Overall, the biotic indices measured in Lata Janggut have indicated moderate disturbance, river health, and water quality, specifically downstream with high recreational activities." **20693.** Fekete, J.; Buchner, D.; Leese, F.; Padisák, J.; Várbiro, G. (2021): Application of eDNA method in the detection of *Cordulegaster* (Insecta: Odonata) species. *ARPHA Conference Abstracts 4: e65041: 1-2.* (in English) [Verbatim: The aim of this pilot study was to investigate the potential of eDNA techniques to detect the presence of the two dragonfly species *Cordulegaster heros* and *Cordulegaster bidentata*. Both species are classified as "near threatened" according to the IUCN Red List and are strictly protected in several countries. Monitoring these species with traditional sampling methods is often difficult, time-consuming and invasive. In this pilot study, we first collected tissue samples from *C. heros* and *C. bidentata* to sequence the traditional DNA-barcode gene fragment COI. We then collected further dragonfly COI sequences from BOLD to design species-specific primers. This, however, was impossible given the enormous variability of COI. Therefore, we refrained from species-specific eDNA assays and followed eDNA metabarcoding protocol using universal (BF2/BF2) and a newly designed dragonfly specific primer. For the evaluation of the method, we took water samples from places where *Cordulegaster* specimens are known to occur. After the extraction, we used two sequential PCR steps for obtaining the desired amplicon (two-step PCR) using universal primers in the first step, and group (dragonfly) specific primers or universal primers. Amplicons were sequenced on an Illumina MiSeq platform and then analysed the data with the JAMP pipeline. With the newly designed primers and we could effectively detect the targeted dragonfly species from tissue samples, and also from filtered environmental samples. The detection of the species with the traditional method is time consuming and involves the destruction of the specimens. In comparison, with the eDNA method we could easily detect these near threatened odonates and other dragonfly species in a noninvasive way.] Address: Fekete, Judit, Univ. of Pannonia, Veszprém, Hungary. **20698.** Ge, Y., X. Meng, J. Heino, J. Garc'ya-Gir'on, Y. Liu, Z. Li, and Z. Xie (2021): Stochasticity overrides deterministic processes in structuring macroinvertebrate communities in a plateau aquatic system. *Ecosphere* 12(7):e03675.: 19 pp. (in English) ["Deterministic and stochastic processes are two major factors shaping community dynamics, but their relative importance remains unknown for many aquatic systems, including those in the high-elevation Qinghai-Tibet Plateau. Here, we explored the causes of multidimensional beta diversity patterns (i.e., taxonomic, functional, and phylogenetic) of a macroinvertebrate metacommunity in this large aquatic system by using multiple approaches (i.e., null models, phylogenetic signal testing, and ordination-based approaches). To obtain insights into community assembly mechanisms, we also analyzed beta diversity in two deconstructed sub-metacommunities (e.g., different tributaries and the main lake body). We found that most functional traits showed significant phylogenetic signals, indicating that the functional traits were profoundly influenced by evolutionary history. The null models showed randomness of functional and phylogenetic beta diversities for the whole basin and its tributaries, confirming the importance of stochasticity over deterministic processes in controlling community structure. However, both phylogenetic and functional community structures were clustered in the Qinghai Lake, probably reflecting the importance of environmental filtering. Ordination-based approaches also revealed that both environmental factors and spatial processes accounted for variation in taxonomic, functional, and phylogenetic beta diversity. More specifically, environmental filtering was more important than spatial processes for the functional dimension, but the opposite was true for the taxonomic and phylogenetic dimensions. The paleogeographic history of the Qinghai Lake basin may have contributed substantially to the prevalence of stochastic processes. Overall, this study provides a better understanding of ecological patterns and assembly mechanisms of macroinvertebrate communities across this poorly known high-elevation aquatic system that is highly sensitive to climate warming." **20700.** G-Santoyo, I.; González-Tokman, D.; Tapia-Rodríguez, M.; Córdoba-Aguilar, A. (2021): What doesn't kill you makes you stronger: Detoxification ability as a mechanism of honesty in a sexually selected signal. *Functional Ecology* 35(8): 1666-1678. (in English) ["1. Sexual selection leads to the expression and maintenance of colourful signals. The metabolic pathways to produce such signals often involve toxic byproducts that can reduce survival. However, rather than discarding these otherwise harmful byproducts, animals may use them by integrating them into sexually selected traits. 2. We tested this using the damselfly *Hetaerina americana*, where males bear a red wing spot (RWS) that has evolved by intrasexual competition. 3. By using confocal microscopy and several biochemical techniques, we determined that the RWS are generated by ommochrome pigments derived from tryptophan metabolism. 4. Second, we injected a group of males with the toxic precursor of these ommochromes, 3-hydroxy-kynurenine(3-Hk), confirming the toxicity of this compound in adult males. 5. Finally, we showed that adult males injected with a median lethal concentration of 3-Hk had more ommochromes in their RWS than controls but similar survival, suggesting that the deposition of ommochrome pigment in the wing counteracts the 3-HK toxicity. 6. Thus, we report that sexually selected pigmented signals may involve the co-option of excreted compounds that could otherwise have lethal effects, a hypothesis we call 'detoxifying ability signalling'. Our results provide new insights about the evolution of sexual signals, elucidating a mechanism for the evolution of honest indicators of quality that could have arisen due to natural selection." **20702.** Hossie, T.J.; Chan, K.; Murray, D.L. (2021): Increasing availability of palatable prey induces predator-dependence and increases predation on unpalatable prey. *Scientific Reports* volume 11, Article number: 6763: 12 pp. (in English) ["Understanding the factors governing predation remains a top priority in ecology. Using a dragonfly [*Aeshnidae*] nymph-tadpole system, we experimentally varied predator density, prey density, and prey species ratio to investigate: (i) whether predator interference varies between prey types that differ in palatability, (ii) whether adding alternate prey influences the magnitude of predator interference, and (iii) whether patterns of prey selection vary according to the predictions of optimal diet theory. In single-prey foraging trials, predation of palatable leopard frog tadpoles was limited by prey availability and predator interference, whereas predation of unpalatable toad tadpoles was limited by handling time. Adding unpalatable prey did not affect the predator's kill rate of palatable prey, but the presence of palatable prey increased the influence of predator density on the kill rate of unpalatable prey and reduced unpalatable prey handling time. Prey selection did not change with shifts in the relative abundance of prey types. Instead, predators selected easy-to-capture unpalatable prey at low total densities and harder-to-capture palatable prey at high densities. These results improve our understanding of generalist predation in communities with mobile prey, and illustrate that characteristics of the prey types involved govern the extent to which alternate prey influence the predator's kill rate." **20703.** Ilhamdi, M.L.; Idrus, A.A.; Santoso, D.; Hadiprayitno, G.; Syazali, M. (2021): Species richness and conservation priority of dragonflies in the Suranadi Ecotourism Area, Lombok, Indonesia. *Biodiversitas* 22(4): 1846-1852. (in English) ["Dragonflies are insects that have attractive colors and play an important role to balance ecosystems. They also act as bioindicators of the aquatic environment. The purpose of this study was to investigate the species richness and conservation priorities of dragonflies in the Suranadi Ecotourism Area, Lombok, Indonesia, expecting that the dragonflies will be used as charismatic species to support ecotourism. The research was conducted in August-December 2020 by surveying transect lines across 9 types of habitat. We then determined the conservation priority for each species found by referring to the Government Regulation using scoring method through a Focus Group Discussion (FGD) involving five experts. The score for each species was determined based on the percentage of the opinion from the experts. We found 18 dragonfly species from 2 suborders (Zygoptera and Anisoptera) and 5 families (Chlorocyphidae,

Coenagrionidae, Platycnemididae, Aeshnidae and Libellulidae). The habitat type that supports the highest species richness was the waterway and irrigation (16 species), while the lowest species richness was found in the areas inside the forest habitat (2 species). The species that had the highest conservation priority scores were *Pseudagrion pilidorsum declaratum*, *Libellago lineata*, and *Gynacantha subinterrupta*. These three species can be used as conservation priority species in the ecotourism area of Suranadi, Lombok, Indonesia." (Authors)] Address: Ilhamdi, M.L., Dept of Biology Education, Faculty of Teacher Training and Education Science, Universitas Mataram. Jl. Majapahit 62, Mataram 83125, West Nusa Tenggara, Indonesia. **20704.** IUCN (2021): The conservation status of species and habitat in freshwater Key Biodiversity Areas (KBAs) and key additional sites from the Sebou Basin. Project WAMAN (Water MANagement) Sebou Project, Málaga: 57 pages + annexes- (in English) ["This report presents the results of a broad assessment of the freshwater diversity in four Key Biodiversity Areas (KBAs)1 and some key additional sites in the Sebou river basin in Morocco. The Sebou river basin houses a large proportion of the Moroccan human population that depends on the river for their livelihood. The basin has important ecosystems for threatened species that are currently being recognized as Ramsar sites or national parks. Additionally, four sites have been identified as Key Biodiversity Areas (KBAs) for the persistence of freshwater biodiversity. Assessments were made on the effectiveness of the existing Key Biodiversity Areas (KBAs) in containing important populations of trigger species. During the summers of 2018 and 2019, biodiversity surveys of the taxa used to identify freshwater KBAs (fishes, molluscs, dragonflies and damselflies, crabs and aquatic plants) were undertaken by a team of experts in 39 sampling points, of which 29 were located in KBAs, and the remaining 10 were located in surrounding areas. A total of 192 species was recorded: 17 fish, 6 bivalve, 17 gastropod, 44 Odonata, 2 crayfish/crab species and 106 aquatic plant species. Twenty-one of these species are classified as threatened with extinction in the IUCN Red List of Threatened SpeciesTM (7 aquatic plant species, 2 fish species, 1 damselfly species, 1 crayfish species, 4 bivalve species, and 6 gastropod species). The highest native freshwater biodiversity was recorded in the South and East of KBA Oued Imouzzar Kandar. Also, in the central-east of KBA Oued Tizguite & Oued Ouaslane a high number of native species were found, especially aquatic plants. On the other hand, the number of threatened species was especially high in the KBA Oued Bouhlou and the KBA Oued Tigrigra. KBA Oued Bouhlou and its surroundings hosted a high number of threatened fish and a total of 7 threatened molluscs, including the Critically Endangered *Pseudunio maroccanus* (assessed as *Margaritifera marocana* in the IUCN Red List) and *Unio foucauldianus*. Many threatened molluscs species were also found in the surroundings of the KBA Oued Tigrigra, as well as the Endangered damselfly species *Calopteryx exul* and several threatened aquatic plants. For the surrounding areas, high freshwater biodiversity was found in the main channel of Oued Sebou, especially a high number of fish and dragonfly species. A major threat to the survival of the freshwater biodiversity is the introduction of non-native species that might outcompete the native species. A total of 11 non-native fish species were found in this study. High numbers of non-native fish were found in KBA Oued Tizguite & Oued Ouaslane and KBA Oued Tigrigra, as well as in the lakes' region (Dayat Iffer/ Dayat Yfrah/ Dayat Afourgah) and the sites in

Aguelmam n'Tifounassine and Sidi Ali. Habitat Quality Assessments (HQA) produced high values for KBAs and surrounding areas, but the Habitat Modification scores (HMS) were neither clearly negative nor positive. The region around the KBA Oued Tizguite & Oued Ouaslane is especially affected by human activity, and management plans have to be implemented to properly protect the biodiversity in the area. Other important threats are the construction of dams that are hindering the environmental flow required by many threatened species, soil erosion and siltation of river substrate and wastewater/solid waste disposal in the rivers. The Sebou basin has a high socio-economic importance for the Moroccan population, and is extensively used both for agriculture and industry. The effluents from agricultural or industrial activities have caused high contamination levels, that are harmful to humans, their livestock and the biodiversity. Another issue is the water shortage due to the water extraction for agricultural and urban uses, causing extreme droughts in some sites, especially in KBA Imouzzar Kandar. This intensive water extraction causes soil saline extrusion and increased water conductivity, as has been witnessed in the sites Aguelmam n'Tifounassine & Sidi Ali. Lastly, many of the springs and lakes are becoming unsustainable tourism destinations and have been completely altered and polluted, with the risk of a complete destruction of the freshwater biodiversity in the near future. The inclusion of freshwater biodiversity into the management plan for the Sebou basin, with the involvement of local authorities and communities, is necessary in order to preserve these high valued freshwater ecosystems. In the river Bouhlou crossing the Tazekka natural park, one of the best recruiting populations of the freshwater mussel *Pseudunio maroccanus* (assessed as *Margaritifera marocana* in the IUCN Red List), one of the world's 100 most threatened species, was detected. In order to protect this precious freshwater biodiversity, several measures should be taken to adjust the agricultural and industrial sector: inclusion of freshwater biodiversity into the water management plans and the increase of riparian buffers, wastewater treatment plans, the prevention of cattle overgrazing and bank destruction by trampling near the river banks. Campaigns on the correct management of the channels and the control of recreational activities by local authorities, could aid to manage the environmental flow necessary for many native species. For the rivers/lakes suffering from droughts, it will be necessary to setup an aquifer management plan covering the catchment of the aquifer on which the rivers/lakes depend, and develop artificial reservoirs to enable the reduction of exploitation of ground water. Finally, measures should be taken to stop the active restocking of fish in order to avoid non-native species outcompeting the native species. Further studies should be conducted to have a better understanding on the freshwater biodiversity in the Sebou basin. It is necessary to re-evaluate some of the KBAs to assess the presence of their trigger species and other threatened species. Finally, many of the additional sites that were studied here could be included as extension of the KBA, or a new KBA should be created to help focusing conservation efforts and promoting management actions that allow the persistence of the biodiversity elements present in there." **20705.** Janssens, L.; Verberk, W.; Stoks, R. (2021): The pace-of life explains whether gills improve or exacerbate pesticide sensitivity in a damselfly larva? *Environmental Pollution* 282: (in English) ["Highlights; •Surface area and metabolic rate are important for pesticide uptake and elimination. •Slow-paced (low metabolic rate) animals are more

sensitive to pesticides. •Gill loss increases pesticide sensitivity at fast and decreases it at slow pace. •Importance of oxygen versus pesticide uptake determines effect of gill loss. •Traits predicting pesticide sensitivity can interact. Trait-based approaches are promising to make generalizations about the sensitivity of species and populations to pesticides. Two traits that may shape the sensitivity to pesticides are the surface area (related to pesticide uptake) and the metabolic rate (related to pesticide elimination). We compared the sensitivity of damselfly larvae to the pesticide chlorpyrifos and how this was modified by loss of external gills (autotomy, reducing the surface area) in both fast pace-of-life (high metabolic rate) and slow pace-of-life (low metabolic rate) populations of *Ischnura elegans*. The slow-paced populations were more sensitive to the pesticide than the fast-paced populations in terms of survival, growth and energy metabolism. This suggests the higher metabolic rate of fast-paced populations enabled a faster pesticide elimination. Pesticide exposure also reduced heat tolerance, especially in slow-paced larvae under hypoxia. Gill loss had opposite effects on pesticide sensitivity in slow- and fast-paced populations. In slow-paced larvae, gill loss lowered the sensitivity to the pesticide, while in fast-paced larvae, gill loss increased the sensitivity. This difference likely reflects the balance between the roles of the gills in pesticide uptake (more detrimental in slow-paced populations) and oxygen uptake (more important in fast-paced populations). Our results highlight the need to consider trait interactions when applying trait-based approaches to predict the sensitivity to pesticides." **20709.** Kuznetsova, V.; Maryanska-Nadachowska, A.; Anokhin, B.; Shapoval, N.; Shapoval, A. (2021): Chromosomal analysis of eight species of dragonflies (Anisoptera) and damselflies (Zygoptera) using conventional cytogenetics and fluorescence in situ hybridization: Insights into the karyotype evolution of the ancient insect order Odonata. *Journal of Zoological Systematics and Evolutionary Research* 59(2): 387-399. (in English) ["All Odonata species studied to date using fluorescence in situ hybridization (FISH) belong to the dragonfly (Anisoptera) families Corduliidae and Libellulidae. It was shown that 18S rRNA gene loci locate on one of the largest pairs of autosomes in every species, whereas the "insect" telomere motif (TTAGG)<sub>n</sub> is absent in all but one species. For better understanding the chromosomal organization and evolution of Odonata, we used C-banding and FISH to study the karyotypes and map TTAGG sequences and major rRNA loci on chromosomes of three more dragonfly species from the families Corduliidae, Libellulidae, and Aeshnidae. Moreover, we obtained the first FISH-data on the suborder Zygoptera (damselflies) by analyzing five species of the families Coenagrionidae and Calopterygidae. We showed that all studied dragonfly species had 2n = 24A + X. The same karyotype was observed in the damselfly family Coenagrionidae, whereas in species of the Calopterygidae, the karyotype 2n = 26A + X was found. Both dragonfly and damselfly species had a pair of m-chromosomes; constitutive heterochromatin tended to be concentrated in the terminal regions of their chromosomes. The use of (TTAGG)<sub>n</sub> and 18S rRNA gene probes in dual-color FISH did not generate (TTAGG)<sub>n</sub> fluorescent signals in any species; major rRNA clusters were revealed on one of the largest pairs of autosomes in all Anisoptera species but on m-chromosomes in all Zygoptera species. Our results suggest that the former 18S location pattern was ancestral in the Odonata and the latter pattern had an ancient origin and could arise in a common ancestor of the damselfly superfamilies Calopterygoidea and Coenagrionoidea." **20710.** Lai, Y.-H.; Ma, J.-F.; Yang, J.-T. (2021): Flight maneuver of a damselfly with phase modulation of the wings. *Integrative and Comparative Biology* 61(1): 20-36. (in English) ["We developed a numerical model for four-wing self-propulsion to calculate effectively the flight velocity generated

with varied wing motions, which satisfactorily verified biological experiments. Through this self-propulsion model, we analyzed the flight velocity of a damselfly (*Matrona cyanoptera*) at varied phases. The results show that after phase modulation of the wings, the aerodynamic performance of the forewing is affected by the incoming flow and an effective angle of attack, whereas that of the hindwing is dominated by the vortex interaction and induced flow generated by the shed vortex of the forewing. Cooperating with the flow interaction, in stable flight, the hindwing in the lead phase has a larger vertical velocity, whereas the forewing in the lead phase has a larger horizontal velocity. Regarding the aerodynamic efficiency, the forewing in the lead phase has greater horizontal efficiency, whereas the hindwing in the lead phase has greater vertical efficiency; the overall efficiency does not vary with the phase. This work interprets that a dragonfly adopts the hindwing in the lead phase to generate a larger lift, thus supporting the larger body weight, whereas a damselfly adopts the forewing in the lead phase to have a greater forward velocity, which can supplement the lack of flapping frequency." (Authors)] Address: Yang, J.-T., Dept of Mechanical Engineering, National Taiwan Univ., Taipei, Taiwan. Email: jyang@ntu.edu.tw

**20711.** Lima da Silva, J.R.; Lima da Silva, A.; Santiago, A.S.; da Silveira Júnior, A.M. (2021): Composition, abundance and diversity of immature Odonata (INSECTA) insects living in stretches of middle Araguari River, Amapá State, Amazonian Region, Brazil. *Nature and Conservation* 14(2): 11 pp. (in English, with Portuguese summary) ["Odonata order, popularly known as dragonflies, comprises insects belonging to group Palaeoptera and presents hemimetabolous development encompassing three life cycle stages: eggs, larvae and adults. Odonata order has three suborders, namely: Anisoptera, Zygoptera and Anisozygoptera - the last one is exclusively distributed in Asia. The aim of the current study is to investigate the composition, abundance and diversity of Odonata larvae in middle Araguari River (Amapá, Brazil) by evaluating space-seasonal fluctuations and their association with different substrates. Eight collection sites were set along the river. Quarterly samplings were performed within an annual cycle (April/2018 to April/2019) by positioning a trawl "D" net (Rapiché) on the riverbed and scraping the substrate to collect 2L of sample. Odonata richness, abundance and diversity indices were evaluated. Data were statistically treated based on simple descriptive analysis, means, medians and standard deviations, Kruskal-Wallis test (nonparametric data) and ANOVA (parametric data) in the R-statistics Software. 297 individuals were identified; Libellulidae was the most abundant family (80.13%). Diversity and equitability have shown variations between sampling sites ( $p < 0.05$ ) and collection campaigns ( $p < 0.05$ ). Only abundance was influenced by categorical variables such as downstream/upstream river and substrate type. Higher taxonomic resolution, in combination to environmental variables, could help establishing ecosystem relationships that were not identified in the current study." (Authors)] Address: Lima da Silva, J.R., Universidade Federal do Amapá, Brasil. Email: jho.rodrigues.1701@gmail.com

**20712.** Liu, X.; Hefler, C.; Shyy, W.; Qiu, H. (2021): The importance of flapping kinematic parameters in the facilitation of the different flight modes of dragonflies. *Journal of Bionic Engineering* 18: 419-427. (in English) ["To better understand dragonflies' remarkable flapping wing aerodynamic performance, we measured the kinematic parameters of the wings in two different flight modes (Normal Flight Mode (NFM) and Escape Flight Mode (EFM)). When the specimens

switched from normal to escape mode the flapping frequency was invariant, but the stroke plane of the wings was more horizontally inclined. The flapping of both wings was adjusted to be more ventral with a change of the pitching angle that resulted in a larger angle of attack during downstroke and smaller during upstroke to affect the flow directions and the added mass effect. Noticeably, the phasing between the fore and hind pair of wings varies between two flight modes, which affects the wing-wing interaction as well as body oscillations. It is found that the momentum stream in the wake of EFM is qualitatively different from that in NFM. The change of the stroke plane angle and the varied pitching angle of the wings diverts the momentum downwards, while the smaller flapping amplitude and less phase difference between the wings compresses the momentum stream. It seems that in order to achieve greater flight maneuverability a flight vehicle needs to actively control positional angle as well as the pitching angle of the flapping wings." **20713.** Liu, X.; Hefler, C.; Fu, J.; Shyy, W.; Qiu, H. (2021): Implications of wing pitching and wing shape on the aerodynamics of a dragonfly? *Journal of Fluids and Structures* 101, February 2021, 103208: (in English) ["The forewing and the hindwing of a dragonfly have different geometry that could be an evolutionary specialization for better aerodynamic performance via sophisticated wing pitch control. Under different extent of wing pitching by the wing root musculature, the fore- and hindwings could exhibit different shape deformation and aerodynamic characteristics as a result of passive shape deformation. We measured the flow around the flapping wings using time-resolved particle image velocimetry (TR-PIV) to investigate the consequences of shape and the pitching mechanisms of the wings on the aerodynamics of dragonflies. The flow fields and pitching angle variations of the naturally actuated wing of the dragonfly were compared with that of the same wing artificially actuated only by flapping motion. We found that the trailing edge vortex dynamics and the wake were affected by the wing shape only for the in-vivo experiment with muscle induced pitching. Under the in-vivo with muscle induced pitching, the hindwing took more part in generating horizontal momentum with larger pitching magnitude, due to the larger chord length compared with forewing. Meanwhile, when there was only pitching due to the wing membrane deformation of artificially actuated flapping, a slight difference in the surrounding flow structures was found between the hindwing and the forewing, and the net flow in one period was reduced nearly to zero. These results provided quantified evidence to the extent and importance of the pitching motion of the wings in dragonfly flight. The results of this work can be useful for the design of wings, their actuation mechanism, and the in-flight kinematics control of flapping wing micro air vehicles (MAVs)." **20714.** Martens, A. (2021): Hansruedi Wildermuth: Facetten seiner Libellenstudien. *Libellula Supplement* 16: 13-18. (in German, with English summary) ["Hansruedi Wildermuth: Some highlights of his Odonata studies. Hansruedi Wildermuth is one of the most creative odonatologists in the present time. This paper focuses on two aspects: (1) his special contribution on midges as odonate parasites and (2) the development of his fundamental monography on European

Corduliidae." (Author)] Address: Martens, A., Institut für Biologie, PH Karlsruhe, Bismarckstrasse 10, D-76133 Karlsruhe, Germany. E-mail: martens@ph-karlsruhe.de

**20715.** Martins, R.T.; Brito, B.; Dias-Silva, K.; Leal, C.G.; Leitao, R.P.; Oliveira, V.C.; Oliveira-Júnior, J.M.B.; Ferraz, S.F.B.; de Paula, F.R.; Roque, F.O.; Hamada, N.; Juen, L.; Nessimian, J.L.; Pompeu, P.S.; Hughes, R.M. (2021): Low forest-loss thresholds threaten Amazonian fish and macroinvertebrate assemblage integrity. *Ecological Indicators* 127 (2021) 107773: 12 pp. (in English) ["Deforestation is a major threat globally, but especially in tropical regions because they are biodiversity strongholds and carbon storehouses. Some studies have reported changes in species richness and composition in lotic ecosystems with increased forest-loss in their catchment, presumably resulting from the replacement of sensitive taxa by more resistant or tolerant taxa. Also, sensitive taxa respond to deforestation in a non-linear manner and fish and macroinvertebrates have different sensitivities to landscape pressures. Therefore, it is useful to determine the effects of forest-loss on widespread sensitive or threshold taxa in aquatic ecosystems. We used Threshold Indicator Taxa Analysis (TITAN) to assess forest-loss and land use history impacts in 92 eastern Amazonian stream sites. We determined TITAN peak-change thresholds for fish at 1% and 6% of forest-loss at total-catchment and local-riparian spatial extents, respectively, and at 2% and 40% of land-use intensity change at total-catchment and local-riparian spatial extents, respectively. For macroinvertebrates, TITAN peak-change thresholds were 1% and 11% of forest loss at total-catchment and local-riparian spatial extents, respectively, and at 3% of land-use intensity change for both total-catchment and local-riparian spatial extents. Because of these thresholds, inherent ecoregional variability and key literature, we have three major recommendations. 1) Logging should be prohibited in riparian reserves that are at least 100-m wide on each side of headwater streams and in a network of catchments across all biomes and as many landscape types as possible. 2) An ecologically and statistically rigorous monitoring program with standard methods should be implemented to assess and regulate land uses better. 3) Conservation planning areas should consider aquatic biota as well as terrestrial biota." **20716.** Mehmood, S.A.; Zia, A.; Ahmad, S.; Shah, M.; Ali, W.; Rababa; Irfanullah (2021): Distribution and abundance of odonates fauna of Tanawal region district Mansehra, Pakistan. *Journal of Animal & Plant Sciences* 31(6): 1848-1854. (in English) ["Throughout the present study a total of 425 specimens were collected to assess the distribution and abundance of Odonata fauna. [...]. They are environmental indicators and play important role in biological control of insect pests. Result revealed 19 species belonging to [...] under 6 families. Most abundant family recorded was Libellulidae (74%) followed by Chlorocyphidae and Calopterygidae (11%) and (7%) respectively. Whereas Aeshnidae were found least abundant (2%). Genus *Orthetrum* dominated with percentage (51%) followed by genera *Rhinocypha*, *Neurobasis* and *Pantala* 11%, (7%) and (7%) respectively. While least abundant genus was *Sympetrum* having percentage (2%). Highest richness is observed at locality Galli badral (12.47%) followed by Shungli (12.00%) and Phulra (11.29%) respectively. However lowest richness was recorded at locality Lassan (4.47%). Regarding species

abundance *Orthetrum triangulare triangulare* was dominated (18.11%) followed by *O. prunosum neglectum*, (16.47%), *Neurobasis chinensis chinensis*, (7.05%) and *Rhinocypha quadrimaculata*, (5.88%), respectively. While lowest abundance was observed for *Ictinogomphus rapax* (1.41%). The canonical correspondence analysis showed that all Odonata species were associated with submerged vegetation. Anisoptera and Zygoptera species were associated with sunny and shady biotypes. Two species; *O. triangulare triangulare* and *O. prunosum neglectum* showed positive association with temperature. A Zygoptera species *Megalestes major* was found in moist habitat. Relative humidity was found as an influencing factor for the population growth of Anisopteran and Zygopteran species. Cluster analysis showed that all species were clustered into two groups; genera *Anax*, *Ictinogomphus*, *Crocothemis*, *Neurothemis*, *Orthetrum Palpopleura*, *Pantala* and *Sympetrum* were clustered into group I. Whereas Group II comes up with all Zygoptera species. The current information/data base will be helpful in preservation of ecosystem management approaches of Odonata." **20717.** Miya, M.S.; Gautam, D.; Neupane, B.; Chhetri, A. (2021): Species diversity and abundance of Odonata in Sishaghat of Tanahun district, Nepal. *Journal of Animal Diversity* 3(3): 45-55. (in English) ["Odonates are one of the most ancient, well studied and fascinating insects considered as bio-indicators of aquatic ecosystems. Studies of Odonata have been carried out in many parts of Nepal, but no specific study has been performed in Tanahun. Hence, a study was conducted to determine the species diversity and abundance of Odonata in the Sishaghat region of Tanahun district, Nepal from June to August 2020. A transect survey method was used for data collection. A total of six transects, each with a length of 200 m: - (three in each habitat type: agricultural lands and forest streams) were laid out randomly and each transect was surveyed three times. Data were pooled and analyzed with SPSS. A total of 629 individuals of 26 Odonata species from 20 genera and 7 families were recorded. The overall Shannon-Wiener diversity index was  $H = 2.25$ , Shannon Equitability was  $E = 0.69$  and Margalefs' richness index was  $R = 3.88$ . Sub-order Anisoptera was more diverse ( $H = 1.94$ ) and more abundant ( $n = 545$ ) than Zygoptera ( $H = 1.31$ ,  $n = 84$ ). However, species richness was higher and evenness lower in Zygoptera ( $R = 2.26$ ,  $E = 0.55$ ) than Anisoptera ( $R = 2.22$ ,  $E = 0.72$ ). Anisoptera comprised 15 species under 10 genera from two families and Zygoptera comprised 11 species under seven genera from five families. The family Libellulidae represented the highest species richness ( $R = 1.75$ ). *Neurothemis fulvia* and *Orthetrum prunosum* were the most abundant species ( $RA = 23.21$  and  $21.78$  respectively). While considering the global context, among the recorded Odonata, 25 species are included under the least concern and one under the vulnerable category by IUCN. A higher number of species was found in agricultural lands (nine species); hence, the water bodies around should be preserved to conserve the Odonata." (Authors)] Address: Neupane, B., Tribhuvan Univ., Institute of Forestry, Pokhara Campus, Pokhara, Nepal. E-mail: bijneu@gmail.com

**20718.** Montalvão, M.F.; Guimarães, A.T.A.; Rodrigues, A.S.; Malafaia, G. (2021): Carbon nanofibers are bioaccumulated in *Aphylla williamsoni* (Odonata) larvae and cause REDOX imbalance and changes of acetylcholinesterase activity. *Science of The Total Environment* 756:143991: (in

English) ["Carbon-based materials have been considered very promising for the technological industry due to their unique physical and chemical properties, namely: ability to reduce production costs and to improve the efficiency of several products. However, there is little information on what is the level of exposure that leads to adverse effects and what kind of effects is expected in aquatic biota. Thus, the aim of the present study was to evaluate the toxicity of carbon nanofibers (CNFs) in dragonfly larvae (*Aphylla williamsoni*) based on predictive oxidative-stress biomarkers, antioxidant activity reduction and neurotoxicity. After ephemeral models' exposure to CNFs (48 h; at 500 µg/L), data have shown that these pollutants did not change larvae's nutritional status given the concentration of total soluble carbohydrates, total proteins and triglycerides in them. However, the levels of both nitric oxide and substances reactive to thiobarbituric acid (lipid peroxidation indicators) have increased and the antioxidant activity based on total thiol levels and on 2,2-diphenyl-1-picrylhydrazyl (DPPH) radical scavenging activity (%) has reduced, and it suggests REDOX imbalance induction by CNFs. In addition, larvae exposed to these pollutants showed significant acetylcholinesterase activity reduction in comparison to the control group. Thus, the present study has brought further knowledge about how carbon-based materials can affect benthic macroinvertebrates and emphasized their ecotoxicological potential in freshwater environments." **20719.** Nakamura, H.; Kurimoto, N.; Imura, Y.; Hatakeyama, Y. (2021): The first isolation of microsporidia from dragonflies in Japan. *Jpn. J. Appl. Entomol. Zool.* 65: 29-34. (in Japanese, with English summary) ["Entomopathogenic microsporidia are pathogens of various arthropods and therefore cause disease in important host species ranging from agricultural pests to beneficial insects. Here, we investigated three genera of entomopathogenic microsporidia from dragonflies; these were isolated in Kanagawa, Japan, in 2014. In total, the infection rate was 0.85% (16 of the 1,886 surveyed dragonfly adults). Four strains of microsporidia selected from infected *Orthetrum albistylum speciosum* adults were measured for spore size and analyzed at the molecular level. According to spore size, the four strains were roughly divided into two groups. Analysis of small-subunit ribosomal RNA sequences indicated that the microsporidia strains belonged to the *Trachipleistophora*, *Vavraia*, and *Paranosema* clusters. Microsporidia species that are closely related to the strains isolated in this study have previously been reported to infect insects other than dragonflies. Therefore, we suggest the possibility that the microsporidian strains we isolated in *O. albistylum speciosum* may also infect other insect species." **20720.** Nakamura, Y.; Tominaga, A. (2021): Diet of the American Bullfrog *Lithobates catesbeianus* naturalized on Okinawajima, Ryukyu Archipelago, Japan. *Current Herpetology* 40(1): 40-53. (in English) ["The diet of the nonnative American Bullfrog *Lithobates catesbeianus* occurring in

Ogimi Village of Okinawajima, Ryukyu Archipelago, is investigated. Seventy two of 89 frogs (nine adults, five sub-adults, and 58 juveniles) captured had food items in its stomach. We identified a total of 64 taxa from 253 food items. Our analyses show that (1) the diet consists mainly of terrestrial prey, (2) mollusks and vertebrates are the essential prey groups for adults and subadults, and (3) odonates, mollusks, and arachnids are the main prey for juveniles. Such dietary habits are quite different from those of several conspecific nonnative populations in mainland Japan and other regions. Part of this is most likely related to the absence of the frog's favorite prey, nonnative American crayfish *Procambarus clarkii*, in the study area. We also confirm the predation of a poisonous newt *Cynops ensicauda popei* (Salamandridae) and several aquatic insects by this frog and present some implications for these results." **20722.** Norling, U. (2021): Growth, winter preparations and timing of emergence in temperate zone Odonata: control by a succession of larval response patterns. *International Journal of Odonatology* 24(1): 1-36. (in English) ["As warm-adapted insects of tropical origin, Odonata cope with cold periods by seasonal regulation and diapause. A model for larval-overwintering species is proposed with three response patterns related to the timing of emergence, which can be predicted from seasonal cues during the last few stadia. For emergence during the present season, there is an often time constrained preemergence development, accelerated by long days and higher temperatures. In regulatory development, emergence is postponed to the next season, and a complex of diapause-like delays controlled by photoperiod and temperature prevents premature emergence. Instead, development converges on a winter diapause in sizes suitable for emergence during the following year. Long days are particularly delaying, and thermal responses are variable, sometimes inverted. In early development, with rapid growth, emergence is usually not predicted to season, but short-day winter diapauses may occur, and precocious preparations for a penultimate winter may be predictive. Thermal responses are steep, extremely so if a short-day diapause is suppressed by higher temperatures. Other physiological and also behavioural properties may differ between response patterns. Changes in photoperiod and temperature control the timing of seasonal events, and the transition from regulatory to pre-emergence development follows the increase in temperature and photoperiod after winter,

which is an important time-setter. Interactions of larval size, photoperiod, temperature and previous changes affect development rate, and long-term constant conditions often end in regulatory diapause. Proximate mechanisms of cohort splitting and the implications of the model for design and interpretation of experiments are discussed." **20723.** Oki, D.S. (2021): Numerical simulation of the effects of groundwater withdrawal and injection of high-salinity water on salinity and groundwater discharge, Kaloko-Honokohau National Historical Park, Hawai'i. U.S. Geological Survey Scientific Investigations Report 2021-5004: 59 pp. (in English) ["Kaloko-Honokohau National Historical Park (KAHO) is located on the west coast of the island of Hawai'i and contains water resources exposed in fishponds, anchialine pools, and marine waters that are cultural resources and that provide habitat for threatened, endangered, and other culturally important native species. KAHO's water resources are sustained by and dependent on groundwater discharge. In 1978, the year of KAHO authorization, the lands immediately surrounding KAHO were undeveloped and zoned for conservation purposes; at present, most surrounding lands are either developed or zoned for industrial, commercial, or residential use. Urbanization of the North Kona District has increased the need for additional drinking and nonpotable (irrigation) water. Because KAHO's water resources may be affected by existing and proposed groundwater withdrawals and injections of high-salinity water in the surrounding area, the U.S. Geological Survey, in cooperation with the National Park Service, undertook this study to refine the understanding of how groundwater withdrawals and injection of high-salinity water may affect KAHO's water resources. Changes in KAHO water resources, in terms of changes in salinity and groundwater discharge, were modeled for selected scenarios of groundwater withdrawal and high-salinity water injection in the aquifer. The numerical model was developed using the model code SUTRA, which accounts for density-dependent flow and salinity transport, and included the coastal-confined groundwater system beneath the coastal freshwater-lens system. Model results indicate that withdrawal of additional groundwater from the coastal freshwater-lens system will affect the salinity of KAHO's anchialine pools, which provide habitat for the endangered orangeblack Hawaiian damselfly (*Megalagrion xanthomelas*). The magnitude of the effect is dependent on the amount and location of the withdrawal. Greater withdrawal rates cause greater increases in salinity in KAHO, other factors being equal. For a given withdrawal rate, the greatest increase in salinity in KAHO is associated with wells withdrawing groundwater in an area inland of KAHO and the least increase in salinity is associated with wells near the coast. Model results also indicate that withdrawal of additional groundwater from the coastal freshwater-lens system will affect the groundwater discharge, in terms of the freshwater component (water with zero salinity) of the discharge, through KAHO. Greater withdrawal rates cause greater reductions in freshwater discharge through KAHO. For a given withdrawal rate, the greatest reduction in freshwater discharge through KAHO is associated with wells near the north boundary of KAHO and the least reduction is associated with wells near the coast to the north and south of KAHO. Injection of high-salinity water that is denser than ocean water can affect the salinity of damselfly habitat in KAHO, with the magnitude of the effect dependent on the location of the injection. Model results indicate that salinity

may either increase or decrease in the anchialine pools that provide damselfly habitat in KAHO, depending on the site of injection. Injection inland of KAHO and at sites immediately north and south of KAHO causes a simulated decrease in salinity at the damselfly habitat, whereas injection farther north and south of KAHO causes an increase in salinity. Injection of high-salinity water also causes a reduction in freshwater discharge through KAHO, with the greatest reduction associated with distant injection wells to the north and south of KAHO and the least reduction associated with wells located near and immediately inland from KAHO. The numerical groundwater models developed for this study have a number of limitations. Lack of understanding of the subsurface geology constrains the ability to accurately model the groundwater-flow system. The models developed for this study are nonunique, cannot account for local-scale heterogeneities in the aquifer, and contain uncertainties related to recharge, boundary conditions, assigned parameter values in the model, and representations of the different hydrogeological features. Confidence in model results can be improved by addressing these and other limitations. In spite of these limitations, the three-dimensional numerical model developed for this study provides a useful conceptual understanding of the potential effects of additional withdrawals and injections on groundwater resources in KAHO. Further evaluation of the ecologic effects of the simulated changes in groundwater quality and quantity in KAHO is needed but is beyond the scope of this study." **20724.** Okude, G.; Fukatsu, T.; Futahashi, R. (2021): Electroporation-mediated RNA Interference Method in Odonata. *Journal of Visualized Experiments* (168), e61952: 20 pp. (in English) ["Odonata represent one of the most ancestral insects with metamorphosis, in which they change their habitat, morphology, and behavior drastically from aquatic larvae to terrestrial/aerial adults without pupal stage. Odonata adults have a well-developed color vision and show a remarkable diversity in body colors and patterns across sexes, stages, and species. While many ecological and behavioral studies on Odonata have been conducted, molecular genetic studies have been scarce mainly due to the difficulty in applying gene functional analysis to Odonata. For instance, RNA interference (RNAi) is less effective in the Odonata, as reported in the Lepidoptera. To overcome this problem, we successfully established an RNAi method combined with *in vivo* electroporation. Here we provide a detailed protocol including a video of the electroporation-mediated RNAi method as follows: preparation of larvae, species identification, preparation of dsRNA/siRNA solution and injection needles, ice-cold anesthesia of larvae, dsRNA/siRNA injection, *in vivo* electroporation, and individual rearing until adult emergence. The electroporation-mediated RNAi method is applicable to both damselflies (suborder Zygoptera) and dragonflies (suborder Anisoptera). In this protocol, we present the methods for the blue-tailed damselfly *Ischnura senegalensis* (Coenagrionidae) as an example of damselfly species and the pied skimmer dragonfly *Pseudothemis zonata* (Libellulidae) as another example of dragonfly species. As representative examples, we show the results of RNAi targeting the melanin synthesis gene multicopper oxidase 2. This RNAi method will facilitate understanding of various gene functions involved in metamorphosis, morphogenesis, color pattern formation, and other biological features of Odonata. Moreover, this protocol may be generally applicable to non-model organisms in which RNAi is less effective

in gene suppression due to the inefficiency and low penetrance." **20725.** Okude, G.; Fukatsu, T.; Futahashi, R. (2021): Comprehensive comparative morphology and developmental staging of final instar larvae toward metamorphosis in the insect order Odonata. *Scientific Reports* volume 11, Article number: 5164: 13 pp. (in English) ["The order Odonata is among the most ancestral groups of winged insects with drastic morphological changes upon metamorphosis, and thus important for understanding evo-devo aspects of insects. However, basic developmental descriptions of Odonata have been scarce. In an attempt to establish the foundation of developmental and experimental biology of Odonata, we present an unprecedentedly comprehensive survey of dragonflies and damselflies, in total 158 larvae representing 49 species and 14 families, wherein morphological changes of all the final and/or penultimate instar larvae were photographed and monitored everyday. Although their morphology and development were diverse, we consistently identified two visually recognizable morphogenetic events in the final larval instar, namely start of wing expansion and onset of melanization on the wing sheaths, thereby categorizing the final instar into three stages. While the duration of the first stage ranged 4–66 days across diverse Odonata species, the second or third stages exhibited relatively small variation ranging 3–22 days or 1–8 days, respectively, probably reflecting the steady and irreversible metamorphosis process after stage 2. We also described other characteristic morphological changes during the larval development, although they were observed only in some Odonata species and lineages." **20727.** Pianezze, S.; Perini, M.; Bontempo, L.; Piasentier, E.; Poma, G.; Covaci, A.; Camin, F. (2021): Stable isotope ratio analysis for the characterisation of edible insects. *Journal of Insects as Food and Feed* 7(6): 955-964. (in English) ["Entomophagy, or the act of eating insects, has been practiced since ancient times, but it started to gain more popularity, especially in Western countries, only recently. As sustainability is one of the current emerging themes, the inclusion of insects in our diet is a valid alternative that might help reduce the amount of water and land used for livestock and the associated emissions of greenhouse gasses. Moreover, insects are a source of protein, fibres, vitamins, minerals and fats. Edible insects are considered a novel food, for which no isotopic reference values are yet available. In the present work, samples of farmed edible insects (n=40) belonging to different orders (namely, Coleoptera, Hemiptera, Hymenoptera, Lepidoptera, Odonata and Orthoptera) and insect-based food items (n=4) for human consumption were analysed. The following isotopes, d13C, d15N, d34S, d18O and d2H of the defatted samples, together with the d13C of the fat, were investigated. The aim of the work was to provide the first reference isotopic ratios that can be used for future investigations in the food quality field. The variability of these parameters was dependent on the life stage and diet of insects, their geographical origin, and the addition of ingredients as seasoning." (2021): Tests of search image and learning in the wild: Insights from sexual conflict in damselflies. *Ecology and Evolution* 11(9): 4399-4412. (in English) ["Search image formation, a proximal mechanism to maintain genetic polymorphisms by negative frequency-dependent selection, has rarely been tested under natural conditions. Females of many nonterritorial damselflies [*Ischnura elegans*] resemble either conspecific males or background vegetation. Mate-searching males are assumed to form search images of the majority female type, sexually harassing it at rates higher than expected from its frequency, thus selectively favoring the less common morph. We tested this and how morph coloration and behavior influenced male perception and intersexual encounters by following marked *I. elegans* and noting their reactions to conspecifics. Contrary to search image formation and associative learning hypotheses, although males encountered the minority, male-like morph more often, sexual harassment and clutch size were similar for both morphs. Prior mating attempts or copula with morphs did not affect a male's subsequent reaction to them; males rarely attempted matings with immature females or males. Females mated early in the day, reducing the opportunity for males to learn their identity beforehand. Once encountered, the male-like morph was more readily noticed by males than the alternative morph, which once noticed was more likely to receive mating attempts. Flexible behavior gave morphs considerable control over their apparency to males, influencing intersexual encounters. Results suggested a more subtle proximal mechanism than male learning maintains these color polymorphisms and call for inferences of learning to be validated by behavior of wild receivers and their signalers." **20731.** Shustov, Yu. A.; Lesonen, M.A. (2021): Food competition of roach and perch in the water bodies of the Republic of Karelia. *Hydrobiological Journal*: 17-25. (in English) ["A comparative analysis of the dietary competition between roach and perch in lakes and rivers of Karelia (Onega and Ladoga lakes basins) is presented. It was revealed that in summer competition occurs when fishes feed on aquatic invertebrates (zooplankton and zoobenthos), as well as aerial insects, flying at the water surface. Food competition, according to the diet similarity index, ranged from 39.0 to 49.5. First of all, fish competed for the benthic organisms (30.0-35.5) and zooplankton (5.0-16.5). It was found that there is practically no competition for the aquatic plants (higher plants, algae and detritus), which formed on average 35% of the roach diet. On average, 25% of the perch diet was made by fish. Thus, the perch, which has high physical strength, also feeds on other most mobile and large organisms

of zoobenthos - the waterlouse, lake gammarus and Odonata larvae." (Authors)] Address: Shustov, Yu.A., Petrozavodsk State Univ. Petrozavodsk, Russia North Research Institute of Fishery Petrozavodsk, Russia

**20732.** Steenken, S.; Kleinschmidt, M.; Remy, D. (2021): Erprobungs- und Entwicklungsvorhaben zur Auenrenaturierung – Erfolgskontrollen 20 Jahre später. *BfN-Skripten* 588: 445 pp. (in German) ["The success of four floodplain restoration projects was re-evaluated 10 to 20 years after the completion of the restoration measures. These are former E+E projects on the Berkel, Hase, Oster and Oberweser rivers, which were funded by the Federal Agency for Nature Conservation between 1988 and 2003. The aim of this success control was to evaluate the long-term effects of the implemented renaturation measures and to identify common development patterns that would enable the derivation of generally applicable recommendations for floodplain renaturation. For this purpose, the scientific accompanying studies from the original projects were partially resumed for two vegetation periods. The topics covered were hydrology and morphology, vegetation and use, and fauna. The focus of this success control was on the assessment of the development of the floodplain biocoenosis. In order to improve the comparability of the results from the different study areas, the catalogue of organism groups to be studied has been standardised as far as possible. In detail, vegetation, avifauna, amphibians, dragonflies, grasshoppers, ground beetles, macrozoobenthos (Oster only) and fish (Oster only) were investigated. For a better understanding of the projects, their framework conditions and socio-economic aspects, additional expert interviews were conducted with the former stakeholders. The evaluation was carried out in two basic steps, a longitudinal analysis, in which the projects were examined individually for their long-term effects, and a cross-sectional analysis, in which the results from the four study areas were compared to identify common development patterns. It turned out that all four D+E projects largely met the goals they had set for themselves. However, a closer look revealed that although the projects achieved a fundamental enhancement of the study areas and the investigated organism groups benefited from the renaturations as a whole, the promotion of floodplain-specific biotic communities was often only successful in a limited space or for a limited time. The necessary hydrodynamics and morphodynamics were often lacking in the study areas, even after restoration. A decisive, limiting factor in this context has turned out to be the demand for use of the watercourses as part of the infrastructure. This often prevented self-dynamic processes from being permitted to the extent that would have been necessary to allow the initial activating measures for the redynamisation of the floodplains to develop their potential. Thus, the few areas in which it was possible to give free rein to self-dynamic processes showed that the projects were in principle quite suitable for promoting typical floodplain communities. Furthermore, the comparison has shown that initial measures that use the self-dynamic forces of flowing waters to develop the floodplain are fundamentally more recommendable than engineering attempts to construct dynamic structures. The results of this success control confirm the necessity of a functional unity of floodplain and watercourse. In order to restore the ecological functionality of river floodplains, it is therefore essential that the deficits in the watercourses forming the floodplain are given more consideration in planning and, if necessary, that accompanying measures are planned to compensate for these deficits. In this context, synergies could be used with measures to implement the EU Water Framework Directive and the

federal programme "Blue Ribbon Germany". Translated with www.DeepL.com/Translator (free version)] Address: <https://www.bfn.de/sites/default/files/BfN/service/Dokumente/skripten/skript588.pdf>

Lett.* 17: 20200833. <https://doi.org/10.1098/rsbl.2020.0833>: 6 pp. (in English) ["Monitoring insects across space and time is challenging, due to their vast taxonomic and functional diversity. This study demonstrates how nets mounted on rooftops of cars (car nets) and DNA metabarcoding can be applied to sample flying insect richness and diversity across large spatial scales within a limited time period. During June 2018, 365 car net samples were collected by 151 volunteers during two daily time intervals on 218 routes in Denmark. Insect bulk samples were processed with a DNA metabarcoding protocol to estimate taxonomic composition, and the results were compared to known flying insect richness and occurrence data. Insect and hoverfly richness and diversity were assessed across biogeographic regions and dominant land cover types. We detected 15 out of 19 flying insect orders present in Denmark, with high proportions of especially Diptera compared to Danish estimates, and lower insect richness and diversity in urbanized areas. We detected 319 species not known for Denmark and 174 species assessed in the Danish Red List. Our results indicate that the methodology can assess the flying insect fauna at large spatial scales to a wide extent, but may be, like other methods, biased towards certain insect orders." de Biología, Universidad de los Andes: 10 pp. (in English) ["This study has been purposed to evaluate adaptation strategies in insects of the order Odonata from three main families allocated at the Colombian Guiana shield: Libellulidae, Aeshnidae, and Coenagrionidae. A controlled habitat was used to monitor some previously identified variables to evaluate if there is an environmental effect related to water conditions or quantity that may be responsible for inducing plasticity events, due to stress sensing. All individuals used in this experiment were in the larval stage. Also, we evaluated if there is a behavioral strategy for Odonata larvae to sense different environmental signals that may help them to allocate suitable places to settle. Due to extreme climate changes can make disappear a perfectly suitable place for this type of organism in a short period, it is valuable to know if they have behavioral and/or phenotypic plasticity mechanisms to cope with these demanding conditions. We found relevant information from the Libellulidae family, in which changes in water conductivity had significant effects on their life history. However, we did not find data that supported our main hypothesis about their behavioral mechanisms, but the findings showed some light about some interesting behavior related to the studied families." (Authors)] Address: no details stated.

**20736.** Vila-Verde, G.; Santos, C.R. dos; Bomfim, G.S. (2021): Insetos (Insecta: Hymenoptera, Lepidoptera e Odonata) e as mudanças climáticas. *Terræ Didactica* 17 (Publ. Continua), 1-11, e021054: 11 pp. ["The Earth's climate has been affected by human activities, triggering environmental changes that may affect biodiversity. Furthermore, climate change is related to a higher concentration of CO<sub>2</sub> in the atmosphere and a greater incidence of ultraviolet radiation. Combined with deforestation, agriculture, and urban sprawl, these changes disrupt the environment. Because insects are sensitive to disturbances they can be used as bioindicators, because the changes influence life cycle, geographical distribution limits, and nutrition of insects. This study is a literature review that has examined the effects of climate change on groups of aquatic insects (order Odonata) and terrestrial insects (orders Hymenoptera and Lepidoptera). Climate change has a significant impact on entomofauna, especially in its distribution." **20737.** Zimmermann, F. (2021): 30 Jahre Naturschutz im Land Brandenburg - Eine Bilanz zur Situation der Biodiversität der Arten und Lebensräume. *Naturschutz und Landschaftspflege in Brandenburg* 30(2): 4-35. (in German) ["5.1 Dragonflies In the new Red List of dragonflies, Mauersberger et al. (2017) conclude that of 66 species assessed, 15 are to be assessed as threatened, but no species is considered extinct or missing. The reasons for changes from the previous to the current Red List include increases in knowledge and changes in the method of compiling the Red List. However, real population changes predominate, both for the species that have been upgraded and for those that have been downgraded or removed from the Red List. With 38% downlisting compared to 14% negative category changes, a cautiously positive picture of the current situation of dragonfly species in Brandenburg can be drawn overall. The "winners" are primarily species of flowing waters. On average, the conditions for dragonflies in flowing water habitats have improved significantly in Brandenburg and partly also across Germany. Reduced pollution caused by water pollution, but also renaturation measures have had

positive effects. Examples include *Calopteryx virgo*, *Gomphus vulgatissimus*, *G. flavipes*, *Ophiogomphus cecilia* and *Orthetrum coerulescens*. Species that were previously mainly distributed southwards, such as *Crocothemis erythraea* or more recently the wandering dragonfly (*Pantala flavescens*) - the dragonfly of the year 2021 - seem to benefit from the climatic changes. The latter species was recorded for the first time for Germany in 2019 with a male in the Lower Lusatian post-mining landscape in Brandenburg - apart from earlier displacements (Günther 2019). The "losers", on the other hand, are mainly species of the moors. *Aeshna juncea*, *A. subarctica*, *Leucorrhinia dubia* and *L. rubicunda* show a negative long-term and/or short-term trend. The current climate changes probably also play a not insignificant role in this." (Authors/DeepL)] Address: Zimmermann, F., Landesamt für Umwelt des Landes Brandenburg (LfU), Ref. **20738.** Abdizadeh, G.R.; Farokhinejad, M.; Ghasemloo, S. (2022): Numerical investigation on the aerodynamic efficiency of bio-inspired corrugated and cambered airfoils in ground effect. *Scientific Reports* volume 12, Article number: 19117: 19 pp. (in English) ["This research numerically investigates the flapping motion effect on the flow around two subsonic airfoils near a ground wall. Thus far, the aerodynamic efficiency of the dragonfly-inspired flapping airfoil has not been challenged by an asymmetric cambered airfoil considering the ground effect phenomenon, especially in the MAV flight range. The analysis is carried out on the basis of an unsteady Reynolds-averaged Navier-stokes (URANS) simulation, whereby the Transition SST turbulence model simulates the flow characteristics. Dragonfly-inspired and NACA4412 airfoils are selected in this research to assess the geometry effect on aerodynamic efficiency. Moreover, the impacts of Reynolds number ( $Re$ ), Strouhal number ( $St$ ), and average ground clearance of the flapping airfoil are investigated. The results indicate a direct relationship between the airfoil's aerodynamic performance ( $Cl/Cd$ ) and the ground effect. The  $Cl/Cd$  increases by reducing the airfoil and ground distance, especially at  $h_0=c$ . At  $Re=5 \times 10^4$ , by increasing the  $St$  from 0.2 to 0.6, the values of  $Cl/Cd$  decrease from 10.34 to 2.1 and 3.22 to 1.8 for NACA4412 and dragonfly airfoils, respectively. As a result, the  $Cl/Cd$  of the NACA4412 airfoil is better than that of the dragonfly airfoil, especially at low oscillation frequency. The efficiency difference between the two airfoils at  $St=0.6$  is approximately 14%, indicating that the  $Cl/Cd$  difference decreases substantially with increasing frequency. For  $Re=5 \times 10^3$ , the results show the dragonfly airfoil to have better  $Cl/Cd$  in all frequencies than the NACA4412 airfoil." **20739.** Adu, B.; Dada, O.; Tunwase, V. (2022): An ecological study of freshwater ecosystem and its colligation to Odonates assemblages in Ipogun, Southwest Nigeria. *Bulletin of the National Research Centre* 46 (Art. No. 86): 12 pp. (in English) ["Background: Odonata (dragonfly and damselfly) are particularly good indicators of freshwater ecosystem health. The constant disturbance of freshwater habitats can result in the reduction of Odonata species diversity. Changes in Odonata biodiversity are influenced by several human activities, such as agriculture, urbanization,

input of pollutants in water and construction. This study was carried out to assess the abundance and diversity of Odonata, evaluate the physicochemical characteristics of water, and compare the community structure of Odonata at three selected sites along River Aponmu in Ipogun. Adult odonates were sampled and identified for 11 months using a sweep net, water samples were collected and some parameters were determined during the study period. Results: A total of 906 specimens representing sixty-four (64) species and sixteen genera in seven families (Coenagrionidae, Lestidae, Platycnemididae, Chlorocyphidae, Calopterygidae, Libellulidae, and Gomphidae) were collected and identified. Of the 906 specimens, Libellulidae had the highest percentage composition (44%) with 395 individuals out of which *Trithemis arteriosa* (a pollution tolerant species) had the highest number of individuals (225) and Gomphidae had the lowest percentage composition (0.03%) with 1 individual. Most of the species collected are known for their tolerance to disturbed environments. They include *Pseudagrion melanicterum*, *Paragomphus genei*, and *Orthetrum julia*. Aponmu area had the highest species diversity ( $H' = 2.312$ ) while Idi area had the least species diversity ( $H' = 2.021$ ). Alaasin area had the highest Simpson's  $d$  value (0.8557) and the best taxa distribution (Evenness = 0.524; Equitability $_J = 0.7764$ ) which makes the area more pristine than other sites while Aponmu area had the least distribution (Evenness = 0.3365; Equitability $_J = 0.6798$ ). Analysis of variance (ANOVA) result of physicochemical parameters revealed that temperature ( $^{\circ}C$ ), pH, Dissolved Oxygen (mg/L), turbidity (NTU), Biochemical Oxygen Demand (mg/L),  $NO_3$  (mg/L), and  $PO_4$  (mg/L) did not show significant difference at the three sites while EC ( $\mu S/cm$ ) and TDS (mg/L) which have moderately high mean values indicated significant difference at Aponmu area ( $p < 0.05$ ). *T. arteriosa* exhibited a weak negative correlation to both temperature and DO. Conclusions: This study has provided information on Odonata assemblage at River Aponmu and infers based on the assemblage that the river may be somewhat polluted at the period the research was carried out. It is therefore recommended that efforts should therefore be taken to discourage water pollution in order to preserve the diversity of these insects and the water quality." **20741.** Bota-Sierra, C.A.; García-Robledo, C.; Escobar, F.;

Novelo-Gutiérrez, R.; Londoño, G.A. (2022): Environment, taxonomy and morphology constrain insect thermal physiology along tropical mountains. *Functional Ecology* 36(10): 2685-2685. (in English) ["1. Tropical mountains display limited variation in monthly temperatures, but high spatial climatic variability. It is assumed this stability promotes ecological and physiological adaptations to local temperatures, which may preclude dispersal up or downslope. Determining how environmental, taxonomic, and morphological factors affect thermal limits is fundamental to understand biotic responses to global warming. 2. We selected 54 species of dragonflies and damselflies (Order Odonata) distributed from 300 to 2550 m along one of the most biodiverse regions on the planet, the Tatamá elevational gradient in the Andean - Choco region transition. We estimated for 846 individuals three thermal tolerance parameters: CTmax, the highest temperature preceding the loss of motor control, Tvol, the temperature at which individuals avoid heat, and CTmin, the minimum temperature required for wing movement. 3. For each thermal tolerance parameter, we evaluated associations between physiological and behavioral responses, species elevational distribution, and specialization to forests or open areas. We also evaluated the effect of autecological characteristics such as body mass, sex, and taxonomy on temperature regulation. 4. Temperatures prevalent at different elevations and habitats are associated with odonate upper thermal limits. However, tolerance to low temperatures is not associated with habitat use or elevation. Forest species display lower thermal tolerances. Small species are more tolerant to high temperatures than larger species. Dragonflies are more tolerant to high temperatures than damselflies with similar body mass. Females are more tolerant to high temperatures than males. 5. Our results highlight the importance of considering differences in morphology, life history and behavior when comparing thermal tolerances of organisms along elevational gradients. Only by incorporating such factors, it would be possible to generate accurate predictions on the impact of climate change on tropical organisms." **20742.** Bower, L.M.; Peoples, B.K.; Eddy, M.C.; Scott, M.C. (2022): Quantifying flow–ecology relationships across flow regime class and ecoregions in South Carolina. *Science of The Total Environment* 802, 149721: 14 pp. (in English) ["Highlights: • Quantifying flow-ecology relationships allow for the development of flow standards. • All flow regime components affected fish and benthic macroinvertebrate assemblages. • Aquatic organisms' response to flow varied across flow classes and ecoregions. • Single metric flow standards would underestimate the impacts of any flow alteration. Abstract: The natural flow regime (i.e. magnitude, frequency, duration, timing and rate of change of flow events) is crucial for maintaining freshwater biodiversity and ecosystem services. Protecting instream flow from anthropogenic alterations first requires an understanding of the relationship between aquatic organisms and the flow regime. In this study, we used a unique framework based on random forest modeling to quantify effects of natural flow regime metrics on fish and macroinvertebrate assemblages across ecoregions and flow regime types in the state of South Carolina, USA. We found that all components of the natural flow regime affected both fish and benthic macroinvertebrate assemblages, suggesting that maintaining natural aspects of all flow regime components is critical for protecting freshwater diversity. We identified hydrologic metrics and flow regime

components such as magnitude, frequency, and duration of flow events, that were associated with the greatest ecological responses for individual stream classes to help managers prioritize hydrologic and biological metrics of interest during environmental flow standard development. The response of aquatic organisms to hydrologic metrics varied across stream classifications and ecoregions, highlighting the importance of accounting for differences in flow regime and ecoregion when designing environmental flow standards. We provide a flexible framework based on statistical flow-ecology relationships that can be used to inform in-stream flow management and assess effects of flow alteration on riverine assemblages." **20743.** Brans, K.I.; Tüzün, N.; Sentis, A.; De Meester, L.; Stoks, R. (2022): Cryptic eco-evolutionary feedback in the city: urban evolution of prey dampens the effect of urban evolution of the predator. *Journal of Animal Ecology* 91(3): 514-526. (in English) ["Most research on eco-evolutionary feedbacks focuses on ecological consequences of evolution in a single species. This ignores the fact that evolution in response to a shared environmental factor in multiple species involved in interactions could alter the net cumulative effect of evolution on ecology. We empirically tested whether urbanization-driven evolution in a predator (nymphs of the damselfly *Ischnura elegans*) and its prey (the water flea *Daphnia magna*) jointly shape the outcome of predation under simulated heatwaves. Both interactors show genetic trait adaptation to urbanization, particularly to higher temperatures. We cross-exposed common-garden reared damselflies and *Daphnia* from replicated urban and rural populations, and quantified predation rates and functional response traits. Urban damselfly nymphs showed higher encounter and predation rates than rural damselflies when exposed to rural prey, but this difference disappeared when they preyed on urban *Daphnia*. This represents a case of a cryptic evo-to-eco feedback, where the evolution of one species dampens the effects of the evolution of another species on their interaction strength. The effects of evolution of each single species were strong: the scenario in which only the predator or prey was adapted to urbanization resulted in a ca. 250% increase in encounter rate and a ca. 25% increase in predation rate, compared to the rural predator - rural prey combination. Our results provide unique evidence for eco-evolutionary feedbacks in cities, and underscore the importance of a multi-species approach in eco-evolutionary dynamics research." **20745.** Carvalho-Soares, A.A.; Ferreira, K.G.; Sousa, K.S.; Nascimento, A.C.L.; Mendoza-Penagos, C.C.; Vieira, T.B.; Salcedo, A.K.M.; Oliveira-Junior, J.M.B.; Calvão, L.B.; Dias-Silva, K. (2022): Checklist and new occurrences of Odonata (Insecta) from Volta Grande do Xingu, Pará, Brazil. *Hydrobiology* 1(2): 183-195. (in English) ["The order Odonata (Insecta) is composed of aquatic insects popularly known as dragonflies and damselflies. Members of this order are closely linked to the conservation status of their habitats; however, the Wallacean shortfall in some regions still remains high. The Volta Grande do Xingu region is known to have high endemism of some groups, such as Actinopterygii (fish), which can be applied to other groups that do not yet have their fauna known at the site, such as the order Odonata. The Wallacean shortfall and constant anthropic changes (for example, the construction of the Belo Monte Hydroelectric) have been obstacles in the preservation of these and other groups. In that regard, the main aim of this paper is to provide a checklist of Odonata (Insecta) adult species from the streams of Volta Grande do Xingu, Pará, Brazil. The collections were carried out in 19 streams in the Volta Grande do Xingu region in September 2019, corresponding to the drought period. A total of 526 specimens were collected, where two suborders, six families, 26 genera and 43 species were identified. Three species of Odonata were registered for the first time in the state of Pará: *Erythrodiplax famula* (Erichson in Schomburgk, 1848); *Acanthagrion chacoense* Calvert, 1909 and *Epipleoneura lamina* Williamson, 1915. These data allow us to help increase the knowledge of Odonata fauna in the streams of Volta Grande do Xingu, a region that is under intense anthropic pressure. This helps to reduce the Wallacean shortfall, with another area sampled for the state of Pará." (Authors)] Address: Carvalho-Soares, A.A., Fac.Ciências Biológicas (FCB), Univ. **20746.** Chandran, A.V.; Sherif, K.M. (2022): Comments on "The Dragonflies and Damselflies (Odonata) of Kerala – Status and Distribution". *Journal of Threatened Taxa* 14(6): 21282-21284. (in English) ["This is a rejoinder to the article "The Dragonflies and Damselflies (Odonata) of Kerala – Status and Distribution". In the said paper, certain species are of doubtful occurrence in Kerala and the Western Ghats. First reports of certain species which were available in open-access biodiversity portals and published articles in peer-reviewed journals were ignored. Additions to the checklists have been made without conducting taxonomic investigations, or in one case, even presenting a photograph. These shortcomings will lead to confusion and misunderstanding among odonatologists and naturalists in the region." (Authors)] Address: Chandran, A.V., Charutha house, Ayyappa Nagar, Punkunnam, Thrissur, Kerala 680002, India. Email: avivekchandran2@gmail.com

**20747.** Detilleux, L.; Poligui, R.N.; Iannello, L.; Dogot, T.; Francis, F.; Caparros Megido, R. (2022): Entomophagy in Gabon across the African context. *Journal of Insects as Food*

and *Feed* 8(7): 711-720. (in English) ["Entomophagy is well established in the food habits of Africa; however, country-wide knowledge remains limited for several countries, including Gabon. Here, two surveys on entomophagy were conducted in Gabon through face-to-face interviews. The first survey collected information on insect eating habits from 169 potential consumers. Edible insects formed part of the diet of most Gabonese people, with more than 60% of consumers within participants, and were particularly common among the Teke ethnic group (93%). Familiarity with edible insects was influenced by culture and family, but not by gender or study level. The second survey focused on edible insect species and their host plants, by interviewing a sample of 113 both villagers and retailers. Seventy-five species of insects from six insect orders (Coleoptera, Hemiptera, Isoptera, Lepidoptera, Odonata and Orthoptera) were consumed in Gabon, and were collected from 48 species of host plant. Many insects were formerly reported in the literature related to entomophagy; however, 13 species were newly reported as edible in this study: *Bidessus batekensis*, *Bunaeopsis licharbas*, *Copelatus ateles*, *C. confinis*, *C. fizpaci*, *C. tondangoyei*, *Gonobombyx angulata*, *Gonometa titan*, *Hydrocyrius columbiae*, *Oxychirus semisericeus*, *Philobota* sp., *Psara* sp. and *Ptyelus flavescens*. Consequently, these surveys highlighted that entomophagy is common in Gabon. However, strategies to promote edible insects are needed to have a significant impact on food issues in Gabon (e.g. food insecurity and dependence on foreign food supplies). Additional researches on entomophagy in Gabon are required to further develop these strategies." **20748.** Franke, S.; Pinkert, S.; Brandl, R.; Thorn, S. (2022): Modeling the extinction risk of European butterflies and odonates. *Ecology and Evolution*. 2022;12:e9465. 9 pp. (in English) ["Insect populations have become increasingly threatened during the last decades due to climate change and landuse intensification. Species characteristics driving these threats remain poorly understood. Trait-based analyses provide a straight-forward approach to gain a mechanistic understanding of species' extinction risk, guiding the development of conservation strategies. We combined morphological traits and phylogenetic relationship for 332 European species of butterflies and 115 species of odonates (dragon and damselflies) to model their red list status via phylogenetically controlled ordered logistic regression. We hypothesized that extinction risk increases with increasing body volume and wing area, decreasing range size, and is larger for brighter species. All investigated traits exhibited a strong phylogenetic signal. When controlling for phylogenetic relationship, we found that extinction risk of butterflies increased with decreasing range size. The extinction risk of odonates showed no relationship with the selected traits. Our results show that there is no universal trait defining the extinction risk of our investigated insect taxa. Furthermore, evolutionary history, measured as the phylogenetically predicted part of our analyzed traits, poorly predicted extinction risk. Our study confirms the focus of conservation measures on European butterfly species with small range sizes." **20749.** Futahashi, R. (2022): Sexual differentiation in dragonflies and damselflies. In: Minoru Tanaka & Makoto Tachibana (eds.): *Spectrum of sex. The molecular bases that induce various sexual phenotypes*. Springer, Singapore: 13-35. (in English) ["As represented by gynandromorphs (sexually mosaic individuals), sexual differentiation in insects proceeds primarily cell autonomously depending on sex chromosomes. Insect sex determination systems, although dominated by male heterogamety, are highly diverse. Dragonflies and damselflies (the order Odonata) are the most ancestral winged insects and have male heterogametic sex determination systems. Some species (e.g., *Crocothemis servilia*) have intraspecific polymorphisms in their karyotypes, such as switching from X0 to neo-XY sex chromosome system by chromosome fusion. In dragonflies and damselflies, adults of many species exhibit sexual color dimorphism, color transition upon adult maturation, and intraspecific color polymorphisms within the same sex. Molecular mechanisms underlying sex determination and sexual differentiation in insects have been investigated extensively in the fruit fly *Drosophila melanogaster*, but recent studies have revealed that the upstream genes of insect sex determination cascade are highly diverse. Most insects have sex-specific isoforms for doublesex (*dsx*) gene, which is important for sexual differentiation, and *dsx* gene plays important roles in masculinization not only for males but also for androchrome females in the damselfly *Ischnura senegalensis*. In this review, current knowledge on sex determination and sexual differentiation of insects is summarized, with particular focus on the most ancestral winged insects, dragonflies and damselflies." **20750.** Gómez-Tolosa, M.; Mendoza-Cuenca, L.F.; Rivera-Velázquez, G.; Rioja-Paradela, T.M.; Tejeda-Cruz, C.; Pérez-Farrera, M.A.; López, S. (2022): Using the ecological relationships of Odonata with a habitat integrity index to test the biodiversity ecosystem function framework. *Journal of Insect Conservation* 26: 191-203. (in English) ["As a result of human activities causing changes to their environments, many species are facing an increased risk of extinction. In order to determine such changes and their effects on species assemblages, rapid stream assessment techniques of environmental analysis and monitoring can be used. We determined the Habitat Integrity Index (HII) and its correlation with the composition and assemblage of adult odonates at different taxonomic levels in the region of the Selva Lacandona, Chiapas in southeastern Mexico. Both suborders Zygoptera and Anisoptera, the family Coenagrionidae, and the assemblage of 20 species of the genera *Argia*, *Cora*, *Hetaerina*, and *Heteragrion* (ACHH) were related with the HII. All taxonomic levels were included in the analyses as predictors of habitat integrity. However, we hypothesized that the abundance, species richness, and diversity of stenotopic species (ACHH) could be a better predictor of the HII than the other taxonomic levels. We found a positive and statistically significant relationship between the HII and the ACHH species, richness, and diversity. In contrast, we found a negative and significant relationship between HII and Anisoptera species, abundance, richness and diversity. Implications for insect conservation: in this case, the protected area hosts more specialist species than the surrounding zone. For example, Ejido El Tumbo, which presents a severe level of disturbance and is outside of protected natural areas, has the lowest species diversity of all sites. We recommend further

research to determine the link between disturbance and the prevalence of stenotopic species." **20752.** Halassi, I. (2022): Evaluation du métabolisme lipidique des Odonates bioindicatrices de la qualité de l'eau des écosystèmes aquatiques et étude de leur microflore au cours de leur cycle de développement. PhD thesis, Faculté Sciences de la Nature et de la Vie et Sciences de la Terre et de l'Univers, Département de Biologie, Laboratoire de domiciliation: Biologie, Eau et Environnement: 120 pp. (in French, with English and Arabian summaries) ["Odonates are one of the most important taxa in Algerian and North African wetlands. In this thesis, we aim to study several life history parameters of two populations of *Sympetrum meridionale*, coming from two different habitats across north-eastern Algeria. The first one is a RAMSAR wetland called 'Mekhada' (a perennial water body), and the second one is a temporary pond located at 'Maouna' Mountain (1400 m altitude). Moreover, the evolution of biochemical components was carried out during the larval stages, and MDA levels were evaluated after a chronic exposure to spirodicfen (ENVIDOR® 240 SC). Furthermore, to obtain a first overview of bacterial communities in the gut of odonates and to measure the effect of changes in environmental conditions including diet and water quality on the composition of these communities, microbiological analysis was carried out. The developmental patterns of the two dragonfly populations varied according to the type of habitat occupied by the parental generation of the species (factorial ANCOVA:  $p < 0.05$ ) (Low larval mortality, slow development and low weight in the dragonfly population inhabiting the RAMSAR wetland compared to those inhabiting the Maouna. For biochemical compounds, no significant difference is observed between the two populations. Exposure to Spirodiclofen was revealed insecticidal activity towards larvae with a significant dose response relationship; it induces an increase in MDA levels compared to controls groups We found that

the gut microbiota of the larvae was dominated by Proteobacteria, mainly of the genus *Enterobacter* and *Proteus*. In addition, the microbiota of reared larvae of both species was much richer in terms of taxonomic diversity and number of bacteria compared to the other stage. Such studies will add considerably to our understanding of the mechanisms that are responsible for the possible impacts of environmental changes on the life history traits of dragonflies in the southern part of their range." **20753.** Hasik, A.Z.; Siepielski, A.M. (2022): A role for the local environment in driving species-specific parasitism in a multi-host parasite system. *Freshwater Biology* 67: 1571-1583. (in English) ["(1) The extent and magnitude of parasitism often vary among closely related host species and across populations within species. Determining the ecological basis for this species and population-level variation in parasitism is critical for understanding infection dynamics in multi-host-parasite systems. To investigate such ecological underpinnings of variation in parasitism, we studied *Enallagma damselfly* host species and their water mite (*Arenurus* spp.) ectoparasites in lakes. (2) We first evaluated how host identity and density could shape parasitism. To test the effects of con- and heterospecific host density on parasitism, we used a field experiment with *Enallagma basidens* and *E. signatum*. We found that parasitism did not vary with con- or heterospecific density and was determined by host identity alone, with no spillover effects. (3) We also evaluated the potential role of local adaptation and resource availability in shaping parasitism. To do so, we used *E. signatum* in a reciprocal transplant experiment crossed with a prey resource-level manipulation. This experiment revealed that parasitism declined sharply for one host population in its non-local lake, but not the other source population, with no effects of prey levels. This asymmetry implies that damselflies express enhanced defences against parasitism that are neither population-specific nor dependent on resource abundance, or that mites developed heightened local host specificity. (4) The results of multivariate modeling from an observational study generally supported these experimental findings: neither host density nor resource abundance strongly explained among-population variation in parasitism. Instead, local abiotic conditions (pH) had the strongest relationship with parasitism, with minimal associations with predator density, temperature and a measure of immune function. (5) Collectively, our findings suggest a crucial role for the local environment in shaping host-parasite interactions within multi-host-parasite systems. More generally, these results show that research at the intersection of community ecology and disease ecology is critical for understanding host-parasite dynamics within natural communities." (2022): Into the database of bencoolen Odonata: Synthesis of two years dragonfly survey in Bengkulu Province. 1st Lekantara Annual Conference on Natural Science and Environment (LeNS 2021), IOP Conf. Series: Earth and Environmental Science 1097 (2022) 012056: 181-190. (in English) [Bengkulu, as part of Sumatra, receives less attention for its odonatological aspect during the current advance of life science. Historical records on Odonata were contributed by many foreign researchers from Dutch colonial era, including accounts provided by Lieftinck and Ris. In order to compile Odonata database for Bengkulu, there have been conducted dragonfly surveys from two years ago at some representative sites in this province. Conservation area of Seluma in the southern Bengkulu was visited in 2019 for two weeks survey, while conservation area of Lemo Nakai was surveyed in 2020 for the same work duration. Random survey and continuous citizen science have been performed at Bengkulu City to further the database from human impacted area. Thirty-five species were recorded from Seluma, thirty-nine were from Lemo Nakai and ten species were observed to exist within the human impacted area in Bengkulu City. In total, there were total 52 dragonfly species recorded within the administrative boundary of Bengkulu Province which more than half of historical Odonata records for this province. Thirty-one species belonged to Anisoptera (true dragonflies) and twentyone species are grouped into Zygoptera (damselflies). Some noteworthy records are highlighted in this paper, such as the rare *Dysphaea dimidiata* (Euphaeidae), *Anax panybeus* (Aeshnidae) and *Orthetrum schneideri* (Libellulidae); Sumatran endemic *Heliocypha angusta angusta* (Chlorocyphidae) and *Megalogomphus sumatranus* (Gomphidae); as well as the observation of three aeshnid species within human settlement in Bengkulu City. Further details on prominent Odonata species were also outlined along with their significances." (Authors)] Address: Janra, M.N., Universitas Andalas, Padang, West Sumatra, Indonesia. **20758.** Kalkman, V.J.; Boudot, J.-P.; Futahashi, R.; Abbott, J.C.; Bota-Sierra, C.A.; Guralnick, R.; Bybee, S.M.; Ware, J.; Belitz, M.W. (2022): Diversity of Palaearctic Dragonflies and Damselflies (Odonata). *Diversity* 2022, 14, 966. <https://doi.org/10.3390/d14090966>. (in English) ["More than 1.2 million distribution records were used to create species distribution models for 402 Palaearctic species of dragonflies and damselflies. On the basis of these diversity maps of total, lentic and lotic diversity for the whole of the Palaearctic (excluding China and the Himalayan region) are presented. These maps show a clear pattern of decreasing diversity longitudinally, with species numbers dropping in the eastern half of Europe and remaining low throughout a large part of Russia, then increasing again towards Russia's Far East and Korea. There are clear differences in diversity patterns of lentic and lotic species, with lentic species being dominant in colder and more arid areas. Areas with a high diversity of species assessed as threatened on the IUCN red list are largely restricted to the Mediterranean, Southwest Asia, and Japan, with clear hotspots found in the Levant and the southern half of Japan. The diversity at species, generic, and family level is higher in the south of Japan than in areas at a similar latitude in the western Mediterranean. This is likely to be the result of the more humid climate of Japan resulting in a higher diversity of freshwater habitats and the stronger impact of the glacial periods in the Western Palaearctic in combination with the Sahara, preventing tropical African lineages dispersing northwards." **20759.** Kalniņš, M.; Pipkaleja, Z. (2022): The Latvian Red List of dragonflies Odonata: preliminary results. 11th International Conference on Biodiversity Research (ICBR) to be held in the Daugavpils Univ., Latvia, on 20 – 22nd October, 2022. (<https://biodiversityconference.biology.lv/index.php/ICBR/ICBR2022/paper/view/248>): 1 p-[Verbatim: "The National Red List of dragonflies for Latvia is an extinction risk assessment of Latvian dragonfly species a made in accordance with the IUCN regional Red Listing guidelines. The redlisting process highlights those species that are threatened with extinction at the national level, so thereafter appropriate conservation actions can be undertaken to improve status of threatened species. There are 65 dragonfly species present in Latvia and all of them were assessed within the project framework. Two species were preliminary assessed Endangered (*Aeshna crenata*, *Stylurus flavipes*), five species assessed Vulnerable (*Coenagrion armatum*, *C. johanssoni*, *Cordulegaster boltonii*, *Ischnura pumilio*, *Somatoclora arctica*), and six species assessed Near Threatened (*Aeshna subarctica*, *A. viridis*, *Leucorrhinia albifrons*, *L. caudalis*, *Nehalennia speciosa*, *Ophiogomphus cecilia*). Other species assessed Least Concern, except one species,

which is assessed Data Deficient. The the most recent published recommendation recommendation for the Latvian national Red List of dragonflies contains 17 species. The difference between the number of species recently assessed as endangered/vulnerable/near threatened (13 in total) and the previously recommended number of species (17) can be explained by the category of species included in the Council Directive 92/43/EEC on the Conservation of natural habitats and of wild fauna and flora, but not assessed threatened in Latvia. The main threats to dragonfly species in Latvia are related to the changes in boggy habitats resulting of anthropogenic activity and natural factors, the chance of construction of new, large hydroelectric power plants and ongoing eutrophication of natural flowing waters. The impact of the general insect decline phenomenon (mainly due to agricultural chemicals) on dragonfly populations in Latvia remains unclear. We consider insufficient human resource capacity the most significant factor impacting long term dragonfly protection and conservation in Latvia. There is a limited number of available qualified specialists, which automatically results in the underrepresentation of the dragonfly (and invertebrates' in general) interests in various aspects - from drafting legislative and planning documents to performing specific activities in field." (Authors)] Address: Kalniņš, M., Nature Protection Board, Eksporta iela 5, Riga, LV-1010, Latvia. E-mail: martins.kalnins@dap.gov.lv

**20760.** Kartini, J.; Syachruddin, S.; Ilhamdi, M.L. (2022): The diversity of dragonflies (Odonata) in the Joben Resort area, East Lombok. *Jurnal Biologi Tropis* 22(2): 675-688. (in Indonesian, with English summary) ["Dragonfly is a family of insects that are closely related to water. During their life cycle, especially when laying eggs and at the stage of dragonfly nymphs, they spend their lives in healthy water areas because dragonfly nymphs are very sensitive to polluted water quality. Therefore, dragonflies have an important role for the sustainability of the ecosystem, namely acting as predators and indicators of environmental pollution. The high diversity of dragonflies in an area indicates that the area is still not polluted because the environment supports the life of dragonflies. This study aims to determine the diversity of dragonflies (odonata) in the Joben Resort area of East Lombok. This research is an exploratory descriptive study conducted from November to December 2021. Data collection was carried out 4 times and was repeated within 1 month in the morning and evening (08.00-17.00 WITA). The method used is a survey method with a sweeping net technique following a 500 m research path on 3 research paths, namely lane 1 (the river that borders Joben Ecopark), lane 2 (thepath leading to the Resort Office and Joben Ecopark) and lane 3 (the river that flows through Joben Ecopark). Bordered by rice fields and Kokok Joben Brain Baths). The calculation of the diversity index of dragonflies uses the Shannon-Wiener formula (H'). The results showed that the types of dragonflies (odonata) found in the Joben Resort Area consisted of 20 species with a total number of individuals found from 3 lanes as many as 864 individuals. The diversity index of dragonflies in the Joben Resort area of East Lombok is 2,309. The conclusion is that the diversity of dragonflies in the Joben Resort area of East Lombok is in the medium category." **20762.** Kumianto, A.S.; Purnomo, H.; Septiadi, L. (2022): The Influence of agrochemicals on macroinvertebrate community structure in various agricultural rivers in Jember regency. *Journal of Tropical Biodiversity and Biotechnology* 7(1): 15 pp. (in English) ["The intensive use of agrochemicals in agricultural areas of Jember's Regency presents a potential threat to the freshwater ecosystem's community. The use of the benthic macroinvertebrates community may provide a key to monitor the extent of agrochemical impact to maintain valuable ecosystem services. Macroinvertebrates community structure and environmental factors were studied from September–December 2020 in Jember Regency by comparing three different types of agricultural rivers (organic, semi-organic, and conventional). Five community indices (taxa, individuals, Simpson dominance index, Margalef species richness, and Shannon diversity index) were used to compare the macroinvertebrates community structure between sites. Using community composition and physicochemical properties (bare sediment, width, depth, water current, pH, conductivity, dissolved oxygen (DO), and temperature), we generated CCA triplot and correlogram plot to investigate the grouping and the correlation between variables and sites. Results on macroinvertebrate composition showed the importance of using sensitive taxa-group and community indices as an indicator of environmental changes. The family of Tipulidae, Naididae, Cysticidae, and Nereididae demonstrated relation to semi-organic agricultural rivers. Temperature and water current correlate to the presence of clean water indicator species such as Philorheitridae and Chironomidae, as observed in organic agricultural rivers. Conventional and semi-organic agricultural rivers were grouped and largely contributed by the 5 families including Ampullariidae, Pachychillidae, Baetidae, Enchytraidae, and Gomphidae. Correlogram plot suggests a complex interaction between macroinvertebrate community and environmental variables. It can be concluded that the intensive use of agrochemicals may lead to a detrimental change toward the diminished quality of freshwater community and environment." **20763.** Lashgari, A.M.; Naghash, B.A. (2022): Hover controller design and implementation for a dragonfly-like flapping wing. 13th International Micro Air Vehicle Conference, Delft, December 12–16, 2022: 183–192. (in English) ["The aim of this paper is modelling, simulating and designing a

controller for a micro aerial vehicle (MAV) as well as implementing an innovative scheme for it. The MAV scheme inspired by the dragonfly using clap and fling mechanism with an active rigid abdomen. The gearboxes are responsible for moving two pairs of four flying wings in front and back of the MAV. Also, change in the motors speed generates differential thrust to create a control pitch moment. The linearization about a hover point is performed to analyze the motion and design an LQR controller. Moreover, validity of the linearized equations is verified by comparing the responses of linear and nonlinear models. The theoretical results are experimented with a hardware-in-the-loop testbed. The experimental results demonstrate good agreement between theoretical and validated responses along with accurate and robust hovering at the desired point." **20765.** Lewinsohn, T.M.; Agostini, K.; Freitas, A.V.L.; Melo, A.S. (2022): Insect decline in Brazil: an appraisal of current evidence. *Biology Letters* 18: 20220219: 8 pp. (in English) ["Recent reviews of data on worldwide insect decline include almost no information on Brazil. We gathered evidence from literature searches and a survey sent to researchers, to which 96 replied and 56 provided information and publications. We present 75 instances of trends recorded over an average span of 11 years for aquatic and 22 years for terrestrial insects. These include time-replicated samples and expert opinion based on long-term local collections. Most terrestrial data are for butterflies, bees and scarab beetles. Aquatic studies include several insect orders, usually sorted to genus or family. Terrestrial insects showed significantly more cases of declines than increases, both in abundance (17 : 3) and in diversity (11 : 1). In aquatic cases, no tendency was detected in abundance (2 : 2) or diversity (3 : 4), not counting cases with no trend. Differences in these results among habitats may be due to the shorter span and less change in environmental conditions in the aquatic surveys, which included sites already degraded before sampling. We offer guidelines for future long-term assessments, including resampling of legacy collection sites." (Authors)] Address: Lewinsohn, T.M., Depto de Biologia Animal, Inst. Biol., Univ. of Campinas, 13083970 Campinas, São Paulo, Brazil. Email: thomasl@unicamp.br

**20766.** Lorenzo-Carballa, M.O.; Sanmartín-Villar, I.; Cordero-Rivera, A. (2022): Molecular and morphological analyses support different taxonomic units for Asian and Australo-Pacific forms of *Ischnura aurora* (Odonata, Coenagrionidae). *Diversity* 14(8), 606; <https://doi.org/10.3390/d14080606>.

30 pp. (in English) ["Despite the great technological progress that has aided taxonomical identification, taxonomical issues remain for certain species found in remote and/or understudied geographical areas. The damselfly species *Ischnura aurora* has been the subject of a long-standing taxonomical debate, focused mainly on the existence of morphological and behavioural differences between Asian and Australo-Pacific forms of this species that could justify their placement into two different species. Here, we carried out a comparative morphological analysis of specimens currently identified as *I. rubilio* from India and *I. aurora* from Asia and Oceania, combined with the analysis of mitochondrial and nuclear sequence data, both developed by us and available in public repositories. Our results split the Asian and Australo-Pacific forms of *I. aurora* into two well-differentiated taxonomic units and, hence, different (albeit closely related) species, and support the specific status of *I. rubilio*. The results of our genetic analyses suggest the existence of a third (and even fourth) taxonomic unit, stressing the need to revise all available material belonging to the different *I. aurora* subspecies that have been described. Finally, we have identified several questionable DNA sequences currently available in public repositories, upon which previous conclusions about the phylogenetic position of *I. rubilio* are based. Our study stresses the importance of being able to link available DNA sequence data with voucher specimens as well as to carry out a careful examination of DNA sequence data prior to their inclusion in taxonomical studies." **20770.** Mola, L.M.; Rebagliati, P.J.; Fourastié, M.F.; Agopian, S.S. (2022): Meiotic analysis of Gomphidae species sheds light on the large X chromosome of the family (Anisoptera, Odonata). Diversity 14, 874. <https://doi.org/10.3390/d141-00874>: 17 pp. (in English) ["In most Anisoptera families, the modal diploid number is 25 in males (24 autosomes + X), and the X chromosome is one of the smallest elements of the complement. The family Gomphidae is an exception, as it has a modal diploid number of 23 (22 + X), and the X chromosome is the largest of the complement and of medium-to-large size in many species. We studied the meiosis of three gomphid species from Argentina: *Aphylla* cf. *distinguenda* (Campion, 1920), *Phyllocyca propinqua* Belle, 1972 and *Phyllocyca* sp. Chromosome number is  $2n = 23$ ,  $n = 11 + X$ , except for *Phyllocyca propinqua*, showing  $n = 10 + X$ . The X chromosome of these species is medium-sized and presents heteropyknotic blocks of different sizes. Despite the small number of gomphid species analysed, there is a clear trend of increasing size of the X chromosome with the increasing amount of heterochromatin. Our results, together with those from the literature, suggest that its large size might have been due to a progressive accumulation of repetitive DNA and heterochromatinisation and not to fusion, as previously suggested. This led us to propose that the ancestral number coincided with the modal number of Gomphidae. A revision of the derived sex-determining systems in Odonata is also provided." (Authors)] Address: Mola, Liliana, Laboratorio de Citogenética y Evolución, Depto de Ecología, Genética y Evolución, Instituto de Ecología, Genética y Evolución (CONICET-UBA), Facultad de Ciencias Exactas y Naturales, Universidad de Buenos Aires, Intendente Güiraldes 2160, Ciudad Autónoma de Buenos Aires C1428EGA, Argentina. **20771.** Moreno Pallares, M.I.; Bonilla Gómez, M.A.; Guillot Monroy, G.H.; Torregroza-Espinosa, A.C. (2022): Distribution of *Miathyria marcella* larvae (Odonata: Libellulidae) and water quality of wetlands in Northern Colombia. Journal of Freshwater Ecology 37(1): 569-581. (in English) ["This study aims to assess the physicochemical characteristics regulating the distribution and abundance of *M. marcella* larvae in six wetlands in the northern Colombia. Standardized techniques for collecting invertebrate and physicochemical data were used in 29 sampling points in an intraannual period. Mean pH and temperature oscillated in narrow ranges within wetlands ( $7.7 \pm 0.09$ – $8.6 \pm 0.07$ ;  $28.1 \pm 0.29$ – $32.8 \pm 0.17$  C, respectively), whereas ammonium concentrations and conductivity exhibited a wide variation ( $0.2 \pm 0.03$ – $2.8$

$\pm 0.54$  mg NH<sub>4</sub> L<sup>-1</sup>;  $861 \pm 30.7$ – $19254 \pm 1706$  mS cm<sup>-1</sup>, respectively). A total of 2586 individual *M. marcella* larvae were collected. Abundance was greater in wetlands influenced by the Magdalena River, with  $19.4 \pm 1.7$  and  $9.3 \pm 1.4$  individuals; followed by wetlands hydrologically influenced by seasonal runoff, with  $8.1 \pm 0.4$  and  $6.4 \pm 0.4$  individuals; and lowest in wetlands with influence of the Caribbean Sea, with  $3.9 \pm 0.3$  and  $0.3 \pm 0.1$  individuals. Abundances of *M. marcella* larvae exhibited similar variations at different months during the sampling period. Abundance and distribution of *M. marcella* larvae in wetlands of northern Colombia is strongly dependent on water conductivity, transparency and alkalinity. This study evidence that Odonata larvae are a valuable tool as bioindicators for wetland assessment and monitoring." (Authors)] Address: Moreno Pallares, M.I., Depto de Biología, Univ. Nac. Colombia, Bogotá, Colombia. Email: mimorenop@unal.edu.co

**20773.** Öztürk, S.; Seçer, B.; Sungur, S.; Kökçü, C.A.; Çiçek, E. (2022): Benthic macroinvertebrate fauna of Karagöl and Çiniligöl (Bolkar Mountains, Niğde, Turkey). LIMNOFISH - Journal of Limnology and Freshwater Fisheries Research 8(1): 59-69. (in Turkish, with English summary) ["This study was carried out between June and September 2018 to identify the macrobenthic invertebrate fauna of Karagöl and Çiniligöl which are high altitude lakes in Bolkar Mountains (Niğde). As a result of the systematic examination of the collected benthic samples; macrobenthic fauna of Karagöl consist of 30 taxa belonging to 14 families out of 11 orders (Sphaeriida, Coleoptera, Diptera, Hygrophila, Hemiptera, Rhynchobdellida, Odonata ["Coenagrion sp."], Haplotaksida, Lumbriculida, Trichoptera, Amphipoda) and macrobenthic invertebrate fauna of Çiniligöl composed of 11 taxa belonging to 7 families out of 7 orders (Sphaeriida, Coleoptera, Diptera, Hemiptera, Rhynchobdellida, Haplotaksida, Trichoptera). Except for *Allogamus auricollis*, *Paranais frici* and *Potamothenis hammoniensis* species among the determined taxa, others are new records for these localities. Determining the relationship between diversity of habitats, dominance and population density index was used. According to the results of the Shannon- Wiener (H'), Simpson (S) and Margalef (DMg) indexes used in the calculation of the

species diversity and species richness in habitats, the highest diversity is the Karagöl coast station with values of 3.07, 0.94 and 5.54, respectively. According to the dominance (SD) index results, the highest value was determined as Çiniligöl bottom station with 0.23. According to the results of the Shannon (EH) and Simpson (ES) indexes used in the population density relationship, the highest value was calculated as Karagöl bottom with 0.87 and 0.13, and the lowest value as 0.72 and 0.03, respectively. Cluster analysis based on the Sorensen and Ward's analysis method was applied to show the similarities of the taxa and their distribution in the stations. Accordingly, the highest similarity was observed between the Karagöl coast and Çiniligöl coast stations (0.35), the lowest between the bottom and coast stations of Karagöl (0.15)." **20775.** Ožana, S.; Dolný, A.; Pánek, T. (2022): Nuclear copies of mitochondrial DNA as a potential problem for phylogenetic and population genetic studies of Odonata. Systematic Entomology 47(4): 591-602. (in English) ["The use of mitochondrial markers for taxonomic identification and biodiversity monitoring is not without risks or limitations. Most importantly, the natural transfer of DNA from the mitochondria to the nucleus generates nonfunctional nuclear copies of mitochondrial DNA (NUMTs). Their abundance and size vary significantly among taxa, and NUMTs have been reported to complicate molecular studies based on mitochondrial markers in several insect orders, most prominently in Orthoptera. The significance of this phenomenon in Odonata has not yet been properly addressed. Here, we present a complete mitochondrial genome and a draft nuclear genome of *Leucorrhinia albifrons*, as well as NUMT and *cox1* sequences from the related species *Leucorrhinia dubia*. We document the presence of NUMTs in the *L. albifrons* nuclear genome and in nuclear genomes of two other Odonata species available in public databases. Our results show that NUMTs can have a serious impact on barcoding, phylogenetic, population and phylogeographic studies of Odonata, especially when the barcode is located in the *cox1* gene, the most frequently used molecular marker for Odonata. We suggest that *nad1* should be used alone or in combination with *cox1* to minimize unintended confusion with NUMTs. Finally, we present a mitophylogenomic analysis of Odonata and document several cases of misidentified mitochon-

drial genomes belonging to species different from those indicated in public databases. In conclusion, our findings represent an important step for future metabarcoding studies of Odonata based on mitochondrial DNA markers." **20776.** Péliissié, M.; Johansson, F.; Hyseni, C. (2022): Pushed northward by climate change: Range shifts with a chance of co-occurrence reshuffling in the forecast for northern European odonates. *Environmental Entomology* 51(5): 910-921. (in English) ["Biodiversity is heavily influenced by ongoing climate change, which often results in species undergoing range shifts, either poleward or uphill. Range shifts can occur provided suitable habitats exist within reach. However, poleward latitudinal shifts might be limited by additional abiotic or biotic constraints, such as increased seasonality, photoperiod patterns, and species interactions. To gain insight into the dynamics of insect range shifts at high latitudes, we constructed ecological niche models (ENMs) for 57 Odonata species occurring in northern Europe. We used citizen science data from Sweden and present-day climatic variables covering a latitudinal range of 1,575 km. Then, to measure changes in range and interactions among Odonata species, we projected the ENMs up to the year 2080. We also estimated potential changes in species interactions using niche overlap and co-occurrence patterns. We found that most Odonata species are predicted to expand their range northward. The average latitudinal shift is expected to reach 1.83 and 3.25 km y<sup>-1</sup> under RCP4.5 and RCP8.5 scenarios, respectively, by 2061–2080. While the most warm-dwelling species may increase their range, our results indicate that cold-dwelling species will experience range contractions. The present-day niche overlap patterns among species will remain largely the same in the future. However, our results predict changes in co-occurrence patterns, with many species pairs showing increased co-occurrence, while others will no longer co-occur because of the range contractions. In sum, our ENM results suggest that species assemblages of Odonata—and perhaps insects in general—in northern latitudes will experience great compositional changes." **20779.** Sisa, E.M.; Kamb, J.-C.T.; Pwema, V.K.; Mutambel, D.H.; Bunda, N.P.M. (2022): Structure of Odonata populations in the riparian strips of the Bumbu River watershed in Kinshasa /RD Congo. *International Journal of Science and Research Archive* 6(1): 28-39. (in English) ["The study of the structure of the Odonata populations was undertaken during the dry season 2021, in the watershed of the Bumbu River. After capture with an entomological net, identification and enumeration, 393 individuals were collected and are divided into 2 suborders and 8 families. Several biotic indices were used to study the structure of the population on the one hand, and its diversity on the other. Raw abundance, relative frequency, taxonomic richness, Shannon and Weaver diversity, Jaccard's similarity index, Pielou's equitability and riparian strip quality index were calculated. The evaluation of the biotic indices in the different stations showed that there is a parallelism between them. The Libellulidae family was the most represented with 161 individuals or 40.9% of the total abundance and 15 species. It is followed by the families Lestidae with 97 individuals and 4 species, Coenagrionidae with 87 individuals and 5 species, Corduliidae with 23 individuals and 3 species, Gomphidae with 15 individuals and 3 species, Platycnemidae with 9 individuals and 2 species, Chlorocyphidae with 6 individuals and 2 species and Calopterygidae with 1 individual and 1 species. The relative abundance of the species *Chalcostephia flavifrons*, *Ceriagrion corallinum*, *Lestes virgatus*, *L. ictericus* and *L.s. tridens* can be explained by the aquatic vegetation which serves them as perches and shelters." **20780.** Šigutová, H.; Pyszko, P.; Valušák, J.; Dolný, A. (2022):

Highway stormwater ponds as islands of Odonata diversity in an agricultural landscape. *Science of The Total Environment* 837, 1 September 2022, 155774. (in English) ["Highlights: • Stormwater ponds have a higher Odonata richness and  $\beta$ -diversity. • Stormwater ponds have low taxonomic distinctness. • Stormwater ponds host more variable communities with higher conservation values. • Fish stocking intensity is the most important factor affecting the differences. • Management practices must enhance the biodiversity conservation of stormwater ponds. Abstract: Stormwater management ponds, which are constructed to retain excess runoff and pollutants from traffic, play an important role in the freshwater biodiversity in highly modified areas. However, their roles in agricultural and semi-natural landscapes remain largely unexplored. In this study, we used Odonata as a bioindicator to compare a set of highway stormwater ponds and surrounding ponds within an agricultural and semi-natural landscape to examine the extent to which stormwater ponds act as biodiversity refuges. We analyzed the differences in environmental parameters and the richness, compositions, and conservation values of the odonate communities of stormwater and surrounding ponds. We also examined the factors controlling the differences in the communities of both pond types. The stormwater ponds were smaller, less eutrophicated, less shaded by trees, less stocked with fish, and less connected with other waterbodies than the surrounding ponds. However, they had a higher plant diversity and pH values and were more densely overgrown with vegetation. Compared with surrounding ponds, stormwater ponds had a higher Odonata richness and  $\beta$ -diversity, but their taxonomic distinctness was significantly lower. Therefore, stormwater ponds hosted more variable communities but their assemblages were taxonomically similar. Indicator species were only identified in stormwater ponds. Furthermore, stormwater ponds harbored more species with higher conservation values. The most important factors affecting the differences between stormwater and surrounding ponds were the trophic state, relative tree shading, and fish stocking intensity. With their increase, the richness and rarity decreased. Our results highlight the potential of stormwater ponds to enhance the biodiversity outside urban areas by providing specific habitat conditions that are unique to the surrounding agricultural landscape. In addition, we suggest management practices that can be used to enhance their biodiversity conservation function." (2022): Nature-inspired antimicrobial surfaces and their potential applications in food industries. *Foods* 2022, 11, 844. <https://doi.org/10.3390/foods11060844>: 15 pp. (in English) ["Antimicrobial resistance (AMR) is a growing global concern and has called for the integration of different areas of expertise for designing robust solutions. One such approach is the development of antimicrobial surfaces to combat the emerging resistance in microbes against drugs and disinfectants. This review is a compressive summary of the work done in the field of material science, chemistry, and microbiology in the development of antimicrobial materials and surfaces that are inspired by examples in nature. The focus includes examples of natural antimicrobial surfaces, such as cicada wings or nanopillars, dragonfly wings, shrimp shells, taro leaves, lotus leaves, sharkskin, gecko skin, and butterfly wings, along with their mechanism of action. Techniques, compositions, and combinations that have been developed to synthetically mimic these surfaces against bacterial/viral and fungal

growth in food-processing areas have also been discussed. The applications of synthetic mimics of natural antimicrobial surfaces in food-processing environments is still a naïve area of research. However, this review highlights the potential applications of natural antimicrobial surfaces in the food-processing environment as well as outlines the challenges that need mitigations." **20782.** Späth, J.; Fick, J.; McCallum, E.; Cerveny, D.; Nording, M.L.; Brodin, T. (2022): Wastewater effluent affects behaviour and metabolomic endpoints in damselfly larvae. *Scientific Reports* 12:6830: 13 pp. (in English) ["Wastewater treatment plant effluents have been identified as a major contributor to increasing anthropogenic pollution in aquatic environments worldwide. Yet, little is known about the potentially adverse effects of wastewater treatment plant effluent on aquatic invertebrates. In this study, we assessed effects of wastewater effluent on the behaviour and metabolic profiles of damselfly larvae (*Coenagrion hastulatum*), a common aquatic invertebrate species. Four key behavioural traits: activity, boldness, escape response, and foraging (traits all linked tightly to individual fitness) were studied in larvae before and after one week of exposure to a range of effluent dilutions (0, 50, 75, 100%). Effluent exposure reduced activity and foraging, but generated faster escape response. Metabolomic analyses via targeted and non-targeted mass spectrometry methods revealed that exposure caused significant changes to 14 individual compounds (4 amino acids, 3 carnitines, 3 lysolipids, 1 peptide, 2 sugar acids, 1 sugar). Taken together, these compound changes indicate an increase in protein metabolism and oxidative stress. Our findings illustrate that wastewater effluent can affect both behavioural and physiological traits of aquatic invertebrates, and as such might pose an even greater threat to aquatic ecosystems than previously assumed. More long-term studies are now needed evaluate if these changes are linked to adverse effects on fitness. The combination of behavioural and metabolomic assessments provide a promising tool for detecting effects of wastewater effluent, on multiple biological levels of organisation, in aquatic ecosystems." **20783.** Tongo, I.; Onokpasa, A.; Emerure, F.; Balogun, P.T.; Enuneku, A.A.; Erhunmwunse, N.; Asemota, O.; Ogbomida, E.; Ogbeide, O.; Ezemonye, L. (2022): Levels, bioaccumulation and biomagnification of pesticide residues in a tropical freshwater food web. *International Journal of Environmental Science and Technology* 19: 1467-1482. (in English) ["The study assessed pesticide contamination transfer in Ikpoba River, an important tropical freshwater ecosystem in Southern Nigeria. The study quantified concentrations, bioaccumulation and biomagnification of pesticides in Ikpoba River's food web, with emphasis on less frequently assessed lower trophic-level organisms. Concentrations of pesticides were quantified in water, sediment and biota (phytoplankton, green algae (*Cladophora*), macrophyte (*Comelina erecta*), macrobenthic invertebrates (*Lestes* species, *Caridina africana*, *Enallagma* species, *Gerris lacustris*, *Culex* species, *Pentaneura* species, *Sympetrum* species, *Argyroneta aquatica*, *Lecane* species (*Cladocera*) and pelagic fish (*Tilapia zilli*)). Samples were collected at two separate stations and were analyzed using gas chromatography equipped with electron capture detector. Aldrin was the dominant pesticide in the Ikpoba River food web with

concentrations accounting for 14.4% of the total pesticide residues in the assessed matrices. Sediment samples had significantly higher pesticide concentrations among the matrices assessed, with a total mean concentration of  $0.095 \pm 0.02 \mu\text{g}/\text{kg dw}$ . Among the biota samples, total pesticide levels were significantly higher ( $p < 0.05$ ) in *Commelina erecta*. BAF and BSAF values were also highest in this species indicating that *Commelina erecta* may represent a greater reservoir for pesticides and may be a principal factor in subsequent transfer of pesticides along the food web of Ikpoba River. The BMF values for  $\alpha$ -HCH,  $\gamma$ -HCH,  $\beta$ -HCH, glyphosate, heptachlor, aldrin, heptachlor epoxide, endosulfan I, endrin, carbofuran and diazinon showed that these pesticides have the potential to biomagnify along the trophic levels. The persistence of these pesticides in Ikpoba River supports the need for continuous monitoring." **20784.** Tüzün, N.; Stoks, R. (2022): A fast pace-of-life is traded off against a high thermal performance. *Proc. R. Soc. B* 289: 20212414. 10 pp. (in English) ["The integration of life-history, behavioural and physiological traits into a 'pace-of-life syndrome' is a powerful concept in understanding trait variation in nature. Yet, mechanisms maintaining variation in 'pace-of-life' are not well understood. We tested whether decreased thermal performance is an energetic cost of a faster pace-of-life. We characterized the pace-of-life of larvae of the damselfly *Ischnura elegans* from high-latitude and low-latitude regions when reared at  $20^\circ\text{C}$  or  $24^\circ\text{C}$  in a common-garden experiment, and estimated thermal performance curves for a set of behavioural, physiological and performance traits. Our results confirm a faster pace-of-life (i.e. faster growth and metabolic rate, more active and bold behaviour) in the low-latitude and in warm-reared larvae, and reveal increased maximum performance,  $R_{\text{max}}$ , but not thermal optimum  $T_{\text{opt}}$ , in low-latitude larvae. Besides a clear pace-of-life syndrome integration at the individual level, larvae also aligned along a 'cold-hot' axis. Importantly, a faster pace-of-life correlated negatively with a high thermal performance (i.e. higher  $T_{\text{opt}}$  for swimming speed, metabolic rate, activity and boldness), which was consistent across latitudes and rearing temperatures. This trade-off, potentially driven by the energetically costly maintenance of a fast pace-of-life, may be an alternative mechanism contributing to the maintenance of variation in pace-of-life within populations." **20785.** van Ekström-Ahlby, M.; Svensson, S. (2022): Which ecological drivers affect species turnover? Odonata communities in 16 lakes and ponds in Southern Sweden over a twenty-year period. BcS thesis, Halmstad Univ., School of Business, Innovation and Sustainability: 15 pp- ["Long-term data sets are needed to understand what causes changes in species communities. Odonata communities provide a variety of ecosystem services, for example being biological indicators in freshwater environment to indicate the water quality. Therefore, it is important to understand what is contributing to the species turnover that occurring in lakes on the west coast of Sweden, Halland. We collected and obtained long data sets from 16 lakes in Halland during 2002 to 2022 has been collected and analyzed. Our result shows that the colonization rate is more abun-

dant than the disappearance rate and that there is an ongoing species turnover, where more generalists inhabit the chosen lakes. Due to increased temperature and precipitation as a result of climate change, but also anthropogenic factors, southern species move more northwards. Another result due to climate change is changes in habitat structures. This is some of the reasons that contribute to species turnover in the lakes in Halland. Another driver can be how well species adapt to change overall. In this report we have contributed with new environmental data from 2022, but also long-term data sets, which is highly recommended to use for future research to understand species turnover in Odonata communities and why species are moving northwards." (Authors)] Address: van Ekström-Ahlby, Marianne, Halmstad Univ., School of Business, Innovation & Sustainability

**20786.** Vilenica, M.; Mihaljevic, Z. (2022): Odonata assemblages in anthropogenically impacted habitats in the Drava River — A long-term study. *Water* 2022, 14(19), 3119; <https://doi.org/10.3390/w14193119>. 12 pp. (in English). ["Lotic freshwater ecosystems are among the most threatened ecosystems worldwide due to the effects of multiple stressors, such as intensive land use in their catchments, morphological alterations, flow regulation, pollution, and climate change. Odonata are often used as valuable indicators of ecological integrity and anthropogenic disturbance of freshwater habitats. Here, we present the results of a study on Odonata assemblages in anthropogenically impacted habitats (hydropower plant reservoirs, tailrace canals, drainage ditches, and old river channels) conducted over a nine-year period. The negative impacts of anthropogenic activities on inhabiting biota were confirmed—with only 11 species recorded, the Odonata assemblages were species-poor and had low population densities. Although most species recorded were generalists, some species of national conservation concern were detected. Among the physico-chemical water parameters, the concentrations of ammonium, orthophosphates, nitrates, and mineral oils in the water were found to be the most important determinants of Odonata assemblages. The preservation of near-natural sites in the vicinity of anthropogenically impacted and man-made habitats is important for maintaining the local Odonata fauna and for the preservation of rare species. Our results highlight the importance of long-term data for determining the occurrence of Odonata species and monitoring their population dynamics." (Authors)] Address: Vilenica, Marina, Fac. Teacher Education, Univ. of Zagreb, Trg Matice Hrvatske 12, 44250 Petrinja, Croatia. Email: marina.vilenica@ufzg.hr

**20787.** Watanabe, R.; Ohba, S.-y. (2022): Comparison of the community composition of aquatic insects between wetlands with and without the presence of *Procambarus clarkii*: a case study from Japanese wetlands. *Biological Invasions* 24: 1033-1047. (in English) ["The red swamp crayfish *Procambarus clarkii* (Cambaridae) has been introduced globally and has caused enormous biodiversity losses in freshwater ecosystems. Recently, this invasive species has been acknowledged as factor causing the decline of aquatic insect populations (Odonata, Hemiptera, and Coleoptera) in Japan. Although the negative impacts of *P. clarkii* on aquatic insect communities have been validated by observational studies and laboratory experiments, field studies have not yet been performed. In this study, we investigated whether the presence of *P. clarkii* was a significant factor influencing the community composition of aquatic insects and identified

vulnerable taxa by comparing the aquatic insect communities in wetlands invaded by *P. clarkii* and uninvaded wetlands. We recorded a total of 52 species and 2721 individuals: 50 species and 2405 individuals in non-invaded wetlands, and 23 species and 316 individuals in invaded wetlands. This indicates that the aquatic insect diversity of non-invaded wetlands was higher than that of invaded wetlands. The composition of aquatic insect communities differed between the invaded and non-invaded wetlands. The effect of *P. clarkii* on aquatic insects differed according to their habitat-related traits: species that utilize on the water surface and float near the water surface was less vulnerable than those that utilize aquatic plants as food, oviposition substrates, and perches and hide in the bottom substrate. The eradication of *P. clarkii* at the early stages of invasion, as well as the prevention of its spread in invaded ecosystems is essential to prevent negative impacts on aquatic insects." **20788.** Wijesooriya, M.M.; Jayalath, M.J.; Perera, S.J.; Samanmali, C. (2022): The Odonate fauna (Insecta: Odonata) of Belihuloya, Southern Intermediate zone of Sri Lanka: a preliminary assessment and conservation implications. *Journal of Asia-Pacific Biodiversity* 15(3): 311-328. (in English) ["Highlights: • Odonate fauna from Belihuloya, Sri Lanka includes 36 species (22 in Anisoptera and 14 in Zygoptera). • This includes 12 nationally threatened species (2 CR, 1 EN and 9 VU). • The larval morphology of *Anax indicus* and *Gynacantha dravida* are described for the first time in Sri Lanka. Abstract: Belihuloya situated in a biogeographical transition zone in south-central Sri Lanka is being threatened by land-use changes. Establishing baseline biodiversity knowledge of an indicator taxa within this lesser explored area, the present study systematically assessed Odonates fauna in different habitat types through a transect survey supplemented with incidental observations. Further, the morphology of larvae and exuvia of some Odonates were opportunistically documented from selected water bodies. Transect survey and opportunistic observations identified 36 species of Odonates (22 dragonflies and 14 damselflies) representing ten families, with ten Sri Lankan endemics. Four species of dragonflies and eight damselflies are nationally threatened, including critically endangered *Elattonera centralis* and endangered *Libellago greeni*. The calculated species richness (R), Shannon-Wiener diversity (H'), evenness (E) and Simpson's diversity (1/D) values were, 3.51, 2.40, 0.85 & 7.90, and 2.85, 2.36, 0.92 & 8.68 respectively for dragonflies and damselflies, while two groups show vertical niche segregation. Low Odonate community similarity coefficients among habitat types indicate they are complementary for conservation planning. Out of ten Odonate species for which larval stages were recorded, the larval morphology of *Anax indicus* and *Gynacantha dravida* are described for the first time in Sri Lanka. Baseline data herein are used for evidence-based conservation recommendations." **20789.** Zaika, V.V.; Zabelin, V.I.; Archimaeva, T.P. (2022): Trophic relationship between populations of insects and birds of the River Uyuk (Tava Republic). *Natural Resources, Environment and Society* 3(15): 20-30. (in Russian, with

English summary) ["This paper discusses the interaction of the animal population of aquatic and terrestrial parts of the basin complexes of ecosystems of water flows, using the mountain-taiga river Uyuk, a tributary of the Bolshoi Yenisei, located on the southern macro slope of the Western Sayan. As a result of the studies, the species diversity and features of the distribution of the predominant groups of amphibious insects and birds of the wetland complex were revealed depending on the natural conditions of different parts of the river, and the amount of food resources presented along the river continuum. In total, 52 taxa of aquatic invertebrates were found in the Uyuk River basin, where 26 species of mayflies (Ephemeroptera), 24 species of stoneflies (Plecoptera), 17 species of caddis flies (Trichoptera), and 6 species of dragonflies (Odonata). Diptera species are represented by 6 families. Birds, related to amphibians, are represented by 47 species from 11 families. A small number of species of both was noted in the upper reaches and the mouth part, and the maximum biodiversity in the middle rithral zone. A clear correlation was revealed between the natural conditions of different zones of the river continuum, the number of species and the abundance of invertebrates, near-aquatic and waterfowl: low species diversity and population in the crenal and hyporythral and maximum biodiversity and abundance in the metarithral part of the river channel." (2022): Update on the geographic distribution of the critically endangered *Urothemis edwardsii* (Selys, 1849) (Odonata: Libellulidae) in northeastern Algeria. *Annales de la Société entomologique de France (N.S.)* 58(4): 366-372. (in English, with French summary) ["Assessing temporal changes of the distribution of threatened species is paramount for effective management. Threatened species are sensitive to environmental changes and can be extirpated rapidly due to climatic and anthropogenic effects. Here, we monitor the distribution of the locally critically endangered *Urothemis edwardsii* in northeastern Algeria where the species has been recovering during the last decade after being restricted to a single locality since the 1990s. During the flight seasons in 2018, 2019, and 2021, we conducted field surveys recording the number of males, females, and breeding pairs across 15 sites in northeast Algeria (El Taref province). We found the species at seven sites; reproduction was confirmed at four. In two of the sites, the species was newly recorded but showed no signs of reproduction. We confirmed the maintenance of the reproductive populations that were recently discovered. While the local conservation status of the species is better than that in the 1990s, there are still different threats that need to be addressed and conservation measures that should be implemented or reinforced to ensure maintenance as well as future expansion of the species." (in Dutch) ["Successful breeding of Spotted Flycatchers *Muscicapa striata* in nest-boxes: In 2000, two pairs of *M. striata* were observed from arrival till after fledging at a farm in the province of Friesland (Netherlands). Nest-building took three days; egg-laying started one day after the nests were finished. Incubation lasted 13 days and nestlings fledged at ages between 15 and 16 days old (Table 2). The feeding frequency roughly doubled in the second part of the nestling stage (Table 1). Declines in feeding rate were apparently compensated by providing larger prey items. Of identified prey items, Diptera (n=213) were most common, followed by Odonata (n=45), Lepidoptera (n=27), Coleoptera (n=9) and caterpillars (n=4)." **20792.** Ternois, V.; Gautier, C. (2006): L'évaluation du patrimoine entomologique des étangs piscicoles de Champagne humide (Odonates, Orthoptères et Lépidoptères rhopalocères). *Courrier Scientifique du Parc Naturel Regional de la Forêt d'Orient* 30: 47-62. (in French) ["Conclusion: With odonate 40 species contacted in 2004, including one new species for the Aube department, the odonatological study carried out on the 13 fish ponds of the PNRFO must be considered satisfactory even if it does not allow an exhaustive census for each of the sites studied. The protocol used nevertheless allows a comparison of the sites between them since the survey effort was more or less the same for all the ponds. It is therefore possible to rank the ponds according to their odonatological heritage. The diversity and richness of dragonflies vary greatly from one pond to another. Several elements have been put forward to explain this disparity, such as the general nature of the environment (forest pond, open pond, dry pond, etc.), the diversity and mosaic of the environments present, the impact of fish farming management, whether it be stocking, the nature of the population or the management of water levels. These elements are also at the origin of the patrimonial interest of fishponds for the conservation of dragonflies. Of the 63 known species in Champagne-Ardenne, the ponds of Champagne Humide are home to 54 species, of which thirty or so are remarkable because of their rarity, their degree of threat or their protected status. Some Odonata are dependent on fishponds and their conservation depends largely on the management in place. It would seem that for most owners, fish farming is the primary concern. They therefore allow the peripheral vegetation to develop naturally. However, this spontaneous development towards closed hygrophilous woodland is a limiting factor for the development of Odonata. These require

the presence of hygrophilic border vegetation (rushes and sedges) which allows the emergence of larvae and the maturation of imagos. Management of the entire water body is therefore essential to maintain sufficient biodiversity. Two parameters now seem to be essential to ensure the conservation of Odonata: extensive management of the fish population. This involves favouring the stocking of carnivorous fish while limiting burrowing fish such as carp and tench, in order to limit the turbidity of the water bodies, which is harmful to the larval development of odonates, but also to favour the development of aquatic grass beds, environments used for egg-laying or for the development of larvae. the management of the edges of the ponds to create a mosaic of environments, which is essential for the reproduction and development of the imagos. Floristic diversity will also be ensured by maintaining a natural summer tidal range, which is essential for the development of specific threatened species: *Lestes barbarus*, *L. virens vestalis*, etc." (Authors / DeepL) *Sympecma fusca*; *Lestes barbarus*; *L. dryas*; *L. virens vestalis*; *Coenagrion mercuriale*; *C. pulchellum*; *C. scitulum*; *Cercion lindenii*; *Ischnura pumilio*; *Anax parthenope*; *Brachytron pratense*; *Aeshna isoceles*; *A. affinis*; *A. grandis*; *Somatochlora metallica*; *S. flavomaculata*; *Oxygastra curtisii*; *Epithea bimaculata*; *Gomphus vulgatissimus*; *Onychogomphus forcipatus*; *Cordulegaster boltonii*; *Libellula fulva*; *Orthetrum albistylum*; *O. brunneum*; *O. coerulescens*; *Crocothemis erythraea*; *Sympetrum danae*; *S. fonscolombii*; *S. flaveolum*; *S. meridionale*; *S. vulgatum*; *Leucorrhinia caudalis*; *L. pectoralis*] Address: E-mail: [bonjour@pnrfo.org](mailto:bonjour@pnrfo.org). **20793.** Karsch, A. (2006): Naturschutzfachliches Rahmenkonzept für das Westliche Dachauer Moos. Grundlagenplanung für ein Projekt im BayernNetz Natur. Diplomarbeit. Hochschule Anhalt (FH), Abteilung Bernburg: 204 pp. (in German) [Bayern, Germany; "In this diploma thesis, a nature conservation framework concept for the BayernNetz Nature Project "Westliches Dachauer Moos" is developed, which is understood as basic planning for the further implementation of the project. First of all, the planning basis is determined, which deals with the location, the natural classification, the abiotic conditions, the history and the current situation of the planning area. This is followed by a description of the status of the area in terms of nature conservation. It describes the stock of biotopes and species of selected animal groups and vascular plant species in the planning area. On this basis, a nature conservation assessment is carried out in which significant species and biotopes are identified. Subsequently, suitable areas for compensation measures are identified and existing and possible conflicts are explained. Finally, the concept of objectives and measures compiles proposals for the development of the area in terms of nature conservation .... The dragonfly findings (n=31 species) are mainly distributed among the still waters and ditches in Eschenrieder and Graßfinger Moos and the landscape lake at the Schinderkreppe. The most frequently

recorded species include common and undemanding species such as *Aeshna cyanea*, *Coenagrion puella*, *Platycnemis pennipes* and *Pyrrhosoma nymphula* (see Tab. 5). These are primarily stillwater species with low requirements for the quality of the water bodies and their environment. The only species inhabiting only flowing waters in the PG with relatively many records is *Calopteryx splendens*. There are only a few records or isolated findings of more demanding species such as *Aeshna juncea*, *Coenagrion mercuriale*, *Lestes barbarus* and *Sympetrum flaveolum*. The only more demanding species of which there are several records from different years is *Orthetrum coerulescens*. The species was observed at several ditches in the Eschenrieder Moos and at the landscape lake. At the landscape lake it is also insensitive to major fluctuations in environmental factors (cf.: DROSDOWSKI 1997, p. 240). The species is thus able to colonise a variety of different habitats." **20795.** Xu, Q.-h. (2007): Studies on classification of Fujian odonates, China. Dissertation for Master Degree of Fujian Agriculture and Forestry University: III + 54 pp. (in Chinese, with English summary) ["All the odonate specimens collected from Fujian Province in recent years were studied and identified. 1 new species and 1 new subspecies were described and illustrated, and 14 species were firstly recorded in Fujian. The new species and new subspecies are *Periaeschna zhangzhouensis* sp.nov. and *Planaeschna ishigakiana fujianensis* subsp. nov. The newly recorded species are: *Rhinocypha chaoi* Wilson, *Agriomorpha fusca* May, *Rhipidolestes janetae* Wilson, *Aciagrion olympicum* Laidlaw, *Platycnemis foliacea* Selys, *Anax immaculifrons* Rambur, *Lamelligomphus hainanensis* (Chao), *Merogomphus paviei* Martin, *Phaenandrogomphus chaoi* Zhu et Liang, *Stylurus kreyenbergi* (Ris), *Macromia unca* Wilson, *Macromidia hangzhouensis* Zhou et Wei, *Onychothemis lestacea tonkinensis* Martin and *Zygonyx iris insignis* (Kirby). Based on all the literature records of Fujian odonates and Davies and Tobin system (1984, 1985) of Odonata classification, Fujian odonates were sorted out and revised thoroughly, 16 families, 102 genera and 247 species (subspecies) were

found, which included 233 known species (or subspecies) belonging to 101 genera, 16 families. In the checklist of Fujian odonates, every species was enumerated with relative literature records, amounts of specimens, collected locations and collected times, and distribution. Based on the current methods of entomo-geographical division and the distribution records of 233 known odonates, the faunal analysis of Fujian odonates was conducted. The result showed that the fauna of Fujian odonates belongs to typical Oriental Region, the elements of Oriental Region of Fujian odonate fauna arc dominated by the constituents of Southern Chinese origin. The faunal compositions of Fujian odonates reflect the region characteristics which are obviously discrepant between South-Eastern Fujian and North-Central Fujian which were divided according to entomo-geographical division of agriculture and forestry in Fujian. The gomphid dragonflies of Fujian have an obvious tendency to spread outwards from Indo-Chinese Subregion, which seems to be a center of abundance of the gomphid dragonfly fauna." **20800.** Esch, A. (2011): Die Libellen der Fließgewässer und ihre Begleitfauna im FFH-Gebiet Kottenforst bei Bonn (Insecta: Odonata). Diplomarbeit. Rheinische Friedrich-Wilhelms-Universität Bonn: VIII + 62 pp + Anhang. (in German) ["Summary: In the context of this diploma thesis, the dragonfly fauna of the flowing waters of the FFH area Kottenforst southwest of Bonn was investigated with regard to its dragonfly spectrum and the accompanying aquatic fauna. The aim of the work was to obtain an overview of the frequency and distribution of the typical dragonfly species of smaller, natural flowing waters. The investigation of the aquatic accompanying fauna should provide information about possible predators, but also about the available food supply for dragonflies and their larvae. A comparison with historical data allowed a temporal overview of the spectrum of stream dragonflies in the Kottenforst and a classification in a longer period. From May to October 2010, six streams were examined for dragonfly occurrence and accompanying aquatic fauna at a total of ten survey points, each with six inspections. Both headwater regions, medium stream sections of large and small streams and a relatively newly constructed sand trap were selected as survey points. The inspections were equally distributed over the different times of day. Eleven species were detected during the surveys in 2010. The most species-rich spectrum of dragonflies was observed at the sand trap of the Annaberg stream. Nine of the eleven species recorded in this study were recorded here. Except for one record of Calopteryx splendens, these were dragonfly species typical of still waters. At the other study sites, an average of two dragonfly species were recorded at each stream. A negative exception was the Kluffer Bach, where no dragonflies were recorded between May and October 2010. With Cordulegaster bidentata, C. splendens and C. virgo, three of the four species of small streams occurring in this region could be detected. Only Cordulegaster boltonii was absent from the study area. Due to the known populations of this species in very similarly shaped forests in the area of the Rhine-Sieg district on the right

bank of the Rhine, the Rhine seems to be the current distribution limit of C. boltonii in this region as well. In contrast, Cordulegaster bidentata, which is rare in NRW and classified as critically endangered, was found to be present on the ground at several study sites. It can be regarded as a special feature of the streams in the Kottenforst. The historical data of the NRW dragonfly study group also prove stable occurrences of C. bidentata with simultaneous absence of C. boltonii. In the Kottenforst, the striped damselfly partially colonises stream sections which, compared to previous literature data, are more in line with the known larval habitats of C. boltonii. Whether there is therefore a direct competitive situation between the two damselfly species in the study region, in which C. bidentata has possibly displaced C. boltonii, or whether the Two-striped damselfly has simply not developed the Kottenforst as a habitat so far, remains open. The two damselfly species occurring in the Bonn urban area could only be proven for the Kottenforst through observations of male imagines. Historically, too, only isolated records have been found. This is partly due to the fact that the important requirements of both species for a breeding water, sunny shore sections and lush riparian vegetation, are usually lacking in a forest area. It is therefore not surprising that two of the three records were made outside the actual forest on adjacent streams. Nevertheless, the observations can be interpreted as indications of the occurrence of the two damselflies in the region around the Kottenforst. The accompanying aquatic fauna was mostly dominated by the crayfish Gammarus sp. A special feature was the detection of the crayfish Orconectes limosus in the Katzenloch, which is also a potential predator of dragonfly larvae." (Author)] Address: not stated

**20801.** Billqvist, M (2014): Om exotiska trollsländor i Sverige. fauna & flora 109(1): 10-13. (in Swedish) ["That exotic dragonflies are found in various ways in connection with aquariums, greenhouses, fish farms and similar is known for a long time, and there are quite abundant finds of different species in almost Europe. But what is the situation in Sweden? Here are the three finds that I know of, but there is most likely a large number of unknowns: Agriocnemis pygmaea (Rambur, 1842), Crocothemis servilia (Drury, 1770) and an undetermined species which resembles the genus Ischnura but probably belongs to something of the genera Aciagrion, Xiphiagrion or Amphiallagma." (Author) [https://www.trollslandeforeningen.se/wp-content/uploads/2015/0-1/Exotiska\\_trollsl%c3%a4ndor.pdf](https://www.trollslandeforeningen.se/wp-content/uploads/2015/0-1/Exotiska_trollsl%c3%a4ndor.pdf)] Address: E-mail: magnus.billqvist@gmail.com

**20802.** Kalnins, M. (2014): Resnvedera purvuspares Leucorrhinia caudalis (Charpentier, 1840) sugas aizsardzibas plans. Biedriba "Zala upe", Sigulda. <http://www.slitere.gov.lv/upload/File/DOC/SAPResnvederaPurvuspare-14LV.pdf>: 1-71. (in Latvian, with English summary) ["Lilypad Whiteface (L. caudalis) is one of the species of dragonflies occurring in Latvia, which is considered to be endangered and is included in the regulatory enactments of different levels of conservation of the species. In accordance with the report of Article 17 (FFH Directive), the conservation status assessment of Lilypad Whiteface is adverse; and a negative trend of the conservation status has been found. The assessment of a number of parameters included in the report is based on the grounds of an opinion of an expert or there is no data at all (e.g. as to the hydro-chemical parameters of the microhabitats and habitats of the species). The natural data management system "OZOLS" of Nature Conservation Agency

contains only a few, including inaccurate entries on the fields of the species; therefore it is not possible to plan and carry out appropriate conservation of the fields of the species. When planning the measures of freshwater habitat management, the coastal habitat needs are not assessed in connection of the conservation of Lilypad Whiteface (and other specially protected species of dragonflies). Lilypad Whiteface most commonly is found in eutrophic lakes, less often in diseutrophic lakes and old riverbeds in Latvia. The vegetation in the fields of Lilypad Whiteface in eutrophic lakes and old riverbeds are usually visually moderately abundant to abundant, diverse and rich in species. Typically all zones of aquatic plants – the surface, floating-leaf and submerged – are well-developed. Currently Lilypad Whiteface is found throughout the territory of Latvia. Comparing the historical and contemporary data of the distribution of the species it can be concluded that the number of observations of the species has decreased, which could indicate the decrease of the population of the species in Latvia. The uneven distribution of the species is more referable to the uneven level of research than to the actual distribution of the species. The influencing factors of the population of Lilypad Whiteface are the following: their natural enemies and non-native species, collecting, extreme weather conditions, toxic substances in the environment and the minimum size of the population. However, all these factors hold an unknown or low to medium risk. The non-native species and the minimum size of the populations can be a high risk factor too. The loss of a habitat of the species is a medium risk factor, because it has been established only in some specific places. The fragmentation of habitats (isolation of fields), habitat management (cleaning of water bodies) and mismanagement of habitats of coastal zone (overgrowing) are assessed similarly. However, the combination of these factors can have a major impact on the status of the species' population in Latvia. The protection plan of the species contains a description of the conservation measures of Lilypad Whiteface in the following areas: legislation and conservation planning, conservation of the species and habitats of it, research and monitoring, as well as information and education. A part of the described measures are attributable to the protection of invertebrates or even species and habitats as a whole." **20803.** Robin, K. (2014): Zwergtaucher erbeutet Anax-Larve. *Mercuriale* 14: 67. (in German) [Verbatim: In a harbour area in Schmerikon, at the eastern end of the Zurich Obersee/Switzerland, I spotted two Little Grebes (*Tachybaptus ruficollis*) next to a boathouse and in front of a thin fringe of reeds on 29.11.2013, about 12:30 CET, one of them diving repeatedly. This bird attracted my particular attention because it held a small prey in its beak, but it did not glisten like a wriggling little fish, but seemed immobile and resembled a small branch or piece of reed. The Little Grebe, with its head tilted, kept hitting the surface of the water as if to brush something off. As soon as it had removed this "something" from its beak, it immediately continued diving, and the whole thing was repeated. I managed to photograph the scene several times. I realised that the prey was a large dragonfly larva. After a few minutes and several recaptures, the Little Grebe finally managed to swallow the prey, obviously scratching its throat, because the bird had to gag violently while swallowing with its neck stretched vertically upwards. An analysis of the images showed that the dragonfly larva had temporarily clung to the upper beak. Because of this, the Little Grebe had repeatedly and very forcefully struck its

beak on the water surface. To identify the dragonfly larva, I asked H. Wildermuth and S. Kohl for their assessment. Both experts came up with *Anax* and added that it was most probably *Anax* imperator. Dragonfly larvae as prey of Little Grebes are known (Bandorf 1970: 50), but so far it has only rarely been possible to document this behaviour and to identify the prey with certainty down to the genus level." (Author) Translated with [www.DeepL.com/Translator](http://www.DeepL.com/Translator) (free version)] Address: Robin, K., Im Freudmoos 7, CH-8730 Uznach, Switzerland. Email: klaus.robin@robin-habitat.ch

**20804.** Robin, K. (2014): Graukranich erbeutet Vierfleck (*Libellula quadrimaculata*). *Mercuriale* 14: 68. (in German) [Verbatim: In the Linth Plain, between Lakes Zurich and Walen, lies the Kaltbrunner Riet, a Swiss fen, amphibian spawning area and waterbird and migratory bird reserve of national importance and in the international context of Ramsar Site CH-7. The area is considered an odonatological (Wildermuth et al. 2005) and ornithological (Geisser et al. 2010) hotspot. Among the more than 200 bird species that have been recorded here in recent years is the Grey Crane (*Grus g. grus*), which in the recent past has increasingly been resting in small groups, but then usually moves on. In exceptional cases, individual birds remain into the breeding season or appear for a few days and depart again, as in the present case. The adult bird appeared on 30 May 2014 in the immediate vicinity of the Kaltbrunner Riet on a former *Molinia*-meadow, which had been drained in the 1960s and is currently used as a mowing meadow. I spotted the bird there at 16:30 h CET and observed it foraging. Bending forward, it walked slowly through the tall vegetation, dipping its head low from time to time. When his head came up again, I could often see him holding an earthworm in his beak. A few times, however, I noticed that it paused for a moment and did not aim at the ground, but at an object on a stalk in the tall grass. The crane then snapped its head forward and grabbed the object with its beak. After snapping at it several times, it hurled it into its beak and finally swallowed it. I was able to document this process photographically. Already in the field I recognised that the crane was eating dragonflies. At maximum magnification, I identified the photographed prey as a four-spotted imago (*Libellula quadrimaculata*). It is well known that cranes eat invertebrates and insects (Makatsch 1970). In the present case, the crane's breeding season stay and the seasonal availability of the four-spotted as food for this individual are remarkable. Results: Species diversity: The studies on Odonata fauna of Aravalli Range of Rajasthan reveals that so far 46 species belongs to 8 families under 2 suborders were recorded, in which 12 species are new records from Rajasthan state i.e. *Pseudagrion microcephalum* (Rambur, 1842), *Disparoneura quadrimaculata* (Rambur, 1842), *Neurobasis chinensis* (Linnaeus, 1758), *Anax immaculifrons* Rambur, 1842, *A. parthenope* (Selys, 1839), *Neurothemis fulvia* (Drury, 1773), *N. tullia* (Drury, 1773), *Tholymis tillarga* (Fabricius, 1798), *Tramea basilaris burmeisteri* Kirby, 1889, *T. limbata* (Rambur, 1842), *T. virginia* (Rambur, 1842) and *Trithemis kirbyi* Selys, 1891 (Table 1). The study reveals that *Ceragrion coromandelianum* (Fabricius, 1798), *Brachythemis contaminata* (Fabricius, 1793), *Bradinopyga geminata* (Rambur, 1842), *Crocothemis servilia* (Drury, 1770), *Ischnura aurora* (Brauer,

1865), *Pseudagrion rubriceps* Selys, 1876, *Orthetrum glaucum* (Brauer, 1865), *O. prunosum neglectum* (Rambur, 1842), *O. sabina* (Drury, 1770), *Pantala flavescens* (Fabricius, 1798) and *Trithemis aurora* (Burmeister, 1839) were the dominant species of Odonates of Aravalli Range of Rajasthan. The mass emergence of *P. flavescens*, a migratory species was recorded from May to October in different localities of Aravalli Range of Rajasthan during 2008-11. Annotated checklist of Odonata of Aravalli Range of Rajasthan prepared, followed by detailed systematic account species wise (Table 1).] Address: Sharma, G., Zoological Survey of India, M-Block, New Alipore, Kolkata. 700 053, India

**20806.** Whatley, M.H.; van Loon, E.E.; Vonk, J.A.; van der Geest, G.; Admiraal, W. (2014): The role of emergent vegetation in structuring aquatic insect communities in peatland drainage ditches. *Aquatic Ecology* 48: 267-283. (in English) ["Availability of macrophyte habitat is recognized as an important driver of aquatic insect communities in peatland drainage ditches; however, eutrophication can lead to the decline of submerged vegetation. While emergent vegetation is able to persist in eutrophicated ditches, vegetation removal, carried out during ditch maintenance, can reduce the availability of this habitat. In this study, we applied the landscape filtering approach to determine whether the absence of emergent vegetation is a habitat filter which structures aquatic insect communities in peatland drainage ditches under different trophic conditions. To this end, a field study was carried out in one mesotrophic (Naardermeer) and one eutrophic (Wormer and Jisperveld) peatland in the province of North Holland, The Netherlands. We assigned life history strategies to insect species and applied linear mixed models and redundancy analyses to taxonomic and functional aquatic insect community data. Our results indicate that while differences between peatlands primarily determine the species pool within each wetland, emergent vegetation acted as a secondary filter by structuring functional community composition within ditches. The eutrophic peatland was dominated by insects adapted to abiotic extremes, while species with good dispersal abilities were strongly related to emergent vegetation cover. This study demonstrates the applicability of life history strategies to provide insight into the filtering of species due to availability of emergent macrophyte habitat. To ensure greater diversity of insect communities in ditch habitats, it is recommended that some vegetation be spared during maintenance to leave patches from which insect recolonization can occur." **20809.** Davidovich, H.; Ribak, G. (2016): Flying with eight wings: inter-sex differences in wingbeat kinematics and aerodynamics during the copulatory flight of damselflies (*Ischnura elegans*). *The Science of Nature* 103:65: 8 pp. (in English) ["Copulation in the blue-tailed damselfly, *Ischnura elegans*, can last over 5 hours, during which the pair may fly from place to place in the so-called "wheel position". We filmed copulatory free-flight and analyzed the wingbeat kinematics of males and females in order to understand the contribution of the two sexes to this cooperative flight form. Both sexes flapped their wings but at different flapping frequencies resulting in a lack of synchronization between the flapping of the two insects. Despite their unusual body posture, females flapped their wings in a stroke-plane not significantly different to that of the males (repeated-measures ANOVA,  $F_{1,7} = 0.154$ ,  $p = 0.71$ ). However, their flapping amplitudes were smaller by  $42 \pm 17$  %, compared to their male mates ( $t$  test,  $t_7 = 9.298$ ,  $p < 0.001$ ). This was mostly due to shortening of the amplitude at the ventral stroke reversal point. Compared to solitary flight, males flying in copula increased flapping frequency by 19 %, while females decreased flapping amplitude by 27 %. These findings suggest that although both sexes contribute to copulatory flight, females reduce their effort, while males increase their aerodynamic output in order to carry both their own weight and some of the female's weight. This increased investment by the male is amplified due to male *I. elegans* being typically smaller than females. The need by smaller males to fly while carrying some of the weight of their larger mates may pose a constraint on the ability of mating pairs to evade predators or counter interference from competing solitary males." **20810.** Gangadoo, S.; Chandra, S.; Power, A.; Hellio, C.; Watson, G.S.; Watson, J.A.; Greend, D.W.; Chapman, J. (2016): Biomimetics for early stage biofouling prevention:

templates from insect cuticles. *Journal of Materials Chemistry B* 4: 5747-5754. (in English) ["A biomimetic antifouling material study was carried out utilising superhydrophobic cicada and dragonfly wings replicated with a polymer (epoxy resin). They were tested in a marine biofouling study for up to 1 week in addition to biofouling assays of protein, carbohydrate and DNA absorption. The materials were compared against a commercial antifouling paint and a polymeric smooth surface constituting a control sample. The replicated surfaces demonstrated superior antifouling properties in comparison to the control and similar efficiency in DNA (10% reduction), protein and carbohydrate adsorption (15%) to the commercial anti-fouling paint. As the fabricated surfaces have roughness at the nanometre scale it is probable that the low adsorption properties, at least in the early stages, may be related to air trapped at the surface. Interestingly the most disordered replicated surface (dragonfly wing replicate) demonstrated the lowest values of absorption." **20812.** Huda, N.; Anwer, S.F. (2016): The effects of leading edge orientation on the aerodynamic performance of dragon fly wing section in gliding flight. Chapter: *Fluid Mechanics and Fluid Power – Contemporary Research*. Part of the series *Lecture Notes in Mechanical Engineering*: 1433-1441. ["In this work, we investigate the aerodynamic characteristics and spatio-temporal dynamics of a wing cut section of dragon fly (*Aeshna cyanea* [sic]) at ultra-low Reynolds number corresponding to the gliding flight of this dragon fly. The simulations employ an unstructured triangular mesh based on finite volume discretization. A critical assessment of the computed results is performed. Numerical simulations are performed at ultra-low Reynolds number of 10,000 at different angles of attack. Three insect wing sections are modeled with different orientation of the leading edge. It is shown that among all profiles, Profile LEU has largest gliding ratio at higher angles of attack. The larger gliding ratio is due to the fact that the overall drag coefficient is smaller as compared to other Profiles LES and LED. The smaller drag coefficient is due to the presence of large negative shear regions present in the flow. The negative shear regions are because of vortices formed attached to the leading edge or

inside the pleats. The presence of vortices attached not only reduces the contribution of shear drag but pressure drag also." (Authors)] Address: Anwer, S.F., Department of Mechanical Engineering, ZHCET, AMU, Aligarh, India

**20813.** Hushtan, K.V. (2016): The methodological approaches for allocation of dragonfly's larvae ecomorphs categories (Insecta: Odonata). *Notes of the State Natural History Museum, Lviv* 32: 83-91. (in Ukrainian, with Russian and English summaries) ["We have proposed to use as the main – morphometric method for the allocation of dragonfly's larvae ecomorphs categories. Also, it is proposed to take into account environmental (spatial niche), ethological (type of movement, behavioral characteristics) and morphological criteria (overall shape of the body, the type of mouthparts, the structure of the sense organs and legs). Twenty dimensional characteristics for 15 genera of Ukrainian Carpathians dragonflies larvae [*Aeshna juncea*, *Anax parthenope*, *Brachytron pratense*, *Calopteryx splendens*, *Coenagrion puella*, *Cordulegaster bidentata*, *Cordulia aenea*, *Epitheca bimaculata*, *Gomphus vulgatissimus*, *Lestes barbarus*, *Libellula quadrimaculata*, *Ophiogomphus cecilia*, *Onychogomphus forcipatus*, *Platycnemis pennipes*, *Sympetrum flaveolum*] is studied. Of these, 17 characters are allocated indices reflecting the most complete contact between the larvae and environmental condition. On the basis of the proposed methods first developed a hierarchical classification of dragonfly larvae ecomorphs for the territory of the Ukrainian Carpathians. Were singled out: 3 types, 6 classes and 7 subclasses." (Author)] Address: Email: Katerina-an-tonyuk@yandex.ru

**20814.** Juslén, A.; Pykälä, J.; Kuusela, S.; Kaila, L.; Kullberg, J.; Mattila, J.; Muona, J.; Saari, S.; Cardoso, P (2016): Application of the Red List Index as an indicator of habitat change. *Biodiversity and Conservation* 25(3): 569-585. (in English) ["For the first time ever, the International Union for Conservation of Nature Red List Index for habitat types was calculated for an entire country, Finland. The RLIs were based on species threat assessments from 2000 and 2010 and included habitat definitions for all 10,131 species of 12 organism groups. The RLIs were bootstrapped to track statistically significant changes. The RLI changes of species grouped by habitats were negative for all habitat types except for forests and rural biotopes which showed a stable trend. Trends of beetles and true bugs were positive in rural and forest habitats. Other 16 observed trends of species group and habitat combinations were negative. Several trends observed were in accordance with studies focusing on particular taxa and habitats, and drivers for their change. This study demonstrates the usefulness of the RLI as a tool for observing habitat change based on species threat assessment data." **20815.** Kalkman, V.J.; Orr, A.G. (2016): A description of the larva and discussion of radiation in the phytotelm breeding damselfly genus *Papuagrion* in New Guinea (Odonata: Zygoptera: Coenagrionidae). *International Journal of Odonatology* 19(3): 169-182. (in English) ["The larva of *Papuagrion marijanmatoki* Orr & Richards, 2016 is described and illustrated for the first time based on two specimens collected near Goroka, Papua New Guinea. The larvae were identified by matching the mitochondrial marker COI with that of an adult specimen collected at the same locality. The larvae were found in the leaf axils of *Pandanus* trees which

agrees with earlier observations that adults are often encountered away from water, in the vicinity of Pandanus. Larvae collected from water pooled in the leaf bracts of several Pandanus trees in the Muller Range (PNG) are also thought to belong to the genus *Papuagrion*. Based on these records and further observations it is considered likely that all species of *Papuagrion* live in phytotelmata and that most or even all are found in Pandanus trees. *Papuagrion* is derived from a Papuan radiation of the genus *Teinobasis*, members of which inhabit standing or slow-flowing and often muddy waters, where the larvae probably develop, suggesting that the colonisation of phytotelmata offered by Pandanus trees has led to the radiation of *Papuagrion*, possibly because of the discrete and scattered nature of suitable habitats. The larvae show little difference morphologically from the few known *Teinobasis* larvae. The colonisation of phytotelmata as a larval habitat sometimes followed by an extensive radiation seems to have occurred independently several times within *Coenagrionidae*." **20817.** Kiany, M.; Sadeghi, S.; Ehteshami, F. (2016): New record of *Platynemis kervillei* and *Lestes dryas* (Odonata: Platynemididae & Lestidae) from Iran. 19th National and 7th International Congress of Biology, 30 Aug-1 Sep 2016, University of Tabriz, Iran: 94. (in bilingual in Farsi and English) [Verbatim: *Platynemis kervillei* (Martin, 1909) and *Lestes dryas* (Kirby, 1890) are reported for the first time from North-Western part of Iran. *P. kervillei* also has previously recorded in Iraq and Turkey countries. *L. dryas* is a holarctic widespread species. *P. kervillei* specimens where collected from warm spring near Sarein and river near Namin (Ardabil province) and *L. dryas* specimens where collected from Daylaman (Guilan province). Previous reports of *P. kervillei* from Turkey and Iraq is about 1000 and 500 km far from the Iranian collecting site respectively. With this report extends range of *P. kervillei* to the north. western part of Iran and we can propose that this species replaced with *P. dealbata* in the lowland parts of Caspian marginal zone. This species is distinguishable from other related species with blue pruinosity in the most part of body in fully adult males and no swollen tibia. *L. dryas* also is recognizable with lack of blue pruinosity in apical third of dorsal abdominal segment and more robust abdomen from similar species. Relative abundance

of this species distinctly was lower than other species of the genus in the locality.] Address: Email: [ssadeghi@shirazu.ac.ir](mailto:ssadeghi@shirazu.ac.ir)

**20818.** Kulshrestha, R.; Jain, N. (2016): A note on the biodiversity of insects collected from a college campus of Jhalawar District, Rajasthan. *Biosci. Biotech. Res. Comm.* 9(2): 327-330. (in English) ["The study of biodiversity of insects was conducted in the college campus which covers around half square kilometer area. One boundary of college campus is along NH12. The major vegetation of college campus is neem, banyan, Asoka and amalatas trees and some ornamental and medicinal plants. The main objective of the study was to determine the insect diversity and the relative abundance of the insect species in the campus. The collection of insects was carried out by using sweep nets, hand picking and beating tray in the month of Feb.-March and Sept-Oct in the year 2012. Species diversity and abundance of insects were investigated in college campus and we recorded insects belonging to 7 orders 16 families and 38 species. The largest number of insect identified were of Lepidoptera followed by Hymenoptera, Odonata, Hemiptera, Orthoptera, Coleoptera and Neuroptera. Anthropogenic activities influenced the abundance of insect orders. Thus, greater numbers of insects were observed in small gardens with a greater proportion of bare soil relative to concrete pathways and places with human interference. The study revealed the higher abundance of butterflies among the insects identified. A total 38 different insect species were recorded giving an indication of the species diversity of the college campus." **20819.** Lesch, V.; Kinoshita, A.; Shibata, Y.; Bouwman, H. (2016): Perfluorinated substances in dragonflies (Odonata): an aerial invertebrate predator. Conference: DIOXIN 2016: 1 p. (in English) ["Perfluoroalkyl substance (PFASs) residues have been found globally in both abiotic and biotic media. However, relatively little is known of these compounds in invertebrates, particularly in terrestrial invertebrates. We analysed dragonflies collected from six sites in South Africa, and analysed them individually for perfluorooctane sulfonic acid (PFOS), perfluorooctanoic acid (PFOA), perfluorononanoic acid (PFNA), perfluorodecanoic acid (PFDA), perfluoroundecanoic acid (PFUnA) and perfluorododecanoic acid (PFDoA). We found quantifiable PFOS in all individuals, with the other analytes occurring less frequently. The more remote (further away from industries) northern sites had significantly lower concentrations than the southern sites that were closer associated with industrial areas. The mean PFASs was 0.19 ng/g wet mass for the northern sites. The mean concentration was 9.0 ng/g wm for the southern sites. All PFASs except PFOS occurred at similar mean concentrations at all sites, but PFOS dominated the southern samples. One sample had a concentration of 20 ng/g wet mass. This is the same site where very high concentrations of PFOS were found in bird eggs. The effects of these concentrations and substances on invertebrate aerial predators are not well known, but it may affect aquatic and associated terrestrial ecosystems due to the predation of dragonflies on pollinators. More studies are needed to elucidate the distribution pattern and effects." **20821.** Meadows, A.J. (2016): Lethal and non-lethal effects of predators on *Culex* mosquitoes: Implications for pathogen transmission. Ph.D. thesis, Department of Entomology, Washington State University: XI + 122 pp. (in English) ["Diversity loss, especially at higher trophic levels, can degrade critical ecosystem services such as disease regulation. Predators play pivotal roles in regulating ecosystem services by impacting the abundance, distribution, physiology, condition, and behaviour of their prey. Previous work shows the ecological consequences arising from single-predator nonconsumptive effects (NCEs) can be just as significant as those resulting from actual predation, yet the study of NCEs within naturally-diverse communities is relatively underdeveloped. This dissertation seeks to examine how larval-stage predator community structure influences mosquito (*Culex pipiens*) traits that are relevant to pathogen transmission. When developing mosquito larvae are exposed to predation risk, this stress may produce lasting effects throughout mosquito ontogeny that can influence such key traits as longevity and immune function. The work presented here provides several key findings. First, an examination of how naturally-diverse larval-stage predator communities influence mosquito condition throughout their ontogeny revealed that the presence of *Aeshna* dragonfly naiads, which were limited to the most diverse field predator communities, significantly muted the NCEs evident in mosquitoes. Mosquitoes emerging from *Aeshna* communities experienced increased survival through development, but decreased adult longevity compared to no-*Aeshna* communities. This trend occurred across natural variation in predator community composition, density, and evenness. We designed a follow-up experiment that exposed developing mosquitoes to factorial manipulations of predator diversity and tested adult mosquitoes for variation in phenoloxidase investment (an important component of arthropod innate immunity) and for susceptibility to the fungal pathogen *Beauveria bassiana*. We found that when presented with *Aeshna* cues, mosquitoes had lower phenoloxidase levels than mosquitoes reared in the presence of other predators; however, these negative impacts on mosquito immune investment were offset when mosquitoes were exposed to *Aeshna* in combination with other predators. These results imply that diverse predator communities, in addition to their capacity to suppress vector densities through predation, may lower disease risk by offsetting negative NCEs imposed by less-diverse communities that would otherwise increase vector competence. This dissertation ends with a review and synthesis paper that broadly explores the role of arthropod and mammalian predators in regulating other critical ecosystem services such as biodiversity maintenance." **20823.** Mishra, Y. (2016): Studies on insect fauna collected in light trap during Kharif season at Jabalpur. M.Sc. thesis, Department of Entomology, College of Agriculture, Jabalpur 482004, Jawaharlal Nehru Krishi Vishwa Vidyalaya, Jabalpur, Madhya Pradesh, India: 89 pp. (in English) ["Rice (*Oryza sativa* L.) is an important cereal crop in the world provides a staple food for nearly half of the global population. Over 100 insect pest species attack paddy crop at various stages of its growth of which 20 species cause the economic damage (Pathak & Dhaliwal, 1981). In India average losses in paddy production due to insect pests are 25-30% (Dhaliwal and Arora, 2010) and in Madhya Pradesh about 40-100 % losses were observed (Dhamdhare, 1990). Light trap is an important tool for minimizing the insect pests damage without any toxic hazards (Sharma et al., 2004). Other than this light trap has been used to supplement the knowledge of pest fauna of given locality, geographical distribution and their seasonal activity etc. (Verma & Vaishampayan, 1983 and Sharma et al., 2010). Light trap is also useful to know the effect the weather factors on species abundance (Jonason et al 2014b). Therefore the present research work on "Studies on insect fauna collected in light trap during kharif season at Jabalpur" was under taken with following objectives. 1. Incidence and identification of insect fauna collected in light trap during kharif season at Jabalpur. 2. Study on seasonal incidence of insect pest species of paddy collected through light trap. For the taxonomic documentation, the light trap was operated every night and collection was observed on the next day morning. Total insect fauna was observed and sorted out on the basis of 3 major categories of economic importance: I) Harmful insects. as crop pests. II) Beneficial insects. as bio-control agents (Predators and parasites). III) Beneficial insects. as commercially important. Seasonal incidence study of insect pest species was done by operating the light trap during kharif season of 2015. A insect pest of paddy and predator & parasite was observed on daily basis. In order to study the seasonal incidence, daily trap catch was converted into weekly total and mean per day per week (weekly mean/day). 1. Incidence and identification of insect fauna collected in light trap during Kharif season at Jabalpur. Taxonomic analysis revealed that these 62 insect species belonging to 11 orders and 34 families were recorded throughout the season (kharif 2015).

Based on number of species collected, largest collection was represented by order Lepidoptera 19 species (30%) followed by order Coleoptera 13 species (21%), Hemiptera 12 species (20%), Orthoptera 5 species (8%) and Hymenoptera 5 species (8%) in descending order respectively. Orders of minor significance are represented by Odonata [2 taxa] and Neuroptera having 2 species each while Isoptera, Diptera, Dermaptera and Dictyoptera were represented by one species only. **20825.** Naka, H.; Hashimoto, H. (2016): E-1-1 Relationship between deformation of wings and feathering motion on dragonfly flight. Conference on Information, Intelligence and Precision Equipment: IIP 2016, "E-1-1-1"- "E-1-1-4", 2016-03-14: 4 pp. (in Japanese, with English summary) ["Dragonfly wing is passively deformed in the tip side from nodus flapping flight. Wing deformation is thought to correspond to feathering motion. However, dragonfly perform a feathering motion actively. In this study, the effect of passive deformation of the wing on aerodynamic force in flapping flight with feathering motions was investigated using fluid-structure interaction analysis. In this analysis, nodus wing models, which can deform passively, and rigid wing model, which cannot deform, are used. Feathering angle is three types: 0, 20, 40 deg. As a result, when the feathering angle is 20 deg or less, the nodus wings reduce drag force by deformation of Wing during downstroke. However, when the feathering angle is 20 deg or more, overlarge deformation of wing decreases lift force. Therefore, the wing with the appropriate level of flexibility can reduce drag force without wasting energy of feathering motion." (in English) ["Odonates are considered to be indicator of ecological balance. An inventory was carried out to document the over looked odonate diversity in four habitat types (hill stream, river, reservoir and pond) of Koraput district, southern Odisha, India. The study recorded 64 species representing 45 genera under 9 families. Family Libellulidae was the dominant group representing 32 species. Maximum species (n=58, 90.6%) were recorded along hill streams. Forty-one species were recorded from single habitat type, of which 37 species were confined to hill streams. A decreasing trend in species diversity was observed from the water bodies in the forested areas to human dominated landscapes indicating human impact on odonate species diversity. *Brachythemis contaminata* was most frequently sighted in the water bodies near human habitations, indicating highly polluted water not suitable for human consumption, whereas species like *Ictinogomphus rapax* and *Paragomphus lineatus* were only recorded along hill streams, indicating unpolluted water." **20827.** Patel, R.K.; Ghetiya, L.V.; Patel, S.R. (2016): Odonates of South Gujarat: An Inventory. *Advances in Life Sciences* 5(21): 9952-9958. (in English) ["A study on general inventory of odonates in south Gujarat, India was carried out in south Gujarat by the Department of Entomology, N. M. College of Agriculture, Navsari Agricultural University, Navsari, Gujarat, India. Odonates are commonly found darting and dancing actively near pond, pool, river streams, seashore, plains, hills, agroecosystem, forest ecosystem, muddy places and also in sewage and effluents water. Some species of odonates were recorded perching at different height on plants and trees/buildings considerably away from the water and the dense forest. The survey was conducted in different localities of south Gujarat, which consist of seven districts i.e. Bharuch, Narmada, Surat, Tapi, The Dangs, Navsari and Valsad during 2014-15. Total 37 species of odonates belongs to 28 genera, from eight families of two sub-orders were recorded during study period. Among which 28 species were belongs to sub-order Anisoptera under the families Libellulidae (23), Aeshnidae (2), Gomphidae (2) and Macromiidae (1), whereas remaining 9 species were belongs to sub-order Zygoptera under families Coenagrionidae (6), Platycnemididae (1) Protoneuridae (1) and Lestidae (1). Out of total record, 20 species were reported for first time from south Gujarat. However, Four species namely, *Rhodothemis rufa*, *Tramea limbata*, *Zyxomma petiolatum* and *Gynacantha dravida* were reported first time from Gujarat state." **20829.** Saito, V.S.; Valente-Neto, F.; Rodrigues, M.E.; Roque, F.; Siqueira, T. (2016): Phylogenetic clustering among aggressive competitors: evidence from odonate assemblages along a riverine gradient. *Oecologia* 182(1): 219-229. (in English) ["Studies on phylogenetic community ecology usually infer habitat filtering when communities are phylogenetically clustered or competitive exclusion when communities are overdispersed. This logic is based on strong competition and niche similarity among closely related species—a less common phenomenon than previously expected. Odonata are good models for testing predictions based on this logic because they behave aggressively towards related species due to mistaken identification of conspecifics. This behaviour may drive communities toward phylogenetic overdispersion if closely related species frequently exclude each other. However, phylogenetically clustered communities could also be observed if habitat filtering and/or competitive asymmetry among distantly related species are major

drivers of community assembling. We investigated the phylogenetic structure of odonate assemblages in central Brazil in a watershed characterized by variations in stream width, vegetation cover, aquatic vegetation, and luminosity. We observed general clustering in communities according to two indices of phylogenetic structure. Phylogenetic beta diversity coupled with Mantel tests and RLQ analysis evidenced a correlation between the riverine gradient and phylogenetic structure. Larger rivers with aquatic vegetation were characterized by anisopterans, while most zygopterans stayed in small and shaded streams. These results indicate niche conservatism in Odonata habitat occupancy, and that the environment is a major influence on the phylogenetic structure of these communities. We suggest that this is due to clade-specific ecophysiological requirements, and because closely related species may also have competitive advantages and dominate certain preferred habitats." **20830.** Sanmartín-Villar, I.; Cordero-Rivera, A. (2016): The inheritance of female colour polymorphism in *Ischnura genei* (Zygoptera: Coenagrionidae), with observations on melanism under laboratory conditions. *PeerJ* 4: e2380 <https://doi.org/10.7717/peerj.2380>: 19 pp. (in English) ["Current research on female colour polymorphism in *Ischnura damselflies* suggests that a balanced fitness trade-off between morphotypes contributes to the maintenance of polymorphism inside populations. The genetic inheritance system constitutes a key factor to understand morph fluctuation and fitness. *Ischnura genei*, an endemic species of some Mediterranean islands, has three female colour morphs, including one androchrome (male-coloured) and two gynochromes. In this study, we reared two generations of *I. genei* under laboratory conditions and tested male behavioural responses to female colour morphs in the field. We recorded ontogenetic colour changes and studied morph frequency in three populations from Sardinia (Italy). Morph frequencies of laboratory crosses can be explained by a model based on an autosomal locus with three alleles and sex-restricted expression, except for one crossing of 42 families with unexpected offspring. The allelic dominance relationship was androchrome > infuscans > aurantiaca. Old individuals reared in the laboratory exhibited different levels of melanism in variable extent depending on sex and morph. Results of model presentations indicate a male preference for gynochrome females and the lack of recognition of androchromes as potential mates. *Aurantiaca* females were the most frequent morph in the field (63–87%). Further studies in other populations and islands are needed to understand the maintenance of this polymorphism." **20831.** Santos, E.S.A.; Machado, G. (2016): Sexual dichromatism in wing pigmentation of New World dragonflies follows Rensch's rule. *Journal of Evolutionary Biology* 29(7): 1447-1454. (in English) ["Many animal taxa that display sexual size dimorphism (SSD) exhibit a positive allometric relationship in which the degree of dimorphism increases with body size. This macroevolutionary pattern is known as Rensch's rule. Although sexual selection is hypothesized to be the main mechanism causing this pattern, body size is influenced by several selective forces, including natural and

sexual selection. Therefore, by focusing exclusively on SSD one cannot ascertain which of these selective forces drives Rensch's rule. If sexual selection is indeed the main mechanism underlying Rensch's rule, we predict that other sexually selected traits, including colouration-based ornaments will also exhibit interspecific allometric scaling consistent with Rensch's rule. We tested this prediction using wing pigmentation of 89 species of dragonflies. Studies show that male wing pigmentation is generally under strong intra- and intersexual selection, so that sexual dichromatism in this trait should follow Rensch's rule. Conversely, the available evidence suggests that male body size is usually not sexually selected in dragonflies, so we do not expect SSD to follow Rensch's rule. First, we found that sexual dichromatism in wing pigmentation was consistent with Rensch's rule. The phylogenetic major axis regression slope was significantly greater than one. We also showed that the allometric slope for SSD was not different from unity, providing no support for Rensch's rule. Our results provide the first evidence that a trait which appears to be under strong sexual selection, exhibits a pattern consistent with Rensch's rule." **20833.** Showalter, A.M. (2016): The impact of environmental conditions, food resources, and ecological stoichiometry in structured populations. Doctor of Philosophy, Miami University, Ecology, Evolution and Environmental Biology: XI + 140 pp. (in English) ["In this dissertation, I explore how population structure and the characteristics of individuals within structured populations respond to changes in environmental conditions that affect the quantity and quality of food resources. Chapter 1: For bluegill sunfish, individual size and population size-structure is affected by factors that alter prey availability, including primary productivity, sediment-feeding gizzard shad, and intraspecific competition. In a ten-month study, I manipulated productivity and gizzard shad in experimental ponds with bluegill populations that varied in density, and I used AIC model comparisons to identify the factors most associated with bluegill response variables. Density-dependence, probably driven by resource competition, was the most consistent factor associated with individual bluegill biomass. None of the models I examined were significant in explaining adult/juvenile density or the proportion of adults. Chapter 2: I investigated how elemental imbalance between an individual's diet and its needs varies with ontogenetic diet shifts. I examined ontogenetic changes in stoichiometry in the bluegill sunfish, which undergoes an

ontogenetic diet shift from zooplankton to benthic invertebrates, and I compared imbalance between diet elemental content and organism needs before and after diet shifts. Elemental imbalance estimates indicated potential carbon limitation in all size-classes of bluegill, and the diet shift tended to reduce C imbalance relative to P. My results provide stoichiometrically-explicit support for previous findings that energetics is an important driver of bluegill diet shifts. As a consequence of the need to satisfy carbon requirements, N:P imbalance is exacerbated. Thus, ontogenetic diet shifts can produce trade-offs in elemental imbalance between elemental ratios. Chapter 3: I examined how light and nutrient conditions experienced in larval stages of the damselfly *Enallagma aspersum* affected development time, mass at emergence, and adult body composition. I reared larval damselflies to adulthood in outdoor mesocosms under high and low light and nutrient conditions. Light level consistently affected damselflies by altering temperature and producing temporal changes in food availability. Damselflies reared in high light had faster development times, but did not differ in mass at emergence. In addition, temperature can explain most patterns adult elemental content, although male and female C:P differed in response to light. Overall, differences in light-driven temperature effects appear to be a major factor affecting damselfly life history traits and stoichiometry." (Author)] Address: not stated

**20834.** Sisson, M.S.; Santamaria, C.A.; Smith-Herron, A.J.; Cook, T.J.; Cook, J.L. (2016): Geographical color pattern of *Argia apicalis* (Odonata: Coenagrionidae) in the absence of molecular variation. *Florida Entomologist* 99(3): 355-362. (in English, with Spanish summary) ["*Argia apicalis* Say, is an ecologically vagile species inhabiting both pond and stream environments of the eastern United States. Variation in color pattern in *A. apicalis* occurs between a southeastern United States morph and a south Florida morph. Southeastern populations often are described as "typical" with a predominantly bright blue pterothorax and narrow black humeral stripe, whereas the southern Florida populations are "atypical," with a bright blue pterothorax and larger, wider black humeral stripes. Variability in color pattern has caused some researchers to question the true identity of the Florida morph. This study used color pattern and mitochondrial cytochrome b sequences to test the species identity of the 2 *A. apicalis* geographical color morphs. Mitochondrial cytochrome-b gene sequences showed that there is a single haplotype, showing no divergence between individuals, populations, or regions. This study is the first to test if color pattern variation is correlated with molecular characters within this species." **20835.** Sivasankaran, P.N.; Ward, T.A.; Viyapuri, R.; Johhan, M.R. (2016): Static strength analysis of dragonfly inspired wings for biomimetic micro aerial vehicles. *Chinese Journal of Aeronautics* 29(2): 411-423. (in English) ["This article examines the suitability of fabricating artificial, dragonfly-like, wing frames from materials that are commonly used in unmanned aircraft (balsa wood, black graphite carbon fiber and red prepreg fiberglass). Wing frames made with Type 321 stainless steel are also examined for comparison. The purpose of these wings is for future use in biomimetic micro aerial vehicles (BMAV). BMAV are a new class of unmanned micro-sized aerial vehicles that mimic flying biological organisms (like flying insects). Insects, such as dragonflies, possess corrugated and complex vein structures that are

difficult to mimic. Simplified dragonfly-like wing frames were fabricated from these materials and then a nano-composite film was adhered to them, which mimics the membrane of an actual dragonfly. Finite element analysis simulations were also performed and compared to experimental results. The results showed good agreement (less than 10% difference for all cases). Analysis of these results shows that stainless steel is a poor choice for this wing configuration, primarily because of the aggressive oxidation observed. Steel, as well as balsa wood, also lacks flexibility. In comparison, black graphite carbon fiber and red prepreg fiberglass offer some structural advantages, making them more suitable for consideration in future BMAV applications." **20836.** Tichanek, F.; Tropek, R. (2016): The endangered damselfly *Coenagrion ornatum* in post-mining streams: population size, habitat requirements and restoration. *Journal of Insect Conservation* 20(4): 701-710. (in English) ["*C. ornatum* represents a threatened species of lowland headwater streams. Although the species is threatened in Western and Central Europe, it is known at a system of post-mining drainage ditches in the Radovesicka spoil heap (northwestern Bohemia, Czech Republic). This study aimed to estimate its population size in this post-mining stream system, and to explore habitat preferences of both its larvae and adults with respect to various environmental factors. The adults were captured-recaptured along 5.2 km of the ditches in June 2012; larvae were sampled in 64 study sites (i.e., 27-meter-long sections of the same ditches) in April 2012. The adult population size was estimated via log-linear models with the robust design on 4544 individuals (1560 ± 391 females and 2983 ± 298 males). Larvae were present in a third of the sections. GLMs revealed that both larvae and adults required emergent vegetation with a high proportion of *Eleocharis* spp. plants. The adults preferred the slow-flowing and shallow streams with 2-meter-high banksides covered by intermediately tall vegetation (~40 cm), whereas the larval abundance was supported by a high in-stream vegetation heterogeneity and a patchy cover of rocks on the streambeds. These results indicate that the post-mining streams could represent a valuable secondary habitat for the complete life cycle of this relatively large population of the endangered headwater specialist. Therefore, we recommend consideration of the conservation potential of such ditches during post-mining sites restoration and their subsequent management." **20837.** Tsukamoto, T.; Kondo, H.; Shigehisa, S.; Nishimura, T.; Yamamoto, M. (2016): The verification of environmentally conscious rice farming on biodiversity conservation in Shiga Prefecture, Japan. *Annual Report of The Kansai Plant Protection Society* 58: 119-122. (in Japanese, with English summary) ["The aim of this survey was to evaluate the effects of environmentally conscious farming (ECF) on the conservation of biodiversity by comparison with conventional farming (CF) in rice plant fields. In this survey, biodiversity was measured by using environmental indicator organisms. Water beetles, pond frogs (*Pelophylax*) and wolf spiders (*Lycosidae*) were more abundant in the ECF fields. However, The abundance of damselflies and web spiders (*Tetragnatha*) were not clear differences between in the ECF fields and in

the CF field. In conclusion, it became clear that higher biodiversity was maintained in the ECF fields than in the CF field. This is the first verification that demonstrates the efficacy of ECF in Shiga Prefecture assessed using indicator organisms." (Authors)] Address: not stated

**20838.** Van Dinh, K.; Janssens, L.; Stoks, R. (2016): Exposure to a heat wave under food limitation makes an agricultural insecticide lethal: a mechanistic laboratory experiment. *Global Change Biology* 22(10): 3361-3372. (in English) ["Extreme temperatures and exposure to agricultural pesticides are becoming more frequent and intense under global change. Their combination may be especially problematic when animals suffer food limitation. We exposed *Coenagrion puella* larvae to a simulated heat wave combined with food limitation, and subsequently to a widespread agricultural pesticide (chlorpyrifos) in an indoor laboratory experiment designed to obtain mechanistic insights in the direct effects of these stressors in isolation and when combined. The heat wave reduced immune function (activity of phenoloxidase, PO) and metabolic rate (activity of the electron transport system, ETS). Starvation had both immediate and delayed negative sublethal effects on growth rate and physiology (reductions in Hsp70 levels, total fat content, and activity levels of PO and ETS). Exposure to chlorpyrifos negatively affected all response variables. While the immediate effects of the heat wave were subtle, our results indicate the importance of delayed effects in shaping the total fitness impact of a heat wave when followed by pesticide exposure. Firstly, the combination of delayed negative effects of the heat wave and starvation, and the immediate negative effect of chlorpyrifos considerably (71%) reduced larval growth rate. Secondly and more strikingly, chlorpyrifos only caused considerable (ca. 48%) mortality in larvae that were previously exposed to the combination of the heat wave and starvation. This strong delayed synergism for mortality could be explained by the cumulative metabolic depression caused by each of these stressors. Further studies with increased realism are needed to evaluate the consequences of the here identified delayed synergisms at the level of populations and communities. This is especially important as this synergism provides a novel explanation for the poorly understood potential of heat waves and of sublethal pesticide concentrations to cause mass mortality." **20839.** Wieczorek, M.V.; Bakanov, N.; Stang, C.; Bilancia, D.; Lagadic, L.; Bruns, E.; Schulz, R. (2016): Reference scenarios for exposure to plant protection products and invertebrate communities in stream mesocosms. *Science of The Total Environment* 545-546: 308-319. (in English) ["Highlights: •Using uranine to describe hydrological conditions during exposure scenarios •Mimicking of several realistic exposure scenarios (peak-, hour- and day-scale) •Establishment of invertebrate communities within stream mesocosms •Pre-experimental period and choice of macrophytes determine invertebrate abundance. •MDD classes III and IV were found for several sensitive invertebrate species. Abstract: Higher tier aquatic risk assessment for plant protection products (PPPs) is often based on pond-like mesocosm studies in which transient and dynamic PPP exposure scenarios as observed in lotic systems are hardly achievable. Thus, the present study presents dynamic PPP exposure scenarios at different time scales under flow-through conditions as typical for streams in agricultural landscapes. The stream mesocosm setup allows testing the influence of spatial gradients of exposure over the length of

the mesocosms. The use of the fluorescent tracer uranine revealed the hydraulic processes generally underlying peak- and hour-scale exposure scenarios and demonstrated an optimized application technique to achieve stable day-scale exposures. Furthermore, to account for potential reactions of invertebrates to PPP exposures in streams (e.g. avoidance behavior and drift), the present study thus aimed at a comprehensive evaluation on how PPP exposure and the establishment of invertebrates can be advanced within stream mesocosm testing. For both, peak- and hour-scale exposure as well as the experiments considering the establishment of invertebrates, the presented compilation of experiments was able to highlight the influence of aquatic macrophytes within stream mesocosms. Since the field relevance of the higher tier aquatic risk assessment for PPPs relies qualitatively on the presence of potentially sensitive or vulnerable species, those species were especially considered. Thus, the establishment of aquatic invertebrates in non-dosed streams was evaluated with respect to (i) the presence of different aquatic macrophytes and (ii) the duration of the pre-experimental period. The present study highlights the beneficial influence of complex-structured macrophytes and prolonged pre-experimental periods on the abundance of invertebrate taxa. Furthermore, population dynamics were evaluated statistically by simulating PPP-related declines of 30, 50 and 70%. Thereby, minimum detectable difference (MDD) classes of mostly = III were found for 12 out of 15 taxa for at least two consecutive sampling dates." **20840.** Bazzanti, M.; Mastrantuono, L.; Pilotto, F. (2017): Depth-related response of macroinvertebrates to the reversal of eutrophication in a Mediterranean lake: Implications for ecological assessment. *Science of the Total Environment* 579: 456-465. (in English) ["Highlights: • We studied macroinvertebrates of Lake Nemi during its recovery from eutrophication. • Communities inhabiting the different depth-zones responded differently. • Infralittoral community showed the largest taxonomic and functional responses. • The ecological status was correctly assessed by communities belonging to each zone. A better management of nutrient inflows into lakes has led to an improvement in their conditions (i.e. reversal of eutrophication) and the effects of this on macroinvertebrate communities that inhabit different lake-depth zones is largely unknown. This paper reports a comparison of macroinvertebrate communities living in the eulittoral, infralittoral and sublittoral/profundal zones of Lake Nemi (Central Italy) before and after its natural recovery from eutrophication following the deviation of domestic wastewater. The infralittoral zone responded more rapidly than the other two depth-zones to the improved ecological conditions, as shown by larger differences in community composition between the two periods. In the eulittoral sand, the combined effects of hydromorphological pressures and reversal of eutrophication hindered the biotic response. In the eulittoral and infralittoral zones, typical taxa of mesotrophic waters appeared or increased their abundances after the eutrophication reversal. Benthic invertebrate response was slower in the sublittoral/profundal zone due to deoxygenation that continued to prevail in the deepest area of the lake during summer. However, both tolerant and more sensitive taxa were collected there for the first time. After the reversal of eutrophication, the percentage of molluscan + large crustaceans increased in the infralittoral zone,

whereas the oligochaete/chironomid ratio decreased in both sublittoral/profundal and infralittoral zones. Functional feeding metrics (percentages of filter-feeders, collector-gatherers-miners and scrapers/grazers) differently tracked the reversal of eutrophication in the three depth-zones probably according to the effects of the reduction of nutrients on food-web structure influencing macroinvertebrates. Biological Monitoring Working Party (BMWP) and the Average Score Per Taxon (ASPT) seemed to respond to eutrophication reversal only in the sublittoral/profundal zone, where deoxygenation plays a major role as a structuring agent of the community. Our results suggest that the effects of reversal of eutrophication can be better assessed by examining the response of the communities belonging to each zone individually." **20842.** Hatami, R.; Paul, W.; Soofianib, N.M.; Asadollah, S. (2017): Rapid bioassessment of macroinvertebrate communities is suitable for monitoring the impacts of fish farm effluents. *Aquaculture* 468(1): 19-25. (in English) ["Highlights: • Three methods for biomonitoring of fish farm effluents and receiving waters were compared, ranging from rapid qualitative methods to more time-consuming quantitative methods. • The study was conducted at four sites within each of three trout farms of varying production capacities, and across three seasons. • PERMANOVA was used to analyze the multivariate macroinvertebrate data, and all three biomonitoring methods detected statistically significant main effects and interactions among the farm, site, and season factors. • These results indicate that rapid bioassessment is an effective and cost efficient means for monitoring trout-farm process waters and effluent receiving waters, and as such can improve the economic and environmental sustainability of trout farms. Abstract: Development of the fish farming industry in Iran in an environmentally and economically sustainable manner requires an effective and low-cost means of regularly monitoring receiving environments. Biomonitoring using macroinvertebrates is known to be effective for assessing water quality. The problem, however, is that biomonitoring can be labour intensive and analyses can have a long turnaround time. Rapid bioassessment methods have been developed to overcome these limitations, but it is not known whether they are as sensitive to changes in water quality as are their more time-consuming counterparts. To answer this question, we compared three methods for sampling and measuring macroinvertebrates. We refer to these as the quantitative method, semi-quantitative method, and qualitative method respectively. The quantitative method

was a single habitat method with taxonomic identification of macroinvertebrates to genus level that counted all taxa. The semi-quantitative method involved multi-habitat sampling with identification to family level and quantification as relative abundance. The qualitative method was the same as the semi-quantitative method except that incidence (presence / absence) was recorded instead of abundance. The study was carried out at three fish farms in Iran with sampling done once per season for a year from the outfall of each farm as well as from the receiving rivers, with one sample taken upstream of the effluent discharge and two samples downstream. Analysis by permutational multivariate analysis of variance (PERMANOVA) revealed that the effects of three variables of season, farm, and site on macroinvertebrate communities were significant for all three methods. Qualitative sampling was the only method that showed a statistically significant interaction between farm and season as well as a difference among the sites within each farm. Although the results of a BEST (Bio-Bio) analysis showed that different families were responsible for the differences between the sites, all three methods were able to detect the differences between the sites within each farm. However, pairwise comparisons between sites within farms indicated some differences between the three methods. The quantitative method revealed fewer differences than did the other two methods. The qualitative method did not lose any important information and had the added advantage of saving considerable time and effort in sampling and enumerating. These results suggest that rapid bioassessment could be used to effectively monitor the receiving waters of fish farm effluents. Statement of relevance: This manuscript compares three methods of sampling which are quantitative, semi-quantitative and qualitative methods in order to find the most efficient and cost-effective method of sampling. There is no apparent consensus on the appropriate method of collecting and measuring macroinvertebrates, in particular for investigating the effect of fish farms on the rivers. Our manuscript revealed that rapid bioassessment method as a cost-efficient and effective method can be used in order to develop aquaculture in a sustainable manner, both environmentally and economically. Therefore, authors believe that this manuscript is appropriate for publication by the Journal of Aquaculture." **20843.** Hinchliffe, C.M.; Atwood, T.; Ollivier, Q.; Hammill, E. (2017): Presence of invasive *Gambusia* alters ecological communities and the functions they perform in lentic ecosystems. *Marine and Freshwater Research* 68: 1867-1876. (in English) ["By acting as novel competitors and predators, a single invasive species can detrimentally affect multiple native species in different trophic levels. Although quantifying invasive effects through single-species interactions is important, understanding their effect on ecosystems as a whole is vital to enable effective protection and management. This is particularly true in freshwater ecosystems, where invasive species constitute the single greatest threat to biodiversity. Poeciliid fishes of the genus *Gambusia* are among the most widespread invasive species on earth. In the present study of lentic ecosystems (i.e. lakes), we first showed that *Gambusia* alter zooplankton community composition and size distribution, likely through size-selective predation. Second, we demonstrate that benthic macroinvertebrate communities significantly differ between sites with and without invasive *Gambusia*. The presence of *Gambusia* appears to reduce leaf-litter decomposition rates, which is likely an indirect effect of reductions in detritivore abundances. Reductions in

decomposition rates found in the present study suggest that through trophic cascades, invasive *Gambusia* is able to indirectly alter ecosystem functions. The study has highlighted that the widespread effects of invasive aquatic species are able to permeate through entire ecosystems, being more pervasive than previously recognised." (Authors) Fig. 3. (a) demonstrates the abundance of odonates at sites with *Gambusia* present and *Gambusia* absent.] Address: Hammill, E., School of Life Sciences, Univ. Technology Sydney, Ultimo, NSW 2007, Australia. Email: edd\_hammill@hotmail.com

**20844.** Jones, D.K.; Hintz, W.D.; Schuler, M.S.; Yates, E.K.; Mattes, B.M.; Relyea, R.A. (2017): Inducible tolerance to agrochemicals was paved by evolutionary responses to predators. *Environ. Sci. Technol.* 51(23): 13913-13919. (in English) ["Recent research has reported increased tolerance to agrochemicals in target and non-target organisms following acute physiological changes induced through phenotypic plasticity. Moreover, the most inducible populations are those from more pristine locations, far from agrochemical use. We asked why do populations with no known history of pesticide exposure have the ability to induce adaptive responses to novel agrochemicals? We hypothesized that increased pesticide tolerance results from a generalized stressor response in organisms, and would be induced following sublethal exposure to natural and anthropogenic stressors. We exposed larval wood frogs (*Lithobates sylvaticus*) to one of seven natural or anthropogenic stressors (predator cue (*Anax* spp.), 0.5 or 1.0 mg carbaryl/L, road salt (200 or 1000 mg Cl-/L), ethanol-vehicle control, or no-stressor control) and subsequently tested their tolerance to a lethal carbaryl concentration using time-to-death assays. We observed induced carbaryl tolerance in tadpoles exposed to 0.5 mg/L carbaryl and also in tadpoles exposed to predator cues. Our results suggest that the ability to induce pesticide tolerance likely arose through evolved anti-predator responses. Given that anti-predator responses are widespread among species, many animals might possess inducible pesticide tolerance, buffering them from agrochemical exposure." **20845.** Navas-Bolanos, A.; Sanchez-Guillien, R.; Munguía-Steyer, R.; Cordoba-Aguilar, A. (2017): Isolation barriers and genetic divergence in nonterritorial *Argia* damselflies. *Biological Journal of the Linnean Society* 120: 804-817. (in English) ["Isolation barriers work at different instances during the mating process in odonate insects. In territorial damselflies, heterospecific interactions are mainly precluded by sexual (visual) isolation, while in non-territorial damselflies, heterospecific interactions are mostly precluded by mechanical isolation and sexual (tactile) isolation. In this study we investigated the strength of three premating barriers (visual, mechanical and tactile), genetic divergence and degree of sympatry (on their entire distribution) between four non-territorial *Argia* damselflies (*A. anceps*, *A. extranea*, *A. oenea* and *A. tezpi*). Our results are explained in the light of learned mating preferences and Kaneshiro's hypothesis. We detected a strong reproductive isolation between all pairs of species by the joint action of the three studied barriers [visual (90.6%), mechanical (8.7%) and tactile (0.7%)]. Sexual (visual) isolation was the most important barrier, perhaps driven by learned mating preferences. One of the studied species, *A. extranea*, which is the most derived of the studied species, showed a highly asymmetric isolation in reciprocal crosses, which is consistent with Kaneshiro's hypothesis.

Moreover, we detected a negligible ecological niche differentiation between the studied species (70% of shared distribution). Our results suggest that sexual (visual) selection may be an important force driving speciation in non-territorial species." **20849.** Carvalho, F.G.; de Oliveira Roque, F.; Barbosa, L.; de Assis Montag, L.F.; Juen, L. (2018): Oil palm plantation is not a suitable environment for most forest specialist species of Odonata in Amazonia. *Animal Conservation* 21(6): 526-533. In English. ["Oil palm monoculture is the most rapidly increasing large-scale crop in Amazonia due to favourable environmental conditions and incentives from executives and governing authorities. In this study we assessed the effects of oil palm plantations on Odonata assemblages in Amazonia streams. We hypothesized that (1) the expansion of oil palm plantations over the natural landscape affects the habitat structure and physicochemical properties of streams at different scales (50 m, 500 m and 1000 m) and (2) oil palm plantations affect the species composition of Odonata assemblages, leading to the replacement of forest specialist species by non-forest specialists. A total of 22 streams were sampled which were distributed throughout a landscape comprising areas of oil palm plantations *Elaeis guineensis* Jacq. to streams located inside large forest remnants. The expansion of oil palm monoculture affected the physicochemical properties of the water and habitat of the streams. A larger amount of woody debris was observed within streams surrounded by a greater amount of forest, whereas streams with a greater area of surrounding oil palm had higher pH values and anthropogenic infrastructures (e.g. roads). As expected, the Odonata community was affected by a replacement of forest specialist species with non-forest specialist species. To mitigate this impact, we suggest increasing the area of native riparian corridors along streams that flow through oil palm plantations." **20851.** Tüzün, N. (2018): Effects of urbanisation on the ecology and evolution of a damselfly. Dissertation presented in partial fulfilment of the requirements for the degree of Doctor of Science (PhD): Biology: 225 pp. (in English) ["The rate of urbanisation is increasing on a global scale. Compared to rural areas, cities are warmer, more polluted by chemicals, and more fragmented. Although biodiversity is clearly impacted by this anthropogenic activity, there are large gaps in our understanding on the effects of urbanisation at the population and individual levels. In this thesis, I tested whether urban and rural populations of *Coenagrion puella* differed in their responses to higher temperatures, increased contamination, and more intense habitat fragmentation. For this, I mostly applied a common garden experimental approach, either in the laboratory or in semi-natural outdoor conditions, allowing the identification of genetic adaptation.

To also test the outstanding question whether urbanisation influences sexual selection regimes, I additionally did an experiment with field-collected adult damselflies. All study populations were situated in Flanders, Belgium. I found strong divergence between urban and rural populations in responses to each of the three studied urbanisation-related stressors, suggesting evolutionary responses to urbanisation. The higher temperatures in urban areas influenced the life history of urban damselflies by altering growing season length, yet did not affect behavioural traits. With regard to contamination, damselfly larvae from urban habitats showed different behavioural responses to pesticides when compared to rural larvae. Furthermore, pesticide exposure differently affected behavioural correlations in urban and in rural larvae. Interestingly, several responses to urban-related stressors strongly depended on the sex of the damselfly, as well as the life stage at which they were exposed to the stressor. Finally, the more fragmented habitats in urban areas seem to have selected for better flyers by influencing the dispersal ecology of damselflies, which was further strengthened by sexual selection for a higher flight performance in urban populations. In conclusion, I found clear effects of urbanisation on the evolution and ecology of a damselfly. My findings suggest that differential selection was imposed by the here tested urbanisation-related stressors. Importantly, these stressors were acting in different life stages, highlighting the need for a full life cycle approach when studying the effects of urbanisation.] Address: Tüzün, N., Evolutionary Stress Ecology & Ecotoxicology, Univ. of Leuven, Deberiotstraat 32, 3000 Leuven, Belgium. **20852.** Gärtner, F. (2019): Qualitative Erfassung von Quelljungfern (*Cordulegaster boltonii* und *Cordulegaster bidentata*) an ausgewählten Gewässern im FFH-Gebiet Arnsberger Wald mit Hinweisen für Schutzmaßnahmen. Bachelorarbeit, Geographisches Institut, Stadt. und Landschaftsökologie, Ruhr-Universität Bochum: 79 pp. (in German) ["By examining streams in the Arnsberg Forest for *Cordulegaster* larvae and imagines, it could be shown that the two species (*C. boltonii* and *C. bidentata*) are widespread in the study area and have not become rarer compared to 2003/04. There were clearly more records of *C. boltonii* than *C. bidentata*. No larvae were found on 52 % of the segments examined. The study area is characterised by old spruce stands, with mixed and deciduous forests becoming more frequent, especially near the lower reaches. Potential disturbances such as forestry work, needle litter, forest roads, piping and drought were found on 38 % of the 223 stream segments surveyed. Drought accounted for the largest share of potential disturbances with 14 % of 223 stream segments. In total, five out of 13 streams showed dryness. *C. bidentata* in particular is threatened by habitat loss. The predicted negative water balance may lead to the drying out of springs, on which this species is highly specialised. No clear distribution could be established showing that the larvae of *C. bidentata* colonise the spring area or upper reaches and *C. boltonii* the stretch below. Compared to the 2003/04 survey, one or both species were newly detected on seven of the 13 streams. *C. bidentata* could only no longer be found on one stream. The calculation of habitat preferences showed that *C. bidentata* avoids open land, young forests, wildlife hollows, needle litter and piping, while the species prefers coniferous forests, fine sediment, disturbance by forestry operations and forest roads. Both *Cordulegaster* species prefer influences by forestry as well as the presence of stream fleas. A lot of needle litter and dryness were clearly avoided by both species.

Conservation measures such as the renaturation of water-courses are helpful for the preservation or improvement of the species population. Especially against the background that precipitation cannot be influenced, the (re)creation of near-natural flowing waters is particularly important. In order to be able to better record further population changes, it is recommended to set up monitoring, especially for *C. bidentata*." (in French, with English summary) ["Invasive plants used by some aquatic insects: the dragonflies with endophytic oviposition (Odonata) – Alien plants, some of which are highly invasive, are increasingly found in natural aquatic habitats. Odonata are closely related to these habitats and their associated vegetation, and therefore frequently face these exotic species. Our study reviews some observations made in metropolitan France together with literature references to endophytic egg laying behaviours in alien plant species in Europe. Nine non-native plant species in Europe are used, likely successfully, by at least 15 species of Zygoptera and three species of Anisoptera: Aeshnidae. We dissected stem sections of *Ludwigia peploides* to check whether some eggs had been successfully inserted. We also checked with two different rearing experiments in aquarium that larval hatching and development of *Erythromma lindenii* and *Platynemis* sp. were possible from eggs laid in *L. grandiflora* and *L. peploides*. These observations show that endophytic dragonflies can use alien plants, which are sometimes the sole egg laying material at their disposal. This also shows that endophytic dragonflies are able to lay eggs in a wider diversity of aquatic plants than the literature suggested. We encourage launching more general studies on the effect of alien aquatic plant invasion on the dragonfly communities." **20857.** Assandri, G.; Bazzi, G.; Maggioni, D.; Galimberti, A.; Kunz, B. (2020): Distribution, autecology, genetic characterization, and conservation of the Western Mediterranean endemic dragonfly *Orthetrum nitidinerve* (Selys, 1841): insights from Italy. *International Journal of Odonatology* 23(4): 405-422. (in English) ["Aquatic macroinvertebrates are a primary component of freshwater ecosystems and one of the most threatened by anthropogenic pressures. Among them, dragonflies are a charismatic group of growing scientific and social interest. However, little is known about the natural history of several species. One paradigmatic example is the declining *Orthetrum nitidinerve*, a Western Mediterranean endemic anisopteran. We reviewed published and new data on this species, addressing distribution, autecology, and conservation (with a focus on Italy), and provide its first genetic characterization and phylogenetic placement within the genus. In Italy, the species is known from 50 sites so far (only 17 breeding populations) located in Sardinia and Sicily (1841–2019, only 22 from 1990 onward). Records from continental Italy are due to misidentification. The flight period in Italy spans between May and September. Habitat consists of permanent freshwater (mostly helocrene sources, seepages, and small brooks), slow-flowing, shallow, with muddy bottom deposits at elevation from the sea level up to 1000m asl. All the breeding populations are found in open and sunny landscapes, almost invariably in extensive pasturelands. The species has strongly declined in Sicily, whereas several large populations still occur in Sardinia. The major threats identified so far are agriculture and grazing intensification or abandonment and drought/source desiccation determined by water overexploitation and climate change. The first ever provided mitochondrial COI barcode and ITS nuclear sequences allowed a first tentative phylogenetic placement of the species as a sister group of the *O. brunneum*/*O. lineostigma* lineage." (Authors)] Address: Assandri, G., Area Per L'Avifauna Migratrice (BIO-AVM), Istituto Superiore per la Protezione e la Ricerca Ambientale (ISPRA), Ozzano dell'Emilia, Italy. **20858.** Assandri, G. (2020): Anthropogenic-driven transformations of dragonfly (Insecta: Odonata) communities of low elevation mountain wetlands during the last century. *Insect Conservation and Diversity* 14(1): 26-39. (in English) ["1.

Freshwater environments are experiencing high rates of species extinction due to human impacts, with aquatic insects thought to be strongly threatened by these changes; however, long-term research on this topic is scant. Among aquatic insects, dragonflies are considered valuable indicators of human disturbance at multiple scales. 2. This study addresses transformations of odonate communities of low elevation mountain wetlands in the Alps over the last century, comparing historical and present assemblages based on past records derived from scientific collections or literature and present data derived from site resurveys. 3. About 32.6% of species have been extirpated or strongly declined in the area (mostly temporary lentic and lotic water specialists, or cold-adapted species). Conversely, only 12.2% of species were new or considerably increased (mostly permanent lentic specialists and warm-adapted species). Nearly half of historical populations have been lost. The great majority of species which disappeared from all the study sites also disappeared (or strongly declined) at the regional scale. 4. Although gamma species richness was higher in the historical period compared with the present, mean alpha species richness does not significantly differ between the two, likely suggesting homogenisation of communities from historical to the present period. 5. Present communities of dragonflies show a significantly higher community temperature index compared with historical ones. 6. These patterns are putatively explained by the joint effects of land-use change (drainage and reclamation), land-use intensification or abandonment, environmental pollution, and anthropogenic-driven climate warming." (Author)] Address: Assandri, G., Area Per L'Avifauna Migratrice (BIO-AVM), Istituto Superiore per la Protezione e la Ricerca Ambientale (ISPRA), Ozzano dell'Emilia, Italy. **20859.** Bauerheim, M.; Chapin, V. (2020): Route to chaos on a dragonfly wing cross section in gliding flight. *Physical Review E* 102(1): 1-6. (in English) ["The route from linear towards non-linear and chaotic aerodynamic regimes of a fixed dragonfly wing cross-section in gliding flight is investigated numerically using Direct Navier-Stokes simulations (DNS). The dragonfly wing consists in two corrugations combined with a rear arc, which is known to provide overall good aerodynamic mean performance at low Reynolds numbers. First, the three regimes (linear, non-linear and chaotic) are characterized, and validated using two different fluid solvers. In particular, a peculiar transition to chaos when changing the angle of attack is observed for both solvers: the system undergoes a sudden transition to chaos in less than  $0.1^\circ$ . Second, a physical insight is given on the flow interaction between the corrugations and the rear arc, which is shown as the key phenomenon controlling the unsteady vortex dynamics and the sudden transition to chaos. Additionally, aerodynamic performances in the three regimes are given, showing that optimal performances are closely connected to the transition to chaos." **20860.** Bergmann, M.; Graça, M.A.S. (2020): Bioaccumulation and dispersion of Uranium by freshwater organisms. *Archives of Environmental Contamination and Toxicology* 78: 254-266. (in English) ["Uranium is the heaviest naturally occurring element on Earth. Uranium mining may result in ground and surface water contamination with potential bioaccumulation and dispersion by aquatic invertebrates with aerial stages. We investigated the effects of uranium contamination at community level in terms of abundance, richness,

the composition of invertebrate communities, and functional traits. We also investigated uranium mobility across aquatic food webs and its transfer to land via the emergence of aquatic insects. We sampled water, sediment, biofilm, macrophytes, aquatic invertebrates, adult insects, and spiders in the riparian zone across sites with a gradient of uranium concentrations in stream water (from 2.1 to 4.7  $\mu\text{g L}^{-1}$ ) and sediments (from 10.4 to 41.8  $\mu\text{g g}^{-1}$ ). Macroinvertebrate assemblages differed between sites with a higher diversity and predominance of Nemouridae and Baetidae at the reference site and low diversity and predominance of Chironomidae in sites with the highest uranium concentration. Uranium concentrations in producers and consumers increased linearly with uranium concentration in stream water and sediment ( $p < 0.05$ ). The highest accumulation was found in litter ( $83.76 \pm 5.42 \mu\text{g g}^{-1}$ ) and macrophytes ( $47.58 \pm 6.93 \mu\text{g g}^{-1}$ ) in the most contaminated site. Uranium was highest in scrapers ( $14.30 \pm 0.98 \mu\text{g g}^{-1}$ ), followed by shredders ( $12.96 \pm 0.81 \mu\text{g g}^{-1}$ ) and engulfer predators ( $7.01 \pm 1.3 \mu\text{g g}^{-1}$ ) [*Cordulegaster* sp.]. Uranium in adults of aquatic insects in the riparian zone in all sites ranged from 0.25 to 2.90  $\mu\text{g g}^{-1}$ , whereas in spiders it ranged from 0.96 to 1.73  $\mu\text{g g}^{-1}$ , with no differences between sites ( $p > 0.05$ ). There was a negative relationship between  $\delta^{15}\text{N}$  and uranium, suggesting there is no biomagnification along food webs. We concluded that uranium is accumulated by producers and consumers but not biomagnified nor dispersed to land with the emergence of aquatic insects." **20862.** Chen, P.-Y.; Lin, C.-T.; Yam, R.S.W.; Yuan, H.-W. (2020): Influences of physical vegetation management on Odonata abundance in urbanized ecosystem: a case study in northern Taiwan. *Wetlands* 40: 2061-2070. (in English) ["Physical vegetation management has shown deep and diverse impacts on fauna diversity and abundance. However, it is still unclear to what degree management influences Odonata in urbanized ecosystems. In order to understand the crucial factors among Odonata (adults and larvae) and physical vegetation management in a highly urbanized environment, this study investigated the response of Odonata abundance and species richness to riparian and emergent aquatic vegetation management in artificial ponds. Our results showed that physical management of emergent macrophytes did have a significant effect on larval abundance. However, adult abundance and species richness did not show clear differences between different levels of riparian vegetation coverage. Water temperature, water pH value and the presence of emergent macrophytes were also crucial drivers of larval abundance though macrophytes had a stronger effect as compared to water quality. Overall, this

study highlights the importance of marginal vegetation, especially emergent macrophytes, in highly urbanized environments. Our study suggests key management considerations for plant management in urban ponds which, when implemented, would work to enhance Odonata population and overall ecological value of artificial wetlands in cities." **20863.** Erickson, R.J. (2020): A morphological phylogeny of Odonatoptera: Examining missing data in a group with a lot of "Naturally" Missing Data". PhD, thesis, Department of Biology, Brigham Young University: VII + 79 pp. (in English) ["Odonatoptera exhibit a wide diversity of morphologies for an ancient group of winged insects. A morphological matrix of 463 characters is compiled for 347 extant and fossil representatives used in parsimony analyses, implemented in TNT, to document arrangements of taxonomic groups above the family level. Missing data and other challenges approaches implemented and interpretation of the results. We employ a novel approach to testing monophyly relative to quantities of missing data for each taxon. Phylogenetic reconstructions recover patterns of monophyly and trends based on missing data. We discuss the implications of our findings on missing data as well as limitations to systematics in general for Odonatoptera." (Author)] Address: not stated

**20864.** Liashenko, V.A. (2020): Water quality assessment in the Vorskla River within the Hetmanskyi national natural park in terms of macrozoobenthos organisms. Biodiversity, ecology and experimental biology, 2020(2): 53-59. (in Ukrainian, with English summary) ["The article considers the results of the first field study of the structural characteristics of macrozoobenthos in the Vorskla River within the Hetmanskyi national natural park at ten observation stations that was conducted for the first time in June 2020. Representatives of 36 lower identified taxa of benthic macroinvertebrates were identified in this nature conservation object. The Class Gastropoda (7 species) and the Order Odonata (6 species) predominated in the studied biota in terms of species richness and abundance. Representatives of the two leading taxonomic groups make up 36% of the total number of species and 56% of the total abundance at all observation stations. It is worth paying attention to the presence of *Anax parthenope* species in all of the Vorskla River studied areas. It is a common species of dragonflies in the south of Ukraine, which is gradually appearing in the northern regions. Based on the indicators of species richness and species diversity, a biological indication of surface water quality was conducted. The following widely used biotic indices were calculated: the Trent Biotic Index, the Belgian Biotic Index, the Biological Monitoring Working Party Index. To assess the level of organic pollution, the Zelinka-Marvan saprobity index was calculated. The species diversity of benthic invertebrates was assessed by the Shannon index, and the similarity of species composition was assessed by the Jacquard index with further cluster analysis. At most of the observation stations, biotic indicators point out the high water quality of the Vorskla River. The water quality classes are characterized mainly as 'good' and 'excellent'. Station 8, located near the village of Lutyshche, is characterized by the worst results in all indicators used. The worst values of the Shannon and Jacquard indices were also recorded at this station. It is also worth noting the decline in species richness between stations 9 and 10, separated by a dam across the Vorskla River. We assume that the decrease in species richness of the above-mentioned sections of the river is caused by the

anthropogenic influence. The calculated values of the Zelinka-Marvan saprobity index point out a low level of organic pollution of the Vorskla River. The predominance of oligotrophic (by number)  $\alpha$ -oligosaprobic and  $\beta$ -mesosaprobic waters was established at all observation stations." **20865.** LoScerbo, D.; Farrell, M.J.; Arrowsmith, J.; Mlynarek, J.; Lessard, J.-P. (2020): Phylogenetically conserved host traits and local abiotic conditions jointly drive the geography of parasite intensity. *Functional Ecology* 34(12): 2477-2487. (in English). ["1. The role of biotic interactions in shaping species distributions is a cornerstone of biogeographic theory; yet, it remains elusive. Such interactions are more likely to have an influence on organisms with obligate associations, such as hosts and their parasites. Whereas abiotic conditions may affect the abundance and distribution of parasites in ways similar to free-living species, attributes of the host could also play a part. 2. Here, we focus on parasitic water mites and their dragonfly and damselfly hosts, and use a hierarchical Bayesian model to examine the relative influence of the abiotic environment and biotic factors such as local host community structure and individual host characteristics on parasite intensity along a broad-scale environmental gradient. Specifically, we assessed how climate, surrounding vegetation, water chemistry, host community structure as well the relative abundance and body mass of host species affected the intensity of parasitism on individual hosts along a latitudinal gradient. 3. We found that water chemistry and body mass of the host were the best predictors of variation in parasite intensity among hosts. High parasite intensity was observed in hosts sampled from lakes with high pH, dissolved oxygen, and conductivity. Additionally, we found that the intensity of parasitism was strongly influenced by host species identity. In particular, body mass, which shows strong phylogenetic signal, was negatively related to parasite intensity. It may be that larger species, or individuals within species, are more immune to high level of parasitism and/or body mass is correlated with other traits of the host which relate to immunity. 4. Considering both the abiotic environment and attributes of host species is necessary to understand why certain host individuals and locations exhibit more intense parasitism. Amid widespread decline of insect populations worldwide, some of which are attributed to pathogens and parasites, models predicting rates of parasitism in space and time could become an essential tool for guiding management and conservation efforts." **20866.** Minot, M. (2020): Biological traits and environmental factors shaping local movements and dispersal of dragonflies (Insecta, Odonata) in pond networks. PhD thesis, *Écologie, l'Université de Rouen Normandie*: XII + 231 pp. (in English) ["During the last decades, the number of ponds decreased by more than 50 % in European countries, occasionally reaching up to 90 % in some regions. Their decline in number has led to a strong loss of connectivity between waterbodies. Yet, these small and scattered ecosystems are essential for the life cycle of a high diversity of freshwater species. Land use policies like the creation of Greenways and Blueways in France aim to improve ecological continuities to allow maintenance of existent biological populations and exchanges between them. However, the connectivity between ponds must be considered according to

the dispersal abilities of freshwater species and this information often lacks to guide restoration measures. In the present work, we studied the dispersal abilities of dragonflies on several spatial scales and investigated the biological traits and environmental factors that shaped their movements. In the first part, we evaluated the colonization of 20 ponds in Normandy by dragonflies during three years after pond restoration or pond creation. The results highlight high colonization rates during the first year and no difference in species richness was found between newly created or restored ponds. This suggests that restoration of ponds after complete drought should not always be prioritized over pond creation in management strategies. We found that generalist species were more present in the first year after pond creation or restoration, whereas the occurrence of forest specialists increased with the age of the pond. The results also highlighted that the landscape context around ponds (i.e. forest vs. open lands) had an effect on the composition of dragonfly communities. Finally, the total abundance of odonate species was related to the density of other ponds in the surroundings. This result emphasizes that highly connected ponds can support larger populations than isolated ones and thus, be more resilient to perturbations. The second part provides insights into the larval development of *Anax imperator* and the relationship between morphological traits of larvae and adults. The results suggest that the survival of this species might depend on its body length during the maturation period. We also tried to study the natal dispersal by marking 87 individuals at emergence, but only two males were resighted after the maturation period. Finally, the effect of two water pollutants (i.e. Round-up and DEET) at different concentrations was also investigated on the larval development and adults of *Aeshna cyanea*. Larvae were reared under laboratory conditions and exposed to concentrations up to 30 mg L<sup>-1</sup> of the two pollutants. No effect of the pollutants was detected on the morphological conditions of larvae or teneral, suggesting that *A. cyanea* is tolerant to potential water pollution of ponds. The level of HSP70 stress protein was also similar according to the different treatments, but teneral adults presented higher levels of stress than larvae, suggesting that emergence induced a high stress in the individuals. The third part focuses on the dispersal of *A. imperator*. We first assessed the local movements within a pond network in the Normandy region. Several movements between ponds were recorded, showing that individuals were able to use several ponds during their lifetime. Especially, we found that females used a larger home range than males and were more mobile in the terrestrial surroundings of ponds. We also highlighted the importance of trees used as resting sites in the vicinity of the ponds. The genetic structure of *A. imperator* populations was also investigated at both the regional and the European scales. Results indicate a high gene flow between populations in Normandy, confirming the high movement rates of *A. imperator* at the regional scale. No isolation by distance was found at the European scale. However, a genetic structure was found and Bayesian clustering analyses showed three distinct clusters (i.e. UK, France, eastern European countries). Results suggest that the English Channel may act as a barrier to gene flow. Overall, this study provides quantifications of dragonfly dispersal abilities and insights into the biological traits and factors that could influence them at different scales. It also provides information on terrestrial habitat use by dragonflies. We finally give some recommendations for management policies to better sustain dragonfly populations in pond networks." **20869.** Perneckner, B.; Mauchart, P.; Csabai, Z.; (2020): What to do if streams go dry? Behaviour of Balkan Goldenring (*Cordulegaster heros*, Odonata) larvae in a simulated drought experiment in SW Hungary. *Ecological Entomology* 45, 1457–1465. (in English) ["1. In case of dryings, the hyporheic zone is one of the most important refugia for stream macro-invertebrate communities, including the few Odonata species living in these habitats, such as *Cordulegaster* species. There is no information on the desiccation resistance strategies and methods of any members of the genus, including *C. heros*. 2. We hypothesised that the larvae use burrowing behaviour to survive droughts. In this study, beyond recording the survival rates of the larvae, we tested the effects of the sediment particle size and the body size of the larvae on burrowing behaviour in a 3-week-long simulated drought experiment in an indoor artificial stream system. 3. Eighty larvae were involved in the experiment, from which 60 were treated with drought, and 20 served as controls. Larvae were put into flowing water, into separate special compartments; 1 day later, the flow was ceased, and then, the water level was gradually decreased for 3 weeks. 4. Approximately 15% of larvae could survive the 3 weeks of drying. The survival probability of drought-treated larvae was significantly increased if animals burrowed into the sediment. In addition, the survival probability was higher in case of fine substrate material. Size of the larvae only affected the depth of the burrowing, not the survival rate. 5. However, two-thirds of the larvae did not dig into the sediment, which implies that surviving via burrowing is not the only mechanism of the species to withstand dry periods." (Authors)] Address: Perneckner, B., Dept of Hydrobiology, Institute of Biology, Faculty of Sciences, University of Pécs, Ifjúság útja 6, Pécs, 7624, Hungary. Email: perneckb@gamma.ttk.pte.hu

**20870.** Ruslan, H. (2020): Keanekaragaman capung (Odonata) di sekitar kawasan cagar biosfer Giam Siak Kecil. Bukit Batu Riau [Diversity of dragonflies (Odonata) around the Giam Siak Kecil biosphere reserve. Bukit Batu Riau]. *BIOMA* 16(1): 31-42. (in Indonesian, with English summary) ["Dragonflies are known as bioindicator of clean water. Aim of this study is to record dragonfly biodiversity in Reserve Biosphere of Giam Siak Kecil Bukit Batu Area Riau. This study was performed in May 5th -11th, 2018 with scan sampling using insect nets and camera. Study was done in core zone (secondary forest), industrial plant forest (IPF) and transition zone. We found as many as 48 individuals of 15 species from 3 families in core zone, 19 individuals of 4 species from 1

family in IPF and 31 individuals of 8 species from 2 families in transition zone. The same species were not found in three locations. Diversity index in core zone and transition zone was moderate while diversity index in IPF was low. Evenness index in three places are high. *Orthetrum sabina* was found to have the high index of importance value (IIV) among all three locations. *Rhyothemis phyllis* had the highest number in transition zone. Abiotic factors were similar in all locations, except light was higher in core zone. ... Conclusion: The composition of dragonflies in the core zone is 3 families composed of 15 species with a total of 48 individuals, in the HTI zone there is 1 family composed of 4 species with a total of 19 individuals, in the transition zone there are 2 families composed of 8 species with a total of 31 individuals. The similarity index at the HTI and Transitional locations showed a similarity in species composition (>50%), while the core and Transitional zones, and the core and HTI locations showed no similarity in species composition (<50%). The diversity index of dragonflies in the core and transition zones is moderate, while in the HTI zone it is low. Dragonflies in the secondary forest and HTI zone were found with a high number of individuals on *Orthetrum sabina*, while in the transition zone they were found on *Rhyothemis phyllis*. *Orthetrum sabina* was found to be dominant at all three locations based on IVI values. The abiotic factors at the three locations were almost the same, except that the brightness was higher in the secondary forest compared to the HTI and transition zones." **20871.** Ul Islam, S.; Lin, W.; Islam, W.; Qasim, M.; Ali, H.; Ali, H.; Khan, K.A.; Ghramh, H.A.; Du, Z.; Wu, Z. (2020): Molecular identification of seven new Zygopteran genera from South China through partial cytochrome oxidase subunit I (COI) gene. *Meta Gene* 25, September 2020, 100739: (in English) ["Highlights: • There are 51 sequences of damselflies (Zygoptera), comprising four families, seven genera and ten species in the present study. \*Coenagrionidae family and genus *Ischnura* had dominated in the entire collection. \*Cytochrome oxidase subunit I (COI) gene was used for whole molecular work. Abstract: The study was carried out in eight provinces of China, with 16 different localities. A total of 150 adult damselflies were collected for the study from the area. Mitochondrial (COI) was the target gene to sequence from all 51 representative samples of the entire collection. From the resulted sequences, ten species belonging to seven genera and four families were identified. The families are Calopterygidae, Coenagrionidae, Chlorocyphidae and Devadattiade. After alignment through BioEdit v6, MEGA7 was used for phylogenetic tree construction as well as the calculation of genetic divergence, whereas genetic diversity was calculated by DnaSP v5. All species from the respective families had clustered together within the groups, but divided into sub-groups. Maximum genetic divergence (9.31%) was found in the genus *Rhinocypha*, followed by *Hetaerina* with (8.23%), while, minimum divergence was observed for the genus *Ceriagrion* (0.32%) followed by *Ischnura* (0.48%). However, significant genetic diversity was found for all sequences at 346 mutations confirmed by two tests, Tajima's D and Fu's Fs. Maximum genetic diversity among genera was also observed, the genus *Hetaerina* has maximum genetic diversity (181 mutations) followed by *Rhinocypha* (68 mutations) while minimum genetic diversity was observed for the genus *Ceriagrion* followed by *Ischnura*. The presented results showed a higher diversity of damselflies in the south China regions." (Authors) Address: Ul Islam, S., Fujian Province Key Lab. of Plant Virology, Plant Protection College,

**20874.** Arana Maestre, J.; Carrasco Badajoz, C.; Coayla Peñaloza, P.; Rayme Chalco, C.; Sánchez Peña, M. (2021): Aquatic macroinvertebrates of arid and semi-arid ecosystems of Peru. *Frontiers in Environmental Science* 9:658940. doi: 10.3389/fenvs.2021.658940: 14 pp. (in English) ["Peru is one of the megadiverse countries worldwide, displaying a great diversity of ecosystems due to its tropical location, marine currents, and complex relief, which jointly define environments differentiated by altitude and climatic conditions. The arid and semi-arid ecosystems comprising xeric and Andean shrublands, coastal deserts, and coastal hills, illustrate this diversity of ecosystems; these stretch over 177 358 km<sup>2</sup>, representing 13.8% of the Peruvian territory. Several studies on aquatic macroinvertebrates are being conducted in these ecosystems; although not so numerous

yet, have shown a rise in recent years. The objective of this work was to determine the composition and distribution of aquatic macroinvertebrates in the arid and semi-arid ecosystems of Peru. To this end, we conducted a literature survey; the articles and theses found were reviewed and analyzed. The following keywords were used: macroinvertebrates, macrozoobenthos, bioindicators, diversity of aquatic organisms, and water quality; we used the Google Academic search engine, Scopus, Web of Science, ResearchGate and the thesis repositories of Peruvian universities, additionally a thesis from the University of Barcelona. Of a total of 53 sources of information, 38 are theses and 15 are scientific articles conducted from 1992 to 2020, referring to studies conducted at elevations ranging from 0 to 3,831 m asl. Most studies were conducted at the Lima and La Libertad departments, resulting in 20 and 10 publications, respectively. The topics addressed most frequently were bioindication, biodiversity, taxonomy, and distribution. Most theses were carried in the Universidad Nacional de Trujillo and the Universidad Nacional Mayor de San Marcos, with 12 and 10 theses, respectively. The period 2011–2020 records the largest number of publications (40). According to the type of aquatic ecosystem, rivers (38) were the systems most intensively studied, followed by coastal wetlands (14) and lagoons (2); to note, one thesis studied two types of ecosystems. Specimens were collected mainly with the Surber and D nets; as a result, seven phyla, 10 classes, 39 orders, and 118 families were reported. The highest richness of families corresponds to rivers (110), followed by coastal wetlands (57), and lagoons (12). The western hydrographic slope recorded the highest richness at phylum, class, order, and family levels, likely because most investigations were conducted in this slope. On the other hand, the phyla Cnidaria, Nematoda, and Nematomorpha were not recorded in the eastern slope, which showed fewer orders (19) relative to the western slope (39). A similar trend is observed at the family level: of the 118 families recorded, 59 were reported for the eastern slope. The most common families at both sides were Chironomidae, Baetidae, Simuliidae, Elmidae, Hydrophilidae, Libellulidae, Physidae, Dytiscidae, Ceratopogonidae, Coenagrionidae, Hydroptilidae, Hydropsychidae, and Tipulidae. Separately, the most common families in all types of aquatic ecosystems were Chironomidae, Baetidae, and Dytiscidae. It is recommended to further promote studies on macroinvertebrates living in the eastern slope, addressing taxonomic, and ecological topics, as well as broadening the approach to an integral ecosystem view. Finally, the biotic indices should be calibrated and validated for the main hydrographic basins. This work is an initial effort to review, systematize, analyze, and gather the results of studies on aquatic macroinvertebrates in Peru, particularly in arid and semi-arid ecosystems." **20875.** Bowler, D.E.; Eichenberg, D.; Conze, K.-J.; Suhling, F.; Baumann, K.; Benken, T.; Bönsel, A.; Bittner, T.; Drews, A.; Günther, A.; Isaac, N.J.B.; Petzold, F.; Seyring, M.; Spengler, T.; Trockur, B.; Willigalla, C.; Bruelheide, H.; Jansen, F.; Bonn, A. (2021): Winners and losers over 35 years of dragonfly and damselfly distributional change in Germany. *Diversity and Distributions* 27(8): 1353-1366. (in English) ["Aim: Recent studies suggest insect declines in parts of Europe; however, the generality of these trends across different taxa and regions remains unclear. Standardized data are not available to assess large-scale, long-term changes for most insect groups but opportunistic citizen science data are widespread for some. Here, we took

advantage of citizen science data to investigate distributional changes of Odonata. Location: Germany. Methods: We compiled over 1 million occurrence records from different regional databases. We used occupancy-detection models to account for imperfect detection and estimate annual distributions for each species during 1980–2016 within 5 × 5 km quadrants. We also compiled data on species attributes that were hypothesized to affect species' sensitivity to different drivers and related them to the changes in species' distributions. We further developed a novel approach to cluster groups of species with similar patterns of distributional change to represent multispecies indicators. Results: More species increased (45%) than decreased (29%) or remained stable (26%) in their distribution (i.e. number of occupied quadrants). Species showing increases were generally warm-adapted species and/or running water species, while species showing decreases were cold-adapted species using standing water habitats such as bogs. Time series clustering defined five main patterns of change—each associated with a specific combination of species attributes, and confirming the key roles of species' temperature and habitat preferences. Overall, our analysis predicted that mean quadrant-level species richness has increased over most of the time period. Main conclusions: Trends in Odonata provide mixed news—improved water quality, coupled with positive impacts of climate change, could explain the positive trends of many species. At the same time, declining species point to conservation challenges associated with habitat loss and degradation. Our study demonstrates the great value of citizen science and the work of natural history societies for assessing large-scale distributional change." **20876.** Chuirazzi, C.; Ocampo, M.; Takahashi, M.K. (2021): Influence of prey diet quality on predator-induced traits in wood frog tadpoles (*Lithobates sylvaticus*). *Amphibia-Reptilia* 42(3): 331-341. (in English) ["Diet quality and predation are two critical factors in determining the growth and development of organisms. Various anurans are susceptible to phenotypic changes influenced by these factors. Yet, few studies examined prey diet quality as potential influence over predator-induced traits. Using wood frog tadpoles (*Lithobates sylvaticus*) as a model species, we investigated the effects of three diet compositions (plant-based, animal-based, omnivorous) crossed with presence or absence of chemical cues from predatory dragonfly larvae (Aeshnidae). After 35 days, we recorded 11 morphological measurements, Gosner stage, and intestinal length of tadpoles to assess phenotypic changes under the six different experimental conditions. Our results showed the additive effects of both diet quality and predator chemical cue without detection of interactions between the two. Tadpoles receiving the omnivorous diet grew and developed faster with wider denticle rows than those receiving the plant or animal diets. The growth and development of tadpoles receiving only the animal diet were significantly hindered. These results emphasize the importance of diet quality in the growth and development of larval wood frogs. Chemical cues from predators significantly reduced tadpole body size but, in contrast to previous findings, did not affect tail size. Our experimental procedure of providing water containing predator and injured conspecific chemical cues on a weekly basis likely provided relatively weak predation risk perceived by tadpoles compared to previous studies using caged predators. The predator environment in our experiment, however, represents

one ecologically relevant scenario in which predation risk is not urgent." (Authors)] Address: Chuirazz, Catherine, Dept Biology, Bucknell Univ., Lewisburg, PA 17837-2005, USA

**20877.** Cordero-Rivera, A. (2021): *Forcipomyia paludis* (Diptera: Ceratopogonidae) on the wings of *Ischnura elegans* (Odonata: Coenagrionidae) in Minorca (Balearic Islands). *Boletín de la Sociedad Entomológica Aragonesa* 69: 212-213. (in Spanish, with English summary) ["*Forcipomyia paludis* is reported for the first time for the island of Minorca, Spain, from two coastal wetland systems, parasitising imagines of *I. elegans* in summer 2021. Infestation rate was low (0.04-0.2%) and restricted to early summer." (Author)] Address: Cordero Rivera, A., Depto de Ecología e Biología Animal, Univde Vigo, E.U.E.T. **20878.** Dar, S.A.; Bashir, F.; Sabha, I.; Bhat, S.U.; Ali, M.N.; Bhat, G.A.; Ali, A.; Gojree, B.A.S.; Bhat, M.A.; Ud Din Bhat, S.M.; Aziz, A.; Kattoo, P.A. (2021): Insect fauna with special emphasis on their abundance and diversity in different habitats of Kashmir Valley. *J. Himalayan Ecol. Sustain. Dev.* 16: 106-119, Appendix. (in English) ["An assessment of aerial entomofauna is of utmost significance which offers inputs as part of the understanding for conservation and management of biodiversity. This study provides insights into aerial entomofauna dynamics in different habitats of Kashmir Himalaya. A random sampling design over line transects of 100 m were used for entomofauna collection. Overall, 188 species were collected from 10 different habitats/ecosystems, belonging to 13 orders and 63 families. Among the species collected from the various ecosystems, the order Lepidoptera was the most diverse in number (60 species), followed by Hymenoptera (28 species), Coleoptera (25 species), Diptera (24 species), Odonata (18 species), Orthoptera (12 species), Hemiptera (10 species), Homoptera (3 species), Trichoptera (3 species), Neuroptera (2 species), Heteroptera (1 species), Phasmatodea (1 species), and Mantodea (1 species). The highest number of individuals was recorded in habitats like protected forest areas (127 in Dachigam), followed by aquatic ecosystems (126 in Nigeen and 73 in Dal Lake), and the lowest in high altitude forests (12 in Dhara). Cluster analysis revealed the formation of two main clusters with Gulmarg being a riparian/transitional ecosystem type forming a separate cluster I, while the other 9 habitats forming the II cluster. Shannon-Wiener's diversity indices showed highest diversity of 3.83 at Gulmarg and low diversity of 2.2 at Dhara. The ordination of the abundance data using non-metric multidimensional scaling (NMDS) at stress value 0.11 in 2D space resulted in a clear separation between the locations of the sampled habitats." (Authors) Some of the taxa are quite obscure] Address: Bhat, S.U., Dept of Environmental Science, University of Kashmir, Srinagar-190006, Jammu and Kashmir, India. Email: samiullahbhat11@gmail.com

**20879.** Delsinne, T. (2021): Inventaire et suivi des Lépidoptères, Odonates et Orthoptères du marais d'Ours (Puy-en-Velay, 43). Etude réalisée par la SHNAO pour le CEN Auvergne, avec le support financier de la DREAL AURA: 57 pp.+ annexes. (in French) ["The Ours marsh is a 13-hectare wetland acquired by the State as a compensatory site during the construction of the Puy-en-Velay eastern bypass on the RN88. Its management has been entrusted to the CEN Auvergne since 2011. Monitoring of lepidopterans, odonates and orthopterans was set up in 2012. Repeated in 2016 with an identical protocol, it has also been renewed in 2021 in order to assess the impact of restoration work and management practices on insect populations. Lepidoptera

are identified and counted along 7 transects totalling 1143 metres. Odonates were surveyed at 4 points and 1 transect (30 minutes/point). Orthopterans are identified by sight and hearing and an abundance index is assigned to the species detected. In 2021, this protocol was carried out during five survey days (10 and 26 June, 19 July, 26 August and 27 September). During the monitoring, 39 lepidopteran species were counted along the transects. Ten additional species were observed outside the protocol. Twelve of these are first records for the site. In total, 53 species (49 rhopalocerans and 4 zygens) have been reported at least once since 2010. The cumulative number of species is on average  $16 \pm 4$  per transect, double the values obtained in 2012 ( $8 \pm 3$ ). An increase of a more or less similar order of magnitude was obtained for the number of individuals counted in total (676 in 2021 vs. 372 in 2012), the average number of individuals per transect ( $75 \pm 41$  vs.  $33 \pm 20$ ), the average number of species per 100 linear metres ( $13 \pm 5$  vs.  $7 \pm 3$ ) and the average number of individuals per 100 linear metres ( $61 \pm 28$  vs.  $29 \pm 18$ ). The sectors where the number of species and individuals increased the most were those with flowers (hay meadows, megaphorbia, etc.). For odonates, 16 species were observed during the surveys, including 6 species mentioned for the first time. The inventory of dragonflies counts 19 species since 2010. The most attractive area is the northern pond, which has a sunny open water surface and is surrounded by, among other things, cattails. In 2021, 22-23 species of orthopterans were contacted, including at least 16-17 new ones, resulting in a list of 25-26 taxa for the site since 2012 (the uncertainty is caused by the delicate identification of *Tetrix* spp.) This high contribution of new taxa is partly explained by a targeted search for tree and hedgerow associated orthopterans, carried out for the first time. Similarly, the embankment of the RN88, which is now vegetated, was surveyed for the first time, which brought in species associated with dry herbaceous vegetation. Heritage species linked to wetlands were discovered: *Lycaena dispar* and *Satyrion w-album* for lepidopterans, *Aeshna isoceles* and *Aeshna mixta* for odonates and *Tetrix bolivari/ceperoi* for orthopterans. However, evidence of autochthony was only obtained for *Lycaena dispar* (egg laying). The results of the monitoring and inventories carried out in 2012, 2016 and 2021 unambiguously demonstrate the effectiveness of the restoration measures that were put in place when the site was acquired, with a gradual increase in the specific richness and abundance of the three insect groups studied. However, we believe that the situation can still improve, as some potential species for this type of environment have not been observed. Management recommendations and future studies are proposed." **20880.** Evtimova, V.; Tyufekchieva, V.; Varadinova, E.; Vidinova, Y.; Ihtimanska, M.; Georgieva, G.; Todorov, M.; Soufi, R. (2021): Macroinvertebrate communities of sub-Mediterranean intermittent rivers in Bulgaria: Association with environmental parameters and ecological status. *Ecologia Balkanica, Special Edition* 4: 49-64. (in English) ["Intermittent rivers and ephemeral streams drain more than 50% of the land surface on Earth. Yet, their ecology remains insufficiently understood. In Bulgaria, temporary rivers are typically small, or medium-sized rivers (national type R14), flowing in areas with sub Mediterranean climate. We present the first data focused explicitly on macrozoobenthos from intermittent rivers in four Bulgarian river basins within the drainage of the Aegean Sea. We identified 114 taxa from

nine rivers (5±33 taxa/site), with abundance varying between 61 and 994 ind/m<sup>2</sup>. The most common were taxa of Ephemeroptera and Chironomidae, followed by the crab *Potamon ibericum*. There were considerable differences among macroinvertebrates at different sites at taxon level, with similarities among samples increasing when using lower taxonomic resolution. The distinctness of communities was likely a reflection of the high variability in environmental conditions and local human impacts. Redundancy analysis identified key groups for the sites with fast flow (e.g. Ephemeroptera, Trichoptera, Plecoptera, Coleoptera and Diptera *Varia*, taxa associated with altitude and the higher share of stone substrata). Most of the river sites were classified as having high ecological status according to the Bulgarian legislation. Only the sites in the Vrabcha and Dereorman Rivers were with moderate status; these were the sites with the lowest taxon richness. We could speculate that the structuring of the benthic community was affected by other factors that have not been accounted for in the present study, i.e. great annual fluctuations in river flow, characteristic for R14, or by loading with nutrients or other pollutants." (Authors) The following odonate taxa are listed: *Anax imperator*, *Calopteryx splendens*, *Calopteryx* sp., *Cordulegaster* sp., *Gomphus* sp., *Ophiogomphus* sp., *Onychogomphus* sp.] Address: Tyufekchieva, Violeta, Department of Aquatic Ecosystems, Institute of Biodiversity and Ecosystem Research, Bulgarian Academy of Sciences, 1 Tsar Osvoboditel Blvd., 1000 Sofia, Bulgaria. **20881.** Golab, M.J.; Sniegula, S.; Antol, A.; Brodin, T. (2021): Adult insect personality in the wild — *Calopteryx splendens* as a model for field studies. *Ecology and Evolution*. 2021; 11: 18467-18476. (in English) ["Animal personality has received increasing interest and acknowledgement within ecological research over the past two decades. However, some areas are still poorly studied and need to be developed. For instance, field studies focused on invertebrates are currently highly underrepresented in the literature. More studies including a wider variety of traits measured and species tested are needed to improve our understanding of trait-correlation patterns and generalities. We studied nine behavioral traits, in *C. splendens*, from an array of three experiments: (i) courtship, (ii) aggressiveness, and (iii) boldness, and calculated their repeatability. The behaviors were measured twice in two different contexts: (i) undisturbed territory and (ii) partially deteriorated territory. Traits related to courtship and boldness were all repeatable across the two contexts. Among aggressive behaviors, only one trait (number of hits) was repeatable. This work demonstrates, for the first time, the presence of within-population personality differences in an adult damselfly in the wild. We further propose *C. splendens* as a promising model species for testing personality in the wild under highly controlled environmental conditions." **20882.** Hedges, B.A.; Austin, A.D.; Conran, J.G.; Taylor, G.S.; Madden, C.P.; Weinstein, P. (2021): A likely association of damselflies with the habitat heterogeneity provided by the freshwater swamp lily, *Ottelia ovalifolia*, in Eyre Peninsula granite rock-holes, with a review of potential threats to this ephemeral habitat. *Transactions of the Royal Society of South Australia* 145(8): 1-16. (in English) ["The granite rock-holes (sometimes called gnammas) across northern Eyre Peninsula (EP), South Australia, are a unique but poorly studied ephemeral freshwater habitat containing a complex invertebrate community. Macroinvertebrate predator occurrence

is often sporadic, both spatially and temporally. We aimed to determine if environmental conditions might predict predator occurrence in EP rock-holes. A total of 14 rock-holes were sampled across five granite outcrops along the Eyre Highway. Extensive dip-net sampling was undertaken and nymphs of three damselfly species were recorded from the rock-holes: *Austrolestes annulosus* (Lestidae), *Ischnura aurora*, and *Xanthagrion erythroneurum* (both Coenagrionidae), all in a single rock-hole at Pildappa Rock. This sole rock-hole contained a prominent floating-leaved, rooted aquatic macrophyte: the swamp lily, *Ottelia ovalifolia* (Hydrocharitaceae), which forms a complex, three-dimensional vegetative structure. Damselflies were hypothesised to be associated with the presence of *O. ovalifolia*, possibly as a result of the plant providing both suitable oviposition sites for the adults and habitat for nymphs throughout the water column, opportunities not afforded by the aquatic vegetation present in shallow rock-holes. Our findings contribute to the limited ecological information regarding EP rock-holes. We also briefly review potential threats to these ecosystems, an understanding of which will be critical to their management and conservation." **20883.** Hyseni, C.; Heino, J.; Bini, L.M.; Bjelke, U. Johansson, F. (2021): The importance of blue and green landscape connectivity for biodiversity in urban ponds. *Basic and Applied Ecology* 57: 129-145. (in English) [The negative impact of urbanization on biodiversity can be buffered by blue (e.g., rivers, ponds) and green (e.g., parks, forests) spaces. However, to prevent biodiversity loss and reduce the risk of local extinctions, blue and green spaces need to be connected by corridors, so that organisms may disperse between sites. Landscape connectivity affects local community composition and metacommunity dynamics by facilitating dispersal. The goal of this study was to test the relative roles of pond environmental properties, spatial structure, and functional landscape connectivity on differentiation of invertebrate metacommunities in urban ponds in the city of Stockholm, Sweden. We characterized functional connectivity as blue connectivity (distance to water bodies), green connectivity (land use), and combined blue-green connectivity. We estimated functional connectivity by using electrical circuit theory to identify dispersal corridors. Interestingly, while circuit theory is often used in single-taxon studies, this method has rarely been applied to multiple taxa forming a metacommunity, as we have done in this study. Indeed, our study contributes toward an increased focus on the role of dispersal at the metacommunity level. We determined that functional connectivity was the most important factor in explaining community differentiation, with the local environment contributing comparatively little, and spatial structure the least. Combined blue-green functional connectivity had a major influence on structuring urban pond communities, explaining 7.8% of the variance in community composition across ponds. Furthermore, we found that increased functional connectivity was associated with an increase in the number of species. In summary, our results suggest that to preserve biodiversity in urban ponds, it is important to enhance functional connectivity, and that open green spaces could augment blue corridors in maintaining functional connectivity in urban pond metacommunities. To generalize these findings, future urban biodiversity studies should compare how functional connectivity affects metacommunities across multiple major cities." **20884.** Kathan, B.; Willigalla, C. (2021): Terrestrische Habitatnutzung von *Sympecma fusca* über Jahreszeiten und Generationen hinweg (Odonata: Lestidae). *Libellula* 40 (3/4): 143-160. (in German, with English summary) ["Terrestrial habitat use of *Sympecma fusca* across seasons and generations (Odonata: Lestidae) – A capture-mark-recapture (CMR) study was conducted on *Sympecma fusca* at Spitzberg near Tübingen from 04 March 2018 to 15 February 2019. Further follow-up controls took place in 2020. Including the reproductively active specimens, 267 individuals of the 2017/18 generation were detected at Spitzberg, which used the entire area differentially in both spring and autumn. Of 105 individually marked specimens, 20 could be recaptured several times before the start of the reproductive phase over a maximum of three weeks, always at a short distance from the initial capture point. At a terrestrial habitat 730 m away from the nearest reproductive water body, several individuals were regularly encountered over the years. Out of 62 individuals observed between July and October 2018, only one (1.6%) was encountered at a distance of less than 10 m from a reproduction water body in the forest area of the Spitzberg, all other individuals (98.4%) were recorded further away from a water body. In principle, however, the distribution of the two generations on the Spitzberg differed little from each other, i.e. overlaps of the sites used in spring and summer or autumn were present except for the immediate vicinity of the water bodies and the southern slopes of the "Ödenburg" NSG. Rarely were only single animals found within a habitat structure in spring as well as in autumn, mostly small groups of two to more than ten animals were found in close spatial proximity to each other." **20888.** Minot, M.; Aubert, M.; Husté, A. (2021): Pond creation and restoration: patterns of odonate colonization and community dynamics. *Biodiversity and Conservation* 30: 4379-4399. (in English) ["Ponds are lentic waterbodies with a high conservation value for biodiversity that have long been overlooked by management policies. Recent initiatives aimed to promote the conservation of these ecosystems by restoring or creating new ponds throughout Europe. Therefore, studying responses of aquatic invertebrates to local pond characteristics and connectivity between them is determinant to understand community dynamics and colonization processes of these scattered ecosystems. We studied larval communities of odonates in 20 created or restored ponds to assess their colonization during the first 2 or 3 years. Community dynamics in relation to pond vegetation, landscape context and connectivity with other ponds were also investigated. No difference in species richness was found between restored and created ponds. Most species colonized the ponds during the first year, but a different pattern in colonization was observed between Anisoptera and Zygoptera. Community composition was related to the landscape context of ponds and the time since pond creation or restoration. Abundances were positively related to pond connectivity, especially in the suborder Zygoptera. No relationship was found between vegetation and Anisopteran larvae, while Zygoptera seem more sensible to the vegetation structure due to their endophytic oviposition. This work

confirms the high colonization capacity of odonates and shows that creation of new ponds could be as efficient as pond restoration to enhance the conservation of freshwater species. It also highlights that landscape characteristics and connectivity between ponds are determinant to support higher abundances and a posteriori increase population viability at the landscape scale." (Authors)] Address: Minot, M., UNIROUEN, INRAE, ECODIV, Normandie Univ, Rouen, France. Email: m.minot@hotmail.fr

**20889.** Miya, M.S.; Gautam, D.; Neupane, B.; Chhetri, A. (2021): Species diversity and abundance of Odonata in Sishaghat of Tanahun district, Nepal. *Journal of Animal Diversity* 3(3): 45-55. (in English) ["Odonata are one of the most ancient, well studied and fascinating insect orders considered as bio-indicators of aquatic ecosystems. Studies on Odonata have been carried out in many parts of Nepal, but no specific study has been performed in Tanahun. Hence, a study was conducted to determine the species diversity and abundance of Odonata in the Sishaghat of Tanahun district, Nepal from June to August 2020. A transect survey method was used for data collection. A total of six transects (three in each habitat type: agricultural lands and forest streams), each with a length of 200 m were laid out randomly and each transect was surveyed three times. Data were pooled and analyzed with SPSS. A total of 629 individuals of 26 Odonata species from 20 genera and 7 families were recorded. The overall Shannon-Wiener diversity index was  $H = 2.25$ , Shannon Equitability was  $E = 0.69$  and Margalefs' richness index was  $R = 3.88$ . Anisoptera was more diverse ( $H = 1.94$ ) and more abundant ( $n = 545$ ) than Zygoptera ( $H = 1.31$ ,  $n = 84$ ). However, species richness was higher and evenness lower in Zygoptera ( $R = 2.26$ ,  $E = 0.55$ ) than Anisoptera ( $R = 2.22$ ,  $E = 0.72$ ). Anisoptera comprised 15 species within 10 genera from two families and Zygoptera comprised 11 species within seven genera from five families. The family Libellulidae represented the highest species richness ( $R = 1.75$ ). *Neurothemis fulvia* and *Orthetrum prunosum* were the most abundant species ( $RA = 23.21$  and  $21.78$  respectively). Of the recorded Odonata, 25 species are included under the least concern and one under the vulnerable category of the IUCN. A higher number of species was found in agricultural lands (nine species); hence, the water bodies around this habitat should be preserved to conserve the Odonata." **20890.** Moura de Souza, A.G.; Neto, V.; Pereira Júnior, A. (2021): Revisão integrativa sobre biologia, qualidade da água e a ordem Odonata. Integrative review on biology, water quality and the order Odonata. Revisión integrativa sobre biología, calidad del agua y orden Odonata. *Research, Society and Development* 10(9), e24910917605: 18 pp. (in Portuguese, with Apanish and English summaries) ["Sciences such as biology generate information about ecosystems, such as aquatic ecosystems, and promote integration with ethnic knowledge associated with botany. The objective of this work was to carry out an integrative review about the interrelationship of biology with various environmental areas, under two aspects, conservation, and balance, to investigate the relationship between biology and research on water quality and the use of the order Odonata as bioindicator of the environmental quality of water bodies. The research method was deductively associated with a quantitative and qualitative approach of a basic nature. The data obtained and analyzed indicated that the biological terms are present in most of the selected literature ( $n = 46.2\%$ );

regarding water quality, there was a small reduction ( $n = 30.8\%$ ); the use of the order Odonata as bioindicators of water quality is still scarce ( $n = 22.9\%$ ). As for the use of descriptors in the analyzed research, the following citations were identified: "Biological terms and water quality" ( $n = 65.8\%$ ); "Odonata and water quality" ( $n = 21.1\%$ ); "Biological terms and Odonata" ( $n = 13.2\%$ ). The order Odonata, as a bioindicator, is evolving ( $\Sigma = 33.3\%$ ) and with high frequency ( $fr > 50\%$ ) when compared to the application of Biological Terms and Water Quality. So, the application of biology is already effective in environmental areas such as water quality analysis. However, the use of Odonata as bioindicators of water quality is not used very often yet. Thus it is recommended that there is a greater appreciation by researchers of this relationship, which can contribute to the qualification and monitoring of this natural resource more comprehensively and effectively." **20891.** Mykitchak, T.; Kozlovskyy, V.; Mateleshko, O. (2021): Invertebrate hydrobiont fauna transformation in the Dombrovskiy pit lake during the period of 2014-2018. *Visnyk of the Lviv University. Series Biology* 84: 94-104. ["The aquatic invertebrate community of Dombrovskiy pit lake was investigated during 2014–2018. 25 species were recorded there. The only permanent component of plankton in the community is rotifer *Brachionus plicatilis* Müller, 1786; of benthos and neuston is hemipteran *Sigara lateralis* (Leach, 1817), beetle *Hydrobius fuscipes* (Linnaeus, 1758), flies *Aedes* sp., *Ochlerotatus lepidonotus* (Edwards, 1920), *Culicoides salinarius* Kieffer, 1914, *Ephydra glauca* Meigen, 1830 are permanent components of benthos and neuston. The main diversity of invertebrates is concentrated in littoral zone up to 2 m of depth. This is primarily due to the desalination of these areas by surface runoff. Over the last decade the mineralization of the surface water layer has decreased from 120–138 to 25–28 g/l. Combined with the desalination of water, the increase of species diversity of aquatic invertebrates was noticed in spring seasons (from 7 to 17 taxa). The freshwater taxa, which are not tolerant even to low water salinity, appeared in the community in 2018 (7–25 % of the species diversity), among them *Hydrometra stagnorum* (Linnaeus, 1758), *Rhyacophila tristis* Pictet, 1834, *Coelambus impressopunctatus* (Schaller, 1783), *Enochrus coarctatus* (Gredler, 1863), *Hydrophilus caraboides* (Linnaeus, 1758). The role of freshwater taxa, which are tolerant to low water salinity (up to 5 g/l), increased from 0–10 % of the species diversity in 2014–2015 to 22–35 % in 2018. Among them *Eucyclops serrulatus* (Fischer, 1851), *Candona* sp., *Cypris pubera* O. F. Müller, 1776, *Cloeon dipterum* (Linnaeus, 1760), *Libellula depressa*, *Sympecma fusca*, *Paracorixa concinna* (Fieber, 1848) was noted in 2018 for the first time. On the contrary, the number of saltwater taxa decreased from 20–29 % (2014–2015) to 5–14 % (2018). The saltwater aquatic invertebrate community of this pit lake has transformed into brakish-freshwater one over time. 83 % taxa of aquatic invertebrate communities from freshwater puddles near reservoir coast are noted in the Dombrovska reservoir. The introduction of species from protective canals of the reservoir is unlikely, as only 5 % of taxa from there are marked in it. The main way of the forming communities of invertebrates in this reservoir is the periodical flooding of freshwater coastal puddles." **20892.** New, T.R. (2021): Book Review: Günther Theischinger and John Hawking: The complete field guide to dragonflies of Australia. 2nd edn (with colour illustrations by Albert Orr). CSIRO Publishing, Melbourne, 2021, Paperback, Au \$49.99, ISBN 9781486313747, 424 pp. *Journal of Insect Conservation* 25: 553-554. (in English) [Verbatim: The first edition of this pioneering field guide proved both useful and popular, as attested by several reprintings since it appeared in 2006. It was also a catalyst for further exploration of Australia's unique and remarkable odonate fauna, and these recent discoveries are here incorporated into this welcome second edition, so bringing the most recent practical perspective to what will assuredly be a wide and appreciative readership. Indeed, one recent discovery (the tiny Artesian Pygmyfly, *Nannophya fenshami*) was described only after the deadline for this revised text, and is treated in the introductory species guide rather than in the 'text proper'. Altogether, seven new species have been described, and several other additions to the Australian fauna recorded since 2006. Collectively, 333 species are treated, an increase from 324. Some anomalies and challenges remain: the Newaustralian Emerald (*Hemicordulia armstrongi*) has not been verified in Australia by adult specimens, with its identity based on photographs and larval features. Its relationship to the widespread *H. australiae* is still somewhat unclear, and is discussed by Rowe (2019). The first edition of this book (reviewed in this journal: New 2008) was heralded as the first major field guide to the regional fauna, and this revision follows closely on the very user-friendly format established there with text and illustrations integrated well. An introduction sets a perspective for the book, noting the high level of endemism among Australian Odonata, and summarising their life histories, ecology and major habitats. The brief mention of conservation has not been updated. As in the first edition, the major section of the book, the 'species guide' (pp. 11–315) has text on the left-opening page, providing recognition and diagnostic notes and habitat comments on two or three species, and including (where available) comments on the larva, together with line drawings of key structural features and colour pattern to aid identification, and a distribution map. The facing right-hand page presents colour photographs of adults and, when available, larvae. Many of the photographs of living adult insects have been replaced with new images, and will greatly aid recognition in the field. The systematic arrangement has been updated to reflect recent consensus over family limits in the Odonata and brings Australian family allocations ('for better or worse' as noted in the preface!) in line with those used elsewhere. Modifications are tabulated carefully but, in summary, the Australian Zygoptera now comprise representatives of 10 families (previously 12) and the dragonflies proper of eight families (previously 18) plus 11 genera that are treated as incertae sedis. Families and genera are also characterised succinctly within the main text, and non-specialists will welcome the informative illustrated glossary. This is followed by series of keys to families and some genera and species, as a valuable confirmation of identifications suggested by the main text. Similar illustrated keys to larvae, and several comparative plates of larval habitus drawings ensure that a high proportion of both adult and larval Odonata can be identified. As a field guide, this new edition succeeds admirably. It concludes with sections on 'studying dragonflies', a checklist of species, references and further reading, and indices to scientific and common names. A significant addition to this book is the series of magnificent colour paintings of 40 species prepared by Albert Orr, himself a leading dragonfly expert and entomological illustrator. These plates alone will help to increase appreciation of our remarkable and largely endemic Odonata, and endorse

awareness of their diversity and their values as flagship taxa and tools in evaluating the quality of Australia's inland water ecosystems.] Address: New, T.R., Dept of Ecology, Environment & Evolution, La Trobe University, Bundoora, VIC 3086, Australia. Email: T.New@latrobe.edu.au

**20893.** Reyes-Márquez, I.; Gómez-Vargas, S.; Carrillo-Muñoz, A.I.; López-García, K.; Serrano-Meneses, M.A. (2021): Patterns of sexual dimorphism in flight agility in territorial and non-territorial Odonata. *Journal of Ethology* 39: 129-134. (in English) ["Adult Odonata are amongst the most accomplished flying insects on the planet. The main functions of spatial displacement by flight in these insects are well understood (e.g., escape from predators, foraging, reproduction, thermoregulation), but whether males and females exhibit different degrees of flight agility across species—and why—is by contrast, poorly understood. This is important because flight agility may differ between males and females due to the costs imposed on females by the high levels of sexual selection and sexual conflict observed in certain species. Here we used a wing parameter to estimate sexual dimorphism in flight agility in 63 Odonata taxa. We then used a phylogenetic comparative method to investigate whether sexual dimorphism in flight agility differed between (i) Anisoptera and Zygoptera, and (ii) mating systems (non-territorial, territorial). Our results first show that the distribution of sexual dimorphism in flight agility between Odonata families is non-random. Second, our results suggest that whereas sexual dimorphism in flight agility is not different between non-territorial and territorial Anisoptera, in Zygoptera it is predominantly female-biased in non-territorial species, and male-biased in territorial ones. There may be important behavioural and mating differences between Anisoptera and Zygoptera which explain the different needs of agility observed between suborders and mating systems." **20894.** Shakya, M.; Silvester, E.; Rees, G.; Stitz, L.; Holland, A. (2021): Spatial variation in the amino acid profile of four macroinvertebrate taxa along a highly polluted river? *Environmental Pollution* Volume 284, 1 September 2021, 117536: 9 pp. (in English) ["Highlights: • River affected by acid mine drainage (AMD) from mine 30 years after closure. \*AMD altered community structure and amino acid (AA) profile of macroinvertebrates. \*Inter and Intra-specific variations in AA profiles were detected among four taxa. \*Strongest changes in AA profile were observed within the family Chironomidae. AA profiling offers a new tool for assessing the environmental impact of AMD. Abstract: Acid mine drainage (AMD) is one of the major environmental problems impacting aquatic ecosystems globally. We studied changes in the community composition of macroinvertebrates and amino acid (AA) profiles of dominant taxa along an AMD contamination gradient within the Dee River, Queensland, Australia to understand how AMD can affect the biomolecular composition of macroinvertebrates. Taxa richness and community composition of macroinvertebrates changed widely along the AMD gradient with significantly lower taxa richness recorded at the polluted sites compared to upstream and downstream sites. The Dipteran families: Chironomidae and Ceratopogonidae, the Odonata family Gomphidae, and the Coleoptera family Dytiscidae were the only families found at all sampling sites and were used here for AA analysis. There were significant variations in the AA profiles among the studied taxa. The AA profile of each taxon also varied among upstream, polluted and downstream sites

suggesting that contamination of a river system with acid mine drainage not only alters the overall macroinvertebrate community composition but also significantly influences the AA profile of organisms that are tolerant to AMD. This study highlights the potential of using AA profiling to study the response of aquatic organisms to contamination gradients such as those associated with AMD." (Authors)] Address: Shakya, Manisha, La Trobe Univ., School of Life Sciences, Dept Ecology, Environment & Evolution, Centre for Freshwater Ecosystems, Albury/Wodonga Campus, VIC, 3690, Australia. (2021): Influence of the Mekin hydroelectric dam on the distribution of benthic macroinvertebrates of the Dja stream: South Cameroon region. *World Journal of Advanced Research and Reviews* 12(2): 63-77. (in English) ["This work was conducted with the aim of studying the biodiversity of benthic macroinvertebrates in the Dja River and determining the effect of the Mekin hydroelectric dam on their population in relation to the physico-chemical quality of the water. The study ran from May to October 2020 and samplings were carried out on a monthly basis in four different sampling stations located upstream and downstream of the dam. The physico-chemical analyses were done according to standard methods, while the benthic macrofauna was collected using a turbid net of 400 µm mesh size over a total area of about 6 m<sup>2</sup> per station. Physico-chemical analyses revealed a decreasing evolution from upstream to downstream of the dam of nitrogen forms (NO<sub>3</sub>. (1.67mg/L-0.41mg/L); NH<sub>4</sub><sup>+</sup> (0.31 mg/L-0.21 mg/L) with p>0.05); Electrical Conductivity (21.45µS/Cm-17.1µS/Cm with p<0.05) and Suspended Solids (11.10mg/L-6.57mg/L with p<0.05); while Dissolved Oxygen (49.82%-78.23% with p<0.05) and velocity (0.04m/s-0.23m/s) increased. Organic Pollution Index revealed that the water was moderately polluted (3-4). In total, 1894 individuals, of which 1044 belonging to 2 phyla, 2 classes, 6 orders, 27 families and 47 genera/species were collected upstream; and 850 belonging to 3 phyla, 4 classes, 8 orders, 28 families and 45 genera/species were collected downstream. Odonata was largely abundant and highly represented *Trithemis dorsalis* (96.05%); while downstream, *Heteroptera* was largely abundant and highly represented by *Poissonia* sp1. (79.78%). These results revealed that restoration of the upstream of the dam impacted by organic pollution and physical degradation of the environment is recommended." (Authors) The list of taxa includes European species, not occurring in Africa.] Address: Togouet, S.H.Z., Laboratory of Hydrobiology & Environment (LHE), Fac. **20896.** Adekolurejo, O.A.; Floyd, M.; Dunn, A.M.; Kay, P.; Dean, A.P.; Hassall, C. (2022): Combined effects of increased water temperature and cyanobacterial compounds exert heterogeneous effects on survival and ecological processes in key freshwater species. *Oecologia* 200: 515-528. (in English) ["Climate change is increasing water temperature and intensifying the incidence of cyanobacterial blooms worldwide. However, the combined effects of increased temperature and microcystin concentrations as co-stressors on survival and ecological processes in freshwater species are unclear. Here, using purified MC-LR and crude extract of toxigenic *Microcystis aeruginosa*, we tested the individual and combined effects of three water temperatures (15, 20,

25 °C) and a range of environmentally relevant concentrations of dissolved microcystin and crude extract (0.01–10 µg·L<sup>-1</sup>) on survival, growth inhibition, grazing and predation rates in three freshwater species: phytoplankton (*Scenedesmus quadricauda*), zooplankton (*Daphnia pulex*), and an invertebrate predator (*Ischnura elegans*). Purified MC-LR exerted a higher growth inhibitory effect on *S. quadricauda* compared to crude extract with the same concentration of MC-LR, while neither treatment affected its chlorophyll-a content or survival of *D. pulex*. Crude extract reduced grazing and survival of *D. pulex* and *I. elegans*, respectively. The combined effect of higher temperature and crude extract reduced *I. elegans* survival by 50%. Increased temperature reduced prey handling time in *I. elegans* by 49%, suggesting a higher predation rate. However, warming together with higher concentrations of crude extract jointly increased zooplankton grazing and reduced damselfly predation. Taken together, these results suggest crude extract, and not necessarily microcystin, can affect survival and productivity in freshwater species, although these effects may vary unevenly across trophic levels. Our findings highlight the importance of complex ecological mechanisms by which warming can exacerbate toxic effects of cyanobacterial bloom extracts on survival and functions among species in eutrophic freshwaters." **20897.** Amer, N.R.; Lawler, S.P.; Zohdy, N.M.; Younes, A.; ElSayed, W.L.; Wos, G.; Abdelrazek, S.; Omer, H.; Connon, R.E. (2022): Copper exposure affects anti-predatory behaviour and acetylcholinesterase levels in *Culex pipiens* (Diptera, Culicidae). *Insects* 2022, 13, 1151. <https://doi.org/10.3390/insects13121151>: 14 pp. (in English) ["Simple Summary: Interaction between natural and anthropogenic stressors, such as contaminants and predators, could jointly account for potential ecological risk to organisms. This study quantified the combined effect of copper and/or predation cues (non. consumptive predation) on the anti-predatory behaviour of *Culex pipiens* larvae (swimming distance and speed). As well, we tested the ability of mosquito larvae to escape predation by dragonfly larvae. We also measured the long-term effect of copper on an enzyme important to the nervous system, acetylcholine esterase (AChE) for two successive generations. Copper reduced the movement and velocity of *Cx. pipiens* larvae, even at levels regarded as environmentally safe. Interestingly, copper showed some stronger effects in the second generation than the first one. Copper acted as an AChE inhibitor at 500 µg L<sup>-1</sup>. There was no significant effect of copper on the ability of larvae to escape from the direct predation of dragonflies in the laboratory, where most were consumed rapidly. However, the behavioural and neurological changes documented could result in *Cx. pipiens* larvae being more vulnerable to predation in natural habitats. Copper likely bioaccumulated and was passed on in eggs, and/or had other maternal or gene expression effects, resulting in harmful effects on offspring. Abstract: Copper is an essential metal that occurs chronically in the environment and affects the development and physiology of aquatic insects. In excess amounts, it can impair their nervous system and behaviour. We tested the anti-predatory behaviour of *Cx. pipiens* larvae after seven days exposure with several concentrations of copper up to 500 mg L<sup>-1</sup>. We measured responses to non. consumptive (predation cues) and consumptive predation (dragonfly larvae) across two generations. We also tested the accumulated effect of copper on AChE enzyme activity. We exposed half of treated and control larvae to predation cues (water with

predator odour and crushed conspecifics) and the other half to water without predation cues. We evaluated total distance moved and velocity. Copper reduced the distance moved and velocity, with stronger effects in the second generation. Copper had no significant effect on larvae eaten by dragonflies. Copper inhibited the AChE enzyme across both generations at 500 µg L<sup>-1</sup>. Copper can affect the nervous system directly by inhibiting AChE activity, and possibly also by impairing the olfaction sensors of the larvae, resulting in larval inability to detect predation cues." **20898.** Appel, E.; Michels, J.; Gorb, S.N. (2022): Chapter 2: Native Resilin: Properties, Occurrence and Biological Functions of a Remarkable Bio-elastomer. In: Namita Roy Choudhury, Julie C Liu, Naba K Dutta (eds.): Biomimetic Protein Based Elastomers: Emerging Materials for the Future Editors: 8-44. (in English) ["Resilin is an elastomeric protein that occurs in arthropod exoskeletons and stands out for its almost perfect resilience of 92–97%, the reason why it is often called a rubber-like protein. It consists of long, randomly oriented proline- and glycine-rich polypeptide chains of high mobility and little secondary structure, which are covalently linked by dityrosine and trityrosine cross-links. This structure endows resilin with a low stiffness, high long-range deformability, and outstanding resilience. Resilin often forms composites with chitin via its chitin-binding domain and with other proteins. Based on the amount and purity of resilin, the direction of the embedded chitin fibres, the specific structure of resilin's polypeptide chains, and the ratio of di- and trityrosine cross-links, resilin shows divergent mechanical responses to different directions and types of applied force. So far, resilin has been found in various exoskeleton systems, including leg and wing joints, vein joints and membrane areas, tarsal setae, tendons, sensory organs, and specialised structures like food-pumps, sound production organs, extensible abdominal cuticles, and transparent optical elements. Amongst others, resilin serves the generation of deformability and flexibility, the elastic energy storage, the adaptability to uneven surfaces in contact, and the reduction of material fatigue in these exoskeleton systems. ... 2.3 Conclusion: Resilin occurs in a large variety of exoskeleton systems. This intrinsically disordered protein stands out for its high flexibility, resilience, and long-range deformability and exists in either virtually pure form or as a composite, the latter combining diverse properties and advantages of the involved materials. This allows resilin-supplemented systems to efficiently fulfil a broad range of different, highly specialised functions, ranging from the acceleration of catapult-like jumps and the increase in the transparency of compound eyes or the improvement of tarsal attachment ability to the sealing of wounds and the overall reduction of material fatigue and damage. The extraordinary properties of resilin and resilin composites have probably been the basis for the evolution of such highly diverse resilin-supplemented systems in arthropods and are nowadays the reason for the development of resilin-like polypeptide-based biomaterials and resilin-inspired engineering applications." with English summary) ["River pollution is an environmental problem that often occurs. Community activities and different land uses are strongly suspected of causing pollution. The purpose of this study was to determine the diversity of macrozoobenthos in different land uses and the quality of the aquatic environment in the Petapahan River of the Imbo Putui Indigenous Forest based on the macrozoobenthos diversity index. This study uses 2 indicators, namely macrozoobenthos as a biological indicator and environmental indicators including temperature, brightness, pH, depth, and current velocity. Sampling was carried out at 4 stations with 2 repetitions using the Surber net. The results showed that the macrozoobenthos found came from the order Odonata with the families Gomphidae and Libellulidae and the order Coleoptera with the family Dytiscidae. The diversity index value obtained ranges from H' = 0.58-0.67, the index value shows the diversity of animals is classified as low with uneven or low uniformity (E = 0.53-0.61) and the dominance that occurs is classified as moderate (C = 0.52-0.61). The results of the measurement of environmental parameters showed that the temperature at each station was 28°C with a brightness to the bottom of the waters and a depth of 37-56 cm, current speed ranged from 6.56-12.25 m/s and water pH ranged from 4.9-7.9." **20902.** Balua, R.; Dutta, N.K.; Choudhury, N.R. (2022): Chapter 5: Resilin-mimetic polypeptides and elastomeric modular protein polymers: Amino acid sequence, conformational ensemble, and stimuli responsiveness. In: Namita Roy Choudhury, Julie C Liu, Naba K Dutta (eds.): Biomimetic

Protein Based Elastomers: Emerging Materials for the Future: 108-143. (in English) ["5.7 Conclusions: In summary, the largely unordered structure of RLPs originates from high glycine and proline amino acid content (430%) similar to that of elastomeric IDPs, and the presence of a large fraction (30%) of recurring P-X<sub>n</sub>-G motifs (where X is the other amino acid apart from P and G, and n varies from 0 to 4) repeating every 4 to 9 residues in the primary sequence. The intrinsically disordered structure of RLPs and RLP-based modular protein polymers has also been experimentally established using techniques, such as CD spectroscopy, FTIR, NMR, and SAS, which reveal an ensemble of random coil secondary structure with the coexistence of small fractions of turns and PPII conformation in equilibrium. The multistimuli responsiveness and self-assembly of RLPs originate from their unique amino acid sequence, hydrophilic composition, and dynamic architecture, where the dual-phase transition behavior comes from the fusion of a putative LCST motif (APGGGN) and a UCST motif (GRPSD-SYG) in the primary sequence. The critical solution temperature behavior of RLPs is related to unfavorable solvent entropy, where the polypeptides collapse into amorphous coacervates and their LCST can be modulated by either altering the hydrophobicity of amino acids or their charge. Moreover, the UCST behavior of RLPs is considered to originate from a set of sequence-specific features, such as the overall fraction of charged residues, arginine and aromatic residues, and net charge per residue. The self-assembly (soluble, micellar, fibrillar, and coacervates) of RLPs and RLP-based modular protein polymers are substantially influenced by the RLP chain length, sequence, and hydrophobicity of copolypeptides, their overall composition, and solvent pH. The highlighted key information shall provide fundamental knowledge and understanding of RLPs for improved rational design and development strategies of resilin protein-based smart biomaterials." (in Portuguese, with English summary) ["Benthic aquatic insects in forested and non-forested environments in rivers of the Juruá Valley. Fresh water ecosystems have been constantly threatened by anthropogenic stressors, placing a burden on benthic aquatic insect community structures. Hence, the aim of this study is to evaluate aquatic insect diversity in a gradient of forested and non-forested areas between the dry and rainy seasons in rivers of the Juruá Valley. 675 individuals were collected, 70.63% were collected during the dry season and 29.37% were collected during the rainy season, distributed among the orders Diptera, Ephemeroptera, Odonata e Trichopteran. There was greater abundance of the order Diptera when compared to the other taxons. Significant differences between the forested and non-forested environments in both seasonal periods were observed with greater diversity and equitability found in forested environments. Family richness and diversity presented a relation to oxygen levels dissolved in water and chlorophyll concentrations in forested environments during the dry season, and all environments sampled presented a slightly acidic pH, close to neutral. The study demonstrated there was a large incidence of generalist organisms whose characteristics are adaptive to negative changes, thus demonstrating that impacts caused to the localities

alter aquatic insect composition." (Authors) Taxa are treated at family level.] Address: Barbosa, Hilaritssa Moura, Universidade Federal do Acre, Campus Floresta, Laboratório de Ecologia Aquática CEP 69.980-000, Cruzeiro do Sul – AC, Brasil. Email: hilaritssa@gmail.com

**20904.** Belmont, J.; Miller, C.; Scott, M.; Wilkie, C. (2022): A new statistical approach for identifying rare species under imperfect detection. *Diversity and Distributions* 28(5): 882-893. (in English) ["Aim: Species rarity is often used as a measure to assess the risk of extinction of species, and thus, different methods have been developed to describe the composition of rare species in biological communities. These methods usually depend on species attributes that are not always available and very often ignore imperfect species detection. In this work, we developed a new method to characterize species rarity in a community when species are detected imperfectly. Our modelling framework is based on Bayesian occupancy models to estimate species distributions under imperfect detection using presence-absence data. Innovation: We propose a finite mixture occupancy model to identify rare species based on their occupancy and class-membership probabilities. Here, we explored a two-class finite mixture model to distinguish between rare and common species classes and presented the general modelling framework for a problem with more than two classes. By using simulations, we were able to compare our model results under different scenarios obtaining a high-classification performance across all of them. Additionally, we applied our model to a data set of Odonata occurrence records that were partially observed due to imperfect detection and quantified the proportion of rare species on a national scale across waterbodies in the United Kingdom. Main conclusions: Nowadays, biodiversity conservation involves monitoring programmes that target multiple species within a community where individual species responses may vary widely. This high variability makes the task of identifying the ecological processes that drive distributions of rare species difficult. Thus, our method represents a new approach to characterize the composition of a community in terms of species rarity while correcting for detectability bias. Our modelling framework also suggests lines of research and future developments for the understanding of how species rarity can be measured in a wide range of scenarios." (2022): Trends to adaptation of the Sahara frog (*Pelophylax saharicus*) larvae across an environmental gradient. *Biologia* 77: 2857-2866. (in English) ["Species adjust their behavior and life-history to adapt to local environmental conditions. Species with a broad ecological niche often show signatures of local adaptations to different environment, particularly in extreme ones. Here, we investigate local adaptation in different populations of the North African Sahara frog (*Pelophylax saharicus*) living in various environmental conditions that vary mostly in temperature, precipitation, and elevation by mean of common garden experiment aiming to estimate the growth rate under two predation treatments (absence or presence of non-lethal cues of dragonfly larvae). First, we found an elevational cline in the reproductive phenology where, from low to high elevation, the reproductive season shifts to later dates, whereas that in arid environment was later than all other populations. We suggest that geographic differences in temperature and rainfall

(in arid areas) explain this phenological pattern. Second, hatching success was overall high but showed a slight decline across elevation. Third, growth rate was generally faster in low and intermediate elevation populations, but slower in high elevation and arid environment populations. Populations in low and intermediate elevation responded to predation by reducing growth rate and the size at metamorphosis, but no predatory responses were recorded in high elevation and arid environment populations. Our study shows some life history signatures of local adaptation of *P. saharicus* in Northeast Algeria, which does not go in line with recent genetic analysis showing low population differentiation in the region." **20906.** Brinet, A.; Ziar, A. (2022): Les macroinvertébrés benthiques bioindicateurs de la qualité écologique des milieux lotiques: cas d'Oued Cherf et affluents Nord. Est d'Algérie. MSc. thesis, Faculté des Sciences de la Nature et de la Vie, Sciences de la Terre et de l'Univers, Université 8 Mai 1945 Guelma: VIII + 68 pp. (in French, with English and Arabian summaries) ["This work focuses on the inventory and characterization of the diversity of benthic macroinvertebrates along the Cherf wadi, from samples taken monthly between February and May 2022. Five (5) stations carefully chosen on the longitudinal profile of the course of characterized by temporary to permanent flow regimes often affected by a very high inter-annual variability. The investigation of macroinvertebrates was made during the wet season according to the sampling protocol of the standardized global biological index (IBGN). Thus, a "Surber" with a unit surface of 1/20 m<sup>2</sup> and a mesh size of 100 µm was used at the level of the five stations for the harvesting of macroinvertebrates. Before sampling, ten (10) physico-chemical parameters (temperature, pH, conductivity, water salinity, redox potential, dissolved oxygen concentration, total dissolved solids, resistivity, atmospheric pressure, transparency and depth) were measured at each station. The fauna identified during this study consists of 2794 individuals corresponding to 14 Families belonging to 4 main faunal groups (insects, Molluscs, Annelids and crustaceans). The number of benthic populations showed that Diptera, Ephemeroptera and Trichoptera are the most numerically inventoried. Molluscs, Achètes, Odonates and Crustaceans constitute only a small fraction of the total fauna. The results of the index (IBGN) revealed that the waters of Cherf are of average quality. The preponderance of these three families of pollution-sensitive macroinvertebrates attests to the average quality of this watercourse. The diversity indices indicate that the macroinvertebrate community of Cherf is unbalanced and not very diversified. The intense human activities in this part have resulted in average organic pollution, which results in a proliferation of polluo-sensitive macroinvertebrates to the detriment of polluo-resistant ones. The purpose of this report is to give a first overview of the springtime diversity of benthic macroinvertebrates present, as well as the information they can provide as bioindicators of local contexts." **20907.** Brockhaus, T. (2022): Die Verwandlung der Libellen. lange Zeit ein Mysterium in der Entomologie (Odonata). Teil 1. Entomologische Nachrichten und Berichte 66: 102-111. (in German, with English summary) ["The metamorphosis of dragonflies. a long-time mystery in entomology (Odonata). Part 1. Insect development cycles have been the focus of nature observation since ancient times. Initially, utility consideration were a driving force behind these observations. Aristotle developed the thesis of spontaneous

generation in many insects (genesis automates). The scientific knowledge of Aristotle and Pliny the Elder also shaped the world of thought in medieval scholasticism. Since dragonflies were of no direct benefit for humans, they were for a long time not in focus of observations. Although dragonflies were in early modern times known as flying insects (with more than one name), and their larvae as "water worms" but there was no evidence that these animals belonged together it was not until the 17th and the beginning of the 18th century that naturalists discovered the relationships between larval stages and adults through observation of nature and the use of the microscope. Worth mentioning here are Conrad Gessner, Johannes Goedaerd, Leonhard Baldner, Jan Swammerdam, Johann Leonhard Frisch, Maria Sibylle Merian, August Johann Rösel von Rosenhof and Rene-Antoine Ferchault de Reaumur. During this time dragonflies and damselflies and their larval stages were also included in collections of natural objects, and were listed in their catalogs. The work of Maria Sibylle Merian and August Johann Rösel von Rosenhof ensured the rapid dissemination of this knowledge. This was made possible by the rapid development of the art of printing and painting. Research on the development cycles of various species of dragonflies is still relevant to this day." **20908.** Buczynski, P.; Buczynska, E.; Hunger, H.; Wildermuth, H. (2022): Ein ungewöhnlicher Schlupfunfall bei der Falkenlibelle *Cordulia aenea* (Odonata: Corduliidae). Mercuriale 22: 83-88. (in German, with English summary) ["An unusual emergence accident in *Cordulia aenea*. – In Mai 2022, a "sandwich" consisting of two exuviae and an incompletely emerged imago of *C. aenea* stuck between them was found and photographically documented near Lublin (Poland). Obviously, the abdominal tip of the emerging dragonfly remained stuck in the exuvia because a second larva, ready to emerge, climbed onto the incompletely emerged imago at the same moment. The imago was trapped and could therefore not finish its emergence procedure while the wings unfolded without hindrance. This is the first record of a previously undescribed cause of death in dragonflies during emergence." **20909.** Büsse, S.; Wildermuth, H.; Gorb, S.N. (2022): Morphological adaptations of the mouthparts to the ectoparasitic lifestyle of the biting midge *Forcipomyia paludis* (Diptera: Ceratopogonidae), specialized in Odonata. Zoomorphology 141: 307-314. (in English) ["Damselflies and dragonflies are well-known hosts of the West Palearctic biting midge *Forcipomyia paludis*. Females of this ectoparasitic dipteran mainly cling to the host's wings, sucking hemolymph from the wing veins. The midges are firmly attached to the wing surface with specialized tarsi, thus not being flung away during the host's flight maneuvers. As for another ceratopogonid—*F. odonatophila* from New Guinea—had been suggested, we assumed that in *F. paludis*, the attachment would be reinforced by the mouthparts during the suction action. In the present study, we used behavioral field observations, scanning electron microscopy (SEM) and high-resolution micro-computed tomography (µCT), to study the mouthparts of *F. paludis*. We focused on the mouthpart configuration post sucking and thus on the contact with the host's wing as well as on the piercing process into the wing veins. We foster our understanding of *F.*

paludis being a parasite of Odonata by showing proof of the piercing and therefore the sucking of hemolymph from the wings. Additionally, the mouthparts clearly show contamination with odonate wing wax after the sucking procedure. Furthermore, we discuss probable additional functions of the piercing process for the firm attachment to the flying host of *F. paludis*." **20910.** Cancellario, T.; Miranda, R.; Baquero, E.; Fontaneto, D.; Martínez, A.; Mammola, S. (2022): Climate change will redefine taxonomic, functional, and phylogenetic diversity of Odonata in space and time. *npj Biodiversity* (2022) 1:1; <https://doi.org/10.1038/s44185-022-00001-3>: 14 pp. (in English) ["Climate change is rearranging the mosaic of biodiversity worldwide. These broad-scale species re-distributions affect the structure and composition of communities with a ripple effect on multiple biodiversity facets. Using European Odonata, we asked: i) how climate change will redefine taxonomic, phylogenetic, and functional diversity at European scales; ii) which traits will mediate species' response to global change; iii) whether this response will be phylogenetically conserved. Using stacked species distribution models, we forecast widespread latitudinal and altitudinal rearrangements in Odonata community composition determining broad turnovers in traits and evolutionary lineages. According to our phylogenetic regression models, only body size and flight period can be partly correlated with observed range shifts. In considering all primary facets of biodiversity, our results support the design of inclusive conservation strategies able to account for the diversity of species, the ecosystem services they provide, and the phylogenetic heritage they carry in a target ecosystem." **20911.** Carvalho, F.G.; Duarte, L.; Seger, G.D.S.; Nakamura, G.; Guillermo-Ferreira, R.; Cordero-Rivera, A.; Juen, L. (2022): Detecting Darwinian shortfalls in the Amazonian Odonata. *Neotropical Entomology* 51: 404-412. (in English) ["Among the oldest winged insects, odonates are a monophyletic order that have become important models for ecological studies because of their highly diverse reproductive behaviors and their role as top predators and bioindicators. However, knowledge on evolutionary relationships within the order is still scarce compared to other taxa, and this situation is even more complicated in areas with high biodiversity, such as in the Amazon. Here, we sought to identify knowledge gaps on Amazonian Odonata regarding three main aspects: (i) how the inclusion of Amazonian taxa affects our interpretation of the evolutionary relationships of Zygoptera and Anisoptera; (ii) the position of Amazonian taxa in the existing supertree of the Odonata; (iii) dating evolutionary divergence between nodes using fossil records; (iv) assessing whether more species-rich basins (e.g., Amazon basin) have a larger phylogenetic gap when compared to basins with lower richness in South and Central America; and (v) in the light of our knowledge, we discuss diversification patterns found in the most predominant clades of Amazonian taxa. We built a supertree from currently available phylogenetic information of Odonata. The results show that there is no genetic information for 85% (n: 503) of the Amazonian species and that family level relationships are unknown for 17 genera. After compiling the data, we observed

that clades belonging to Neotropical lineages are the most poorly resolved, with large polytomies. This problem was identified in many Anisoptera genera, such as *Macrothemis*, *Dasythemis*, *Elasmothemis*, and *Erythrodiplax*. Our results also suggest that not always the richest basins have the greatest phylogenetic gaps. As expected, we found important gaps in the existing Odonata phylogenies, especially in clades that include Amazonian representatives, that are also those less known from ecological and conservation perspectives." **20912.** Cetinic, K.A.; Grgic, I.; Previšić, A.; Rožman, M. (2022): The curious case of methylparaben: Anthropogenic contaminant or natural origin? *Chemosphere* 294, May 2022, 133781: 9 pp. (in English) ["Highlights: • Methylparaben both endocrine disrupting compound and naturally produced metabolite. \*In situ and microcosm experiments assessed natural presence and transfer of methylparaben. \*Methylparaben was detected in all biota across sites unimpacted by contamination. \*Methylparaben may have a natural origin and function in moss and invertebrates. \*Our findings suggest methylparaben may not be solely a harmful anthropogenic contaminant. Abstract: The widespread use of methylparaben as a preservative has caused increased exposure to natural aquatic systems in recent decades. However, current studies have suggested that exposure to this compound can result in endocrine disrupting effects, raising much concern regarding its environmental impact. In contrast, methylparaben has also been found to be part of the metabolome of some organisms, prompting the question as to whether this compound may be more natural than previously assumed. Through a combination of field studies investigating the natural presence of methylparaben across different taxa, and a 54-day microcosm experiment examining the bioaccumulation and movement of methylparaben across different life stages of aquatic insects (order Trichoptera), our results offer evidence suggesting the natural origin of methylparaben in aquatic and terrestrial biota. This study improves our understanding of the role and impact this compound has on biota and challenges the current paradigm that methylparaben is exclusively a harmful anthropogenic contaminant. Our findings highlight the need for further research on this topic to fully understand the origin and role of parabens in the environment which will allow for a comprehensive understanding of the extent of environmental contamination and result in a representative assessment of the environmental risk that may pose." **20913.** Cezário, R.R.; Gorb, S.N.; Guillermo-Ferreira, R. (2022): Camouflage by counter-brightness: the blue wings of Morpho dragonflies *Zenithoptera lanei* (Anisoptera: Libellulidae) match the water background. *Journal of Zoology* 317(2): 92-100. (in English) ["Bright iridescent colours are widespread in several aquatic and terrestrial animal taxa and are usually involved in intraspecific communication and/or predator avoidance. Camouflage by iridescence may be one strategy to avoid predators when the animal exhibits bright colours that match the brightness of its surroundings. Hence, animal structural colouration may have a "brightness matching" or "counter-brightness" function when observed against bright or glossy backgrounds. Here, we addressed the role of such counter-brightness effect of the iridescent wings of the Morpho dragonfly *Zenithoptera lanei*

for avoiding detection. We hypothesized that the bright reflectance of the dragonfly wings is cryptic against the bright water surface and the glossy vegetation where they naturally occur, protecting the dragonfly from visually oriented predators, deceiving prey and signalling to conspecifics when desired. We addressed whether (1) the iridescent colours of *Z. lanei* wings function as a visual strategy to reduce their wing detectability by brightness matching the background and (2) the detectability of wings against vegetation and water varies according to the observer. For this, we modelled how conspecifics, dipteran prey and predatory birds see the odonate wings against the vegetation of the Neotropical Savannah and against the water surface where the dragonflies perch. Our results suggest that *Z. lanei* dragonflies can avoid detection by predators, prey and conspecifics when perched on their natural habitats (i.e., ponds) against the bright background of the water surface. Here, we add evidence to the multifunctionality of structural colours in animals and the function of iridescence in camouflage. The bright iridescence and ultraviolet reflective nanostructures of *Z. lanei* wings when coupled with striking behavioural displays may provide a dynamic and safe intraspecific communication channel." **20914.** Chainthong, D.; Boonsoong, B. (2022): Taxonomy and distribution of the gomphid dragonfly *Orientogomphus minor* (Laidlaw, 1931) (Odonata: Gomphidae) in Thailand. *Diversity* 2022, 14(4), 291; <https://doi.org/10.3390/d14040291>: 12 pp. (in English) ["The taxonomy and distribution of *Orientogomphus minor* (Laidlaw, 1931) were investigated in Thailand. Gomphid nymphs were collected from 28 sampling sites in streams in eastern, western, and southern Thailand. The nymph of *O. minor* is described for the first time and the male is re-described and illustrated based on a reared specimen. The taxonomic characteristics of the nymphs of the genus *Orientogomphus* are discussed. The nymph of *O. minor* differs from that of *O. armatus* Chao & Xu, 1987, the only other *Orientogomphus* species with a described nymphal stage, by the presence of lateral spines on abdominal segments six to nine and by a slender, stick-shaped third antennal segment. Multivariate analyses revealed a strong correlation between the distribution of *O. minor* and other three gomphid species with restricted distribution in Thailand (*Nychogomphus duaricus* (Fraser, 1924), *Onychogomphus louissiriusi* Fleck, 2020 and *Stylogomphus thongphaphumensis* Chainthong, Sartori & Boonsoong, 2020). Those species were recorded solely in streams in the western part of the country. Nymphs of *O. minor* were predominantly associated with stony substrates." **20915.** Chakradhari, S.; Tiwari, R. (2022): Insect diversity of the Mukundpur Tiger reserve, Satna (M.P.). *Journal of Entomology and Zoology Studies* 10(2): 110-114. (in English) ["An inventory of species diversity of insects of the Mukundpur Tiger Reserve, Satna (M.P.). Small insects with soft body were collected by hand with the help of a fine camel hair brush and forceps, and then preserved in 70% alcohol by dipping the soft brush in to the medium. Sweeping nets were used to collect the insect from plants. A long stick was used for beating the plants harbouring insects. A big size cloth spread over the ground to collect the falling insects.

Total recorded aquatic insect sp. distribution was expressed in higher to lower order as Coleoptera (36), Hemiptera (22), Odonata (11), Diptera (6), Ephemeroptera (4), and Trichoptera (2). Aquatic insect Order as per the comparative evaluation Coleoptera was found in utmost count compared through Hemiptera, Odonata, Diptera, Ephemeroptera, and Trichoptera. The order Coleoptera consist (45%), Hemiptera (27.16%), Odonata (13.58%) [n=10 taxa], Diptera (7.40%), Ephemeroptera (4.90%), and Trichoptera (2.46%) from observed aquatic insect species. MKPTSR is a well-distinguished place intended for the affluence of coleopteran fauna." (Authors)] Address: Tiwari, R., Department of Zoology, Govt. P.G. College, Satna, Madhya Pradesh, India

**20916.** Chavez Cruz, R.A. (2022): Evaluación de la calidad del agua mediante la bioindicación de macroinvertebrados acuáticos, en un tramo del río Toribio, cienega Magdalena, Colombia. Water quality evaluation through bioindication of aquatic macroinvertebrates, in a section of the Toribio river, cienega Magdalena, Colombia. *Ciencia e Ingeniería* 9(2): 14 pp. (in Spanish, with English summary) ["The main purpose was to assess water quality by identification of aquatic macroinvertebrates in a stretch of the Toribio River. The macroinvertebrates collection was carried out with a Surber network at the points chosen from the Toribio River. A total of 1126 individuals were collected; 642 in the dry period and 484 in the rainy period; a total of 36 morphofamilies were observed (24 in the dry season and 26 in the rainy season). The insecta class was the most abundant 32 morphs; the Odonata order was the most representative with 7 morphs. Regarding the families, only four (4) registered more than one morph: Coenagrionidae (5) [Gomphidae, Libellulidae], Chironomidae (3), Leptophlebiidae (2) and Tricorythidae (2). According to the results of the BMWP and EPT indices, the quality of the water in the monitored section of the Toribio river varies between points and sampling times, establishing that the general condition of this section is "critical to doubtful". Based on the composition and structure of aquatic macroinvertebrates observed, we can say that the studied section of the Toribio River presents some degree of disturbance." (Authors) Taxa are treated at family level] Address: Chavez Cruz, R.A., Universidad Internacional Iberoamericana, Colombia, Ciencia e Ingeniería, Univd de La Guajira, Colombia. **20917.** Chovanec, A. (2022): Reaktion der Kleinen Pechlibelle, *Ischnura pumilio* (Charpentier, 1825) (Odonata: Coenagrionidae), auf sich verändernde Lebensraumbedingungen. *Zeitschrift der Arbeitsgemeinschaft Österreichischer Entomologen* 74: 21-54. (in German, with English summary) ["Response of the Scarce Blue-tailed Damselfly, *Ischnura pumilio* (Charpentier, 1825), to changing habitat conditions (Odonata: Coenagrionidae). – A groundwater-fed, sunny, and shallow wetland with a size of 1.200 m<sup>2</sup> in Maria Enzersdorf (Lower Austria) was subject of an odonatological study carried out from 2016 to 2021. The water body was situated in an overflow and seepage reservoir created in 2014. A high number of observation days (236) within the six years allowed analyses of phenological features, flight periods, etc. *Ischnura pumilio* was recorded at the study site from 2016 to 2019. In each year, teneral and juvenile specimens were found. In 2016, small open water areas and low amphibious vegetation characterised the wetland. In that year, *I. pumilio* was the most abundant species within the odonate community comprising 27 species. It was bivoltine with higher numbers of specimens in the second generation: The spring/early summer generation comprised about 100 individuals, the midsummer generation about

250. In the following years, the rapid expansion especially of *Typha latifolia* led to a complete and dense coverage of the water body. The response of *I. pumilio* to deteriorating habitat conditions was a significant decline in the number of individuals: 2016 – total number 350; 2017 – 30; 2018 – 18; 2019: 5. In contrast to the population structure in 2016, the second generation in 2017 was smaller than the first. In 2018 and 2019, *I. pumilio* was represented by only one generation. The second generation of 2017 and the single generations of 2018 and 2019 occurred during a shorter time compared to the species-specific flight period. Furthermore, a decline of reproduction behaviour was apparent: In 2016, at 23 of the 31 days with records of *I. pumilio* copulae and/or tandems were observed, which corresponds to 74 %. This percentage decreased to 55 % in 2017, and 10 % in 2018. In 2019, no reproduction behaviour was recorded at all." **20918.** Cozzer, G.D.; Rezende, R. de S.; Lara, T.S.; Machado, G.H.; Magro, J.D.; Albeny-Simões, D. (2022): Predation risk effects on larval development and adult life of *Aedes aegypti* mosquito. *Bulletin of Entomological Research* 113(1): 29-36. (in English) ["Biological control is one of the methods available for control of *Aedes aegypti* populations. We used experimental microcosms to evaluate the effects of actual predation and predation risk by dragonfly larvae (Odonata) on larval development, adult longevity, and adult size of *Ae. aegypti*. We used six treatments: control, removal, variable density cues (Cues VD), fixed density cues (Cues FD), variable density predator (Predator VD), and fixed density predator (Predator FD) (n = 5 each). Predator treatments received one dragonfly larva. Cue treatments were composed of crushed *Ae. aegypti* larvae released into the microcosm. For the FD treatments, we maintained a larval density of 200 individuals. The average mortality of *Ae. aegypti* larvae in the Predator VD treatment was used as the standard mortality for the other treatments. Mosquitoes from the Predator VD and Cues VD treatments developed faster, and adults were larger and had greater longevity compared to all other treatments, likely due to the higher food availability from larval density reduction. High larval density negatively affected larval developmental time, adult size, and longevity. Males were less sensitive to density-dependent effects. Results from this study suggest that the presence of predators may lead to the emergence of adult mosquitoes with greater fitness, causing an overall positive effect on *Ae. aegypti* population growth rates." **20919.** Czerniawska-Kusza, I. (2022): Assessing benthic macroinvertebrates in relations to environmental variables and revitalisation works. *Ecological Chemistry and Engineering S* 29(1): 99-110. (in English) ["Macroinvertebrates of two ex-manor ponds located in Chroscina, Opole Region (Poland) were studied from 2015 to 2018 to investigate their community composition and diversity and evaluate the heterogeneity of communities on spatial and temporal scale referring to environmental variables and revitalisation work. A total of 32 taxa were recorded (at the family level, except Oligochaeta), 13 of which were Ephemeroptera, Odonata and Trichoptera, recognised as sensitive groups in lentic ecosystems. Macroinvertebrate richness and diversity varied considerably, especially in spring and summer. It was found that habitat heterogeneity influenced benthic invertebrates

more than basic water parameters. However, the environmental variables together accounted for only 38 % of the observed variations. Thus, other factors, such as fish predation, may have played a leading role in community shaping. The distinct differences between pond communities, four years after the revitalisation works, resulted more from different habitat features than from the previous sediment removal." **20923.** Dimitrov, D.A.; Mollov, I.A. (2022): Effect of the urban heat island in Plovdiv city (Bulgaria) on the species composition and distribution of the dragonflies (Insecta: Odonata). *Ecologia Balkanica* 14(2): 113-121. (in English) ["the current paper researches the impact of the urban heat island effect on the species composition and distribution of dragonflies (Insecta: Odonata) along the Maritsa River in the city of Plovdiv, Bulgaria. The study was conducted on imaginal and larval forms of the species, and the studied area was divided into 3 sub-areas (urban, suburban and rural) according to the proximity to the city center. Along the urban gradient from the rural to the urban zone, an increase in air, water and soil temperature by  $\sim 1-2^{\circ}\text{C}$  was observed. Differences were found also in the dissolved oxygen in the water, which had the highest values in the rural area (10.70 mg/l) and decreased towards the urban area, where it was 9.03 mg/l. Four dragonfly species were confirmed for the study area, and 2 new species were recorded. The most species were found in the urban zone, probably due to the higher temperatures compared to the other two areas, while at the same time, no larvae were found there, due to the lower amount of dissolved oxygen in the water. The current paper gives a better understanding of the impact that the urban heat island effect has on dragonflies in cities and aims to contribute for timely measures and decisions for the management of wetlands around urban areas." **20925.** Dow, R.A.; Singa, H. (2022): Previously unpublished Odonata records from Sarawak, Borneo, part IX: More Odonata from Limbang Division, including the first records from Gunung Buda National Park. *International Dragonfly Fund. Report* 173: 1-32. (in English) ["Records of Odonata made in Limbang Division in Sarawak during three surveys in 2021-2022 made possible by funding from the International Dragonfly Fund are reported. All locations surveyed are within Limbang District and are grouped into two categories: locations surveyed on day trips from Limbang Town and

locations in the Sungai Mendalam area further inland. All locations are in the lowlands of the division. The lowlands of Limbang Division had not been well studied for Odonata and the results presented here include 50 first records for Limbang Division, bring the total number of species known from the division to 173. In fact slightly more species were recorded during the 2021-2022 surveys than had been recorded from the division prior to 2021. Three of the new additions for Limbang are also first records for Sarawak (*Libellago phaethon*, *Rhinocypha humeralis* and *Oligoaeschna platyura*). The discovery of a large population of *Macrogomphus phalantus* not far from Limbang town is another significant result of the 2021-2022 surveys and is discussed in some detail. Other notable records include *Dysphaea lugens*, *Coeliccia kenyah*, the black form of *Copera vittata*, *Argioconemis rubescens rubeola*, *Teinobasis cryptica*, *Macrogomphus* sp., *Chlorogomphus* sp., the true *Pornothemis serrata* and *P. starrei*. This report includes the first records of Odonata from Gunung Buda NP (a checklist is given in the appendix), where 76 species have been found so far." **20926.** Dow, R.A.; Wahyudi, D.; Lupiyaningdyah, P. (2022): Odonata from the Loa Buluh Field Station area in East Kalimantan, Indonesia. *Faunistic Studies in Southeast Asian and Pacific Island Odonata* 39: 1-17. (in English) ["The results of a survey of the Odonata in the Loa Buluh Field Station area in Kutai Kartanegara Regency, East Kalimantan, Indonesia, conducted in 2009, are reported. The history of odonatological activity in East Kalimantan is briefly summarised and the primary types of Odonata that originate from the province are listed. Details of the locations at which the 2009 survey took place are given. Sixty-six species were recorded during the survey but because it was not possible to export specimens, so that identifications were made with a hand lens in the field, there is uncertainty over the identity of some of the taxa concerned. Nevertheless, as far as we are aware there are no previously published records of six of the species recorded during the survey (*Elatoneura aurtiaca* (Selys, 1886), *Prodasineura dorsalis* (Selys, 1860), *Prodasineura verticalis* (Selys, 1860), *Archibasis incisura* Lief tinck, 1949, *Mortonagrion* sp. cf *aborensis* (Laidlaw, 1914) and *Macrogomphus decemlineatus* Selys, 1878) from East Kalimantan before. The need for further work on the Odonata of East Kalimantan to be conducted sooner rather than later, especially given the large changes that will occur in the province due to the planned construction of the new Indonesian capital there, is discussed briefly. Previously undocumented variation in *Prodasineura tenebricosa* Lief tinck, 1937 is discussed in the context of one of the species of uncertain identity found during the 2009 survey." **20928.** Eloranta, A.P.; Kjærstad, G.; Power, M.; Lakka, H.-K.; Arnekleiv, J.V.; Finstad, A.G. (2022): Impacts of piscicide-induced fish removal on resource use and trophic diversity of lake invertebrates. *Science of The Total Environment* 835: 12 pp. (in English) ["Highlights: • Lake benthic invertebrate taxa showed contrasting responses to rotenone treatment. \*Predatory invertebrates increased while grazers and collectors decreased in abundance. \*A partial niche expansion by benthic invertebrates in two out of three treated lakes. \*Holistic understanding of ecosystem impacts of chemical treatments are urgently needed. Abstract: Chemical eradication of non-native species has become a widely used method to mitigate the potential negative impacts of altered competitive or predatory dynamics on biodiversity and natural ecosystem processes. However, the responses of non-target species can vary from rapid full recovery to delayed or absent recolonization, and little is known about the potential shifts in resource use and trophic diversity of native species following chemical treatments. We used a before-after-control-impact approach to study the effects of rotenone piscicide treatment on abundance and trophic niche of benthic invertebrates in three untreated and three treated lakes in central Norway, the latter group hosting non-native roach (*Rutilus rutilus*) and pike (*Esox lucius*) prior to rotenone treatment. Based on community composition data, the relative abundance of invertebrate grazers and collectors decreased while that of predators increased following fish removal in the treated lakes. The stable isotope data indicated minor shifts in resource use of, and trophic diversity among, benthic invertebrate communities. While the predatory dragonfly larvae (Odonata) and grazer snails (Lymnaeidae) showed increased  $d^{13}C$  values indicating increased reliance on littoral benthic algae, the collector mayfly larvae (*Leptophlebia*) showed decreased  $d^{13}C$  values following fish removal in treated lakes. Grazer snails also showed a shift to a lower trophic position, while the predatory dragonflies and collector mayflies showed no changes in  $d^{15}N$  values following fish removal. The community-level isotopic niches of benthic invertebrates showed no consistent changes, although the sample-size corrected and Bayesian estimates of standard ellipse areas (SEAC and SEAB) slightly increased in two of the three treated lakes due to an increased range in  $d^{15}N$ . In conclusion, our study findings indicate some changes in species assemblages but minor shifts in the resource use and trophic diversity of benthic invertebrate communities following fish removal in rotenone treated lakes." **20929.** Eriksen, T.E.; Jacobsen, D.; Demars, B.O.L.; Brittain, J.E.; Søli, G.; Friberg, N. (2022): Effects of pollution-induced changes in oxygen conditions scaling up from individuals to ecosystems in a tropical river network. *Science of*

*the Total Environment* 814 (2022) 151958: 11 pp. (in English) ["Highlights: \*O<sub>2</sub> regulation capacity (ORC) of tropical aquatic ectotherms was studied in Myanmar. \*River reach diel O<sub>2</sub> deficits were investigated using oxygen loggers. \*Eutrophication/organic pollution induced O<sub>2</sub> deficits in rivers. \*Closed-chamber studies used to derive ORC for riverine macroinvertebrates (MI) \*Individual ORC scaled up to ecosystem MI composition mirroring O<sub>2</sub> deficits. Abstract: Anthropogenic inputs of nutrients and organic matter are common in tropical lowland rivers while little is known about the pollution-induced changes in oxygen availability and respiratory performance of ectotherms in these high temperature systems. We investigated the effects of agriculture and urban land-use on river water oxygen levels (diel measurements), decomposition rates (Wettex) and macroinvertebrate assemblages (field studies), as well as the oxy-regulatory capacity of eight riverine macroinvertebrate taxa (laboratory study) from a tropical lowland river network in Myanmar. The highest decomposition rates (0.1.5.5 mg Wettex degree day.<sup>-1</sup>) and oxygen stress (.91% saturation deficits) were found in reaches draining degraded catchments with elevated concentrations of nutrients. All individual macroinvertebrate taxa investigated were to some extent able to regulate their respiration when placed under oxygen stress in the laboratory (regulation value of 0.74.0.89). The oxy-regulation capacity of macroinvertebrate assemblages in the river network were, as predicted, inversely related to diel oxygen stress (maximum deficit;  $lm$ ,  $R^2 = 0.69$ ), where taxonomic richness and pollution sensitivity (ASPT metric) also declined sharply ( $lm$ ,  $R^2 = 0.79$ ). Our study shows that eutrophication and organic pollution induce oxygen deficits in tropical rivers but stimulate decomposition rates, which may further deplete oxygen levels. Furthermore, macroinvertebrate oxyregulatory capacity predicts assemblage composition along gradients in oxygen stress at the ecosystem-level. Our findings suggest that tropical lowland river systems could be highly sensitive to pollution by nutrients and organic matter leading to substantial impacts on ectotherm community composition and ecosystem functioning." **20930.** Everling, S.; Johansson, F. (2022): The effect of temperature and behaviour on the interaction between two dragonfly larvae species within the native and expanded range. *Ecological Entomology* 47(3): 460-474. (in English) ["\* Studies on interaction between species are needed to observe and predict the effects of climate change on species distributions. Here we studied intra- and interspecific competition and behaviour in larvae of a native and a northward expanding dragonfly species, *Sympetrum vulgatum* and *Sympetrum fonscolombii*, respectively. We estimated growth, mortality, and behaviour (prey capture success, activity, and boldness) at 20°C and 23°C. \*The northward expanding *S. fonscolombii* had a higher growth rate and a higher survival compared with the native *S. vulgatum* in interspecific competition. In intraspecific conditions, there was no significant difference between species in mortality and growth. Temperature had no significant effect on growth and survival of *S. fonscolombii*, but *S. vulgatum* showed both a higher growth rate and a higher mortality at 23°C under intraspecific conditions. There was a correlation between growth and mortality, suggesting that cannibalism and intraguild predation caused the growth differences between treatments in the competition experiments. \*Temperature had no significant effect on any of the behaviours. There were very few significant correlations between any of

the behaviours and the life-history traits survival and growth and there were also very few significant correlations between any of the behaviours. Repeatability of behaviours over ontogeny was low. \*The results of the present study suggest that the range expanding *S. fonscolombii* has the potential to outcompete the native species, but that this competition advantage does not seem to be driven by the temperature effects explored in this study." **20931.** Feindt, W.; Hadrys, H. (2022): The quality of sequence data affects biodiversity and conservation perspectives in the Neotropical damselfly *Megaloprepus caerulatus*. *Diversity* 14(12):1056: 19 pp. (in English) ["Ideally, the footprint of the evolutionary history of a species is drawn from integrative studies including quantitative and qualitative taxonomy, biogeography, ecology, and molecular genetics. In today's research, species delimitations and identification of conservation units is often accompanied by a set of — at minimum — two sequence markers appropriate for the systematic level under investigation. Two such studies re-evaluated the species status in the world's largest Odonata, the Neotropical damselfly *Megaloprepus caerulatus*. The species status of the genus *Megaloprepus* has long been debated. Despite applying a highly similar set of sequence markers, the two studies reached different conclusions concerning species status and population genetic relationships. In this study, we took the unique opportunity to compare the two datasets and analyzed the reasons for those incongruences. The two DNA sequence markers used (16S rDNA and CO1) were re-aligned using a strict conservative approach and the analyses used in both studies were repeated. Going step by step back to the first line of data handling, we show that a high number of unresolved characters in the sequence alignments as well as internal gaps are responsible for the different outcomes in terms of species delimitations and population genetic relationships. Overall, this study shows that high quality raw sequence data are an indispensable requirement, not only in odonate research." **20933.** Gärtner, F. (2022): Monitoring der Libellenfauna (Odonata) „Auf dem Mörth“ im FFH-Gebiet Schwalenberger Wald (Kreis Lippe, NRW). Masterarbeit, Geographisches Institut, Stadt- und Landschaftsökologie, Ruhr-Universität Bochum: 92 pp. (in German, with English summary) ["Monitoring of the Odonata fauna on the "Mörth" in the Special Area of Conservation (SAC) Schwalenberger Wald (Lippe, North Rhine-Westphalia) – In 2022, the dragonfly fauna was surveyed at eight peatland ponds in the "Mörth"-area in the Special Area of Conservation Schwalenberger Wald, district Lippe, North Rhine-Westphalia. The results were compared with a survey of the same ponds by Mathias Lohr from 2014.

A total of 24 dragonfly species were found, of which 18 are definitely or probably established. Except for *S. danae*, the peatland species *Coenagrion hastulatum*, *Lestes virens*, *Aeshna juncea*, *Leucorrhinia dubia*, *L. pectoralis* and *Symptetrum danae* were found to be definitely or probably established. *C. hastulatum* and *L. pectoralis* are "critically endangered" in North Rhine-Westphalia. Compared to 2014, five species could no longer be found. Seven species have been added. Despite this increase in dragonfly species overall, the peatland species *Aeshna subarctica* and *Leucorrhinia rubicunda* could no longer be observed in 2022. In both 2014 and 2022, two ponds had the highest dragonfly diversity in general and also most peatland species. For these ponds, a loss of four established peatland species could be determined. The changes in occurrences can be explained by global warming, the resulting change in vegetation, and biotic homogenization. In another pond, three peatland species could no longer be detected as established, for which the introduced Goldfish (*Carassius gibelio forma auratus*) could be responsible. While *C. hastulatum*, *L. dubia* and *S. danae* show a negative trend nationwide, these species could be observed in the study area in 2014 as well as in 2022. The occurrence of *L. pectoralis* in 2022 is to be rated as very positive, since one of the largest occurrences of the species in North Rhine-Westphalia was found in 2014 at a pond in the study area. It was shown that, despite a slight deterioration in the occurrence of peatland species since 2014, the ponds in the Mörth-area represent an important habitat for many of the endangered peatland dragonfly species for the Weserbergland and North Rhine-Westphalia." **20934.** García-Ríos, R.; Moi, D.A.; Melo, A.S.; Mormul, R.P. (2022): Insect dispersal ability is crucial to overcome limitations in patch colonization of *Eichhornia crassipes* floating meadows. *Limnology* 23(2): 287-298. (in English) ["Dispersal is a pivotal process in ecology since it determines species presence across patches in landscapes. Therefore, understanding dispersal may be critical in light of current environmental changes. Here, we conducted an experiment to evaluate how richness, density, and beta-diversity of insects with strong and/or weak aquatic and aerial dispersal abilities are influenced by colonization limitation of aerial and aquatic patches of a floating macrophyte. We used nets to isolate the aquatic (by roots) and aerial (by leaves) routes by which insects may colonize floating macrophytes. We found that strong aquatic and aerial dispersers were not affected by colonization limitation, since the richness and density of these groups did not decrease with limited colonization. Conversely, limited colonization resulted in a strong decrease in the richness and density of weak aquatic and aerial dispersers. Also, the beta diversity of weak dispersers strongly increased with limited colonization, whereas strong dispersers produced more homogeneous communities (low beta diversity). Our findings illustrate that increasing habitat fragmentation and destruction should have stronger impacts on weak dispersers as they are not able to overcome the habitat scarcity. Consequently, only strong dispersers may persist, leading to high community similarity." **20935.** Gomes, D. (2022): Non-consumptive killing of a con-specific dragonfly. *Frontiers in Ecology and the Environment*

20(9): 530. (in English) [Verbatim: Intraspecific competition for resources, such as food, mates, or territory, is widespread across the animal kingdom. Larval dragonflies (*Epithea cynosura*), for example, commonly cannibalize each other (Ecology 1996; doi.org/10.2307/2265668); however, larval damselflies (*Megaloprepes coerulatus*) are sometimes killed but not consumed by conspecifics (Oecologia 1994; doi.org/10.1007/bf00317138), which can reduce competition for food. Adult dragonflies, as in the case of *Perithemis tenera*, are known to defend breeding territories near water, whereby they fight off intruding conspecifics (Ethology 2004; doi.org/10.1046/j.1439-0310.2003.00942.x). On occasion, a territorial male may even catch a competitor, in which case that competitor would likely end up as food. Here, I observed a female western pondhawk (*Erythemis collocata*) chase and kill, but not consume, another female conspecific that had recently emerged. The attacking *E. collocata* chewed through the pronotum (a cover of the thorax) of the attacked *E. collocata*, which stopped moving immediately. The aggressor then departed to the shore of the pond, with no signs of returning to its victim. Occasionally predators kill "surplus" prey that they do not immediately eat, but may later consume (J Zool 1972; doi.org/10.1111/j.1469-7998.1972.tb04087.x). Yet certain taxa have been found to non-consumptively kill members of their own species, as observed with the black-capped chickadee (*Poecile atricapillus*) (J Field Ornithol 2012; doi.org/10.1111/j.1557-9263.2012.00377.x) and the Australian dingo (*Canis familiaris*) (Ethol Ecol Evol 2018; doi.org/10.1080/03949370.2017.1316522). It is unclear just how widespread non-consumptive killing of conspecifics is across the tree of life.] Address: Gomes, D., Cooperative Inst. for Marine Resources Studies, Oregon State Univ., Newport, OR, USA

**20936.** Gómez-Anaya, J.A.; Novelo-Gutiérrez, R. (2022): Richness and structure of an Odonata larval assemblage of a cloud forest stream in western Mexico. *Odonatologica* 51(3/4): 225-246. (in English) ["Cloud forest in Mexico is an ecosystem largely fragmented and reduced in recent decades by human influence. In this type of vegetation, ravine streams generally contain a particular odonate species composition. We describe the structure, composition, and temporal changes of the Odonata larval assemblage from El Colorín ravine stream in the cloud forest of Chinicuil-Coalcomán region, Michoacán, based on a bi-seasonal sampling 1-year cycle. The assemblage parameters were related to some physicochemical water properties. In total, 17 species were recorded (9 Zygoptera, 8 Anisoptera). Zygoptera was more diverse at supraspecific level with four families vs two of Anisoptera. Six species of Libellulidae were recorded with four species belonging to Brechmorhoga. However, the dominant species throughout the year was the calopterygid *Hetaerina capitalis*. Although there were changes in water temperature, pH, conductivity, and oxygen throughout the year, the structural changes of the odonate larval assemblage were more related to seasonality. Also, the Odonata adult assemblage of El Colorín was compared to other adult assemblages from eastern and central Mexico. We propose sub-assemblages of Brechmorhoga, Hetaerina, and Archilestes species as potential indicators of well-conserved conditions of mountain streams." **20938.** Gorb, S.N.; Wildermuth, H.; Kohl, S.; Büsse, S. (2022): Tarsal attachment structures of the biting midge *Forcipomyia paludis* (Diptera: Ceratopogonidae), a specialized ectoparasite of Odonata imagines. *Zoomorphology* 141: 297-306. (in English) [Switzerland "The female of the biting midge *Forcipomyia paludis* is a dipteran ectoparasite of West Palaearctic damselflies and dragonflies, sucking haemolymph mainly from wing veins of their hosts. This tiny midge remains firmly attached to the wings even during fast flight and aerial flight maneuvers as shown in the present paper by field studies of the large dragonfly, *Cordulegaster boltonii*. Since individuals of *F. paludis* firmly attach themselves to the challenging wing surface of their host and can successfully withstand drag and vibrations during flight, we assume that this midge species has specific microstructural adaptations on its legs for attaching to the wing surface. In our morphological study, we used scanning electron microscopy (SEM) and confocal laser scanning microscopy (CLSM), to study the structure of *F. paludis* tarsi, as well as the micro morphology of the wing surfaces of their host. Additionally, for the first time, we were able to show attachment devices of the midges dried out in contact with the host's surface. The spatulae of the plantar setae and especially the empodial setae, are capable of replicating nanoscale wax crystals of the super hydrophobic wing coverage of the dragonfly wing membrane, in order to increase an effective contact area and therefore adhesion. This ability requires extremely soft materials of the spatula, which seems to be rather unique even in comparison to the leg attachment devices of other dipterans and other insect taxa in general." **20940.** Guignard, Q.; Allison, J.D.; Slippers, B. (2022): The evolution of insect visual opsin genes with specific consideration of the influence of ocelli and life history traits. *BMC Ecology and Evolution* (2022) 22:2: 9 pp. (in English) ["d: Visual opsins are expressed in the compound eyes and ocelli of insects and enable light detection. Three distinct phylogenetic groups of visual opsins are found in insects, named long (LW), short (SW) and ultraviolet (UV) wavelength sensitive opsins. Recently, the LW group was found to be duplicated into the LW2b and the LW2a opsins. The expression of LW2b opsins is ocelli specific in some insects (e.g., bees, cricket, scorpion flies), but the gene was not found in other orders possessing three or less ocelli (e.g., dragonflies, beetles, moths, bugs). In flies, two LW2b homologs have been characterised, with one expressed in the ocelli and the other in the compound eyes. To date, it remains unclear which evolutionary forces have driven gains and losses of LW opsins in insects. Here we take advantage of the recent rapid increase in available sequence data (i.e., from insect genomes, targeted PCR amplification, RNAseq) to characterize the phylogenetic relationships of 1000 opsin sequences in 18 orders of Insects. The resulting phylogeny discriminates between four main groups of opsins, and onto this phylogeny we mapped relevant morphological and life history traits. Results: Our results demonstrate a conserved LW2b opsin only present in insects with three ocelli. Only two groups (Brachycera and Odonata) possess more than one LW2b opsin, likely linked to their life history. In flies, we hypothesize that the duplication of the LW2b opsin occurred after the transition from aquatic to terrestrial larvae. During this transition, higher flies (Brachycera) lost a copy of the LW2a opsin, still expressed and duplicated in the compound eyes of lower flies (Nematocera). In higher flies, the LW2b opsin has been duplicated and expressed in the compound eyes while the ocelli and the LW2b opsin were lost in lower flies. In dragonflies, specialisation of flight capabilities likely drove the diversification of the LW2b visual opsins. Conclusion: The presence of the LW2b opsin in insects possessing three ocelli suggests a role in specific flight capabilities (e.g., stationary flight). This study provides the most complete view of the evolution of visual opsin genes in insects yet, and provides new insight into the influence of ocelli and life history traits on opsin evolution in insects." **20941.** Hettige, N.D.; Hashim, R.; Kutty, A.A.; Ash'aari, Z.A.; Jamil, N.R. (2022): Using benthic macroinvertebrate distribution and water quality as organic pollution indicators for fish farming areas in Rawang Sub-basin, Selangor River, Malaysia: A correlation analysis. *Journal of fisheries and environment* 46(1): 180-197. (in English) ["Fish farming activities are essential to the economy of many countries. However, the discharge of fish farm effluents into nearby rivers can negatively impact benthic macroinvertebrates and water quality. In Malaysia, the correlation between water quality and benthic macroinvertebrates in areas impacted by fish farming has not been discussed comprehensively. Hence, this research investigated the connection between benthic communities and water quality in the Rawang sub-basin of the Selangor River using several statistical methods. Based on ease of accessibility and proximity to freshwater fish farms, and by using a random sampling method, seven sampling sites in six rivers were chosen including one reference site. Sampling of benthic macroinvertebrates and river water was carried out between April 2019 and March 2020. Principal Component Analysis (PCA) revealed that fish farming operations influence various water quality parameters such as dissolved oxygen (DO), biochemical oxygen demand (BOD5), chemical oxygen demand (COD), total suspended solids (TSS), pH, and ammonia-nitrogen. Canonical Correspondence Analysis (CCA) revealed that families Aeolosomatidae, Chironomidae, Lumbriculidae, Naididae, Planorbidae, and Tubificidae are tolerant to organic pollution. Their abundance was correlated with high BOD5, COD, turbidity, TSS, and ammonia-nitrogen. On the other hand, the families Caenidae, Gomphidae, Aytidae, Leptophlebiidae, Thiaridae, and Viviparidae are sensitive to organic pollution and were correlated with DO concentration. This research revealed that the correlation between benthic macroinvertebrate communities and water quality in the area is affected explicitly by fish farms." **20943.** Hochkirch, A.; Casino, A.; Penev, L.; Allen, L.; Tilley, L.; Georgiev, T.; Gospodinov, K.; Barov, B. (2022): European Red List of Insect Taxonomists. Luxembourg: Publication Office of the European Union: 41 pp. (in English) ["Insects play a significant role in the functioning of healthy ecosystems and human well-being. By providing vital services such as pollination, matter decomposition, and bio-control, they greatly influence the living world. Our ability and expertise to recognise insect species and biodiversity are fundamental for their conservation. However, there is increasing concern regarding our capacity to identify insects and describe and name new insect species. This capacity has

traditionally been provided by taxonomists, working in museums, institutes or universities. This European Red List of Insect Taxonomists provides the first assessment of the status of taxonomic expertise capacity in Europe. Based upon a quantitative analysis of taxonomic papers published in scientific journals during the last decade as well as an online questionnaire, a detailed overview is given of the taxonomic capacity for each insect order and for each EU country. This European Red List of Insect Taxonomists is a call to the community of experts to bring their expertise into the public focus, and a call to society at large to acknowledge the role of taxonomy and support its sustainability in the long term. Overall, taxonomic capacity is threatened or eroded for 41.4% and 34.5% of the insect orders at the European and EU levels, respectively. The degree of erosion of taxonomic capacity is calculated as a Red List Index following Butchart et al. (2007), ranging between 0 (taxonomic capacity fully eroded) and 1 (all taxa covered by adequate capacity). There is substantial variation in the number of insect orders covered by taxonomists among countries: the highest Red List Index RLI is found in Czechia, followed by Germany and Russia. The lowest RLI is found in Albania, Azerbaijan and Belarus, and among the EU countries, Luxembourg, Latvia, Ireland and Malta. The number of insect orders covered by taxonomic expertise in each country correlates well with the Red List Index. The four largest insect orders (Coleoptera, Diptera, Lepidoptera, Hymenoptera) were all covered by >80% of the countries (in the case of Coleoptera and Lepidoptera even (by >90%)), but Adequate Capacity is only attained in 26% (Coleoptera) to 58% (Hymenoptera) of all countries. Three sets of recommendations – on strategic actions, science and societal engagement, are provided, with the aim of ensuring the long-term sustainability of taxonomic expertise in Europe. Strategic recommendations providing the framework to foster taxonomy: a. Provide targeted and sustainable funding specifically directed at increasing taxonomic capacity across Europe; b. Integrate the valuable role of taxonomists into policy formulation and implementation at the EU and national level. Science recommendations reinforcing the far-reaching impact of taxonomy: c. Ensure the continuous overview of the available taxonomic capacity, for example, by periodic reassessment of the Red List of Taxonomists. Expand the approach to other biodiversity groups. d. Increase the taxonomic capacity through dedicated knowledge exchange, education, training and development opportunities for professional taxonomists. e. Promote networking among taxonomists by maximising the use of modern technologies in research, publishing and knowledge exchange. Societal recommendations engaging society in taxonomy: f. Increase the recognition and awareness of the importance of taxonomic expertise by using effective means of communication with the public. g. Engage with citizen science initiatives to maximise the synergies between their efforts and taxonomic expertise in efficient research and monitoring of biodiversity." (Authors) In the case of Odonata each for Europe and European Community the situation is assessed as "Adequate Capacity".] Address: Pensoft Publishers, Prof. Georgi Zlatarski Street 12, 1700 Sofia, Bulgaria. **20945.** Isworo, S.; Oetari, P.S. (2022): Flora and fauna in the areas around artisanal gold mining in Selogiri Sub-district, Wonogiri, Indonesia. *Biodiversitas* 23: 6600-6618. (in English) ["Artisanal or small-scale gold mining has devastating impacts on the environment due to negligence of the principles of good environmental management. In particular, the mining activities often involve vegetation clearing and topsoil removal, which affect the biotic elements of the mined landscape. Selogiri Sub-district, Wonogiri District, Central Java Province, has a gold mineral resource that drives many traditional mining activities that have an indirect impact on the ecosystem's species diversity and community structure. This research aimed to investigate the diversity of flora and fauna in Selogiri Sub-district by comparing the area where the artisanal gold mining occurred (the inside area) and the areas surrounding the mining (the outside area). Six groups of taxa were observed in this study, including the plant group using the plot method, avifauna (birds) using Indices Ponctuels d'Abondance method, Odonata (dragonflies) and Lepidoptera (butterflies) both using visual encountering survey (VES) method, micromammals (Rodentia) using traps, VES, and camera traps and herpetofauna (amphibians and reptiles) using VES method. The diversity values of each taxa group in the inside and outside area were calculated and Sorensen's Coefficient Similarity Index formula was analyzed to see the community similarity between the two areas. A total of 243 species were found, consisting of Lepidoptera (35%), flora taxa (29%), avifauna (16%), herpetofauna (9%), Odonata (7%), and mammals (3%). The avifauna and Odonata had higher diversity values in the outside area than in the inside area. Similarly, the outside area had a higher diversity value for mammalian taxa documented using the VES method. Meanwhile, using the trap method, the taxa of Lepidoptera, herpetofauna, and mammals had higher diversity value in the inside area than in the outside. Nonetheless, the two areas had moderate similarity in the composition of flora and fauna species, with a community similarity value of less than 60% for all taxa studied. Conservation activities and off-site tree planting are solutions for restoring ecosystem structure and function to support ecological stability and biodiversity." **20946.** Jamil, M.; Noman Latif, Jaweria Gul, Muhammad Kashif, Arsalan Khan, Mubarik Ali, Norina Jabeen, Muhammad Shehzad Khan, Imran Qazi, & Namat Ullah. (2022): A review: An insight into the potential of biological control of ticks in domestic and wild Animals. *Abasyn Journal of Life Sciences* 5 (Issue 2): 51-67. (in English) ["Ticks are hematophagous arthropods that transmit pathogens to humans, animals and poultry birds, mostly in tropical and subtropical regions globally, causing considerable economic and health losses by serving infectious vectors. In endemic locations of the world, tick-borne diseases have become a public health issue. Ticks biting causes anemia in animals and also impair their hide quality. Therefore, the current review article focused on the biological control of ticks. Ticks, like any other creature, are susceptible to various infectious agents (*Anaplasma phagocytophilum*, *Babesia bigemina*, *B. gibsoni*, *Hepatozoon canis*, *H. americanum*, *Theileria annulate*, *T. taurotragi* etc). Ticks can become infected with rickettsia,

spirochetes, viruses, bacteria, and fungi. Some protozoans and worms infiltrate ticks and reproduce inside them, killing them. Fungus (*Metarhizium anisopliae*, *Verticillium lecanii*, *Beauveria bassiana*), bacteria (*Bacillus*), nematodes (*Steinernema glaseri*, *S. carpocapsae*), and parasitoids (*Ixodiphagus* species.) have proved effective biological agents to control ticks. Insects are also a type of natural tick enemy. Ticks that are engorged with blood and while moulting are the most vulnerable to insect predation and eaten by spiders, ants, beetles, dragonflies, and wasps (*Ixodiphagus*). Ticks are also preyed upon by amphibians and reptiles. Birds such as yellow-billed oxpecker (*Buphagus africanus*), helmeted guineafowl and Galliformes are good predators of ticks. Biological agents affect only target pests (ticks), do not destroy beneficial natural enemies and are safer for the ecosystem and humans. By keeping in view, the significance of biological agents, we highly recommend them in integrated tick management program that could minimize the tick population." (Authors) In spite the fact the authors name dragonflies as predators of ticks, I could not find any literature source where this behaviour is document.] Address: Jamil, M., PARC Arid Zone Research Centre, Dera Ismail Khan-29050-Pakistan. **20947.** Jödicke, R.; Borkenstein, A. (2022): Matutinal and vespertine reproductive behaviour in *Cordulia aenea* (Odonata: Corduliidae). *Notulae odonatologicae* 9(10): 473-481. (in English) ["A survey of crepuscular activities in *Cordulia aenea* was carried out at a site in north-western Germany (52.9° N) with an abundant population; this was during the optimal flight season, in favourable weather conditions under a clear sky. Diel activity commenced before sunrise and ceased after sunset. The species therefore belongs to the small group of species exhibiting both matutinal and vespertine activity. Activity during the diurnal period between dawn and dusk never ceased, resulting in a duration of daily flight activity of up to 17 h and 41 min in mid-June. In both twilight periods we predominantly saw patrolling males but also ovipositing females and formation of mating wheels. In the evening, males sometimes briefly interrupted their patrol flight for foraging and feeding. The primary utilization of dawn and dusk for reproductive activities, as occurred in *C. aenea*, is limited among European dragonflies to a small number of aeshnids and corduliids. A 24-hour rhythm of flight activity under the midnight sun, north of the Arctic Circle, is discussed." (Authors)] Address: Jödicke, R., Am Liebfrauenbusch 3, D-26655 Westerstede, Germany. (2022): The mouthparts of the adult dragonfly *Anax imperator* (Insecta: Odonata), functional morphology and feeding kinematics. *Journal of Morphology* 283(9): 1163-1181. (in English) ["Insects evolved differently specialized mouthparts. We study the mouthparts of adult *Anax imperator*, one of the largest odonates found in Central Europe. Like all adult dragonflies, *A. imperator* possesses carnivorous-type of biting-chewing mouthparts. To gain insights into the feeding process, behavior and kinematics, living specimens were filmed during feeding using synchronized high-speed videography. Additionally, the maximum angles of movement were measured using a measuring microscope and combined with data from micro-computed tomography ( $\mu$ CT). The resulting visualizations of the 3D-geometry of each mouthpart were used to study their anatomy and complement the existing descriptive knowledge of muscles in *A. imperator* to date. Furthermore, CLSM-projections allow for estimation of differences in the material composition of the mouthparts'

cuticle. By combining all methods, we analyze possible functions and underlying biomechanics of each mouthpart. We also analyzed the concerted movements of the mouthparts; unique behavior of the mouthparts during feeding is active participation by the labrum and distinct movement by the maxillary laciniae. We aim to elucidate the complex movements of the mouthparts and their functioning by combining detailed information on (1) in vivo movement behavior (supplemented with physiological angle approximations), (2) movement ability provided by morphology (morphological movement angles), (3) 3D-anatomy, and (4) cuticle composition estimates." **20949.** Jouault, C.; Nel, A.; Perrichot, V.; Legendre, F.; Condamine, F.L. (2022): Multiple drivers and lineage-specific insect extinctions during the Permo-Triassic. *Nature Communications* | (2022) 13:7512: 17 pp. (in English) ["The Permo-Triassic interval encompasses three extinction events including the most dramatic biological crisis of the Phanerozoic, the latest Permian mass extinction. However, their drivers and outcomes are poorly quantified and understood for terrestrial invertebrates, which we assess here for insects. We find a pattern with three extinctions: the Roadian/Wordian (~266.9 Ma; extinction of 64.5% insect genera), the Permian/Triassic (~252 Ma; extinction of 82.6% insect genera), and the Ladinian/Carnian boundaries (~237 Ma; extinction of 74.8% insect genera). We also unveil a heterogeneous effect of these extinction events across the major insect clades. Because extinction events have impacted Permo-Triassic ecosystems, we investigate the influence of abiotic and biotic factors on insect diversification dynamics and find that changes in floral assemblages are likely the strongest drivers of insects' responses throughout the Permo-Triassic. We also assess the effect of diversity dependence between three insect guilds; an effect ubiquitously found in current ecosystems. We find that herbivores held a central position in the Permo-Triassic interaction network. Our study reveals high levels of insect extinction that profoundly shaped the evolutionary history of the most diverse non-microbial lineage." **20950.** Kadadevaru, G.G.; Hosamani, M.B. (2022): Reproductive ecology of Narrow mouthed frog *Microhyla ornata*. *International Journal of Ecology and Environmental Sciences* 48(5): 597-602. (in English) ["Abstract: Reproductive ecology of Narrow mouthed frog *Microhyla ornata* was studied at selected breeding sites around Dharwad, Karnataka India during the wet periods between May 2017 and December 2018. The breeding activity varied depending upon the amount of rainfall. It was higher during monsoon when there was higher rainfall, whereas, when rainfall was scanty less activity was observed. Males begin the calling activity in the evening after the sunset at 1098min reaching its peak at around 1200min and extend till the early morning of the next day. Gravid females arrive at the breeding site one to one and half hour after the calling was initiated in the early pre-monsoon and monsoon period and amplexus took place soon after the arrival of females within one hour during peak calling days. Size assorted matting was observed in *M. ornata* and showed significant positive correlation. The female body size was positive correlation with clutch

size. However, there was no significant correlation between female body size and egg size. Breeding activity of *M. ornata* spanning for seven months suggest that, this species is a prolonged breeder. The eggs and larvae of *M. ornata* were under constant threat by the predatory larva of the aquatic insects like dragonfly and water beetle. Few clutches during non rainy period faced the risk of desiccation. The breeding sites of many anurans are affected by urbanization and habitat fragmentation. There is a need to adopt the strategy to conserve the habitats to protect the species." (Authors)] Address: Hosamani, M.B., Dept of Zoology, Karnatak University, Dharwad, Karnataka, India. **20951.** Kesti, P.; Hiltunen, M.; Strandberg, U.; Vesterinen, J.; Taipale, S.; Kankaala, P. (2022): Lake browning impacts community structure and essential fatty acid content of littoral invertebrates in boreal lakes. *Hydrobiologia* 849: 967-984. (in English) ["Many lakes in the northern hemisphere are browning due to increasing concentrations of terrestrial dissolved organic carbon (DOC). The consequences of lake browning to littoral invertebrates, however, are not fully understood. We analyzed community structure and fatty acid (FA) profiles of littoral invertebrates in humic (DOC-rich) and clear-water lakes in Eastern Finland. We found higher abundance of chironomids (Diptera: Chironomidae) in humic compared to clear water lakes, whereas stoneflies (Plecoptera) and mayflies (Ephemeroptera: Baetidae) were more abundant in clear-water lakes. Taxon explained 65% of the differences in the FA composition of littoral invertebrates. However, the proportion and content of polyunsaturated FAs of several taxa were significantly higher in clear-water lakes compared to humic lakes. Our results reveal differences in both community structure and nutritional quality of littoral invertebrates for fish between humic and clear-water lakes." **20952.** Khan, M.K.; Herberstein, M.E. (2022): Parasite-mediated sexual selection in a damselfly. *Ethology* 128(8): 572-579. (in English) ["Sexual selection can improve population fitness and purge deleterious mutation from the gene pool by promoting condition-dependent mate selection. One ecological factor that reduces individual condition is parasitism. Parasitism tends to increase hosts' mutation load and likely indicates inferior host genetic quality. Parasite-mediated selection, therefore, should favour the mating success of parasite-resistant individuals over parasitised individuals. We tested this hypothesis in male *Agriocnemis pygmaea* damselflies, which are parasitised by *Arrenurus* water mites. We calculated frequency (i.e. the proportion of parasitism) and intensity (i.e. the number of parasites per parasitised individual) of parasitism in free-flying males and males in copula in seven natural populations. We predicted that males observed mating will be less likely to be parasitised than expected based on the frequency of parasitism in the population. We further predicted that parasite intensity would be lower in males caught in copula than single males. We found that parasitised males were significantly less likely to be found in copula than non-parasitised males, independent of their occurrence frequency. However, there was no difference in the average parasite load between males captured in copula or free-flying males. Our study shows that in addition to natural selection, sexual selection is a strong agent against parasitism and implies that it could promote local adaptation to counteract parasite driven extinction risks." Sciences, Macquarie University, Macquarie Park, New South Wales, Australia. Email: bmbkawsar@gmail.com

**20953.** Khan, S.U.; Mehmood, S.A.; Ali, H.; Waqas, W.; Rahbar, B. (2022): The role of selected odonate nymphs in biological control of *Culex quinquefasciatus* larvae, and effect of glyphosate herbicide on their predatory performance. *Journal of Tropical Insect Science* 42(2): 1859-1864. (in English) ["Mosquitoes are potent vectors of many diseases such as malaria, dengue, yellow fever, and filariasis. Mosquitoes are controlled by various traditional methods including the widespread uses of synthetic chemicals. These applications have led to environmental degradation and loss of beneficial species. However, biological control, an ecofriendly control of mosquitoes through potential predators, is the key interest of today's researchers. During the current research, predatory performance of three selected odonatan nymphs (*Pantala flavescens*, *Trithemis aurora*, *Libellula fulva* [sic]) was investigated against mosquitoes' 3rd instar larvae. Furthermore, the effect of glyphosate herbicide on the predatory performance of these nymphs was also assessed. Results indicated higher larval consumption by *P. flavescens*, followed by *T. aurora* while less consumption by *L. fulva* during 24-h study. The difference among their predatory performance was not significant ( $p > 0.05$ ). The predatory performance of *P. flavescens* was significantly reduced compared to the control by 1.0, 2.5 and 5.0 ppm glyphosate, that of *T. aurora* by 2.5 and 5.0 ppm glyphosate while that of *L. fulva* by 5.0 ppm glyphosate. Thus, the performance of all the nymphs decreased with increasing glyphosate concentration. The study concluded that odonatan species play a vital role in control of mosquito larvae. However, anthropogenic activities such as excessive use of herbicides in agriculture pose a real threat to these natural predators." **20956.** Kozina, A. (2022): Distribution and potential endangerment of dragonflies and damselflies (Odonata) of the Bloke plateau. MSc. thesis, Univerza v Ljubljani, Biotehniška Fakulteta Studij Ekologije in Biodiverzitete: 72 pp. (in Slovene, with English summary) ["The Bloke Plateau is one of the better odontologically studied areas in Slovenia, however, most of the data were obtained at the end of the last century. The purpose of the master's thesis was to investigate the current distribution of dragonflies in the area and to check for their possible endangerment. We conducted 29 field days in 2021, which were planned to cover different parts of the adult dragonfly flight season. Larvae and exuvias were also sampled during the surveys. The presence of dragonflies was recorded at 48 study sites, of which 27 were surveyed first time during our survey. We recorded 35 species of dragonflies. We confirmed the reproduction of 26 dragonfly species at Bloke plateau. During the survey, Green emerald damselfly (*Chalcolestes viridis*) and Dainty bluet (*Coenagrion scitulum*) were recorded for the first time in the area. In total, we recorded six threatened and two protected species of dragonflies. Ornate bluet (*Coenagrion ornatum*) and Balkan goldenring (*Cordulegaster heros*) are listed in the Annexes of the Habitats Directive. The highest number of species (23) were recorded at the site Fishponds 500 m south of Godicevo. During the survey, we did not record the Common hawkler (*Aeshna juncea*), which was a common species at the Bloke plateau in the past, but today it seems to be endangered or even locally extinct. Dragonflies on the Bloke plateau are threatened by the loss of a suitable habitat due to the drying up and overgrowing of bog habitats, as well as the development of mass tourism and excessive introduction of fish into some water bodies." (Author)] Address: not stated

**20957.** Kroth, N.; Rezende, R.; Magro, J.D.; Albeny-Simões, D. (2022): Top-down effects on aquatic communities in subtropical lentic microhabitats. *Austral Ecology* 47(5): 1006-1015. (in English) ["Natural lentic microhabitats are important for aquatic invertebrate communities in subtropical aquatic systems, which are usually dominated by mosquitoes, predators and zooplankton. Subtropical lentic microhabitats might be strongly affected by top-down effects of predators. We evaluated the predator effects on aquatic macroinvertebrate and zooplankton communities by using black plastic buckets (10 L) to simulate lentic microhabitats, which were divided into four treatments: predator absence and presence, and initial (on experiment start) and final (on experiment end) community controls. Large top predators (Odonata) had a stronger effect on community structure by their sit-and-wait predatory behaviour. The richness of total

macroinvertebrates, *Culex* genus (most abundant organism), and zooplankton was highest in predators' absence. On the other hand, the sit-and-wait behaviour increased the density of organisms by selective predation on macroinvertebrates that feed in the bottom of the system. Also, the sit-and-wait behaviour increased the density of gathering and filtering collectors (top swimmers) by differences in space preference. We observed a positive species-specific relationship between *Culex* and predators. We concluded that predators' presence contributes to the balance of lentic microhabitat in subtropical lentic microhabitats by top-down control." **20958.** Lee, C.Y.; Kim, M.K.; Kim, D.-G. (2022): Ecological responses of *Nannophya koreana* (Odonata: Libellulidae) to temperature: Following converse Bergmann's Rule. *Biology* 2022, 11(6), 830; <https://doi.org/10.3390/biology-11060830>: 16 pp. (in English) ["Simple Summary: Bergmann's rule explains the phenomenon where populations and species of larger sizes are found at higher latitudes and colder environments, whereas populations and species of smaller size are found at lower latitudes and in warmer regions. In insects, adult sizes tend to be smaller in warmer environments than at cooler temperatures and higher latitudes; the response is called the temperature-size rule. *Nannophya koreana* is an endangered species in Korea and represents a flagship species for wetland conservation. We found that the body size of the larvae was smaller in a cold-water-temperature region than in a warm-water-temperature area, which is contrary to the rules mentioned above. The two regions were geographically close to each other, with no differences in air temperature and precipitation. We identified the reasons for the difference in water temperature between the two regions and established the relationship between temperature and body size in *N. koreana*. In addition, we analyzed how *N. koreana* compensated for low water temperature to maintain its life cycle, which is known as univoltine. Abstract: Ecological rules such as Bergmann's rule and the temperature-size rule state that body-size decline is a universal response to warm temperatures in both homeotherms and poikilotherms. In the present study, we investigated the biological responses of *Nannophya koreana*, an endangered dragonfly species in Korea, by comparing body size in two habitats with large differences in water temperature, Mungyong-si (MG, terraced paddy fields) and Muui-do (MU, a mountainous wetland). To conserve the dragonfly populations, the collected larvae were photographed and released, and their head widths and body lengths were measured. There was no difference in the annual mean air temperature and precipitation between the two sites; however, the annual mean water temperature was substantially lower in MU than in MG. There was little difference in larval head width between the two sites; however, body length in the MU population was smaller than that in the MG population. Larval growth rate per 100-degree-days was 0.75 mm for MG and 1.16 for MU. The relationship between temperature and body size of *N. koreana* larvae showed opposite trends to Bergmann's rule and the temperature-size rule. Since the larval growth period during a year in MU was shorter than that in MG, the MU population potentially exhibits a higher growth rate as a mechanism of compensating for the low water temperature. Our study established the relationship between temperature and body size of *N. koreana* in two wetlands that had

an obvious difference in water temperature despite being geographically close. The results highlight the importance of considering detailed factors such as habitat type when studying the temperature–size responses of organisms." **20960.** Leung, T.K.C.; So, K.Y.K.; Shum, B.T.W.; Hau, B.C.H. (2022): Optimal mowing regime in enhancing biodiversity in seasonal floodplains along engineered channels. *Sustainability* 2022, 14(7), 4002; <https://doi.org/10.3390/su14074002>: 16 pp. (in English) ["The vegetation grown on grasscretes along channelized rivers have been regularly mown in Hong Kong. However, no baseline information on the relationship between different mowing regimes and the biodiversity of such riverbed vegetation is available. We therefore carried out a manipulative experiment along a channelized river to test the effect of mowing frequency and intensity on the abundance and species richness of terrestrial biodiversity. We conducted point counts and transect counts to survey birds, butterflies and Odonates, night surveys for amphibians and reptiles, quadrat surveys for vegetation and sweep net and pan traps for other macroinvertebrates. The results from Generalized Linear Mixed Models (GLMMs) showed a taxon-specific effect of mowing regime. Bird species richness was significantly suppressed in plots mown with high frequency. Both butterfly abundance and species richness were greatly enhanced by low intensity and low frequency mowing. Odonate abundance, and the abundance and species richness of other macroinvertebrates remained high whenever a portion of vegetation was retained as refuge. Amphibians and reptiles did not prefer to utilize the vegetation grown on grasscretes, and thus showed no impact from different mowing regimes. The overall species richness of vegetation was not affected by mowing regimes, but the domination of tall invasive *Brachiaria mutica* was suppressed by any mowing activity. To cater for the need of most taxa, we propose a mosaic mowing regime, in which most parts along the channelized river could be mown infrequently to 600 mm tall while some of the patches remain unmown.... 3.4. The Effects of Mowing Regimes on Odonates A total of 501 individual Odonates were recorded from the point and transect count surveys. The monthly mean abundance for each treatment (including the control) ranged from 0 to 7.1, while that of the mean richness ranged from 0 to 2.2. The results of the GLMMs suggested that the abundance of Odonates was significantly higher for Treatment B, D and Control than Treatment A (GLMMs: A–B: t.ratio = –4.237,  $p < 0.001$ ; A–D: t.ratio = –4.296,  $p < 0.001$ ; A–Control: t.ratio = –4012,  $p < 0.001$ . Table 3). Species richness

of Treatment B and D were significantly higher than Treatment A (A–B: t.ratio = –3.693,  $p = 0.002$ ; A–D: t.ratio = –3.291,  $p = 0.010$ ), but were not significantly different from those of Control and Treatment C (Figure 2 and Table 3). No interaction was detected between the effects of treatment and season." **20961.** Luan, S.; Cao, H.; Deng, H.; Zheng, G.; Song, Y.; Gui, C. (2022): Artificial hyper compound eyes enable variable-focus imaging on both curved and flat surfaces. *ACS Appl. Mater. Interfaces* 2022, 14, 40, <https://doi.org/10.1021/acsmi.2c15489>: 46112-46121. (in English) ["The artificial compound eye (ACE) with zoom imaging requires complex power sources. Meanwhile, its curved substrate makes it difficult for the ACE to realize the zoom imaging on flat surfaces. To realize a wide field of view and a zoom function on both curved and flat surfaces simultaneously, a novel ACE is proposed, which is a bionic design inspired by an ancient creature, trilobite. Compared with a dragonfly, photosensitive units of a trilobite's compound eye are composed of ommatidia with different focal lengths. By learning from this concept, an artificial hyper compound eye (AHCE) was fabricated. Its basic components are five microlenses with different curvatures, and they are capable of being treated as five ommatidia with different focal lengths. Five ommatidia form a photosensitive unit to realize a zoom function. AHCE is capable of variable-focus imaging on curved surfaces. With the information share function, we found that the AHCE not only images on curved surfaces but also has a zoom-imaging function on flat surfaces. The results confirm that the AHCE demonstrates an advanced imaging capability, a variable-focus imaging function on both curved and flat surfaces, which may open new opportunities in developing advanced micro-optical devices." **20962.** Ludányi, M.; Peeters, E.T.H.M.; Kiss, B.; Gáspár, A.; Roessink, I.; Magura, T.; Müller, Z. (2022): The current status of *Pacifastacus leniusculus* (Dana, 1852) and their effect on aquatic macroinvertebrate communities in Hungarian watercourses. *Aquatic Invasions* 17: (in English) ["The freshwater crayfish *Pacifastacus leniusculus* is among the most widespread invasive crayfish species in Europe. *Pacifastacus leniusculus* invaded Hungary around 1998 and here we investigated the recent expansion of this species and its impact on other aquatic macroinvertebrates. The colonization of watercourses throughout Europe by the signal crayfish resulted in negative impacts on the present aquatic communities. Our investigation (i.e. in Rába, Pinka, Gyöngyösstream, Répce, Arany-stream and Strém systems) revealed that the distribution range of signal crayfish is still in expansion in the western part of Hungary and in all likelihood impacting the aquatic communities in these watercourses. Our results obviously demonstrated that signal crayfish densities were highest in habitats with gravel or coarse particulate organic matter, which seems to reflect a species-specific habitat preference. Our investigation proved that the presence of *P. leniusculus* had negative effects on a number of protected species such as *Calopteryx virgo* and *Onychogomphus forcipatus* next to a significant negative effect on the Odonata and Trichoptera species richness as well as on the abundances of Ephemeroptera, Odonata and Trichoptera. Our study in Hungary supports the notion of the significant negative impact of signal crayfish on native freshwater invertebrate

communities throughout Europe. In order to assess whether these impacts are restricted to fast flowing waters only, an adequate monitoring plan providing more knowledge on this species with respect to biotic and abiotic preferences and aquatic macroinvertebrate composition is required.... Impact on protected species: In order to assess the potential impact of *P. leniusculus* on protected species, the occurrences of these species were compared between the invaded Gyöngyös-stream and the non-invaded Kerca stream. Despite the invasion of *P. leniusculus*, the Gyöngyös-stream still harboured many protected species comprising *Agnatina elegantula*, *Aquarius najas*, *Calopteryx virgo*, *Cordulegaster bidentata*, *C. heros*, *Gomphus vulgatissimus*, *Macronychus quadrituberculatus*, *Oligoneuriella rhenana*, *Onychogomphus forcipatus*, *Ophiogomphus cecilia* and *Unio crassus*. In the Gyöngyös-stream concerned, the relative abundance of *Calopteryx virgo* ( $2.94 \pm 1.08$  ind./m<sup>2</sup>  $\pm$  S.E.), *G. vulgatissimus* ( $4.32 \pm 1.66$  ind./m<sup>2</sup>  $\pm$  S.E.) and *O. cecilia* ( $5.58 \pm 1.57$  ind./m<sup>2</sup>  $\pm$  S.E.) was the highest. *C. virgo*, *C. heros*, *G. vulgatissimus*, *O. forcipatus*, *O. cecilia* and *U. crassus* occurred in the crayfish affected Gyöngyös and crayfish free Kerca as well. However, due to the low abundances of most of these protected species, a proper comparison was only possible for *C. virgo*, *G. vulgatissimus* and *O. forcipatus*. According to the GLM analysis, the relative abundance of *C. virgo* and *O. forcipatus* was significantly lower in the presence of *P. leniusculus*, while the relative abundance of *G. vulgatissimus* did not show significant relationship with the crayfish occurrence (Figure 4, Table 3).] " (Authors)] Address: Ludányi, Mercédesz, BioAqua Pro Ltd. 4032 Debrecen, Soó Rezső utca 21, Hungary. **20963.** MacLeod, N.; Price, B.; Stevens, Z. (2022): What you sample is what you get: ecomorphological variation in *Trithemis* (Odonata, Libellulidae) dragonfly wings reconsidered. *BMC Ecology and Evolution* (2022) 22:43: 29 pp. (in English) ["Background: The phylogenetic ecology of the Afro-Asian dragonfly genus *Trithemis* has been investigated previously by Damm et al. (in *Mol Phylogenet Evol* 54:870–882, 2010) and wing ecomorphology by Outomuro et al. (in *J Evol Biol* 26:1866–1874, 2013). However, the latter investigation employed a somewhat coarse sampling of forewing and hindwing outlines and reported results that were at odds in some ways with expectations given the mapping of landscape and water-body preference over the *Trithemis* cladogram produced by Damm et al. (in *Mol Phylogenet Evol* 54:870–882, 2010). To further explore the link between species-specific wing shape variation and habitat we studied a new sample of 27 *Trithemis* species employing a more robust statistical test for phylogenetic covariation, more comprehensive representations of *Trithemis* wing morphology and a wider range of morphometric data-analysis procedures. Results: Contrary to the Outomuro et al. (in *J Evol Biol* 26:1866–1874, 2013) report, our results indicate that no statistically significant pattern of phylogenetic covariation exists in our *Trithemis* forewing and hindwing data and that both male and female wing datasets exhibit substantial shape differences between species that inhabit open and forested landscapes and species that hunt over temporary/standing or running water bodies. Among the morphometric analyses performed, landmark data and geometric morphometric data-analysis methods yielded the worst performance in identifying ecomorphometric shape distinctions between *Trithemis* habitat guilds. Direct analysis of wing images using an embedded convolution (deep learning) neural network delivered the best performance. Bootstrap and jackknife tests of group separations and discriminant-function stability confirm that our results are not artifacts of

overtrained discriminant systems or the “curse of dimensionality” despite the modest size of our sample. Conclusion: Our results suggest that *Trithemis* wing morphology reflects the environment’s “push” to a much greater extent than phylogeny’s “pull”. In addition, they indicate that close attention should be paid to the manner in which morphologies are sampled for morphometric analysis and, if no prior information is available to guide sampling strategy, the sample that most comprehensively represents the morphologies of interest should be obtained. In many cases this will be digital images (2D) or scans (3D) of the entire morphology or morphological feature rather than sparse sets of landmark/semilandmark point locations." **20965.** Maldonado, M.A.; Manara, E.; Martín, P.R. (2022): Macroinvertebrates in the diet of the Apple snail *Pomacea canaliculata* in its native range. *Malacologia* 65(1-2): 59-69. (in English) ["The study of diet and how a species obtains food is relevant to understand its role within natural environments. The apple snail *Pomacea canaliculata* (Lamarck, 1822) is a freshwater dweller that primarily consumes aquatic macrophytes and detritus but also incorporates resources of animal origin in its diet. Our aim was to investigate the ingestion of macroinvertebrates by *P. canaliculata* in four watercourses from its native range by analyzing its digestive contents. The frequency of occurrence of animal remains in the digestive contents of *P. canaliculata* snails was 68.50% across different seasons, with values of more than 50% in each of the watercourses studied. The spring-summer contents showed high frequencies of animal remains, whereas in autumn they were recorded only in 10% of the contents from one of the watercourses. The macroinvertebrates ingested belonged to six different insect orders, crustaceans, mites, bivalves, and gastropods. The frequencies of occurrence were higher for arthropods than for mollusks in two watercourses and similar in the other two. In two watercourses, the relative abundances of mollusks were higher than those of arthropods and the opposite was true in the other two. The number of individuals ingested by an average *P.*

canaliculata was highest for the snail *Heleobia parchappii*, followed by arthropods, *H. parchappii* eggs, and the snails *Physella acuta* and *Chilina parchappii*. Most ingested macroinvertebrates were small, slow or with little or no mobility, such as snails and case-bearing insects. Arthropods able to swim or to swiftly escape, such as Amphipoda and nymphs of Odonata and Ephemeroptera, were not detected at all in the digestive contents. Ingestion of macroinvertebrates appears to be opportunistic and even accidental and probably depends more on their microhabitats or behavior than on preferences of *P. canaliculata*. Notwithstanding, the high frequency of ingestion observed on some species of snails could have a significant negative effect on the abundance of their populations." **20966.** Maneechan, W.; Vitheepradit, A.; Prommi, T.O. (2022): Nutritional compositions of aquatic insects living in rice fields, with a particular focus on odonate larvae. *Insects* 2022, 13, 1131. <https://doi.org/10.3390/insects13121131>: 13 pp. (in English) ["Simple Summary: Food security concerns are growing due to the rapid increase in the world population. From this perspective, insects are a possible sustainable food source because of their nutritional value and the sustainability of their production system. Although the human consumption of edible insects has been a culturally long-standing practice, the nutritional literature on aquatic insects is not complete. Thus, the aims of the present study were to: (1) confirm the nutritional characteristics of odonate larvae (*Libellulidae*: *Pantala* sp.), including quantifying the bioaccumulation; and (2) investigate the microplastic accumulation in odonate larvae living in rice fields. The results show that odonates such as *Pantala* sp. are a good source of protein, minerals, essential amino acids, and long-chain polyunsaturated fatty acids. However, although the odonates seem to be a good source of nutrition, they may typically contain bioaccumulation, including microplastics, from their diets and habitats. Abstract: Although the human consumption of aquatic insects is prevalent in many regions, the nutritional composition of the insects has not been comprehensively determined. The proximate composition of *Pantala* sp. was shown to be a good source of protein ( $49.45 \pm 0.32$  g/100 g DW), as well as of minerals such as sodium, calcium, potassium, phosphorus, zinc, and iron. All nine essential amino acids are present in this species, with valine being the most abundant. The major fatty acids are palmitic acid ( $1.19 \pm 0.02$  g/100 g DW), oleic acid ( $0.63 \pm 0.02$  g/100 g DW), and linoleic acid ( $0.55 \pm 0.01$  g/100 g DW). Lead (Pb), arsenic (As), and cadmium (Cd) showed a value of  $0.18 \pm 0.01$  mg·kg<sup>-1</sup>,  $3.51 \pm 0.12$  mg·kg<sup>-1</sup>, and  $0.17 \pm 0.00$  mg·kg<sup>-1</sup>, respectively. Furthermore, microplastic (MP) contamination in odonate larvae (419 individuals belonging to three identified families) was found in varying shapes, e.g., fibers, fragments, and rods. FTIR analysis revealed the following MP polymers, polyethylene terephthalate, polyvinyl acetate, bis(2-ethylhexyl), polybutadiene, poly(methyl methacrylate-co-methacrylic acid); P(MMA-co-MA), poly(ethylene glycol) tetrahydrofurfuryl ether, poly(acrylonitrile-co-butadiene), and polypropylene glycol. The results of this work could be a nutritional reference for food security and the risk of eating insects." **20967.** Manger R.; De Knijf, G. (2022): Mass reproduction of the Vagrant Emperor (*Anax ephippiger*) in Belgium and the Netherlands in the summer of 2019. *Brachytron* 23: 7-21. In Dutch, with English summary. ["From 7 June 2019 onwards, an invasion of *A. ephippiger* was observed in much of Belgium and the Netherlands with not less than 482 individuals and 1744 individuals being observed respectively. Ovipositing behavior was found at 31 locations. In August and September 2019 exuviae and freshly emerged imagoes were found at 1 site in Belgium and 6 sites in the Netherlands. More than 1000 exuviae or teneral were found in an urban city pond of Antwerp (Belgium) and at Millingerwaard, in the river valley of the river Waal near Nijmegen (the Netherlands), being the two most important sites. First emergences of *A. ephippiger* were noticed on 23 August in the Netherlands and on 29 August in Belgium, resulting in a larval development time of respectively 78 and 81 days. Reproduction habitat consisted mainly of partially drying ponds characterized by high water temperatures in the summer of 2019. Those habitats were situated in diverse landscape configurations such as an urban area, dune ecosystems, fens in heathland, and ponds in a river valley ecosystem. Emergence took place during the night and maiden flight only occurred just before the onset of the sun and lasted not much more than 10 minutes. Most of the exuviae were found on aquatic plant stems and leaves above the water. At 80% of the locations where ovipositing of *A. ephippiger* was observed in June 2019, successful reproduction of *Sympetrum fonscolombii* was found later summer." **20969.** Masih, S.C.; Pathak, R.K. (2022): Odonate ecology and diversity. A review. *International Journal of Entomology Research* 7(12): 150-152. (in English) ["One of the most prevalent insects flying over forests, fields, meadows, lakes, and streams are dragonflies and damselflies, which are collectively known to as odonates. The number of living species worldwide is about 6,000. With more over 500 species currently known, India is very diversified. One of the oldest groups of insects is the Odonata. It first originated along with mayflies during the Carboniferous era, some 250 million years ago (Ephemeroptera). Monsters include up the Odonata group from the Carboniferous period; for instance, *Meganeprosis americana* from that time had wingspan of 71 cm, which is almost as long as a pigeon. Ancient insect species like dragonflies and mayflies were some of the first to acquire wings and take to the air. Dragonflies have perfected the art of flight and are still skilled acrobats. The order Odonata is divided into three categories depending on morphology: the Anisozygoptera, the Zygoptera, and the dragonflies (Anisoptera). *Epiophlebia laidlawi*, one of the two species mostly in suborder Anisozygoptera, is documented from Darjeeling. In the field, dragonflies and damselflies are easily distinguished. Although their morphologies are very different, they have similar overall life histories." **20970.** Maslo, B.; Mau, R.L.; Kerwin, K.; McDonough, R.; McHale, E.; Foster, J.T. (2022): Bats provide a critical ecosystem service by consuming a large diversity of agricultural pest insects. *Agriculture, Ecosystems & Environment* Volume 324, 1 February 2022, 107722: 11pp. (in English) ["Highlights: • Bats consumed at least 160 known agricultural pests or disease vectors. \*Big brown bats greatly expand their consumption of pest species in late June. \*Bats serve as comprehensive samplers of flying insects. \*DNA metabarcoding of guano is equivalent to broad-spectrum, non-specific insect monitoring methods (i.e. blacklight traps). Abstract: Biodiversity directly influences the delivery of multiple ecosystem services, most notably within agriculture. Projected future global demands for food, fiber and bioenergy will require enhancement of agricultural productivity, but favoring biodiversity-based ecosystem services generally remains underutilized in agricultural practice. In addition, agricultural intensification is a key driver of biodiversity loss. A significant obstacle preventing the adoption of ecologically sensitive practices is a lack of knowledge of the species delivering the services. Insectivorous bats have long been suggested to regulate insect pest populations and may be a critical component of biodiversity-based ecosystem services. Bats may also serve as agents of insect pest surveillance through environmental DNA (eDNA) monitoring approaches. However, the biological and economic importance of bats to agriculture remains under-quantified.

Here we catalogued the dietary niche of two North American bats, little brown bat (*Myotis lucifugus*) and big brown bat (*Eptesicus fuscus*), through DNA metabarcoding of guano collected from seven roosting sites over a 26-week period. We measured the frequency of occurrence of known pest species in guano samples, compared interspecific differences in diet, and examined seasonal patterns in prey selection. Overall, we detected 653 unique prey species, 160 of which were known agricultural pests or disease vectors. Species diversity of prey species consumed varied by bat species and across the season, with big brown bats accounting for the majority of arthropod diversity detected. However, little brown bats consumed relatively more aquatic insects than big brown bats, suggesting that increased bat species richness in a landscape can amplify their net pest regulation service. Further, we hypothesized that detection probabilities of target insect pests would be higher in guano samples than in conventional survey methods. Multi-survey occupancy modeling revealed significantly lower detectability in bat guano than in conventional monitoring traps, however, highlighting important tradeoffs in selection of survey methods. Overall, the results presented here contribute to a growing evidence base supporting the role bats play in the provisioning of biodiversity-based ecosystem services." (Authors) Classification of taxonomically identified amplicon sequence variants (ASVs) in the diets of big brown bats (*Eptesicus fuscus*) and little brown bats (*Myotis lucifugus*) in New Jersey, 2017: only one species of "Odonata" was sampled] Address: Maslo, Brooke, Department of Ecology, Evolution and Natural Resources, Rutgers, The State University of New Jersey, New Brunswick, NJ, USA. **20971.** McEachin, S.; Drury, J.; Anderson, C.; Grether, G. (2022): Mechanisms of reduced interspecific interference between territorial species. *Behavioural Ecology* 33(1): 126-136. (in English) ["Interspecific territoriality has complex ecological and evolutionary consequences. Species that interact aggressively often exhibit spatial or temporal shifts in activity that reduce the frequency of costly encounters. We analyzed data collected over a 13-year period on 50 populations of rubyspot damselflies (*Hetaerina* spp.) to examine how rates of interspecific fighting covary with fine-scale habitat partitioning and to test for agonistic character displacement in microhabitat preferences. In most sympatric species, interspecific fights occur less frequently than expected based on the species' relative densities. Incorporating measurements of spatial segregation and species discrimination into the calculation of expected frequencies accounted for most of the reduction in interspecific fighting (subtle differences in microhabitat preferences could account for the rest). In 23 of 25 sympatric population pairs, we found multivariate differences between species in territory microhabitat (perch height, stream width, current speed, and canopy cover). As predicted by the agonistic character displacement hypothesis, sympatric species that respond more aggressively to each other in direct encounters differ more in microhabitat use and have higher levels of spatial segregation. Previous work established that species with the lowest levels of interspecific fighting have diverged in territory signals and competitor recognition through agonistic character displacement. In the other species pairs, interspecific aggression appears to be maintained as an adaptive response to reproductive interference, but interspecific fighting is still costly. We now have robust evidence that evolved shifts in microhabitat preferences also reduce the frequency of interspecific fighting." **20974.** Mola, L.M.; Vrbová, I.; Tosto, D.S.; Zrzavá, M.; Marec, F. (2022): On the origin of neo-sex chromosomes in the Neotropical dragonflies *Rhionaeschna bonariensis* and *R. planaltica* (Aeshnidae, Odonata). *Insects* 2022, 13(12), 1159; <https://doi.org/10.3390/insects13121159>: 14 pp. (in English) ["Simple Summary: Odonata are very interesting insects from a cytogenetic point of view. Their chromosomes do not have a typical centromere and their meiosis process differs in some respects from the canonical meiosis process. Sex in Odonata is usually determined by two X chromosomes in females and only one X chromosome in males (a Y chromosome is not present). In this work, we studied sex chromosome evolution in two dragonfly species of the genus *Rhionaeschna* that have a derived sex chromosome system: neo-XX in females and neo-XY in males. This variation is the result of chromosome rearrangements. In *R. planaltica*, meiotic analysis and fluorescence in situ hybridization with a ribosomal DNA probe revealed that the original X chromosome was inserted into the smallest autosome, giving rise to the neo-X chromosome, while the homologous autosome became a neo-Y chromosome. In contrast, the neo-X chromosome in *R. bonariensis* evolved by a terminal fusion of the original X chromosome with the largest autosome, whose homolog became the neo-Y chromosome.

Our results suggest an independent origin of neo-sex chromosomes in these dragonfly species and contribute to our understanding of the distinct mechanisms of sex chromosome evolution. Abstract: Odonata have holokinetic chromosomes. About 95% of species have an XX/X0 sex chromosome system, with heterogametic males. There are species with neo-XX/neo-XY sex chromosomes resulting from an X chromosome/autosome fusion. The genus *Rhionaeschna* includes 42 species found in the Americas. We analyzed the distribution of the nucleolar organizer region (NOR) using FISH with rDNA probes in *Rhionaeschna bonariensis* ( $n = 12 + \text{neo-XY}$ ), *R. planaltica* ( $n = 7 + \text{neo-XY}$ ), and *Aeshna cyanea* ( $n = 13 + X0$ ). In *R. bonariensis* and *A. cyanea*, the NOR is located on a large pair of autosomes, which have a secondary constriction in the latter species. In *R. planaltica*, the NOR is located on the ancestral part of the neo-X chromosome. Meiotic analysis and FISH results in *R. planaltica* led to the conclusion that the neo-XY system arose by insertion of the ancestral X chromosome into an autosome. Genomic in situ hybridization, performed for the first time in Odonata, highlighted the entire neo-Y chromosome in meiosis of *R. bonariensis*, suggesting that it consists mainly of repetitive DNA. This feature and the terminal chiasma localization suggest an ancient origin of the neo-XY system. Our study provides new information on the origin and evolution of neo-sex chromosomes in Odonata, including new types of chromosomal rearrangements, NOR transposition, and heterochromatin accumulation." (2022): Biometric differences across three populations of *Boyeria irene* from the southern Iberian Peninsula (Odonata: Aeshnidae). *Odonatologica* 51(3/4): 247-262. (in English) ["*B. irene* is mainly a West Mediterranean species. The instar distribution during winter is that of a 'summer species' sensu Corbet (1964). Little is known about how the geographical location of the population may affect the biometric peculiarities of *B. irene* larvae. Eight biometric variables were studied in male and female larvae belonging to three southern Iberian populations, with the objective of ascertaining whether there are differences between populations. The southernmost population (Los Alcornocales) shows the largest sizes for most of the variables measured, while the northernmost population (Sierra Madrona) shows the smallest sizes for most of the variables. Winter water temperatures may be the cause of the size divergences, due to a longer arrest in time of larval growth in the northernmost population." (2022): Differential behavioral responses of benthic and nektonic tadpoles to predation at varying water depths. *Canadian Journal of Zoology* 100: 526-538. (in English) ["Predators influence microhabitat selection and activity level of tadpoles, but it is still unclear how such responses to predators differ among species and how water column's depth influences this predator-prey interaction. Here, we experimentally tested whether the presence of Odonata water-nymphs influenced spatial use and activity of benthic and nektonic tadpoles in different food availability contexts. Benthic tadpoles occupied and consumed more food at the bottom level, irrespective

of predator's presence. However, when predators were at bottom, benthic tadpoles remained close to the cages, suggesting a typical "stay-still" defensive behavior known for *Physalaemus nattereri* (Steindachner, 1863). Nektonic tadpoles occupied shallower depths on predator's presence, and they also consumed less food and avoided predator by selecting food sources far from it. When predator was at bottom level and food was available, the distance of tadpoles to the cage tended to be smaller. *Scinax fuscovarius* (Lutz, 1925) tadpoles were more active when food was absent regardless of predator's presence. When food was available, these tadpoles generally occupied and consumed more food at bottom level. Tadpoles' responses depended not only on predator's presence, but on a complex net of factors, which include tadpoles' habit, anti-predatory behavior, availability and location of food." (2022): Chlorantraniliprole application differentially affects adult emergence of *Sympetrum* dragonflies in rice paddy fields. *Paddy and Water Environment* 20: 177-183. (in English) ["Rice paddy fields are important habitat for many dragonfly species. In Japan, populations of dragonflies inhabiting rice paddies, in particular *Sympetrum* (Odonata: Libellulidae), have decreased greatly in the last few decades. A major cause of the decline has been suggested to be the use of systemic insecticides (e.g., phenylpyrazole and neonicotinoid) in nursery boxes of rice seedlings. In this study, we examined the effects of chlorantraniliprole (CAP), a novel anthranilic diamide insecticide, on adult emergence of *Sympetrum* dragonflies in ten rice paddy fields by counting their exuviae remaining on the rice plants as an abundance index. Our results suggest that CAP is a potential factor that reduced the emergence rate of *S. infuscatum* but not of *S. frequens*. This difference may be due to differential sensitivity to CAP, different lengths of the nymphal stage, or different effects of bottom-up controls via reduction of prey organisms that are highly sensitive to CAP." (2022): Different roles of concurring climate and regional land-use changes in past 40 years' insect trends. *Nature Communications* 13, 7611 (2022). <https://doi.org/10.1038/s41467-022-35223-3>: 12 pp. (in English) ["Climate and land-use changes are main drivers of insect declines, but their combined effects have not yet been quantified over large spatiotemporal scales. We analysed changes in the distribution (mean occupancy of

squares) of 390 insect species (butterflies, grasshoppers, dragonflies), using 1.45 million records from across bioclimatic gradients of Switzerland between 1980 and 2020. We found no overall decline, but strong increases and decreases in the distributions of different species. For species that showed strongest increases (25% quantile), the average proportion of occupied squares increased in 40 years by 0.128 (95% credible interval: 0.123–0.132), which equals an average increase in mean occupancy of 71.3% (95% CI: 67.4–75.1%) relative to their 40-year mean occupancy. For species that showed strongest declines (25% quantile), the average proportion decreased by 0.0660 (95% CI: 0.0613–0.0709), equalling an average decrease in mean occupancy of 58.3% (95% CI: 52.2–64.4%). Decreases were strongest for narrow-ranged, specialised, and cold-adapted species. Short-term distribution changes were associated to both climate changes and regional land-use changes. Moreover, interactive effects between climate and regional land-use changes confirm that the various drivers of global change can have even greater impacts on biodiversity in combination than alone. In contrast, 40-year distribution changes were not clearly related to regional land-use changes, potentially reflecting mixed changes in local land use after 1980. Climate warming however was strongly linked to 40-year changes, indicating its key role in driving insect trends of temperate regions in recent decades." **20980.** Nelsen, J.A.; Yee, D.A. (2022): Mosquito larvicides disrupt behavior and survival rates of aquatic insect predators. *Hydrobiologia* 849: 4823-4835. (in English) ["Understanding the environmental effects of chemicals used in pest control on aquatic systems is crucial to ensure the conservation of beneficial non-target organisms. Mosquito larvicides are commonly applied to aquatic habitats; however, their non-target effects are not well understood. Our goal was to determine lethal and behavioral effects of insect growth regulators (IGRs) and surface films (SFs) on predaceous diving beetle adults and larvae, and damselfly [*Ichnura* sp.] and dragonfly [*Pachydiplax longipennis*] nymphs in roadside ditch habitats. Behavioral effects were determined via bioassays quantifying predator movement, location, and larval mosquito predation. Using Principal Components Analyses, correlated behaviors were determined for each taxa, and compared within SF and IGR treatment levels. Surface films were lethal to beetle adults in the genus *Laccophilus* (Dytiscidae) at recommended and high concentrations. *Laccophilus* adult behavior changed in response to IGRs, those exposed to recommended and high concentrations were more active than controls. Larval *Laccophilus* mosquito consumption varied between SFs and IGRs. We conclude that SFs can harm aquatic organisms that require atmospheric oxygen, and both larvicides may have sublethal effects on hunting behaviors of aquatic insects. Future studies should focus on different larvicides, and a wider variety of aquatic taxa that interact with mosquito larvae." **20983.** Ogidiaka, E.; Ikomi, R.B.; Akamagwuna, F.C.; Edegbene, A.O. (2022): Exploratory accounts of the increasing pollution gradients and macroinvertebrates structural assemblage in an afrotropical estuary. *Biologia* 77: 2103-2114. (in English) ["Forcados Estuary is a key water body in Delta State, Nigeria, serving various purposes such as fishing and oil exploration sites. However, the ecological health integrity of the estuary is seriously degrading due to crude oil and gas production, as well as run-off from surrounding communities. In this study, we investigated the structural assemblage of macroinvertebrates of the estuary to provide an exploratory account of the water quality status of the estuary. Physico-chemical variables and macroinvertebrates were sampled in five stations for 24 months between April 2012 and March 2014. Physico-chemical variables collected in the estuary classified the sampling stations into potential ecological categories, reflecting an increasing pollution gradient, with Stations 1 and 2 classified as heavily polluted stations. There was a relatively high mean concentration of iron ( $39.7 \pm 20.71 \text{ mg L}^{-1}$ ), copper ( $12.22 \pm 5.33 \text{ mg L}^{-1}$ ) and lead ( $2.97 \pm 1.98 \text{ mg L}^{-1}$ ) in Station 1 compared to the remaining four stations. Whereas the highest mean zinc concentration was recorded in Station 2 ( $23.12 \pm 11.96 \text{ mg L}^{-1}$ ). Principal Component Analysis (PCA) conducted for both wet and dry seasons showed that season played a key role in the pollution gradient of the estuary. A total of 14,685 macroinvertebrate individuals were recorded in the entire study period. *Pachymelania fusca* (freshwater snail) was the most preponderant taxa with 2,095 individuals recorded during the study period, followed by *Tympanotonus fuscatus* (brackish water snail) with 2,011 individuals. *Coenagrion pulchellum* (damselfly) was the least represented taxa, with only one taxon recorded throughout the study period. The non-metric multi-dimensional scaling (NMDS) showed no distinct cluster for macroinvertebrates collected in both wet and dry seasons. Canonical correspondence analysis (CCA) revealed differential responses of macroinvertebrates to physico-chemical variables, with species such as *Callinectes latimanus* and *Macra nitida* increasing the non-disturbed Stations 4 and 5, whereas *Corixa punctata* and *Thias callifera* dominated the disturbed Stations 1 and 2. Overall, the study provided useful information on the ecological pollution status of the Forcados Estuary and this will serve as a baseline for future research on the assessment of the ecological integrity of the estuary." (Authors)] *C. pulchellum* is an

European species not occurring in Africa.] Address: Edegbene, Augustine Ovie, Institute for Water Research, Rhodes University 6140, Makhanda (Grahamstown), South Africa

**20984.** Okude, G.; Moriyama, M.; Kawahara-Miki, R.; Yajima, S.; Fukatsua, T.; Futahashi, R. (2022): Molecular mechanisms underlying metamorphosis in the most-ancestral winged insect. *PNAS* 119(9), e2114773119: 12 pp. (in English) ["Significance: As caterpillars metamorphose to butterflies, insects change their appearance dramatically through metamorphosis. Some insects have an immobile pupal stage for morphological remodeling (homometaboly). Other insects, such as cockroaches, have no pupal stage, and the juveniles and adults are morphologically similar (hemimetaboly). Notably, among the most-ancestral hemimetabolous insects, dragonflies drastically alter their appearance from aquatic nymphs to aerial adults. In dragonflies, we showed that transcription factors Kr-h1 and E93 are essential for regulating metamorphosis as in other insects, while broad, the master gene for pupation in holometabolous insects, regulates a number of both nymph-specific genes and adult-specific genes, providing insight into what evolutionary trajectory the key transcription factor broad has experienced before ending up with governing pupation and holometaboly. Abstract: Insects comprise over half of the described species, and the acquisition of metamorphosis must have contributed to their diversity and prosperity. The order Odonata (dragonflies and damselflies) is among the most-ancestral insects with drastic morphological changes upon metamorphosis, in which understanding of the molecular mechanisms will provide insight into the evolution of incomplete and complete metamorphosis in insects. In order to identify metamorphosis-related genes in Odonata, we performed comprehensive RNA-sequencing of the blue-tailed damselfly *Ischnura senegalensis* at different developmental stages. Comparative RNA-sequencing analyses between nymphs and adults identified eight nymph-specific and seven adult-specific transcripts. RNA interference (RNAi) of these candidate genes demonstrated that three transcription factors, Krüppel homolog 1 (Kr-h1), broad, and E93 play important roles in metamorphosis of both *I. senegalensis* and a phylogenetically distant dragonfly, *Pseudothemis zonata*. E93 is essential for adult morphogenesis, and RNAi of Kr-h1 induced precocious metamorphosis in epidermis via up-regulation of E93. Precocious metamorphosis was also induced by RNAi of the juvenile hormone receptor Methoprene-tolerant (Met), confirming that the regulation of metamorphosis by the MEKRE93 (Met-Kr-h1-E93) pathway is conserved across diverse insects including the basal insect lineage Odonata. Notably, RNAi of broad produced unique grayish pigmentation on the nymphal abdominal epidermis. Survey of downstream genes for Kr-h1, broad, and E93 uncovered that unlike other insects, broad regulates a substantial number of nymph-specific and adult-specific genes independently of Kr-h1 and E93. These findings highlight the importance of functional changes and rewiring of the transcription factors Kr-h1, broad, and E93 in the evolution of insect metamorphosis." **20986.** Olsen, K.; Svenning, J.-C.; Balslev, H. (2022): Climate change is driving shifts in dragonfly species richness across Europe via differential dynamics of taxonomic and biogeographic groups. *Diversity* 2022, 14, 1066: 22 pp. (in English) ["Understanding how changes in species richness pattern correlate with range changes in different taxonomic and biogeographic groups is important for conservation because it allows for generalizations about which species are at greatest risk. Here, we assessed whether changes in species richness patterns result from generalized range shifts across taxonomic and biogeographic groups or from changes in specific subsets of species. Using data from 1988 and from 2010, we studied changes in distributional range of European dragonfly species, using outline distribution maps for all dragonflies combined and separately for taxonomic suborders (Zygoptera and Anisoptera) and biogeographic groups (Boreo-alpine, Eurasian, Mediterranean, and Tropical). The results demonstrated differing range dynamics for Zygoptera and Anisoptera, with Anisoptera driving local turnover in species richness to a greater extent than Zygoptera. The distributional range of Tropical and Mediterranean species had expanded to a much greater extent than that of Eurasian and Boreo-alpine species. Large-scale changes in species richness arose from several divergent, group-specific processes. Overall, local diversity especially declined in parts of southern and south-eastern Europe, reflecting local losses in multiple species rather than major range contractions among Mediterranean or Eurasian species. In fact, among the biogeographic groups, overall range declines were most prominent among Boreo-alpine species,

highlighting the particular threat from climate change to this group." (Authors)] Address: Olsen, K., Research & Collections, Natural History Museum Aarhus, Wilhelm Meyers Allé 10, DK-8000 Aarhus, Denmark. Email: kent@nathist.dk

**20989.** Parr, A.J. (2022): Migrant and dispersive dragonflies in Britain during 2021. *J. Br. Dragonfly Society* 38(2): 100-112. (in English) ["The 2021 reporting year was a relatively

eventful one for migrant and dispersive species in Britain. *Anax ephippiger* continued its recent run of autumn influxes, with well-documented records from nearly 20 localities between 9 September and 22 November, and with several 'possibles' also being reported. *Sympetrum fonscolombii* showed well during spring and early summer, with all but one individual being fully mature when first discovered, rather implying that most individuals were immigrants rather than locally bred. Perhaps surprisingly there were, however, few autumn records of the species, implying that both the emergence of a locally bred second generation and also any late season immigration had been limited. Of our other traditional migrant species, *Anax parthenope* and *Aeshna affinis* were both widely reported during the year, but the growing strength of local breeding populations that have become established over the last decade or so made detailed analysis of migration difficult, particularly in the case of *A. parthenope*. In addition to conventional migrants, *Aeshna isocetes* continued its recent range expansion, with a sighting at Wykeham Lakes in North Yorkshire on 20 July being of particular note. At least some of this expansion may be being driven by immigration from the Continent, but increased internal dispersal must be a major factor. During 2021 there was also evidence for significant mid- to long-distance dispersal within Britain by several other species. *Calopteryx virgo*, for example, appeared on the Isles of Scilly during late August, some 45 kilometres away from the nearest known breeding sites on the Cornish mainland. A male *Orthetrum cancellatum* was also recorded from Scilly during the year, this being only the second record for the islands. Finally, it is worth noting that *Chalcolestes viridis*, one of Britain's recent colonist damselflies, had yet another successful season with considerable range expansion, particularly in a north westerly direction. An individual seen near Wolverhampton on 23 September represents the new "most westerly" sighting for Britain while, further south, three records in the general area of the New Forest are also of note." (Author) Additional species treated: *Lestes barbarus*, *L. dryas*, *Coenagrion scitulum*, *Erythromma viridulum*, *Ischnura pumilio*, *Aeshna mixta*, *Sympetrum striolatum*, *S. danae*.] Address: Parr, A.J., 10 Orchard Way, Barrow, Bury St Edmunds, Suffolk, IP29 5BX, UK

**20990.** Peck, R.; Nash, S. (2022): Characterization of a Small Population of the Orangeblack Hawaiian Damselfly (*Megalagrion xanthomelas*) in Anchialine Pools at Kaloko-Honokohau National Historical Park, Hawai'i Island. *Proceedings of the Hawaiian Entomological Society* 54: 93-109. (in English) ["The endangered *M. xanthomelas* is a lowland inhabitant of freshwater and brackish wetland environments. Formerly one of the most widely distributed native insects in Hawai'i, it now appears restricted to small populations on the islands of O'ahu, Moloka'i, Maui, and Hawai'i. On Hawai'i island, anchialine pools provide important habitat for *M. xanthomelas*, and Kaloko-Honokohau National Historical Park (Park) supports one of only a few documented populations on the western side of the island. This study aimed to estimate the population size of *M. xanthomelas* at this Park, characterize its habitat, and identify substrates on which females oviposit eggs. We conducted visual surveys for adult *M. xanthomelas* at anchialine pools during June 2016–August 2017. On average, the observed population was 10.7 individuals per month (range = 5–20; standard error = 1.3). Males were observed 6.1 times more frequently than females, likely reflecting the less cryptic nature of males compared to females. Females exhibited oviposition behavior on a variety of substrates, but small branches were used most frequently. Factors restricting this population are

poorly known, but invasive fish may limit its distribution across the Park. Removal of invasive fishes from anchialine pools and 'Aimakapa Fishpond may restore much habitat for this rare species in the Park." (2022): Response of Odonata communities to dry season in a deciduous forest in the northern Minas Gerais, Brazil. *Entomobrasilia* 15: e1020: 9 pp. (in English) ["Odonata sampling effort in the state of Minas Gerais has intensified throughout the 21st century. However, research on these insects in some regions and ecosystems such as the Deciduous Forest are incipient, and the effect of prolonged dry periods over these insects is still unknown. This study thus aimed to assess changes in adult Odonata species composition over one year in a Brazilian Deciduous Forest and the Odonata species richness in the Mata Seca State Park in the Manga and Itacarambi municipalities in the Northern region of the state of Minas Gerais State, Brazil. Twenty-four days of sampling were distributed in February, May, July and November, adopting an active search through entomological nets close to lentic environments (Lagoa Angical, Lagoa Comprida, Lagoa Encantada, Lagoa da Prata and two wetlands of Lajedo da Lua); lotic environments (São Francisco river) and in associated terrestrial ecosystems. In total, 55 species were collected. Rainy and dry periods altered Odonata communities' composition but did not affect species richness and abundance due to the presence of permanent lagoons associated with the São Francisco river. This study shows the importance of the Mata Seca State Park for preserving Odonatofauna in the state of Minas Gerais and for protecting those permanent lagoons." **20993.** Piña, A.E.; Lougheed, V.L. (2022): Macroinvertebrate community composition in wetlands of the desert southwest is driven by wastewater-associated nutrient loading despite differences in salinity. *Wetlands* 42(128): 15 pp. (in English) ["The relatively rare freshwater ecosystems in the arid southwestern United States serve as biodiversity hotspots, yet they remain among the most threatened systems in the world due to human impacts and climate change. Globally, arid region wetlands remain understudied with respect to their ecology, making assessments of quality or restoration efforts challenging. To address these needs, this project aims to better understand the factors that drive

water quality and macroinvertebrate community composition of wetlands of the US desert Southwest. Water quality and macroinvertebrate data were collected over three years from 14 different wetland and riparian sites spanning across West Texas, New Mexico and Arizona. Principal Component Analysis (PCA) indicated that salinity related variables such as chloride, sulfate and conductivity were the greatest drivers of environmental variance (32%) among sampled desert wetlands. Nutrients such as nitrate and phosphate described a second axis, with 22% of variation in environmental data explained, where we found a clear distinction between wastewater and non-wastewater wetlands. Nutrients were shown to have the greatest impact on macroinvertebrate communities with wetlands receiving wastewater showing more uneven distribution of functional feeding groups and lower Simpson Index scores. These sites were dominated by filter feeders and had lower relative abundances of predator and collector-gatherer taxa. There was also a significant decrease in metrics related to diversity and environmental sensitivity such as % Ephemeroptera-Odonata-Trichoptera (EOT) within high nutrient sites. Increased salinity levels were also shown to correlate with lower Simpson Index scores indicating that increased salinity resulted in a decline in macroinvertebrate diversity and evenness. Overall, the nutrients within effluent water have shown to significantly alter community composition especially in desert wetlands where macroinvertebrates may be more adapted to high salinity. Though macroinvertebrate communities in wastewater sites may not fully resemble those of natural wetlands over time, creation of these sites can still benefit landscape level diversity." **20994.** Ponomareva, N.M.; Popova, O.N.; Yurlova, N.I. (2022): Odonata (Insecta) larvae as the second intermediate hosts of the trematodes of genus *Plagiorchis* in the basin of Chany Lake, Western Siberia. *Contemporary Problems of Ecology* 15: 631-641. (in English) ["Trematodes of the genus *Plagiorchis* are widespread endoparasites with a life cycle involving several hosts. The second intermediate hosts of the trematodes of genus *Plagiorchis* are studied for the first time in the basin of Lake Chany in the forest-steppe zone of Western Siberia, which is crossed by the migration way of many species of aquatic and near-water birds—final hosts of these trematodes. This study was conducted in 2014–2015 in the reed beds of Lake Fadikha, which is a habitat of the first intermediate hosts of plagiorchids: snails. Invertebrates from classes Insecta, Malacostraca, and Gastropoda, as possible second intermediate hosts of the Plagiorchidae trematodes, are studied for the prevalence and intensity of trematode infection. Metacercariae (larvae inhabiting the second intermediate hosts) of genus *Plagiorchis* (*P. elegans* and *P. multiglandularis*) are found only in the insects from order Odonata. The largest portion among infected larvae is comprised of larvae of *Sympetrum vulgatum* (68%), followed by *S. flaveolum* (18%), *S. sanguineum* (9%), and *Aeshna serrata* (5%). The prevalence of the metacercariae of the detected trematode species for the four Odonata species during the study years varied from 3.3 to 45.5%; the intensity of infection varied from 2 to 4 trematodes per 1 odonate larva. Infection with metacercariae increases with the age of odonate larvae. A trend towards a positive correlation between the infection (prevalence) of the first (snails) and the second (odonate larvae) intermediate hosts is identified. A significant relationship is identified between the prevalence of metacercariae of the odonate larvae and their population density, which varies throughout

the season. Seasonal changes in the infection of odonates with metacercariae of the trematodes of genus *Plagiorchis* are associated with the phenology of these insects. Periods of increased infection are registered just prior to the mass emergence of odonates, when the abundance of odonate larvae in the water body is the highest, and vice versa, periods of decline in infection are registered after the mass metamorphosis of odonates." (2022): Effects of integrated rice-duck farming on weed pressure, herbivore-predator interactions and economic benefits. *Biocontrol Science and Technology* 32(6): 715-730. (in English) ["This study was conducted to evaluate whether conventional farming can be replaced by a lower chemical pollution farming system, integrated rice-duck farming in a suburban agricultural area in northern Zhejiang, Southeast China. We comprehensively assessed the impacts of integrated rice-duck farming on weeds and herbivorous insects along with their natural enemies during the rice-growing season. We found that the rice-duck system effectively controlled weeds within the paddy fields. Nevertheless, the abundance of herbivores, particularly planthoppers and leafhoppers was increased in the duck-roaming paddy fields compared to the control and conventional fields, indicating the inefficiency of the rice-duck system in the control of rice main herbivore pests. Rice-duck farming significantly reduced the abundance of predators, especially spiders and dragonflies, therefore an 'enemy-free space' was created for herbivores which might be responsible for the observed herbivore increase in the rice-duck fields. Despite the inefficiency of rice-duck farming in the control of rice main herbivore pests, the net income of the rice-duck treatment with an organic certification was 7.6 and 1.4 times higher compared to the conventional and control treatments, respectively. In the view of the favourable results obtained in this study, the integrated rice-duck farming system might be suggested as a high economic return organic farming method suitable for modern farmers." **20998.** Ranjana, S. (2022): A survey study on Odonata in Rabo Dam Area, Raigarh, Chhattisgarh, India. *IOSR Journal of Humanities and Social Science (IOSR-JHSS)* 27(6): 1-7. (in English) ["An extensive study provides current status, species richness and distribution pattern of Odonate diversity in Rabo dam area. Rabo Dam is constructed on the Kurkut River a tributary of the river mand in Bagbhara area, District Raigarh, (Chhattisgarh) India. The geographical location of the Rabo Dam area provides suitable environmental conditions for Odonatan's habitat and diversity. An observation on Odonata diversity was carried out during the period from March 2021 to February 2022. Three study sites were selected to assess the diversity of Odonatan species. A total 41 of Odonata species were identified [...]. Zygoptera contributed 18 species under 5 families and Anisoptera with 23 species under 3 families. Zygoptera and Libellulidae was most dominant family by contributing 18 species but Libellulidae was the most common species found in all three study sites. Chlorocyphidae was least common species which restricted to only one study site. In the present study 10 species of Coenagrionidae, 3 species of Gomphidae, 3 species of Protoneuridae, 2 species of Platycnemididae, 2 species of Lestidae, 2 species of Aeshnidae were recorded. The observation showed the interesting perching 'Obelisk pose, in species *Trithemis pallidinervis*. Observation also showed 'tandem position, in species *Copera marginipes*. In this area the odonate diversity is still unexplored hence the present study will provide the current status and base line data of Odonata diversity for further attention and research activities." **21000.** Ribeiro, C.; Rodrigues, M.E.; Sahlén, G.; Roque, F. (2022): Dragonflies within and outside a protected area: a comparison revealing the role of well-preserved atlantic forests in the preservation of critically endangered, phytotelmatous species. *Journal of Insect Conservation* 26: 271-282. (in English) ["Understanding the interactions between protected areas and the surrounding landscape has become a central issue to conservation of biodiversity. The important role of protected areas in the preservation of biodiversity in tropical hotspots is widely recognized, but the role of the landscape surrounding those hotspots is poorly understood, particularly with regard to insects. In this study, we evaluated the species richness, composition, and beta diversity of Odonata assemblages inside and in the surroundings of a protected area in the Atlantic Forest hotspot. Sampling was carried out in the Private Reserve of Natural Heritage Veracel Station and its surroundings in the southern region of Bahia. Forty sites were sampled, 22 within the reserve and 18 in the surrounding areas. We found both a greater total species richness, and a greater richness with regard to the suborder Anisoptera in the surrounding areas. In addition, the species composition differed less between the sampling sites inside the protected area. Some of the species found inside the protected area did, however, make a greater contribution of the individual species to beta diversity (SCDB). Our study suggests that the surroundings of a protected area can contribute to the maintenance of regional diversity of dragonflies, but the protected areas play a vital role in supporting critically endangered species and populations of forest specialists, e.g., phytotelmatous species. Implications for insect conservation: Our results show that the composition of the odonate species assemblages may provide a means to assess the importance of protected areas to Odonata communities. Our study also highlights the importance of PAs to the maintenance of the regional Odonata species pool, especially to forest specialist species and to threatened species." (2022): Abundance and diversity of adult Odonates in Dunumadalawa forest reserve, Kandy. *Proceedings of FARS2022*: 21. (in English) [Sri Lanka; Verbatim: Species richness and abundance of adult Odonates in Dunumadalawa forest reserve in Kandy, were observed. The samplings of Odonates were carried out by visual encounter surveys by walking within the area on hourly basis in a period of one year. A total of 91 Odonates species represented by 45 dragonfly and 46 damselfly with two endemic species, *Euphaea splendens* and *Paragomphus henryi* have identified. The suborder Anisoptera which comprises with 45 species belonging to two families contributed 49% of total odonates were recorded. Among the Zygoptera, the family Calopterygidae was widely distributed with high percentage 27% (n=14) while the family Platycnemididae and Lestidae both were equally distributed with a percentage composition of 11% (n=10). The observed distribution of the families of Coenagrionidae and Euphaeidae were 9% (n=8) and 4% (n=4) respectively. Highest relative abundance values showed 9% *Orthetrum triangulare* belongs to family Libellulidae in suborder Anisoptera followed by *Lestes elatus* belongs to family Lestidae with 7%. Highest Sorenson coefficient value (0.43) indicated locations near "Roseneath Tank" in the middle of the site and the fresh water streams nearby it have high overlapping of similarity of Odonates. The highest species diversity (Shannon index 0.85) is found in the locations near the "Dunumadalawa weva" area. The highest species richness observed in the same locations as with the highest Margalef's index (3.67). The lowest diversity was observed with a Shannon index (0.10) in the forest area with no water bodies.] Address: Senadeera, G.K.A.T., Dept Zool., The Open University of Sri Lanka, Sri Lanka. **21010.** Sharma, M.; Oli, B.R. (2022): Odonates (Insecta: Odonata) associated with rice ecosystems in Sunwal municipality, central Nepal. Journal of Natural History Museum 32(1): 35-48. (in English) ["This paper aims to list the odonates fauna associated with rice fields and to study their behaviour in Sunwal, Central Nepal. Research was conducted from June to November 2019 in a rice field by establishing three study plots of (50×50) m<sup>2</sup> each. A total of 33 Odonata species (11 damselflies and 22 dragonflies) from six families were recorded. Six of them were sporadic, while the rest were common. Territorial behaviour of Odonates was observed and the reproductive behavior of 11 species was thoroughly investigated. The copulatory period varied between species, ranging from two seconds to 49 minutes. Females attempted to mate up to three times. The second and third mating were both brief. Homing behaviour [dormitory] was observed in *Orthetrum sabina*. In this research, we noticed odonates to be predatory as well as prey species." **21011.** Shin, I.-C.; Kim, M.-H.; Eo, J. (2022): Analysis of community stability and characteristics of macroinvertebrates in paddy fields by cultivation method. Ecology and Resilient Infrastructure 9(1): 15-23. (in Korean, with English summary) ["This study was conducted to investigate in relation to characteristic of macroinvertebrates in conventional and organic paddy fields. The investigation was conducted five times a year for Suwon, Ansong, Boeun, Gunsan, Gimje, Hamyang, divide into conventional paddy fields and organic paddy fields from 2009 to 2011. The macroinvertebrates collected from the surveyed between conventional

and organic paddy fields belonged to 84 species, 47 families, 16 orders, and 6 classes in 3 phyla. In the habitat oriented groups, climbers, swimmers and sprawlers were considerably occupied in conventional and organic paddy fields. In relation to the functional feeding groups, predators such as Odonata, Coleoptera, and Hemiptera were only the highest in paddy field ecosystem, regardless of cultivation method. As a result of community stability analysis, organic paddy fields has been identified much as species high resistance and resilience to environmental change in paddy field ecosystem. Species belonging to the I groups is considered to be important in organic paddy field such as *Stemolophus rufipes*, *Hydrochara affinis*, *Helochares nipponicus*, which has high mobility. In conclusion, it was found that the introduction of coleoptera as a food source was higher than that of conventional paddy fields in organic paddy field where primary consumers were abundant such as Chironomidae spp. and Dixidae sp.."] (Authors)] Address: Eo, J., Climate change Assessment Division, National Institute of Agricultural Science, Wanju 55365, Korea. **21013.** Sidra, S.; Mahmood, A.; Moavia, M.; Saadaat, H.B. (2022): Anisopteran diversity in two riverine habitats of southern Punjab, Pakistan. Inland Water Biology 15: 361-367. (in English) ["Dragonflies are an important indicator species for freshwater ecosystems. While their diversity in Pakistan has been well studied in the northern areas of the country, odonate diversity in the southern, warmer areas is still not well documented. The current study determined the Anisopteran diversity and abundance along two riverine tracts of Southern Punjab for a duration of five months. The collected specimens (n = 725) belonged to three families; Aeshnidae, Gomphidae, and Libellulidae. Anisopteran fauna was dominated by Libellulidae family represented by thirteen species out of total sixteen species identified from the study area. *Crocothemis erythraea* was the most abundant species (Relative Abundance – R.A = 14%) followed by *Braconopyga geminata* (R.A = 10%). The Shannon wiener diversity index value (H = 2.74) indicated a moderate level of Anisopteran biodiversity in the area. Since the dragonflies prefer warmer humid climates, species diversity was highest during the summer season with no odonates found during the colder month of December." (Authors)] Address: Sidra, S., Wildlife and Ecology, University of Veterinary and Animal Sciences, Lahore, Pakistan

**21014.** So, K.S.; Won, C.G. (2022): The first 'Megapodagrionidae' (Odonata, Zygoptera) from the Lower Cretaceous of Democratic People's Republic of Korea. *Cretaceous Research* 130, February 2022, 105054: (in English) ["Highlights: • *Phyonganpodagrion ryonsangae* sp. nov. is firstly described from the Sinuiju Formation, Sinuiju Group. \*The remarkable taxon belongs to the family 'Megapodagrionidae' (Insect: Odonata). \**Phyonganpodagrion* expands the geographic distribution of the family 'Megapodagrionidae'. Abstract: A new fossil genus and species, *Phyonganpodagrion ryonsangae* sp. nov. ('Megapodagrionidae') is described from the third member, the Sinuiju Formation, Barremian–Aptian, Lower Cretaceous, Ryonsang-dong, Sinuiju City, North Phyongan Province, DPRK. The new species distinctly differs from *Cretapodagrion sibelleae* Huang et al., 2018 in postnodal area with only 17 postnodal crossveins; a single row of cells (partly with two rows of cells) between IR1 and RP1; distal side of discoidal cell not oblique; base of RP3/4 well basad of subnodus; base of IR2 aligned with subnodus." **21018.** Tsalkatis, A.; Martens, A. (2022): Reproductive behaviour, phenology, and reproductive lifespan of *Chalcolestes parvidens* at an intermittent stream on a Greek island (Odonata: Lestidae). *Odonatologica* 51(3/4): 263-287. (in English) ["At a summer-dry stream on the Aegean island of Lesbos, a population of *Chalcolestes parvidens* (Artobolevski, 1929) was studied during the reproductive period from late August to November 2018. Mediterranean intermittent streams display unique characteristics with a seasonal sequence of abiotic and biotic regulation and provide valuable habitats for *C. parvidens*. Abundance at the breeding water and perching positions on plants of males, females and pairs were recorded, and a mark-recapture study with 412 males was conducted. The damselflies perched mostly on dry plant parts of *Salix fragilis* and *Nerium oleander* that dominated the site. Males perched mainly on exposed twig tips near or over the water and some individuals were quite philopatric. A minimum adult male life span of 30 days after maturation was determined. Oviposition was observed exclusively in branches of *S. fragilis*. Differences in reproductive behaviour between *C. parvidens* and its sister species *C. viridis* appear to be very small or not distinguishable at all." Diplomarbeit, Institut für Angewandte Physik, Fakultät für Physik der Technischen Universität Wien: 93 pp. (in English, with German summary) ["The antibacterial properties of cicada wings originate from hexagonal pillar-like nanostructures with species-dependent heights of approximately 330 nanometers and a tip spacing of about 188 nanometers. These multi functional nanostructures are also superhydrophobic and selfcleaning. This diploma thesis presents investigations of two New Zealand cicada species *Am. phipsalta cingulata* and *Kikihia scutellaris*, the Austrian dragonfly *Sympetrum striolatum* as well as an US American cicada species *Magiccicada septendecim* with various methods such as Atomic Force Microscopy, Scanning Electron Microscopy, and bacterial tests with live-dead staining. The surfaces investigated comprise the cicada wings themselves, negative replicas of the wings made with the molding material Polyvinyl siloxane and positive replicas in various resins. The main focus lies in establishing low-cost bioreplication techniques for the transfer of the antibacterial properties to man-made surfaces such as hospital surfaces, medical instruments,

smartphone displays and door handles. A recent publication of Senevirathne and co-workers support my findings where I see challenges in using the nanopillars as bactericides." (Author)] Address: not stated

**21020.** Vasconcelos, B.D.; Brandao, R.A. (2022): Predation on *Tamandua tetradactyla* (Pilosa: Myrmecophagidae) by *Caiman latirostris* (Crocodylia: Alligatoridae) in a highly seasonal habitat in Central Brazil. *North-Western Journal of Zoology* 18(2): 218-221. (in English) ["*Caiman latirostris* is an opportunistic predator found in rivers, mangroves, and wetlands throughout eastern South America. We report here the predation of *Tamandua tetradactyla* by *Caiman latirostris* in an old cattle dam in the Serra da Bodoquena National Park, Brazil. The adult caiman was accompanied by its hatchlings that fed on the lacerated parts of the Lesser anteater and possibly the insects attracted by the carcass. Although *Caiman latirostris* acts as a fundamental organism for the balance of ecosystems, most of the species' diet records are anecdotal, making this record relevant for understanding the ecology of the species." (Authors) In Table 1, prey items are compiled for *C. latirostris* from studies carried out in nature in South America and including Corduliidae and Libellulidae larvae.] Address: Vasconcelos, Beatriz, Laboratory of Fauna and Conservation Units, Department of Forestry Engineering, University of Brasilia, Brasilia, Brazil. **21021.** Vaughn, S.N.; Jackson, C.R. (2022): Evaluating methods of preserving aquatic invertebrates for microbiome analysis. *Microorganisms* 2022, 10, 811. <https://doi.org/10.3390/15pp>: 15 pp. (in English) ["Research on the microbiomes of animals has increased substantially within the past decades. More recently, microbial analyses of aquatic invertebrates have become of increased interest. The storage method used while collecting aquatic invertebrates has not been standardized throughout the scientific community, and the effects of common storage methods on the microbial composition of the organism is unknown. Using crayfish and dragonfly nymphs collected from a natural pond and crayfish maintained in an aquarium, the effects of two common storage methods, preserving in 95% ethanol and freezing at -20 °C, on the invertebrate bacterial microbiome was evaluated. We found that the bacterial community was conserved for two sample types (gut and exoskeleton) of field-collected crayfish stored either in ethanol or frozen, as was the gut microbiome of aquarium crayfish. However, there were significant differences between the bacterial communities found on the exoskeleton of aquarium crayfish stored in ethanol compared to those that were frozen. Dragonfly nymphs showed significant differences in gut microbial composition between species, but the microbiome was conserved between storage methods. These results demonstrate that preserving field-collected specimens of aquatic invertebrates in 95% ethanol is likely to be a simple and effective sample preservation method for subsequent gut microbiome analysis but is less reliable for the external microbiome." (Authors)] Address: Vaughn, Stephanie. Dept of Biology, Univ. of Mississippi, University, MS 38677, USA

**21022.** Voinov, I.O. (2022): The first record of *Orthetrum sabina* (Drury, 1770) (Odonata: Libellulidae) in Russian Federation. *Amurian Zoological Journal* 14(4): 616-619. (in English, with Russian summary) ["The paper reports the results of the odonatological examination of ponds in the Natural Ornithological Park in the Imeretinskaya Lowland in Adler (43°24'1"N; 39°58'22"E) carried out on 22 July 2020. In total, we found 12 Odonata species, including *Orthetrum*

*sabina* (Drury, 1770) that was recorded on the Russian territory for the first time. The found specimens correspond exactly to the subspecies *Orthetrum sabina nigrescens* (Bartenev 1929; Bartenev 1930) described by Bartenev from Lake Inkit. The current status of the subspecies is discussed. Including this discovery, the dragonfly fauna of the Russian Federation comprises 157 species." **21025.** Wildermuth, H. (2022): Zur Bedeutung des Teufelsabbiss *Succisa pratensis* Moench (Caprifoliaceae) für Insekten und Spinnen (Insecta, Arachnida). *Entomo Helvetica* 15: 73-90. (in German, with English and French summaries) ["Insects and spiders associated with the Devil's bit *Succisa pratensis* Moench. In litter meadows of the eastern Swiss Plateau, *S. pratensis* is the only plant species that blooms profusely in late summer and early autumn. At this time of year, it constitutes the only abundant source of food for many insects in the vicinity of intensely used agricultural land and dense forests. Based on this fact, all macroinvertebrates associated with *S. pratensis* found from late August to late September 2021 in selected litter meadows in the southeastern region of the canton of Zurich

were photographically documented. Altogether, 48 insect and 6 spider spp. were recorded. Flower and fruit heads were exploited by 9 bee spp., 13 fly spp., 9 butterfly spp. and 4 bug spp., whereas 8 orthopteran spp. mainly used the leaf rosette of the plant as a hiding place, for thermoregulation and food. The foliage served as an oviposition site and a source of larval nourishment for the oligophagous Marsh Fritillary *Euphydryas aurinia*. Spiders used the flower heads as a site to ambush their prey and employed the whole plant to fasten cobwebs and for shelter. The complex interactions between *S. pratensis* and their arthropod visitors are discussed and illustrated by a few examples. ... *Succisa* was used in two cases by a female *Sympetrum fonscolombii* as a perch for hunting flights. On several occasions, *S. sanguineum* males were observed flying erratically between stalks and stems in vegetation with dense *Succisa* stands in search of females, but they never sat down." (Deepl/Autor)] Address: Wildermuth, H., Haltbergstr. 43, CH-8630 Rütli, Switzerland. E-mail: hansruedi@wildermuth.ch

**21026.** Yavorskaya, N.M. (2022): Quantitative zoobenthos characteristics of the Udyl Lake basin (Udyl Nature Reserve, Khabarovsk Region). *Amurian Zoological Journal* 14(4): 594-615. (in Russian, with English summary) ["The article reports the results of the study on zoobenthos in the wetlands of Lake Udyl and its 12 tributaries (the Lower Amur, Udyl Nature Reserve) during the 2021 summer flood. Except for the Bichi River, benthic communities of the rivers and streams in the Lake Udyl basin were studied for the first time. The study found that the composition, structure and quantitative characteristics of the bottom communities of Udyl Lake and the Bichi salmon river differed from the previous results obtained in the 1930s–1940s and the 1990s. The results revealed a rich taxonomic composition of invertebrates (19 groups), low values of density and biomass in the water bodies of the reserve. The zoobenthos was dominated by amphibiotic insects (57% of the total density and 43% of the total biomass). We established that oligochaetes and chironomids in the Udyl Lake basin differed in the highest quantitative indicators. The quality of water was determined using classical (GW, TBI, IB, ND/Nex, NCh/Nex) and modified (IPM, TBIM) bioindicative indices and metrics. The results show that, in general, the ecosystem of Lake Udyl and the watercourses flowing into it is in a relatively satisfactory condition." (Author) The author considers Odonata at order level.] Address: Yavorskaya, Nadezhda M., Institute of Water & Ecology Problems, Far Eastern Branch of the Russian Acad. of Sciences, 56 Dikopoltseva Str., 680000, Khabarovsk, Russia. **21029.** Zebsa, R.; Mahdjoub, H.; Khelifa, R. (2022): Similar response of a range expanding dragonfly to low and high-elevation predators. *Diversity* 2022, 14, 302. <https://doi.org/10.3390/d14040302>: 12 pp. (in English) ["Recent range expansion of many species northward and upward in elevation suggests that the expanding species are able to cope with new biotic interactions in the leading edge. To test this hypothesis, we used a common garden experiment expanding the elevation range of an obligatorily univoltine dragonfly (*Sympetrum striolatum*) to investigate whether the growth, behavioral (food intake), and morphological (8th and 9th abdominal lateral spine) responses differed when confronted with dragonfly predators that dominate low-elevation (*Aeshna cyanea*) and high-elevation (*A. juncea*) lentic freshwater systems under two temperature treatments (20 °C and 24 °C). Growth rate and growth efficiency increased at higher temperature. Overall, low and high-elevation predators induced a similar increase in growth rate and growth efficiency but a decrease in food intake at 24 °C. Lateral abdominal spines were longer only in low-elevation dragonflies at 18 °C. Our study suggests that range-expanding species may have been successful in colonizing new areas at higher elevations because they respond to dominant high-elevation predators in a similar way to the more familiar low-elevation predators." (Authors)] Address: Zebsa, R., Laboratoire Biologie, Eau et Environnement (LBEE), Université 8 Mai 1945, Guelma 24000, Algeria

**21030.** Zhong, H.; Qiu, J.G.; Pan, Y.Q.; Yang, J., Lin, D.; Ouyang, B.; Jiang, K. (2022): Investigation of Odonata insect resources in Jिंगgangshan Nature Reserve. *Biotic Resources* 44(5): 461-466. (in Chinese, with English summary) ["In order to clarify the species resources and community characteristics of Odonata insects in Jिंगgangshan Nature Reserve, and provide a theoretical basis for the protection and rational utilization of Odonata resources, dragonfly resources were investigated in Changguling (470 m above sea level), Dajing (930 m above sea level) and Huangyangjie (1200 m above sea level) of Jिंगgangshan from 2018 to 2021. Shannon-Wiener diversity index, Pielou evenness index, Berger-Parker dominance index and Simpson dominance concentration index were used to analyze the diversity of dragonflies in three sampling sites. A total of 483 specimens were collected and identified, belonging to 23 species, 16 genera, 8 families, 2 suborders. Among them, Libellulidae occupied an absolute advantage,

and the numbers of genera and species accounted for 37.50% and 56.52% of the total, respectively. There was no significant difference in community structure index between Dajing and Huangyangjie ( $P > 0.05$ ). The diversity index and evenness index of Dajing and Huangyangjie were significantly higher than those of Changguling ( $P < 0.05$ ), while the dominance index and dominance concentration index were significantly lower than those of Changguling ( $P < 0.05$ ). This indicates that the diversity of Odonata community is low in Changguling, which is at a lower altitude in Jinggangshan Nature Reserve, but the dominant species are more prominent." **21031.** Zieritz, A.; Lee, P.S.; Eng, W.W.H.; Lim, S.Y.; Sing, K.W.; Chan, W.N.; Loo, J.S.; Mahadzir, F.N.; Ng, T.H.; Yeo, D.C.; Gan, L.X.; Gan, J.Y.; Gibbins, C.; Zoqratt, M.Z.H.; Wilson, J.-J. (2022): DNA metabarcoding unravels unknown diversity and distribution patterns of tropical freshwater invertebrates. *Freshwater Biology* 67(8): 1411-1427. (in English) ["1. Tropical freshwater invertebrate species are becoming extinct without being described, and effective conservation is hampered by a lack of taxonomic and distribution data. DNA metabarcoding is a promising tool for rapid biodiversity assessments that has never been applied to tropical freshwater invertebrates across large spatial and taxonomic scales. 2. Here we use DNA metabarcoding to comprehensively assess the benthic freshwater invertebrate fauna of the Perak River basin, Malaysia. Specific objectives were to: (1) assess performance of two DNA metabarcoding protocols; (2) identify gaps in reference databases; (3) generate new data on species diversity and distribution; and (4) draw conclusions regarding the potential value of DNA metabarcoding in tropical freshwater conservation. 3. Organisms were collected by hand and net at 34 sites and divided into small (retained in 0.5-mm but passing through 1-mm mesh) and large (retained in 1-mm mesh) fractions, and a 313-bp cytochrome c oxidase subunit I fragment amplified and sequenced using general Metazoa primers. 4. Bioinformatic analysis resulted in 468 operational taxonomic units (~species) from 12 phyla. Only 29% of species could be assigned binominal names through matches to public sequence libraries, indicating varying levels of library completeness across Orders. Extraction of small-fraction DNA with a soil kit resulted in a significantly higher species count than with a general kit, but this was not even across taxa. 5. Metabarcoding (amplification) success rate, estimated via comparison to morphological identifications of the large-fraction specimens, was high in most taxa analysed but low, for example, in ampullariid and viviparid gastropods. Conversely, a large proportion of species-site records for Decapoda and Bivalvia came from metabarcoding only. Species richness averaged  $29 \pm 16$  species per site, dominated by Diptera, Annelida, and Odonata, and was particularly high in tributaries of the mountainous Titiwangsa Range. At least eight species are new records for Malaysia, including the non-natives *Ferrissia fragilis* (Gastropoda) and *Dugesia notogaea* (Platyhelminthes). 6. Our study showed that DNA metabarcoding is generally more effective in detecting tropical freshwater invertebrate species than traditional morphological approaches, and can efficiently improve knowledge of distribution patterns and ranges of native and non-native species. However, current gaps in reference databases, particularly for bioindicator taxa, such as the Plecoptera, Ephemeroptera, and Coleoptera, need to be addressed urgently. tributaries of the mountainous Titiwangsa Range. At least eight species are new records for Malaysia,

including the non-natives *Ferrissia fragilis* (Gastropoda) and *Dugesia notogaea* (Platyhelminthes)." (Authors)] Address: Zieritz, Alexandra, Univ. of Nottingham, Sir Clive Granger Building, University Park, NG7 2RD Nottingham, UK. Email: alexandra.zieritz@nottingham.ac.uk

**21033.** Culler, L.E.; Ohba, S.-y.; Crumrine, P. (2023): Predator-prey ecology of Dytiscids. In: Yee, D.A. (eds) *Ecology, Systematics, and the Natural History of Predaceous Diving Beetles (Coleoptera: Dytiscidae)*. Springer, Cham. [https://doi.org/10.1007/978-3-031-01245-78\\_373-399](https://doi.org/10.1007/978-3-031-01245-78_373-399). (in English) ["Dytiscids are top invertebrate predators in most freshwater habitats, particularly in lentic systems such as wetlands and ponds. Adult and larval dytiscids are often considered to be generalists, feeding on zooplankton, aquatic macroinvertebrates, larval amphibians, and fish; however, some species selectively feed on certain prey types relative to others and many engage in cannibalism and intraguild predation. These predator-prey interactions cause a variety of consumptive and non-consumptive effects on prey abundance and community composition in freshwater habitats. Dytiscids are also notable predators of mosquito larvae and thus explored as biological agents for mosquito suppression, particularly in areas where mosquitoes are vectors of diseases and in northern areas. Dragonfly nymphs, fish, amphibians, reptiles, birds, and mammals are known predators of dytiscids, although the extent to which these organisms rely on dytiscids for food remains unclear. Given the prominent role of dytiscids in freshwater food webs, future research should be aimed at improving basic knowledge of dytiscid feeding ecology, using dytiscids to test predator-prey and trophic theory, describing the potential for dytiscids in conservation biological control, and examining how environmental change affects the role of dytiscids as predators of vector and nuisance species." (Authors)] Address: Culler, Lauren E., Dartmouth College, Hanover, NH, USA

**21034.** Darshetkar, A.; Patwardhan, A.; Koparde, P. (2023): A comparison of four sampling techniques for assessing species richness of adult odonates at riverbanks. *Journal of Threatened Taxa* 15(1): 22471-22478. (in English, with Marathi summary) ["Members of the insect order Odonata are known as good ecological indicators. Many are sensitive to habitat modifications and are easily monitored for use in environmental assessment studies. Rapid assessments rely on efficient sampling techniques. However, there is limited information available on sampling techniques for adult odo-

nates, and protocols require evaluation. To do this, we standardized counting methods during sampling of odonates from August to November 2016 at the Mula River, Pune, India. We used four counting techniques; full-width belt transect (FWBT), full-circle point count (FCPC), half-width belt transect (HWBT), and half-circle point count (HCPC). For HWBT and HCPC areas facing the river were sampled, and for each technique we took multiple temporal replicates. We compared species detected per unit time, species detected per unit area, new species detected per unit time, and new species detected per unit area. Additionally, we compared species estimates. With HCPC we detected the maximum number of species and new species per unit area, whereas FWBT returned maximum coverage of recorded species. We recommend our proposed techniques be considered in the future across various habitats to decide the most suitable sampling strategy for the different habitats or situations." **21035.** Gerstle, V.; Manfrin, A.; Kolbenschlag, S.; Gerken, M.; Mufachcheri Islama, A.S.M.; Entling, M.H.; Bundschuh, M.; Brühl, C.A. (2023): Benthic macroinvertebrate community shifts based on Bti-induced chironomid reduction also decrease Odonata emergence? *Environmental Pollution* 316 (2023) 120488: 8 pp. (in English) ["Highlights: • Bti ( $2.88 \times 10^9$  ITU/ha) was applied three times per year over two years. • In treated floodplain pond mesocosms (FPM), chironomid larvae were reduced by 41%. • Community shift was explained by fewer chironomid, Libellulidae and Coenagrionidae. • Emergence of Libellulidae was reduced by 53% in Bti-treated FPMs. • Aquatic effects may propagate to terrestrial food webs via reduced insect emergence. Abstract: Chironomid larvae often dominate aquatic macroinvertebrate communities and are a key food source for many aquatic predators, such as odonate larvae. Changes in aquatic macroinvertebrate communities may propagate through terrestrial food webs via altered insect emergence. *Bacillus thuringiensis israelensis* (Bti)-based larvicides are widely used in mosquito control but can also reduce the abundance of non-biting chironomid larvae (Diptera: Chironomidae). We applied the maximum field rate of Bti used in mosquito control three times to six mesocosms in a replicated floodplain pond mesocosm (FPM) system in spring for two consecutive years, while the remaining six FPMs were untreated. Three weeks after the third Bti application in the first year, we recorded on average a 41% reduction of chironomid larvae in Bti-treated FPMs compared to untreated FPMs and a shift in benthic macroinvertebrate community composition driven by the reduced number of chironomid, Libellulidae and Coenagrionidae larvae (Odonata). Additionally, the number of emerging Libellulidae (estimated by sampling of exuviae in the second year) was reduced by 54% in Bti-treated FPMs. Since Odonata larvae are not directly susceptible to Bti, our results suggest indirect effects due to reduced prey availability (i.e., chironomid larvae) or increased intraguild predation. As Libellulidae include species of conservation concern, the necessity of Bti applications to their habitats, e.g. floodplains, should be carefully evaluated." and automated collection methods increasingly depend on image recognition to provide the amounts of observational data research and management needs. Recognition models, meanwhile, also require large amounts of data from these sources, creating a feedback loop between the methods and tools. Species that are harder to recognize, both for humans and machine learning algorithms, are likely to be under-reported, and thus be less prevalent in the training data. As a result, the feedback loop may hamper training mostly for species that already pose the greatest challenge. In this study, we trained recognition models for various taxa [including Odonata], and found evidence for a 'recognizability bias', where species that are more readily identified by humans and recognition models alike are more prevalent in the available image data. This pattern is present across multiple taxa, and does not appear to relate to differences in picture quality, biological traits or data collection metrics other than recognizability. This has implications for the expected performance of future models trained with more data, including such challenging species." **21038.** La Porta, G.; Landi, F.; Leandri, F.; Assandri, G. (2023): The new Checklist of the Italian Fauna: Odonata. *Biogeographia – The Journal of Integrative Biogeography* 2023, 38 (1): ucl009: (in English) ["17 years after the publication of the last checklist of the Odonata found in Italy, an updated list has been compiled. This list reports 95 species belonging to 10 families and 38 genera and includes 2 national endemic and 1 sub-endemic species. Compared to the previous checklist, three species were removed, two subspecies were granted species status, and 10 species were added as new taxa for Italy. The checklist summarizes the current state of the knowledge on the geographical distribution of the Italian species with a regional detail. After the online publication of this dataset on the LifeWatch Italy website in 2021, some minor updates will be included in future releases. The newly discovered species are the result of increased exploration of the national territory combined with some possible range shifts, especially of Libellulidae species of Afro-Asiatic origin. This increased coverage of the country is the result of the efforts of many contributors. It stems from the rapidly growing interest in this zoological group, also enhanced by the activation of a nationwide citizen science project promoted by the Italian Society for the Study and Conservation of Dragonflies (Odonata.it)." **21041.** Rothfels, C.J. (2006): The dragonflies and damselflies (Odonata) of Halton Region, Ontario. Halton Natural Areas Inventory 2006: Volume 2 Species Checklists. Hamilton Naturalists' Club, Halton-North Peel Naturalists' Club, and South Peel Naturalists' Club. Hamilton, Ontario: 135-158. (in English) ["Key results: Diversity: Halton's tally of 80 species is impressive for an area of its size. Much of this diversity of odonates is due to the variety of habitats found within Halton, and to the north-south spread of the Region. Some species are typical of more "northern" habitats (e.g. *Libellula quadrimaculata*) and are absent or rare in Halton below the Escarpment, while others (e.g. *Pachydiplax*) are largely confined to the southern areas of the Region. Species: The two most significant results of the recent odonate investigations are the large local populations of Unicorn Club-tail (*Arigomphus villosipes*) and Arrowhead Spiketail (*Cordulegaster obliqua*). Prior to 2002, there were approximately 13 records of *Arigomphus villosipes* from Ontario, and it was extirpated at some of those (Rothfels, in press). Since 2002, this species has been discovered to be locally widespread (with five stations in Hamilton and eight in Halton). These 13 sites double the known Ontario records! Our current data suggest that western Lake Ontario is the centre of this species' distribution in Ontario (Rothfels, in press). *C. obliqua* is even rarer; by the end of 2003 there were only 11 records for the province, none from Halton (Bree 2004a). Unlike *A. villosipes*, *C. obliqua* is not confined to southern Ontario. Instead, its records are scattered thinly across the province from a historic Hamilton record in the south, east to the Ottawa area, and northwest to Sudbury. The Halton records are particularly significant in light of Bree's observation that

the previous recent records were confined to the Canadian Shield, and he was concerned that the Arrowhead Spiketail's "continued occurrence off of the Shield [is] doubtful" (Bree 2004a)." **21043.** Lockwood, M. (2008): Los Odonatos de Cataluña. I jornadas sobre la conservación de los artrópodos en Extremadura. Centro de Educación Ambiental de Cuacos de Yuste 16, 17 y 18 de Junio de 2007. Edición: Fondos LIFE-Proyecto LIFE 2003/NAT/E/000057 "Conservación de Artrópodos Amenazados de Extremadura". Junta de Extremadura. Consejería de Industria, Energía y Medio Ambiente. Coordinación técnica: Javier Pérez Gordillo y Ángel Sánchez García. Depósito legal: BA-004-2008: 103-115. (in Spanish) ["Conclusions: Undoubtedly, the hobby in the Iberian Peninsula for dragonflies is booming without having even come close to reaching the levels of popularity that exist in other European countries, where the tradition of the amateur naturalist goes back literally centuries, and where there are dental societies that gather thousands of people. However, the advent of new digital technology in the imaging world, with near-professional performance cameras at pocket-friendly prices, has helped encourage a new crop of naturalists to head out into the countryside in search of spectacular images. And it has been the Odonata, insects with intense colors and intriguing behavior where they exist, that have captured the imagination of many of these amateur photographers. We hope that these new trends bear fruit, which we believe can complement the work of universities and, increasingly, the interest in this group of insects

that is palpable in certain regional administrations. The organization of the World Dentistry Congress in Vigo in 2005, the First Conference on Arthropods in Extremadura in June 2007 and the field work undertaken in Catalonia, Valencia and Extremadura could be the first firm steps towards a new respect for the Odonata and the arthropods in general in the Iberian Peninsula." (2008): Spiders residing in odonate exuviae — An update and request for information. *Argia* 20(3): 19- (in English) [ Verbatim: In early August, at the DSA annual meeting in Bend, Oregon, I gave a presentation on the use of dragonfly exuviae for roosting and nesting by a jumping Spider, *Sassacus vitis*. I have observed this behavior to be fairly common at a site along the American River near my home in Sacramento, California, but would like to get a better idea of just how widespread this practice might be (the Spider in question is common and wide-ranging in Western North America, from British Columbia to Panama). As luck would have it, the day after my presentation, Steve Krotzer told me he had found a small jumping spider in an exuvia of *Macromia magnifica* (Western River Cruiser) he had collected along the John Day River a few days prior. Steve graciously provided me with the spider, and lo and behold — it was a male *Sassacus vitis*! I know a lot of ARGIA readers collect exuviae, at least occasionally, and would love to hear from any of you about any Spiders, especially — but not limited to, jumping Spiders, you may find in them. You may even send me specimens (alive or dead) if you like.] Address: Manolis, T., 808 El Encino Way, Sacramento, CA, 95864, USA

**21045.** Mezquita, I. (2008): Primera cita de *Oxygastra curtisii* (Dale, 1834) (Odonata: Corduliidae) para la provincia de Bizkaia (País Vasco, España). *Boletín de la S.E.A.* 42(1): 438- (in Spanish) ["In the municipality of Ajangiz (a town close to Gernika) the Oca River (Oka in Basque) flows on its way to its mouth in the Urdaibai Biosphere Reserve. It is a medium-sized river with plenty of gallery trees and little current in this section. Bordering all this space there is a dense grove, mainly oak. It is within the perimeter belonging to the "Lurraska" School of Environmental Education. In a section of this river (30TWN258943) the wooded gallery that protects it has an open space of approximately a couple of hectares next to it, where groups of *Juncus* sp. precede a large mass of bramble (*Rubus fruticosus*). It is here that *O. curtisii* was located. On June 18, 2007, an anisopteran resembling *O. curtisii* was seen in a nearby pond, but its secure identification was not possible as it could not be captured. The next day the first contact takes place in which the species is perfectly identifiable. Three males are sighted at 08:10 solar time that are disputing a territory (the aforementioned stretch with *Juncus* sp. and *Rubus* sp.). The dispute between these males lasts from 08:10 in the morning until 14:30 in the afternoon, when they disappear. The temperature around 30° and the relative humidity above 90%, the sky is absolutely free of cloudiness. Pictures are taken of the males perched on the *Juncus* sp. The next day a single female is observed in the reed area, quite trusting and with fairly short flights after which she remains clinging to them, when she is photographed. Its activity ceases at 08:30, having started at 07:20 solar time. The sky gradually clouded over, until around 10:00 a.m. it began to rain with some intensity." The dates and specimens observed They were the following: "Valparaíso": 23.VI.2007, 1male; "He Plano": 03.VIII.2007, 8males; Hillside south: 28.VIII.2007, 1 male. Due to its rarity, only one specimen was collected." (Author/google translate)] Address: Rodríguez, P.C., La Manzanera, 13 bajo. 26004, Logroño, La Rioja, Spain. Email: patekphi@yahoo.es

## 2010

**21048.** Forestry Bureau, Council of Agriculture (2010): Taiwan's special rare wildlife habitat use surveys and plans to create a co-ordination Four spot fine Featherlegs [*Mortona-giron hirosei*] habitat conservation and education promotion plan. Results report. Corp. Taiwan Society of Wilderness, Republic of China on December 31, 2010: 144 pp. (in Chinese) ["7.4 Designation of important habitats for wild animals *M. hirosei* is listed as vulnerable by the World Conservation Union (IUCN) and is only distributed in a few places such as Taiwan, Japan, and Hong Kong. In the water purification park planning and basic design entrusted technical service project, the relevant domestic and foreign literature was collected, and with the observation and survey results of volunteers, it was suggested that the existing habitat of the four-spotted weeter should be well protected, and the habitat range should be expanded. Relevant experiential education facilities can play the role of environmental education. At the same time, it is suggested that relevant government units should allocate funds as soon as possible to carry out investigation and research on the species and habitat of *M. hirosei*. The area is a protected area or an important habitat for wild animals, and a management plan for the habitat of the four-spotted weed is formulated to protect its habitat and avoid human interference. The survival crisis of the ethnic group, including habitat degradation and other factors, has caused a rapid decline in the distribution range and density of the ethnic group in the past five years. This

result shows that our efforts and progress in the conservation of the four-spotted species are far from enough, and related conservation work is urgent. In eyebrows, the local government and the agricultural committee and other competent authorities should face up to this problem, invest in the required conservation research and habitat management resources as soon as possible, and designate the Wugu wetland as a wild habitat. An important habitat for animals to effectively preserve their habitat. In Taiwan, the rare and beautiful habitat of *M. hirosei* is close to the two major metropolitan areas of New Taipei City and Taipei City. It is the blessing and pride of the residents of the two metropolitan areas. The best indicator of district health, quality of life for residents, and sustainable values. Based on a one-year investigation and research, this plan puts forward the above suggestions for the conservation work of *M. hirosei*." (Authors/Google translate)]

## 2011

**21049.** Costes, A. (2011): État des lieux des connaissances des populations de trois libellules d'intérêt communautaire en Midi-Pyrénées: *Macromia splendens*, *Oxygastra curtisii* et *Gomphus graslinii*. Conservatoire d'espaces naturels Midi Pyrénées: 33 pp. (in French) ["Three dragonflies species of community interest are attached to the large rivers of southern France. These three species are currently covered by the "National Odonate Action Plan". Although the Midi-Pyrénées has a significant conservation responsibility for these species, their distribution is currently poorly known. Numerous actions should eventually be envisaged at regional level for the preservation of these three species. Beforehand, it is necessary to draw up an inventory of their distribution. This report presents a synthesis of data collected from various structures and individuals in the Midi-Pyrénéan natural landscape, supplemented by the results of a survey in 2011 on regional waterways in search of new sites favourable to the development of these three dragonflies. The aim is to update and strengthen knowledge of *M. splendens*, *O. curtisii* and *G. graslinii* in the Midi-Pyrénées." (Authors/DeepL) [http://cen-mp.org/wp-content/uploads/2018/07/rapport\\_odonates\\_Costes2011\\_cenmp.pdf](http://cen-mp.org/wp-content/uploads/2018/07/rapport_odonates_Costes2011_cenmp.pdf)] Address: Conservatoire d'espaces naturels Midi Pyrénées, 75 Rue Luce Boyals, 31300 Toulouse, France

**21050.** Jones, J.I.; Murphy, J.F.; Collins, A.L.; Sear, D.A.; Naden, P.S. (2011): The impact of fine sediment on macro-invertebrates. *River Research and Applications* 28(8): 1055-1071. (in English) ["The sustainable use of water resources requires clear guidelines for the management of diffuse pollution inputs to rivers. Without informed guidelines, management decisions are unlikely to deliver cost-effective improvements in the quality of rivers as required by current water policy. Here, we review the evidence available for deriving improved guidelines on the loading of fine sediment to rivers based on the impact on macro-invertebrates. The relationship between macro-invertebrates and fine sediments is poorly defined. Studies of the impacts of fine sediment on macro-invertebrates have been undertaken at various scales, which has an influence on the range of responses displayed and the reliability of the results obtained; results obtained from investigations at smaller scales may not manifest at the scale required to manage rivers and vice versa. Many of the identified effects of increased loading of fine sediment on macro-invertebrates occur as a consequence of deposition on the river bed, yet many current management guidelines are based on suspended sediment targets. On this basis, existing water quality 2013 guidelines for sediment

management are unlikely to be appropriate." (Authors) *Xanthocnemis zealandica*, *Ischnura aurora*] Address: Jones, J.I., School of Biological and Chemical Sciences, Queen Mary University of London, Mile End Road, London, E1 4NS, UK. E-mail: [j.i.jones@qmul.ac.uk](mailto:j.i.jones@qmul.ac.uk)

**21052.** Hou, Y.; Wang, F. (2012): Vibration, structural engineering and measurement II. *Applied Mechanics and Materials* 226 - 228: 844-849. (in English) ["Flapping-wing flying is a kind of rhythmic movement with symmetry of time and space essentially, and this movement is generated and controlled by Central Pattern Generator (CPG). A 2-DOF flapping mechanism was designed according to the flapping-wing flying principle of insects, and the flapping-wing flying CPG model was constructed by nonlinear oscillators. The system responses were studied, and the influences of the model parameters to the system characteristics were analyzed. Through the engineering simulation of flapping-wing flying control model, the first modal vibration of the system was selected, and the different flying modes of bionic aircraft were realized by adjusting system parameters. This kind of bionic control strategy promoted the movement and control ability of flapping-wing flying, and provided a new method to the generation and control of flapping-wing rhythmic movement. ... According to the mass, wingspan of dragonfly wing, take the equation parameters as follows:  $m=20\text{mg}$ ,  $l_w=0.04\text{m}$ ,  $l_1=0.02\text{m}$ ,  $l_2=0.018\text{m}$ ,  $l_3=0.01\text{m}$ ,  $k_1=320\text{N/m}$ ,  $k_2=320\text{N/m}$ ,  $c_1=0.00005\text{Ns/m}$ ,  $c_2=0.00005\text{Ns/m}$ ,  $c_3=0.00001\text{Ns/m}$ . Through calculating, the two natural frequencies ..." (Authors)] Address: Hou, Y., College of Mechanical Automation, Wuhan University of Science and Technology, Wuhan, China. **21054.** Soissons, A.; Martinant, S.; Barbarin, J.-P. (2012): Déclinaison régionale du plan national d'actions en faveur des Odonates - Auvergne - 2012-2016. Conservatoire d'espaces naturels d'Auvergne - Société d'histoire naturelle Alcide d'Orbigny - DREAL Auvergne: 116 pp. (in French) ["The first restoration plans were initiated by the Ministry of Ecology in 1996. More than forty national plans are currently being developed or implemented. The Office for Insects and their Environment (Opie) was responsible for drafting the National Action Plan for Odonates (PNA Odonates). It was drafted in collaboration with the French National Odonatology Society (Sfonat) during 2009. Its validation by the Conseil National de Protection de la Nature (CNP) has been effective since June 2010 (DUPONT, 2010). This plan has two main objectives: - to acquire quantitative data on

the conservation status of species, - to improve the conservation status of species and their habitats in France. In accordance with the provisions of the PNA Odonates, the operational phase involves the production of regional versions. The drafting of the regional version of this plan for the Auvergne region was entrusted to the Conservatoire d'espaces naturels d'Auvergne (Sylvie Martinant, coordinator & Aurélie Soissons, odonatologist) for the coordination and drafting of the plan, in collaboration with the Société d'Histoire Naturelle Alcide d'Orbigny (Jean-Philippe Barbarin, odonatologist expert) for the synthesis of knowledge and drafting of the naturalistic section. The actions selected in the framework of this first Regional Action Plan for Odonates (PRA Odonates) in the Auvergne region cover the period 2012-2016. The 15 species selected for Auvergne, including 10 from the PNA Odonates and 5 added, are all rare and threatened either at national level or in Auvergne. However, these 15 species should not in any way mask the interest of the entire odonatological suite present in Auvergne, which to date numbers 74 species. The 15 species selected, whose habitats are representative of the topographical and altitudinal diversity of Auvergne, are "flagship" species that should serve as a lever for preservation actions that could benefit all Odonata. Furthermore, the geographical position of the Auvergne in the heart of France and the Massif Central, at a climatic crossroads, makes it a privileged "sentinel" region for the evaluation of current or future climate changes. ### 2013

**21055.** Hamill, S.E. (2013): Recovery Strategy for the Pygmy Snaketail (*Ophiogomphus howei*) in Ontario. Ontario Recovery Strategy Series. Prepared for the Ontario Ministry of Natural Resources, Peterborough, Ontario: v + 14 pp. (in English) ["Executive Summary: *O. howei* is a small, brightly-coloured dragonfly which lives in large rivers with steady flow. Adults are thought to forage in the canopy of forests surrounding the rivers. Eggs are laid into the water where they are carried downstream and eventually sink. During the day the larvae burrow into sand or gravel sediments. At night they come to the surface and prey on other invertebrates or small fish. This species is a globally rare dragonfly which occurs only in Eastern North America. In Canada it has been found in 11 locations in New Brunswick and at one site in Ontario. The Ontario location is on the Namakan River in the Rainy River district of northwestern Ontario. The species is listed as endangered on the Species at Risk in Ontario (SARO) List under Ontario's Endangered Species Act, 2007 (ESA). The greatest potential threat to *O. howei* in Ontario is the impoundment of running waters, but others include forest harvesting and invasive species. Other threats common to dragonflies, such as road-kill, recreational use of waters during the emergence period, construction and pollution, may be of lower concern due to the remote northern location. Limiting factors include a need for pristine conditions and the species' short travel distance. Knowledge gaps are many, but major ones are the complete lack of information on population size and the unknown precise egg-laying location in Ontario. The recovery goal is to ensure

the long-term survival of *O. howei* in Ontario by protecting the existing population. The protection and recovery objectives are to: \*protect and maintain the quality and quantity of habitat on the Namakan River in Ontario where Pygmy Snaketail occurs; \*implement a monitoring program at the location where Pygmy Snaketail is known to exist; \*conduct additional inventories for Pygmy Snaketail in suitable habitat. When adult Pygmy Snaketails and/or breeding sites are found, it is recommended that the protection provided by a habitat regulation should be applied to those areas, including the river and 200 metres of forested habitat on either side." **21058.** Shulze, C.D.; Semlitsch, R.D.; Trauth, K.M. (2013): Mosquitofish dominate amphibian and invertebrate community development in experimental wetlands. *Journal of Applied Ecology* 50: 1244-1256. (in English) ["1. Restored and constructed habitats can play important conservation roles. Predators help shape communities in these habitats through complex interactions with prey, other predators and biotic and abiotic characteristics of the environment. However, introduced predators can have dramatic effects that may be difficult to predict. 2. Using regression models, we compared influences of introduced invasive western mosquitofish *Gambusia affinis* to those of two naturally colonizing predators (crayfish and dragonflies), and vegetation, on three anuran species in experimentally constructed wetlands. Using analyses of covariance, we also examined influences of mosquitofish and vegetation on aquatic invertebrate communities. 3. We found that mosquitofish reduced abundances of grey treefrogs *Hyla versicolor* and *H. chrysoscelis* and boreal chorus frog *Pseudacris maculata*, but had no significant influence on green frog *Lithobates clamitans*. Mosquitofish also reduced invertebrate abundance, but their effect on richness was less clear. Vegetation cover did not significantly increase most anuran or invertebrate abundances. However, vegetation increased invertebrate richness. After fish removal, invertebrate abundance increased. Fish removal may have facilitated chorus frog recolonization into wetlands with low abundance of invertebrate predators. 4. Our results indicate that mosquitofish are detrimental to wetland communities, and we recommend that

managers avoid stocking mosquitofish. We also encourage temporary or drainable wetlands to prevent mosquitofish persistence if colonization occurs. Implementing these recommendations will improve the conservation potential of restored wetlands." (Authors) Address: Shulse, C.D., Missouri Dept Transportation, P.O. **21062.** Barry, M.J. (2014): The energetic cost of foraging explains growth anomalies in tadpoles exposed to predators. *Physiological and Biochemical Zoology* 87(6): 829-836. (in English) ["Theoretical models predict that predator-induced phenotypes should have lower fitness in the absence of predators. Tadpoles frequently respond to invertebrate predators by reducing activity levels and changing their body proportions. While some studies have shown that induced defenses in tadpoles reduce growth rates, others have found no effect. The aim of this study was to measure the effects of predator presence [*Anax imperator*] on energy expenditure in tadpoles. Predator exposure lowered overall metabolic rate by 19%, while specific dynamic action due to food consumption increased resting metabolism by 11%. Control tadpoles moved significantly more ( $93.6 \pm 3.9$  cm/min) than predator-exposed animals ( $50.1 \pm 7.5$  cm/min), and swimming increased metabolic rate by up to 400% compared to stationary tadpoles, indicating that activity can be energetically expensive and can consume as much as 37% of assimilated energy. These findings suggest that the costs of reduced foraging are context dependent and may even be beneficial in environments where high-quality resources are closely spaced but detrimental when extensive movement is required to obtain optimal resources for growth. ... The aim of this study was to measure the main components of energy expenditure in tadpoles of the Arabian toad (*Bufo arabicus*) in the presence and absence of predation cues from dragonfly larvae. ... The dragonfly larvae were fed two

$50 \pm 10$ -mg tadpoles daily." (Author)] Address: Barry, M.J., Biology Dept, Sultan Qaboos University, PO Box 36 AL Khoud, Muscat, 123, Oman. E-mail: mjbarry@squ.edu.om

**21063.** Bolshakov, L.V. (2014): [The first information on the dragonfly fauna (Insecta: Odonata) in the Ugra section of the Ugra National Park (Kaluga region)]. *Proceedings of the Mordovia State Nature Reserve named after P. G. Smidovich* 12: 414-418. (in Russian) [Google translate: "At least 43 species of dragonflies are currently recorded on the territory of the Kaluga region, without taking into account 5 species unusual for this region, previously indicated on the basis of definitions for larvae, the presence of which in the fauna of the region requires confirmation (Bolshakov, 2013). However, the territory of the region has been studied very unevenly in terms of odonatology. The vast majority of dragonfly species are known in the Zhizdrinsky section of the Ugra National Park, much less in some other areas. In particular, data on the fauna of dragonflies in the Ugorsky section of the national park have so far been practically absent in the literature, except for 13 eurytopic and numerous species recognized, taking into account data from adjacent areas, distributed throughout the territory of the Kaluga region (Bolshakov, 2013). In 2013, the author conducted entomological studies in the Dzerzhinsky district of the Kaluga region, mainly in the southern part of the Ugorsky site, related to the Galkinsky forestry of the national park. At the same time, for the first time in this part of the region, collections of dragonflies were held. This year, the first dragonflies were observed here on May 16, but after August 30, the research was interrupted due to prolonged rains. As a result, 28 species of dragonflies were identified in the Galkinsky forestry, of which 3 were new for the Kaluga region. The material is stored mainly in the collection of the author, partially (species new to the region) - in the Zoological Museum of Moscow State University. It should be noted that the area under consideration is located in the subzone of coniferous-deciduous forests. The river network is represented by the river Ugra and its tributaries. In the forests of the Galkinsky forest area there are numerous swamps, among which low-lying black briers and grass swamps predominate. However, most of the collections in the Galkino locality were carried out on the famous Galkinsky swamp, a unique and relict natural complex, including extensive sphagnum quagmire with specific taiga-boreal biota. Collections in the Gorbenki locality were carried out on the no less famous Zalidovsky meadows, where there are oxbow lakes and small grassy swamps, which partially dry up in summer. In the proposed list, the order system is adopted according to (Belyshev, Kharitonov. 1981), the nomenclature according to (Skvortsov. 2010). Species reported for the first time for the Kaluga Region are marked with an asterisk (\*). Annotations of species previously known in the area are limited to localities and frequency of occurrence during the research period, since the bibliography by species and their ecological characteristics were covered in detail (Bolshakov. 2013). More detailed comments are given on the most rare and new species of fauna." The list includes species as *Coenagrion johanssoni*, *Sympecma paedisca*, *Nehalennia speciosa*, *Aeshna cyanea*, *Gomphus vulgatissimus*, *Ophiogomphus cecilia*, *Cordulia aenea*, *Leucorrhinia dubia*, *L. rubicunda*, *L. pectoralis*] Address: Bolshakov, L.V., Russian Entomological Society (Tula branch), Russia. **21066.** Herremans, M.; De Knijf, G.; Hansen, K.; Westra, T.; Vanreusel, W.; Martens, E.; Van Gossum, H.; Anselin, A.; Vermeersch, G.; Pollet, M. (2014): Monitoring van beleidsrelevante soorten in Vlaanderen met inzet van vrijwilligers. Rapporten van het Instituut voor Natuur- en Bosonderzoek 2014 (rapportnr. INBO.R.2014.1628917). Instituut voor Natuur- en Bosonderzoek, Brussel: 88 pp. (in Dutch) ["This final report sets out the framework for using volunteers to carry out structured monitoring networks. Chapters 1 and 2 provide basic information on the taxonomic scope and monitoring methods. Chapter 3 broadly describes the data used for the 2013 HRL/VRL reporting. The subsequent chapters (4-8) look in more detail at the individuality of the volunteer work. Specific focus here is on the significance of loose observations (Ch. 4), the blueprint review process (Ch. 5), specific concerns for (Ch. 6), and the dynamics of this operation (Ch. 7). It then outlines a conceptual framework for guiding and supporting volunteers in monitoring networks, and launches a concrete proposal (Ch. 8). Following this, the existing nature data systems in Flanders are mapped, as well as the existing and planned partnerships between Natuurpunt and the other volunteer organisations (Ch. 9). The future monitoring network application is also briefly explained here. Chapter 10 provides an overview of relevant aspects for the monitoring network budget. ... 5.2.6 BD-LIB - Dragonflies Volunteer organisation involved: Libellenvereniging Vlaanderen (LVV). Three monitoring network types are proposed for dragonflies: transect counts, area counts, and larval skin counts on a fixed route. LVV sees co-standardised monitoring of species as a goal of the association and wants to do its utmost to achieve this. However, it cannot do this alone, and there is an important demand for professional supervision (by guiding the volunteer organisation), and for finding and deploying volunteers from outside the association. Natuurpunt still sees significant opportunities for this in its fabric. **21067.** Joest, R.; Jaworski, N.; Langenbach, A.; Rödel, A. (2014): Entwicklung der Libellenfauna in der renaturierten Lippeaue. *Natur in NRW* Nr. 1/2014: 28-31. (in German) ["Conclusion: In the Lippe floodplain in the area of the Klos-

termersch and the Hellinghauser Mersch (Nordrhein-Westfalen, Germany), a number of dragonfly species characteristic of lowland rivers and their floodplains occur. The dragonfly fauna shows great similarity to other floodplain areas of Westphalian lowland rivers, especially the Ems (ARTMEYER 2000, CONZE 2000). Similar species communities and their developments on regenerated floodplain waters were also observed by LOHR (2010) on the basis of long-term studies of the dragonfly fauna in the floodplains of the Upper Weser (Germany) and the Lower Allier (France). The results also correspond to experiences made, for example, after renaturation measures on the Main (SCHLUMPRECHT et al. 2004). The species diversity of dragonflies has increased since the beginning of the surveys in parallel with the renaturation measures carried out. For species of flowing waters, the creation of bank breaks with shallow water zones and flow-calmed sections has created favourable living conditions. Species of temporary water bodies and flood zones depend on near-natural flood dynamics. Their habitats could be improved by creating small water bodies and reactivating the floodplain by removing the embankment and creating flood channels that allow even smaller floods to enter the floodplain more quickly. In addition to these measures acting in the area, supra-regional factors such as climate warming have also contributed to the increase in the number of species. Species such as the firefly, which have expanded their range due to climatic changes, can only colonise the floodplains if suitable habitats are available. Thus, floodplain restoration is also a prerequisite for adaptation to climate change by enabling species to shift their range. The renaturation of floodplains in particular creates a great diversity of habitats and enables water storage during drier summers (STRÄTER et al. 2010). This also applies to the Lippe floodplain, where without renaturation measures even otherwise permanent water bodies would dry up in dry years." **21069.** Patrício, P.M.B. (2014): How does exposure to the fungus *Batrachochytrium dendrobatidis* affects the tadpoles of the common toad, *Bufo bufo*, under different stresses? Tese de mestrado. *Biologia (Biologia da Conservação)*, Faculdade de Ciências, Universidade de Lisboa: 49 pp. (in English, with Portuguese summary) ["The current global decline of amphibians is caused by multiple factors, and one of the most important is the spread of the fungus *Batrachochytrium dendrobatidis* (Bd) which is directly responsible for the infection of 350 amphibian species. The factors

that influence susceptibility to infection by Bd are not completely known, but it is known that factors such as density, intra- and inter-specific competition, and predation may have consequences for the development and possibly the immune system of larval amphibians. The effects of single stresses on anurans have been widely studied and documented, but studies examining the extent to which anurans can respond to multiple stresses are scarce. We tested the effect of stress-inducing factors, namely intraspecific competition, the existence of chemical and visual signals indicating the presence of a predator [*Aeshna cyanea*], and environmental exposure to Bd, in tadpoles of *Bufo bufo* (common toad), in a factorial experiment that tested all combinations of the three stress-inducing agents considered. Tadpole mortality was very low and not related with infection by Bd. In fact, all the tadpoles were cleared of Bd at the end of the experiment. However, our results demonstrated that the non-lethal infection by Bd can be a stressor and have impacts on larval life-history traits. The responses we found included reduced activity levels, shortened larval period, reduced ability to jump after metamorphosis, and differential use of the aquarium. So, the fungus does not directly affect *B. bufo* survivorship, but influences traits related to behavior, growth and development. Our study did not support the hypothesis that the exposure to natural stresses resulting from predation and/or competition increases susceptibility to *B. dendrobatidis*, and shows that a link between stress exposure and disease susceptibility cannot be assumed in all cases." **21070.** Shi, X.-j.; Yu, H.-y. (2014): Dragonfly wing structural stiffness of the finite element analysis. *Journal of Anhui Agricultural Sciences* 2014, (5): 1395-1397, 1400. (in Chinese) ["Objective: To explore the important role of arching in the space structure of dragonfly wings. Method: The finite element analysis software ANSYS was used to analyze the deformation of each model under different loads, and the arch structure of dragonfly wings was studied. The effect of stiffness. Result: Under the same load conditions, the structural stiffness of the two mesh models increases with the increase of the arching height. When the load and arching height are the same, the deformation of the mesh with membrane is smaller than that of the mesh without membrane. The stiffness of the hexagonal grid is significantly enhanced; under the same load conditions, the deformation of the hexagonal grid is always greater than that of the combined grid model. Provide new ideas." (Authors/Google translate)] Address: not stated

**21071.** Stockwell, M.P.; Srorrie, L.J.; Pollard, C.J.; Clulow, J.; Mahony, M.J. (2014): Effects of pond salinization on survival rate of amphibian hosts infected with the chytrid fungus. *Conservation Biology* 29(2): 391-399. (in English, with Spanish summary) ["The chytrid fungus *Batrachochytrium dendrobatidis* has been implicated in the decline and extinction of amphibian populations worldwide, but management options are limited. Recent studies show that sodium chloride (NaCl) has fungicidal properties that reduce the mortality rates of infected hosts in captivity. We investigated whether similar results can be obtained by adding salt to water bodies in the field. We increased the salinity of 8 water bodies to 2 or 4 ppt and left an additional 4 water bodies with close to 0 ppt and monitored salinity for 18 months. Captively bred tadpoles of green and golden bell frog (*Litoria aurea*) were released into each water body and their development, levels of *B. dendrobatidis* infection, and survival were

monitored at 1, 4, and 12 months. The effect of salt on the abundance of nontarget organisms was also investigated in before and after style analyses. Salinities remained constant over time with little intervention. Hosts in water bodies with 4 ppt salt had a significantly lower prevalence of chytrid infection and higher survival, following metamorphosis, than hosts in 0 ppt salt. Tadpoles in the 4 ppt group were smaller in length after 1 month in the release site than those in the 0 and 2 ppt groups, but after metamorphosis body size in all water bodies was similar. In water bodies with 4 ppt salt, the abundance of dwarf tree frogs (*Litoria fallax*), dragonfly larvae, and damselfly larvae was lower than in water bodies with 0 and 2 ppt salt, which could have knock-on effects for community structure. Based on our results, salt may be an effective field-based *B. dendrobatidis* mitigation tool for lentic amphibians that could contribute to the conservation of numerous susceptible species. However, as in all conservation efforts, these benefits need to be weighed against negative effects on both target and nontarget organisms." **21072.** Suriana; Dwi Arinto Adi; dan Wa Ode Dian Hardiyanti (2014): Dragonfly (Odonata) stocktaking around river and Moramo swamp, Sumber Sari village, Moramo district, South Konawe Regency, southeast Sulawesi. *Bio-wallacea* 1(1): 49-62. (in Indonesian, with English summary) ["The aim of this research was to know the dragonfly (Odonata) species around River and Moramo Swamp, Sumber Sari Village, Moramo District, South Konawe Regency, South-East Sulawesi. Dragonfly captured on three site namely river, swamp I and swamp II/Moramo swamp. This research used descriptive method. There are 28 species of dragonfly which are include of 8 family namely Lindeniidae, Libellulidae, Megapodagrionidae, Lestidae, Coenagrionidae, Calopterygidae, Chlorocyphidae and Platycnemididae. Suborder Eiprocta found 13,33% family and 50% suborder Zygoptera of all families. There are 12 species in river, 15 species in swamp I and 13 species in swamp II/Moramo swamp. The Calopterygidae, Megapodagrionidae and Platycnemididae only found in river, whereas *Lestes concinnus* found in swamp only. The dragonfly species found in river were different from swamp I and swamp II/Moramo swamp." **21073.** Lopes, A.S.P. (2015): Biodiversidade e ecologia de borboletas (Lepidoptera) e libélulas (Odonata) do planalto superior da Serra da Estrela. M.Sc. thesis, *Ecologia Aplicada*, Universidade de Aveiro: 73 pp. (in Portuguese, with English summary) [Portugal "Serra da Estrela has a high natural value due to the presence of rare habitats and a remarkable biodiversity. The aim of this study was to evaluate the importance of different areas of the upper plateau of Serra da Estrela for the conservation of nature through the study of two bio-indicators groups, Odonata and Lepidoptera. The sampling methodology was based on the count of adult individuals, using fixed transects with a length of 150 meters along four different habitats: natural ponds, small dams, large dams and inland areas (dry spots). In 2301 observed individuals, 55 Lepidoptera species were identified, and in 2580 individuals, 23 species of Odonata were identified. The presence of Lepidoptera species *Vanessa virginiensis*,

Cyaniris semiargus and Coenonympha iphioides, and Odonata species Aeshna juncea and Sympetrum flaveolum, is noteworthy, since they are considered rare or vulnerable in Portugal. Significant differences on the biodiversity of both orders were found between the different types of studied habitats. The biodiversity of butterflies was higher in large dams, mainly due to the existence of a greater richness and abundance of nectariferous plant species, while the diversity of Odonata species was higher in natural lakes and some small naturalized dams, where disturbance levels are low. In these habitats exists some stenotopic species, and also species very sensitive to disturbance. Due to the high diversity of species present in Serra da Estrela with the status of vulnerable, rare, endemic or protected by the law, appropriate management measures should be promoted, and the protection of habitats may be the one of greatest relevance." **21074.** Payandeh, R. (2015): Verbreitung und Ökologie der Vogel-Azurjungfer, *Coenagrion ornatum* (SELYS, 1850) in der Steiermark. MSc. thesis, Karl-Franzens-Universität Graz: 118 pp. (in German, with English summary) ["In a GIS-based randomized sampling procedure, 61 rivulets were pre-selected in the eastern, southern and western parts of Styria to study the distribution and ecology of the Ornate Bluet (*Coenagrion ornatum*). In May, June and July 2014, field trips were carried out and data on the Odonata fauna and several habitat parameters were collected. GIS and MaxEnt tools allowed us to estimate the likelihood of the occurrence of *C. ornatum* for whole Styria. Dragonflies could be recorded along 55 of the 61 water bodies, and *C. ornatum* was present along 14 rivulets. The analysis of habitat parameters showed that the presence of this species depends mainly on the altitude, flow velocity, width of the rivulet and on the water depth. *C. ornatum* utilizes lowland rivulets (200 to 450 meters) and prefers a stream velocity between 0 and 20 seconds per 5 meters. Furthermore, the rivulet width should not exceed 4.5 m and a depth of 50 cm. The inclination should not exceed 5 degrees. The presence of *C. ornatum* also correlates positive with e.g. a higher number of serene days, a larger drainage area of the rivulet and a total rainfall in spring of about 220 mm. *C. ornatum* localities are concentrated in the east and southeast parts of Styria with one exception in the district Voitsberg." **21075.** Gottardo, M.; Dallai, R.; Mercati, D.; Hörschemeyer, T.; Beutel, R.G. (2016): The evolution of insect sperm - an unusual character system in a megadiverse group. *Journal of Zoological Systematics and Evolutionary Research* 54(4): 237-256. (in English) ["Spermatozoa provide an unusual character system, with a limited number of components organized in a single cell. Similar spermatozoa occur in groups widely separated in the phylogenetic tree of Metazoa. Nevertheless, the character system contains phylogenetic information. Hexapoda have acquired spermatophores along with the switch from aquatic to terrestrial habitats, and related to this, a multitude of different sperm types. The aim of this study is a formal evaluation of the phylogenetic information content of spermatozoa. For the first time, sperm characters are coded for formal phylogenetic analyses. Different approaches are used and compared. Mainly due to a high level of homoplasy, the evaluation of sperm characters alone is insufficient for a reconstruction of the phylogeny of the group. Yet, a reliable reconstruction of the evolution of insect sperm is possible when character transformations are

assessed using a phylogeny based on extensive molecular data. Important changes took place in the early evolution of Hexapoda. Sperm characters support some major clades (e.g. Hexapoda, Dicondylia, Polyneoptera, Psocodea), but important steps in the evolution are not reflected by transformations of spermatozoa, notably the rise of Pterygota or Holometabola. Important innovations are the formation of mitochondrial derivatives and the acquisition of accessory microtubules. Some features are conservative, whereas others evolved rapidly (e.g. presence or absence of the acrosome vesicle). Some groups are conservative in their sperm features (e.g. Odonata, Heteroptera), whereas the evolution of spermatozoa was distinctly accelerated in others (e.g. Ephemeroptera). The rate of evolution can change drastically in closely related groups. Profound changes in the morphologically uniform Zoraptera underline that sperm evolution can follow a pattern very different from the general somatic morphology. The mode of character reconstruction preferred here will be useful for the evaluation of specialized morphological character systems and strengthen the concept of evolutionary morphology." **21076.** Hushtan, K.V. (2016): The ecomorphological classification of dragonflies larvae (Insecta: Odonata) of the Ukrainian Carpathians. *The Kharkov Entomol. Soc. Gaz.* 24(1): 5-21. (in Russian, with Ukrainian and English summaries) ["The main classifications of the ecological and morpho-ecological types of dragonflies' larvae have been analyzed. The papers that could be the basis for creation the unified ecomorphological classification of Odonata are analyzed. Morphological method is suggested as the main for selecting the categories for ecomorphs of dragonflies' larvae. It is suggested to take into account ecological (spatial niche), ethological (the type of movement, behavioral characteristics) and morphological (body shape, type of mouthparts, structure of sense organs and legs) criteria. Twenty dimensional features have been analyzed for larvae of 15 genera of water dragonflies from the Ukrainian Carpathians. Seventeen indicators have been selected, which exactly characterize relations of larvae with environment. On the base of suggested approach, hierarchical classification for dragonflies' larvae from the Ukrainian Carpathians has been developed. It includes 3 types, 6 classes, and 10 subclasses." **21077.** Kolozsvary, M.B.; Holgerson, M.A. (2016): Creating temporary pools as wetland mitigation: How well do they function? *Wetlands* 36(2): 335-345. (in English) ["Temporary forested pools are an important ecological resource throughout northern and eastern North America, yet they are often destroyed or degraded. Pool creation offers a potential mitigation solution, but long-term monitoring to assess the functioning of created pools is scarce. Furthermore, studies rarely integrate multiple, interacting levels of the pool ecosystem, including physical, chemical, and biological parameters. To address this knowledge gap, we compared the physical habitat, water chemistry, productivity, and community composition of macroinvertebrates and amphibians from 7-year old created pools (n=77) to reference pools (n=6). Created pools were smaller in size, received more sunlight, had greater amounts of *Lemna*, *Typha*, and *Phragmites*, and were less likely to dry. Created pools had higher pH and conductivity, but algal biomass did

not differ. Macroinvertebrate richness was similar across pools, but composition starkly differed. Amphibian species richness and composition was similar between created and reference pools; however, created pools had fewer focal pool-breeding amphibians, including the spotted salamander and wood frog. By assessing the entire pool ecosystem, we found that the ability of created pools to mimic the physical conditions and ecological functions of natural temporary pools is suspect." **21078.** Koparde, P. (2016): Damsels in distress – seasons, habitat structure and water pollution changes damselfly diversity and assemblage in urban wetlands. *Animal Biology* 66(3-4): 305-319. (in English) ["Odonates are considered to be good ecological indicators, hence, they are used in biological assessment of habitat quality. However, species responses may vary spatiotemporally and therefore, it is useful to establish species-habitat relationships at a regional level. To test if tropical urban odonates respond to seasons, and to explore species-habitat relationships with an emphasis on water pollution, I studied six wetlands in the city of Pune for a year. I also investigated whether combining data on dragonflies and damselflies, as is often done in many studies, skews the results. I recorded seasons, water pollution and habitat attributes as predictors of the odonate diversity and assemblage. I analyzed the data on dragonflies, damselflies and odonates (dragonfly-damselfly combined) separately for seasonal variation, and species-habitat relationships. I used multiple regression and canonical correspondence analyses. Forty-four species were recorded during the study. No seasonal variation was detected, except for damselflies, which showed an increase in the diversity and species number post-monsoon. Multiple regression analysis showed that damselfly and dragonfly diversity varied as a function of season and water pollution, and monsoon respectively. In pre-monsoon, damselfly diversity marginally increased with pollution. Both the analyses suggest that combining data on dragonflies and damselflies may skew the end results. Therefore, I recommend further intensive and long-term research using accurately sampled habitat and pollution attributes, as well as habitat restoration through conserving urban green spaces and promoting gardens with streams and ponds." **21079.** Kosterin, O.E. (2016): A survey of Odonata of Mondulkiri, the elevated eastern province of Cambodia, for ten days in June 2014. IDF-Report 98: 1-85. (in English) ["Results of an odonatological survey of Mondulkiri Province of Cambodia, at the foothills and Central Plateau of the Annamese Mts. in June 8 - June 17, 2014 are presented. Of 106 Odonata species met (46 zygopterans, 60 anisopterans), 97 were identified to previously known named species, of which 17 are reported for the first time for Cambodia, namely *Mnais mneme* Ris, 1916, *Rhinocypha seducta* Hämäläinen et Karube, 2001, *Philoganga loringae* Fraser, 1927, *Rhinagrion hainanense* Wilson et Reels, 2001, *Amphiallagma parvum* (Selys, 1876), *Ceragrion chaoi* Asahina, 1967, *Paracercion malayanum* (Selys, 1876), *Prodasinieura doisuthensis* Hoess, 2007, *Protosticta grandis* Asahina, 1985, *Tetracanthagyna waterhousei* McLachlan, 1898, *Gomphidia kruegeri* Martin, 1904, *Heliogomphus chaoi* Karube, 2004, *Leptogomphus baolocensis* Karube, 2001, *Microgomphus*

*jurzitzi* Karube, 2000, *Onychothemis culminicola* Förster, 1904, and two species for which the specimens collected on this trip were described as new subspecies: *Indolestes gracilis* expressor Kosterin, 2015, *Coelicerca poungyi* dasha Kosterin, 2016. Five species collected on this trip have been described elsewhere as new to science, namely *Onychargia priyadak* Kosterin, 2015, *Prodasinieura hoffmanni* Kosterin, 2015, *Asiagomphus reinhardti* Kosterin et Yokoi, 2016, *Euthygomphus schorri* Kosterin, 2016 and *Risiophlebia guentheri* Kosterin, 2015. So the total number of the first country records of named species made on this trip is 22. Still five species found may be undescribed. The number of named species recorded in Cambodia has reached 179. Remarks on taxonomy and variation of *Euphaea masoni* Selys, 1879, *E. ochracea* Selys, 1859, *Aciagrion approximans* (Selys, 1876), and *Lamelligomphus castor* Lieftinck, 1941 are provided. Characters of mature males of *R. seducta* are updated. Notes on habitats and habits of some species are provided. *Onychothemis culminicola* and *O. testacea* Laidlaw, 1902 seem to exclude each other at rivers, the former occupying smaller and more elevated ones; a putative hybrid male was observed. General notes on the area and field impressions are briefly outlined." (Author)] Address: Oleg E. Kosterin, O.E., Institute of Cytology & Genetics SB RAS, Acad. **21080.** Rohmare, V.B.; Rathod, D.M.; Parasharya, B.M. (2016): Diversity and population dynamics of Odonata (Insecta: Odonata) in rice growing area of central Gujarat. *Journal of Biological Control* 30(3): 129-137. (in English) ["Odonates diversity was studied in Paddy field of Central Gujarat during 2012 to 2015. Total 39 species belonging to 25 genera, under six families and two suborders were recorded. Total 17 species of Zygoptera and 22 species of Anisoptera were recorded. Community structure and population dynamics of adult odonates were studied at Lingda village during July to December, 2012 through monitoring their population by point count method on three microhabitats (paddy field, village pond and fish farm). Total seventeen species were encountered in the point count. Diversity index (H') was highest (2.13) for paddy fields followed by fish farm (2.07) and village pond (1.99). Evenness value of the odonates also ranged between 0.7 and 0.8. Total four species (Viz. Ditch Jewel (25.0%), Green Marsh Hawk (17%), Ruddy Marsh Skimmer and Coromandal Marsh Dart (16% each) were dominant species in all three microhabitats. Both suborders showed similar trend of population fluctuation during the study. Relative abundance was higher and remained constant during 4th week of September to 2nd week of October." **21081.** Sjöwall, P.; Lundström, R (2016): The environmental and anthropogenic impact on freshwater biodiversity in Lajeado, RS, Brazil.: A study of using dragonflies as indicators for the environmental status in freshwater biomes. Independent thesis Basic level (university diploma): 31 pp. (in English) ["Fragmentation of the Atlantic rainforest and alteration of waters due to agricultural expansion has greatly affected the species diversity in Brazil. In this study, we investigate how different environmental factors affect dragonfly communities and dragonfly species richness in sixteen different locations in Rio Grande do Sul, Brazil. A total of 328 individuals distributed among 46 species and eight families were collected. At each sampling location the water was

analyzed and the surrounding environment recorded and plotted. Our goal was to investigate if we could find species for use as bio indicators on water quality and if the fragmentation of the forests in Rio Grande do Sul affects the species richness negatively. Our data suggested that the amount of forest, pH level and water temperature have a strong correlation to the number of species. For the number of specimens we found that amount of forest, pH level, water temperature, conductivity, amount of dissolved solids in the water and amount of surrounding urban area affects the population. We found that still water holds more species as well as specimens than current water. *T. binotata*, *M. ocellata*, *Oxyagrion* sp., *L. pictus*, *M. stawiariskii*, *R. planaltica*, *L. auritus* and *L. dichrostigma* could possibly be used as indicators for pH level, and that *S. reticulata*, *L. bipupillatus*, *B. furcata*, *R. bonariensis*, *D. mincki* and *T. cophysa* possibly could be used as indicators for conductivity. Further studies has to be done in order to be certain about the use of these species as indicators." (Authors)] Address: not stated

**21082.** Staats, E.G.; Agosta, S.J.; Vonesh, J.R. (2016): Predator diversity reduces habitat colonization by mosquitoes and midges. *Biology Letters* 12(12): 4 pp. (in English) ["Changes in predator diversity via extinction and invasion are increasingly widespread and can have important ecological and socio-economic consequences. Anticipating and managing these consequences requires understanding how predators shape ecological communities. Previous predator biodiversity research has focused on post-colonization processes. However, predators can also shape communities by altering patterns of prey habitat selection during colonization. The sensitivity of this nonconsumptive top down mechanism to changes in predator diversity is largely unexamined. To address this gap, we examined patterns of dipteran oviposition habitat selection in experimental aquatic habitats in response to varied predator species richness while holding predator abundance constant. Caged predators [larval *Celithemis eponina*, larval *Enallagma* spp. and first-year *Procambarus* crayfish] were used in order to disentangle behavioural oviposition responses to predator cues from potential post-oviposition consumption of eggs and larvae. We hypothesized that because increases in predator richness often result in greater prey mortality than would be predicted from independent effects of predators, prey should avoid predator-rich habitats during colonization. Consistent with this hypothesis, predator-rich habitats received 48% fewer dipteran eggs than predicted, including 60% fewer mosquito eggs and 38% fewer midge eggs. Our findings highlight the potentially important links between predator biodiversity, prey habitat selection and the ecosystem service of pest regulation." **21083.** van Strien, A.J.; Gmelig Meyling, A.W.; Herder, J.E.; Hollander, H.; Kalkman, V.J.; Poot, M.J.M.; Turnhout, S.; van der Hoorn, B.; van Strien-van Liempt, W.T.F.H.; van Swaay, C.A.M.; van Turnhout, C.A.M.; Verweij, R.J.T.; Oerlemans, N.J. (2016): Modest recovery of biodiversity in a western European country: The Living Planet Index for the Netherlands. *Biological Conservation* 200: 44-50. (in English) [oas 68; Highlights: •In line with the global Living Planet Index, we calculated a LPI for the Netherlands based on 361 animal species. •Overall, the state of biodiversity has slightly increased from 1990 to 2014. •This was mainly due to the growth of freshwater animal populations. •In farmland and in open semi-natural habitats animal populations have

been declining and in woodland they were stable. •The LPI enables us to monitor the state of biodiversity in a clear and consistent way. Abstract: We calculated a Living Planet Index (LPI) for the Netherlands, based on 361 animal species from seven taxonomic groups occurring in terrestrial and freshwater habitats. Our assessment is basically similar to the global LPI, but the latter includes vertebrate species and trends in population abundance only. To achieve inferences on trends in biodiversity more generally, we added two insect groups (butterflies and dragonflies) and added occupancy trends for species for which we had no abundance trends available. According to the LPI, the state of biodiversity has slightly increased from 1990 to 2014. However, large differences exist between habitat types. We found a considerable increase in freshwater animal populations, probably because of improvement of chemical water quality and rehabilitation of marshland habitats. We found no trend in the LPI for woodland populations. In contrast, populations in farmland and open semi-natural habitats (coastal dunes, heathland and semi-natural grassland) declined, which we attribute to intensive agricultural practices and nitrogen deposition, respectively. The LPI shows that, even in a densely populated western European country, ongoing loss of animal biodiversity is not inevitable and may even be reversed if adequate measures are taken. Our approach enabled us to produce summary statistics beyond the level of species groups to monitor the state of biodiversity in a clear and consistent way." **21085.** Števo, B.; Kováč, V. (2016): Ontogenetic variations in the diet of two invasive gobies, *Neogobius melanostomus* (Pallas, 1814) and *Ponticola kessleri* (Günther, 1861), from the middle Danube (Slovakia) with notice on their potential impact on benthic invertebrate communities. *Science of The Total Environment* 557-558: 510-519. (in English) ["Highlights: •Bioinvasions can affect negatively native ecosystems through trophic interactions. •Diet and impact of two invasive gobies (fish) in the Danube were examined. •Both gobies preferred chironomids when small, bighead goby shifted to fish when large. •In contrast to round goby, invasive species predominated in the diet of bighead goby. •The impact of invasive gobies develops over time after the onset of the invasion. Abstract: In this study, ontogenetic variations in diet of invasive bighead goby *Ponticola kessleri* and round goby *Neogobius melanostomus* from the

middle Danube were analysed. Index of stomach fullness, Fulton's condition factor, index of food importance, frequency of occurrence, biomass, electivity, and proportions of invasive organisms in their diet were examined. Changes in the diet during ontogeny of both species emphasise the differences in their trophic niches. Our results combined with literary data suggest that bighead goby may threaten small native benthic fish species as a predator (especially in the invasion front), whereas round goby can potentially impact native fish species of all ontogenetic phases by competing for food. Round goby appear to have strong impact on bivalves, especially in the invasion front. High consumption of invasive organisms by bighead goby may help the native macroinvertebrate community. Thus, in contrast to round goby, bighead goby does not seem to be a hot candidate for being a nuisance invader." (Authors) The publication includes a passing reference to Odonata.] Address: Števo, B., Dept of Ecology, Faculty of Natural Sciences, Comenius University, Mlynská dolina, 842 15 Bratislava, Slovakia. ## 2017

**21086.** Bolshakov, L.V. (2017): New species of Odonata for the Tula Province. 2. *Eversmannia* 49: 51- (in Russian, with English title) [Verbatim (Google Translate): When studying the odonatofauna of the Tula region, 2 species of dragonflies new to the region were identified. The definition was made by the author. The material is stored in the museum-reserve "Kulikovo Pole" (Tula) and the Tula Regional Exotarium. Species annotations give arealogical characteristics based on [Belyshev and Kharitonov, 1981; Dijkstra, Lewington, 2006] and other cited sources, details of finds and ecological characteristics; the names of localities are accompanied by their numbers in the working list ["Consolidated...", 2007]. *Onychogomphus forcipatus* is a western Palearctic (to the Trans-Urals, Western Asia) temperate species. In our region, it was reliably known in the more northern subtaiga regions (cited after (Bol'shakov, 2003, 2013)), but relatively rare. Material: Pavlovskoe (36b), 29.08.2016, 1 female (leg. A. Evsyunin). According to the literature, rheophilic appearance. According to the latest observations in the Kaluga region (Yukhnovsky district, Papaev, 07/30/2014, 1 female, 3 specimens recorded, L. Bolshakov), dragonflies stay along the river banks and sit on coastal vegetation. *Aeshna isocetes* ... is a west-central Palearctic (to Central Asia) subboreal species. In our region, it was first noted at the very end of the 20th century. in the vicinity of Moscow [Matyukhin, 2000] and in the eastern regions of the Lipetsk region [Melnikov, 2000]. Probably, it settled more widely in the forest zone only in the 21st century. due to the softening of wintering conditions; recently found in the Kaluga region (Bol'shakov, 2014). Material: Tula (51), TsPKiO, July 8, 2011, 1 specimen noted; 06/6/2012, 2 specimens noted. (L. Bolshakov); Lupishki (129), 5.06.2013, 1 male (up to 6 specimens noted); 07/04/2013, 3 specimens noted; Krasnopolye (129a), 06/5/2013, 1 male, 2 specimens noted. (L. Bolshakov). The first sightings in Tula were not previously put into circulation, because before the capture of dragonflies in 2013, the identification of an unfamiliar species in flight did not seem reliable. A moderately eurytopic limnophilous species that develops in various stagnant water bodies and, probably, in backwaters of rivers. Dragonflies were noted only above water bodies and near them. After the publication of the latest addition (Bol'shakov, 2012), 45 species of dragonflies become known in the fauna of the Tula region. Thanks. The author thanks A.A. Evsyunin (Tula Regional Exotarium) for providing the collected material. The research was partly

funded by the Kulikovo Pole Museum-Reserve.] Address: Bolshakov, L.V., Russian Entomological Society (Tula branch), Russia. Email: l.bol2012@yandex.ru

**21087.** Brown, T. (2017): Predator-prey space use in response to chemical cues of predation. Undergraduate Research Theses, Ohio State University. Dept of Evolution, Ecology, & Organismal Biology: 22 pp. (in English) ["Interactions between predators and prey are a major component of ecosystems and have the potential to shape ecosystem dynamics. As predators and prey move together spatially and temporally throughout their habitat, each makes decisions to increase its own fitness. To make optimal movement decisions, individuals must accurately interpret their surroundings using available information. Two chemical cues are important for predator-prey interactions: predator kairomones and prey alarm cues, the chemical cue components of a typical predation event. How organisms use available information to make movement decisions and how their space use differs after chemical cue exposure is not yet fully understood. We measured space use within a system of predatory dragonfly larvae (*Anax junius*) and green frog tadpoles (*Rana* [=Lithobates] clamitans) exposed to chemical cues. To determine how predators and prey interpret predation events and make movement decisions, we conducted experiments using the components of a predation event: kairomones and alarm cues. We hypothesized that tadpoles would respond more strongly when exposed to a combination of chemical cues and that *Anax* would attempt to match prey distributions to increase its predation success rate. We found that tadpoles only responded with antipredator behaviours (i.e., spatially move away from perceived predation risk) when exposed to both *Anax* kairomones and conspecific alarm cues and that predatory *Anax* do not differ in their space use after chemical cue exposure. Our results suggest that tadpole prey minimize potentially costly antipredator behaviour by selectively responding to environmental information and that predators are behaviourally managing prey fear. Our research has shed insight into how predators and prey use different chemical cues when making movement decisions. Our results can be applied to aquatic and terrestrial systems where predator-prey species rely on chemical cues." (Author)] Address: not stated

**21088.** Harabis, F. (2017): Does the management of surrounding terrestrial habitats increase the tendency of odonates to leave aquatic habitats? *Biodiversity and Conservation* 26(9): 2155-2167. (in English) ["Generally, dragonflies and damselflies (odonates) are considered aquatic invertebrates. However, the ecological requirements of their adults are not different from those of fully, terrestrial insects. Surprisingly, there is a very little information on whether the management and structure of surrounding habitats has any influence on the diversity and seasonal dynamics of odonates. This is important to know because recently, a large proportion of freshwater habitats in Central Europe have become surrounded by intensively managed habitats. The aim of this study was to investigate the effects of different types of terrestrial habitats on their long-term utilization by dragonflies and damselflies. I assumed that this pattern varied over time; therefore, I used generalized additive mixed models to analyze the effects of management on seasonal changes in the abundance of individuals in terrestrial environments. From my results, it was evident that the management practices of surrounding terrestrial habitats had a significant impact on the population dynamics of dragonflies. The abundance of dragonfly adults in surrounding terrestrial habitats increased toward the end of the season. However,

this was only, when the natal aquatic habitat was not affected by fish farming and was able to supply surrounding terrestrial habitats with offspring. This was evidenced by the fact that, compared to areas with extensive water management, in sites with fish farming, seasonal increases in abundance was negligible. There is no doubt that the structure of surrounding terrestrial habitats has a significant influence on the diversity of terrestrial invertebrates. However, we must not forget that terrestrial habitats, regardless of their management, are not able to replace the poor quality of the aquatic (natal) habitat. Interestingly, the abundance of damselflies decreased toward the end of the season, regardless of the management practices of the surrounding areas. This indicates that their dynamics is more controlled by time stress or other similar mechanisms than that of dragonflies." (Author)] Address: Harabiš, F., Dept Ecol., Fac. **21092.** Rajabi, H.; Ghoroubi, N.; Stamm, K.; Appel, E.; Gorb, S.N. (2017): Dragonfly wing nodus: A one-way hinge contributing to the asymmetric wing deformation. *Acta Biomaterialia* 60: 330-338. (in English) ["Dragonfly wings are highly specialized locomotor systems, which are formed by a combination of several structural components. The wing components, also known as structural elements, are responsible for the various aspects of the wing functionality. Considering the complex interactions between the wing components, modelling of the wings as a whole is only possible with inevitable huge oversimplifications. In order to overcome this difficulty, we have recently proposed a new approach to model individual components of complex wings comparatively. Here, we use this approach to study nodus, a structural element of dragonfly wings which has been less studied to date. Using a combination of several imaging techniques including scanning electron microscopy (SEM), wide-field fluorescence microscopy (WFM), confocal laser scanning microscopy (CLSM) and micro-computed tomography (micro-CT) scanning, we aim to characterize the spatial morphology and material composition of fore- and hindwing nodi of the dragonfly *Brachythemis contaminata*. The microscopy results show the presence of resilin in the nodi, which is expected to help the deformability of the wings. The computational results based on three-dimensional (3D) structural data suggest that the specific geometry of the nodus restrains its displacements when subjected to pressure on the ventral side. This effect, resulting from an interlocking mechanism, is expected to contribute to the dorso-ventral asymmetry of wing deformation and to provide a higher resistance to aerodynamic forces during the downstroke. Our results provide an important step towards better understanding of the structure–property–function relationship in dragonfly wings. Statement of Significance: In this study, we investigate the wing nodus, a specialized wing component in dragonflies. Using a combination of modern imaging techniques, we demonstrate the presence of resilin in the nodus, which is expected to facilitate the wing deformability in flight. The specific geometry of the nodus, however, seems to restrain its displacements when subjected to pressure on the ventral side. This effect, resulting from an interlocking mechanism, is suggested to contribute to dorso-ventral asymmetry of wing deformations and to provide a higher resistance to aerodynamic forces during the downstroke. Our results provide an important step towards better understanding of the structure–property–function relationship in dragonfly wings and might help to design more efficient wings for biomimetic micro-air vehicles." (2018): Diet and helminth parasites of freshwater turtles *Mesoclemmys tuberculata*, *Phrynops geoffroanus* (Pleurodira: Chelidae) and *Kinosternon scorpioides* (Cryptodira: Kinosternidae) in a semi-arid region, Northeast of Brazil. *Acta Herpetologica* 13(1): 21-32. (in English) ["In this study, the *Kinosternon scorpioides*, *Mesoclemmys tuberculata*

and *Phrynops geoffroanus* freshwater turtles collected in the Cariús River, State of Ceará, were analysed as to their diet composition and presence of helminths. Among the 63 examined turtles 55 (87.3%) were parasitized. We found three Nematoda species (*Physaloptera retusa*, *Serpinema monospiculatus* and *Spiroxys figueiredoi*) and one Trematoda species (*Gorgoderina* sp.). *Phrynops geoffroanus* had the highest indexes of prevalence (97.56%) and mean intensity of infection (33.5), followed by *M. tuberculata* (70% and 12.64, respectively) and *K. scorpioides* (50% and three, respectively). Host body size was positively related to helminths abundance in both male and female Chelidae species. A significant difference in helminths abundance between the sexes was found only in *P. geoffroanus*, where females had more parasites than males. Regarding diet, the main food items ingested by *M. tuberculata* were Odonata nymphs (Aeshnidae and Libellulidae), whilst *P. geoffroanus* feeds mainly on Diptera larvae (Chironomidae), Odonata nymph (Aeshnidae) and Notonectidae, and only seeds were found in the stomach contents of *K. scorpioides*. Here, we present the first record of *S. monospiculatus* parasitizing *K. scorpioides*, *Gorgoderina* sp. and *P. retusa* were reported for the first time in *P. geoffroanus*, and *M. tuberculata* represents a new host to *P. retusa* and *S. figueiredoi*." **21097.** Hushtan, K.V. (2018): The diversity of amphibiotic insects (Insecta: Ephemeroptera, Plecoptera, Odonata) of Latorica river basins ecosystems. Research and development of the State-owned research and development Center 34: 69-74. (in Ukrainian, with English summary) ["The taxonomic and eco-morphological diversity of amphibiotic insects in the ecosystems of the Latoritsa River basin was studied. If all 52 species of amphibiotic insects have been identified (32 species of Ephemeroptera, 7 species of stoneflies, 13 species of dragonflies). The main of the number and biomass of the community in the studied localities of the Latoritsa River basin is the families Baetidae and Heptageniidae. The rarity components of this region are investigated. The 3 types of Odonata, 5 types of Ephemeroptera and 3 types of Plecoptera larvae for Latoritsa river basin are discovered. The ecomorphological structure of dragonflies is represented by the following classes: rheophilic drifting and rheophilic velox larvae with spoonlike labium. The largest species diversity of the Ephemeroptera was recorded in 4 types of eco-morphs: siphonuroides (47% from species diversity), plane-plots (32%), larvae with "tusks" (12%) and "kryshkovoziabrovi" larvae (9%). Among the Plecoptera there are 3 dominant types: lithophilous cryptobionts (42%), phytophilic cryptobionts (31%) and cryptobionts of gaps (27%)." **21098.** Jiang, B.; Mikolajewski, D.J. (2018): Shift in predation regime mediates diversification of foraging behaviour in a dragonfly genus. *Ecological Entomology* 43: 525-533. (in English) ["1. Behavioural adaptations to avoid and evade

predators are common. Many studies have investigated population divergence in response to changes in predation regime within species, but studies exploring interspecific patterns are scant. Studies on interspecific divergence can infer common outcomes from evolutionary processes and highlight the role of environmental constraints in shaping species traits. 2. Species of the dragonfly genus *Leucorrhinia* underwent well-studied shifts from habitats being dominated by predatory fish (fish lakes) to habitat being dominated by predatory invertebrates (dragonfly lakes). This change in top predators resulted in a set of adaptive trait modifications in response to the different hunting styles of both predator types: whereas predatory fish actively search and pursue prey, invertebrate predator follow a sit-and-wait strategy, not pursuing prey. 3. Here it is shown that the habitat shift-related change in selection regime on larval *Leucorrhinia* caused species in dragonfly lakes to evolve increased larval foraging and activity, and results suggest that they lost the ability to recognise predatory fish. 4. The results of the present study highlight the impact of predators on behavioural trait diversification with habitat-specific predation regimes selecting for distinct behavioural expression." **21099.** Jiang, B. (2018): Predators promote trait diversification in prey. Ph.D. thesis, Dept of Biology, Chemistry and Pharmacy of Freie Universität Berlin: III, 132 pp. (in English) ["Predator-prey interactions have a major influence on species diversification. The performance and fitness of prey species are heavily dependent on their antipredator responses to specific predators. In nature, predators are distributed heterogeneously across different habitats. Because different predators vary in their predation strategies, a change in the top predators can dramatically alter preys' defensive traits. Larval *Leucorrhinia* ancestrally came from lakes dominated with predatory fish (fish lakes). However, they shifted their habitats from fish lakes into lakes with only large invertebrate predators (dragonfly lakes) several times. In this thesis, I examined a series of antipredator traits (burst-escape behavior related traits, behaviour, growth rate, ontogenetic pattern and morphological traits) in order to understand how different predation regimes drive prey trait diversification in European *Leucorrhinia* species. We found a clear diversification pattern in most antipredator traits. However, unique pattern of traits was also found in growth rate related physiological traits. Eventually, we got a full picture of antipredator traits in *Leucorrhinia* system. These research I have presented is critical for improving our understanding of adaptive trait plasticity and its widespread occurrence across species and community types. Moreover, the facts that the larval stage is restricted in its distribution and that the adults have a high dispersal ability make odonates as an important model bridging ecology and evolution. My results indicate that it might be possible to disentangle the forces behind natural selection (e.g. directional selection, stabilizing selection) by using *Leucorrhinia* species." **21100.** Kaulfuss, U.; Lee, D.E.; Wartho, J.-A.; Bowie, E.; Lindqvist, J.K.; Conran, J.C.; Bannister, J.M.; Mildenhall, D.C.; Kennedy, E.M.; Gorman, A.R. (2018): Geology and palaeontology of the Hindon Maar Complex: A Miocene terrestrial fossil Lagerstätte in southern New Zealand. *Palaeogeography, Palaeoclimatology, Palaeoecology* 500(1): 52-68. (in English)

["Highlights: • Hindon Maar Complex is a new mid-Miocene Fossil-Lagerstätte in New Zealand. • Anoxia in maar lakes allowed exquisite preservation of plant and animal fossils. • The biota is from a lake and *Nothofagus/podocarp*/mixed broadleaf forest ecosystem. • Fossils record high diversity at humid, warm Southern Hemisphere mid-latitudes. Abstract: This paper highlights the geology, biodiversity and palaeoecology of the Hindon Maar Complex, the second Miocene Konservat-Lagerstätte to be described from New Zealand. The Lagerstätte comprises four partly eroded maar-diatreme volcanoes, with three craters filled by biogenic and highly fossiliferous lacustrine sediments. The exceptionally well-preserved and diverse biota from the site is derived from a mid-latitude Southern Hemisphere lake-forest palaeoecosystem, including many fossil taxa not previously reported from the Southern Hemisphere. The most common macrofossils are leaves of *Nothofagus*, but the flora also includes conifers, cycads, monocots (such as *Ripogonum* and palms), together with Lauraceae, Myrtaceae and Araliaceae leaves and flowers. The small maar lakes were surrounded by *Nothofagus/podocarp*/mixed broadleaf forest growing under humid, warm temperate to subtropical conditions. The fossil fauna comprises insects in the orders Odonata, Hemiptera, Thysanoptera, Coleoptera, Diptera, Hymenoptera and Trichoptera, and the fish assemblage includes a non-migratory species of the Southern Hemisphere Galaxiidae (*Galaxiidae*) and a significant new record of the freshwater eel *Anguilla* (*Anguillidae*). The fossil assemblage also includes the first pre-Quaternary bird feathers from New Zealand and abundant coprolites derived from fish and volant birds, presumably waterfowl. Palynomorph analysis and a <sup>40</sup>Ar/<sup>39</sup>Ar age of 14.6 Ma obtained from basanite associated with the maar complex indicate that the Hindon Maar Complex is of mid-Miocene age (Langhian; New Zealand local stage: Lillburnian). It thus provides a new and unique perspective on Neogene terrestrial biodiversity and biogeography in the Australasian region, around the end of the mid-Miocene thermal optimum and prior to late Miocene–Pleistocene climate cooling episodes when many warm-temperate and subtropical forest components became extinct in New Zealand." **21101.** Kim, J.-S.; Lee, S.-D.; Kim, D.-P. (2018): The relationship between the dragonfly diversity and the environmental factors in the Juam wetland. *Korean Journal of Environment and Ecology* 32(1): 66-76. (in Korean, with English) ["This study surveyed the species and population of dragonflies in 20 study sites in the Junam wetland in May and July 2015 to investigate the relationship between the dragonflies and the inhabited environment. We measured the environmental factors such as the area of emergent plants, the area of floating and floating-leaved plants, the area of water surface, the area of water plants, and the nearby land-use type and analyzed the relationship to the dragonfly species, population, and diversity index. We found 757 dragonflies belonging to 21 species of 6 families. The area of floating and floating-leaved plants and the area of water surface affected the species diversity. The area of floating and floating-leaved plants and the area of surface water, in particular, showed the positive correlation with the species richness and the dominance value, respectively. The area of water surface showed the negative correlations with Shannon's diversity index and evenness. Among the type of surrounding land-uses, the dry fields and orchards showed significantly lower average species richness than wetlands. Among the species, *Cercion calamorum* and *Crocothemis*

servilia were positively correlated with floating and floating-leaved plants. *Cercion v-nigrum* and *Ephthalmia elegans* were positively correlated with the area of water surface, and *Ischnura asiatica* and *Ceragrion nipponicum* were negatively correlated. The recent uncontrolled proliferation of lotus colony in the Junam wetland is likely to affect greatly the species composition of dragonflies which have a close relationship with plant species." **21103.** Martínez-Lendeck, N.; Golab, M.J.; Osorio-Beristain, M.; Contreras-Garduño, J. (2018): Sexual signals reveal males' oxidative stress defenses: testing this hypothesis in an invertebrate. *Functional Ecology* 32(4): 937-947. (in English) ["1. The hypothesis that sexual traits reveal the oxidative stress resistance of their bearers has been widely tested in vertebrates but remains unexplored in invertebrates. Here, *Hetaerina americana* was used to test whether oxidative stress defenses are advertised by male wing spot size and color (a male sexual trait). To this end we asked (1) whether oxidative stress reduced survival, (2) whether wing spot size revealed males' antioxidant defenses, and (3) how wing spot size and color were affected by oxidative stress. 2. We elevated oxidative stress by injecting adult males with paraquat (a compound that favors the production of free radicals) and then examined how this affected male survival and wing spot size. We then related the expression of wing spot size to indicators of oxidative stress – H<sub>2</sub>O<sub>2</sub> and total Antioxidant Capacity (TAC), Super Oxide Dismutase (SOD) and Catalase (CAT) – in adult males (whose wing spot is fixed) injected with Paraquat (PQ). In teneral males, whose wing-spots are still forming, we compared wing-spot size, color (red and yellow chroma) and brightness in individuals injected with paraquat, or water as a control. 3. Oxidative stress reduced the survival of adult and teneral males. While the H<sub>2</sub>O<sub>2</sub> and TAC markers of antioxidant defenses were positively correlated with wing spot size, there was no correlation with CAT and a negative correlation with SOD. In teneral males, PQ increased the yellow chroma and brightness of wing spots, but did not affect spot size or red chroma. 4. Our results highlight the importance of measuring different markers as indicators of male oxidative stress defenses, and that the sexual signals of invertebrates may reveal the oxidative stress status of their bearers." **21104.** Nurminen, L.; Hellén, N.; Olin, M.; Tiainen, J.; Vinni, M.; Grönroos, M.; Estlander, S.; Horppila, J.; Rask, M. Lehtonen,

H. (2018): Fishing-induced changes in predation pressure by perch (*Perca fluviatilis*) regulate littoral benthic macroinvertebrate biomass, density, and community structure. *Aquatic Ecology* 52: 1-16. (in English) ["We aimed to study whether the varying changes in predation pressure by perch (*Perca fluviatilis*) reflect the biomass, density, and community structure of the benthic macroinvertebrates. Prey preference is size-dependent, and overall predation pressure is density dependent, and thus the size structure of the *P. fluviatilis* population should affect the structure of the macroinvertebrate community, and the population density of *P. fluviatilis* should reflect the overall density of benthic macroinvertebrates. We sampled the littoral benthic community in a boreal lake that had been divided into two parts that were subjected to two different fishing procedures during 2007–2012 period and analyzed the macroinvertebrate diet of fish. The benthic macroinvertebrate community reflected the predation pressure. Total macroinvertebrate biomass increased during the study period in the lake division with a non-size-selective fishing procedure (NSF), i.e., all invertivorous perch size-classes targeted, but decreased in the section with negatively size-selective fishing procedure (SSF), i.e., large invertivorous individuals = 16 cm were not targeted. This difference was a result of the increase in large-sized species, such as Odonata, for the NSF procedure and decrease in the SSF procedure. In contrast to total biomass, total macroinvertebrate density did not show a response to predator size structure but rather total macroinvertebrate density decreased with increasing fish density. The study demonstrates the effect of predation pressure of *P. fluviatilis* on benthic communities, thus highlighting the keystone predator role of the species in boreal lakes and gives more insight on the multiple effects of fish predation on littoral benthic communities." Oslo: 18 pp. (in Norwegian) [Google Translate: Summary / conclusion. (1) Gårdeemma nature reserve, where *O. cancellatum* was first discovered in Telemark, together with the nearby Hytterdøbukta, most likely constitutes a habitat with a stable population of the species. The stock in both bays seemed to be good at the time of the survey in 2018. (2) Other parts of Volls fjorden / Frierfjorden seem to be less suitable for *O. cancellatum*, possibly with the exception of the areas adjacent to Røraelva's outlet on the north side of Volls fjorden (but the species was not registered here on a slightly windy day in 2018). (3) Other investigated localities in both brackish water and fresh water seem to be unsuitable as breeding sites for the species, possibly with the exception of the groundwater areas in the innermost part of Fjærekielen. There is great uncertainty as to whether the two inland localities where the species has been proven may be relevant as breeding sites (only one of these was assessed in the field in 2018, as the other was not published at that time).] Address: BioFokus: Gaustadalléen 21, 0349 Oslo, Norway. **21106.** Pereira, J.M.; Otero, J.C. (2018): Nuevas citas de *Coenagrion mercuriale* (Charpentier, 1840) (Odonata, Coenagrionidae) en la Comunidad de Cantabria (norte de España) - New records of *Coenagrion mercuriale* (Charpentier, 1840) (Odonata, Coenagrionidae) in the Community of Cantabria (north of Spain). *Boletín de la Asociación española de Entomología* 42(1/2): 147-152. (in Spanish, with English caption)

["The selection of these localities is intended, on the one hand, to reach the greatest number of areas where the species is present and, on the other hand, to cover as representative a sample as possible of all the habitats favourable to the species. Eight localities have been selected, distributed among the Sites of Community Importance (SCI): Río Miera, Montaña Oriental, Dunas del Puntal and Estuario. Dunas del Puntal and Estuario del Miera, or in areas close to them. Sampling began in April and ended in August to cover most of their flight cycle. The methodology used is that proposed by TORRALBA-BURRIAL et al. (2012), consisting of 100 m longitudinal routes along the banks of the stream, pond, lagoon or river. The number of adults, pairs and clutches observed at a distance of up to 5 m along the sides of the route is assessed (15 min). (15 min). The visits were carried out on favourable days (sunny, temperature > 20 °C and between 11:00 h and 16:00 h) with a minimum fortnightly frequency, as weekly surveys can be complicated due to the long flight period of the species (TORRALBA-BURRIAL et al., 2012), which could generate errors in the census when counting the same individuals in different surveys. In addition, the average longevity of adults is usually 6-7 days (CORDERO-RIVERA & STOKS, 2008), which may also contribute to counting the same individuals. A total of 186 specimens of *C. mercuriale* were found in six of the eight localities sampled, representing six new populations for the Community of Cantabria. The localities with presence of the species were the following: (a) La Regata (huso 30T, 441510E-4803365N, Ceceñas, Medio Cudeyo, 39 m): 25.IV.2016, 3 ej.; 09.V.2016, 14 ej.; 25.V.2016, 7 ej.; 07.VI.2016, 8 ej.; 22.VI.2016, 8 ej.; 06.VII.2016, 3 ej. (2018): Contrasting patterns of macroinvertebrates inshore vs. offshore in a plateau eutrophic lake: Implications for lake management. *Limnologica* 70: 10-19. (in English) ["Worldwide there has been deterioration of lakeshore habitat and increasing eutrophication. These stresses have impacted littoral macroinvertebrate communities. However, bioassessment and rehabilitation have been largely carried out offshore, and the inshore macroinvertebrates have received less attention especially in shallow plateau lakes. In this study, we compared inshore and offshore macroinvertebrate communities in a shallow plateau lake, Lake Dianchi, China. The environmental parameters determining the distribution of macroinvertebrates were analyzed with partial redundancy analysis. Our results showed that macroinvertebrate communities differed significantly between inshore and offshore. Taxonomic richness was much higher inshore than offshore, due to higher habitat heterogeneity. By contrast, both density and biomass inshore were significantly lower than those of offshore. Generally, vegetation and substrate type were the key environmental parameters shaping macroinvertebrate communities. Eutrophication exerted great effect on offshore communities, while its impacts on inshore communities varied spatially. Shoreline degradation and seasonal eutrophication effects resulted in the limited density and biomass of inshore communities. Our results emphasized the significance of inshore habitats for macroinvertebrates in Lake Dianchi, and provided important implications for bioassessment and ecological rehabilitation in shallow lakes." **21112.** Patten, M.A.; Hjalmarson, E.A.; Smith-Patten, B.D.; Bried, J.T. (2019): Breeding thresholds in opportunistic Odonata records. *Ecological Indicators* 106, November 2019, 105460: 6 pp. (in English) ["Highlights: • Breeding status can be deduced from opportunistic data, including from citizen science efforts. • Predictors of breeding vary across taxonomic groups—one size does not fit all. • Female counts, as opposed to unsexed adults only, greatly reduces threshold estimates. • Recording behavior also tends to reduce thresholds. Abstract: Numerous interacting abiotic and biotic factors shape an organism's spatial distribution, and these factors vary spatially and temporally, such that habitat used for breeding may differ from habitat used at other times of the life cycle. We address this complex issue in the context of citizen science and opportunistic species occurrence records, a valuable data source for biogeography and conservation. We focus on the insect order Odonata, the dragonflies and damselflies, which as adults are popular in citizen science programs. Our goal was to devise a means to estimate with high confidence whether a site supports a breeding population if only opportunistic data are available. Our approach fitted logistic curves from occupancy models of observations of teneral (newly emerged adults that cannot yet disperse from a natal site) against counts of all adults, adult females only, and incidence of breeding behaviors (ovipositing, mate guarding, tandem pairs). Models included median body size and abundance class as covariates of detectability. We subjected logistic curves to a Bayesian two-segment piecewise regression to obtain best estimates of the threshold (with associated credible intervals as an estimate of uncertainty) to assess if a given predictor (e.g., adult count) or combination of predictors was associated with breeding occurrence. We found that no single threshold fit all odonates: thresholds of varying precision were identified for the suborders (dragonflies, damselflies) and for families and select genera in each suborder. Counts of females greatly reduced the required threshold, whereas breeding behavior data reduced the threshold in some cases. Our study shows it is possible to identify breeding occurrences in opportunistic adult Odonata records. It also highlights how citizen scientists should record not only a sound species list with rudimentary counts of adults but also note the sex and breeding behavior. The identification of breeding occurrences in extensive opportunistic data is pertinent to understanding species' distributions and habitat requirements along with their ecological sensitivity and value as bioindicators." **21115.** Staentzel, C.; Combroux, I.; Barillier, A.; Grac, C.; Chanez, E.; Beisel, J.-N. (2019): Effects of a river restoration project along the Old Rhine River (France-Germany): Response of macroinvertebrate communities. *Ecological Engineering* 127: 114-124. (in English) ["Highlights: • New mesohabitats were characterized by low flow velocity and fine substrates. • The gain observed on the whole study site favoured burrowing taxa. • Inter-annual analysis showed a decrease in invasive populations, across all sections. • The sustainability of ecological effects is highly dependent of groynes maintenance. The rise of restoration projects on large rivers is a response to the increasing human-induced pressures on these ecosystems. Despite this, there is a relative lack of data documenting restoration success using macroinvertebrate communities in such environments, with those existing frequently producing contrasting results. Here, we examined post-restoration responses of macroinvertebrates following a unique experimental restoration approach based on controlled bank erosion and artificial groyne implementation, initiated in 2013 on the Old Rhine River (France-Germany). We investigated how macroinvertebrate communities have responded to restoration-induced variations in three main abiotic parameters, i.e. water depth, flow velocity and substrate type, by comparing the restored section with unrestored ones. The Eco-hydro-morphological index (EHMID), a modified version of a hydro-morphological diversity index, showed a gain in mesohabitat heterogeneity along the whole site. Newly created mesohabitats with low flow velocity and finer substrate were dissimilar to those along the rest of the Old Rhine channel, favouring burrowing taxa such as Odonata. The presence of such insect larvae was related to the post-restoration emergence of typical alluvial terrestrial-aquatic border connectivity, and the rise in macrophytes over time. On the whole site, changes in composition or in functional profile diversity were highly related to the high degree of mesohabitat heterogeneity from the restored section, which would persist as long as groynes remain. The main inter-annual effect concerned the decrease in invasive

taxa abundance that also varied according to any changes in fluvial forms. Our findings confirmed that macroinvertebrate responses are highly influenced by hydrological events and are dependent on the study-scale monitoring, clearly putting forward fine-scale hydromorphological gradients. Biological results from this restoration project should approach those obtained in smaller rivers restored using deflectors, suggesting a potential application of the hydraulic law of similarities. However, the accuracy of biological prediction using said application is limited by the distance from source populations, biological invasions and internal river dynamics.... Among new taxa observed in the restored section, we observed *Calopteryx splendens*, *G. vulgatisimus*, *Onychogomphus* sp., *Platycnemis* sp., and *Pyrrhosoma nymphula*. However, only a weak correlation was observed between richness in Odonata ( $R^2=0.22$ ,  $p = 0.005$ ) and the first NMDS axis, though just a few individuals ( $n < 10$ ) were recorded during campaigns apart from 2017 where 73 individuals were found in the restored section compared to UP ( $n=30$ ) and DOWN ( $n=31$ ) sections." ## 2020

**21116.** Cranston, J. (2020): Drivers, consequences and perceptions of newly arriving range-shifters in the United Kingdom. PhD thesis, Dept Biological Sciences: 216 pp. (in English) ["Species distributions are rapidly altering in the 21st century. Climate change and other anthropogenic effects threaten historic ranges but also open up new regions for expansion. Distributional changes will create novel biotic interactions that may significantly affect ecosystems, and humanity, both positively and negatively. Range-shifters create conservation conundrums, which may require us to balance the conservation value of newly arriving species against their impacts on existing biodiversity. To tackle these conundrums we will have to understand why and how species are moving, be able to make predictions of what potential effects may be felt in the new range and recognise how species are perceived when they arrive there. APPROACHES: I explore three aspects of species redistribution: processes, consequences, and perceptions. To better understand the redistribution process, I investigate the importance of climate, habitat, and proximity to source populations in predicting 14 range-shifting birds' distributions in Britain. I explore consequences by estimating effects of a range-shifting damselfly on UK Odonata with dynamic multispecies occupancy (DMSO) models. Finally, I explore perceptions by surveying UK wildlife recorders' attitudes towards range-shifting species and their management. RESULTS: I found that climate did not predict most analysed range-shifters' British distributions effectively. Despite being comparatively better, neither habitat nor distance from European breeding sites were good absolute predictors. Counter-intuitively, our DMSO model predicted that 15/17 resident dragonflies were more likely to persist at sites where the range-shifting damselfly established. Survey responses revealed that recorders opposed efforts to either control or support range-shifters, instead favouring non-intervention. IMPLICATIONS: The poor predictive power of climate suggests that we should explicitly study the full potential suite of range-shift processes, including biotic interactions and constraints on species movement. The absence of a negative association between the range-shifting damselfly and most Odonata species should be welcomed, but cautiously as other factors (e.g. habitat) may confound the range-shifters' effect.

Recorders' averseness to interventions suggests that ecological research focused on the feasibility of both assisted colonisation and range-shifter threat should also seek to understand social contexts for successful conservation. Integrating these findings, I argue that we should use rapidly growing ecological datasets to not just detect but to test and refine theories of range-shift. Future model refinement alongside fuller understanding of stakeholder perspectives will help enable equitable – and ecologically beneficial – range-shift management." (Author)] Address: Cranston, J., Centre for Ecology & Conservation, Univ. of Exeter, Penryn Campus, Penryn, UK. <https://ore.exeter.ac.uk/repository/bitstream/handle/10871/126808/CranstonJ.pdf?sequence=2&isAllowed=y>

**21117.** de Pennart, A.; Matthews, P.G.D. (2020): The bimodal gas exchange strategies of dragonfly nymphs across development. *Journal of Insect Physiology* 120, January 2020, 103982: (in English) ["Highlights: • Aeshnid and libellulid dragonfly nymphs can breathe both water and air as late final instars. • They develop functional mesothoracic spiracles preceding metamorphosis. • Gas exchange is partitioned between air and water simultaneously when the nymph is half submerged. • Aeshnid nymphs of all instars use their rectal gill to breathe air in response to aquatic hypoxia. Abstract: Dragonfly nymphs are aquatic and breathe water using a rectal gill. However, it has long been known that the nymphs of many species appear to possess the ability to breathe air, either during their final instar when they leave the water prior to metamorphosis, or during periods of aquatic hypoxia. The aerial gas exchange associated with these activities has not been quantified. This study used flow-through respirometry to measure the rate of aerial CO<sub>2</sub> release (VCO<sub>2</sub>) of dragonfly nymphs as a proxy for their aerial gas exchange, both across development and in response to progressive aquatic hypoxia. It examined a total of four species from two families (Libellulidae, Aeshnidae). In both families, the late-final instar nymphs developed functional mesothoracic spiracles, allowing them to breathe air by positioning their head and thorax above the water's surface. While breathing air in this position, the nymphs could also ventilate their submerged rectal gill. Thus, during bimodal gas exchange in normoxic water, it was calculated that aeshnid nymphs expelled 39 % of their respiratory CO<sub>2</sub> into the air through their spiracles, while libellulid nymphs expelled 56 % into the air. Decreasing the aquatic PO<sub>2</sub> to 2.5 kPa and then below 1 kPa increased the proportion of respiratory CO<sub>2</sub> expelled into the air from 69 % to ~100 %, respectively. Thus, bimodally breathing late-final nymphs can vary how they partition gas exchange between their spiracles and their gill depending on aquatic PO<sub>2</sub>. Aeshnid nymphs of all developmental stages were also found to use their rectal gill as an air-breathing organ; pre-final nymphs performing 'surface skimming' while late final nymphs aspirated air bubbles directly into their gill's branchial basket. Mass-specific rates of aerial V CO<sub>2</sub> also increased as the nymphs approached metamorphosis. These findings indicate that aeshnid nymphs are capable of accessing aerial O<sub>2</sub> across development using their rectal gill as an air breathing organ, while the aquatic nymphs of both aeshnid and libellulid dragonflies undergo a progressive shift towards using the atmosphere for respiration as they approach metamorphosis." **21118.** Góral, N. (2020): Odonata in an human-engineered world: Potential and threats. In: H.A. KRETEK (red). [Implementation of the idea of the European Green Deal on the

basis of the social market economy as a determinant of management in the implementation of the assumptions of sustainable development]. Państwowa Wyższa Szkoła Zawodowa w Raciborzu, Racibórz: 151-160. (in English, with Polish summary) ["The article summarizes the role and status of Odonata in the world of growing anthropopressure. Human activity contributes to degradation of habitats, posing a threat for some Odonata species. Some artificial elements in environment and anthropogenic water reservoirs might act like ecological traps. Natural water bodies often vanish or periodically dry out due to climate change. Many restoration methods are designed to bring back the environment to its natural state. On the other hands, artificial and astatic water bodies may create refuges for pioneer species occurring on highly-disturbed sites. Some forms of human activity (like traditional fish farming) may be good for maintenance of mosaic of diverse microhabitats supporting species with different ecological niches. New restoration methods should therefore rely on thorough examination of ecological requirements of a target species." **21119.** Kuznetsova, V.G.; Golub, N.V. (2020): A checklist of chromosome numbers and a review of karyotype variation in Odonata of the world. *CompCytogen* 14(4): 501-540. (in English) ["The ancient insect order Odonata is divided into three suborders: Anisoptera and Zygoptera with approximately 3000 species worldwide each, and Anisozygoptera with only four extant species in the relict family Epiophlebiidae. An updated list of Odonata species studied regarding chromosome number, sex chromosome mechanism and the occurrence of m-chromosomes (= microchromosomes) is given. Karyotypes of 607 species (198 genera, 23 families), covering approximately 10% of described species, are reported: 423 species (125 genera, 8 families) of the Anisoptera, 184 species (72 genera, 14 families) of the Zygoptera, and one species of the Anisozygoptera. Among the Odonata, sex determination mechanisms in males can be of X(0), XY and X1X2Y types, and diploid chromosome numbers can vary from 6 to 41, with a clear mode at  $2n = 25(60\%)$  and two more local modes at  $2n = 27(21\%)$  and  $2n = 23(13\%)$ . The karyotype  $2n = 25(24A + X)$  is found in each of the three suborders and is the most typical (modal) in many families, including the best-covered Libellulidae, Corduliidae (Anisoptera), Lestidae, Calopterygidae, and Platycnemididae (Zygoptera). This chromosome set is considered ancestral for the Odonata in general. Chromosome rearrangements, among which fusions and fissions most likely predominated, led to independent origins of similar karyotypes within different phylogenetic lineages of the order. The karyotype  $2n = 27(26A + X)$  prevails in Aeshnidae and Coenagrionidae, whereas the karyotype  $2n = 23(22A + X)$  is modal in Gomphidae and Chlorocyphidae, in both pairs of families ..."] (Authors)] Address: Kuznetsova, Valentina, Dept of Karyosystematics, Zool. Inst., Russian Acad. Sci., Universitetskaya emb. 1, St. Petersburg 199034, Russia. E-mail: valentina\_kuznetsova@yahoo.com

**21122.** O'Malley, Z.G.; Compson, Z.G.; Orlofske, J.M.; Baird, D.J.; Curry, R.A.; Monk, W.A. (2020): Riparian and in-channel habitat properties linked to dragonfly emergence. *Scientific Reports* 10:17665: 12 pp. (in English) ["In freshwater ecosystems, habitat alteration contributes directly to biodiversity loss. Dragonflies are sentinel species that are key invertebrate predators in both aquatic (as larvae) and terrestrial ecosystems (as adults). Understanding the habitat factors affecting dragonfly emergence can inform management practices to conserve habitats supporting these species and the functions they perform. Transitioning from larvae to adults, dragonflies leave behind larval exoskeletons (exuviae), which reveal information about the emergent population without the need for sacrificing living organisms. Capitalizing on Atlantic Canada's largest freshwater wetland, the Grand Lake Meadows (GLM) and the associated Saint John/Wolastoq River (SJWR), we studied the spatial (i.e., across the mainstem, tributary, and wetland sites) and temporal (across 3 years) variation in assemblages of emergent dragonflies (Anisoptera) and assessed the relative contribution of aquatic and terrestrial factors structuring these assemblages. The GLM complex, including the lotic SJWR and its tributaries and associated lentic wetlands, provided a range of riparian and aquatic habitat variability ideal for studying dragonfly emergence patterns across a relatively homogenous climatic region. Emergent dragonfly responses were associated with spatial, but not temporal, variation. Additionally, dragonfly communities were associated with both aquatic and terrestrial factors, while diversity was primarily associated with terrestrial factors. Specific terrestrial factors associated with the emergence of the dragonfly community included canopy cover and slope, while aquatic factors included water temperature, dissolved oxygen, and baseflow. Our results indicate that management of river habitats for dragonfly conservation should incorporate riparian habitat protection while maintaining aquatic habitat and habitat quality." **21123.** Rebecca, G.W. (2020): Merlin breeding season diet on Deeside, North-east Scotland, in relation to area and land-use change. *Scottish Birds* 40(3): 195-205. (in English)

["As part of a study of Merlin breeding ecology in North-east Scotland, diet was assessed from prey remains found at occupied breeding areas during 1980–2003. Small birds weighing 20–80 grams predominated, with five species - Meadow Pipit, Wheatear, Starling, Chaffinch and Skylark - making up around 80% of numbers and biomass (collective weight) from 10,657 bird items. A further nine bird species each accounted for at least 1% of numbers or biomass. In total, 59 bird species were recorded as prey, ... In addition, 547 moths and 21 other items were found, but these were unimportant in biomass terms. ... A total of 11,225 prey items was recorded during 1980–2003 (Table 2). This comprised 10,657 birds of 59 species, 547 moths, almost all from two species, and 21 other items covering small mammals, butterflies, dragonflies, ground beetles and a frog." **21124.** Saxton, N.A.; Powell, G.S.; Bybee, S.M. (2020): Prevalence of leg regeneration in damselflies reevaluated: A case study in Coenagrionidae. *Arthropod Structure & Development* Volume 59, November 2020, 100995: 6 pp. (in English) ["Highlights: • Odonates exhibit effective leg regeneration abilities that result in a fully functional limb. Prevalence of leg regeneration in Vanuatu basis reported as much higher than previously understood. Sex and species do not explain the extent of regeneration suggesting environmental factors may play a larger role. Abstract: The leg regeneration capabilities of damselflies are understudied. Here we present the first data of regenerated limbs across a genus of damselfly based on adult specimens collected in the field to illustrate the prevalence of limb loss among nymphs. We show that this phenomenon is much more prevalent than previously thought, as 42% of individuals were found with regenerated limbs. Furthermore, we test for patterns within these data to begin to unravel the potential causes of limb loss in nymphal damselflies, showing that intrinsic factors such as sex and species cannot explain the patterns of limb loss pointing to environmental factors as the probable cause. We argue that Odonata limb regeneration provides a potentially unique perspective into the nymphal stage of these organisms." **21125.** Souza, Y. C. Mossioli de (2020): Influência do predador sobre o uso do espaço e a atividade por girinos bentônicos e nectônicos - Predator influence over space use and activity by benthic and nektonic tadpoles. MSc. thesis, Universidade Estadual Paulista (UNESP): 66 pp. (in Portuguese, with English summary) ["Interactions between species influence community structure, population dynamics, morphology, physiology and species' behavior. Mortality is a direct effect caused by the interaction with a predator, but even the simple presence of predators can lead to other indirect effects such as alterations on prey's behavior. In aquatic environments, prey may detect predation risk by visual, mechanical, and chemical cues. When detecting a predator, the prey can use strategies to escape predation such as shoal formation, changes on habitat use pattern, and reduction on swimming activity. Despite decreasing predation rates, the antipredatory strategies have costs for the prey and set up a trade-off. For example, the same behavior that raises the prey's chance to escape from a predator, decreases its foraging activity, leading thus to a reduction in the prey's growth and survivorship. Among tadpoles, morphological and physiological aspects are important to determine water column occupation. But could predation also be

an important pressure that determines the way tadpoles occupy the water column? Understanding how predation influences tadpoles' behavior may elucidate populational dynamics and community structuring aspects, as well as the mechanisms that regulate anuran evolutionary patterns. In this sense, this dissertation presents a study, in a manuscript form, that tested experimentally the influence of an aquatic predator (Odonata water nymph; *Micrathyrta* sp.) on the use of space, activity and foraging behavior of benthic (*Physalaemus nattereri*) and nektonic (*Scinax fuscovarius*) tadpoles." **21128.** Arimoro, F.O.; Abubakar, M.D.; Obi-Iyeye, G.E.; Keke, U.N. (2021): Achieving sustainable river water quality for rural dwellers by prioritizing the conservation of macroinvertebrates biodiversity in two Afrotropical streams. *Environmental and Sustainability Indicators* 28: 53444-53457. (in English) ["Motivated by the UN Global Sustainable Development Goals on achieving sustainable freshwater ecosystem, this study was undertaken to examine two important water bodies in north central Nigeria (Baka Jeba and Penyan Rivers) protected locally by the rural community and serving as sources of water supply, for biodiversity

conservation and protection. The status of macroinvertebrate biodiversity as important variable in assessing the environmental health and suitability of the water quality of the rivers was evaluated for a period of 8 months, between February and September, 2017 using standard methods. The mean values of Physicochemical variables recorded during the study period revealed that the nutrient loads (nitrites and phosphates levels) was relatively low for both streams as well as conductivity levels ( $<82\mu\text{S}/\text{cm}$ ). Dissolved oxygen values indicated that the water bodies were well aerated with values ranging between 5.21 and 7.83mg/l in both the dry and wet seasons. A total of 65 invertebrate taxa from 34 families in 10 orders were recorded during the study, dominated by aquatic insects with a few representation of decapods and gastropods, and Arachnids were sporadically present. The overall abundance of macroinvertebrates was not significantly different ( $p > 0.05$ ) among the sampling stations with number of individuals caught ranging between 1208 and 1728 per station. Of the major faunal groups, Ephemeroptera contributed the highest percentage of individuals ( $>29\%$ ) in both streams. Generally, Beka Jeba Stream contained more diverse taxa of macroinvertebrates compared to Penyan Stream. The Ephemeroptera-Trichoptera-Odonata (ETO) were the dominant groups collected in the river systems indicating fairly good water quality conditions. The Chironomids and other tolerant macroinvertebrate larvae were only sporadically present. Overall, the values of the physical and chemical parameters (low BOD, low nutrient levels and high dissolved oxygen) obtained for the two rivers and the wide diversity of sensitive macroinvertebrates portends the water body to be of good quality. Therefore utmost care should be taken to conserve and preserve these species as indicators of water quality by reducing the impact of key drivers of declines in macroinvertebrate biodiversity, including habitat degradation and pollution." (Authors) Taxa are treated at genus levels, and for Odonata some taxa are questionable (eg. *Cordulia* sp., *Calopteryx* sp.).] Address: Arimoro, F.O., Applied Hydrobiology Unit, Dept Animal Biol., Federal Univ. Tech., P.M.B, Minna 65, Nigeria. Email: francisarimoro@gmail.com

**21129.** Bertoli, M.; Piazza, G.; Pastorino, P.; Prearo, M.; Cozzoli, F.; Vignes, F.; Basset, A.; Pizzul, E. (2021): Macroinvertebrate energy densities and ecological status in freshwater watercourses (Friuli Venezia-Giulia, Northeast Italy). *Aquatic Ecology* 55: 501-518. (in English) ["The present study provides energy density (ED) data and models for four macroinvertebrate genera inhabiting freshwater lotic environments (*Baetis*, *Hydropsyche*, *Rhyacophila*, and *Onychogomphus*). Samples were collected in the hydrological freshwater network of the Region Friuli Venezia Giulia within different watercourse types (creeks, streams, rivers channels, and ditches), and energy density was directly measured using an adiabatic bomb calorimeter. Measured ED expressed in  $\text{Joule g}^{-1}$  wet weight was strongly and positively correlated with percentage of dry weight (DW%) for all genera investigated ( $r^2 > 0.9504$ ), allowing to obtain genus-specific predictive models based on the relationship between ED and DW%. Models were validated and showed good predictive power, as 90th percentile of observed percentage errors ranged between 4.23% and 5.18% while medians ranged between 1.32% and 2.83%. ANCOVA disclosed significant differences between the models, as those for *Rhyacophila* and *Onychogomphus* differed significantly from the others. The empirical models were used to build a dataset of estimated energy density, to assess the relationship between energy density and ecological status of the monitored riverine systems, assessed in

compliance with European and Italian law by the application of four different ecological indices (ICMi, RQE, IBMR, STAR, ICMi, and LIMeco). Information regarding ED levels for freshwater macrobenthic invertebrates is still neglected in biomonitoring programs, but it could be useful to interpret some ecological situations in the context of ecological status assessment, especially in relation to the trophic condition of the investigated riverine systems." **21130.** Borges, L.R.; Barbosa, M.S.; Alves Carneiro, M.A.; Santos, J.C. (2021): Habitat integrity drives Odonata diversity in Eucalyptus-dominate. *Environmental Monitoring and Assessment* volume 193, Article number: 12 (2021): 14 pp. (in English) ["Silviculture can be considered a sustainable alternative to the extraction of wood from natural forests in Brazil. However, the high demand for wood products has decreased the area of natural Cerrado due to land transformation for forestry activities. This transformation could lead to the loss of species, including insects that cannot tolerate the new environment dominated by exotic plant species. This study aims to evaluate whether the presence of an extensive Eucalyptus silviculture in the Brazilian Cerrado decreases the integrity of nearby riparian environments and, consequently, decreases odonate diversity. Thirteen ponds were selected in patches of Cerrado embedded within a matrix of Eucalyptus silviculture in order to assess habitat integrity of ponds and their riparian zones and collect adult odonates. The physical integrity of the study sites was measured using a Habitat Integrity Index (HII) designed to determine the degree of conservation of aquatic environments. The HII of the study sites varied between 0.44 and 0.80, indicating differences in the degree of conservation. Therefore, a positive relationship was found between odonate richness and abundance and HII, and between the abundance of zygopterans and anisopterans and HII. These findings may be due to the fact that these insects are adapted to the natural resources maintained at the most conserved habitats, and which were lost in degraded riparian zones, such as the presence of aquatic vegetation and a diversity of organic debris on pond banks. We conclude that the conversion of natural areas to Eucalyptus silviculture can alter the integrity of nearby riparian zones and, consequently, odonate diversity. ... The collected odonates represented six families, 21 genera and 36 species. Some species with restricted distributions were found at study sites with higher HII values (S3, S5, S8, and S9), such as *Erythrodiplax ana*, *Acanthagrion gracile*, *Cyanallagma nigrinuchale*, *Oxyagrion santosi*, *Oxyagrion terminale*, and *Tigriagrion* sp. nov (Table 2). Others only appeared at areas with lower HII values (S4, S11, and S13), as *Ischnura fluviatilis*, *Homeoura chelifera*, and *Mnesarete pudica* showing that habitats with different degrees of conservation can present different species composition." assembly, sex-biased gene expression and dosage compensation in the damselfly *Ischnura elegans*. *Genomics* 113(4): 1828-1837. (in English) ["The evolution of sex chromosomes, and patterns of sex-biased gene expression and dosage compensation, are poorly known among early winged insects such as odonates. We assembled and annotated the genome of *Ischnura elegans* (blue-tailed damselfly), which, like other odonates, has a male-hemigametic sex-determining system (X0 males, XX females). By identifying X-linked genes in *I. elegans* and their orthologs in other insect genomes, we found homologies between the X chromosome in odonates and chromosomes of other orders, including the X chromosome in Coleoptera. Next, we showed balanced expression of X-linked genes between sexes in adult *I. elegans*, i.e. evidence of dosage compensation. Finally, among the genes in the sex-determining pathway only fruitless was found to be X-linked, while only doublesex showed sex-biased expression. This study reveals partly conserved sex chromosome synteny and independent evolution of dosage compensation among insect orders separated by several hundred million years of evolutionary history." **21133.** Danflous, S. (2021): Rapport d'étude Inventaire & Suivi des Odonates d'intérêt communautaire sur le Barrage du Pinet – résultats 2021. EDF, voie du TOEC BP 57611 - 31076 - Toulouse cedex 3, France: 57 pp. (in French) ["5. Conclusion: Estimated impact of work on odonates: A lowering of the water level by 3 metres is planned as part of the work scheduled for 2023 on the Pinet reservoir. The targeted period would be weeks 21 to 23, i.e. between 23 May and 12 June. In the continuity of the previous report (Danflous, 2020), the above discussion elements aimed to try to understand the link between the local stationary conditions, the hydroelectric dam and the state of the current populations of *Macromia splendens*. The elements discussed above seem important for the understanding of the expected impact of the planned emptying of the dam in 2023. *Macromia splendens*: The inventories carried out in 2020 and 2021 on the Pinet dam show that the emptying of the dam by 7m in 2019 did not have a significant impact on *M. splendens*, which is the main local issue still present. This lowering took place at the same time as the one planned for 2023. It therefore appears that the works planned for 2023 should not have a massive impact on the population of *M. splendens* at the dam. This seems consistent with the late cycle of emergence at the site. However, precautions are necessary in view of the strong responsibility of this population, whose numbers are very important at the Deptal level, if not more. Monitoring The monitoring of this species begun in 2020 should be continued in order to specify the population numbers, its local dynamics and phenology in particular. This monitoring should therefore be repeated in 2022 (before the works), as well as in 2023 (year of the works) and in 2024 (post works). In view of the phenology observed on the site, it seems important to carry out three passes in June, July and August. The June pass during the 2022 campaign will be important for estimating the proportion of the population potentially more directly impacted by the works. The issues mentioned above (p.49) will have to be taken into account during the monitoring in order to improve our local and global understanding of the biology of this protected dragonfly. Sensitivity zone A mapping of the sensitivity zones on the reservoir was envisaged before the works, in order to put in place targeted measures to mitigate the effects of the lowering of the levels. This mapping is superfluous following

the results of the 2021 inventory. The protected species *M. splendens* breeds throughout the reservoir area. Only global reduction measures can therefore be considered. Reduction of the impact of the works Concerning the emptying in 2023, we recommend the following measures: \* a slow lowering of the water level, as slow as possible. This will facilitate the displacement of *Macromia* larvae, which would then be in the water level when the lowering takes place. \* Regular passages along the banks between the lowering phases to carry out "safeguard fishing" seems to be the most effective way of reducing possible larval mortality induced by the emptying. This action would consist of releasing directly into the water on the spot the dragonfly larvae, in particular *Macromia*, which would have been surprised by the lowering of the water and would have remained dry on the banks/partitions. This intervention would be superfluous if the larvae were observed descending to take refuge in the water or rising to emerge. Given the vast area to be covered for this action, it is recommended that priority be given to the known areas of highest density, i.e. Bouchouns, Grès and Nauq, as well as the left bank. We now consider that *Oxygastra curtisii* and *Gomphus graslinii* have disappeared from the same site, probably due to the cumulative effect of hydroelectric activity on the Tam valley. This does not appear to be reversible in the present state of knowledge." (2021): Evolutionary history and divergence times of Odonata (dragonflies and damselflies) revealed through transcriptomics. *iScience* 24(11), 103324: 34 pp. (in English) ["Highlights: • Evolutionary relationships of Odonata are unraveled using transcriptomes. Earliest flying insects – dragonflies, damselflies, and their extinct ancient relatives – date back to Permian period. Both extant Odonata started diverging in the Triassic period. Summary: Odonata are among the earliest flying insects with extant representatives. However, unravelling details of their long evolutionary history, such as egg laying (oviposition) strategies, is impeded by unresolved phylogenetic relationships particularly in damselflies. Here we present a transcriptome-based phylogenetic reconstruction of Odonata, analyzing 2,980 protein-coding genes in 105 species representing nearly all the order's families. All damselfly and most dragonfly families are recovered as monophyletic. Our data suggest a sister relationship between dragonfly families of Gomphidae and Petaluridae. According to our divergence times estimates, both crown-Zygoptera and –Anisoptera arose during the late Triassic. Egg laying with a reduced

ovipositor apparently evolved in dragonflies during the late Jurassic/early Cretaceous. Lastly, we also test the impact of fossil choice and placement particularly of the extinct fossil species, †Triasolestodes asiaticus, and †Proterogomphus reneateae on divergence time estimates. We find placement of †Proterogomphus reneateae to be much more impactful than †Triasolestodes asiaticus." (Authors)] Address: Kohli, M., Dept Invertebrate Zool., American Mus. **21141.** Kundanati, L.; Das, P.; Pugno, N.M. (2021): Prey capturing dynamics and nanomechanically graded cutting apparatus of dragonfly nymph. *Materials* 14(3), 559; <https://doi.org/10.3390/ma14030559>: 13 pp. (in English) ["Aquatic predatory insects, like the nymphs of a dragonfly, use rapid movements to catch their prey and it presents challenges in terms of movements due to drag forces. Dragonfly nymphs are known to be voracious predators with structures and movements that are yet to be fully understood. Thus, we examine two main mouthparts of *Pantala flavescens* that are used in prey capturing and cutting the prey. To observe and analyze the preying mechanism under water, we used high-speed photography and, electron microscopy. The morphological details suggest that the prey-capturing labium is a complex grasping mechanism with additional sensory organs that serve some functionality. The time taken for the protraction and retraction of labium during prey capture was estimated to be  $187 \pm 54$  ms, suggesting that these nymphs have a rapid prey mechanism. The Young's modulus and hardness of the mandibles were estimated to be  $9.1 \pm 1.9$  GPa and  $0.85 \pm 0.13$  GPa, respectively. Such mechanical properties of the mandibles make them hard tools that can cut into the exoskeleton of the prey and also resistant to wear. Thus, studying such mechanisms with their sensory capabilities provides a unique opportunity to design and develop bio-inspired underwater deployable mechanisms." **21142.** Li, B.; Su, Q.; Yu, L.; Liu, W.; Dong, S.; Ding, S.; Zhang, M.; Du, G.; Xu, B. (2021): Biomimetic PVDF/LLTO composite polymer electrolyte enables excellent interface contact and enhanced ionic conductivity. *Applied Surface Science* 541 1 March 2021, 148434: (in English) ["Highlights: • The bio-inspired PVDF/LLTO-CPEs are fabricated through simple evaporation strategy. • The special design creates cellular structures on the surface of PVDF/LLTO-CPE. • The ultrathin PVDF/LLTO-CPE shows a high mechanical strength of 10 Mpa. • The full battery delivers an excellent performance under folding and bending states. Abstract: Composite polymer electrolyte (CPE) with enhanced ionic conductivity, excellent flexibility and strong strength are urgently required for all-solid-state lithium metal batteries (LMBs). Inspired by the dragonfly wings that are super-lightweight and ultrathin but have excellent stability when subject to bending and twisting during flapping, we have constructed Li<sub>0.35</sub>La<sub>0.55</sub>TiO<sub>3</sub> (LLTO) nanowires-filled polyvinylidene fluoride (PVDF). In our design, the PVDF is used to construct the ultrathin membrane, the 1D LLTO nanowires are acted as the veins to give rise to a high mechanical strength of 10 Mpa. The special design creates cellular surface of PVDF/LLTO-CPE, which guarantees the excellent flexibility as well as a good interface contact between CPE and Li anode. When evaluated as electrolyte for LiFePO<sub>4</sub> | Li battery, the PVDF/LLTO-CPEs can suppress Li dendrites growth, and thus presents an excellent cycling stability of 140 mAh g<sup>-1</sup> after 200 cycles. Moreover, the flexible LiFePO<sub>4</sub> | PVDF/LLTO-CPE | Li<sub>4</sub>Ti<sub>5</sub>O<sub>12</sub> pouch cell delivers a satisfactory rate performance and cycle stability under folding and bending states. The excellent performances are attributed to the unique cellular structure and super mechanical strength of biomimetic PVDF/LLTO-CPE. All results show the PVDF/LLTO-CPE is a promising solid-state electrolyte for flexible electronic devices." (Authors)] Address: Li, B., School of Materials Science & Engineering, Shaanxi Univ. **21143.** Mafuwe, K.; Broadley, S.; Moyo, S. (2021): Use of maximum entropy (Maxent) niche modelling to predict the occurrence of threatened freshwater species in a biodiversity hotspot of Zimbabwe. *African Journal of Ecology* 60(3): 557-565. (in English) ["Globally, freshwater species are under threat from human mediated stressors. Therefore, there is an urgent need for methods to estimate population and species occurrences for conservation purposes. Here, we used a predictive species distribution model to determine the occurrence of three endangered species (*Amietia inyangae*, *Chlorolestes elegans* and *Strongylopus rhodesianus*) in Southern Africa (Eastern Highlands of Zimbabwe). The study revealed that the probability of occurrences for the three species increase with an increase in elevation and annual precipitation and decrease with an increase in annual mean temperature. Our results indicated that the highest probability of occurrences for *A. inyangae*, *C. elegans* and *S. rhodesianus* is in the Nyanga, Stapleford and Chimanimani highland areas, with some probabilities of occurrence falling outside protected areas. Our findings suggest that the areas covered by protected areas may need to be reevaluated. Our findings will be useful for managing threatened species." **21144.** Marinissen, J.; de Vries, H. (2021): Het gedrag van

de groene glazenmaker. *Vlinders* 1/2021: 19-21. (in Dutch) [ groene glazenmaker = *Aeshna viridis*. "Overall results Much of the behaviour observed appeared to be linked to a landscape element. Different elements were distinguished: short-cut grassland ('Mono grass'), strip with grasses and rushes ('Multi Grass'), water, reed, crabgrass, forest, bushes and maize. The frequency with which behaviour occurred at different landscape elements varied. The following were evident at all four sites: - Most observations of green glassmakers were made around ditches with crabweed, i.e. close to the breeding site (e.g. Figures 1 and 3). - The high vegetation edges and reeds along the canals were mainly used for resting (shown in figures 2 and 4 in the 'Multi Grass' category). - Hunting was mainly over the cut grasses, by both males and females. - Males seemed to have a preference for hunting outside their demarcated territory and then picking up their patrol above the crabgrass again. - Males mainly showed territorial behaviour above water and crab beds, where females could also be expected. - Females were depositing eggs on crab beds for most of the observation time. For site management, the following points seem important. Firstly, the conservation of the crab shear fields is important, given the plant's crucial role in the reproduction of this dragonfly species. Second, the high vegetation and reed edges along the ditches are frequently used by the dragonflies for resting and, in Akmarijp, even for mating. Further research could be done to verify whether the presence of this landscape element positively affects survival and reproduction rates. Thus, if this is the case, the species would benefit if the tall vegetation is not mowed or only after the flight period. Besides results focusing on landscape use, another observation was made that could help optimise site management. Namely, in the Woldlake forest, swans at the time of the study unexpectedly had a major impact on the crab shrub fields by grazing away much of the plant. This thus had a direct effect on the dragonfly's habitat. Measures could be devised for this too. Sufficient reason therefore for a follow-up survey in the coming green glazier flying season." **21145.** Meng, Y.; Wu, H.-t.; Guan, Q.; Lu, K.-I. (2021): The ecological response of Odonata larvae to hydrologic connection blocking in riverside wetlands of the Wusuli River. *Chinese Journal of Ecology* 40(2): 453-459. (in Chinese, with English summary) ["The composition integrity of macrobenthos community can be used to indicate and predict the health and change trend of aquatic environment, as being widely verified in literature. However, the complexity of sampling at the community level retards their convenient application. Odonata larvae, with an extraordinary amphibious life cycle, are relatively easy to be sampled and recognized among the macrobenthos. The diversity of Odonata larvae and their sensitive reaction to changes of water properties make them a very broad and appropriate bio-indicator for wetlands. We analyzed the ecological impacts of the dyke barriers on riverside wetlands and evaluated the environmental indicator role of Odonata larvae on riverside wetlands by comparing the community composition of Odonata larvae in the riverside wetlands of different reaches on both sides of the artificial embankment of the Wusuli River. The results showed that the diversity of Odonata larvae in the riverside wetlands was increasing along the Wusuli River from the upstream to the downstream. Blocking hydrologic connection had a negative effect on the survival and breeding of Odonata larvae. The closer to the downstream, the more significantly the Odonata larvae were affected by artificial dykes. The density of different species on both sides of the dyke had limited variation, while the main difference existed in the

relatively large fluctuation range of diversity index value in the sampling sites directly connected with the river hydrology." (Authors)] Address: Wu, H.-t., Northeast Institute of Geography & Agroecology, Chinese Academy of Sciences, Changchun 130102, China. Email: wuhaitao@iga.ac.cn

**21146.** Misak, K. (2021): Faunistic study of the dragonfly fauna of Nagydobrony (Ungvár district). MSc. thesis, Transcarpathian Hungarian Institute named after Ferenpl Rakopy P, Dept of Biology and Chemistry, Berehovo: 47 pp. (in Hungarian, with Ukrainian summary) ["The following conclusions can be drawn from the summary of the faunistic data. Our field collections were carried out in the area of the Great Dobronyi Game Reserve in the autumn of 2019 and summer of 2020. A total of 10 collection areas were designated following the field survey. Two collection areas were located in the area of a lake (Lake 1 and Lake 2), which is sometimes filled by the Latorca River, while eight additional collection areas were designated along the channels built during the draining of the Szernye marsh (Cs1, Cs2, Cs3, Cs4, Cs5, Cs6, Cs7, Cs8). During our work we collected 264 dragonfly larvae and 32 exuviae (296 specimens in total). The larvae were collected using a hand scraper net. The collected specimens were stored in bottles containing 70% ethyl alcohol until identification. Exuviae were collected from vegetation along the water's edge. Species identification was carried out using a stereomicroscope according to the determination manuals BROCHARD (BROCHARD et al. 2012) et al., CHAM (CHAM, 2012) and GRAND (GRAND et al. 2014) et al. Reviewing the complete faunistic list, we can see that 15 dragonfly species were found as a result of our collection efforts in 2019-20. These species are *Ischnura elegans*, *Calopteryx splendens*, *Anax imperator*, *A. parthenope*, *Libellula quadrimaculata*, *Sympetrum sanguineum*, *S. vulgatum*, *Platycnemis pennipes*, *Lestes virens*, *L. sponsa*, *L. barbarus*, *L. viridis*, *Aeshna mixta*, *Coenagrion puella*, *Crocothemis erythraea*). The species are members of 6 different families, which are Coenagrionidae (31 specimens), Calopterygidae (57 specimens), Aeshnidae (86 specimens), Libellulidae (40 specimens), Platycnemididae (1 specimen), Lestidae (45 specimens). During the exuvium collection we added 2 new species to our species list, including *Aeshna cyanea* and *Hemianax ephippiger*. Previous surveys had been carried out in the Great Dobrony Game Reserve in 1997. In their work VI-ZSLÁN and HUBER described 17 species of dragonflies from the whole area of Great Dobrona, of which 10 species (6 Zygoptera, 4 Anisoptera) were found in the area of the Great Dobrona Game Reserve. During my work, I was able to detect 7 dragonfly species (4 Zygoptera, 3 Anisoptera). A further 8 species were detected in the reserve (*L. viridis*, *A. mixta*, *A. parthenope*, *L. barbarus*, *L. virens*, *S. sanguineum*, *P. pennipes*, *C. erythraea*). Of the 15 species described by me, the following species have also been described in the area of Kisdobrony: *L. virens*, *C. puella*, *A. imperator*, *S. sanguineum*. In the course of my research, I was the first to describe *Anax parthenope*. It was detected in the first section of the canal (Cs1) (1 specimen), but we also found specimens of it in exuviae (2 specimens). During our exuvium collection work, 32 specimens were found, including *Hemianax ephippiger*, *A. cyanea*, *A. mixta*, *A. imperator*, and *A. parthenope*. *Hemianax ephippiger* and *Aeshna cyanea* were the only species collected as exuvium only, not as larvae. No previous exuvium surveys have been conducted in the areas. Based on the ISOI index, a high habitat classification category (high) was defined based on the odonatological survey of the Great Draky Game Reserve, which indicates the species richness and habitat importance of the area. **21151.** Nazari, V. (2021): Taxonomy at face value: An assessment of entomological postage stamps as effective teaching aids for science educators. *Research Ideas and Outcomes* 7: e68056: 12 pp. (in English) ["Entomological postage stamps are unique means of communication of science with the public and have been suggested as effective teaching tools in primary and secondary education. A survey of the taxonomic and other information contained on insect- and arachnid-themed stamps issued globally from 1891 to 2020 reveals that 30% of these stamps contain various errors and are scientifically unreliable. In addition, representations of insects are highly biased towards only two orders (Lepidoptera and Odonata), while other mega-diverse orders (e.g. Coleoptera, Diptera, Hymenoptera) are poorly represented or not represented at all. This phenomenon can negatively affect public perception of priorities in biodiversity and conservation. Standardization of taxonomic information on entomological stamps and implementation of rigorous quality control measures are encouraged to assure dissemination of accurate scientific information." (2021): Morphological and phylogenetic evaluation of Libellulidae dragonflies from district Attock, Punjab, Pakistan. *International Journal of Agruculture & Biology* 26: 393-400. (in English) ["Dragonflies under the family Libellulidae and order Odonata have included among the ecosystem friendly insects. In the present study, we aimed to evaluate the phylogenetics and evolutionary history of dragonflies at the cross junction of Punjab and Khyber Pakhtunkhwa provinces of Pakistan. The studies were principally based on the morphological characters of head and wing venation and phylogenetic analysis based on the nucleotide sequence of 12S rRNA gene. DNA was extracted using phenol-chloroform method and the DNA fragment was amplified through Polymerase Chain Reaction using 12S rRNA primers. A total of 233 collected specimens were identified into ten species from four genera (*Crocothemis*, *Orthetrum*, *Sympetrum* and *Zygonyx*) according to their morphological and morphometric characterization. The nucleotide sequence analysis of 12S rRNA gene had shown genetic affinities among the subject genera. The phylogenetic tree constructed by morphological data and 12S rRNA revolved two clades and supported the grouping of collected specimens. Further phylogenetic analysis based on nucleotide sequences of 12S rRNA from GenBank generated the phylogenetic tree with four clades of related species. On the basis of our findings, *Crocothemis*

*erythraea* were placed phylogenetically adjacent to *Orthetrum cancellatum*, *O. sabina* to *Libellula nodistica* (EF640400.1), *O. glaucum* to *Libellula saturata* (EU054935.1), *O. brunneum* to *O. brunneum* (DQ021416.1), *Sympetrum fonscolombii* to *Orthemis ferruginea* (EF640402.1), and *Zygonyx torridus* to *O. pruinatum* (EF640403.1) with minute differences in bootstrap values. The present report describes an aspect to record and catalogue the ecosystem friendly insects mostly being threatened." **21153.** Nogueira, J. G.; Sousa, R.; Benaissa, H.; De Knijf, G.; Ferreira, S.; Ghamizi, M.; Gonçalves, D.; Lansdown, R.; Numa, C.; Prié, V.; Riccardi, N.; Seddon, M.; Urbánka, M.; Valentini, A.; Vihrev, I.; Varandas, S.; Teixeira, A.; & Lopes-Lima, M. (2021): Alarming decline of freshwater trigger species in western Mediterranean key biodiversity areas. *Conservation Biology* 35: 1367-1379. (in English) ["The identification of key biodiversity areas (KBA) was initiated by the International Union for Conservation of Nature in 2004 to overcome taxonomic biases in the selection of important areas for conservation, including freshwater ecosystems. Since then, several KBAs have been identified mainly based on the presence of trigger species (i.e., species that trigger either the vulnerability and/or the irreplaceability criterion and thus identify a site as a KBA). However, to our knowledge, many of these KBAs have not been validated. Therefore, classical surveys of the taxa used to identify freshwater KBAs (fishes, molluscs, odonates, and aquatic plants) were conducted in Douro (Iberian Peninsula) and Sebou (Morocco) River basins in the Mediterranean Biodiversity Hotspot. Environmental DNA analyses were undertaken in the Moroccan KBAs. There was a mismatch between the supposed and actual presence of trigger species. None of the trigger species were found in 43% and 50% of all KBAs surveyed in the Douro and Sebou basins, respectively. Shortcomings of freshwater KBA identification relate to flawed or lack of distribution data for trigger species. This situation results from a misleading initial identification of KBAs based on poor (or even inaccurate) ecological information or due to increased human disturbance between initial KBA identification and the present. To improve identification of future freshwater KBAs, we suggest selecting trigger species with a more conservative approach; use of local expert knowledge and digital data (to assess habitat quality, species distribution, and potential threats); consideration of the subcatchment when delineating KBAs boundaries; thoughtful consideration of terrestrial special areas for conservation limits; and periodic field validation." **21156.** Soares, D.M.; Borges, L.R.; Falcão da Silva, M.F.; Luche, L.D. (2021): Effect of substrates of native and exotic plant species on the initial period of colonization of benthic macroinvertebrates in the Cerrado biome. *Community Ecology* 22(2): 127-134. (in English) ["The introduction of exotic species can generate changes in the composition of organic debris of alien origin in aquatic ecosystems close to the places of introduction. This new debris can cause impacts at the level of communities and ecosystems. Therefore, the present work aims to answer the following question: are the macroinvertebrate communities present in substrates formed by leaves of the exotic species *Pinus caribaea* Morelet (Pinaceae) and *Eucalyptus grandis* Hill ex Maiden (Myrtaceae) similar to those found in substrates composed by the mix of these two species and substrates composed by a mix of native species? For the collection of macroinvertebrates, sets of four types of artificial substrates were submerged in a stream inside the Ecological Station of Panga (Uberlândia—MG, Brazil). The treatments were: leaves of *P. caribaea*, leaves of *E. grandis*, leaves of both exotic species and leaves of two native species. In the 20 sample units, about 250 individuals were found, belonging to the orders Coleoptera, Diptera, Ephemeroptera, Heteroptera, Megaloptera, Odonata, Plecoptera and Trichoptera. The effects of the treatments were observed in the exponential decay of the substrate mass and in the structure of the benthic macroinvertebrates communities. The composition of these communities differed among treatments, with high dissimilarity observed between *P. caribaea* treatments and the mix

of exotic species. Therefore, the results demonstrate the importance of substrate complexity for benthic macroinvertebrates, as well as the possible effects of biological invasion and co-invasion by species widely used in silviculture activities." **21158.** Yu, C.; Qin, H.; Shen, Q.; Yu, K.; Chen, C.; Wang, H.; Bai, Y. (2021): Effects of wetland environmental diversity on Odonata species diversity. *Journal of Taizhou University* 43(3): 42-47. (in Chinese, with English summary) ["In order to explore the impact of wetland environmental diversity on the species diversity of Odonata insects, the species diversity of Odonata in different wetland environments of Taizhou [Zhejiang province, China] was investigated from July to August in 2020. The dragonflies were collected by scanning net method, and the Shannon-Wiener Diversity Index and Correlation Index were used for the analysis. The results showed that the species of Odonata were the most abundant in all the plots. Among them, the *Pantala flavescens* had a large number of individuals in wetland environments with low vegetation, and the *Crocothemis servilia* was found in reservoirs and streams with more ponds. There were quantities of *Pseudothemis zonata* in the wetland environment with tall trees and intertwined ponds, and there were plenty of *Deilidia phaon* in places with better environments around the reservoir. Correlation analysis showed that there was a negative correlation between the species diversity of Odonata and the ratio of water area to land area. With the increase of water area, the species diversity of Odonata showed a

downward trend. However, as the proportion of land and water area ranging from 9% to 12%, the species diversity index of Odonata was the highest. The results provided biodiversity data support for wetland environmental protection and water quality assessment." **21159.** Zhang, H.-m.; Cai, Q.-h. (2021): Biodiversity and fauna study of Odonata from Shennongjia Mountains. Resources and Environment in the Yangtze Basin 30(6): 1393-1399. (in Chinese, with English summary) ["From 2012 to 2015 surveys, 39 locations of dragonflies were investigated in Shennongjia mountains. 88 species of dragonflies belonging to 55 genera, 15 families and 2 suborders were obtained. Anisoptera species are dominant, with 34 genera and 61 species, occupied 61.82% and 69.32% of the total respectively. Libellulidae is the most abundant family, with 25 species, occupied 28.41% of the total species. Zygoptera with 21 genera and 27 species, occupied 38.18% and 30.68% of the total respectively, Calopterygidae, Platycnemididae and Coenagrionidae are dominant groups with 5 species each, occupied 5.68% of the total. The main characteristic of Shennongjia dragonfly fauna is the oriental species are dominant, with 49 species recorded, occupied 55.68% of the total species, including 4 distribution types; 39 species are the Palaearctic-Oriental distribution type, occupied 44.32% of the total species, including 9 distribution types. The results show that Shennongjia mountains is an important dragonfly habitat, and dragonfly resources have significant regional characteristics. In order to further protect the diversity of dragonflies, effective conservation strategies should be taken." **21160.** Adu, B.W. (2022): Assessment and inventory of Odonata (Insecta) and water quality parameters of the Abaa, Malaika, and Isokun rivers in south-western Nigeria. *Biologia 77*: 2563-2570. (in English) ["Odonata can be found in most inland waters except in Antarctica. Some species of this insect are habitat-specific partly due to their sensitivity and tolerance to changes in the environment. This study evaluated dragonflies and damselflies composition, and physico-chemical characteristics of three water bodies (Abaa, Malaika, and Isokun rivers) in Ondo State, Nigeria. The study span through a period of six months. Specimens of Odonata and water samples were collected at the three rivers for analyses once a month for six months (April-September, 2019). The mean values for the physicochemical parameters and diversity of species of Odonata were calculated. Analysis of data revealed that ambient temperature, water temperature, and flow rate were not significantly different ( $p > 0.05$ ) between the study sites. The pH value of the water sample from the three sites were fairly alkaline with mean values ranging from  $8.65 \pm 0.34$  to  $9.10 \pm 0.88$ . The dissolved oxygen (DO) values of the three study sites ranged from  $5.13 \pm 1.02$  to  $6.95 \pm 0.88$ , indicating little variability in the DO content of the water. The lowest values for Shannon-Weiner H' (2.247) and Simpson 1-D (0.8794) were recorded at Abaa, while the highest values for both indices (2.729 and 0.9191, respectively) were recorded for Isokun. The dominant dragonflies and damselflies at the three sites are the ubiquitous type associated with the disturbed environment, they include *Trithemis kirbyi*, *Palpopleura lucia*, *Pseudagrion*

*kersteni*, *P. melanicterum* and *Trithemis arteriosa*. This study revealed that the three water bodies investigated inhabited ubiquitous odonate fauna linked with both disturbed and moderately polluted environments. The Abaa River was the most disturbed with the least number of species due to the high rate of anthropogenic activities, the presence of some sensitive species at the Isokun River, and the outcome of biodiversity indices analysis revealed that the Isokun River was the most stable odonate community among the three rivers." **21161.** Agdamar, S.; Sac, G. (2022): Growth and feeding ecology of a small-bodied freshwater fish species *Petroleuciscus borysthenicus* (Kessler, 1859) in an artificial water body of an island ecosystem (Gökçeada, Turkey). *Journal of Advanced Research in Natural and Applied Sciences 8*(1): 76-85. (in English) ["Bio-ecological studies and life-history traits of small-bodied fishes are critical for the understanding of their ecological role as well as the assessment of their position and continuity in the ecosystems. This study aims to present initial data on the growth and feeding habit of small-bodied *Petroleuciscus borysthenicus* inhabited in an island ecosystem (Gökçeada, Turkey). During the seasonally sampling surveys from May 2020 to January 2021, a total of 163 specimens were collected from Sahinkaya Reservoir using electrofishing. Standard length and body weight of fish samples varied between 2.6–10.0 cm and 0.32–25.68 g, respectively. Length-weight relationship and condition factor were calculated for all specimens as  $W=0.017 \times SL^{3.114}$  ( $r=0.988$ ) and  $2.04 (\pm 0.28)$ , respectively. F:M sex ratio was found to be 1:1.33 with no significant difference from the ratio of 1:1 ( $X^2=0.02$ ;  $p>0.05$ ). Diet of the species comprised of ten different food items. Plant (63.6%) was the most preferred food item in terms of frequency of occurrence (F%), followed by Diptera (31.8%) and Odonata (12.7%). According to the index of relative importance IRI (%) values of food items, Diptera was the dominant food item in all seasons. Levins' measure of niche breadth (B) and standardised niche breadth (BA) values were estimated as 3.18 and 0.24, respectively. The results showed that *P. borysthenicus* was more selective on conveniently accessible food materials in the environment and its food preference was affected by seasonal food supply." **21162.** Augusto, F.G.; Graça, M.A.S.; Martinelli, L.A.; Caçador, I.; Arce-Funck, J. (2022): Do aquatic insects disperse metals from contaminated streams to land? *Hydrobiologia 849*: 1437-1451. (in English) ["Mining activities often produce large amounts of pollutants that lead to streams affecting aquatic biota. Aquatic insects have a key role in energy transference from streams to terrestrial systems since emergent insects contribute to the diet of riparian predators. If streams are polluted, emergent insects may act as pollutant conveyors from water to land. Our objective was to investigate if insects inhabiting streams contaminated by heavy metals accumulate, biomagnify, and transfer metals to land. We selected eight streams with different levels of pollution and three metallic pollutants: copper (Cu), manganese (Mn), and zinc (Zn). We sampled (i) water and sediments, (ii) organic matter, macrophytes, and biofilm, (iii) aquatic insects [including "Anisoptera, Zygoptera"], and (iv) riparian spiders (land predators). We classified the organisms in functional feeding groups (FFG) and used the nitrogen stable isotope ( $d^{15}N$ ) to determine the position of organisms in the food

web. We found that contaminants in the sediments, but not in the water, were related to contaminant concentrations in biological samples. Biomagnification processes were metal dependent: Cu was biomagnified, Mn underwent biodilution, and no tendency was observed for Zn. The emergence of aquatic insects from metal-polluted rivers is a potential way of Cu, not Mn or Zn, flux to land." (Authors)] Address: Augusto, F.G., Lab. Isotope Ecology, Center for Nuclear Energy in Agriculture, Univ. of São Paulo, Av. Pádua Dias, 330, São Dimas, Piracicaba, SP, CEP 13416-000, Brazil

**21163.** Balázs, A.; Šipoš, J.; Matúšová, Z.; Hamerlík, L.; Novikmec, M.; Svitok, M. (2022): Comparison of conservation values among man-made aquatic habitats using Odonata communities in Slovakia. *Biologia* 77: 2549-2561. (in English) ["Odonates are one of the best-known aquatic insect groups, with the renowned ability to reflect the quality of freshwater ecosystems. In the last few decades, major emphasis has been placed on the importance of secondary aquatic habitats as refugia for odonates. Biota of man-made habitats, especially dams, are burdened by countless negative anthropogenic impacts. Nevertheless, some habitat types appear to be able to support species with high conservation value. Here, we used generalised linear models to analyse the effects of several environmental characteristics, such as pH, conductivity, water area and perimeter of selected sites, to clarify the effects of drivers in terms of species richness of odonates. Water dams, flooded quarries, flooded gravel quarries and flooded sandpits have been compared based on the Dragonfly Biotic Index (DBI). We recorded 44 odonate species, including several red-listed ones, such as *Epithea bimaculata*, *Leucorrhinia caudalis* and *L. pectoralis*. Although the highest numbers of species were found at water dams, at such habitats, the lowest values of DBI were revealed. The fractional effect of habitat types on DBI was also proven to be significant. Increased conductivity resulted in a decrease of species richness. The positive correlation between habitat area and DBI was also proven to be significant. Our results indicate a high conservation value of different types of flooded quarries counter to water dams, based on the presence of several nationally threatened species with high values of DBI." i. Bertoli, M.; Pastorino, P.; Lesa, D.; Renzi, M.; Anselmi, S.; Prearo, M.; Pizzula, E. (2022): Microplastics accumulation in functional feeding guilds and functional habit groups of freshwater macrobenthic invertebrates: Novel insights in a riverine ecosystem. *Science of The Total Environment* 804, 15 January 2022, 150207: 10 pp. (in English) ["Highlights: • Microplastics contamination was assessed in a macrobenthic invertebrate community. • Cellulosic fibers associated to polyester were found in 48.5% of the taxa. • The highest microplastics amount was detected in the collector-gatherers. • There was no difference in microplastics amount among the functional habit groups. Abstract: Microplastics pose a major threat for aquatic ecosystems, but the contamination dynamics in organisms inhabiting freshwater ecosystems is still little studied. Largely used for biomonitoring, macrobenthic invertebrates provide a pivotal trophic resource for many fish and bird species. In this study, we investigated the microplastics contamination in a macrobenthic invertebrate community (2772 individuals belonging to 33 taxa identified) in a high-plain riverine ecosystem (Vipacco River, northeast Italy) and compared the amount of microplastics accumulated in functional feeding guilds/functional habit groups. Microplastics (cellulosic fibers associated with polyester) were found in 48.5% of the taxa, with the highest amount detected in the collector-gatherers, followed by predators. The collector-gatherers showed a significantly higher microplastic accumulation than the other functional feeding guilds, whereas there was no difference among the functional habit groups. The main source of microplastics pollution was most likely urban wastewater discharge points located along the river. Our study reports a novel approach about microplastic pollution assessment in lotic environments, as it focuses into the microplastic contamination dynamics in an entire macrobenthic invertebrate community perspective and underlines the need for further study." **21165.** Brenkman, A.B. (2022): After 112 years, again an observation of an imago of *Zygonyx torridus* on Gran Canaria (Spain). *Brachytron* 23(1/2): 48-52. (in Dutch, with English summary) ["Ringed Cascader (*Zygonyx torridus*) has been reported from the Canary Islands from the islands of La Palma, La Gomera, Tenerife and Gran Canaria. On 11 August 2018 I observed an imago in the Barranco de Azuaje, in the north of Gran Canaria. This is the first observation of an imago in more than 100 years for Gran Canaria. A short description of the habitat is provided." (Author)]

**21166.** Buczyński, P.; Piwowarczyk, A.; Taficzuk, A.; Bojar, P.; Mikolajczuk, P.; Góral, N. (2022): Dragonflies (Odonata) of the Lake Orchowe Nature Reserve (Western Polesie). *Przegląd Przyrodniczy* XXXIII(2): 79-93. (in Polish, with English summary) ["In 2021 the fauna of dragonflies was studied in the Lake Orchowe Nature Reserve (Leczynsko-Włodawska Plain, Western Polesie, eastern Poland). Four sites were surveyed: the dystrophic Lake Orchowe (No. 2), a fen with a permanent water body (No. 4) and two peat bogs of a mainly transitional nature: open and permanently hydrated (No. 3) and overgrowing with young forest and mostly drying up in the summer season (No. 1). 40 species were recorded (54% of the national fauna). The most interesting were: *Nehalennia speciosa*, *Aeshna juncea*, *A. subarctica*,

*Orthetrum coerulescens*, *Leucorrhinia pectoralis*. Between 9 and 27 species occurred at particular sites. The fauna of Lake Orchowe was the richest, while the fauna of peatlands was moderately rich or poor. The lake was characterized by fauna of an intermediate nature between lake and peatland, indicating its low productivity. The fauna of peatlands was typical of these habitats, but on one site the impact of drying-up was noticeable. Six "special concern" species were recorded: three legally protected species in Poland; one from the IUCN Red List, one from the Red List of Europe, one from the Red List of the European Union, two from the Red List of dragonflies of Poland and four umbrella species for the studied habitats. Their occurrence and abundance as well as good preservation of the peatland fauna at most sites confirm the high natural value of the Lake Orchowe Nature Reserve for the protection of dragonflies and – indirectly – also for the protection of peatland habitats and their biota. There were no significant changes of the fauna, related to climate warming. The new data of *Nehalennia speciosa* and *Aeshna subarctica* is significant to the knowledge on their distribution in the Leczynsko-Wlodawska Plain and its vicinity. It is worth mentioning that individuals of *Nehalennia speciosa* were found not only in reedbeds with the domination of *Carex lasiocarpa*, but also *C. elata*, which is a more regular case now in Poland, yet still scarce. Both species have isolated distribution areas here, with 7 localities of *Nehalennia speciosa* and 4 of *Aeshna subarctica* known today. Due to this isolation, each population is important as part of a metapopulation within such an area." (Authors) *Nehalennia speciosa*, *Aeshna juncea*, *A. subarctica*, *Anax parthenope*, *Orthetrum coerulescens*, *Leucorrhinia pectoralis*] Address: Buczynski, P., Dept Zool., Maria Curie-Skłodowska Univ., Akademicka 19, 20-033 Lublin, Poland. **21167.** Cezario, R.R.; Therezio, E.M.; Marletta, A.; Gorb, S.N.; Guillermo-Ferreira, R. (2022): Ontogenetic colour change of a sexual ornament in males of a damselfly: female mimicry, crypsis or both? *Die Naturwissenschaften* 109(1):2: 9 pp. (in English) ["Female mimicry by males is a widespread phenomenon in several taxa and may be involved in aggression avoidance or facilitated access to resources. In early developmental stages, female mimicry may be a mechanism involved in signalling sexual immaturity or, when coupled with strategies related to visual camouflage, may be involved in the avoidance of male-male agonistic interactions. Here, we addressed whether the delayed colour maturation of a sexual ornament in males of *Mnesarete pudica* damselflies might be a case of crypsis, female mimicry or both. We analysed how conspecifics and predators perceive the pigmented wings of juvenile males by contrasting the wing spectra against a savannah background and the wings of both juvenile and sexually mature males and females. Our results based on the modelled visual system of conspecifics and predators suggest that the colour maturation of juvenile males may function as both crypsis and female mimicry. We discuss whether these results related to age- and sexual-dichromatism might be a mechanism to avoid unwanted intraspecific interactions or to avoid territorial and aggressive males. We conclude that the female mimicry and crypsis in juvenile males of *M. pudica* are mechanisms involved in avoidance of predators and unwanted intraspecific interactions, and the signalling of sexual maturity." (Authors)] Address: Guillermo-Ferreira, R., Lestes Lab, Univ. Federal do Triangulo Mineiro, Uberaba, MG, Brazil. Email: rhainerguilermo@gmail.com

**21168.** Chacko, S.; Kandambeth, P.P. (2022): Studies on

trematode metacercariae infecting libellulid larvae from the Western Ghats, Wayanad region. *Parasit. Dis.* 46(1): 159-165. (in English) ["Understanding the host specificity of trematode larvae is vital in predicting the mode of trophic level transfer of trematode parasites and their evolution. In this study, six species of trematode metacercariae, *Eumegacetes* sp., *Orthetrotrema monostomum*, *Ganeo tigrinus*, *Mehraorchis* sp., *Pleurogenoides* sp. and *Phyllodistomum* sp. infecting the larvae of the odonate family Libellulidae from the water bodies in the Wayanad region of the Western Ghats are recorded. ... A total of 198 anisopteran larvae were subjected for study of which the most abundant was that of the family Libellulidae (154). Family Gomphidae was represented by 24 larvae, Macromiidae with 10 and Aeshnidae with 10 larvae. Five species of libellulid larvae under three genera, *Orthetrum*, *Pantala* and *Trithemis* were recorded as second intermediate hosts, in the present study. The larvae of the family Libellulidae were infected with six species of trematode metacercariae: *Eumegacetes* sp., *Orthetrotrema monostomum*, *Ganeo tigrinus*, *Mehraorchis* sp., *Pleurogenoides* sp. and *Phyllodistomum* sp. (Table 1). Out of 154 libellulid larvae examined, 53 were infected with trematode metacercariae. The prevalence of infection were 5.8%, 2.0%, 10.4%, 9.1%, 2.6% & 1.3%, the mean intensity of infection 4.44, 1.67, 5.38, 6.21, 6.00 & 17.50 and the mean abundance were 0.26, 0.03, 0.56, 0.56, 0.16 & 0.23, respectively (Table 2). Of the 24 larvae under Gomphidae two were found infected with *Eumegacetes* sp. (prevalence 8.3%, mean intensity 6.5 and mean abundance 0.54) and one with *Phyllodistomum* sp. (prevalence 4.2%, mean intensity 12 and mean abundance 0.5). No metacercarial larvae were recorded from other two families of the insect larvae." **21169.** Choong, C.Y. (2022): Perkembangan larva *Tamea transmarina euryale* Selys, 1878 (Insecta: Odonata) - Larval development *Tamea transmarina euryale* Selys, 1878 (Insecta: Odonata). *Serangga* 27(3): 54-65. (in Malaysian, with English summary) ["The objective of the study was to record the larval development of *Tamea transmarina euryale*. The eggs of *T. transmarina euryale* were incubated until larval emergence in the laboratory. The eggs were collected from an egg-laying female at a pond in Universiti Kebangsaan Malaysia, Bangi Campus, Selangor, Malaysia. The fresh eggs were in yellow colour with a mean length of  $0.46 \pm 0.01$  mm and mean width of  $0.37 \pm 0.01$  mm. The egg incubation period needed at least seven days. The larval development of *T. transmarina euryale* consisted of 12–14 stadia. The rudimentary wing sheaths appeared at the 7th instar. The larvae turned into a greenish yellow colour in the last few instar stages. The whole larval development took 50–62 days to complete. The duration of larval development in *T. transmarina euryale* is generally short if compared to the other Libellulidae species. The information of larval development until adult stage of *T. transmarina euryale* is important for the breeding and conservation purposes, as well as its potential to be applied as biological control agent." **21171.** Chovanec, A. (2022): The assessment of the dragonfly fauna (Insecta: Odonata) as a tool for the detailed typological characterisation of running waters. *Acta ZooBot Austria* 158: 129-147. (in English, with German summary) ["Odonata play an increasing role as indicators in the assessment of the ecological status of running water systems in modern water management. In this connection, the application of the Rhithron-Potamon Concept dealing with the longitudinal distribution patterns of aquatic communities along biocoenotic regions has proven to be a sound approach. Central aspect of the assessment procedure is the comparison of the odonatological status quo with a river type-specific reference state, which focuses on the potential dragonfly community at the (near-)pristine character of the water body investigated. A more detailed method of defining reference species is required particularly with regard to special river types, as the exclusive assignment of the biocoenotic region may cause misleading results. This present paper deals with one of the last near-natural hyporhithron river sections in Austria, the lower course of the Antiesen. Taking into account the Antiesen's canyon-like geologic features with reduced availability of different habitat types for dragonflies in the riparian ecotones, the predetermined spectrum of hyporhithron reference Odonata species was adapted by discussing autecological requirements and river-morphology and revealed two river type-specific core reference species (*Calopteryx virgo* and *Onychogomphus forcipatus*) and five river type-specific accompanying reference species. The comparison of these reference species with the results of a comprehensive field study carried out in 2020 at the Antiesen confirmed the unique features of this river type and the dominating hyporhithron characteristics. It also revealed, however, a slight epipotamon influence indicated by the high abundance of *Calopteryx splendens*, one of the river type-specific accompanying reference species, probably due to increased water temperatures." (Author)] Address: Chovanec, A., Krotenbachgasse 68, 2345 Brunn am Gebirge, Austria. Email: andreas.chovanec@bml.gv.at

**21173.** Dilushika, P. (2022): Effects of neonicotinoid exposure on anti-predator behaviour and learned recognition of novel predator odour of larvae *Lestes* spp. (Odonata: Zygoptera). MSc thesis, Dept of Biology, University of Saskatchewan: X + 69 pp. (in English) ["Neonicotinoids are widely used water-soluble neurotoxic insecticides. The effects of these insecticides on non-target aquatic organisms have become a major environmental concern since they affect both pests and non-target insects. Along with lethal effects, these insecticides could cause visual and chemoreception impairment. This can lead to behavioural alterations in aquatic organisms by disrupting the sensory systems used for detecting predators, thereby affecting anti-predator behaviours. Therefore, in this thesis, I investigated the effect of imidacloprid, a neonicotinoid insecticide, on the anti-predator response and learned recognition of novel predator odour in damselfly larvae (*Lestes* sp). In the first experiment (chapter 2), damselfly larvae were exposed to water contaminated with a series of concentrations (0.0µg/L, 0.1µg/L, 1.0µg/L, and 10.0µg/L) of imidacloprid and the change in number of feeding bites performed after injecting a conspecific damage-released alarm cue solution and a predator kairomone solution was observed and recorded on day 2, 5, and 10. On days 2 and 5, both the control and 0.1µg/L groups showed appropriate anti-predator behaviour to alarm cues and predator odour, but this was not the case for damselflies exposed to 1.0µg/L. By day 10, larvae in the 1.0 and 10.0µg/L groups no longer responded to alarm cues and all exposure groups ceased responding to predator odour. In the second experiment (chapter 3), I investigated the effect of exposure to a series of concentrations of imidacloprid on learned recognition of predatory stimuli by damselfly larvae. Damselflies were conditioned to recognize risk by exposing them to zebrafish odour (a novel odour) combined with conspecific damage-released alarm cues or control of dechlorinated water. Larvae in the control group learned to respond to the predator odour based on their prior conditioning with alarm cues but not water. Learning of predator odour also occurred for larvae in the 0.1µg/L treatment group but failed for individuals exposed to the higher concentrations of 1.0µg/L and 10.0µg/L. In the third experiment (chapter 4), I exposed damselfly larvae to imidacloprid (at an initial pulse solution of 3.0µg/L and reaching a final concentration of 0.01µg/L) during the conditioning period and evaluated the effect on learned recognition of novel predatory stimuli. Damselflies were conditioned to recognize risk by exposing them to zebrafish odour with true conditioning (alarm cue + predator odour) with or without imidacloprid and another group was given sham conditioning (water + predator odour) with or without imidacloprid exposure. Larvae given true conditioning without imidacloprid exposure correctly learned to recognize the predator odour as a threat, while larvae given sham conditioning, and those exposed to imidacloprid, failed to learn to respond to the predator odour. Overall, this study highlights that acute and chronic exposure to imidacloprid at both environmental relevant and higher concentrations impairs the anti-predator response to conspecific alarm cues and predator odour by damselfly larvae. Further, this study demonstrates that imidacloprid affects learned recognition of novel predator odour by damselfly larvae with the interaction between chemical cues and imidacloprid potentially playing a key role in this impairment." **21174.** Ertas, A.; Yorulmaz, B.; Sukatar, A. (2022): Comparative analysis of biotic indices for assessment of water quality of Balaban Stream in West Anatolia, Turkey. *Biologia* 77: 721-730. (in English) ["Drinking water basins are freshwater

resources that need to be protected and sustained of water quality. However, these areas are lately facing pressures such as agricultural, industrial and urbanization activities. This study was carried out to determine water quality of Balaban Stream and to compare the performance of the indices. Five sampling stations were determined and the samplings were carried out seasonally. Biotic and diversity indices based on benthic macroinvertebrates have been applied using Asterics software. By using UPGMA analysis, the similarities between the stations were clustered based on benthic macroinvertebrates. Pearson's based correlations were applied to the indices in order to determine the proper biotic indices. A total of 62 taxa which belong to Ephemeroptera, Plecoptera, Trichoptera, Diptera, Odonata, Coleoptera, Arhynchobdellida, Haplotaxida, Basommatophora and Amphipoda were detected. The most dominant group between the benthic macroinvertebrates (51 taxa) was found among Insecta. The 4th and 5th stations were the most similar according to the benthic macroinvertebrates assemblages. As a result of this research, the water quality of Balaban Stream was determined as unpolluted-slightly polluted. BMWP- O, BMWP- S, BMWP- H, ASPT- O, ASPT- H and ASPT- C indices were more proper than SI, FBI and BBI indices to determine the water quality of Balaban stream." (Authors)] Address: Ertas, A., Fac. Science, Dept Biology, Ege Univ., Bornova, 35100, Izmir, Turkey

(in English) ["*Pantala flavescens* (Fabricius 1798) appeared in unprecedented numbers in summer and autumn 2020 on the island of Malta. Several males were observed holding territory over largely bare, small bodies of water, mostly at Chadwick Lakes and Fiddien. Breeding activity was witnessed several times and 128 exuviae were found of which 124 were collected." (Author)] Address: Gauci, C., 28 Triq il-Kissier, Mosta, Malta. Email: cjgauci48@yahoo.com

**21179.** Grace, M.K.; Akçakaya, H.R.; Bennett, E.L. et al., (2022): Testing a global standard for quantifying species recovery and assessing conservation impact. *Conservation Biology* 35(6): 1833-1849. (in English, with Spanish summary) ["Recognizing the imperative to evaluate species recovery and conservation impact, in 2012 the International Union for Conservation of Nature (IUCN) called for development of a "Green List of Species" (now the IUCN Green Status of Species). A draft Green Status framework for assessing species' progress toward recovery, published in 2018, proposed 2 separate but interlinked components: a standardized method (i.e., measurement against benchmarks of species' viability, functionality, and preimpact distribution) to determine current species recovery status (herein species recovery score) and application of that method to estimate past and potential future impacts of conservation based on 4 metrics (conservation legacy, conservation dependence, conservation gain, and recovery potential). We tested the framework with 181 species representing diverse taxa, life histories, biomes, and IUCN Red List categories (extinction risk). Based on the observed distribution of species' recovery scores, we propose the following species recovery categories: fully recovered, slightly depleted, moderately depleted, largely depleted, critically depleted, extinct in the wild, and indeterminate. Fifty-nine percent of tested species were considered largely or critically depleted. Although there was a negative relationship between extinction risk and species recovery score, variation was considerable. Some species in lower risk categories were assessed as farther from recovery than those at higher risk. This emphasizes that species recovery is conceptually different from extinction risk and reinforces the utility of the IUCN Green Status of Species to more fully understand species conservation status. Although extinction risk did not predict conservation legacy, conservation dependence, or conservation gain, it was positively correlated with recovery potential. Only 1.7% of tested species were categorized as zero across all 4 of these conservation impact metrics, indicating that conservation has, or will, play a role in improving or maintaining species status for the vast majority of these species. Based on our results, we devised an updated assessment framework that introduces the option of using a dynamic baseline to assess future impacts of conservation over the short term to avoid misleading results which were generated in a small number of cases, and redefines short term as 10 years to better align with conservation planning. These changes are reflected in the IUCN Green Status of Species Standard." (Authors)] Address: Grace, Molly, Dept Zool., Univ. Oxford, Oxford, OX1 3SZ, UK. E-mail: molly.grace@zoo.ox.ac.uk

**21180.** Graham, Z.A.; Diehl, K.M.; Davis, D.; Loughman, Z.J. (2022): Death from below: Sit-and-wait predatory behavior

in a burrowing crayfish (*Lacunicambarus thomai*). Food Webs 31, e00225: 4 pp. (in English) ["The biology of burrowing crayfishes remains elusive to biologists, primarily because these animals spend a majority of their lives within the confines of their burrow. Scattered observations of burrowing crayfishes have suggested that burrowing crayfish may exhibit a greater degree of surface activity than previously thought. Surface behavior may be related to social interactions, predator defense, or prey capture. But documentation of these behaviors is rare, and few studies have been conducted on the predatory behaviors of burrowing crayfishes. Here, we report the findings of 24-h video recording surveys conducted on a burrowing crayfish species, the Little Brown Mudbug (*Lacunicambarus thomai*). In total, we recorded and watched 633 h of video. We observed *L. thomai* sitting atop their burrow engaging in sit-and-wait predatory behavior. This ambush predatory behavior was used on several different animal prey items, including spiders (Lycosidae), slugs (Philomycidae), and dragonfly nymphs (Aeshnidae). We also recorded crayfish cutting terrestrial vegetation near their burrow entrance and pulling it down into their burrow. Additionally, we analyzed the gut contents of 23 *L. thomai* from 4 populations to understand the generality of our foraging observations. Indeed, gut content analyses confirmed that all populations consumed both animal prey and vegetation. Overall, our recordings demonstrate that sit-and-wait predatory behavior may be a common foraging behavior among burrowing crayfishes. Further, our observations highlight the trophic role of burrowing crayfish species and emphasizes how these animals forage on both animal and plant communities in terrestrial habitats." **21181.** Grieve, A.; Broom, J. (2022): Range extension of an endangered Sydney Hawk Dragonfly *Austrocordulia leonardi* (Anisoptera, Libelluloidea incertae sedis) population in the Nepean River, near Sydney, Australia. *Agrion* 26(2): 49-53. (in English) ["A targeted survey for exuviae of the Sydney Hawk Dragonfly *Austrocordulia leonardi* Theischinger, 1973 was undertaken along the Nepean River and Cataract River in the Sydney basin, over four days in December 2021. The aim of the survey was to determine if the population of *A. leonardi* occupied riverine habitats upstream from its known location at Maldon Bridge and downstream to Menangle weir. Where accessible, riverine emergence structures were inspected using an inflatable boat as transport. However due to instream barriers several sections of river and habitats were navigable only by foot. A total of 324 *A. leonardi* exuviae were recovered from emergence habitats spanning 26km of the Nepean River, and seven *A. leonardi* exuviae were recovered from the lower reaches of the Cataract River, representing a new river system in which the species resides. Additional inspections undertaken in Kangaroo Creek in December 2019, 2020 and 2021, and the Woronora River in December 2019 indicate that the species is either present in other previously known locations in very small numbers or not at all." **21184.** Hou, D.; Zhong, Z. (2022): Comparative analysis of deformation behaviors of dragonfly wing under aerodynamic and inertial forces. *Computers in Biology and Medicine* 145, June 2022, 105421: (in English) ["Highlights: • Aerodynamic and inertial forces on flapping dragonfly wing are computed and compared. • Dynamic responses of dragonfly wing under flapping and rotation velocities are simulated. • Passive deformation mechanisms of dragonfly wing are revealed. Abstract: Insect wings are typically deformed under aerodynamic and inertial forces. Both the forces are related to kinematic and morphology parameters of the wing. However, how the insects utilize complex wing morphologies and kinematics to generate the forces, and what the exact contributions of the two forces in wing deformation are still unclear. In the study, the aerodynamic and inertial forces produced by a dragonfly forewing are compared quantitatively. Then the dynamic deformation behaviors are studied with a three-dimensional finite element model. Finally, roles of the two forces in wing deformation are fully discussed. The two forces increase along the wingspan every moment and they reach maximal consistently near the pterostigma. Because of the asymmetry of angle of attack, the maximal resultant aerodynamic force is about 4 times of that in upstroke. By comparison, the normal component of aerodynamic force plays the leading role in downstroke while the inertial force works mainly in tangential in upstroke. The finite element simulation demonstrates the bending and twisting deformation behaviors of the wing considering both flapping and rotation. The average strain energy in one flapping cycle is  $1.23 \times 10^{-3}$  mJ under inertial force and  $0.43 \times 10^{-3}$  mJ under aerodynamics respectively. In addition, the rapid rotation can enhance inertial deformation by 6 times. As a result, deformation of dragonfly wing is dominated by its own inertia in flight. The deformation mechanism addressed could inspire the design of flexible flapping airfoils in morphology and kinematics." (Authors)] Address: Zhong, Z.,

**21185.** Infante Álvarez, C. (2022): Las comunidades de odonatos y su relación con el hidroperiodo en lagunas temporales del LIC de Lagunas de los Oteros en la provincia de León. Trabajo de fin de Grado, Universidad de León: 32 pp. (in Spanish, with English summary) ["The odonate communities and their relationship with the hydroperiod in temporary ponds of the LIC of Lagunas de los Oteros in the province of León: It is intended to describe the odonate communities in the temporary ponds of the LIC of Lagunas de los Oteros in the Province of León. The study was based on two independently obtained data sets: exuviae and imagines. From a sampling of exuviae, an attempt was made to elucidate whether the hydroperiod is a determining factor for these communities, for which classification and correlation analyzes were used with the collected exuviae. The richness obtained for all the study ponds was twenty-one species, ten from the exuviae and nineteen in the case of adults, with *Lestes barbarus*, *Lestes dryas*, *Sympetrum sanguineum* and *Sympetrum striolatum* being the dominant species of the community. Using Whittaker's  $\beta$  diversity, it was found that the differences in taxonomic composition between hydroperiods were greater in the juvenile stages (exuviae) than in the imagines, something that is not surprising given the high dispersal capacity of the imagines. Finally, from the correlation analysis it was determined that there is a positive relationship between the increase in the hydroperiod and the increase in species richness, both exuviae and imagines." (Author)] Address: not stated

**21186.** Johansson, F.; Kollberg Hedström, T.; Anderson, R.C.; Divakaran, P.K.; Kakkassery, F.K. (2022): Wing shape differences along a migration route of the long-distance migrant Globe Skimmer Dragonfly *Pantala flavescens*. *Journal of Tropical Ecology* 38: 17-24. (in English) ["Animals which migrate by flying should be subject to selection for optimal wing characteristics that maximize energy efficiency during migration. We investigated wing shape and wing area variation in the Globe Skimmer Dragonfly *Pantala flavescens*, which has the longest known migration of any insect. Wing shape and wing area differences between individuals in southern Peninsular India, and migrating individuals at a stop-over site on the Maldives, were compared. Results suggest that individuals which successfully reached the Maldives, on their way from India to Africa, had a broader wing base and an overall more slender wing shape than individuals in southern India. Contrary to our expectations, wing area did not differ significantly in most of our comparisons between southern India and the Maldives, suggesting that wing shape is more important than wing area for successful migration in *P. flavescens*. The results provide indirect evidence of natural selection on wing shape in a migrating dragonfly." (Authors)] Address: Frank Johansson: Email: frank.johansson@ebc.uu.se

**21187.** Kalkman, V.J.; Boudot, J.-P.; Futahashi, R.; Abbott, J.C.; Bota-Sierra, C.A.; Guralnick, R.; Bybee, S.M.; Ware, J.; Belitz, M.W. (2022): Diversity of Palaearctic dragonflies and damselflies (Odonata). *Diversity* 2022, 14, 966. <https://doi.org/10.3390/d14030966>. 15 pp. (in English) ["More than 1.2 million distribution records were used to create species distribution models for 402 Palaearctic species of dragonflies and damselflies. On the basis of these diversity maps of total, lentic and lotic diversity for the whole of the Palaearctic (excluding China and the Himalayan region) are presented. These maps show a clear pattern of decreasing diversity longitudinally,

with species numbers dropping in the eastern half of Europe and remaining low throughout a large part of Russia, then increasing again towards Russia's Far East and Korea. There are clear differences in diversity patterns of lentic and lotic species, with lentic species being dominant in colder and more arid areas. Areas with a high diversity of species assessed as threatened on the IUCN red list are largely restricted to the Mediterranean, Southwest Asia, and Japan, with clear hotspots found in the Levant and the southern half of Japan. The diversity at species, generic, and family level is higher in the south of Japan than in areas at a similar latitude in the western Mediterranean. This is likely to be the result of the more humid climate of Japan resulting in a higher diversity of freshwater habitats and the stronger impact of the glacial periods in the Western Palaearctic in combination with the Sahara, preventing tropical African lineages dispersing northwards." (Authors)] Address: Kalkman, V.J., Naturalis Biodiversity Center, 2300 RA Leiden, The Netherlands. Email: vincent.kalkman@naturalis.nl

**21188.** Karunaratne, S.; Surendran, S.N. (2022): Mosquito control: A review on the past, present and future strategies. *Journal of the National Science Foundation of Sri Lanka* 2022 50 (Special): 277-292. (in English) ["Nearly half a million deaths occur worldwide annually due to mosquito-borne diseases. Mosquito control has become the major strategy in controlling these diseases, especially in the absence of effective vaccines for disease prevention. At the beginning of the last century, mosquito control was mainly done by personal protection methods and larval control by application of petroleum oil and Paris green powder to water bodies. A breakthrough in mosquito control came in the 1940s with the introduction of synthetic neurotoxic insecticides which could suppress mosquito populations rapidly throughout the globe. However, a resurgence of populations with resistance to these insecticides was witnessed within a decade after their introduction. Environmental pollution caused by synthetic insecticides also became a major concern. Novel personal protection methods, community-level operations on source reduction, insect growth regulators and polystyrene beads for larval control, and biological control were introduced as alternatives. Biological control was mainly by larval predators such as fish, dragonfly nymphs, microcrustaceans and *Toxorhynchites* larvae; bacterial larvicides such as Bti; plant-based mosquitocides; and green-fabricated nanoparticles. However, even today, mosquito control programmes heavily depend on synthetic neurotoxic insecticides applied through insecticide residual spraying (IRS), fogging, larviciding and impregnated bed nets. Increased detoxification and target site insensitivity, developed as major insecticide resistance mechanisms, have been extensively studied in mosquitoes assisting proper management of available insecticides for which not many alternatives are available. Despite all our efforts, an unprecedented global emergence of mosquito-borne diseases is evident demanding novel strategies for mosquito control. The introduction of transgenic strains of mosquitoes to suppress or replace mosquito populations reducing disease transmission has become the latest effort. Population reduction has been achieved via releasing mosquitoes with a dominant lethal gene (RIDL) and by combining the conventional sterile insect technique (SIT) with *Wolbachia* mediated incompatible insect technique (IIT). Population replacement has been successful via releasing *Wolbachia* infected mosquitoes that are refractory to pathogen development and transmission. Advancement of gene- and allelic- drive systems will soon allow us to effectively spread refractory genes and insecticide susceptible alleles into mosquito populations overriding normal inheritance." **21192.** Kim, H.G.; Jang, R.H.; Kim, S.; Tho, J.-H.; Jung, J.-W.; Cheong, S.; Yoon, Y.-J. (2022): Developing habitat suitability index for habitat evaluation of *Nannophya koreana*

(Odonata: Libellulidae). *Journal of Ecology and Environment* 46:33: 10 pp. (in English) ["Background: *N. koreana*, is an endangered dragonfly with an increasing risk of extinction owing to rapid climate changes and human activities. To prevent extinction, the *N. koreana* population and their habitat should be protected. Therefore, suitable habitat evaluation is important to build the *N. koreana* restoration project. The habitat suitability index model (HSI) has been widely used for habitat evaluation in diverse organisms. Results: To build a suitable HSI model for *N. koreana*, 16 factors were examined by seven experienced researchers. A field survey for *N. koreana* observed sites and spatial analysis were conducted to improve the model. Five factors were finally selected by this procedure (crown density, open water surface, water depth, pioneer plant cover, and type of water source). Finally, the *N. koreana* HSI model was generated with the five adjusted factors based on interview, field survey, and spatial analysis. This model was validated by a current *N. koreana* habitat in 2021. With this model, 46 sites in Uljin-gun, Korea, were surveyed for *N. koreana* habitats; five sites were identified as core habitats and seven as potential core habitats. Conclusions: This model will serve as a strong foundation for the *N. koreana* restoration project and as a reference for future studies on *N. koreana* and other endangered insect populations. Further analysis and long-term data will improve the efficacy of this model and restore endangered wildlife." (Authors)] Address: Yoon, Y.-J., Res. center for Endangered Species, National Inst. Ecology, Yeongyang 36531, Rep. of Korea. E-mail yjyoon@nie.re.kr

**21193.** Koroiva, R.; Nóbrega Gomes, V.G.; Vilela, D.S. (2022): DNA barcoding and new records of Odonates (Insecta: Odonata) from Paraíba State, Brazil. *Diversity* 2022, 14(3), 203: 14 pp. (in English) ["Odonates are important insects in the food chains of freshwater environments around the world, being used as a model species for areas of behavior and analysis of environmental quality. In Brazil, especially in the Northeastern region, both knowledge about the distribution and molecular information of odonate species found in the two main biomes of the region is still limited. Aiming to improve these issues, here, we carried out an Odonata survey in two locations and built a DNA barcode database for species from the state of Paraíba. In total, 15 first records were reported for this Brazilian state and 142 specimens from 27 genera and 45 species had their 'Former' cytochrome c oxidase subunit I (COI) fragment evaluated. The database we generated includes data for 70% of the Odonata species found in Paraíba state. For 16 species, this is the first DNA barcode available in public sequence repositories. Our results demonstrate that using the COI in the regional scale can help identify and delimit those evaluated. Eight species (17%) showed a low percentage of differentiation (<2%) compared to other species currently deposited in the GenBank or BOLD System; nevertheless, we present morphological traits that reaffirm our identifications. Barcode data provide new insights into Neotropical diversity and deliver basic information for taxonomic analyses... 3.1. Sampling: Our samples added 15 new species records to the odonatofauna of Paraíba: *Dasythemis venosa* (Burmeister, 1839), *Dythemis nigra* Martin, 1897, *Epipleoneura metallica* Rácenis, 1955, *Erythrodiplax cf. fervida* (Erichson in Schomburgk, 1848), *Idioneura ancilla* Selys, 1860, *Macrothemis imitans* Karsch, 1890, *Metaleptobasis bicomis* (Selys, 1877), *Micrathyria didyma* (Selys in Sagra, 1857), *Micrathyria mengeri* Ris, 1919, *Nephepeltia berlai* Santos, 1950, *Orthemis flavopicta* Kirby, 1889, *Perithemis lais* (Perty, 1834), *Tauriphila australis* (Hagen, 1867), *Telebasis griffinii* (Martin, 1896) and *Triacanthagyna septima* (Selys in Sagra, 1857).

After performing the morphological analysis, all specimens (including those deposited in the DSEC/UFPB) that had previously been identified as *Anatya guttata* (Erichson in Schomburgk, 1848) were now identified as *Anatya januaria* Ris, 1911." **21196.** Laciak, M.; Zajac, T.; Adamski, P.; Bielanski, W.; Cmiel, A.; Laciak, T.; Lipinska, A. (2022): Small monsters: Insect predation limits reproduction of yellow-bellied toad *Bombina variegata* to ponds in their earliest successional stage. *Aquatic Conservation: Marine and Freshwater Ecosystems* 32(5): 817-831. (in English) ["The disappearance and deterioration of amphibian breeding habitats is a major cause of their global extinction. In Europe, this problem affects the yellow-bellied toad *Bombina variegata*, which inhabits small ponds in the early stages of succession, where no predatory invertebrate species normally occur. Nonetheless, as habitats, small temporary ponds are highly endangered, a situation that is intensifying with urban spread. A system of 13 pairs of artificial ponds was constructed in 2012 for the breeding of *B. variegata* with the aim of reconnecting disjunct populations. During the 2 years of the study, one of the twin ponds was regularly cleared of emergent vegetation and invertebrates. The survival rates of the tadpoles released in the cleared and uncleared ponds were analysed. The survival rate of the tadpoles released into the cleared ponds was higher than of those introduced into the uncleared ones. Tadpole survival rates were also higher in new, single ponds, constructed in 2013. The lower survival rates of the introduced tadpoles are best explained by the presence of predatory aquatic invertebrates, particularly the large diving beetle *Dytiscus marginalis*. Experimentally obtained consumption rates indicate that one *Dytiscus* larva is capable of destroying a typical clutch of *B. variegata* tadpoles

within a few hours, much faster than any of the other insect predators tested. The impact of freshwater invertebrates on tadpoles is frequently studied but rarely quantified. For conservation measures to be effective, quantitative standards need to be applied that describe the impact of predation in a predictable manner. Construction of artificial small ponds is broadly accepted as an important conservation measure compensating for the disappearance of natural amphibian breeding sites. This function of artificial ponds may be substantially enhanced by the periodic removal of invertebrate predators. ... The experiment was carried out in May–August 2015 and June–August 2016 in the laboratory. Specimens of presumed insect predators were collected from 39 ponds. They belonged to three orders: dragonflies (Odonata – Anisoptera: *Aeshna cyanea* (larvae), *Cordulia aenea* (larvae)); Zygoptera: *Coenagrionidae* (larvae)); bugs (Hemiptera – Heteroptera: *Notonecta glauca* (imagines), *Nepa cinerea* (imagines), *Corixidae* sp. (imagines); and beetles (Coleoptera – Dytiscidae: *Dytiscus marginalis* (larvae, imagines), *Ilybius* sp. (larvae, imagines))." **21197.** Li, F.; Zhang, Y.; Altermatt, F.; Zhang, X.; Cai, Y.; Yang, Z. (2022): Gap analysis for DNA-based biomonitoring of aquatic ecosystems in China. *Ecological Indicators* 137, April 2022, 108732: 11 pp. (in English) ["Highlights: • COI records of freshwater fish, aquatic insects and molluscs in Chinese rivers are analyzed. • Gaps in barcode coverage of species in three aquatic animal groups of China is 40–70%. • Nearly 90% of the COI sequences of aquatic species in China come from other countries. • The pairwise genetic distance of local barcodes is 3 to 5 times lower than non-local barcodes. • Nearly 60% of aquatic species in each catchment in China have at least one barcode. Abstract: DNA-based taxon identification is improving the assessment and management of biodiversity in rivers. However, the lack of comprehensive DNA barcode reference libraries and globally highly unequal coverage are still hindering the application prospects of this method worldwide. Here, we analyzed the COI barcode gap in two reference libraries, Barcode of Life Data Systems (BOLD) and NCBI GenBank, with a focus on three aquatic animal groups (freshwater fish, aquatic insects and molluscs) in Chinese rivers. Our data show gaps in barcode coverage (e.g., organisms without barcodes) of ca. 40–70% of taxa in these groups in the BOLD or NCBI GenBank database, respectively. These gaps can rise even further if the barcode thresholds are set to contain at least five reference sequences per taxon. Furthermore, most barcodes are from non-local samples, and only 14.4% (BOLD) and 28.8% (NCBI GenBank) of reference sequences were from organisms sampled in China, respectively. The pairwise genetic distance of local barcodes is 3 to 5 times lower than non-local barcodes, indicating that the latter may not be a good substitute. When looking at individual catchments, ca. 60% of the potentially occurring aquatic species have one or more barcodes, yet the barcode coverage varies slightly across ten major river catchments, ranging from 54.3% (Liao River basin) to 68.2% (Huai River basin). The taxa Salmoniformes and Perciformes in freshwater fish, Odonata and Diptera in aquatic insects, and *Bivalvia* in molluscs have the best barcode coverage in most catchments (mean coverage >70%). This study gives the first overview and current status of barcode reference libraries of three major aquatic animal groups in Chinese rivers. Our results will help to better interpret current metabarcoding studies from China, and also provide a basis to develop a strategy of filling the gaps

in the reference libraries of aquatic species in China." (Authors)] Address: Zhang, Y., Institute of Environmental & Ecological Engineering, Guangdong Univ. Technology, Guangzhou 510006, China. E-mail: zhang.yuan@gdut.edu.cn

**21198.** Lienard, M.A.; Valencia-Montoya, W.A.; Pierce, N.E. (2022): Molecular advances to study the function, evolution and spectral tuning of arthropod visual opsins. *Philosophical Transactions B* 3772021027920210279 <http://doi.org/10.1098/rstb.2021.0279>: 14 pp. (in English) ["Visual opsins of vertebrates and invertebrates diversified independently and converged to detect ultraviolet to long wavelengths (LW) of green or red light. In both groups, colour vision largely derives from opsin number, expression patterns, and changes in amino acids interacting with the chromophore. Functional insights regarding invertebrate opsin evolution have lagged behind those for vertebrates because of the disparity in genomic resources and the lack of robust in vitro systems to characterize spectral sensitivities. Here we review bioinformatic approaches to identify and model functional variation in opsins as well as recently developed assays to measure spectral phenotypes. In particular, we discuss how transgenic lines, cAMP-spectroscopy, and sensitive heterologous expression platforms are starting to decouple genotype-phenotype relationships of LW opsins to complement the classical physiological-behavioral-phylogenetic toolbox of invertebrate visual sensory studies. We illustrate the utility of one heterologous method by characterizing novel LW Gq opsins from 10 species, including diurnal and nocturnal Lepidoptera, a terrestrial dragonfly and an aquatic crustacean, expressing them in HEK293T cells, and showing that their maximum absorbance spectra ( $\lambda_{max}$ ) range from 518 to 611 nm. We discuss the advantages of molecular approaches for arthropods with complications such as restricted availability, lateral filters, specialized photochemistry and/or electrophysiological constraints." (in French, with English summary) [More than 72 minutes: About a record duration of underwater oviposition in *Coenagrion mercuriale* (Odonata: Coenagrionidae). "The site is a back channel ("contre-canal") located at Donzère, on the banks of the Rhône (44.41431°N, 4.70648°E, 54 m altitude). On this section (Fig. 1), the water is running, permanent and clear, mainly fed by phreatic resurgences. Observation: A male floating on the surface of the water spotted a female laying eggs just below (at 13 h 46' (t0)). The male quickly flew away and a female was discovered at a depth of 5 cm already laying eggs in a large foot of *Iris pseudacorus* (Fig. 2). She was therefore already immersed before the observation started, probably for several minutes. The observation continued to find out if she was really using the *Iris* as an oviposition support and then to time her immersion time. For more than an hour, she progressively descended along the stem to about 15 cm under water, the bottom being at a depth of 20 cm. At 14 h 58' (t + 72min) it suddenly rose like an air bubble to the surface (Fig. 3). At 15 h 00' (t + 74min) it flew away easily to land nearby on a leaf in the sun and clean its head. She appeared to be little harassed by males, perhaps because she was andromorphic. She was lost to view at 15 h 04' (t +78 min) when she flew away again." **21204.** Manna, S.; Manna, S.; Roy, A. (2022): Habitat specificity of phyto-diversity in semiurban lotic system: A case study. *Indian Hydrobiology* 21(2): 103-112. (in English) ["Biological diversity plays pivotal role in maintaining the physico-chemical conditions vis-à-vis homeostasis of ecosystems. The unicellular to complex multicellular forms of different biodiversity components prove their importance by providing the security of ecological health of ecosystems especially the aquatic once. The objective of this study was to find out the habitat specificity of Phyto-diversity sustained throughout the different segments of Bariti Beel based on variation of some environmental factors. It is revealed that, there was significant alteration in planktonic population in zone-A and zone-B. The macrophyte vegetation with five distinct stands supports to sustain different insect communities especially Odonates, Hemipterans and Coleopteran beetles. Most predictable abiotic factors controlling growth and reproduction of different growth forms of algae were derived through

multiple regressions along with the prediction model with high significance level ( $p = 0.15$ ). Specificity in establishment and distribution of some floral species as a result of their response to the environmental factors of the habitats both in micro and macro level was noted. This study would be helpful in wetland management through biomonitoring and maintenance of water quality with necessary biotic community." **21205.** Massote, C.; Almeida Pessoa, D.M.; Cardoso Peixoto, P.E. (2022): The conspicuousness contradiction: brighter males have lower mating chances in the damselfly *Argia hasemani* but not in *Argia croceipennis*. *Biological Journal of the Linnean Society* 137(1): 47-53. (in English) ["In odonates, male coloration is often more conspicuous than female coloration. This difference is frequently attributed to the role of male colour in male-male competition to access females. However, there are sexually dimorphic odonate species, such as the damselflies *Argia hasemani* and *Argia croceipennis*, in which male-male interactions are much less intense. In these species, it might be that male coloration affects male success directly when interacting with females. Therefore, we hypothesized that males with more intense coloration present higher copulation success. To investigate this hypothesis, we registered which males copulated in the field during 4 days and estimated the coloration of all observed males in the female visual spectrum. Surprisingly, we found that dull males had higher chances of copulation in *A. hasemani*, whereas in *A. croceipennis* male coloration did not influence the chances of copulation. Our data also indicated that brighter males of *A. hasemani* were also more conspicuous to potential avian predators, whereas this was not the case in *A. croceipennis*. We suggest that females of *A. hasemani* might avoid brighter males owing to increased risk of predation during copulation." **21206.** Miguel, T.B.; Calvão, L.B.; Alves-Martins, F.; Batista, J.D.; Rodrigues, M.E.; Guillermo-Ferreira, R.; De Marco Júnior, P.; Juen, L. (2022): Odonates in warm regions of south america largely do not follow Rapoport's rule. *Biodiversity and Conservation* 31: 565-584. (in English) ["One of the major challenges of ecologists and biogeographers is to understand how species are globally distributed. Two of the most well-studied large-scale patterns in species distributions are the Rapoport's rule and the Latitudinal Diversity Gradient (LDG). We aimed to address whether Neotropical odonates follow the Rapoport's rule and if there is a latitudinal gradient in species diversity. A total of 1076 records for 190 species, covering a large area from southeastern to the northern regions of Brazil that extends from 23°S (Cerrado) to 3°N (Amazon Rainforest). Generalized Linear Models were used to address whether Neotropical odonates follow the Rapoport's rule, and if there is a latitudinal gradient in species diversity, based on our predictions. We found a Rapoport effect in the Amazon biome and an inverse Rapoport effect in the Amazon-Cerrado Transition Forest and Cerrado biome. Regarding LDG, we found no significant effect of latitude on species richness patterns when we considered all the species, and a significant relationship between species richness and latitude for zygopteran. The spatial patterns of odonates geographic distribution may be

an outcome of geographical barriers, for instance, the continental geometry of South America, which is broader in the north and limits geographical expansion towards the south. Furthermore, species ecophysiological mechanisms may also hamper their expansion and drive the pattern observed in our study, mainly because of evolutionary thermoregulatory adaptations that each taxon exhibits along its environmental gradient." **21207.** Mollier, S.; Kunstler, G.; Dupouey, J.-L.; Bergès L. (2022): Historical landscape matters for threatened species in French mountain forests. *Biological Conservation* 269, 109544: 19 pp. (in English) ["Ancient forests are known to host a biodiversity of high ecological distinctiveness and are likely to provide habitat for red-listed species. Yet, few studies have investigated the role of forest continuity for the conservation of threatened species. We used species-presence data on red-listed species from 12 taxonomic groups (Spermatophyta, Pteridophyta, Bryophyta, Lichens, Chiroptera, Aves, Squamata, Amphibia, Coleoptera, Lepidoptera, Odonata and Orthoptera) to ascertain if ancient forests are an important habitat for threatened species in five mountain and subalpine protected areas in France. We compared the effect of the amount of historical forest (1853–1860) with the effect of the amount of current forest on the distribution of red-listed species in six circular landscape buffers ranging in radius from 100 to 1500 m. We showed that the amount of historical forest in the landscape had a positive effect on forest Spermatophyta, Bryophyta, Coleoptera and edge forest Pteridophyta with a better predictive power than current forest area, highlighting a colonization credit in recent forests. Conversely, edge-forest lepidopterans were more negatively affected by historical than by current forest area, highlighting an extinction debt in recent forests. Our findings underline that implementing protective measures of ancient forests would be a better strategy than afforestation to preserve threatened forest species in mountain and subalpine forest landscapes." (Authors) In my opinion many of the bird and dragonfly taxa - I only checked these - are classified wrong in Appendix C to this publication. (2022): Relación de las larvas de Odonata con las raíces de *Eichhornia crassipes* en la ciénaga la Larga, Atlántico, Colombia. *Intropica* 17 (2): 10 pp. (in Spanish, with English summary) ["The purpose of this study was to evaluate the association of Odonata larvae with the roots of *Eichhornia crassipes* in La Larga wetland. For the capture of Odonata larvae, standardized sampling techniques for aquatic macroinvertebrates were used. Six samplings were carried out and in each sampling 100 individuals of *E. crassipes* were collected. The length and volume of each root were obtained. A total of 738 individuals and 10 species of Odonata were collected; *Miathyria marcella* presented the highest abundance, with 83 % of the total sampled. The percentage of occupation of the roots of *E. crassipes* by Odonata larvae was 58 % (346 of the 600 roots collected). The collected roots varied between 5 and 58 cm in length and between 5 and 450 ml in volume. Significant differences were found in the composition and structure of the larvae with respect to the volume of the roots.

Larval lengths ranged from 2.4 to 24.3 mm; most of the collected individuals were found in the length range between 5.1 and 10 mm. In conclusion, the size of the root is not a determinant for the distribution of odonates in the roots of *E. crassipes*, while the volume of the roots of *E. crassipes* does influence the composition of larvae." **21210.** Nel, A. (2022): Revision of the damselfly *Hesperagrion praevolans* (Odonata, Zygoptera, Coenagrionidae) from the uppermost Eocene of Florissant (Colorado, USA). *Palaeoentomology* 5.6.2: 517-519. (in English) ["The damselfly family Coenagrionidae is rather frequently found in the Cenozoic fossil record (Nel & Paicheler, 1993), but it remains unknown in the Mesozoic. The known fossils are generally isolated wings, very difficult to accurately attribute to precise genera, to the point that many fossils can be only considered as 'genera and species undetermined' (Nel et al., 1997). The oldest described coenagrionid fossil is the late Palaeocene *Marado marado Petrulevicius*, 2021 (Maíz Gordo Formation, Argentina), a genus and species based on an isolated incomplete wing. Thus, other Eocene representatives of the family are important for future accurate dating of the occurrence of the family and its subdivisions, especially those that have been attributed to extant genera; a future step after the important work of Dijkstra et al. (2014) for the understanding of the evolution of these damselflies." (Author)] Address: Nel, A., Lab. Ent. Mus. Natn. Hist. Nat., 45 rue Buffon, F-75005 Paris, France. E-mail: anel@mnhn.fr

**21211.** Niwa, H.; Hirata, T. (2022): A new method for surveying the world's smallest class of dragonfly in wetlands using unoccupied aerial vehicles. *Drones* 2022, 6(12), 427; <https://doi.org/10.3390/drones6120427>: 6 pp. (in English) [„Field surveys in wetlands are limited by the difficulty in ac-

cessing the site, hazards during surveys, and the risk of disturbing the ecosystem. Thus, the use of unoccupied aerial vehicles (UAVs) can overcome these limiting factors and can assist in monitoring small organisms, such as plants and insects, that are unique to wetlands, aiding in wetland management and conservation. This study aimed to demonstrate the effectiveness of a survey method that uses a small drone equipped with a telephoto lens to monitor dragonflies, which are unique to wetlands and have been difficult to survey quantitatively, especially in large wetlands. In this study, the main target species of dragonflies was *Nannophya pygmaea*, which is the world's smallest dragonfly (about 20 mm long). The study area was Mizorogaike wetland (Kita Ward, Kyoto City, Japan). The UAV was flown at a low speed at an altitude of 4 m to 5 m, and images were taken using 7× telephoto lens on Mavic 3 (7× optical and 4× digital). A total of 107 dragonflies of seven species were identified from the photographs taken by the drone. *N. pygmaea*, about 20 mm long, was clearly identified. Eighty-five dragonflies belonging to *N. pygmaea* were identified from the images. Thus, by using a small drone equipped with a telephoto lens, the images of *N. pygmaea* were captured, and the effects of downwash and noise were reduced. The proposed research method can be applied to large wetlands that are difficult to survey in the field, and can thus provide new and important information pertaining to wetland management and conservation. This research method is highly useful for monitoring wetlands as it is non-invasive, does not require the surveyor to enter the wetland, requires little research effort, and can be repeated." **21212.** Nurmaisah; Septiawan, R.A. (2022): The diversity of insects found in polycultural land of green spinach (*Amaranthus* sp) in Sinar Harapan Farming Group, Tarakan. The 1st International Conference On Indigenous Knowledge For Sustainable Agriculture 2022. ISBN: 978-623-331-387-2: 1-7. (in English) ["The diversity of insect species has an important role in the ecosystem stability. The farming system in kampung enam village used a polyculture farming system. Polyculture farming can increase the ecosystem stability since providing a better environment for the predatory insects and parasitoids in controlling the natural pest population in a commodity. One horticultural commodity found in polyculture land in Sinar Harapan Farmer Group of Tarakan is spinach. The declining quality and production of spinach is caused by several plant-disturbing organisms, such as insects. This research aimed to figure out the diversity and dominance of insects in the polyculture land of green spinach (*Amaranthus* sp) in the Sinar Harapan Farmer Group of Tarakan. The data were collected using traps, such as yellow traps and pitfall traps. Furthermore, identification was conducted at the Plant Protection Laboratory, Faculty of Agriculture, Universitas Borneo Tarakan. The obtained data were analysed using the Shannon Wiener diversity index and Simpson dominance. The research results show that the obtained insects were included into 9 orders, 36 families, 58 species with a total number of 912 individuals. Based on the analysis results using the Shannon Wiener diversity index and Simpson dominance, the diversity of insects in polyculture land of green spinach (*Amaranthus* sp) was 3.12 (H') in which the diversity was categorised into high. Meanwhile, the value of insect dominance index was 0.02 with the dominant insect type of dragonfly (*Pantala flavescens*) with a total number of 115 individuals." **21214.** Pacheco, J.P.; Calvo, C.; Aznarez, C.; Barrios, M.; Meerhoff, M.; Jeppesen, E.; Baatrup-Pedersen, A. (2022): Periphyton biomass and life-form responses to a gradient of discharge in contrasting light and nutrients scenarios in experimental lowland streams. *Science of the Total Environment* 806 (2022) 150505: 9 pp. (in English) ["Highlights: • We tested periphyton responses to discharge and different light and nutrient availability. • Light availability modulated contrasting periphyton responses to discharge. • High light and nutrients enhanced periphyton biomass with increased discharge. • Low light, induced periphyton loss and low profile dominance with higher discharges. • Discharge and nutrients, but not light drove changes in periphyton life-forms. Abstract: Climate-induced changes in precipitation and land-use intensification affect the discharge of streams worldwide, which, together with eutrophication and loss of riparian canopy, can affect periphyton biomass and composition, and therefore, ultimately the stream functioning. We investigated the responses of periphyton biomass and life-forms (i.e., high profile, low profile and motile) to these changes applying an experimental approach by modulating nutrients (nutrient diffusion substrates enriched with 0.5 M NH<sub>4</sub>NO<sub>3</sub> + 0.031 M KH<sub>2</sub>PO<sub>4</sub> and without nutrient enrichment) and light availability (50% shade and full light) along a gradient in discharge ranging from 0.46 to 3.89 L/s (0.7 to 6.5 cm/s) in twelve large-sized (12- m long) outdoor flumes resembling lowland streams. We also analysed the potential effects of other environmental variables including macro-invertebrates on the responses of periphyton to discharge, nutrients, and light. Light and nutrient availability drastically affected periphyton biomass and composition responses to discharge. Periphyton biomass decreased with increasing discharge when shaded but this did not happen when exposed to full light. Under full light conditions, nutrient enrichment mediated an increase in the periphyton biomass with increasing discharge, possibly reflecting an increased metabolism, but this did not happen under non-enriched conditions. Enrichment further affected the compositional responses of periphyton to discharge, with an increase in the biomass of motile, fast growing, small-sized flagellated at

low discharge conditions, and mitigating a loss of high profile periphyton under higher discharges. Light did not affect periphyton composition, and the abundance or feeding-group composition of the macroinvertebrates did not affect biomass or composition of the periphyton either. Our results suggest that nutrient enrichment and light play an important synergistic role in the responses of the periphyton biomass and composition to discharge and emphasize the relevance of riparian canopy conservation and eutrophication control to avoid periphyton growth under increased discharge scenarios in small lowland streams. ... Predator macroinvertebrates were the second most abundant group (Appendix S6), mainly represented by Coleoptera (Dytiscidae, Gyrinidae and Noteridae), Anisoptera, and Chironomidae (Tanyptodinae)." **21217.** Portilla, G.; Rendón, A. (2022): Diseño de estudio del movimiento de microplásticos en la cadena trófica. Tesis de grado, Escuela Superior Politécnica del Litoral, Guayaquil: 49 pp. (in Spanish, with English summary) ["Microplastics biomagnification have been extensively studied in marine ecosystems. However, studies in freshwater ecosystems are less frequent. Many invertebrates, such as Diptera and Odonata [*Erythemis vesiculosa*], begin their life cycle in these ecosystems and are constantly exposed to microplastics and are constantly exposed to microplastics which facilitates MP transport to organisms at other trophic levels.

This study proposes a protocol to evaluate insects as vectors of microplastics using fluorescent particles to determine the risk of biomagnification and possible adverse effects on aquatic organisms. This project collected information on the effects of microplastics of different sizes at various concentrations and exposure times on dipterans, odonates, anurans, and arachnids. To determine the accumulation of microplastics in the internal organs, dissection, extraction and chemical digestion were chosen. While visualization of fluorescent particles was performed with epifluorescence microscopy to quantify the number of particles per individual. The results showed that the most prevalent particles were the smallest and the organ with the highest accumulation was the gastrointestinal tract. Likewise, the biomagnification factor was greater than 1 in all interactions except for anurans. This study demonstrates that the use of fluorescent particles plus chemical digestion allows determining the transfer of microplastics from mosquitoes to other organisms and that the smallest particles have a greater impact on the biomagnification of these particles in the internal organs of aquatic organisms.] Address: not stated

**21218.** Prat, N. (2022): A case of phoresis of midges on Zygoptera. *Chironomus* 35: 43. (in English) [Verbatim: Several midges live phoretically on different invertebrates, as was described by Thienemann in his book *Chironomus* (Thienemann 1974) and may be found in many papers published since. For example, I found some time ago a *Podonomus* living on the gastropod *Chilina dombeiana* (Prat et al. 2004). This is a classic topic in midge studies; I found the first revision of the topic in White et al. (1980). Phoresis between Chironomidae and Odonata was one of the most common phoretic associations. Last year, two colleagues working on Odonata sent me several larvae of midges living on Zygoptera larvae. In the first sample (Fig. 1), tubes of *Rheotanytarsus* larvae were attached to *Calopteryx virgo meridionalis*. Larvae of the midge inside the tubes were very small. In the second sample examined, cases were simple tubes, and the midges were from the genus *Paratanytarsus*, and were present on *Calopteryx haemorrhoidalis* and *Calopteryx xanthostoma* (R. Martin pers. comm.). Both samples are from the River Tordera, in Catalonia (NE Spain). More details of the sites and the number of larvae found, and the instar of the Odonata may be found in Martin and Maynou (2021). Although phoresis between Chironomidae and Odonata has been frequently described over many years, the picture of this occurrence may be of interest to people working on midges.] Address: Prat, N., Freshwater Ecology, Hydrology and Management group (F.E.H.M), Dept de Biologia Evolutiva, Ecologia i Ciències Ambientals, Univ. de Barcelona. (2022): Using Red List Indices to monitor extinction risk at national scales. *Conservation Science and Practice*. 2022; e12854: 12 pp. (in English) ["The Red List Index (RLI) measures change in the aggregate extinction risk of species. It is a key indicator for tracking progress toward nine of the Aichi and many proposed post-2020 Global Biodiversity Framework Targets. Here, we consider two formulations of the RLI used for reporting biodiversity trends at national scales. Disaggregated global RLIs measure changing national contributions to global extinction risk and are currently based on five taxonomic groups, while national RLIs measure changing national extinction risk and are based on taxonomic groups assessed multiple times in country. For 74% of nations, the disaggregated global RLI is currently based on three or fewer taxonomic groups. Meanwhile, national RLIs from selected pilot countries Finland, South Africa, and Brazil are computed from twelve, eight, and nine taxonomic groups, respectively. The national RLI and the disaggregated global RLI measure different aspects of biodiversity, in that the former detects national trends in populations of species for which each country is responsible while the latter provides standardized comparisons of nations' contributions to the global extinction risk of the same species groups. As governments commit to the post-2020 Global Biodiversity Framework, we encourage them to monitor a standard set of taxonomic groups representing different biomes using both RLI formulations to ensure effective target tracking and accurate feedback on their conservation investments." **21221.** Ranjith, M.; Bajya, D.R.; Ramya, R.S. (2022): Abundance and composition of arthropods in sugarcane (*Saccharum officinarum*) ecosystem. *Indian Journal of Agricultural Sciences* 92(11): 1386-1390. (in English) ["A short investigation was devised by Dept of Agricultural Entomology, Tamil Nadu Agricultural University, Coimbatore in 2022 to document the arthropod composition in sugarcane (*Saccharum officinarum* L.) ecosystem. Arthropod fauna was collected from sugarcane ecosystem in farmers' field at Puthur of Coimbatore district, Tamil Nadu at weekly intervals. Totally, 2,310 individuals of the subclass Pterygota were collected and among them most of specimens belonged to Exopterygota. The exopterygota (1,029) were represented by 5 orders, viz. Hemiptera, Odonata, Orthoptera, Isoptera and Dermaptera. Majority of the individuals belonged to the family Aphididae (330) under the order Hemiptera. Under order Orthoptera, Gryllidae (46) was the dominant family closely followed by Acrididae (45). Among these, the dominant species was *Gryllus* spp. The order Odonata was represented by a single family Libellulidae (38) (*Orthetrum sabina* Drury, 1773). Under Endopterygota, 4 orders were identified and among these, Hymenoptera was the most common order with 740 numbers, followed by Diptera (237), Coleoptera (215) and Lepidoptera (89). Under the order Coleoptera, 3 families were recorded, with most of them falling under the family Coccinellidae (172) followed by Cicindelidae. Hymenopteran order comprised majorly of ants, belonging to the family Formicidae, of which 3 species were

identified. Lepidoptera consisted of single species *Ariadne merione* Cramer, 1779 belonging to family Nymphalidae. Majority of Arachnida was represented by order Araneae. Under the order Araneae most of them pertained to families Araneidae, Lycosidae and Thomisidae. *Neoscona* sp., *Hippasa* sp., *Pardosa* sp. and *Pardosa birmania* Simon were found to be common in sugarcane ecosystem." **21222.** Rippel, C.A. (2022): Control biológico de culicidos: análisis de la capacidad predatoria de estadios inmaduros de insectos del orden Odonata. PhD thesis, Facultad de Ciencias Exactas, Químicas y Naturales, Universidad Nacional de Misiones, Posadas: 105pp. (in Spanish, with English summary) ["Mosquitoes are a major global health problem. The life cycle of these insects includes an aquatic stage, during which immature stages develop, and is the period during which many of the processes of population regulation occur. Predation is considered one of the most important biological interactions in aquatic environments. Given the need for ecological strategies to address the problem of mosquito proliferation vectors poses natural enemies as an attractive option. The order Odonata (Insecta) has immature aquatic states and flying adults. Although there are no ecological studies in the area on the predatory-prey relationship of odonates and mosquitoes, the capacity and efficiency of several Odonata species have been evaluated worldwide. For a sustainable biological control program, it is a prerequisite to characterize the trophic relationships between native species. Therefore, in the first place, we surveyed the fauna of Odonata present in the area. Larvae and adults were collected and raised in streams and drainage channels in the southern part of the province of Misiones. Sites from the Selva Paranaense ecoregion were also surveyed. Artificial breeding sites (swimming pools) were examined, where the composition of the accompanying entomofauna was determined at the highest possible taxonomic level, in addition to odonates and mosquitoes. After determining the distribution and partially the breeding conditions of insects of the order Odonata, we proceeded with the characterization of predatory activity. The predatory capacity of Odonata larvae on culicids was evaluated in laboratory and in swimming pools (artificial hatches used by both orders). Predation capacity and performance tests were performed on a gradient of conditions with varying difficulties. Functional response was evaluated for *Pantala flavescens* (Anisoptera: Libellulidae). Finally, different ways of observing the preys after intake were evaluated through dissections, fecal matter and extraction and amplification of the DNA prey of the digestive tract of odonates with markers of the mitochondrial gene Cytochrome Oxidase I. The results show that odonates are present in various environments in the province of Misiones, including those where urbanization is advancing. In artificial breeding sites, such as swimming pools, the immature stages of *Pantala flavescens* coexist with mosquito larvae and these are part of their diet. The presence of predators of the orders Hemiptera and Coleoptera is also recorded in these farms. The predatory capacity of the analyzed Odonata larvae shows that they are voracious predators with a functional response of type II. Post-intake analyses allowed the identification of the larvae consumed by *Culex quinquefasciatus*. The coexistence and regulation of Odonata and mosquitoes occurs naturally in favorable conditions. Then through protection of water and vegetation, biological control could occur spontaneously in biodiverse areas such as the province of Misiones." (Author)] Address: not stated

**21223.** Sadasivan, K.; Nair, V.P.; Palot, M.J.; Samuel, A.; Shereef, A. (2022): Taxonomic notes on the genus *Helio gomphus*, with a redescription of *H. kalarensis*. *International Journal of Odonatology* 25: 107-120. (in English) ["The taxonomy and distribution of dragonflies of the genus *Helio gomphus* from the Western Ghats of southern India are discussed. A morphological study of fresh male specimens from the field, as well as holotypes and lectotypes from repositories was undertaken. Contradicting statements in scientific literature, we found that the markings on the occiput and thorax are not dependable features in distinguishing sympatric *Helio gomphus promelas* (Selys, 1873) and *H. kalarensis* Fraser, 1934. The structure of the epiprocts and the male genitalia were key features for differentiating them. *H. pruinans*, Fraser, 1922 is removed from the synonymy of *H. promelas* and is synonymized with *H. kalarensis* instead based on the analysis of the structure of its epiproct. In accordance with the provisions of ICZN Article 23.9.1.2, in suppression of the unused senior synonym, the taxon name *H. kalarensis* is retained as a nomen protectum. *H. unifasciatus* is treated as nomen nudum. Taxonomic notes and updated distribution summaries of the two species from the Western Ghats with an identification key to the males are provided. *H. kalarensis* is redescribed from fresh field-collected specimens, including details of the male genitalia and anal appendages. Fieldwork in the Western Ghats revealed that *H. kalarensis* is the most common of the two *Helio gomphus* species in Kerala state. The published records of *H. promelas* and *H. kalarensis* from this region need to be revisited in light of the facts presented here." **21224.** Samways, M.J.; Deacon, C. (2022): Extinction re-trieve for the ancient and imperiled dragonflies at the southern tip of Africa. Imperiled: The Encyclopedia of Conservation. Publisher: Elsevier: 471-484. (in English) ["The ancient mountains of southern Africa are rich in local endemic species, including dragonflies. Despite the mountains experiencing hot and dry summers, the perennial mountain streams enable the dragonflies to survive the harshest of summers. This has continued for millions of years, with some species having an ancient phylogenetic history. Yet today, these insects are experiencing significant novel impacts from human activity, especially from invasive trees impacting the mountain streams. However, the tide of local extinction risk has turned around. A large-scale national project has successfully removed many of the alien trees. This timely conservation action has resulted in effective recovery of many of these ancient dragonflies with great success. Southern Africa is rich in localized biota. The ancient mountains create complex rainfall patterns and support many perennial streams, making them an evolutionary stage for many endemic dragonfly species. These mountain streams enable the dragonflies to survive the hot, dry summers characteristic of the region. However, these insects are now facing significant impacts from human activity, especially invasion from alien trees along the streams. But all is not lost. A strategic national project has already removed many of the alien trees with great success, showing how targeted conservation action can be highly effective for imperiled dragonflies, and as sentinels for recovery of entire freshwater ecosystems." (2022): Antipredatory Behavioural Responses of Microplastic-Exposed Tadpoles of the Italian Agile Frog. *Environmental Science and Pollution Research* 30: 13688-13696. (in English) ["Microplastics (MPs) are nowadays abundant, persistent, and ubiquitous in the environment, representing a new threat for terrestrial, marine, and freshwater ecosystems. Although anuran populations and species are globally declining, the effect of MP exposure on this taxon has been poorly investigated. With the aim of assessing the effects of microplastic exposure on the defensive responses of Italian agile frog (*Rana latastei*) tadpoles, we exposed them to three different concentrations (1, 7, and 50 mg L<sup>-1</sup>) of a mixture of plastic polymers (HPDE, PVC, PS, and PES) for 2 weeks. Then, we measured the total distance covered by individual tadpoles before and after exposure to tadpole-fed dragonfly larvae (*Aeshna cyanea*) cues. As expected, predation risk sharply lowered the total distance travelled by tadpoles; however, MP concentration did not affect their defensive performances. We also collected data on tadpole development, activity, and mortality. In contrast with previous experiments, neither tadpole growth nor mortality varied with MP concentration. Our results indicate that the intensity of MP effects on growth and development may depend on tadpole size, with large tadpoles being less susceptible to the negative effects of MP exposure." **21228.** Siepielski, A.M.; Gómez-Llano, M.; McPeck, M. (2022): Environmental conditions during development affect sexual selection through trait-fitness relationships. *American Naturalist* 199(1): 34-50. (in English) ["Sexual selection can be shaped by spatial variation in environmental features among populations. Differences in sexual selection among populations generated through the effects of the environment could be shaped via four paths: differences in mean absolute fitness, differences in the means or variances of phenotypes, or differences in the absolute fitness-trait function relationship. Because sexual selection occurs only during the adult life stage, most studies have focused on identifying environmental features that influence these metrics of fitness and trait distributions among adults. However, these adult features could also be affected by environmental factors experienced in early life stages that then shape the trajectory for sexual selection during the adult life stage. Here we investigated how among-population variation in environmental conditions during the juvenile (larval) stage of two species of *Enallagma* damselflies [*E. ebrium*, *E. geminatum*] shapes sexual selection on male body size. We found that environmental factors related to predation pressures, lake primary productivity, and habitat availability play a role in shaping spatial variation in sexual selection. This acts mainly through how the environment affects absolute fitness-body size associations, not spatial variation in mean fitness or body size means and variances. These results demonstrate that the underpinnings of sexual selection in the wild can arise from environmental conditions during prereproductive life stages." **21229.** Sirois-Delisle, C.; Kerr, J.T. (2022): Climate change aggravates non-target effects of pesticides on dragonflies at macroecological scales. *Ecological Applications* 32(2), e2494: (in English) ["Critical gaps in understanding how species respond to environmental change limit our capacity to address conservation risks in a timely way. Here, we examine the direct and interactive effects of key global change drivers, including climate change, land use change, and pesticide use, on persistence of 104 odonate species between two time periods (1980-2002 and 2008-2018) within 100 X 100 km quadrats across the United States using phylogenetic mixed models. Non-target effects of pesticides interacted with higher maximum temperatures to contribute to odonate declines. Closely related species responded similarly to global change drivers, indicating a potential role of inherited traits in species' persistence or decline. Species shifting their range to higher latitudes were more robust to negative impacts of global change drivers generally. Inherited traits related to dispersal abilities and establishment in new places may govern both species' acclimation to global change and their abilities to expand their range limits, respectively. This work is among the first to assess effects of climate change, land use change, and land use intensification together on Odonata, a significant step that improves understanding of multi-species effects of global change on invertebrates, and further identifies conditions contributing to global insect loss." (2022): Penyusunan ensiklopedia Berbasis keanekaragaman capung (Odonata) di Kawasan Air Terjun Teleng Ngawi sebagai sumber belajar kelas X [Compilation of an encyclopedia based on the diversity of dragonflies (Odonata) in the Teleng Ngawi Waterfall Area as a learning resource for class X]. *Jurnal Edukasi Matematika dan Sains* 10(2): 424-430. (in Indonesian, with English summary) ["This study aims to compile a product in the form of an encyclopedia of learning resources for class X diversity of dragonflies (Odonata) in the Teleng Ngawi Waterfall area. This research is a qualitative research that identifies and processes data from observations in the teleng waterfall field in accordance with the facts, circumstances and data during the research. This study describes the situation that occurs with the relevant data. The identification of dragonflies (Odonata) was carried out from February to June 2022, and found 7 species, namely *Rhinocypha fenestrata*, *Vestalis luctuosa*, *Euphaea variegata*, *Copera marginipes*, *Orthetrum sabina*, *Crocothemis servilla*, and *Neurothemis terminata*. The findings of this study became the material for compiling an encyclopedia of dragonfly diversity (Odonata). The stages of compiling the encyclopedia include: (a) drafting of the encyclopedia, (b) validation of the encyclopedia, (c) revision of the validation result of the encyclopedia based on the validator's criticisms and suggestions, (d) printing of the encyclopedia product. Validation was carried out by 2 validators, namely the material expert validator and the media expert validator. An Encyclopedia was formed with the title: "The Encyclopedia of Odonata Diversity in the Teleng Ngawi Waterfall Area". The result of the calculation of the validation of the Encyclopedia is 79%, which means that the Encyclopedia is suitable to be used as a learning material for class X high school based on local wisdom." **21231.** Sophian, A.; Nasir, L.O. (2022): Analysis of purity and concentrations of DNA isolated in dragonfly (*Onychogomphus forcipatus*). *Wahana-Bio: Jurnal Biologi dan Pembelajarannya* 14(2): 130-136. (in English, with Indonesian summary) ["Analysis of the purity and concentration of DNA isolation results was carried out using samples of dragonflies (*Onychogomphus forcipatus*) species of insects. This research is important because there are many kinds of research in the molecular field that require good DNA isolation techniques to support the success of the research. The purpose of this paper is to provide information about the quality of the isolated DNA seen using the purity and concentration parameters. The extraction method uses the centrifuge column method. The isolated data were analyzed statistically using the average test. The results of DNA isolation showed that the average concentration value was in the range of 60.10 – 69.95. The analysis of the purity of the isolated DNA read at the A260/A280 ratio was in the range of 1.817 – 1.929, while the purity analysis at the A260/A230 ratio was in the range of 0.760 – 0.822. Based on the results of the study, it can be concluded that the analysis of the purity and concentration of DNA from the isolation of dragonfly samples was in a good category at the A260/A280 ratio, while the purity read at the A260/A230 ratio was below the value categorized as good." (Authors) The authors don't give any information where the studied material was sampled. *O. forcipatus* is a western Palaearctic faunal element, and is not occurring in Indonesia.] Address: Sophian, A., Pusat Pengembangan Pengujian Obat dan Makanan Nasional, Badan POM, Jl. **21233.** Stelzer, V.; Rütten, M. Krenkel, L. (2022): Numerical Investigation of a 3D Dragonfly Wing Captured with a High-Resolution Micro-CT. 8th European Congress on Computational Methods in Applied Sciences and Engineering, ECCOMAS Congress 2022, 5-9 June 2022, Oslo, Norway: (in English) [Verbatim: "The special wing geometry of dragonflies consisting of veins and a membrane forming a

corrugated profile leads to special aerodynamic characteristics. To capture the governing flow regimes of a dragonfly wing in detail, a realistic wing model has to be investigated. Therefore, this study aimed to analyze the aerodynamic characteristics of a 3D dragonfly wing reconstructed from a high-resolution micro-CT scan. Afterwards, a spatially high discretized mesh was generated using the mesh generator CENTAUR™ 14.5.0.2 (CentaurSoft, Austin, TX, US) to finally conduct Computational Fluid Dynamics (CFD) investigations in Fluent® 2020 R2 (ANSYS, Inc., Canonsburg, PA, US). Due to the small dimensions of the wing membrane, only the vein structure of a *Camacinia Gigantea* was captured at a micro-CT voxel size of 7 microns. The membrane was adapted and connected to the vein structure using a Boolean union operation. Occurring inconsistencies after combining the veins and the membrane were corrected using an adapted pymesh script [1]. As an initial study, only one quarter of the wing (outer wing section) was investigated to reduce the required computational effort. The resulting hybrid mesh consisting of 10 pseudo-structured prism layers along the wing surface and tetrahedra in the farfield area has 43 mio. nodes. The flow around the wing was considered to be incompressible and laminar using transient calculations. When the flow passes the vein structures, steady vortices occur in the corrugation valleys leading to recirculation zones. Therefore, the dragonfly wing resembles the profile of an airfoil. This leads to comparable lift coefficients of dragonfly wings and airfoil profiles at significantly reduced structural weight. The reconstructed geometry also included naturally occurring triangular prismlike serrated structures at the leading edge of the wing, which have comparable effects to micro vortex generators and might stabilize the recirculation zones. Further work aims to investigate the aerodynamic properties of a complete dragonfly wing during wing flapping." (Authors)] Address: Stelzer, Vera, Fak. **21235.** Susanto, M.A.D. (2022): The diversity and community structure of dragonflies (Odonata) in various types of

habitat in Lakarsantri District, Surabaya. Program Studi Biologi, Fakultas Sains Dan Teknologi, Universitas Islam Negeri Sunan Ampel, Surabaya: 129 pp. (in Indonesian, with English summary) ["Lakarsantri District is one of the areas in the city of Surabaya that has various types of aquatic habitats so that it has a big role for the sustainability of various living things, especially dragonflies (Odonata). Dragonflies are flying insects that spend most of their life cycle in the water, so the existence of aquatic ecosystems is very important for the survival of dragonflies. Diversity and community structure of dragonflies have an important role in an ecosystem, including as a bioindicator of environmental quality and predators of insect pests and disease vectors. The purpose of this study was to determine the species diversity and community structure of dragonflies in various habitat types in Lakarsantri District. The data collection method in this study used the Visual Encounter Survey (VES) method, which is an observation method by tracing all predetermined observation locations by recording the diversity of dragonfly species and counting the number of individuals of each dragonflies species observed. The study was conducted at 6 observation locations during July, August and September 2021. The results of this study showed that there were 22 species with a total of 1028 individuals from 4 families. The diversity index value shows that the Open Pond location has the highest dragonflies diversity value with a value of  $H' = 2.23$  with 19 species of dragonflies found in 4 families with a total of 351 individuals. Meanwhile, the location with the lowest dragonflies diversity index was at the Unesa Reservoir with a value of  $H' = 0.55$  with 11 dragonfly species found with a total of 94 individuals." (2022): Morphological variation and reproductive isolation in the *Hetaerina americana* species complex. *Scientific Reports* 12, Article number: 10888: 10 pp. (in English) ["Incomplete premating barriers in closely related species may result in reproductive interference. This process has different fitness consequences and can lead to three scenarios: niche segregation, sexual exclusion, or reproductive character displacement. In morphologically cryptic species, isolation barriers can be difficult to recognize. Here, we analyzed the morphological, behavioral, and genetic differences between two sympatric cryptic species of the genus *Hetaerina* to determine the characters that contribute the most to reproductive isolation and the effect of the high rates of behavior interference between the species. We found complete genetic isolation and significant differences in the morphometry of caudal appendages and wing shape, as well as body size variation between species. In contrast, we did not find clear differences in the coloration of the wing spot and observed high rates of interspecific aggression. Our results suggest that divergence in the shape of the caudal appendages is the principal pre-mating barrier that prevents interspecific mating. Moreover, a scenario of

character displacement on body size was found. Nevertheless, size could play an important role in both inter- and intrasexual interactions and, therefore, we cannot differentiate if it has resulted from reproductive or aggressive interference." **21238.** Ziter, C.D. (2022): Cryptic eco-evolutionary feedback in the city. *Journal of Animal Ecology* 91(3): 510-513. (in English) ["Research Highlight: Brans, K. I., Tüzün, N., Sentis, A., De Meester, L., & Stoks, R. (2021). Cryptic eco-evolutionary feedback in the city: Urban evolution of prey dampens the effect of urban evolution of the predator. *Journal of Animal Ecology*. <https://doi.org/10.1111/1365-2656-13601>. Despite the strength and ubiquity of urban stressors on multiple taxa, there have been minimal attempts to determine the ecological consequences of urban evolution on multiple species. Brans & Tüzün et al. use a well-known predator-prey system—damselfly nymphs *Ischnura elegans* and water fleas *Daphnia magna*—to test whether scenarios in which both species evolve in response to urbanization differ from scenarios in which only the predator or prey evolves. The authors show that urban damselflies showed higher encounter and predation rates when paired with rural prey, but that the advantages conferred by urbanization-driven adaptation disappeared when urban predators encountered urban prey. This represents a cryptic eco-evolutionary feedback, where evolution of both predator and prey concealed the effect of evolution in each partner individually. Results suggest that mismatches in the evolutionary responses of interacting species may have significant ecological consequences, and highlight the importance of a multi-species approach in eco-evolutionary dynamics research." (in German, with English summary) ["Sphagnum paludiculture as a habitat for birds, amphibians, Odonata, and Lepidoptera – What habitat quality do sustainably managed raised bogs provide? - Peatland species are often highly endangered and isolated in their populations due to large-scale drainage-based use and destruction of their habitats. Current climate policy goals are leading to new approaches for a wet, sustainable use of peatland sites, so-called paludiculture. On raised bog soils, the cultivation of peat mosses ('Sphagnum farming') is suitable, which creates potential habitats for peatland species due to the wet conditions and the establishment of vegetation typical for raised bogs. This study investigated the extent to which this potential can be used by birds, amphibians, dragonflies, damselflies, butterflies and moths. In 2017 and 2018, comparative surveys were carried out at two Sphagnum farming sites (established from 2015 to 2016), two rewetted cut-over restoration sites, and two near-natural bogs in Lower Saxony (Germany). In particular, the Sphagnum farming sites showed high potential for characteristic peatland bird species and lowland breeders, as well as for characteristic Odonata species. For the moor frog, the only peatland amphibian species in this study, Sphagnum farming sites could serve as valuable connecting elements in habitat corridors. In contrast, the habitat quality for Lepidoptera was low due to site management and the lack of windbreak structures." (Authors)] Address: Zoch, Lotta., Institut für Umweltplanung,

**21240.** Abhilash, H.R.; Mahadevaswamy, M.; Shashank, K.R.; Nagaraj, M.; Kumar, A. (2023): Biodiversity and abundance of aquatic insects in two freshwater lakes of Mysore district, Karnataka, India. *Arthropods* 12(1): 1-15. (in English) ["A study on aquatic insects biodiversity and abundance along with physicochemical parameters of two lentic water bodies (Varuna and Dalvoy) of Mysore district was carried out on monthly basis from October 2018 to March 2019. A total of 31 species belonging to 19 families and 6 orders were recorded during the study period. At order level, Coleoptera showed maximum relative abundance (57%) followed by Hemiptera (13%) in Varuna Lake, while in Dalvoy Lake, the order Hemiptera (66%) was most abundant, followed by Coleoptera (16%). Computation of dominant status of different species of aquatic insects in lakes based on Engelmann's scale revealed that *Canthydrus laetabilis* and *Gyrinus distinctus*, from the order Coleoptera, were dominant in Varuna Lake, while two Hemipteran species, *Diplonychus rusticus* and *Anisops* sp., were dominant in Dalvoy Lake. The highest Shannon diversity index (2.803) and evenness values (0.66) were recorded in Varuna Lake, which was slightly greater than Dalvoy Lake (2.028 and 0.45). Similarly, the Biological Working Party Score (BMWP) and Average Score Per Taxon (ASPT) values were 80 and 5.33 in Varuna Lake and 53 and 4.08 in Dalvoy Lake. This indicates Varuna Lake is less polluted and has higher species diversity than Dalvoy Lake. In terms of the physico-chemical properties of water, a significant difference was noted in electrical conductivity, total dissolved solids, free carbon dioxide, dissolved oxygen, total alkalinity, hardness, nitrate, sulphate, and chloride concentrations between Dalvoy Lake and Varuna Lake. The results of physicochemical analysis and diversity indices suggest stressed and disturbed water quality conditions at Dalvoy Lake." **21241.** Alfieri, J.M.; Jonika, M.M.; Dulin, J.N.; Blackmon, H. (2023): Tempo and mode of genome structure evolution in insects. *Genes* 2023, 14, 336. <https://doi.org/10.3390/genes14020336>: 11 pp. (in English) ["The division of the genome into discrete chromosomes is a fundamental characteristic of eukaryotic life. Insect taxonomists' early adoption of cytogenetics has led to an incredible amount of data describing genome structure across insects. In this article, we synthesize data from thousands of species and use biologically realistic models to infer the tempo and mode of chromosome evolution among insect orders. Our results show that orders vary dramatically in the overall rate of chromosome number evolution (a proxy of genome structural stability) and the pattern of evolution (e.g., the balance between fusions and fissions). These findings have important implications for our understanding of likely modes of speciation and offer insight into the most informative clades for future genome sequencing. ... In Odonata, we had a total of 203 species present on our phylogeny and in our karyotype dataset. The species in our karyotype dataset had a haploid chromosome count range from 2 to 20. The species that could be included in the comparative analysis (species that were shared between the phylogeny and karyotype dataset) had a haploid chromosome count from 4 to 14. Using the simple two-parameter model, we estimated rates of

0.004 (95% HPD Interval: 0–0.01) and 0.001 (95% HPD Interval: 0–0.001) for fusions and fissions, respectively (Figure 2). Using the more complex model we estimated rates of 0.004 (95% HPD Interval: 0–0.005), 0.001 (95% HPD Interval: 0–0.001), and 0.035 (95% HPD Interval: 0.01–0.06) for fusion, fission, and polyploidy, respectively. We calculated the mean normalized rates ratio as 0.86 (95% HPD Interval: 0.77–0.95) (Figure 3)." **21242.** Aristizabal-Botero, A. (2023): Ecological dynamics of macroinvertebrates from inselbergs of the Colombian Guiana Shield. PhD thesis, Sciences & Bioengineering Sciences, Facultad de Ciencias, Universidad de los Andes: 144 pp. (in English, with Spanish and Dutch summaries) ["Understanding ecological dynamics implies disentangling the connections and interactions between living and non-living components of an ecosystem. Here, we studied links between the unique physical environment of the granite outcrops of the Guiana Shield, one of the most ancient bedrock formations on Earth, and local biodiversity. On these outcrops – also known as inselbergs – there are eroded depressions that become rock pools that can periodically hold water from rain or river input, allowing for the development of a unique diversity of microorganisms, plants, and animals. Although the fauna of temporary rock pool systems on rocky outcrops has been documented in temperate, arid, and semi-arid regions, little is known about similar systems in the Neotropics. The first challenge was to characterize the complex three-dimensional (3D) structure of the habitat; for this, we used remote sensing via an unoccupied aerial vehicle (UAV). We concluded that drone imagery could help to reconstruct spatial variation in microhabitat structures that would be impossible to quantify using ground-level observations or satellite images. In addition, we managed to reconstruct relevant proxies for habitat quality, like photosynthetic activity and rock pool connectivity, via stream network modeling based on a digital elevation model. Even though inselberg ecosystems are renowned for their plant diversity, little was known about the aquatic fauna associated with this habitat, and certainly not in this region. In the second chapter, we explored the aquatic biodiversity of macroinvertebrates in the early and late phases of the rainy season. This section presents the first biodiversity survey and first characterization of the water properties of this ecosystem in the Neotropics. We found strong seasonality with both taxonomic and functional differences in communities. Early inundation communities were dominated by microcrustaceans and gathering collectors. At the same time, predators almost doubled their relative abundance and increased their contribution to community diversity from 40 % to 50 % later in the rainy season. However, the species pool also housed predators such as specialized dragonflies with adaptations that helped them to exploit resources from the beginning of inundations. Finally, in chapter three, we showed strong differentiation in Odonata communities between pools that differ in permanence. To help explain this variation in habitat use, we performed a large-scale life-history experiment with three Odonata families. Here, we tested whether slight variations in dissolved salt concentrations and water level are used by naiads as cues for impending pond drying and could stimulate them to accelerate development. The chapter illustrates how developmental plasticity triggered by different cues can help odonates avoid mortality and exploit prey in short-lived habitats. It also contributes to a better understanding of the requirements and flexibility of odonates in response to environmental conditions. Overall, this project

provides the first documentation of the inhabitants of this peculiar and unexplored aquatic microcosm system in South America. Using innovative technologies, faunistic inventories, multivariate analysis, and life-history experiments, we gained more insights into the fundamental ecological processes that determine the composition of local macroinvertebrate communities. This can facilitate their inclusion in informed land management and conservation initiatives. .... Abstract Chapter 3: Developmental plasticity can help organisms to survive in temporally variable environments. At the same time, heterogeneous environments can allow the coexistence of species with differences in their life-history traits. Our main goal was to evaluate to which extent life-history plasticity can help to explain the coexistence of a diverse assemblage of odonates in a peculiar tropical freshwater habitat characterized by substantial variation in pond permanence. Some dragonflies and damselflies (Odonata) can accelerate their development to leave the water before their temporary rock pool habitat dries. However, how they sense habitat drying is poorly understood. Here, we experimentally tested to what extent elevated concentrations of salts in water or reductions in water level can be used as cues for developmental acceleration in a Neotropical Odonata assemblage from granite rock pools. Libellulidae dragonflies were found along the pond permanence gradient and accelerated their growth in response to elevated dissolved salts (measured as conductivity). *Anax amazili* Burmeister, 1839 (Aeshnidae) was also found in all environments and did the same in response to lower water levels. On the contrary, larvae of *Telebasis simulata* (Coenagrionidae) were restricted to deeper long-lived pools and did not respond to the tested cues. The work illustrates how differentiation in life-history strategies can contribute to niche differentiation in this diverse predator assemblage and how developmental plasticity triggered by different cues can help them avoid mortality and exploit short-lived habitats. The global acceleration of freshwater salinization due to human activities might disrupt the delicate links between low levels of dissolved salts and life-history responses and represent a significant threat to these ecosystems and their biodiversity." **21243.** Bartkowska, A.; Mieczan, T.; Plaska, W. (2023): Colonization of artificial substrates by invertebrate macrofauna in a river ecosystem — Implications for forensic entomology. *International Journal of Environmental Research and Public Health* 20(4): 2834. <https://doi.org/10.3390/ijerph20042834>: 11 pp. (in English) ["Forensic entomology includes the analysis of organisms colonizing various parts of the body in order to determine the circumstances of an incident, mainly the time, place, and cause of death. The presence of insects and other arthropods on carcasses can be a source of knowledge for the judicial system. However, this type of research (on submerged bodies) is less published. The aim of our study was to analyse the qualitative and quantitative structure of macroinvertebrates colonizing potential evidence in an upland river. The experimental research involved an eight-week exposure to articles of clothing made of different materials: natural materials (bottom sediments with plants from a river), synthetic (socks), and cotton (t-shirts). Control samples of water after 2, 4, 6, and 8 weeks were taken from experiment locations in the River Bystrzyca with a tube apparatus and hand net. The results indicated that the abundance of organisms on a given substrate depended on the period of development of invertebrate macrofauna and the time of exposure of the substrates. The abundance of aquatic macrofauna on the exposed items increased in direct proportion to the duration of the experiment,

which may indicate the adaptability of these organisms to new habitat conditions. Among the taxonomic groups used in forensic entomology, Diptera, Coleoptera, and Odonata were the most abundant. The remaining taxa (including Heteroptera), though not widely used in judicial proceedings, can also provide valuable information about the circumstances of an incident." **21245.** Carbonell, J.A.; Wang, Y.-J.; Sentis, A.; Stoks, R. (2023): Evolution of predator–prey interactions during range expansion in an aquatic insect predator. *Functional Ecology* 36: 3060-3072. (in English) ["1. Many ectotherms are shifting their distributions polewards, which has been associated with the evolution of phenotypic traits and their thermal plasticity. Trophic interactions may determine the dynamics and ecological impact of range expansions. However, it is largely unknown how trait evolution in edge populations shapes trophic interactions. 2. We studied evolutionary changes in the short-term (functional response) and long-term predator–prey interactions between an aquatic insect predator (the damselfly *Ischnura elegans*) and its prey (the water flea *Daphnia magna*) during the predator's ongoing poleward range expansion in northern Europe. 3. Using a common-garden warming experiment at 20 and 24°C we tested for differentiation between predator populations from edge and core regions in metabolic rate and functional response parameters, and used these empirical data to estimate the effects of range expansion on the short- and long-term predator–prey interaction strengths. 4. Metabolic rates did not differ between populations from edge and core regions nor between rearing temperatures. Functional response parameters and their thermal plasticity showed signals of evolution during the range expansion. Attack rates did not differ between predators from edge and core regions, but only decreased under warming in predators from the edge region. Handling times decreased under warming in predators from the edge region but increased under warming in predators from the core region. While handling times were shorter in predators from the core region at 20°C, these did not differ between regions at 24°C. As a result, the short-term interaction strength was higher for predators from the core region at 20°C, but not different between regions at 24°C. The predator–prey system from the edge region showed lower long-term system stability at 20°C, but this region difference disappeared under warming because the edge region stability then increased. 5. Our results suggest that rapid evolution of functional response parameters during a predator's range expansion reduced the direct feeding impact on its prey and made the predator–prey system from the edge region more unstable, but not under warming. This provides rare evidence that functional responses can rapidly evolve during range expansions, potentially destabilizing food web dynamics." **21246.** Ceia-Hasse, A.; Boieiro, M.; Soares, A.; Antunes, S.; Figueiredo, H.; Rego, C.; Borges, P.A.V.; Conde, J.; Serrano, A.R.M. (2023): Drivers of Insect Community Change along the Margins of Mountain Streams in Serra da Estrela Natural Park (Portugal). *Insects* 2023, 14(3), 243; <https://doi.org/10.3390/insects14030243>: 14 pp. (in English) ["Simple Summary: Mountain ecosystems are important biodiversity hotspots since they host many unique species and provide valuable services. In this study, we analyze the diversity patterns of butterflies and odonates in a mountainous area of high conservation value—Serra da Estrela Natural Park (Portugal)—and we assess which factors are responsible for insect community change between study sites. The insects were sampled along 150 m transects near the margins of three mountain streams, at three elevation levels (500, 1000, and 1500 m). Butterfly species richness was lowest at high altitudes, while odonate species richness did not differ between elevations. Interestingly, species replacement drove the changes between butterfly assemblages, while changes in odonate communities were mostly due to species richness differences. Climatic factors, namely temperature and precipitation, were the main drivers of community change between sites for the two insect groups. The study of mountain insect biodiversity is key to further our understanding on the community assembly processes and provides valuable information to help predict the impacts of environmental changes on mountain biodiversity. Abstract: Mountain ecosystems are important biodiversity hotspots and valuable natural laboratories to study community assembly processes. Here, we analyze the diversity patterns of butterflies and odonates in a mountainous area of high conservation value—Serra da Estrela Natural Park (Portugal)—and we assess the drivers of community change for each of the two insect groups. The butterflies and odonates were sampled along 150 m transects near the margins of three mountain streams, at three elevation levels (500, 1000, and 1500 m). We found no significant differences in odonate species richness between elevations, but marginal differences ( $p = 0.058$ ) were found for butterflies due to the lower number of species at high altitudes. Both insect groups showed significant differences in beta diversity ( $\beta_{total}$ ) between elevations, with species richness differences being the most important component for odonates ( $\beta_{rich} = 55.2\%$ ), while species replacement drove the changes between butterfly assemblages ( $\beta_{repl} = 60.3\%$ ). Climatic factors, particularly those depicting harsher conditions of temperature and precipitation, were the best predictors of total beta diversity ( $\beta_{total}$ ) and its components ( $\beta_{rich}$ ,  $\beta_{repl}$ ) for the two study groups. The study of insect biodiversity patterns in mountain ecosystems and of the role played by different predictors contribute to further our understanding on the community assembly processes and may help to better predict environmental change impacts on mountain biodiversity." **21247.** Coayla-Peñalozza, P.; Cheneaux-Díaz, A.A.; Moreno-Salazar, C.V.; Cruz-Remache, C.E.; Colque-Rondón, E.W.; Damborenea, C. (2023): Benthic macroinvertebrate communities and water quality assessment in high Andean wetlands Callali-Oscollo, Arequipa-Cusco, Peru. *Revista Mexicana de Biodiversidad* 94 (2023): e944206: 13 pp. (in English, with Spanish summary) ["High Andean wetlands are fragile systems, vulnerable to human activity and climate change. In the Arequipa region (Peru), there are high Andean lotic and lentic systems currently affected by livestock

raising, fish farming, and dams. The aim of the study was to evaluate the aquatic invertebrate community in the Callali-Oscollo wetlands and the possible impact of human activities. Samples were taken from November 2017 to October 2018 at 4 sampling stations in lotic environments and 2 in lentic environments. Macroinvertebrates were identified to the family level. The following were determined to evaluate community structure: richness, relative abundance, Shannon-Wiener diversity, Simpson dominance, Pielou evenness, and true diversity. The indices ABI, BMWP/Bol and nPeBMWP were applied to evaluate the ecological quality of the environments sampled. Thirty families were recorded in lotic environments, the most abundant being Chironomidae, Naididae, Limnesiidae, Elmidae, Baetidae and Lumbriculidae. The ecological quality was good, except at the station associated to the dam, where it was doubtful. Twenty-six families were recorded in lentic environments, the most abundant being Cyprinidae, Naididae and Corixidae. The macroinvertebrate communities in high Andean environments reflect ecosystem conditions. Environments associated to human activity have lower ecological quality." **21248.** Dash, S.S.; Nayak, S.K.; Dhal, A. (2023): Biodiversity of Insects in Black Gram [*Vigna mungo* (L.) Hepper] during Rabi in the western undulating zone of Odisha. *International Journal of Current Science* 13(1): 505-527. (in English) [This study „was conducted at Research farm, College of Agriculture, OUAT, Bhanuipatna to study about insect biodiversity, their succession and influence of climatic factors on the population growth of insects during rabi-21. During the study period twenty seven insects belong to seven orders and twenty two families were noticed during different growth stages of crop in an overlapping manner. Beside the insects twelve numbers of predators, three numbers of parasitoids and two pollinators were also recorded. The highest diversity index and evenness of insects were recorded at 42 SMW (0.902 and 1.000) followed by 50 SMW (0.833 and 0.710) respectively. The diversity of insects was almost uniform because of the evenness of the species. The insect order Homoptera and the insect white fly came under superdominant class of dominance during all the growth stages of crop, whereas Coleoptera and Hemiptera were categorized under sub-dominant class at vegetative stage and flowering to podding stage of crop growth respectively. The insect orders Hemiptera, Coleoptera, Diptera and Hymenoptera and the insects i.e. galerucid beetle, jassid, stem fly, aphids and thrips came under recedent class of dominance. The relative abundance and dominant status of insect's revealed that the maximum numbers of insects belonged to orders Homoptera (75.22%) followed by Hemiptera (7.92%), Coleoptera (6.30%), Diptera (4.62%), Hymenoptera (4.05%), Orthoptera (0.89%), Lepidoptera (0.86%) and Odonata [Aeshnidae] (0.09%)." **21252.** Galbiati, M.; Lapadula, S.; Forlani, M.; Barzaghi, B.; Manenti, R. (2023): Both light stimuli and predation risk affect the adult behavior of a stygobiont crustacean. *Diversity* 2023, 15, 290. <https://doi.org/10.3390/d15020290>: 11 pp. (in English) ["Stygobiont species show common, typical traits derived from their adaptation to subterranean life. Due to the general absence of light in cave environments, the majority of them are eyeless. Although the absence of eyes generally does not allow them to perceive luminous stimuli, some stygobionts still present phototaxis. Previous studies determined that different species of the eyeless amphipod crustaceans of the genus *Niphargus* are able to react to light; this has been interpreted as an adaptation to avoid dangerous surface habitats, even if recent studies suggest that this could also be an adaptation to exploit them when a

situation is less dangerous (i.e., during the night). *Niphargus thuringius* is a stygobiont amphipod that can also be observed in spring environments despite possessing all the main morphological features of subterranean organisms, such as depigmentation and a lack of eyes. In the present study, we test how the species respond to light stimuli according to the light cycle and predation risk experienced during a conditioning period. We assessed the reactions to light stimuli of adult individuals of *N. thuringius* after 30 days of rearing in microcosms with different conditions of light occurrence (total darkness or a light/darkness daily cycle) and predation risk (without predators, with one predator, and with two predators). Both light stimuli during the test and rearing conditions affected the behavior of *Niphargus thuringius*. With light stimuli, individuals presented a strong photophobic response. Moreover, individuals reared in conditions of high predation risk preferred a more sheltered environment during behavioral tests than individuals reared in safe conditions. Our results add a new species to those of stygobiont amphipods known to display negative phototaxis, confirming that this pattern is widespread and conserved in the field. *N. thuringius* could be a good candidate model to perform further studies aiming to assess if differences occur between spring populations and populations present in deeper groundwater. ... The conditions representing risk of predation included the following: controls (no predator); meso-predators (four fire salamander larvae (*Salamandra salamandra*), permitted to wander across the microcosm); and meso-predators plus one top-predator (four salamander larvae wandering across the microcosm, plus one large dragonfly larva (*Cordulegaster boltonii*) placed in a small cage inside the microcosm; see below). Salamander larvae are considered to be meso-predators as, in nature, they are often preyed on by dragonfly larvae [32]. Fire salamanders were widespread in the study area [38] and often bred in springs and subterranean environments along with *Niphargus* amphipods [13,33]] Address: Lapadula, S., Laboratorio di Biologia Sotterranea "Enrico Pezzoli", Parco Regionale del Monte Barro, Località Eremo, 1, 23851 Galbiate, Italy. However, understanding and analyzing the coloration of these animals depends on an interdisciplinary knowledge (biology, chemistry and physics), as well as the use of appropriate equipment and protocols. Therefore, in this essay, we seek to present the methodologies used to measure coloration in Odonata, and the possible problems of the techniques employed. Mainly, we present techniques of optical spectrometry, analysis of photographs and of the vision of the animals. These methods can be employed in

several ecological, evolutionary, physiological and behavioral analyses, which we discuss as possibilities for future studies." (Authors/DeepL)] Address: Guillermo-Ferreira, R., Lestes Lab, Universidade Federal do Triângulo Mineiro. Uberaba, Brasil. Email: rhainer.ferreira@uftm.edu.br

**21255.** Harabiš, F.; Hronková, J.; Holer, T.; Šípková, J. (2023): Selective effect of fish farming management on freshwater diversity. *Biodiversity and Conservation* 32: 735-753. (in English) ["In some European regions, ponds are the dominant freshwater habitat type. The ecological value of ponds is decreasing owing to human activities, including intensive fish farming involving predation pressure from fish, reduction of macrophytic vegetation, high nutrient loads, and turbidity. Studies have shown the negative effects of high fish stocks on the diversity of macroinvertebrates. Nevertheless, the effect of fish predation on invertebrate communities could be strongly influenced by other factors, such as the structural complexity of aquatic vegetation. Consequently, we aimed to analyze the effects of environmental-trait interactions on the responses of amphibians, odonates, aquatic true bugs, and diving beetles that are directly or indirectly related to pond management. Each monitored group reflected very different variables. Odonates were sensitive to variables reflecting the quality of the aquatic environment and the overall landscape structure, and accurately reflected differences in the management intensity of ponds. Amphibians reflected only the landscape structure, while diving beetles reflected the quality of the aquatic environment. The aquatic Heteroptera community structure was very indifferent to the management and habitat quality. With the exception of oviposition strategies, we were unable to identify functional traits that could present adaptive advantages or disadvantages in relation to management intensity. We deduced that fish farming management is a selective mechanism that operates with an enormously high intensity which fundamentally homogenizes the structure of assemblages and therefore there is no morphological or phenological variability among species. It is therefore difficult to implement appropriate management measures that would benefit species across taxonomic groups. The key is to maintain the variability of the ponds and surrounding landscape mosaic. Moreover, farm ponds are secondary habitats whose role in supporting biodiversity may be important but cannot be seen as an equal alternative to natural wetlands." **21257.** Hasik, A.Z.; Tye, S.P.; Ping, T.; Siepielski, A.M. (2023): A common measure of prey immune function is not constrained by the cascading effects of predators. *Evolutionary Ecology* 37: 13-30. (in English) ["Simultaneously defending against predators, stymieing competitors, and generating immune responses can impose conflicting demands for host species caught in the entanglement of a food web. Host immunity is not only shaped by direct interactions among species, but also many indirect cascading effects. By reducing competition, predators in particular can affect resource acquisition necessary for hosts to mount energetically costly immune responses. However, identifying the links between predators and host immune responses determined by resource acquisition is a complex affair, because predators can (1) reduce host density and thus competition among hosts, (2) exert non-consumptive trait-mediated effects on host resource acquisition behavior, and (3) generate natural selection on host resource acquisition behavior. To examine the relative contributions of these potential predator driven density- and trait-mediated effects on a key aspect of immune function (total phenoloxidase activity, total PO), we conducted mesocosm and field experiments with larval damselflies (*Enallagma signatum*) and their dominant fish predator (*Lepomis macrochirus*). Although we expected to observe declines in total PO activity with increases in damselfly density, we found no relationship between density and total PO activity. We also found no support for the prediction that total PO activity would vary as a result of either non-consumptive trait-mediated effects or selection on damselfly foraging activity underlying resource acquisition. Despite the lack of trait- or density-mediated effects, we did find that total PO activity increased with damselfly prey density among lakes, implying resource limitation for this aspect of immune function. These unexpected results point to the need to better understand the ecological conditions whereby predators and competitors constrain immune functions necessary for species to defend themselves in complex food webs." (2023): Odonata (Insecta) communities in a lowland mixed mosaic forest in Central Kalimantan, Indonesia. *Ecologies* 2023, 4; <https://doi.org/10.3390/ecologies4010006>: 55-73. (in English) ["Assessing a taxon's response to change in environmental variables is fundamental knowledge to understanding trends in species diversity, abundance, and distribution patterns. This is particularly needed on Borneo, where knowledge on Odonata populations in different habitats is poor. To address this gap, we present the first study investigating the relationship between morphology and species distribution of Odonata communities in a heath (kerangas)-dominated mixed-mosaic lowland forest in southern Borneo. We sampled 250m line transects in three habitat types: mixed peat swamp, kerangas, and low-pole peat swamp,

with weekly surveys from December 2019 to February 2020. A total of 309 individuals were detected from 25 species. Anisoptera and Zygoptera diversity was the highest in mixed peat swamp and lowest in low pole, while abundance was the highest in low pole and lowest in kerangas; with kerangas notably harboring a very small sample size. Odonata community assemblages differed most between mixed peat swamp and low pole. Morphological data were compared between suborders and habitats. Anisoptera showed significantly larger thoraces, hindwings, and hindwing-to-body ratio than Zygoptera. Anisoptera in low pole were significantly smaller in body, thorax, and hindwing compared to both kerangas and mixed peat swamp. Anisoptera showed a strong association with pools and Zygoptera with flowing water. Heterogeneity, habitat characteristics, presence of specialists, body size, and the interaction between species' morphological traits and habitat characteristics likely explained the trends observed." **21259.** Hettige, N.D.; Hashim, R.; Kutty, A.A.; Ashaari, Z.H. (2023): A new model for organic contamination assessments using benthic macroinvertebrates as biological indicators. *Turkish Journal of Fisheries and Aquatic Sciences* 23(8), TRJFAS22423. <https://doi.org/10.4194/TRJFAS22423>: 15 pp. (in English) ["The main goal of this study was to develop a model for organic pollution assessment. Seven sampling sites in six rivers in the Rawang sub-basin, Selangor River, Malaysia, were selected with one reference site. The sampling sites near the fish farm were used to develop the model. SR2 was used for the validation of the developed model. Benthic macroinvertebrates and water sampling were conducted from April 2019 to March 2020. The Principal Components Analysis (PCA) and regression were conducted to select the most representing benthic macroinvertebrates family. Based on the score value (variance coefficient) of each benthic macroinvertebrates family, the cumulative score value of each sampling site was calculated (i.e., 18=6 sampling sites x 3 replicates). The nine benthic macroinvertebrate families (Baetidae, Libellulidae, Protonuridae, Chironomidae, Curbicullidae, Hydropsychidae, Tubificidae, Lumbriculiade, and Naididae) were identified using PCA and regression. The cluster analysis and mean confidence intervals were used to classify water quality classes precisely. Finally, three different value scales were produced to represent the level of contamination (i.e., <0.69 as organically polluted, 0.69-0.87 as slightly organic polluted, and >0.87 as clean status). The newly developed model was validated. The results produced after validation were better than the water quality status from other studies based on the BMWP/BMWPThai score. This study concludes that the developed model can evaluate river organic contamination successfully. model can evaluate river organic contamination successfully" (Authors)] Address: Hashim, Rohasliney, Universiti Putra Malaysia, Faculty Forestry & Environmental Science, Dept Environment, 43400 UPM, Serdang, Selangor, Malaysia. **21260.** Holuša, O.; Holušová, K.; Balázs, A. (2023): Is the current forest management to the northernmost population of *Cordulegaster heros* (Anisoptera: Cordulegastridae) in Central Europe (Czech Republic) threatening? *Forests* 14(2):228. DOI: 10.3390/f14020228: (in English) ["*C. heros* is included in the EN category on the IUCN Red List for the territory of the Czech Republic, where it inhabits an area of approximately 100 km<sup>2</sup>. All of the localities are located in

the forest complex in Chriby hills, and all of the forests fall into the category of management forests. Most of the forest stands have a high and very high degree of naturalness; they are natural forest stands. The predominant management units are Nutrient sites in middle elevations (78.2 % of the area) and Oligotrophic sites in middle elevations (2.1 % of the area), with stand types of *Fagus sylvatica* representing 92.5 % of the area, and forest stand types of *Quercus* sp. representing 5.7 % of the area. The wider alluvia in forest streams are classified as being in management unit alder and ash sites on waterlogged and floodplain soils (1.1 %), with the forest stand type of *Alnus glutinosa*. The forest stands are restored by regeneration under shelterwood (97.8 % of the area). The waterlogged alluvia, if a separate management unit is established for them, are restored by a regeneration by strip method. Realistically, seven factors were recorded in *C. heros* habitats, but they mostly have only point effects. Within forestry management, the factors of logging directly in the habitats and the subsequent transport of harvested timber in the habitat were recorded. The most intrusive effects were found on tractor logging roads, where fine soil washes into the stream and causes prolonged turbidity. Of the water management structures in the study area, logging roads with bridges and culverts are constructed, stream banks are reinforced with longitudinal walls at points, and stone steps in the channels are constructed only sporadically. The current forest management system can be described as a nature-friendly system, and therefore, it fully ensures the conditions for the survival of the *C. heros* population in the Czech Republic." **21261.** Huang, Q.; Tian, F.-B.; Young, J.; Lai, J.; Ravi, S. (2023): Numerical study of passively pitching tandem dragonfly wings for hovering flight. *AIAA 2023-1027*. Session: Bio-Inspired and Low-Reynolds Number Flows I. Published Online: 19 Jan 2023 <https://doi.org/10.2514/6.2023-1027>: 9 pp. (in English) ["Insect flapping-wing kinematics and aerodynamics have been studied extensively by researchers worldwide. Wing pitching motion in insect flapping flight has been recognized as a passive phenomenon induced by inertial and aerodynamic forces. The performance of passively pitching tandem dragonfly wings was investigated by varying the phase angle between the forewing and the hindwing. The simulations were conducted by a fluid-structure interaction solver based on an immersed boundary-lattice Boltzmann method. The primary performance metric of interest is the power economy (PE), which indicates the extent of lift generation of the wing concerning the power required to operate it. The flapping-wing system was rotated at a stroke plane angle that the total horizontal drag was precisely zero for each case. Results show that the variation of PE is small as the change of the phase angle. The stroke plane angle has a significant variation at phase angle -45° and 45°, while it is still in the range of the stroke plane angle reported in the literature. The effects of different material elasticities and corresponding power expenditures will be investigated and reported in future works." (Authors)] Address: Huang, Q., Univ. **21262.** Hushtan, K.; Hushtan, H.H. (2023): The approbation of web resource «Biodiversity of Ukraine» on example of dragonflies (Insecta: Odonata) of Ukrainian Carpathians. *Proceedings of the State Natural History Museum* 38: 237-

244. (in Ukrainian, with English summary) ["The paper examines of individual possibilities of the "Biodiversity of Ukraine" web resource for the analysis of collections, observations and literary data on the example of dragonflies for the territory of Ukrainian Carpathians. The possibility of analyzing the spatial distribution of Odonata in terms of physical and geographical regions of the model territory was studied. Their faunal similarity was determined using the Sorensen and Jaccard indexes integrated into the web resource. Mountain massifs have been established, which are promising for further research into the fauna and ecology of dragonflies. Preliminary data on the spatial distribution of dragonflies for the territory of the Ukrainian Carpathians were obtained as a result of the approbation of the information capabilities of the "Biodiversity of Ukraine" web resource, in the context of administrative and physical-geographic regions. The most studied is the Ciscarpathians Upland (58 species). Territories that are the least studied and require thorough faunal studies of dragonflies have been identified, namely the Marmarosh-Chyvchyny region The perspective of the expediency of using the "Biodiversity of Ukraine" web resource to compare the dragonfly fauna of different administrative regions of the Ukrainian Carpathians has been established. It should be noted that the national biomonitoring system involves development on a pan-European basis, the use of modern methods of data collection, accumulation, analysis and information exchange, and the creation of conditions for free access to information by a wide range of interested. All these principles are provided by the Data Center "Biodiversity of Ukraine", as shown in this paper." **21264.** Junaidi, F.A.; Soendjoto, M.A.; Dharmono, D. (2023): Practicality of popular scientific book on Odonata. *Jurnal Biologi-Inovasi Pendidikan* 5(1): 117-124. (in English, with Indonesian summary) ["The Popular Scientific Book (PSB) on Odonata that inhabits the Tabanio Coastal Forest, Tanah Laut Regency has been completed, but its practicality has yet to be determined. The aim of the research was to determine the practicality of the PSB. The determining parameters were readability, applicability, and student responses which in this case are undergraduate students of the Biology Education Study Program. Readability was tested by three students using the one-to-one method. The implementation was tested by five observers through a small group assessment (on five students using the PSB) to get the expected implementation value and field test assessment (on 10 students) so that the actual implementation

was obtained. Student responses were obtained from small groups (five students) and field tests (10 students). The result is that the readability of the book is categorized as Very Good, the implementation of expectations and actual implementation is categorized as Very Good, as well as the expected and actual responses from students Strongly Agree. With these categories, this PSB on Odonata is stated to be practical to use." **21266.** Kaunisto, K.M.; Suhonen, J. (2023): Territorial males have larger wing spots than non-territorial males in the damselfly *Calopteryx splendens* (Zygoptera: Calopterygidae). *International Journal of Odonatology* 26: 1-6. (in English) ["Males of *C. splendens* use two alternative mating tactics, territoriality, and non-territoriality. These different mating tactics are shown to vary between males within the same population and previous studies have shown that territorial males have considerably higher fitness than non-territorial males. In this paper, we tested whether the wing spot size as sexual ornament, wing length, relative wing spot size, asymmetry in wing length, asymmetry in wing spot size, or asymmetry in relative wing spot size differed between the territorial and non-territorial males. We sampled *C. splendens* males, representing both mating tactics, from a river system in south-west Finland. According to our results, territorial males have larger wing spot than non-territorial males. In contrast, there were no differences in the other tested traits between the territorial and non-territorial males. In conclusion, our data show that the size of pigmented wing spots may predict the alternative mating tactic of *C. splendens* males." **21267.** Landmann, A.; Landmann, M. (2023): Habitat requirements, habitat variability, and altitudinal distribution of *Coenagrion hylas* (Odonata: Coenagrionidae) in the Lechr river valley and beyond (Tyrol, Austria). *Libellula* 41(3/4): 89-105. (in English, with German summary) ["*C. hylas* is the

rarest Central European odonate species and – at present – populations are exclusively known from an extremely limited area of occurrence of about 42 km<sup>2</sup> in the North-western Tyrol. Since 1973 the species has been recorded at 27 single sites in Tyrol whereof 15 (currently 10), and all sites with larger self-sustaining populations, are situated in the Lech valley, which thus can be regarded as the European stronghold of the species. The perception of the habitat niche breadth of *C. hylas* and the knowledge about the range of its altitudinal distribution are still somewhat superficial and biased in the literature. In particular, the “mountain lake myth” persists, stating that *C. hylas* in Europe is mostly bound to clear mountain lakes in the submontane to lower montane zone. Here, we therefore analyse and compare habitat characteristics of the 27 Tyrolean sites and, in addition, offer a pictorial overview of the habitats used by *C. hylas* in Tyrol. Our compilation indicates that *C. hylas* in Europe has a broader habitat niche than expected from its Siberian origin and as stated in literature. According to the chemistry, size, depth, sources of water, and the predominant vegetation we were able to distinguish six main types of *C. hylas* habitats. These comprise rather different waters including clear cold mountain lakes (3 cases only), dystrophic bog lakes, fishponds, spring water swamps, and shallow flood plain pioneer habitats. However, despite this wide spectrum of habitats used by *C. hylas*, a closer analysis of the data reveals that the few habitats constantly used by larger populations for reproduction have a combination of specific habitat features in common. The presence of waterbodies with very shallow water and stands of the sedge *Carex rostrata* along or near to incoming (or outgoing) small spring creeks with cold water or zones with cold groundwater entering seems to be required. Since such conditions currently mainly seem to be fulfilled at about a dozen sites in the Lech valley, the strict preservation and enhancement of these places via management measures as well as the creation of appropriate steppingstone habitats in between are the main issue to conserve the species. Such measures are already in progress as part of the current LIFE-Lech program Dynamic River System Lech." **21268.** Liao, J.; Wu, Z.; Wang, H.; Xiao, S.; Mo, P.; Cui, X. (2023): Projected effects of climate change on species range of *Pantala flavescens*, a wandering glider dragonfly. *Biology* 2023, 12, 226. <https://doi.org/10.3390/biology120-20226>: 17 pp. (in English) ["Simple Summary: In this study, we simulated the distribution range and its shift of *Pantala flavescens* in past, present, and future scenarios, and revealed its habitat properties. Except at high latitudes near the poles (e.g., Antarctica and near the Arctic Circle), it is found almost everywhere in the world, with the most suitable habitat mainly in East Asia and the United States. The max temperature of the warmest month and the precipitation of the wettest month are important factors affecting its distribution, and its suitability decreases with the increase of altitude. Climate warming promoted the shift of lowly and moderately suitable habitats into moderately and highly suitable habitats, especially in equatorial regions, which increased the total habitat area. This study provides a global dynamic distribution pattern of *P. flavescens* across large temporal and spatial scales, and provides a reference for further understanding of its biodiversity and conservation. Abstract: Dragonflies are sensitive to climate change due to their special habitat in aquatic and terrestrial environments, especially *Pantala flavescens*, which have extraordinary

migratory abilities in response to climate change on spatio-temporal scales. At present, there are major gaps in the documentation of insects and the effects of climatic changes on the habitat and species it supports. In this study, we model the global distribution of a wandering glider dragonfly, *P. flavescens*, and detected the important environmental factors shaping its range, as well as habitat shifts under historical and future warming scenarios. The results showed a global map of species ranges of *P. flavescens* currently, including southern North America, most of South America, south-central Africa, most of Europe, South, East and South-east Asia, and northern Oceania, in total, ca. 6581.667 × 104 km<sup>2</sup>. BIO5 (the max temperature of warmest month) and BIO13 (the precipitation of wettest month) greatly explained its species ranges. The historic refugia were identified around the Great Lakes in the north-central United States. Future warming will increase the total area of suitable habitat and shift the type of suitable habitat compared to the current distribution. The habitat suitability of *P. flavescens* decreased with elevation, global warming forced it to expand to higher elevations, and the habitat suitability of *P. flavescens* around the equator increased with global warming. Overall, our study provides a global dynamic pattern of suitable habitats for *P. flavescens* from the perspective of climate change, and provides a useful reference for biodiversity research and biological conservation." **21269.** Manthey, C. (2023): The evolution of complete metamorphosis in insects. PhD thesis, Dept of Biology, Chemistry, Pharmacy, Freie Universität Berlin: 232 pp. (in English) ["Metamorphosis, the change (meta) in form (morphé), is a common phenomenon in the animal kingdom, where it has evolved several times independently. The most dramatic metamorphic changes occur in the most successful group of animals: the insects, which comprise more than 60% of all living animals. Within the group of insects, the Holometabola (e.g. beetles, butterflies, flies and bees) comprise more than 80% of all insect species. Holometabolous insects undergo complete metamorphosis. In a non-feeding pupal life stage, intercalated between the larval and adult stages, their entire anatomy is radically remodelled, including the digestive tract, which undergoes apoptosis and proliferation. The second major group of insects, the Hemimetabola (e.g. grasshoppers, true bugs, and dragonflies), undergo incomplete metamorphosis. Compared to Holometabola, hemimetabolous insects metamorphose more gradually, less drastically and without a pupal stage. Holometaboly is one of the key evolutionary innovations explaining insects' enormous and unique biodiversity. However, how the evolution of the pupal stage is related to the success of insects is unknown. The remodelling of the larval gut poses a significant challenge to the gut microbiota, as the gut is replaced during pupation, which does not occur in Hemimetabola. It gives holometabolous insects the unique opportunity to drive a change between the larval and adult microbiota, facilitating niche shifts by allowing the insect to acquire specialised symbionts for a life-stage specific diet, ecology and physiology- one barely studied adaptive hypothesis explaining the evolution of the pupa. In chapter II, using 16S rRNA gene metabarcoding, I studied 18 different herbivorous insect species from five orders of holometabolous and three orders of hemimetabolous insects. Comparing larval and adult specimens, I found a much higher beta-diversity and hence microbiota turnover in holometabolous insects than in hemimetabolous insects. My results support

the idea that the pupa offers the opportunity to change the gut microbiota and hence facilitates niche shifts. This possible effect of niche shift facilitation could explain a selective advantage of the evolution of complete metamorphosis. The unique opportunity to change the microbial composition throughout insect development by gut remodelling during complete metamorphosis also puts holometabolous insects at a higher risk of infections. Holometabola must control their gut microbiota and initiate an immune response to avoid infectious diseases during metamorphosis. In chapter III, using RNAseq, I compared the expression of immune effector genes in the gut during metamorphosis in two holometabolous and a hemimetabolous insects. I found high read count abundances of differentially expressed immune effectors in the gut at the larval-pupal moult in the two Holometabola; no such high abundances were observed at the nymphal-adult moult in Hemimetabola. My findings confirm that only complete metamorphosis elicits a prophylactic immune response as an adaptive response in holometabolous insects, which controls the microbiota during gut replacement. Another barely studied and not mutually exclusive hypothesis explaining the success of holometabolous insects could be that intercalating the pupal stage decouples growth and differentiation. Most growth is confined to the larval stages in holometabolous insects, while most development occurs in the pupa, allowing for fast larval growth. In chapter IV, I conducted a literature review and calculated growth rates and ratios. I compared 33 species from three holo- and seven hemimetabolous insect orders. I found faster larval growth, higher growth ratios, and much higher variances for those traits in holometabolous than hemimetabolous insects. I also found much shorter growth periods of the larval stages in holometabolous than hemimetabolous insects. My results support the decoupling of the growth and differentiation hypothesis in holometabolous insects, allowing fast larval growth. In this thesis, I investigated two barely studied and not mutually exclusive hypotheses explaining the evolution of the pupa in holometabolous insects, which constitute the majority of animal diversity. I could show a microbiota turnover in holometabolous insects, which is also under the control of the host gut immunity and allows the Holometabola to occupy different niches throughout development. The second hypothesis, which proposes that decoupling growth and differentiation allows for fast larval growth, is supported by my findings of faster larval growth rates in holometabolous than hemimetabolous insects. The facilitation of niche shifts by changes in the gut microbiota could be considered an essential driver of the evolution of the pupa. The microbiota turnover could also be driven by other selective factors such as growth rate. Fast larval growth could be a selective factor for decoupling growth and differentiation, ultimately resulting in the evolution of the pupa in holometabolous insects." (Author) The thesis includes many references to Odonata.] Address: not stated.

**21270.** Mesaglio, T.; Callaghan, C.T.; Samonte, F.; Gorta, S.B.Z.; Cornwell, W.K. (2023): Recognition and completeness: two key metrics for judging the utility of citizen science data. *Frontiers in Ecology and the Environment* published: 8 pp. (in English) ["Biodiversity citizen science data are being collected at unprecedented scales, and are key for informing conservation and research. Species-level data typically provide the most valuable information, but recognition of specimens to species level from photographs varies among taxa. We examined a large dataset of Australian photographic observations of terrestrial invertebrates uploaded to iNaturalist to quantify recognition to species across different taxa. We also quantified the proportion of Australian

species that have been uploaded to iNaturalist. Across 1,013,171 observations covering 14,663 species (17.8% completeness), 617,045 (60.9%) were recognized to species. Dragonflies/damselflies and butterflies were the best-recognized and most complete taxa, and therefore represent the best groups for researchers and managers intending to use existing iNaturalist data at large spatial and temporal scales. The recruitment of additional experts to identify records, and enhanced support for accessible resources for hard-to-identify taxa, will likely increase recognition for other taxa." **21272.** Moreno Pallares, M.I.; Bonilla Gómez, M.A.; Guillot Monroy, G.H.; Torregroza-Espinosa, A.C. (2023): Macroinvertebrates composition as determinants of larval abundance in the dragonfly *Miathyria marcella* in tropical wetlands. *Global Journal of Environmental Science and Management*: 12 pp. (in English) ["Background and objectives: Odonate larvae play an important role in macroinvertebrate trophic networks and are excellent proxies for wetland quality. However, despite their ecological importance, research on odonates and how they interact with their environment is scarce. This study aims to assess macroinvertebrate composition as determinants of larval abundance in *Miathyria marcella*. Methods: 29 samples were collected from six wetlands with different hydrological influence using standardized invertebrate sampling techniques in the Dept of Atlántico, northern Colombia. Standardized invertebrate sampling techniques were used in 29 sampling points. Obtained data were used to analyze invertebrate abundance and a non-parametric multidimensional scaling analysis was applied. In addition, a correlation analysis was conducted between macroinvertebrate composition and *M. marcella* larval abundance. Findings: A total of 2586 larvae, and 12925 individual macroinvertebrates were collected, distributed in 25 orders and 58 families. The most abundant orders were Neotaenioglossa (26 percent), Odonata (15 percent) Calanoida (10 percent) and Diptera (8 percent). Heatmap and

scaling analysis indicated different macroinvertebrate compositions in the sampled wetlands. A high positive correlation between *Miathyria marcella* and the orders Odonata ( $R^2 = 0.84$ ,  $p$ -value = 0.05), Coleoptera ( $R^2 = 0.52$ ,  $p$ -value = 0.05), Basommatophora ( $R^2 = 0.60$ ,  $p$ -value = 0.05) and Hemiptera ( $R^2 = 0.50$ ,  $p$ -value = 0.05). Conclusion: The results suggest that the abundance of *Miathyria marcella* responds to the accompanying macroinvertebrates, the composition of which depends on the type of hydrological influence. Approaches focused on the relationships between macroinvertebrate taxa are important conservation tools for biodiversity assessment. Results from this study will serve as a baseline to propose monitoring and follow-up strategies on the environmental sustainability in wetlands in this region. Highlights: \*The hydrological influence of wetlands has an effect on the distribution of macroinvertebrates; \*The abundance of *marcella* responds to the accompanying macroinvertebrates; \*The nMDS indicated a difference in the composition of the macroinvertebrates according to the sampled wetlands; \*A high positive correlation was found between *marcella* and the orders Coleoptera, Basommatophora and Hemiptera." (Authors)] Address: Moreno Pallares, M.I., Depto de Biología, Universidad Nacional de Colombia, Bogotá, Colombia. Email: mimorenop@unal.edu.co

**21273.** Musinguzi, L.; Olokotum, M.; Nakiyende, H.; Egessa, R.; Kiggundu, V.; Pabire, G.W.; Bassa, S.; Nsega, M.; Kamya, A.; Rwezawula, P.; Lugya, J.; Magezi, G.; Nalwayiro, J.; Natugonza, V. (2023): Primary biodiversity data on zooplankton, macroinvertebrates, and fish from freshwater ecosystems of Uganda. *J. Limnol.* 2023; 82: 2117: 10 pp. (in English) ["Effective conservation requires reliable data and information on the status of biodiversity. The conservation of freshwater biodiversity lags behind terrestrial and marine biodiversity because data and information limitations are greatest in freshwater ecosystems. Given that freshwater ecosystems are inhabited by disproportionately more species than other ecosystems, the paucity of data and information is disadvantageous to many species and dependent ecosystem services. Data and information on freshwater biodiversity are limited mainly because few freshwater ecosystems are considered for regular monitoring. Existing data is also scattered and in non-user-friendly formats, limiting accessibility and use. It is desirable to make freshwater biodiversity data and information accessible everywhere to attain their full potential in guiding conservation. Here, we present 34 datasets, covering three major freshwater taxa (zooplankton, macroinvertebrates, and fish) in freshwater ecosystems in Uganda. The datasets provide occurrence records and corresponding abundance data, where applicable, for the three groups. The datasets which are available through the Global Biodiversity Information Facility (GBIF), cover many years (1971-2021) and have a total of 56,104 occurrence records. The datasets were mainly mobilized from archives of biodiversity surveys conducted at the National Fisheries Resources Research Institute (NaFIRRI) in Uganda. The surveys cover most of the water bodies in the country. The datasets are envisaged to increase accessibility to data for freshwater conservation research, decision making, and capacity building. Indeed, part of the data, especially on fish, has already been used to develop conservation tools and assess conservation status of species at both the global and national levels." **21274.** Nel, A.; Piney, B. (2023): Odonatopteran approaches to the challenges of flight: Convergence of responses subject to a common set of morphological constraints. In: Bels, V.L. & A.P. Russell (Eds.): *Convergent Evolution. Animal Form and Function.* Springer Cham: 21-36. (in English) ["Effective flight capacity is a crucial survival attribute of volant animals. Several vertebrate clades have acquired gliding capabilities and at least three of them independently acquired powered flight. Contrastingly, wings were probably acquired only once by pterygotan insects. Despite this, insects have developed a great variety of structural approaches that have diversified their collective flight capacity. Flight was a key contributor to their diversification during the Late Carboniferous (at least 330 Ma), and flying insects have remained the most diverse animal clade since then. Among pterygotans, representatives of the superorder Odonatoptera, which includes the extant Odonata, have developed impressive performance associated with the highly complex morphological structure of their wing venation. Some venation patterns, such as the nodus, discoidal complex, and arculus, were acquired only once, whereas others have been convergently acquired several times. One example of a pattern acquired more than once is the sclerotized pterostigma, convergently appearing in the Permian Protanisoptera and its sister group, the Discoidalia, these comprising the modern Odonata. All odonatopterans with broad wings were confronted by a major problem, that of 'how to strengthen the basal third of the wing' to prevent it from breaking longitudinally. At least eight different convergent 'solutions' have been 'adopted' that have resulted in the incorporation of structures oriented perpendicular to the main axis of the wing. Additionally, several clades within the Odonatoptera have convergently developed petiolated wings, adapted for flying in cluttered environments. The width and length of the petiole can vary greatly, with the most impressive ones being those of the 'giant' Permian-Triassic Triadophlebiomorpha. This great morphological disparity represents 'variations on a theme' of the already complex wing venation established by the first Carboniferous odonatopterans. It is possible that some of the 'solutions' arrived at by extinct clades allowed for performance that was more effective than that of modern odonatans. Many of these groups flourished and co-existed with the ancestors of modern taxa for millions of years. Extant odonatans have been adopted as models for the bio-mimetic development of small drones. The wing patterns of extinct clades should also be investigated for their potential for bio-mimetic inspiration and application." (Authors)] Address: Nel, A., Lab. Ent., Mus. Natn. Hist. (2023): Differential abundance, composition and mesohabitat use by aquatic macroinvertebrate taxa in ponds with and without fish. *Aquatic Sciences* (2023) 85:25 <https://doi.org/10.1007/s00027-022-00922-y>: 17 pp. (in English) ["Fish are known to pose strong effects on invertebrate abundance, species richness and assemblage structure. Littoral vegetation may play a crucial role as a refuge for invertebrates vulnerable to fish predation. We studied relative densities and taxonomic composition of water mites, aquatic beetles and bugs in large lake-like ponds with different fish status (fish-free and containing fish) and mesohabitats (emergent littoral vegetation and open water zone). The macroinvertebrate taxa differed in their responses to the fish presence and in mesohabitat preferences. The density and species richness of water mites were greater in fish-containing ponds, while no differences were

found between littoral and open-water habitats. In contrast, beetles were far more numerous and species-rich in fish-free ponds and in littoral vegetation. Total densities of aquatic bugs were non-significantly higher in fish-containing ponds, and they preferred littoral areas, but species richness was independent of fish presence and mesohabitat. No statistical interactions between fish presence and the densities of individual macroinvertebrate groups in the littoral habitat were detected, indicating that their use of emergent littoral vegetation was not an antipredator response to fish. The assemblages of the three macroinvertebrate taxa exhibited nested structures of a different order, consistent with their species richness patterns. Our research stresses the importance of littoral vegetation for the distribution and abundance of aquatic insects; however, high fish presence may not affect or may even benefit ecologically important macroinvertebrate groups, such as water mites or bugs." **21279.** Papastavropoulou, K.; Xiao, J.; Proestos, C. (2023): Edible insects: Tendency or necessity (a review). *e-Food* 4(1) e58: 17 pp. (in English) ["Eating insects has been a widespread habit in many cultures for many years. Edible insects represent an innovative food source with many advantages that will help the problem of protein and energy shortages created by the rapid growth of the world population. Using insects as food can increase the economy and help protect the environment and the human survival. Their nutritional value is excellent, since according to many studies insects have high protein content, high concentrations of various essential amino acids, a well-balanced fatty acid profile, with a high content of monounsaturated, polyunsaturated fatty acids and many minerals, trace elements, and vitamins. However, there are several risks in the use of edible insects, which need to be researched more extensively. Main goals are to spread knowledge and change the process of obtaining edible insects in better and safer ways. So that the edible insect food industry can develop on a solid basis, through the expansion of the composition of the insects already used and the future legalization of new species of edible insects as well as the establishment of additional legislative frameworks for the breeding, development, processing, storage, and safety of these innovative new foods. ... The most commonly consumed insect orders and their consumption rates are: ... dragonflies and Zygoptera (Odonata, 3%)..." **21281.** Pinilla-Rosa, M.; Garcia-Sauco, E.G.; Santiago, E.A.; Ferrandis, P.; Men, E.M. (2023): Can botanic gardens serve as refuges for taxonomic and functional diversity of Odonata? The case of the botanic garden of Castilla-La Mancha (Spain). *Limnology* 24(1): 37-50. (in Damselfly Dragonfly Functional trait Insect conservation Urban) ["In a scenario with declining biodiversity and habitat loss, botanic gardens could serve as refuges for invertebrates, but the opportunities they offer for animal conservation are still poorly understood. Odonata is a good model group for conservation studies, because it includes threatened species and responses to habitat disturbance are well documented. In this study, we assessed the role of the botanic garden of Castilla-La Mancha in Spain as a refuge for members of Odonata by analysing their taxonomic and functional diversity. We explored if the small size of the botanic garden might constrain the taxonomic diversity of Odonata and if low habitat diversity might limit their functional diversity. We

sampled adult Odonata from five water bodies along a gradient of human impact and characterized the Odonata communities based on 12 functional traits in Odonata. We used a species-area relationship to control for differences in the size of water bodies. Compared with natural lakes, the Odonata communities contained less species and their functional diversity was lower in the botanic garden ponds, where generalist species were basically hosted. Despite these limitations, the botanic garden ponds hosted the number of species expected for natural water bodies with the moderate surface area and functional diversity, thereby demonstrating that they are a valuable habitat for Odonata in an urban environment. Appropriate management involving the removal of exotic fish and habitat diversification, including creating lotic environments, would increase the taxonomic and functional diversity of Odonata in this urban system." **21282.** Rincón, V.; Velázquez, J.; Gülçin, D.; López-Sánchez, A.; Jiménez, C.; Özcan, A.U.; López-Almansa, J.C.; Santamaría, T.; Sánchez-Mata, D.; Çiçek, K. (2023): Mapping priority areas for connectivity of Yellow-winged darter (*Sympetrum flaveolum*, Linnaeus 1758) under climate change. *Land* 2023, 12, 298: 39 pp. (in English) ["*S. flaveolum*, which is associated with high mountain areas, can be considered a flagship species. Due to climate change, its natural range will be negatively affected. In this study, we propose global potential distributions for this species up to the year 2100, considering four time periods (2021-2040, 2041-2060, 2061-2080, and 2081-2100) and three shared socioeconomic pathways (optimistic-SSP245, middle of the road-SSP370, and worst-SSP585), by using an ecological niche model to produce two sets of distribution models (80% to 100% and 60% to 100%). It is foreseen that in the worst of the considered climate scenario (SSP585-2100 year), the distribution of this species could be reduced by almost half, which could pose a risk for the species and provoke the shift from vulnerable to endangered. An analysis of connectivity has also been carried out for all the studied scenarios by applying the MSPA and PC indices, showing that the core habitat of this species will become more important, which is consistent with the decrease in the distribution range. Over time, the importance of the most valuable connectors will increase, implying a greater risk of some populations becoming isolated." (2023): Lista preliminar e novos registros de Libélulas e Donzelinhas (Insecta: Odonata) para o Sul do estado de Alagoas, Brasil. *Hetaerina* 5(1): 17-26. (in Portuguese) ["The Northeast region of Brazil is still considered little known in terms of Odonata diversity due to the few collection campaigns carried out there. For example, only three studies have recorded Odonata for the state of Alagoas. The lack of information on the local diversity becomes an obstacle for the management and conservation of these organisms. Therefore, the present study aimed to provide a preliminary list of Odonata species reporting new occurrences in the south of Alagoas State. For this purpose, collections were carried out in eight sampling points on the margins of water bodies in the Marituba do Peixe Environmental Protection Area and adjacent areas. We collected 14 species in eight genera and three families, with a total of 43 specimens, of which nine species were new records for the state of Alagoas. For Anisoptera, 37 specimens were collected, distributed among the families Gomphidae and Libellulidae. The suborder Zygoptera

was represented only by the family Coenagrionidae, with six specimens. This study contributes to increase the knowledge about the occurrence and distribution of Odonata in the state of Alagoas, which already has 56 recorded species. Ongoing and future studies in the area will allow a better knowledge of the odonatofauna of Alagoas." **21289.** Sumah, A.S.W.; Banna, M. Z.A. (2023): Dragonfly diversity in a residential environment. Jurnal Biologi Tropis 23(1): 290-295. (in Indonesian, with English summary) ["...This study was to determine the diversity of dragonflies in three types of habitats and their correlation with environmental factors. The research was conducted in a residential area in Palembang City in November 2022 using the scan sampling method. The total number of dragonflies found was 18 species and 538 individuals ... *Orthetrum sabina* is the dominant dragonfly species found (136 sp). Meanwhile, *Ischnura verticalis* [sic!], *Pseudagrion microcephalum*, *Agriocnemis rubescens* and *Nososticta* sp. is the rarest species of dragonfly to be found. The diversity value of the Shannon-Wiener index indicates that dragonflies prefer open habitats. Habitat shape and plant vegetation affect the number of dragonflies found, but does not affect the abundance of these dragonflies. The results of the analysis show that wind speed and temperature affect the presence of dragonflies during the observation." **21290.** Svensson, E.I.; Gómez-Llano, M.; Waller, J.T. (2023): Out of the tropics: Macroevolutionary size trends in an old insect order are shaped by temperature and predators. Journal of Biogeography 50(3): 489-502. (in English) ["Aim: Global interspecific body size distributions have been suggested to be shaped by selection pressures arising from biotic and abiotic factors such as temperature, predation and parasitism. Here, we investigated the ecological and evolutionary drivers of global latitudinal size gradients in an old insect order. Location: Global. Taxon: Odonata (dragonflies and damselflies). Methods: We compiled data on interspecific variation in extant and extinct body sizes of Odonata, using an already existing database (The Odonate Phenotypic Database) and fossil data (The Paleobiology Database). We combined such body size data with latitudinal information and data on biotic and abiotic environmental variables across the globe to investigate and quantify interspecific latitudinal size-gradients ("Bergmann's Rule") and their environmental determinants. We used phylogenetic comparative methods and a global published phylogeny of Odonata to address these questions. Results: Phylogenetic comparative analyses revealed that global size variation of extant Odonata taxa is negatively influenced by both regional avian diversity and temperature, with larger-bodied species in the suborder Anisoptera (dragonflies) showing a steeper size-latitude relationship than smaller-bodied species in the suborder Zygoptera (damselflies). Interestingly, fossil data show that the relationship between wing size and latitude has shifted: latitudinal size trends had initially negative slopes but became shallower or positive following the evolutionary emergence and radiation of birds. Main Conclusions: The changing size-latitude trends over geological and macroevolutionary time were likely driven by a combination of predation from birds and maybe pterosaurs and high dispersal ability of large dragonflies. Our study reveals that a simple version of Bergmann's Rule based on temperature alone is not sufficient to explain interspecific size-latitude trends in Odonata. Our results instead suggest that latitudinal size gradients were shaped not only by temperature but also by avian predators, potentially driving the dispersal of large-sized clades out of the tropics and into the temperate zone." **21293.** van Strien, A.J.; van Grunsven, R.H.A. (2023): In the past 100 years dragonflies declined and recovered by habitat restoration and climate change. *Biological Conservation* 277 (2023) 109865: 7 pp. (in English) ["The availability of opportunistic dragonfly data in the Netherlands spanning >100 years gave us the opportunity to quantitatively assess long term changes in range size. We estimated changes in the number of occupied 5 km × 5 km sites by applying a modified List Length method, which takes into account changes in observation effort. Trends were assessed for nearly all Dutch dragonfly species and the trends were then summarised in Multi-Species Indicators by taking the geometric mean of the species indices. Overall, dragonflies severely declined in range size between the periods 1850–1950 and 1975–1990. In the period thereafter, strong increases happened, during which many species compensated their earlier losses. The factors driving the changes in dragonflies shifted over time. Until 1975 dragonfly species declined due to deterioration of water systems. After 1975 both climate change and habitat restoration contributed to the recovery of many species. Restoration of dragonfly communities was most successful in running water and least effective in moorland pools." (Authors)] Address: van Strien, A.J., a Statistics Netherlands, 24500, 2490 HA The Hague, the Netherlands

**21294.** Wei, Y.; Guo, H.; Zhang, S.; Li, J.; Wang, Y.; Liu, C. (2023): Bionic mechanical analysis of dragonfly wings: The feasibility of mesh combination to improve structural stiffness. *European Journal of Computational Mechanics* 31(4): 459-504. (in English) ["The nodes of the object will show different degrees of deformation and displacement or even damage over time. The mesh structure is flexible and different mesh shapes and arrangements will affect the structural stiffness of the object. The unique structure of dragonfly wing veins allows the dragonfly to withstand pressures several times higher than itself and to fly freely. This study is based on dragonfly wing bionics to disassemble the structure of dragonfly wing vein geometry. And it aims to investigate the deflection under different geometries and three-dimensional spatial structures by using the drawing software Auto CAD to draw dragonfly sample graphics, the finite element software Hyper mesh to build the model and the solver OptiStruct to analyze the structure of wrinkling, arching deflection, z-direction maximum displacement, y-direction maximum

rotation angle, combined displacement test under the different loads. The results show that: (1) The dragonfly wing vein mesh structure can enhance the stiffness under load. (2) In contrast, the displacement deformation of quadrilateral and combined hexagonal is smaller. (3) The structural stiffness of quadrilateral hexagon is enhanced as the height of wrinkling and arching increases. (4) The improvement of grid deflection with membrane structure is better than that without membrane structure. According to the above experimental results, the quadrilateral wrinkling and hexagonal arching structure has a significant improvement on the load bearing and deflection of the mesh, and has the potential to make structural optimization of the mesh series products, which is suitable for practical application and promotion." **21297.** Jehangir, Z. (1997): Taxonomic studies of Odonata of Gilgit and Baltistan areas. MSc. thesis, Fac. Agriculture, University of Agriculture Faisalabad. IV + 92 pp. In English [The adult Odonata collected during the summer months of 1994-95 from 24 different localities of Gilgit and Baltistan were identified into 27 species and subspecies belonging to 18 genera, 6 families and 2 suborders. Fourteen species, viz., *Anax nigrolineatus*, *Aeshna juncea*, *Cordulegaster brevistigma*, *Orthetrum chrysostigma luzonicum*, *O. sabina*, *Trithemis aurora*, *T. festiva*, *Tramea virginia*, *Palpopleura sexmaculata sexmaculata*, *Diplacodes lefebvrei*, *Ischnura aurora*, *I. senegalensis*, *Ceriagrion coromandelianum* and *Megalestes major* were recorded for the first time from this area. Of these, *Aeshna juncea* has been recorded for the first time from Pakistan. The characters of the taxa above the genus level have not been given in this manuscript because they are easily available in monographs, catalogues, faunal works and textbooks. The deviating characters of genera, species and subspecies have been given in this manuscript. *Libellula quadrimaculata*, *Ophiogomphus reductus* and 1st form of the female *Ischnura senegalensis* were described in detail, as they differ greatly from the published descriptions. A family Key, to the species, distribution of various species and measurements of various parts like abdomen, hindwing, forewing, pterostigma and anal appendages have been provided in this manuscript. Different statistics, such as range, mean and Standard deviation for measuring differences in various body parts have also been used. (Author)not stated

**21298.** Russell, R.W.; Wilson, J.W. (1997): Radar-observed "fine lines" in the optically clear boundary layer: Reflectivity contributions from aerial plankton and its predators. *Boundary-Layer Meteorology* 82(2): 235-262. In English ["Sensitive Doppler radars regularly detect fine lines of enhanced reflectivity in mesoscale boundary-layer convergence zones. Recent studies have concluded that these "fine lines" are attributable primarily to backscatter from concentrations of small, weakly flying insects ("aerial plankton") entrained in the convergence zones. Such concentrations are likely to be attractive to aerial predators that feed on small insects, raising the question of whether the presence of the predators themselves may contribute significantly to the radar-observed fine lines. In this paper, we examine the relative contributions of aerial plankton and its predators to fine-line reflectivity, using field data from visual and radar studies together with a compilation of literature data on radar cross sections of birds and insects. Visual counts of birds and dragonflies in convergence zones, together with simultaneous remote radar observations during the CaPE project in Florida, indicated that aerial predators usually contributed little to fine-line reflectivity (median contribution ss 2%). Assuming that the size distribution of insect targets was spatially invariant, the density of insects composing the aerial plankton was inferred to be on average, about one

order of magnitude higher inside convergence zones than in nearby areas. These results suggest that clear-air radar reflectivity may be a useful measure of the quantity of aerial plankton in boundary-layer convergence zones. This finding is relevant to biology because it indicates that remote sensing techniques can be usefully employed to document patterns and processes in the distribution of aerial plankton. The results presented here also have relevance for operational meteorology, because most of the organisms comprising the plankton probably serve as passive tracers of horizontal air motions, and are therefore ideal targets for remotely detecting wind patterns. In contrast, the aerial predators move actively and rapidly, rendering them less useful as tracers of wind fields in studies using Doppler radars. The influence of atmospheric structure on the ecology of aerial predators and their prey has received little attention, but we believe that sensitive radars with clear-air observational capabilities offer great potential as research platforms for future studies of aerial plankton and aerial planktivory. ## 2001

**21300.** Ketelaar, R. (2001): De speerwaterjuffer in Nederland: verspreiding, ecologie en bescherming. De Vlinderstichting, rapport VS2001.032, Wageningen. 75 pp. In Dutch [*Coenagrion hastulatum* is a highly endangered dragonfly species in the Netherlands. In 2001, it occurs at 16 locations in the Netherlands. Since 1980, *C. hastulatum* has disappeared from 7 locations. Two strongholds can be distinguished: the first in North Brabant south of Eindhoven and a second in the Achterhoek/Twente. Outside of that, *C. hastulatum* has completely disappeared except for two small populations on the Kampina and the Vressels Bos. From loose observations of floaters it can be deduced that *C. hastulatum* is not very mobile. In the Netherlands, *C. hastulatum* is only found on fens and in the edge zones of raised moors. There is one deviating population in weakly

flowing water. The habitats of the damselfly are characterized by the following aspects: • The vegetation of locations with damselflies is characterized by a species-poor deciduous vegetation with species that are minerotrafent for nutrient-poor systems and which indicate groundwater influence, such as Lesser Bladderwort, FieldRus and Knotweed Pondweed. • The vegetation is heterogeneous in character with both large and small floating leaf plants, emerge vegetation (sedges, reeds, mat rushes) and relatively few floating sphagnum mosses. • Peat formation and/or embankment landings occur on many fens. • *C. hastulatum* are small in size and usually no deeper than 1.5 metres. • *C. hastulatum* are quite acidic and have a fairly low ELV. Compared to other fens, the concentrations of potassium, iron, calcium and bicarbonate are relatively high. As with other fens, the ammonium content is sometimes quite high. • The habitats of the damselfly are weakly buffered by a slight influence of groundwater. The fens are generally located on an apparent water table in which the groundwater emerges for short periods, for example after heavy rainfall. The hydrological system that feeds the fens is local to at most supra-local (usually within 500 meters of the fen). • The water level is stable. • *Coenagrion puella* is a numerous species, and *Erythromma najas*, fire damselfly and emerald dragonfly are also guide species for the presence of *C. hastulatum*. High numbers of the water sniffer, on the other hand, are a bad signal. The disappearance of suitable habitat of the larvae and egg-laying substrate is the main reason for the disappearance of the damselfly damselfly from many fens and still poses a threat. The deterioration and disappearance of the specific heterogeneous vegetation structure is caused by: • acidification as a result of the loss of groundwater influence and increased ammonium deposition. • fluctuating water levels, so that the (cross) vegetation is dominated by pitrus • alkalization through intake of hard surface water • cleaning up fens • stocking herbivorous fish In addition, there are indications that internal acidification as a result of banks drying up poses a potential risk for the damselfly. Using a logistic regression, a model was made based on a habitat quality index that can be used to estimate the suitability of a fen for the damselfly damselfly. The model seems to work well in practice, but still needs to be validated. In the follow-up process, work must be done on the following aspects: • drawing up a protection plan for damselfly damselflies as soon as possible • informing managers • changes in management • restoration of groundwater influence and development of new habitat • expansion of monitoring. **21301.** Machado Caballero, J.E. (2001): Inventario y estudio comparativo de la fauna de Odonata en tres áreas de Honduras. Tesis presentada como requisito parcial para optar al título de Ingeniero Agronomo en el grado académico de Licenciatura. Zamorano Carrera de Ciencia y Producción Agropecuaria. Zamorano. XI, 31pp. In Spanish [The odonate assemblages (84 species) of 3 areas in the departments of Atlantida and Francisco Morazan (Honduras) are described, and the odonate faunae of Honduras, Belize, Costa Rica and Nicaragua are briefly analysed and compared. „For the conservation of forests and the diversity they have, a better knowledge of the species that inhabit them, their distribution and classification is necessary. Most of this diversity is made up of insects. The group of odonata, by its nature, helps in the control of some pests and can be used as an ecological indicator of the quality of ecosystems. Currently there is little information on them in Honduras. The

objectives were: to carry out an inventory of the species of the Odonata order, create a database and compare the fauna found with that of Belize, Nicaragua and Costa Rica. Captures were made from February to October in the Zamorano Valley (Yeguaré) and in April and August in the Cuero y Salado Wildlife Refuge and the Pico Bonito National Park, complementing with specimens provided by parataxonomists and those existing in the ecological inventory of Zamorano. The trapped insects were laterally placed in paper envelopes and placed in acetone for 24 hours to prevent decomposition and color loss. Then they dried for one or two hours and were transferred to a transparent envelope with data on location, date and collector, as well as family, genus and species. A database was generated to compare the fauna of the three study areas with each other, and with the fauna of Belize, Nicaragua and Costa Rica. There are 84 species in the three study areas, belonging to 43 genera and 10 families. The families with the greatest richness of cspccics were Libellulidac, Cocragionidac and Aeshnidae, which together account for more than 83% of the total fauna found. Two species, *Mecistogaster linearis* and *Brechmorhoga nubecula*, reported in the Pico Bonito National Park, are new records for Honduras. Contrasting the odonatafauna of Honduras with that of Belize, 114 species (65%) were found in common of 174 reported in that country. Costa Rica. There are 84 species in the three study areas, belonging to 43 genera and 10 families. The families with the greatest richness of cspccics were Libellulidac, Cocragionidac and Aeshnidae, which together make up more than 83% of the total fauna found. Two species, *Mecistogaster linearis* and *Brechmorhoga nubecula*, reported in the Pico Bonito National Park, are new records for Honduras. Contrasting the odonatafauna of Honduras with that of Belize, sc found 114 cspccics (65%) in common of the 174 reported in sc country. Costa Rica shares with Honduras 132 (49%) of its 268 registered species, and Nicaragua coincides with 82 species (82%) of the 100 registered species. Despite having found a high diversity of Odonata species in Honduras, a good percentage is unknown. It is recommended to complete the information with collections in the departments of Ocotepeque, Lempira, Intibuca and La Paz that have not been studied.”] Address: <https://bdigital.zamorano.edu/server/api/core/bitstreams/4f21289a-a6f9-41e5-9cda-57e6b3-627e77/content>

**21302.** Obara, K.; O, Mishima, H.; Yodoe, K.-i. (2001): Insects fauna in the Sada-cho, Shimane Prefecture. Bull. Hoshizaki Green Found. 5: 139-160. In Japanese, with English summary [ "Insect fauna was surveyed in the Sada-cho, Shimane Prefecture, in 2000. From May to October, we surveyed in the area six times, and 647 species belonging to 13 orders were recorded. This faunal record contains 261 species of Lepidoptera (42. 9% of all faunal record), 133 species of Coleoptera (21. 1 % of all faunal record) and 104 species of Hemiptera (16. 5% of all faunal record). These three orders occupy 78. 9% of all faunal record. In this report, *Ethmia epitrocha* (Meyrick) and *Ilema nachiensis* (Marumo) are recorded from Shimane Prefecture for the first time. The fauna was characterized by species being common with those in lower mountains of eastern Japan." (Authors)] Address: Obara, K., Otsu 426-7, I-zumo City, Shimane Prefecture, 693-0011 Japan

## 2002

**21303.** Dolny, A.; Kraut, M.; Horcicko, I. (2002): Dragonflies (Odonata) of Natural Reserve Stepán (bioregion Poodri).

Cos. slez. Muz. Opava (A) 51: 259-269. In Czech, with English summary. ["The object of this work was based on an intensive research that lasted from 1998 to 2000. We were set to find and to value qualitative and quantitative pieces of information about the constitution of odonatofauna in Štěpán natural reserve (Czech Republic, Silesia, square 6175). The collections of material (adults and larvae) were realized in 49 days. During the research was valued habitat selection. There were found together five types of biotopes: surface area of the pond and contiguous (shore, waterside) parts, growths of reed, pool, contiguous meadows, contiguous part in a protected area on the banks of the Opava river. There were found 31 species of the order Odonata (31 presented species makes perhaps 44 % from the whole number of species in the Czech Republic), 11 species of the suborder Zygoptera, 20 species of the suborder Anisoptera. The developmental process was proved in 16 species when juvenile adult or larva was caught and we believe that other 13 species are likely to have undergone the same process. Natural reserve Štěpán makes acceptable habitat for any different odonatocoenoses with relation to their cenotop, including tyrofil representatives *Somatochlora flavomaculata*, *Sympetrum danae* and *Leucorrhinia pectoralis*. Two species of the Czechoslovak Red Data Book (Škapec 1992) were found – *Calopteryx splendens* and *Leucorrhinia pectoralis*." (in Japanese, with English summary) ["65 species of the dragonflies were taken in Chantaburi, where is located around the border with Thailand and Cambodia, by the authors in March, 1998. An unknown dragonfly of the genus *Idionyx*, probably new to science, was taken. Undescribed female figure of *Coeliccia yamasakii* is shown. *Merogomphus parvus* and *Aethriamanta gracilis* are the first records in this area. We report the list of the collected dragonflies and the observation records." (Authors)] Address: Kitagawa, K., Imai 1-11-6, Asahi-ku, Osaka C., Osaka, 535-0011, Japan

**21305.** Kuijter, A.A. (2002): Libellen en insecticiden. Een literatuuronderzoek naar en risicobeoordeling van de effecten van insectenbestrijdingsmiddelen op libellen in Nederland. Wetenschapswinkel Biologie, Universiteit Utrecht; Rapportnummer: P-UB-2002-01. 34 pp. In Dutch [For butterflies have shown that agricultural pesticides may pose a high risk. Dragonflies life during a vulnerable phase of life in the water. It is not unlikely that they were in contact can be dissolved in the water with pesticides from agriculture. The Butterfly Foundation therefore, the Science of Biology at Utrecht University the following questions: • How sensitive dragonflies to insecticides? • What are the risks in current use in the Netherlands? To answer these questions in this report, a risk assessment on the basis of data from the literature. First, an inventory of literature about the effects on dragonflies in field situations pesticide used in the Netherlands. In addition, toxicity data controlled toxicity studies published. From these eight pesticides for short-term toxicity data obtained for dragonflies. From these data the long-term toxicity data calculation necessary for the risk assessment. These short and long term toxicity data compared with the maximum tolerable concentrations (MACs) of these pesticides. This MTR values are derived from toxicity data for different species and by the government used to provide the environmental quality of surface fixed. In addition, the risk assessment in the most recent measurements of these

pesticides compared to toxicity data. In field studies with pesticides dragonflies seem no more or less bothered by pesticides than other insects. Any decreases in dragonfly populations in addition to the direct toxic effects sometimes attributed to indirect effects such as loss of prey. If the concentrations of pesticides in surface water equal to the MPR values the risk of these pesticides for dragonflies minimal. This shows the sensitivity of dragonflies to pesticides from controlled experiments. However, there are significant breaches of the MTRwaarde of some pesticides detected. It is not known how often and how long overruns occur. Such overruns may pose a significant risk for some dragonfly species. From this preliminary risk assessment can be concluded that pesticides, given the low risk for dragonflies, probably not a major cause of the decline in its position dragonfly. During peak loads may be local effects. The main causes of the decline should rather be sought in habitat alteration and destruction. (Author/Google translate)] Address: not stated

## 2003

**21308.** Kalkman, V.J. (2003): Ongewervelde fauna van het Rijntakkegebied, met veldstudie in uiterwaarden rond Zaltbommel deelrapport libellen (Odonata). European Invertebrate Survey – Nederland. 33 pp. In Dutch ["In 2001 and 2002, EIS-Nederland carried out an inventory of terrestrial invertebrates in five floodplains along the Waal around Zaltbommel (Gelderland) on behalf of Rijkswaterstaat, Directie Oost. These are the Broomwaard, the Gamerensche Waard, the Heesseltsche Waard, the Hurwenensche Waard and the Rijswaard. This report discusses the results of this inventory with regard to dragonflies (Odonata). The first aim of the project was to obtain a frame of reference for the diversity of the floodplains of the Rhine tributaries. In addition, the results are related to the flooding regime of the river and indicator species are determined for biotope types in the floodplains. Each floodplain was examined twice in 2001 and 2002 for the presence of dragonflies. In addition, during fieldwork on the ecology of the river rump *Gomphus flavipes*,

each groyne section was specifically examined for the occurrence of this species. In order to place the results in a broader context, an overview of the species known from the floodplains of the Dutch Rhine branches has been compiled with the help of the national dragonfly database NVL/De Vlinderstichting/EIS-Nederland. Based on this overview, the species were determined with a preference for the Rhine branches. Since 1980, 45 species of dragonflies have been found in the Rhine branches area, of which 15 are rarely or never breeding in the Rhine branches area and have mainly been observed as vagrants. Of the 30 other species, 14 have a significant preference for the Rhine branches. Three species that are bound to running water occur in the Rhine tributaries area. Two of these (*Calopteryx splendens* and *Gomphus vulgatissimus*) are quite rare in the Rhine branch area and are much more common in streams in the east and south of the Netherlands. The third species, *Gomphus flavipes*, has a very strong preference for the Rhine branches area and the majority of the Dutch populations are located here. The majority of the species of the Rhine Branches area in the Netherlands are general species with little critical choice of biotope. A large proportion of the species with a preference for the Rhine branches area also fall into this category. An important exception to this are three species (*Aeshna isoceles*, *Brachytron pratense*, *Libellula fulva*) that occur in waters with land vegetation such as old oxbows. In the Netherlands, these species are mainly found in low peat bogs, but are quite scarce elsewhere. These species have probably declined in the river area but are still numerous locally. In addition to the above-mentioned types of land vegetation, the green glazier *Aeshna viridis* also occurred in the Rhine branches area at the beginning of the 20th century. This species only reproduces in extensive crab shaving fields, a vegetation type that is no longer found in the floodplains today. 26 species of dragonflies have been found in the floodplains of Zaltbommel. With the exception of the plasombout *Gomphus pulchellus*, all species with a preference for the Rhine branches area were found during the inventory. Species diversity increases as the distance from the river increases. Most species are found in areas with extensive water and riparian vegetation. These vegetations are mainly present in the channels against the winter dike. More frequent and more intensive flooding makes the emergence of this type of vegetation impossible. Shrubs and woods located on the upstream side seem to have a protective effect for the riparian vegetation and therefore lead to species-rich dragonfly biotopes." (Author/Google translate)] Address: Kalkman, V.J., European Invertebrate Survey - Nederland, p/a Nationaal Natuurhistorisch Museum - naturalis, Postbus 9517, 2300 RA Leiden, The Netherlands. **21310.** Kumar, A.; Sharma, G. (2003): Fauna of Asan Wetland. Odonata. Wetland Ecosystem Series 5: 11-13. In English [The study of Odonata diversity surrounding Asan reservoir area reveals 43 species spreading to 29 genera under seven families. Out of these, 16 species (37%) under

13 genera are Oriental, one species (2%) under one genus is Palaearctic, 16 species (37%) under six genera are Tropical, two species (5%), under two genera are Ethiopian four species (9%) under three genera are Australian and four species (9%) under four genera are Cosmopolitan in distribution. *Anax parthenope*, *Diplacodes lefebvrei* and *Urothemis s. signata* have been recorded for the first time from Dehra Dun valley where as the latter two are new records from the western Himalaya as well (Mitra, 1999). The most important ecological phenomenon is the presence of both stream species as well as the standing water species, which indicates that the both ecosystem are properly maintained. The running water breeding species like, *Calicnemia eximia*, *Neurobasis ch. chinensis* were much more abundant at the confluence of the river Asan with the reservoir. The inlet channel coming from Dakpathar barrage is deep and with unstable or altered ecological conditions that hardly any dragonfly species is able to breed there and, therefore, its surrounding remained somewhat barren except some species from the reservoir occasionally visiting the area. Classified list of 43 species of dragonflies, including 14 species of Zygoptera and 29 Anisoptera available at Asan reservoir is given below. The scientific name of each species is followed by the name of the authority and year of the original description of species. The habitat preference study revealed seven stream breeding species (160/0) and 13 reservoir (standing water) breeding species (30%) whereas 23 species (54%) were common in both the habitats. Interestingly all the 43 species are breeding residents at the Asan reservoir and contiguous areas." (Authors)] Address: Kumar, A., Zoological Survey of India, Northern Regional Station, Dehra Dun, India

**21311.** Swer, S.; Singh, O.P. (2003): Coal mining impacting water quality and aquatic biodiversity in Jaintia hills district of Meghalaya. ENVIS Bulletin Vol 11(2): Himalayan Ecology. 29-36. In English [The Jaintia hills, one of the seven districts of Meghalaya, lies between latitude 25°5'N to 25°4'N and longitude 91°51'E to 92°45'E. The district is bound by the state of Assam on the north and east, the East Khasi Hills on the west and Bangladesh in the south. The water bodies are badly affected by contamination of Acid Mines Drainage (AMD) originating from mines and spoils, leaching of heavy metals, organic enrichment and silting by coal and sand particles. Pollution of the water is evidenced by the colour of the water which in most of the rivers and streams in the mining area varies from brownish to reddish orange. Low pH (between 2-3), high conductivity, high concentration of sulphates, iron and toxic heavy metals, low dissolved oxygen (DO) and high BOD are some of the physico-chemical and biological parameters which characterize the degradation of water quality. Observations on physico-chemical and biological characteristics of water are discussed below and summarized in Tab. 1. Low pH, low DO, higher sulphate content and turbidity in water of coal mining areas are affecting the aquatic life. Study on benthic macroinvertebrates revealed presence of only a few tolerant species namely *Chironomus* larvae (Diptera), dragonfly larvae and water bugs (Hemiptera) in rivers and streams of the area. Analysis further revealed lower abundance and species diversity of macroinvertebrates. The presence of only a few tolerant species of benthic macroinvertebrates and the absence of most of the aquatic organisms particularly the sensitive species are most likely due to acidic water contaminated with AMD. Further, most of the river of the mining area lack commonly found aquatic organisms such as fish, frog and crustacean." **21314.** Gao, X.-T.; Liu, Y.; Wang, C.; Zhao, L.; Guo, D.-S.; Liu, D.-Z. (2004): Ecological distribution of damselflies in Beijing area. *Entomological Knowledge* 41(5): 426-430. In Chinese, with English summary ["A survey on the ecological distribution of Zygoptera and the influencing factors was carried out in Beijing area from March of 2002 to October of 2003. Ten species of damselflies, which belonged to 3 families and 7 genera, were found in our study. Among them, *Cercion calamorum* and *Ischnura asiatica* were dominant and widespread species. The results of Principal Components Analysis (PCA) indicated that the coverage of freely-floating aquatic plants, emergent aquatic plants, plants around the plots and the submergent aquatic plants were significant factors affecting the distribution of those two damselflies. They contributed 30.49, 24.14, 17.45 and 15.26%, of the total variation respectively. Moreover, *Calopteryx atratum*, and *Matrona basilaris* were merely recorded within the waters of the southwestern and northern parts in which the water flowed rapidly, with shallow depth and less pollution. *Cercion plagiosum*, *Ischnura elegans*, and *Platycnemis foliacea* were comparatively uncommon species of damselflies, which occurred only in the edges of rivers, lakes and reservoirs. *Mnais mnome*, *M. earnshawi* and *Copera annulata* were restricted-ranged species that were only found in the mountain areas of Beijing." (Authors)] Address: Gao, X.-T., Lab. Bio-div. Sci. & Ecol. Engineering, Inst. Ecol., Beijing Normal Univ., Beijing-100875, PRC

**21315.** McAbendroth, L. (2004): Ecology and conservation of Mediterranean temporary ponds in the UK. Ph.D. thesis, Faculty of Science and Technology, University of Plymouth: XV + 247 pp. (in English) ["Macroinvertebrate and plant assemblage composition and abiotic habitat characteristics were examined in 76 ponds, in the New Forest (Hampshire, UK) and on the Lizard Peninsula (Cornwall, UK), in order to

unravel the ecological processes influencing ponds at a range of spatial scales and provide a clear definition of Mediterranean Temporary Pond (MTP) habitat (92/43/EEC) in the UK. In addition, a set of newly created experimental ponds were monitored on the Lizard to examine patterns of colonisation and evaluate the use of habitat creation in temporary pond conservation. The findings are synthesised into a number of management recommendations for ponds in the regions, with a particular focus on MTPs. MTPs equated to ephemeral, winter-flooded ponds occurring in shallow depressions on the Lizard, which had some floristic similarities to other western Atlantic fringe sites. They were dominated by low growing grasses, rushes and rare annual species of the Nanocyperion alliance along with a depauperate macroinvertebrate assemblage comprising Coleoptera (including characteristic rare taxa), Trichoptera and Chironomidae. The strength of physicochemical and spatial pattern in assemblage composition varied between the regions. Lizard macroinvertebrate assemblage similarity was spatially autocorrelated and related to water chemistry and pond area but New Forest macroinvertebrate similarity was not related to any of the measured physicochemical parameters. Plant assemblage composition was only weakly related to wet phase physicochemistry. Pond vegetation structured macroinvertebrate assemblages in different ways at different spatial scales. At large-scales, macrophyte richness and composition affected macroinvertebrate assemblage composition in both regions, whereas, at smaller-scales, macrophyte structural complexity (measured using fractals) influenced body size scaling and overall biomass of macroinvertebrates. Assemblages in both regions were significantly nested, indicating that species-poor sites tended to be subsets of rich sites. Macroinvertebrate nesting, on the Lizard, was not due to passive sampling, and was best explained by pond area, with habitat parameters and isolation being of secondary importance. Nested and idiosyncratic taxa differed in their spatial response to factors which structured assemblage-level nestedness; idiosyncratic taxa tended to possess broad ecological tolerance and good dispersal capacity, whilst nested species had narrower tolerance or limited powers of dispersal. Experimental pond macroinvertebrate assemblage similarity converged with pond age, despite continued variation in physicochemistry, and the assemblages that developed were not significantly different from small natural ponds in the region. Augmentation of current MTP habitat could therefore be achieved by creating new sites in close proximity to existing water bodies." (Author) The only odonate taxa mentioned is "*Sympetrum* spp.".] Address: not stated

**21316.** Annon, M.R. (2005): Life history studies of the damselfly *Sympetma paedisca* BRULL [sic] (Odonata: Libellulidae) in a shallow pond in Garmat-Ali, Basraii. *Mesopotamian Journal of Marine Science* 20(2): 297-310. (in English) ["Life history of *S. paedisca* been investigated in a combined field and laboratory study. The field study is conducted at a shallow pond in Garmat-Ali, Basrah in the period from October 1997 to September 1998. Some environmental factors such as temp., D.O., pH. and salinity were measured. The field results indicate that the life cycle is univoltine, however this species is unique in that it does not enter nymphal diapause. Emergence is rather an unsynchronized and dispersed temporally. Sexual maturation requires four weeks. Oviposition site is Potamogeton. The laboratory study revealed that incubation period was 14 days at 27 °C. The nymphal stage includes twelve instars and requires 252.5 days for completion the development. The whole life cycle

requires 266.5 days." (Author)] Address: Annon, M.R., Dept of Biology, College of Education, University of Basrah, Iraq

**21317.** Briers, R.A.; Biggs, J. (2005): Spatial patterns in pond invertebrate communities: separating environmental and distance effects. *Aquatic Conserv: Mar. Freshw. Ecosyst.* 15: 549-557. In English ["(1.) The nature and extent of spatial pattern in communities has important implications for their dynamics and conservation. Previous studies of pond ecosystems, over relatively small spatial scales, have found little evidence of spatial autocorrelation of community composition. Patterns in community composition over greater spatial distances have not been documented. (2.) Here, data on macroinvertebrate communities [including 10 odonate species without further specification] and physico-chemical characteristics of 102 ponds over a 60 x 60 km area of Oxfordshire, UK, were used to examine evidence for spatial autocorrelation in community composition and to separate the effects of environmental similarity and physical distance on community similarity. (3.) Overall similarity between communities was low, but showed significant positive spatial autocorrelation. There was evidence for both environmental and physical distance effects on spatial autocorrelation of community similarity. Community similarity was negatively related to differences in environmental conditions, but effects were only significant for large environmental differences. (4.) When environmental effects were accounted for, there was significant positive spatial autocorrelation of community composition over inter-site distances of up to 13 km. These results suggest that interactions between pond sites, potentially through dispersal, are evident over larger spatial scales than has previously been appreciated, and emphasize the need to consider spatial issues when developing strategies for pond conservation." (Authors)] Address: Briers, R.A., School of Life Sciences, Napier Univ. Merchiston Campus, Edinburgh, EH10 5DT, UK. E-mail: r.briers@napier.ac.uk

**21318.** Chartier, A. (2005): Twin-spotted spiketail: new sight record for Wayne county and record late date. *Williamsonia* 9(1): 3. In English [Verbatim: (*Cordulegaster maculata*) has been recorded from most of the UP and northern LP counties in Michigan, and from about a third of the Southern LP counties (14), including six in the southeast (MOS website). On the cool morning (58° F, -9:00 AM EST) of 22 Aug 2004, while checking mist nets at my bird banding Station in a closed area of Lake Erie Metro Park, Wayne Co., I encountered a Twimspotted Spiketail hunting over an open grassy field surrounded by shrub, hedgerow, and woodland. Initially, I thought it was the Canada Damer (*Aeshna canadensis*) that I had seen a short time earlier. But, when it landed near me I immediately saw the paired yellow triangular spots on the abdomen and I suspected it was a *Cordulegaster* instead, but I wasn't sure which species. I got my digital cam out of the car and took a few photos, hoping to identify it when I got home, as I had no dragonfly references handy. Due to the temperature, it was very cooperative. I then turned my attention back to the bird I needed to band at that moment. I did not take the spiketail as a specimen because I had no way to keep it from getting damaged, and my purpose this day was bird banding, not dragonfly collecting. I determined the species once I got home, and also determined that it was a male. Color photos of this individual can be viewed on my website at: [www-amazih.net/images/Inverts/Odonata/Cordulegaster\\_maculata.htm](http://www-amazih.net/images/Inverts/Odonata/Cordulegaster_maculata.htm). The flight period for the Twimspotted Spiketail in our region is described as late May through the end of July (Holder 1996, Legier 1998, Mead 2003), and to early August

in New Hampshire (Dunkle 2000). This is likely a record late date in our region, and possibly within the entire range of the species. Mead (2003) describes the habitat for *C. maculata* as "clean, clear streams and smaU rivers in wooded areas..." To the west of the site (within 0.25 mile) is an area of freshwater marsh that drains south into the Huron River, and to the south of the site (also within 0.25 mile) is a wooded creek near the Pte. Mouülee State Game Area Headquarters which also drains southeast into the mouth of the Huron River. More freshwater marsh and a stream (not wooded) that drains into Lake Erie occurs to the east of the site. To the north is an open woodland, and a golf course is to the northwest. It seems possible that streams in this area could have provided breeding habitat for the species, though it seems equally possible that this individual was simply a very tardy vagrant.] Address: Email: amazial@comcast.net

**21319.** Kishida, O.; Nishimura, K. (2005): Multiple inducible defences against multiple predators in the anuran tadpole, *Rana pirica*. *Evolutionary Ecology Research* 7: 619-631. In English ["Question: What conditions are required for evolution of predator-specific inducible defences? Hypotheses: (1) Prey organisms distinguish among predators to which they are exposed. (2) Prey individuals with a predator-specific defence must attain higher survivorship than those with a mismatched defensive phenotype. Organisms: Prey, anuran tadpoles (*Rana pirica*); biting type predator, dragonfly larvae. (*Aeshna nigroflava* = *Aeshna serrata*); swallowing type predator, salamander larvae (*Hynobius retardatus*). Methods: *Rana pirica* tadpoles were exposed to the predator signal in close proximity to or remote from the dragonfly larvae or the salamander larvae to determine whether the tadpoles develop predator-specific morphologies and whether they utilize predator-specific signals in the induction process. We conducted predation trials to determine whether the tadpoles with induced phenotypes were more resistant to the attack in the corresponding predator environment. Results: *Rana pirica* tadpoles developed predator-specific morphologies in response to exposure to two different types of predator. The tadpoles discriminated between the predators – that is, different signals were required to develop the specific phenotypes in the induction process. The survival rate of tadpoles of specific phenotypes was higher than that of tadpoles of mismatched or non-induced phenotypes when exposed to predation by the corresponding predators." **21320.** Niechoj, S. (2005): Die Libellenfauna des Naturschutzgebietes Krickenbecker Seen. Diplomarbeit. Westfälische Wilhelms-Universität Münster. 69 pp. + Anhang. In Geman [In 2004, the dragonfly fauna was examined in ten bodies of water in the NSG KS. The recording mainly took place in flowing waters, for which only few data are available up to now. With 33 proven dragonfly species, more than half of which are native, the NSG KS can be described as particularly species-rich. A third of the recorded species are on the red list of North Rhine-Westphalia (SCHMIDT & WOIKE 1999) and Germany (OTT & PIPER 1998). Considering the small number of water body types examined, the importance of this area for dragonflies becomes clear. If you add the data from other mappings in recent years, the total number of species and the number of proofs of indigeneity continue to increase. By recording the watercourses, *O. coerulescens* could be detected again in the NSG KS for the first time since 1990, and *S. metallica* was proven to be indigenous to a section of the Nette. The importance of the

area for *L. fulva* could be clarified, and the wide distribution within the NSG KS could be proven on the basis of the numerous finds of exuviae. The indices commonly used to compare the composition of species in the various bodies of water, such as the Sørensen quotient or the WAINSTEIN index, cannot be used appropriately for dragonfly zoenoses. The need to include not only the factors considered by Sørensen and WAINSTEIN, but also (potential) indigenoussness, abundance and relative find rates is discussed. The influence of the temperature increases in recent years could be documented in the phenological data for 2004 and the discovery of the Mediterranean species *C. erythraea*. The use of the term "ubiquist" appears premature for many species based on the literature and our own surveys and has been discussed. Since mapping always involves a certain degree of subjectivity, a method for the objective recording of horizontal vegetation density with the help of a computer program was presented. Due to the heterogeneous water body structures, many photographs of the vegetation have to be taken, so that the effort involved in digital post-processing is too high and this method becomes unprofitable. For low-growing, more homogeneous structures, however, this method is considered to be useful. It is established that those seeking relaxation in the NSG KS not only pose a threat to flora and fauna by entering the waterfront, but also create structures through this disruption that are used by some dragonfly species for hatching. The nutrient input into the waters is a serious problem in the NSG KS. This entry can be counteracted by simple measures such as removing the cuttings from the embankment. Measures such as the extensification of agricultural areas in the catchment area of Nette and Renne and the replacement of private small sewage treatment plants with connections to large sewage treatment plants are necessary to reduce the inputs themselves. The neozoa muskrat and coypu not only damage embankments and dams, but also decimate the natural aquatic vegetation with their food spectrum, which can have negative effects on the dragonfly fauna. (Author/Google translate)] Address: not stated

**21321.** Schmidt, C. (2005): Pflege und Bewirtschaftung von ausgewählten Gräben im LSG „Nassau und Elbwiesen bei Brockwitz“ unter besonderer Berücksichtigung der Libellenfauna. Diplomarbeit. Hochschule für Technik und Wirtschaft Dresden (FH). 78 pp + Anhang. In German ["In the course of this work, structural mapping was carried out on the ditches of the study area as a basis for the care and management concept. At the same time, the dragonflies occurring there were recorded. To characterize the sections of the ditch, different parameters were considered (e.g. information on the longitudinal and transverse profile, bed structure, vegetation and environment), which represent the current condition of the respective body of water. Since open water areas are necessary for most dragonfly species, a follow-up mapping was carried out in August, with a focus on vegetation. The existence of an optical profile-narrowing effect and the covering of the water surface by the embankment vegetation as well as the density of the emersed plants were recorded. A total of 22 dragonfly species were found in the study area. These include seven species that BROCKHAUS & FISCHER (2005) continue to propose for the red list based on the latest distribution findings, and one species for the early warning list. Target species among these particular species is *Coenagrion ornatum*, which is listed in Appendix II of the Habitats Directive. It is given special consideration within this concept. Other threatened species are *Calopteryx virgo*, *Coenagrion pulchellum*, *Lestes barbarus*, *Orthetrum brunneum*, *O. coerulescens*, *Sympetrum flaveolum*

and *S. pedemontanum*. Based on the evidence, the sections of the ditch were later divided into four maintenance zones: first sections with an occurrence of *C. ornatum*, then sections for the promotion of *C. ornatum*, then sections with the occurrence of other special dragonfly species and finally sections without direct earmarking to certain dragonfly species. Finally, specifications for necessary maintenance measures (slope mowing, weeding and clearing) were developed in terms of ditch management in line with nature conservation and taking into account the requirements of the various special dragonfly species. Furthermore, statements are made on flanking measures that serve to improve the habitat properties or to increase the structure in the study area. These are the construction of waterfront strips, the clearing of existing rows of trees, the leveling of the embankments, the removal of the river bed structures, the conversion of arable land to grassland and the disclosure of piped ditch sections. Finally, based on the existing structures, the individual maintenance and supplementary measures were summarized in action maps." (Author/Google translate)] Address: Schmidt, C., Louisenstr. 45, 01099 Dresden

**21322.** Schultz, H. (2005): Vergleichsstudie March im Abschnitt Marchegg (Fluss km 15,00 – 25,00): Odonata. Endbericht. Im Auftrag des Umweltbundesamtes Wien, Wien, Mai 2005: 49 pp. (in German) ["As part of the project "Bank and profile design measures and measures to connect the meanders for the March in the Marchegg section (river km 15.00-25.00)", 13 test sites were selected with a focus on the March to evaluate the design types. The biocenotic parameters total species inventory, proportion of autochthonous species, proportion of sensitive species, indigenoussness of the species and abundance (relative frequency) were determined for each sampling site. The maximum abundance is given, whereby the species are classified according to the inspection date with the largest number of individuals found at the individual sampling sites. This database also enables the dominant species, the dragonfly communities and a characterization of the examined locations based on the dragonfly fauna to be addressed. A total of 22 dragonfly species (8 Zygoptera and 14 Anisoptera) from 8 families were identified. Of these, 11 species are classified in the Red List of Lower Austria (RAAB & CHWALA, 1997). For 6 species, the indigenoussness could not be clearly confirmed. However, it can be assumed that the species in question are mostly native to the Marchauen. The autochthonous evidence of *Sympetrum meridionale* is to be emphasized as a special proof, since the species is considered "extinct or missing" in Lower Austria. In addition, the endangered dragonfly species *Gomphus flavipes* and *Epithea bimaculata* as well as the highly endangered species *Lestes barbarus* and *Ophiogomphus cecilia* could be detected. *O. cecilia* and *G. flavipes* are protected animal species throughout Europe according to the EU Habitats Directive, with *O. cecilia* as a protected object of the Natura 2000 area "March-Thaya-Auen" subject to the strict area protection according to Article 6 of the Habitats Directive subject. On the March in the investigation section, the running water community *Gomphus - Calopteryx splendens - coenosis* has dev2008eloped, which corresponds to the biotope type of the brisk to sluggishly flowing rivers of the plain. The indicator species are the rheophilic dragonfly species *Gomphus vulgatissimus*, *O. cecilia* and *Calopteryx splendens*, which are accompanied by *Platycnemis pennipes* (cf. JACOB, 1969; STARK, 1976; WARINGER, 1989). A total of 10 dragonfly species from 7 families could be identified as being sensitive. These are stenöke, i.e. narrowly niche, species that place special demands on their habitat and are

therefore particularly well suited as bioindicators. The occurrence of a total of 3 species out of 4 species of the family Gomphidae known for Lower Austria is remarkable. On the other hand, the sensitive species *L. barbarus*, *Aeshna affinis* and *S. meridionale* were detected at the two sampling sites away from the main river. The 13 sampling sites range from 1.09 to 3.95 on a scale from 1 for eu- and parapotamal permanent water bodies (habitat type H1) to 5 for temporary standing water bodies (habitat type H5). The surveyed AUI range of 2.86 can therefore be assessed as wide. The study sections along the March itself all correspond to habitat type H1. The results for sample site 8 in meander IV with 3.44 and for sample site 12 on the wet meadow with 3.95 are at the opposite ecological end of the spectrum of riverine and amphibious alluvial sites. The mean AUI of 1.73 shows the focus of the recordings on H1 habitat type sites. Tables 13 and 14 provide a summary of the evaluation of the sampling sites and the design types on the March based on the dragonfly fauna surveyed. The design types A2 (partial removal of the bank protection on the impact bank), B3 and B4 (accentuation of the transverse profile through measures on the slip bank), E2 (relocation of bed sediment) and E3 (installation of wooden structures) are rated positively. Sample site 11 with design type B4 represents an extremely valuable habitat for the dragonfly fauna on the March. At this site, by far the highest density of individuals of the endangered dragonfly species *G. flavipes* and most of the individuals of the very rare *O. cecilia* raised. Design type C1 (selective lowering of the bank edge) with the aim of improving or restoring the lateral surrounding area network cannot be confirmed based on the available results. Due to the inspections in 2004, the execution of the measures must be rated rather negatively, since the trenches were dry on all inspection dates with the exception of April and the local subsidence was well above the level of the March. Improved networking of the main river with the floodplains and their backwaters and wet meadows is essential for their existence in order to counteract silting up or complete drying out. A dynamization of the meander IV could not be determined in the inspection period 2004. For sampling point 8 along the former inflow opening, a value of 3.44 was created as part of the calculation of the floodplain index based on native dragonfly species. Thus, meander IV in the examined section corresponds to standing water with no connection to the main river at medium water levels, but with a strong tendency to silt up. The planned integration of the meanders is to be demanded in accordance with the model typical of the river. The connection to the main river also counteracts the progressive silting up of the meanders. When carrying out the design measures for the meander inflow area to connect the meander, an approach should be chosen with consideration for the rare and in some cases highly endangered dragonfly fauna. If the meanders are fully integrated into the course of the river with year-round flow, the preservation of areas protected from the current, separate sections of water or similar is a decisive compensatory measure. Based on the available ecological results on the dragonfly fauna, tendencies and comprehensible differences between built and unbuilt or demolished sections can be determined. Undeveloped or dismantled sites on the March (corresponding to natural conditions) clearly show the better values in terms of the species inventory recorded, the proportion of native and sensitive species and the abundances. They have a larger and more specific range of species. With one exception, all trial tillages with hard-built banks due to heaped heaps generally show poorer values. From a dragonfly point of view, preference should therefore be given to all measures that create or promote a near-natural and less disturbed state and increase the range of structures. The

strengthening of the bank with monotonous heaps of heaps is to be rejected. In general, the structural heterogeneity of the March has been improved by the design measures carried out, but there are long stretches of deficits in the area of water-land connectivity and the structural equipment, especially of the riparian bank." Malindang, Misamis Occidental. Southeast Asian Regional Center for Graduate Study and Research in Agriculture (SEARCA). Biodiversity Research Programme for Development in Mindanao: Focus on Mt. Malindang and Environs. ISBN 971-560-125-1: 177 pp. (in English) [Philippines; An assessment of arthropod diversity and analysis of the interrelationships with other resources were conducted in 10 barangays in Oroquieta City, Don Victoriano, Lopez Jaena, and Calamba, Misamis Occidental from June 2003 to May 2005. The current inventory of Mt. Malindang arthropods includes 741 species in 340 genera, 135 families, 21 orders, and 5 classes. The most speciose orders, the Coleoptera, Hemiptera, Hymenoptera, Diptera, and Araneida account for 78.37 percent of all the species. Arthropod species diversity is generally higher in forest ecosystems than in agroecosystems. When treated per vegetation and per site, diversity is highest in the mixed dipterocarp forest of Peniel, Lopez Jaena, with 82 restricted species (60% beetles) out of 316 species. In terms of species composition, three major clusters of similarity among vegetation types are discernible: a) five agroecosystem sites in Gandawan, Mansawan, Lake Duminagat, Mamalad, and Mialen, with Gandawan and Mansawan having the most similar arthropods; b) montane-mossy forest and agrocereal grassdominated type and almaciga forest in Sebucal; and c) mixed lowland dipterocarp-plantation forests, agrocereal, agroforest, and mixed dipterocarp forest. Three vegetation types appeared to show little species similarities among each other or with any of the three clusters.] Address: Gapud, V.P., Univ. Philippines, Coll. Agr., Pest. **21325.** Groenendijk, D.; Bouwman, J. (2006): Ecologische status van de Hoogveenglanslibel in Noord-Brabant. Rapportnummer VS2006.035, Wageningen. 24 pp. In Dutch ["Introduction There is a population of *Somatochlora arctica* in the Reuselse Moeren in North Brabant. This is one of the five known populations of this endangered species in the Netherlands. The population in the Reuselse Moeren is relatively small (but viable) and therefore vulnerable. This project plan focuses on the protection of the moorland dragonfly in the province of North Brabant and is a result of the activities of the species protection plan moorland dragonfly

(Ketelaar et al., 2005). This report reports on the ecological inventory planned for 2006. Ecology The high moor shine dragonfly is a special species. It is one of the few species of dragonflies in Europe of which relatively little is known. Chapter 2 of this report devotes relatively extensive attention to ecology. This information can also largely be found in the species protection plan. Fieldwork 2006 The fieldwork in 2006 concentrated on the Reuselse Moeren. The main goal was to trace the exact breeding sites in this reserve. Secondly, 10 other possibly suitable peat remnants were searched for other populations in the province of Noord-Brabant. The areas where historical observations of the high moor shine dragonfly are known were also visited. Results: dissemination and management The high moor shine dragonfly is only found in the Reuselse Moeren. In the remaining areas, the presence of the species could not be established. The population in the Reuselse Moeren is located in the core of this area. The management of the Reuselse Moeren must be aimed at combating desiccation and maintaining small peat pits with sufficient peat mosses in the core. Bottlenecks and measures The peat pits in the Reuselse Moeren where the high moor shine dragonfly is located reproduces, contain very little open water and a large surface area of sphagnum moss. The current bottlenecks in the Reuselse Moeren mainly lie in the desiccation of the area. Measures should primarily be aimed at restoring the hydrology of the area. This is the main route. In addition to this first trajectory, Chapter 5 also proposes a second trajectory with measures for the short term." **21326.** Schleicher, J. (2006): Les peuplements de lépidoptères rhopalocères et d'odonates du bassin versant de la Drôme. État des lieux et mise en place d'un suivi des rhopalocères, d'odonates et des macrophytes aquatiques comme descripteurs des milieux alluviaux et fontinaux du bassin versant. FRAPNA DROME 38 Avenue de Verdun 26000 Valence. 146 pp. In French ["The biodiversity observatory, set up as part of the SAGE de la Drôme, plans to monitor the populations of rhopaloceres, odonates and aquatic macrophytes linked to alluvial and fontinal environments. As part of this study, we have established an inventory of knowledge of the populations of rhopaloceres and odonates at the level of the watershed. This inventory is based on an analysis of existing data in various naturalist databases. We analyzed the observation pressure and the specific richness by municipality of the catchment area. To each known species in the study area, we assigned an abundance/rarity index (in relation to occurrences in the database), as well as an index that takes into account the abundance or rarity of stations of the species. According to the different natural environments and types of wetlands, we have identified processions of characteristic species. In the second part of the study, we explain the implementation and methodology of monitoring at the sampling sites. We present each sampling site as well as the monitoring plots. For the rhopalocere sites, we describe the natural habitats sampled (according to the CORINE biotope nomenclature). For odonate and macrophyte sites, we describe the environmental parameters and we present a simplified phytosociological analysis for each one. The phytosociological analysis is based on our macrophyte surveys. The third part reports the results of the sampling by site. We present the specific diversity, abundance / density of imagos as well as the abundance of heritage species. For each site, we also present diagrams of the species composition of the populations, grouped by

plot/transect. The results of the 2006 monitoring campaign represent the baseline for future monitoring. The results are analyzed in relation to the specific diversity and the balance of the populations of each site and for odonates in relation to the Global Quality Index (IQG) of odonatological value." (Author/Google translate)] Address: Schleicher, J., FRAPNA Drôme, 38 Avenue de Verdun 26000 Valence, France

**21327.** Dinger, E.C.; Marks, J.C. (2007): Effects of high levels of Antimycin A on aquatic invertebrates in a warmwater Arizona stream. *North American Journal of Fisheries Management* 27: 1243-1256. (in English) ["Restoration of native fish to freshwater habitats often requires nonnative fish removal via chemicals such as antimycin A. Despite widespread use, there are limited field studies quantifying the effects of antimycin A on aquatic macroinvertebrates. We studied the immediate and short-term effects of antimycin A on macroinvertebrates during a fish renovation project in Fossil Creek, Arizona. We employed before-after control-impact (BACI) designs to measure the effects of antimycin A (at extraordinarily high levels of .54 and .100 lg/L) on macroinvertebrate drift, density, and species composition. We used the Hilsenhoff biotic index, a measure of invertebrate pollution tolerance, to study changes in species composition. At the highest dose (.100 lg/L), drift was five times the pretreatment drift level and invertebrate standing stocks in pools and riffles decreased immediately. Densities rebounded in riffles within 5 months but remained depressed in pools. At the lower concentration (.54 lg/L), macroinvertebrate mortality, measured as increased drift, was 24 times the pretreatment level. At this lower concentration, however, macroinvertebrate densities in the benthos were not reduced. Under both concentrations, species composition shifted toward more tolerant species. Although antimycin A effects were mostly short term, several species were locally extirpated. We found no explanation for the loss of some species over others. These results indicate that there is a high end concentration at which antimycin A can have deleterious effects on aquatic invertebrates. We caution managers contemplating the use of antimycin A in fish restoration to consider the risks to macroinvertebrates. We suggest the use of pretreatment surveys and bioassays at anticipated treatment levels to predict the effects upon macroinvertebrates, especially sensitive species. Where there are sensitive species, steps should be taken to mitigate effects." (Authors) At treatment site 1 *Hetaerina* sp. was extirpated. "By August 2006, five taxa had recolonized treatment site 1 (*Baetodes*, *Bezzia*, *Metrichia*, *Rhagovelia*, and *Tinodes*, whereas four taxa had not returned (*Chimarra*, *Hetaerina*, *Lutrochus*, and *Tricorythodes*)."] Address: Dinger, E.C., Merriam-Powell Center for Ecological Research, Dept of Biology, Northern Arizona Univ., Box 5640, Flagstaff, Arizona 86011, USA

**21328.** Walia, G.K. (2007): Chromosome variation in three libellulid species due to effect of pollutants in the aquatic ecosystem. *Journal, Punjab Academy Sciences* 4(1&2): 73-74. (in English) ["Chromosomal analyses have been carried out on three species belonging to family Libellulidae viz. *Brachythemis contaminata*, *Crocothemis servilla* and *Pantala flavescens*. All the species were collected from the vicinity of stagnant polluted water bodies affected with environmental pollution. Type number of the family Libellulidae is 2n= 25m and n=13m, shown by 30% of the cells. Majority of the cells (70%) possess variation in chromosome number due to autosomal fragmentations and fusions. The chromosome number varies from n= 11-18 in

*Brachythemis contaminata contaminata*, n= 10-19 in *Crocothermis servilia servilia* and n= 10-13 in *Pantala flavescens*. This type of autosomal fragmentations and fusions due to the effect of pollutants has been reported for the first time in the family." ## 2008

**21329.** Anonymus (2008): Salamander, Prachtlibelle und Quelljungfer. Die Gemeinde Rüti verfügt über ein einzigartiges Tierinventar der grossen und kleinen Fließgewässer. Naturschutzverein Rüti ZH Rundbrief No. 63. 2 pp. In German ["Natural and near-natural streams are characterized by high water quality and a course rich in structure. They are equipped with various small habitats: with rock, gravel and sand bottoms, bank cavities and plant pads, calm pools and fast-flowing sections. The diversity of animal organisms increases with the number of different small habitats. The quality of small rivers as a habitat can be seen from selected animal species. In our region, the fire salamander and four types of dragonflies are suitable: banded and blue-winged demoiselle, two-striped and striped damson. All five species are protected, living as larvae in running water and as adults on land. The development of the larvae in the fire salamander takes three months, in the dragonfly one to two years and in the spring maiden around five years. During the entire larval period, they are continuously dependent on clean, relatively cool and oxygen-rich running water. However, the habitat requirements of the five species differ in detail. Their connection to certain structural properties of the small streams, their position in the food web and their conspicuousness make them excellent pointer organisms or bioindicators. As a retired biologist, our association member Hansruedi Wildermuth wanted to know specifically where fire salamanders, dragonflies and spring mermaids occur in the community. The aim of his project, which came about on his own initiative, was an inventory of running water with mapping of all occurrences of the five species in the municipal area of Rüti. The population sizes and spatial focal points of development should also be determined and the structural conditions of the streams and ditches should be recorded at the same time. In this way, over the course of two years, a complete overview of the distribution of the five animal species and their population situation in the community was created. The detailed report on the inventory has been available for a good six months. The maps clearly show that each of the five animal species has its own distribution pattern. While the occurrence of the fire salamander is limited to the eastern and southern parts of the municipality, *Calopteryx virgo* and the *Cordulegaster boltonii* are widespread outside the settlement area in suitable places. *Calopteryx splendens* probably only occurs as a guest in Rüti and *Cordulegaster bidentata* is extremely rare due to the lack of favorable larval waters. The fire salamander develops almost exclusively in small, fish-free spring waters with calmed current pools in the forest area between Weier and Batzberg. The two-striped spring damselfly also inhabits the larger streams, provided that there are calmed sections with fine sediments, and the blue-winged demoiselle needs additional sun and cushions from aquatic plants or fine-rooted nests floating freely in the water. The striped spring maiden only finds favorable development conditions in two small bodies of water close to the source on the southern flank of the Batzberg. For natural or man-made reasons, none of the five focus species are able to settle on

many stretches of stream in the community. Routes where three species occur together are rare. The Rütivaldbächli, Weierbächli/Feienbächli, Laufenbach im Tüfental, Dachseggbächli, Chüeweidbächli, Förholz bächli and Gubelbächli in certain sections as well as the two ditches in the Weierbachried and in the Gründ Ost Ried have proven to be the most valuable bodies of water for the focus species. For the fire salamander, all waters that are used for breeding brown trout are unavailable because they eat the salamander larvae. All 34 officially registered watercourses in the municipality and two additional reed ditches are briefly characterized together with their importance for the focus species. It is also shown to what extent the larval habitats of the five species overlap or separate. The positive and negative factors for colonization are also listed, as well as the possibilities for upgrading the water bodies, provided that this does not require a great deal of effort. Rüti is probably the only municipality in Switzerland with such a detailed animal inventory of all watercourses. The report is now available to the municipality (nature and environment agency, building authority, nature and environment commission). It should not only impart collected knowledge, but also have an effect: it forms an indispensable basis for nature conservation practice by clarifying where there is a need for improvement measures with regard to habitat optimization. At the instigation of René Gilgen, nature conservation officer for the canton and municipality in Rüti, some biotope upgrades were already implemented in the course of the inventory work: clearing of wooded stream edges and structural improvements to reed ditches. They are already having a positive impact." **21330.** Buschbeck, E.K.; Friedrich, M. (2008): Evolution of insect eyes: Tales of ancient heritage, deconstruction, reconstruction, remodeling, and recycling. *Evo. Edu. Outreach* 1: 448-462. In English ["The visual organs of insects are known for their impressive evolutionary conservation. Compound eyes built from ommatidia with four cone cells are now accepted to date back to the last common ancestor of insects and crustaceans. In species as different as fruit flies and tadpole shrimps, the stepwise cellular patterning steps of the early compound eye exhibit detailed similarities implying 500 million years of developmental conservation. Strikingly, there is also a cryptic diversity of insect visual organs, which gives proof to evolution's versatility in molding even the most tenacious structures into something new. We explore this fascinating aspect in regard to the structure and function of a variety of different insect eyes. This includes work on the unique compound-single-chamber combination eye of twistedwinged insects and the bizarre evolutionary trajectories of specialized larval eyes in endopterygote insects." (in Spanish) ["The genus *Macromia* is eminently tropical, as of the 100

or so recognised species, only one (*splendens*) is found on the European continent, and only about 10 in North America. The lack of knowledge of the biology of *M. splendens* is undoubtedly due to its rarity (living in slow habitats in rivers), the difficulty of capture and the fact that its populations are usually found in areas that are difficult to access. In addition, the flight period does not seem to last more than 4-5 weeks. The detection of the populations of this species is greatly hindered by this fact, so in the future it would be advisable to carry out searches for exuviae. In recent years, new populations have been found in the northwest and central-west of the Iberian Peninsula (including Galicia, northern Portugal, Castilla y León and Extremadura), which suggests that the distribution of the species is somewhat wider than previously thought. The conservation of the populations of this species requires the maintenance of favourable microhabitats for larval development, which include areas of sand, leaf litter and roots in slow, deep sections of rivers, and feeding areas in forest clearings for adults." **21333.** Hofhansl, F.P.; Schneeweis, S. (2008): Banderillas: Effects of deforestation on dragonflies (Insecta, Odonata) in the Pacific lowland of Costa Rica. *Stapfia* 88: 237-247. (in English, with Spanish summary) ["Deforestation in the past is responsible for the loss of large forest areas in all tropical regions and this process is ongoing. The reclamation of cultivated land reinforces the disappearance of natural habitats and reproductive sites for many species typical for pristine forests. Lotic waters may remain when the trees are gone, but their characteristics will have changed dramatically and species tied to these water bodies face different challenges maintaining self-sustaining populations. This study contributes to the question of whether changes in land use affect species assemblages and their ability for recruitment, and

whether streams embedded in cultivated landscapes provide viable reproductive habitats for dragonflies. We surveyed dragonflies at four forest sites, two sites at forest margins and four sites at streams in an agricultural landscape. At each site, adult dragonflies were recorded twice along a 50 m transect in January and February 2007. We found significant differences in species richness, species assemblages and proportion and number of widespread species between forest and cultivated area. Only 3 of 11 species found in forests were also observed at streams in agricultural areas. Our results indicate that rivers in agricultural environment do not represent suitable reproductive habitats for the majority of 'forest species'. Therefore, deforestation poses an enormous threat for these species." **21336.** Grand, D. (2009): Les Libellules et le réchauffement climatique. Rev. sci. Bourgogne-Nature 9/10: 124-133. (in French) [f tropical origin, dragonflies are insects very sensitive to thermal variations. Their promptness to react to this parameter and their exceptional ability to fly make them ideal indicators for detecting possible global warming. The scientific documentation published from 1950 to the present day makes it possible to verify the arrival of several Afro-tropical dragonflies on the Iberian Peninsula and then to follow their spread in Andalusia and the neighboring provinces, one of these species even reaching the south of France. The situation is a little more complicated for our country, but recent inventories highlight a northern migratory push of a majority of southern species which, to move over great distances, follow the Rhône-Saône axis to the east and, to the west, run along the Atlantic coast to the Loire Valley which serves as a springboard for them to go north. In recent years, several southern species have colonized Belgium and neighboring countries, some not hesitating to cross the Channel to spread to the British Isles, one of them seems to have established itself there permanently. If global warming promotes the diversification of dragonflies in all regions of our country, the worrying counterpart is a significant and recent scarcity of the most sensitive Euro-Siberian species." Dissertation, Fachbereich VI (Geographie/Geowissenschaften) der Universität Trier. 241 pp. In German and English ["The biogeography of the dragonflies of the Palaearctic and their relevance for conservation law setting and application. While the first nature scientists, such as von Humboldt and Darwin, in the field of classical biogeography studied especially the breakdown of the distribution of species, Wallace developed the recognition that there are causal reasons for the distribution of species. Wallace as well as de Lattin gained their findings by the fact that they projected distribution patterns of species over each other resulting in dispersal centres. In recent decades various possibilities of computer-based analysis offer special advantages for the analysis of distribution patterns, which are used in this thesis to write an interdisciplinary work at the intersection of nature science and conservation law. In five chapters various aspects of the field of classical biogeography are analysed and discussed. In the first chapter of this work, the biogeographic structure of dragonflies in the western Palaearctic is investigated by distribution analysis. The second contribution deepens the view with a regional analysis of the biogeography of Odonata and butterflies in Romania. A third paper concludes that West Palaearctic block with an analysis of island biogeography of the western Mediterranean region. In a second Eurasian block the fourth contribution, worked out the biogeographic pattern of Eurasia. Finally, the fifth article of the phylogeography of *Nehalennia speciosa* is offered as an example of trans-palaearctic distributed species. Besides their importance in basic research, these five chapters are a substantial basis for the elaboration of the legal treatise. In the legal treatise, with the aid of previous findings, various aspects are discussed that may have led the dragonflies underrepresented in the Habitats Directive. These aspects are a lack of uniform pan-European risk assessment, the lack of a protection criterion "dispersal ability" and a questionable approach when considering what species should be examined on their back for protection." **21344.** Farkas, A. (2013): Emergence characteristics of riverine dragonflies (Odonata: Gomphidae). PhD thesis, Department of Hydrobiology, Centre of Arts, Humanities and Sciences, Faculty of Science and Technology, University of Debrecen, Egyetem tér 1, H-4032 Debrecen, Hungary: 170 pp. (in Hungarian, with English summary) ["Emergence characteristics of riverine dragonflies (Odonata: Gomphidae) were studied in details on the basis of the systematic collections of exuviae along Hungarian rivers. Our aims were to find out the species composition, abundance, phenology, emergence pattern, sex ratio at emergence, mortality during emergence as well as larval emergence behaviour of the riverine dragonflies at different sites. Systematic collections of exuviae were carried out during the whole emergence period in three years (2008, 2009 and 2011) at six different sites along the rivers Tisza, Szamos and Danube. At each sampling site exuviae were collected on standardised areas, 20 meter long stretches of the riverbanks. To study emergence behaviour, in the case of all exuviae found in situ, the distance travelled by the larvae from the water line to the emergence site and the type of the selected emergence support were recorded. Emergence behaviour was occasionally studied along the river Rába and several small watercourses too. To quantify the rates and the causes of mortality, dead and damaged specimens as well as dragonfly wings left behind by birds were collected and the causes of mortality were noted. In our study new data were given on the distribution and abundance of species. In the case of the Danube branches along the Szentendrei-sziget the co-occurrence of the four Hungarian gomphid species as well as data on the size of their populations were reported for the first time. Remarkable differences were found in species composition and abundances of gomphids between sites along the river Tisza, while the Tisza site upstream the mouth of the river Szamos and the Szamos site were similar. The Danube sites and the dammed Middle-Tisza site were similar in abundances but differed in species number. In this study we gave the first evidence of the negative influence of paving on the abundance of *G. flavipes*. The knowledge on the phenology of the studied species was supported by our new results. The described seasonal placement and separation of emergence periods of the studied species are most likely to be general in the rivers of the Carpathian basin. Our results support that the classification of species into 'spring' or 'summer' species based on the emergence pattern is not unambiguous in every case. Moreover, emergence pattern of a given species can be of either 'spring' or 'summer' type under different conditions. Up to date it was the first attempt to study the relationships between the daily numbers emerging and the actual water temperature and the actual water level in riverine dragonflies. In the former case positive, while in the latter case negative correlation was found. However, the influence of the two factors could not be clearly distinguished. Based on our results the temperature sums and the actual water temperatures jointly determine the onset of emergence, but it may also be influenced by

the temperature sum during the whole period of larval development. In all studied species the protandry, which is thought to be typical of riverine dragonflies, was confirmed by our results. The sex ratio at emergence showed no consistent bias toward one sex, but varied between sites and years. In the two *Gomphus* species the sex ratio at emergence was correlated with the water temperature in the year preceding emergence. We concluded that the effect of water temperature can be mediated through cohort-splitting; temperature-dependent development of minor cohorts, including unequal proportions of males and females due to the faster development of male larvae, affects the sex ratio at emergence. The distance travelled by the larvae from the water line to the emergence site proved to be typical of the species, but was influenced by local factors (e.g. water level, slope of the riverbank). Long distance climbed by *G. vulgatissimus* larvae (in which it takes a long time to complete the emergence) may reduce the risk of being washed away by rapid floods during emerging. Furthermore, the scattering of the specimens in a larger area may also decrease the risk of predation. In this study the gomphid larvae were not found to choose a given type of support in higher ratio than the other ones. Support-selection for emergence was dependent on the ratio of available structures within the distance the larvae crawled from the water line to the emergence site. Thus, not the type but the appropriate distance from the water line of the substrate is substantial for emergence. The mortality rate remarkably differed between the two *Gomphus* species, such as the factors contributing to mortality. The difference may be in association with the population size and the emergence strategy: mortality rate is higher in populations of individuals emerging in larger numbers close to the water line in a rather narrow stretch (*G. flavipes*), while mortality rate is lower in populations of individuals emerging in small numbers far from the water line and being scattered in a larger area (*G. vulgatissimus*). Higher mortality in dense populations is mainly attributed to higher predation pressure; on the other hand individuals emerging close to the water line suffer higher mortality caused by artificial waves. The latter should be considered as an important factor in point of view of nature protection." (Author)] Address: Farkas, Anna, Dept Hydrobiology, Centre of Arts, Humanities & Sciences, Faculty of Science & Technology, University of Debrecen, Egyetem tér 1, H-4032 Debrecen, Hungary. Pinto, A.P. (2013): Análise cladística de Sympetrinae Tillyard, 1917 com ênfase no grupo de armadura femoral especializada: os gêneros de 'Erythemismorpha' (Insecta: Odonata: Libellulidae) - A cladistics analysis of Sympetrinae Tillyard, 1917 with an emphasis in the group of specialized femoral armature: the genera of 'Erythemismorpha' (Insecta: Odonata: Libellulidae). PhD. thesis, Instituto de Biociências da Universidade de Sao Paulo. Departamento de Zoologia: 187 pp. (in Portuguese, with English summary) ["Libellulidae comprises the largest family of Anisoptera with more than a thousand of species and one of the most abundant among dragonflies' families. Die investigations of its phylogenetic pattern of relationships, especially among their genera have been shown complex, with widely divergent hypotheses, and considered tricky. A first cladistic analysis of 'Sympetrinae' based on 171 characters from adults morphology, with an emphasis on the 'aimed leg group'

(Erythemismorpha) including the genera *Acisoma*, *Carajathemis*, *Cyanothemis*, *Erythemis*, *Poipax*, *Rhodopygia*, *Rhodothemis* and *Viidithemis* is presented here. Representatives of almost all Libellulidae subfamilies, as well as all genera of 'Sympetrinae' were also included, summing up a total of 69 terminal taxa. Diis broad sampling aimed to provide a strong test to hypothesis of monophyly of Erythemismorpha and identify monophyletic groups in 'Sympetrinae'. Two different analyzes were performed, each Fitch and Sankoff parsimony, both with distinct weighting schemes. The Sankoff parsimony was adopted to minimize the influence of 'gaps' on the results, but proved be inappropriate for to obtain stability indexes with resampling techniques, due to the high cost of computational requirements. Erythemismorpha was shown be monophyletic and further than to those genera previously cited, also includes, at least *Erythrodiplax castanea*. The genera *Acisoma*, *Rhodothemis*, and *Rhodopygia* were has each their hypotheses of monophyly also supported by the analyses performed here, however *Erythemis* showed be paraphyletic in almost all trees contradicting previous results. Almost all of the internal nodes of Erythemismorpha are inconclusive, however *Cyanothemis* + *Poipax*, as well as *Carajathemis* + *Rhodopygia* presents both high support. The entire composition of Erythemismorpha still open, pending the inclusion of other data sources. Also was discussed the misconceptions about homoplasy and its implications on venational characters of Anisoptera dragonflies. Is advocated the already discussed prevalence of pattern over process in cladistics paradigm. Homoplasy in cladistics is an error, more precisely an error of establishment of homologues (primary homology), thus convergence, reversal and similar terms are process tied ad hoc hypotheses over a pattern of inclusive hierarchy and not is concrete neither observable in real world." (Author)] Address: Pinto, A.P., Laboratório de Biologia e Sistemática de Odonata (LABIOSIS), Depto de Entomologia, Museu Nacional, Universidade Federal do Rio de Janeiro, Quinta da Boa Vista s/n, São Cristóvão 20940-040 Rio de Janeiro-RJ, Brazil. ## 2014

**21347.** AK Libellen NRW; Conze, K.-J.; Joest, R. (2014): Die Grüne Flussjungfer etabliert sich wieder in NRW. Ergebnisse einer gezielten Suche nach der Grünen Flussjungfer (*Ophiogomphus cecilia*) an der Lippe im Kreis Soest. *Natur in NRW* 1/13: 28-31. In German [In recent years, there have been increasing numbers of observations of the *O. cecilia* in NRW, which had disappeared here for a long time. This is also of particular interest as it is given special protection under Appendix IV of the Habitats Directive and is one of the planning-relevant species in NRW. Due to its habitat requirements, including greater flow diversity, it is considered a good indicator of near-natural watercourses. After individual finds in previous years, a targeted search for the species was carried out on the Lippe in the district of Soest in the summer of 2012. As a result, there is a total of twenty records of one to five individuals, distributed over a 27 km stretch along the Lippe. Most of the finds come from the more intensively examined renatured Lippe sections. The current data situation suggests that the green river maiden will become firmly established again in NRW in the next few years. This development should be pursued further by means of a targeted search. Instructions are given for this. A new designation of special protection areas does not seem necessary at the moment, but planning measures should also be coordinated with their habitat requirements if necessary. Overall, the species benefits from the improvements made as part of the implementation of the Water Framework Directive and above all from the renaturation of floodplains on larger bodies of water in the state." (Authors/Google translate)] Address: AK Libellen NRW c/o K.-J. Conze, Listerstr. 13, 45147 Essen, Germany. E-Mail: [kjc@loekplan.de](mailto:kjc@loekplan.de)

**21349.** Horvath, G.; Csabai, Z. (2014): Polarization vision of aquatic insects. Polarized light and polarization vision in animal sciences (2014): 113-145. (in English) ["In this chapter we show that primary aquatic insects fly predominantly in mid-morning, and/or around noon and/or at nightfall. We describe the different types of their diurnal flight activity rhythm characterised by peaks at low and/or high solar elevations. We present here experimental evidence that the polarization visibility  $Q(0)$  of water surfaces is always maximal at the lowest (dawn and dusk) and highest (noon)

angles of solar elevation 6 for dark waters, while  $Q(\emptyset)$  is maximal at dawn and dusk (low solar elevations) for bright waters both under clear and partly cloudy skies. The  $\lambda$ -dependent reflection-polarization patterns, combined with an appropriate air temperature, clearly explain why polarotactic aquatic insects disperse to new habitats in mid-morning, and/or around noon and/or at dusk. This phenomenon is called the "polarization sundial" of dispersing aquatic insects. We also show that non-biting midges (Chironomidae, Diptera) are positively polarotactic and like many other aquatic insects, their females are attracted to horizontally polarized light. We present here measured thresholds (i.e., the minimum degrees of linear polarization of reflected light that can elicit positive polarotaxis) of the ventral polarization sensitivity in mayflies, dragonflies and tabanid flies. The mayflies *Palingenia longicauda* swarm exclusively over the river surface; thus, they need not search for water. It could be assumed that this species is not polarotactic. We show here that also *P. longicauda* has positive polarotaxis, which, however, can be observed only when the animals are displaced from the water and then released above artificial test surfaces. *P. longicauda* is the first species in which polarotactic water detection was demonstrated albeit it never leaves the water surface, and thus, a polarotactic water detection seems unnecessary for it. The yellow fever mosquito, *Aedes aegypti*, has been thought to locate its breeding habitats exclusively by chemical cues. We demonstrate here that horizontally polarized light can also attract ovipositing *A. aegypti* females when they are deprived of chemical cues. *Aedes aegypti* is the first known water-associated species in which polarotaxis exists, but does not play a dominant role in locating water bodies and can be constrained in the presence of chemical cues. Finally, we deal with the negative polarotaxis in the desert locust, *Schistocerca gregaria*, the ventral eye region of which detects the horizontally polarized water-reflected light, and thus can navigate towards or away from large water surfaces." **21350.** Khandozhivska, A.; Krazhan, S.; Mruk, A.; Koba, S. (2014): Diet of European grayling (*Thymallus thymallus*) from rivers of Zakarpattia in current conditions. Fisheries science of Ukraine 2/2014: 22-30. (in Ukrainian, with Russian and English summaries) ["Goal. To determine the feeding spectrum, qualitative and quantitative composition of the food lump of different age groups (2+, 1+, 0+) of *T. thymallus* of the Teresva and Tereblya rivers of the Transcarpathian region. Method. Primary material in the amount of 28 specimens of European grayling of different ages were collected during fieldwork on Transcarpathian rivers with the assistance of "Zakarpatterzhrybohorona". Fish were removed from poaching nets and fixed in 10% formalin solution. Processing of the recorded material was carried out in laboratory conditions according to generally accepted methods. The results. The nutrition of different age groups (2+, 1+, 0+) of the European grayling of the Teresva and Tereblya rivers of the Transcarpathian region was studied. It has been established that grayling consumes, mainly, bottom invertebrates, giving preference to amphibious organisms of the Insecta class. Organisms of the genera Diptera, Trichoptera, Plecoptera, Coleoptera, Ephemeroptera, Odonata, Amphipoda were common in the feeding of three-, two- and one-year-old grayling. The index of stomach filling in this yearling grayling with an average weight of  $12.3 \pm 0.72$  g was on average  $384.54 \pm 114.01\text{‰}$ , in two-year-olds with an average weight of  $29.53 \pm 2.14$  g –  $177.75 \pm 16.41\text{‰}$ ,

three-year-olds with an average weight of  $91.4 \pm 11.42$  g –  $168.49 \pm 25.44\text{‰}$ . Scientific novelty. Information on the feeding of European grayling in the rivers of Transcarpathia in modern conditions is fragmentary and insufficiently studied, since the indicated fish species is included in the Red Book of Ukraine, which limits the obtaining of material for research. Practical significance. The obtained data will make it possible to scientifically determine the extent of introduction of young European grayling into the Transcarpathian rivers in order to preserve and replenish its natural populations. Key words: European grayling, nutrition, stomach filling index, Transcarpathian rivers." (Authors/Google translate)] Address: Khandozhivska, Anna, Institute of Fisheries of NAAS, Kyiv, Ukraine. **21352.** Noskovi, J.; Rakovska, A.; Porhajasova, J.; Ceryova, T. (2014): Agroecosystems and their effects on the structure of benthic invertebrate communities in the Nature Reserve alluvium Zitavy. Research Journal of Agricultural Science 46(2): 249-257. (in English) ["Agricultural activity permanently affected ecosystems - agroecosystems are particularly in terms of ensuring of nutrition for human society, very important functional units of the biosphere. Represent economically important organisms and their environment. Very often are surrounded by natural ecosystems, which are usually very closely linked. Although their relationship is twosided, agroecosystems can induce not only reduce the heterogeneity of the country but also may affect the biodiversity of the surrounding terrestrial and aquatic habitats. In order to assess the impact of agricultural activities on the water quality characteristics, as well as on the biodiversity and the structure of communities of aquatic organisms, we carried out sampling of water from six sampling sites at regular quarterly intervals, 24 water samples was collected, in the year 2007 in the Nature reserve Alluvium Zitavy located in the southwestern part of Slovak Republic, in the geomorphologic unit of Podunajska rovina. As the basic biological material we used organisms of macrozoobenthos living at the bottom of the aquatic habitats. This group of individuals is an important indicator of water quality, based on their species and numerical representation can be evaluated the water quality of monitored biotopes. Analysis of samples of water we obtained 9920 individuals, deterministic as 110 species of fourteen systematic groups of invertebrates. Of them, the largest proportion in the structure of benthic macrozoobenthos had Gastropoda (24.01%), Isopoda (13.47%), Ephemeroptera (10.60%), Heteroptera (9.33%), Coleoptera (8.49%), individuals of family Chironomidae (8.25%) and Diptera (7.40%). The species with the smallest proportion in the structure of zoobenthos of monitored wetlands (ranging from 1.61% to 4.32%) included representatives of systematic groups Turbellaria, Odonata, Hirudinea, Trichoptera, Amphipoda, Bivalvia and Oligochaeta. The most of species that formed monitored community of aquatic organisms belongs to the good indicators of water quality. Therefore, not only based on the structure of community of macrozoobenthos but also based on the calculated saprobic index (Si), the water which is used by this community as their habitat corresponds to  $\beta$ -mezosaprobic zone, slightly polluted water. Between sampling sites the significant differences in

the quality and purity of water was recorded, even not only in the numerous represented of benthic fauna. Some differences in representation of species were observed, because each of the representatives of zoobenthos has different requirements for water quality characteristics. Despite this, agriculture fertilizer application, spillage of the oil substances and their floating could result in deterioration of water quality of monitoring wetlands and thus the structure and biodiversity of benthic invertebrates." **21354.** Sacha, D.; David, S.; Waldhauser, M.; Buczynski, P.; Tonczyk, G.; Juchiewicz, M.M.; Martynov, A.V.; Heltai, M.G.; Mancini, C.O.; Jovic, M. (2014): Draft Red List of dragonflies (Odonata) of the Carpathians. In: Kadlecik, J. (Ed.) *Carpathian Red List of Forest Habitats and Species, Carpathian List of Invasive Species (Draft)*. The State Nature Conservancy of the Slovak Republic, 234 pp: 172-185. (in English) ["There are 78 species of dragonflies ever reported from the Carpathians in total. Among them, two species are represented by dubious historical data only; no specimens exist which would confirm the identification. Four species are identified correctly and there is a material proving the identification, however they are vagrants or occasional occurrences (blown by the wind etc.) only and therefore cannot be considered permanent members of the Carpathian fauna. The rest 72 species are proven to have breeding populations in the region. Since Carpathians are a very diverse bioregion in terms of their north-south extent and altitude levels, the dragonfly fauna constitutes mainly of Eurasian elements, accompanied by a fair proportion of thermophilous (Mediterranean) and boreo-mountainous elements. Most species are stagnicolous, whereas rheophilous species represent only a minority. With respect to quality of data, there is a bit inconsistency in-between the individual countries. Whereas countries in the north of the range (PL, CZ, SK, HU) have relatively good and ample datasets, countries in the south and east (UA, RO, RS) show deficit of knowledge or even locally profound lack of data. This fact showed up most visibly in Serbia, where the species have been classified either LC, or DD, and no other categories came to use. There also seems to be some variability in interpretation of the IUCN methodology among individual experts, resulting in a rather different classification of the same species in the individual countries, that cannot be always

and fully explained only by differences of the species populations, trends, areas etc. Taking all this information into account, the submitted list can only be considered the very first version of the Carpathian Red List of Dragonflies. A lot of effort still has to be put into research, statistical analysis and providing and maintaining consistent set of data before the Red List, strictly following the IUCN rules, can be compiled. Overview of the status of dragonflies of the Carpathians is in Table 1." (Authors)] Address: Šácha, D., Podtatranského 31, SK – 031 01 Liptovský Mikuláš, Slovakia. E-mail: dusan.sacha@vazky.sk

**21356.** Frati, F.; Piersanti, S.; Rebora, M.; Salerno, G. (2016): Volatile cues can drive the oviposition behavior in Odonata. *Journal of Insect Physiology* 91-92: 34-38. (in English) ["Highlights: •The role of olfactory cues during oviposition in Odonata is overlooked. •The use of olfaction in oviposition by *I. elegans* was tested in choice assays. •*elegans* prefers to oviposit in larval rearing water than in distilled water. •Female EAG response was stimulated by rearing water. •*elegans* may rely on conspecific or food odour for oviposition site selection. Abstract: Selection for the oviposition site represents the criterion for the behavioural process of habitat selection for the next generation. It is well known that in Odonata the most general cues are detected visually, but laboratory investigations on the coenagrionid *Ischnura elegans* showed through behavioural and electrophysiological assays that adults were attracted by olfactory cues emitted by prey and that males of the same species are attracted by female odour. The results of the present behavioural and electrophysiological investigations on *I. elegans* suggest the involvement of antennal olfactory sensilla in oviposition behaviour. In particular, *I. elegans* females laid in the laboratory significantly more eggs in water from larval rearing aquaria than in distilled or tap water. Moreover, the lack of preference between rearing water and tap water with plankton suggests a role of volatiles related to conspecific and plankton presence in the oviposition site choice. *I. elegans* may rely on food odour for oviposition site selection, thus supporting the predictions of the "mother knows best" theory. These behavioural data are partially supported by electroantennographic responses. These findings confirm a possible role of olfaction in crucial aspects of Odonata biology." **21357.** Futahashi, R. (2016): Color vision and color formation in dragonflies. *Current Opinion in Insect Science* 17: 32-39. (in English) ["Highlights: •Dragonflies have a remarkable number of opsin genes. •Opsin genes are differentially expressed between stages and regions in dragonflies. •Multilayer structure is widely detected among iridescent coloured dragonflies. •Wrinkles or wax crystals enhances multilayer structural colour in some dragonflies. •Colour change

in red dragonflies is regulated by redox states of ommochrome pigments. Dragonflies including damselflies are colourful and large-eyed insects, which show remarkable sexual dimorphism, colour transition, and color polymorphism. Recent comprehensive visual transcriptomics has unveiled an extraordinary diversity of opsin genes within the lineage of dragonflies. These opsin genes are differentially expressed between aquatic larvae and terrestrial adults, as well as between dorsal and ventral regions of adult compound eyes. Recent topics of colour formation in dragonflies are also outlined. Non-iridescent blue colour is caused by coherent light scattering from the quasiordered nanostructures, whereas iridescent colour is produced by multilayer structures. Wrinkles or wax crystals sometimes enhances multilayer structural colours. Sex-specific and stage-specific colour differences in red dragonflies is attributed to redox states of ommochrome pigments." **21358.** Ichter, J.; Krieg-Jacquier, R.; de Knijf, G. (2016): The dragonfly fauna of the Aude department (France): contribution of the ECOO 2014 post-congress field trip. *Martinia* 32(1): 9-24. (in English, with French summary) ["After the third European Congress of Odonatology (ECOO) which took place from 11 to 17 July in Montpellier (France), 21 odonatologists from six countries participated in the week-long field trip that was organised in the Aude department. This area was chosen as it is undersurveyed and offered the participants the possibility to discover the Languedoc-Roussillon region and the dragonfly fauna of southern France. In summary, 43 sites were investigated involving 385 records and 45 dragonfly species. These records could be added to the regional database. No less than five species mentioned in the Habitats Directive (*Coenagrion mercuriale*, *Gomphus flavipes*, *G. graslinii*, *Macromia splendens* and *Oxygastra curtisii*) and three regionally important species (*G. simillimus*, *Onychogomphus uncatus* and *Cordulegaster bidentata*) could be observed and are discussed. Several populations of these species were discovered: *G. graslinii* and *M. splendens*, considered as very rare prior to our investigations, were especially found in the western Corbières and in the middle course of the Aude River. Furthermore many new populations of *Oxygastra curtisii* were detected. A small population of *C. mercuriale* was found in a drainage ditch in a peat land in the Montagne Noire at 850 m a.s.l. in the northern Aude. One of the most remarkable observations was the finding of an exuvia of *G. flavipes* along the Aude River, ca 30 km to the west from the hitherto only record of this species for the department, proving the extension of the range of this species to the southwest. Range extension was also highlighted for *Trithemis annulata*, another increasing species in Europe." (Authors)] Address: Ichter, J., 11, rue Michelet, F-94200 Ivry-sur-Seine, France. **21359.** Ilg, C.; Oertli, B. (2016): Effectiveness of amphibians as biodiversity surrogates in pond conservation. *Conservation Biology* 31(2): 437-445. (in English, with Spanish summary) ["Amphibian decline has led to worldwide conservation efforts, including the identification and designation of sites for their protection. These sites could also potentially play an important role in the conservation of other freshwater taxa. We assessed the effectiveness of amphibians as surrogate for a selection of four taxonomic groups representative of the same freshwater habitats (dragonflies, aquatic beetles, aquatic gastropods and aquatic plants), in 89 ponds

located in Switzerland, all characterized by their high value for amphibian conservation. We tested whether these ponds could also contribute to the conservation of other taxonomic groups. Amphibians showed a weak congruency with the other taxonomic groups for the three metrics of biodiversity assessed: species richness, conservation value and community composition. Paired comparisons for the five groups considered also showed that, for each metric, amphibians presented the lowest degree of congruence. These results imply that site designation for amphibian conservation do not necessarily provide protection for freshwater biodiversity as a whole. In order to provide adequate protection for freshwater species, we recommend that rather than using only amphibians as a surrogate group for site designation, other taxonomic groups should also be taken into account in the prioritization and site designation process." **21360.** Martins, F.A (2016): Determinants of odonata diversity in Brazil: a multi-scale approach. Tese (Doutorado em Ecologia e Evolução), Instituto de Ciências Biológicas, Universidade Federal de Goiás, Goiânia: 176 pp. (in Portuguese, with English summary) ["The interactions between the organisms and their physical environment and among the organisms themselves occur at definite spatial scales, and give rise to spatial patterns that may be assessed to a better understanding of these relationships. Thus, in order to understand the variation in species diversity, it is necessary to link the scale in which the variation is measured to the scale in which the processes operate. The main objective of this work is thus to identify the factors that best explain the diversity of dragonflies' tropical assemblages and determine how they interact across scales. The work is based on the Community Assembly conceptual framework that relies on the idea that community assembly is affected by spatial processes hierarchically arranged. Dragonflies are good models because they comprise two distinct groups of species regarding to body size, thermoregulatory responses and dispersal ability. Due to their ecological differences, they may respond differently to local as well as to regional environmental conditions. Despite of their ecological differences, our results suggest that richness patterns for both groups are affected by the same factors, i.e., they respond in a similar fashion to the analysed factors. In regional scales, environmental filters, such as temperature seasonality, affect species richness. The abundance is the main predictor of local species richness. Nevertheless, the assemblages' compositional patterns are different. Comparatively, Zygoptera (low-dispersal group) assemblages are more affected by local scale processes than Anisoptera. Our results suggest a better integration of metacommunity theory (focused on the role of dispersal shaping different spatial dynamics in the assemblages) and community assembly theory. The fact that the dispersal processes is more important at smaller scales indicate the potential importance of occupancy dynamics at this scale, calling for explicitly incorporating dispersal, affecting the spatial dynamics at different spatial scales. Furthermore, our results suggest that rather than being mutually exclusive, neutral and deterministic processes acts jointly on community assembly." **21362.** Rajabi, H.; Ghoroubi, N.; Malaki, M.; Darvizeh, A.; Gorb, S.N. (2016): Basal complex and basal venation of Odonata wings: Structural diversity and potential role in the wing deformation. *PLoS ONE* 11(8): e0160610. doi: 10.1371/journal.pone.0160610: 17 pp. (in English) ["Odonata are known to be excellent fliers with versatile flight capabilities. The ability to fly over a wide range of speeds, high manoeuvrability and great agility are a few characteristics of their flight. The architecture of the wings and their structural elements have been found to play a major role in this regard. However, the precise influence of individual wing components on the flight performance of these insects remains unknown. The design of the wing basis (so called basal complex) and the venation of this part are responsible for particular deformability and specific shape of the wing blade. However, the wing bases are rather different in representatives of different odonate groups. This presumably reflects the dimensions of the wings on one hand, and different flight characteristics on the other hand. In this article, we develop the first three-dimensional (3D) finite element (FE) models of the proximal part of the wings of typical representatives of five dragonflies and damselflies families. Using a combination of the basic material properties of insect cuticle, a linear elastic material model and a nonlinear geometric analysis, we simulate the mechanical behaviour of the wing bases. The results reveal that although both the basal venation and the basal complex influence the structural stiffness of the wings, it is only the latter which significantly affects their deformation patterns. The use of numerical simulations enabled us to address the role of various wing components such as the arculus, discoidal cell and triangle on the camber formation in flight. Our study further provides a detailed representation of the stress concentration in the models. The numerical analysis presented in this study is not only of importance for understanding structure-function relationship of insect wings, but also might help to improve the design of the wings for biomimetic micro-air vehicles (MAVs)."] (Authors)] Address: Rajabi, H., Institute of Zoology, Functional Morphology and Biomechanics, Kiel University, Kiel, Germany. **21363.** Reynolds, A.M.; Reynolds, D.R.; Sane, S.P.; Hu, G.; Chapman, J.W. (2016): Orientation in high-flying migrant insects in relation to flows: mechanisms and strategies. *Phil. Trans. R. Soc. B* 371: 20150392: 12 pp. (in English) ["High-flying insect migrants have been shown to display sophisticated flight orientations that can, for example, maximize distance travelled by exploiting tailwinds, and reduce drift from seasonally optimal directions. Here, we provide a comprehensive overview of the theoretical and empirical evidence for the mechanisms underlying the selection and maintenance of the observed flight headings, and the detection of wind direction and speed, for insects flying hundreds of metres above the ground. Different mechanisms may be used

— visual perception of the apparent ground movement or mechanosensory cues maintained by intrinsic features of the wind—depending on circumstances (e.g. day or night migrations). In addition to putative turbulence-induced velocity, acceleration and temperature cues, we present a new mathematical analysis which shows that 'jerks' (the time-derivative of accelerations) can provide indicators of wind direction at altitude. The adaptive benefits of the different orientation strategies are briefly discussed, and we place these new findings for insects within a wider context by comparisons with the latest research on other flying and swimming organisms." **21364.** Shanku, A.G. (2016): Insights Into evolution and adaptation using computational methods and next generation sequencing. Ph.D., Rutgers, The State University of New Jersey: xxxiv, 244 pp. (in English) ["Historically, much of the research in evolutionary biology and population genetics has involved analysis at the level of either a single locus or a few number thereof. However, Next Generation sequencing technology has opened the floodgates with respect to both the sheer volume and quality of sequence data that researchers have long needed to address and answer long-standing questions in their fields. Scientists are now, by and large, no longer hampered in their efforts by technological hurdles to obtain data, but are in fact facing the problem of how best to use the vast amount of data that are accumulating at an ever-increasing rate. This is a good problem to have. The following research described in this dissertation is an attempt to derive answers to questions in the fields of population genetics and evolutionary biology that, until recently, have been either intractable or, at best, extremely difficult to address. In the first chapter I provide an introduction and a brief historical look at the research efforts that have proceeded my own. In the second chapter I describe how modern sequencing methods and computational analysis can be used to study, analyze, and answer evolutionary questions about the non-model organism, *Enallagma hageni*, in order to 1) determine this organism's phylogenetic position within Arthropoda, 2) provide answers and insight into the evolutionary history of the protein-encoding genes in the *Enallagma* transcriptome, and 3) give functional annotation to these expressed proteins. In the third chapter I examine how natural selection acts on the genome and derive a method that can accurately determine the evolutionary cause of nucleotide fixations, having occurred either through positive selection or neutral processes. I then apply the methodology to North American populations of *Drosophila melanogaster*, providing further evidence as to how adaptive evolution proceeds in a newly established population. This is an important question, for though there have been multiple approaches devised to determine the targets and modes of evolution in the genome, to date there has not emerged a definitive method which can determine both the location and type of a selective process, and as a result, the picture of how and where adaptive evolution proceeds in the genome has remained opaque. In the fourth chapter I examine how levels of natural selection within the genome have the potential to inhibit the ability to accurately learn population demographic history. Using a number of modern algorithms and extensive simulations, I first examine whether or not demographic histories that are learned under simple biological assumptions will yield accurate results when the actual data itself does not adhere to these assumptions. Further, I go on to examine more complicated models of demographic history, looking specifically at how

positive selection biases inference, which directions these biases occur, and at what levels of selection do inference methods fail to be robust. Finally, I describe potential evolutionary scenarios where these inference methods may be more prone to fail, as well as methods which might mitigate positive selection's effects, thus allowing for more accurate histories to be inferred. The work contained in this dissertation, at the broadest scale, is an effort to marry state-of-the-art techniques in statistics, computer science, and machine learning algorithms to the technological advances of next generation sequencing; the potent combination of these technologies has provided a means with which to derive answers to multiple, long-standing questions in population genetics and evolutionary biology." (Author)] Address: unknown

**21365.** Slim, M.; Zouaki, N.; Lougraimzi, H.; Elghali, L.; Zidane, L.; Fadli, M. (2016): Diversity, composition and systematic structure of the terrestrial entomofauna of a Ramsar site: The biological reserve of Sidi Boughaba, Mehdiya (Morocco). *Journal of Entomology and Zoology Studies* 4(4): 975-982. (in English) ["The region of Sidi Boughaba which is an important biological reserve (Northwest of Mehdiya, Morocco) offers a favorable conditions for the development of diversity of the wildlife. It is characterized by a sub-humid bioclimate and a mild winter. The objective of the present study is to make an entomological inventory in five different areas of floristic cortege perspective (herbaceous, shrub) and other medium (soil, water). A statistical study was performed by environmental indices of composition and structure. Sampling was done from mid-April 2013 to December 2013. The analysis of the entomofauna revealed the existence of 73 species distributed in 7 systematic orders and 28 families. Beetles are represented by 19 species, Orthoptera by 13, Diptera by 12 species; Hemiptera, Hymenoptera and Lepidoptera are represented by 8 species for each; Odonata come in last place with 5 species [Anax parthenope, A. ephippiger, Orthetrum trinacria, Lestes virens, Ischnura graellsii]. Similarly, the results showed that the values of Shannon-Weaver diversity vary between 2.654 and 3.411 which express the diversity of the sampled population." (Authors)] Address: Slim, M., Lab. **21366.** Verzijden, M.N.; Svensson, E.I. (2016): Interspecific interactions and learning variability jointly drive geographic differences in mate preferences. *Evolution* 70(8): 1896-1903. (in English) ["Co-occurrence of closely related species can cause behavioral interference in mating and increase hybridization risk. Theoretically, this could lead to the evolution of more species-specific mate preferences and sexual signaling traits. Alternatively, females can learn to reject heterospecific males, to avoid male sexual interference from closely related species. Such learned mate discrimination could also affect conspecific mate preferences if females generalize from between species differences to prefer more species-specific mating signals. Female damselflies of *Calopteryx splendens* learn to reject heterospecific males of *C. virgo* through direct pre-mating interactions. These two species co-occur in a geographic mosaic of sympatric and microallopatric populations. Whereas *C. virgo* males have fully melanized wings, male *C. splendens* wings are partly melanized. We show that *C. splendens* females in sympatry with *C. virgo* prefer smaller male wing patches in conspecific males after learning to reject heterospecific males. In contrast, allopatric *C. splendens* females with experimentally induced experience with *C. virgo* males did not discriminate against larger male wing patches. Wing patch size might indicate conspecific male quality in allopatry. Co-occurrence

with *C. virgo* therefore causes females to prefer conspecific male traits that are more species-specific, contributing to population divergence and geographic variation in female mate preferences." **21367.** Bastos, R.C. (2017): Implicações das condições ambientais de riachos e déficit Wallaceano sobre Odonata no Nordeste, Brasil. Universidade Federal do Maranhão: 37 pp, Annex. (in Portuguese, with English summary) ["Implications of the environmental conditions of streams and Wallaceano deficit on Odonata in Northeast Brazil: Alterations in land use resulting from anthropogenic actions modify biotic and abiotic conditions due to loss of environmental quality. This is worrying in regions where knowledge of biodiversity is derisory. Considering this scenario, the present study's objectives were to evaluate the effects of anthropogenic alteration on the integrity of stream habitat in the eastern region of Maranhão, Northeast Brazil (i); to verify how these stream conditions affect Odonata species (ii); and to evaluate the known distribution of the species recorded in this study and discuss knowledge gaps on Odonata (iii). A total of 269 specimens, represented by 17 genera and 30 species were collected. Of the 30 species collected, 17 are new records for the state of Maranhão; of these, 47.05% are geographically widespread species, occurring in practically all regions of Brazil. Considering the records in the literature, there was a 68% increase in the number of Odonata species known for Maranhão. In addition to demonstrating the alteration of stream environmental quality, our work contributes to reducing the Wallacean shortfall in a transition area between the Cerrado-Caatinga biomes, an area severely threatened by the advance of the region's agricultural frontier." **21368.** Bode-Oke, A.T.; Zeyghami, S. Dong, H. (2017): Aerodynamics and flow features of a damselfly in takeoff flight. *Bioinspiration & Biomimetics* 12(5). 056006. doi: 10.1088/1748-3190/aa7f52. PMID: 28699620. (in English) ["Flight initiation is fundamental for survival, escape from predators and lifting payload from one place to another in biological fliers and can be broadly classified into jumping and non-jumping takeoffs. During jumping takeoffs, the legs generate most of the initial impulse. Whereas the wings generate most of the forces in non-jumping takeoffs, which are usually voluntary, slow, and stable. It is of great interest to understand how these non-jumping takeoffs occur and what strategies insects use to generate large amount of forces required for this highly demanding flight initiation mode. Here, for the first time, we report accurate wing and body kinematics measurements of a damselfly during a non-jumping takeoff. Furthermore, using a high fidelity computational fluid dynamics simulation, we identify the 3D flow features and compute the wing aerodynamics forces to unravel the key mechanisms responsible for generating large flight forces. Our numerical results show that a damselfly generates about three times its body weight during the first half-stroke for liftoff. In generating these forces, the wings flap through a steeply inclined stroke plane with respect to the horizon, slicing through the air at high angles of attack (45°-50°). Consequently, a Leading Edge Vortex (LEV) is formed during both the downstroke and upstroke on all the four wings. The formation of

the LEV, however, is inhibited in the subsequent upstrokes following takeoff. Accordingly, we observe a drastic reduction in the magnitude of the aerodynamic force, signifying the importance of LEV in augmenting force production. Our analysis also shows that forewing-hindwing interaction plays a favorable role in enhancing both lift and thrust production during takeoff." **21369.** Catling, P.M., Kostiuk, B.; Kuja, S.; Kuja, A. (2017): Migrations and unidirectional movements of dragonflies in northeastern North America. Toronto Entomologists' Association, Occasional Publication: 69 pp. (in English) ["This guide addresses questions concerning dragonfly migration and movement in northeastern North America such as: (1) which dragonflies migrate? (2) when? (3) how can they be identified? (4) how many? (5) in what direction? and (6) under what conditions? It includes illustrations and information for: (1) 8 species of dragonflies known to be migratory including: *Anax junius*, *Epiaeschna heros* *Libellula pulchella*, *L. semifasciata*, *Pantala flavescens*, *P. hymenaea*, *Tamea carolina*, *T. lacerta*; (2) Other species for which unidirectional movements have been observed including: *Aeshna constricta*, *A. eremita*, *A. interrupta lineata*, *Celithemis elisa*, *Pachydiplax longipennis*, *Sympetrum corruptum*, *S. rubicundulum*, *S. vicinum*; and (3) Two species for which more information is needed including: *Aeshna sitchensis*, and *Sympetrum danae*. Information is provided for six excluded species. The term "migration" is used in the strict sense to refer to a regular and predictable mass movement of most members of a population in a particular direction from an emergence area to a reproductive area, followed by a return trip to the emergence area. The term "unidirectional movement" can be used for observations that do not quite fit the strict definition of migration. Sudden appearance of a species in the absence of a local adult population of that species is circumstantial evidence of migration. Migrations and other movements may occur to (1) to avoid mortality due to dry season or cold periods, (2) in response to a dense population, or (3) in response to parasites. Autumn migrations often follow the passage of a cold front (as in bird migration), and spring migrations have been associated with drought and long periods of winds from the south. The number of dragonfly individuals in a migration varies from less than a hundred to millions. Direction is partly governed by topography and coastlines but re-orientation may occur in the presence of obstacles such as large bodies of open water. There are approx. 200 species of dragonflies in northeastern North America and 17 are reported to migrate or undertake unidirectional flights. Dragonflies make good environmental monitors because they inhabit both aquatic and terrestrial habitats, but monitoring migrations is particularly useful because they represent large areas. Migration may be of much greater ecological significance than is currently imagined and much remains to be understood." **21370.** Kalogianni, E.; Vourka, A.; Karaouzas, I.; Vardakas, L.; Laschou, S.; Skoulikidis, N.T. (2017): Combined effects of water stress and pollution on macroinvertebrate and fish assemblages in a Mediterranean intermittent river. *Science of the Total Environment* 603–604: 639–650. (in English) ["Highlights: • The effects of multiple stressors on aquatic biota are still poorly understood. • Intermittent rivers are highly susceptible to chemical stress and water scarcity. • We compared biotic responses to different levels of water

stress and pollution. • Combined stressors affect negatively macroinvertebrates and fish. • Future efforts should focus on untangling stressors interactions. Abstract: Water stress is a key stressor in Mediterranean intermittent rivers exacerbating the negative effects of other stressors, such as pollutants, with multiple effects on different river biota. The current study aimed to determine the response of macroinvertebrate and fish assemblages to in stream habitat and water chemistry, at the microhabitat scale and at different levels of water stress and pollution, in an intermittent Mediterranean river. Sampling was conducted at high and low summer discharge, at two consecutive years, and included four reaches that were targeted for their different levels of water stress and pollution. Overall, the macroinvertebrate fauna of Evrotas River indicated high resilience to intermittency, however, variation in community structure and composition occurred under acute water stress, due to habitat alteration and change in water physico-chemistry, i.e. water temperature increase. The combined effects of pollution and high water stress had, however, pronounced effects on species richness, abundance and community structure in the pollution impacted reach, where pollution sensitive taxa were almost extirpated. Fish response to drought, in reaches free of pollution, consisted of an increase in the abundance of the two small limnophilic species, coupled with their shift to faster flowing riffle habitats, and a reduction in the abundance of the larger, rheophilic species. In the pollution impacted reach, however, the combination of pollution and high water stress led to hypoxic conditions assumed to be the leading cause of the almost complete elimination of the fish assemblage. In contrast, the perennial Evrotas reaches with relatively stable physicochemical conditions, though affected hydrologically by drought, appear to function as refugia for fish during high water stress. When comparing the response of the two biotic groups to combined acute water stress and pollution, it is evident that macroinvertebrates were negatively impacted, but fish were virtually eliminated under the two combined stressors." **21372.** Labat, F. (2017): A new method to estimate aquatic invertebrate diversity in French shallow lakes and ponds. *Ecological Indicators* 81: 401–408. (in English) ["Shallow lakes and ponds are valuable ecosystems for conservation

management. Aquatic invertebrates constitute a large proportion of diversity in these ecosystems, but their assessment is potentially time consuming and requires great expertise. The use of indicator taxa to estimate invertebrate diversity may resolve part of these difficulties. These indicators are rarely identified or their reliability is uncertain, i.e. they are based on partial inventories, neglecting groups with high diversity. In this study, invertebrate richness was assessed from 46 sites in France in various altitudinal, climatic, geological, human-impacted, and hydro-morphological contexts. Invertebrate identification was performed as accurately as possible in all taxonomic groups. Several potential indicators of diversity based on five key criteria were tested: strong direct correlation, identification facilities, strong cross-taxon congruence, low complementarity of the sampled habitats, and ubiquity for selected indicators. Three approaches were proposed to define these indicator groups: (1) a single taxonomic group as indicator, (2) a combination of targeted groups, and (3) a holistic inventory at low taxonomic resolution as a classical rapid assessment method for freshwater ecosystems. Results show that it is not recommended to use only one indicator group. The choice of several targeted groups could be a good intermediate solution but is not without bias. The rapid assessment inventory proposed is the most valuable method, and allows the estimation of invertebrate richness with a quasi-perfect correlation." (Author) Taxa are treated at order level.] Address: Labata, F., Research and Development Pole, Aquabio, rue Hector Guimard 63800 Courmon d'Auvergne, France. Email: frederic.labat@aquabio-conseil.fr.

**21373.** Leaute, J. (2017): Analyse de l'influence du paysage terrestre sur la composition des communautés d'Odonates de l'Indre-et-Loire. 2016-2017. Rapport de stage, Master 2 Mention Génie Ecologique, Université de Poitiers, U.F.R. Sciences Fondamentales et Appliquées: 51 pp. (in French, with English summary) ["This study takes its origins in the Od'Spot project, leaded by both Caudalis naturalistic association and the Research Institute for Insect Biology. This project includes the creation of an Odonata Atlas repartition in Indre-et-Loire department (France), and researches about this taxa's movements, landscapes' structure and territory occupancy. This study aims to: 1. Improve knowledges on links between Odonata and the terrestrial landscapes surrounding their home site, and highlight the interactions between the different landscapes components that have the greatest impact on these Damselflies' and Dragonflies' communities. 2. Suggest an analytic method that allows to use opportunistic data like Atlas's data, which are easy-to-collect and without constraints data. Results shows negative interactions between agricultural landscape (homogenous and heterogenous structure) and species richness under 800m radius near studied sites, and positive relationship of number of rivers on species richness under 400m. Effect of site quality on species richness is also found. Use of statistical models to analyse these non-protocolled data is successful, and could be improved by including some additional parameters like reproduction indicators." **21375.** Chovanec, A. (2018): Libellenkundliche Untersuchungen am restrukturierten Unterlauf der Naarn (Oberösterreich) im Jahr 2018. im Auftrag des Amtes der Oberösterreichischen Landesregierung, Abt. Wasserwirtschaft: 46 pp. ["In 2018, the restructuring measures carried out between 2008 and 2016 on the 11.5 km long lower reaches of the Naarn were evaluated from a dragonfly perspective. The applied assessment approach is based on the length-zonal classification of the dragonflies according to biocenotic regions and on checking the occurrence of water body type-specific reference species (indicative and accompanying species). In accordance with the national water body management plan, the Naarn is assigned to the middle epipotamal water body (barbel region) in this area of the Bavarian-Austrian Alpine foothills bioregion, for which the following rheophilic and rheobiontic indicator species were defined as part of this study: *Calopteryx splendens*, *Gomphus vulgatissimus*, *Onychogomphus forcipatus* and *Ophiogomphus cecilia*. In addition, five first-order types of accompaniment and 18 second-order types of accompaniment were also defined. Eight test sections, each 100 m long, were mapped in five restructuring areas: Perg/Kickenau: 3 sections, Hauswiesen: 2, Naarn at the mouth of the Tobra Canal: 1, Labing/Kaindlau: 1 and mouth: 1. The number and selection of the routes were based on the type of hydraulic engineering design types realized and thus on the structural heterogeneity of the study areas. Another route was chosen in a regulated area of water (Haid). Between 10.5. and 29.8.2018 the nine routes were committed on five dates. The dragonfly ecological status of the investigation areas Hauswiesen, Naarn at the mouth of the Tobra Canal, Labing/Kaindlau and mouth was rated as "good", that of the Perg/Kickenau area as "very good", which proves the success of the measures. The radiation effect of the restructured areas led to a "good" dragonfly ecological status in the Haid area. The green river damsel, which is protected throughout Europe and listed in Annexes II and IV of the EU Fauna-Flora-Habitat Directive, was definitely or probably native to five of the six test sections located directly on the main channel of the Naarn. The results were also analyzed for each mapped habitat type: river: six stretches; side arm connected on two sides: one section, side arm connected on one side: one section; Bay: a stretch. The inspections of the investigation stretches located directly on the main channel (habitat type river) yielded the highest total number of species and the highest number of definitely and probably native species. Only in the bay habitat type were (possibly) native reference species sighted that were not observed on the river itself: *Libellula depressa* and *Orthetrum albistylum*. The creation of this habitat type is therefore a suitable measure to promote the accompanying limnophilic species. The side arm connected on two sides was the investigation section on which reliable native habitation of the common damsel damsel and the lesser pincer dragonfly was demonstrated in the Perg/Kickenau area. *Calopteryx virgo* is the indicator species of the hyporhithral and companion species of the epipotamal. The development of their abundances in the course of the entire lower reaches of the Naarn proves a rhithral aspect that reaches far into the lower reaches of the Naarn and thus a rhithral / potamal transitional character. The hydraulic rehabilitation measures in the Perg/Kickenau area were completed in 2016. The evidence of an exuvia of the common damsel damsel and a freshly hatched individual of the small pincer dragonfly on the tributary connected on both sides in the Perg/Kickenau area prove how quickly dragonflies ac-

cept newly created, suitable habitats. Both types have a development time of two to three years; This means that the area was already colonized by the two species in the year the construction work was completed and reproductive behavior took place. In addition to the specific ecological requirements, the rapid reaction of dragonflies to changed habitat conditions underpins their importance as indicators for typological characterization and for the assessment of the ecological status of water bodies." **21379.** Ouimette, S. (2018): Thermal limits across life stages do not predict contemporary geographic distributions. M.Sc. thesis, Faculty of Arts and Science, Biology, Concordia University: 45 pp. (in English) ["Rapid and ongoing climate change is causing a complete redistribution of life on Earth. To predict species' geographic responses to climate change, it is critical that we establish the role of species' thermal tolerances in shaping their climatic envelopes. Using experimentally-derived measures of thermal limits and a database of georeferenced occurrence records, we

test whether thermal limits can predict the hottest and coldest temperatures experienced within the geographic distributions of 13 North American odonate species. We measure thermal limits in both odonate larvae and adults to account for potential life stage-related differences. Lastly, we use a time-calibrated phylogeny of North American odonates to estimate the effects of evolutionary history on the relationship between species' thermal and climatic limits. We find that, even after accounting for ontogenetic differences and phylogeny, thermal limits do not translate into climatic limits. Further, we determine that species' thermal limits are constrained by phylogeny, while climatic limits appear to have evolved free from phylogenetic associations. This suggests that the evolvability of odonates' thermal limits is limited and that currently, species are in disequilibrium with their environment. Additionally, other traits or processes, such as biotic interactions, are potentially shaping odonates' geographic distributions. In the face of climate change, odonates are unlikely to adapt to novel environmental conditions and thus will likely have to continue to shift their geographic distributions in order to track their ancestral thermal niches. Further, purely climate-based models will likely be insufficient for predicting odonates' geographic responses to climate change." **21380.** Ramamonjisoa, N.; Rakotoeloely, H.; Natuhara, Y. (2018): Defense investments and growth responses under different predation risks and gape-limitation predation threats in a tadpole prey. *Behavioral Ecology and Sociobiology* 72:144. (in English) "Theories on growth and defense investments in prey have typically revolved around predators' traits (gape and foraging tactics) and the level of predation risk in the environment, yet how these factors interact on prey responses remains poorly understood. We examined the phenotypic investments and growth rates of *Rhacophorus arboreus* tadpoles when exposed to "full cues" (predator present in aquaria) and to "chemical cues" (predator rearing water only) from gape-constrained newt and gape-unconstrained large *Anax* dragonfly larva predators at intermediate food level in a controlled laboratory experiment. Investments in behavioral defense were higher in the presence of dragonfly larvae although both predators were equally dangerous for the tadpoles. Predator identity interacted with cues level to affect defense investments but not growth in the tadpoles. Morphological changes were predator-specific: a larger tail fin in the presence of dragonfly larvae and a thicker tail muscle in the presence of newts. Investments in behavioral and morphological defenses increased from predator chemical cues to full cues. Our results provide weak support to prevailing theoretical predictions: no growth depression in the tadpoles despite strong investments in defense in the presence of dragonfly larvae and no evidence of growth acceleration in the presence of gape-limited newts. The tadpoles, however, accelerated growth when exposed to chemical cues from dragonfly larvae, but this trait disappeared in the full cues treatment when investments in defense increased. Our results indicate that predators' gape may not necessarily predict life-history responses in prey; instead, local selection regime and the level of

predation risk might modulate these responses. Significance statement: Multiple theories predict the evolution of growth and defense in prey in response to predator's gape and the level of risk in the environment. At high predation risk, an investment in defense at the cost of growth is anticipated in the presence of gape-unconstrained predators, whereas a rapid growth strategy could be advantageous in the presence of gape-limited predators. We exposed tadpole prey to different cue levels of gape-constrained newt and gape-unconstrained aeshnid dragonfly larva predators. Predator identity and cue level interacted on tadpole defensive phenotypes, but not on growth. The tadpoles accelerated growth when exposed to lower concentration cues of dragonfly larvae but prioritized defense at higher cue concentration, indicating that cue level can influence prey decision on whether to invest in growth or defense. Growth responses did not follow any theoretical predictions, but could be more related to the local selection regime than to predator's gape." **21381.** Sánchez-Montoya, M.M.; von Schiller, D.; Barberá, G.G.; Diaz, A.M.; Arce, M.I.; del Campo, R.; Trockner, K. (2018): Understanding the effects of predictability, duration, and spatial pattern of drying on benthic invertebrate assemblages in two contrasting intermittent streams. *PLoS ONE* 13(3): e0193933. <https://doi.org/10.1371/journal.pone.0193933>: 17 pp. (in English) ["In the present study, we examined the effects of different drying conditions on the composition, structure and function of benthic invertebrate assemblages. We approached this objective by comparing invertebrate assemblages in perennial and intermittent sites along two intermittent Mediterranean streams with contrasting predictability, duration, and spatial patterns of drying: Fuirosos (high predictability, short duration, downstream drying pattern) and Rogativa (low predictability, long duration, patchy drying pattern). Specifically, we quantified the contribution of individual taxa to those differences, the degree of nestedness, and shifts in the composition, structure and function of benthic invertebrate assemblages along flow intermittence gradients. We observed greater effects of drying on the benthic invertebrate composition in Fuirosos than in Rogativa, resulting in a higher dissimilarity of assemblages between perennial and intermittent sites, as well as a lower degree of nestedness. Furthermore, a higher number of biotic metrics related to richness, abundance and biological traits were significantly different between perennial and intermittent sites in Fuirosos, despite a shorter dry period compared to Rogativa. At the same time, slightly different responses were detected during post-drying (autumn) than pre-drying (spring) conditions in this stream. In Rogativa, shifts in benthic invertebrate assemblages along increasing gradients of flow intermittence were found for three metrics (Ephemeroptera, Plecoptera and Trichoptera (EPT) and Odonata, Coleoptera and Heteroptera (OCH) abundances and aerial active dispersal. Furthermore, we demonstrated that combined gradients of dry period duration and distance to nearest perennial reach can generate complex, and different, responses of benthic invertebrate assemblages, depending on the flow intermittence metric. Our study advances the notion that special attention should be paid to the predictability, duration and spatial patterns of drying in intermittent streams in order to disentangle the effects of drying on benthic invertebrate assemblages, in particular in areas subject to high spatial heterogeneity and temporal variability in drying conditions." **21382.** Sriolpan, S.; Bumrungsri, S.; Jantarit, S. (2018): The wrinkle-lipped free-tailed bat (*Chaerephon plicatus* Buchannan, 1800) feeds mainly on brown planthoppers in rice fields of central Thailand. *Acta Chiropterologica* 20(1): 207-219. (in English) ["The brown planthopper (*Nilaparvata lugens*) is one of the major insect pests of rice fields in Southeast Asia. They have been widely acknowledged for causing significant rice yield losses. However, the wrinkle-lipped free-tailed bat (*Chaerephon plicatus* Buchannan, 1800) is a known agent of pest suppression for white-backed planthoppers (*Sogatella furcifera*), and may also suppress brown planthopper populations. Hence, it is important to investigate the diet of *C. plicatus* in areas where brown planthoppers are common to determine whether these bats feed on these insects. To accomplish this objective, we analyzed the diet of *C. plicatus* from two caves that differed in the percentage of surrounding land area occupied by rice fields (70% versus 22%). Bat fecal pellets were collected monthly for a year. A total of 720 fecal pellets were analyzed, and the results revealed that *C. plicatus* feeds on at least eight insect orders, including Coleoptera, Homoptera, Hemiptera, Diptera, Lepidoptera, Odonata, Hymenoptera and Orthoptera. Specifically, homopterans comprised the greatest diet volume in the rice growing season, whereas coleopterans were most abundant in the diet when rice fields were fallow. Moreover, most homopterans were identified as brown planthoppers. To estimate the relative numbers of brown planthoppers consumed during each month, the number of genitalia of male brown planthoppers was counted. We recorded the greatest numbers of genitalia during the rice planting period, with an average of four genitalia per fecal pellet. Examining both the percent volume and percent frequency of each insect order in the diet of *C. plicatus* revealed that the two study caves were no significantly different, even though the proportion of surrounding active rice fields was different. Our results suggest that tens of millions of brown planthoppers are consumed by this bat species each night. The similar diets of the two study colonies may be due to their high altitude foraging and preference for migratory insects. Our results indicate that the wrinkle-lipped free-tailed bat is an important biological suppression agent of brown planthoppers in rice fields." **21383.** Van Tol, J.; Günther, A. (2018): The Odonata of Sulawesi and adjacent islands. Part 8. Revision of the genus *Rhinocypha* Rambur, 1842 (Chlorocyphidae). *Odonatologica* 47(3/4): 299-386. (in English) ["All known species of the genus *Rhinocypha* Rambur (Odonata: Chlorocyphidae) from Sulawesi and adjacent islands are revised, with descriptions of both sexes, illustrations of key characters, distribution maps and a key to the species. This revision is mainly based on material held in Naturalis Biodiversity Center, Leiden. These specimens were collected from localities in many parts of Sulawesi by the authors during the 1980s and 1990s. Eight species are distinguished, of which five are new to science, namely, *Rhinocypha flavipoda* sp. nov. (Central Sulawesi), *R. pelengensis* sp. nov. (Peleng Islands), *R. sangihensis* sp. nov. (Sangihe Islands), *R. togeanensis* sp. nov. (Togian Islands) and *R. virgulata* sp. nov. (Central Sulawesi); and one new subspecies, *R. frontalis sulselensis* ssp. nov. (south-western Sulawesi). We also discuss the status, morphological variation and distribution of the previously described species and present a concise analysis of the

phylogenetic relationships of the Sulawesi clade within the so-called *R. tinctoria*-complex based partly on molecular characters." (Authors)] Address: van Tol, J., Naturalis Biodiversity Center, P.O. Box 9517, 2300 RA Leiden, The Netherlands. E-mail: jan.vantol@naturalis.nl

**21389.** Radkova, K. (2019): Diverzita vodního hmyzu Nové Kaledonie. Diversity of aquatic insects in New Caledonia. MSc thesis, Faculty of Science, Masaryk University, Department of Botany and Zoology: 79 pp. (in Czech, with English summary) ["This thesis deals with the diversity of aquatic insects, with a special focus on mayflies (Ephemeroptera), on Pacific archipelago New Caledonia, mainly on the biggest island Grande Terre. New Caledonia belongs to 25 endangered regions with exceptional biodiversity connected with unique environmental diversity, specific geomorphological and geographical characteristics of the landscape. Literature research of the thesis was devoted to general introduction of New Caledonia and its tectonic history playing important role in high endemism of this archipelago. Further, history of settlement, exceptional biota, and anthropogenic influences changing the landscape of New Caledonia in an unprecedented way were described. Diversity and endemism of aquatic insects of New Caledonia, including Ephemeroptera, Odonata, Heteroptera, Trichoptera, Coleoptera, and Diptera, were summarized. Practical part of the thesis dealt with the mayflies of New Caledonia. A database of all published and available unpublished records of mayfly species from 1949, 1966, 1968, 1972, and 1997-2000 was prepared. In total, 643 records of 46 species belonging to 19 genera were assembled from Grande Terre and Île de Pins. They were collected by seven researchers and their teams: L. E. Cheesman, J. Ulies, F. Starmühlner and team, W. L. Peters and team, and N. Mary. Species richness of sites, species frequency and abundance, and distribution of all species were evaluated based on these data. Distribution of all species was shown on maps. ... 5.2 Odonata The first information about the dragonflies of New Caledonia comes from the first half of the last century (CAMPION 1921; SCHMIDT 1938), when 27 species were known from New Caledonia. New information about the diversity of dragonflies was brought in 1965 by prof. Starmühlner and the aforementioned expedition from 1972, when dragonflies were found in 34 locations. The list of species found expanded to 40, of which 18 species were from the suborder Zygoptera and 22 species from the suborder Anisoptera (LIEFTINCK 1975, 1976). Of the total, 14 species were found only on Grande Terre and 16 species were recorded from Grande Terre and the Loyauté Archipelago. In 2014, a key to the identification of all known species of adult dragonflies occurring in New Caledonia (Grande Terre and Île de Pins) and Wallis and Futuna was published, which also tabulated all known species and their distribution (GRAND et al. 2014). 55 species from 8 families are known from the island of Grande Terre and Île de Pins, of which Zygoptera include representatives of Lestidae (2 species), Argiolestidae (6), Isostictidae (5), Coenagrionidae (4) and among Anisoptera species of the following families: Aeshnidae (6), Corduliidae

(3), Libelluloidea (8) and Synthemistidae (8) (GRAND et al. 2014). There are a total of 55 species on the island of Grande Terre, 6 species on the island of Ouvéa, 7 species on the ile de Pins and 9 species on the Lifou (GRAND ET AL. 2014). Almost 45% of the representatives are locally or regionally endemic, with all representatives from the families in bold being endemic exclusively to Grande Terre. A total of 23 species are considered endemic to New Caledonia, for example: *Caledopteryx sarasini*, *Trineuragrion percostale*, *Caledopteryx maculata* (Argiolestidae), *Isosticta humilior*, *I. spinipes* (Isostictidae), *Ischnura pamela* (Coenagrionidae), *Aeshna brevistyla*, *Oreaeschna dominatrix* (Aeshnidae), *Metaphya elongata* (Corduliidae), *Synthemis miranda* and *S. pamela* (Synthemistidae)." **21391.** Arias, S.L.; Devorkin, J.; Spear, J.C.; Civantos, A.; Allain, J.P. (2020): Bacterial Envelope Damage Inflicted by Bioinspired Nanostructures Grown in a Hydrogel. *ACS Applied Bio Materials* 3(11): 7974-7988. (in English) ["Surface-associated bacterial communities, known as biofilms, are responsible for a broad spectrum of infections in humans. Recent studies have indicated that surfaces containing nanoscale protrusions, like those in dragonfly wings, create a hostile niche for bacterial colonization and biofilm growth. This functionality has been mimicked on metals and semiconductors by creating nanopillars and other high aspect ratio nanostructures at the interface of these materials. However, bactericidal topographies have not been reported on clinically relevant hydrogels and highly compliant polymers, mostly because of the complexity of fabricating nanopatterns in hydrogels with precise control of the size that can also resist aqueous immersion. Here, we report the fabrication of bioinspired bactericidal nanostructures in bacterial cellulose (BC) hydrogels using low-energy ion beam irradiation. By challenging the currently accepted view, we show that the nanostructures grown in BC affect preferentially stiff membranes like those of the Gram-positive bacteria *Bacillus subtilis* in a time-dependent manner and, to a lesser extent, the more deformable and softer membrane of *Escherichia coli*. Moreover, the nanostructures in BC did not affect the viability of murine preosteoblasts. Using single-cell analysis, we demonstrate that indeed *B. subtilis* requires less force than *E. coli* to be penetrated by nanopores with dimensions comparable to those of the nanostructured BC, providing the first direct experimental evidence validating a mechanical model of membrane rupture via a tension-induced mechanism within the activation energy theory. Our findings bridge the gap between mechano-bactericidal surfaces and low-dimensional materials, including single-walled carbon nanotubes and graphene nanosheets, in which a higher bactericidal activity toward Gram-positive bacteria

has been extensively reported. Our results also demonstrate the ability to confer bactericidal properties to a hydrogel by only altering its topography at the nanoscale and contribute to a better understanding of the bacterial mechanobiology, which is fundamental for the rational design of bactericidal topographies." (Authors) The publication includes references to "dragonflies".] Address: Arias, Sandra, Dept Bioengineering, Univ. of Illinois at Urbana-Champaign, Urbana, Illinois 61801, United States. **21392.** Futahashi, R. (2020): Diversity of UV reflection patterns in Odonata. *Front. Ecol. Evol.* 8(Article 201): 8 pp. (in English) ["Odonata are large-eyed diurnal insects that exhibit a variety of color patterns on their wings and/or bodies. Because Odonata can perceive light with wavelengths extending from ultraviolet (UV) to red, the color patterns with UV reflection can be visually recognized by each other. The UV reflection patterns of Odonata have been investigated by using a UV camera and optically measuring the reflectance of body and wing surfaces. The UV reflection of Odonata can be classified into three classes, namely, iridescent UV reflection, wax-based UV reflection, and UV reflection by epidermal granules. In this review, I present UV images of these three classes and representative examples of reflectance. Among the Odonata with colorful iridescent wings consisting of multilayer structures, some species (e.g., *Chalcopteryx scintillans*) predominantly reflect UV light, whereas other species (e.g., *Calopteryx japonica*) mostly reflect light at wavelengths above 400 nm. Whitish wax (called pruinescence) on the body and/or wing surface strongly reflects light including UV, due to the light-scattering fine structures produced by the wax. The chemical composition of the dragonfly's abdominal UV-reflective wax differs from previously identified waxes of other organisms. The *Ischnura* species exhibit immature-adult-specific UV reflection by the pteridine pigment-based selective light scattering and absorption. Iridescent coloration and wax-based color changes are generally important for mate recognition and male-male competition in Odonata, although the ecological importance of UV reflection remains largely unknown except for few examples in damselflies." **21394.** Gutiérrez, D.E.B. (2020): Evaluación del estado ecológico de diez quebradas ubicadas en Tarrazú, zona de Los Santos, San José, Costa Rica, mediante la ecología de náyades de Odonata (Insecta) y uso del suelo. Tesis de Licenciatura, Universidad Nacional, Heredia, Costa Rica: VIII + 58 pp. (in Spanish) ["The Odonata larvae allow us to acquire a greater knowledge of the ecological state of the ten streams investigated. In addition, it is possible to evaluate to what extent the riparian forest and the shaded coffee have an important role in the preservation of the ecological integrity of streams surrounding the coffee plantations. The objective of this study was to evaluate the ecological status

of 10 streams located in Tarrazú, Los Santos area, San José, Costa Rica, by studying the ecology of dragonfly naiads, and land use, during April, July, and October 2015. The dragonfly naiads were collected in 10 streams at three points 30 m apart. Physical analyses were made of the water, maximum flow, and number of trees in the riparian forest in the streams, and for soil use two categories were taken: 1) forest patches, and 2) shaded coffee cultivation. The Visual Evaluation Protocol for Ravines was also used. A total of 527 dragonfly naiads were collected from 6 families and 12 genera. The genus *Hetaerina* was the most abundant (248 individuals); while *Archilestes*, *Brachymesia*?, *Cordulegaster*, and *Micrathyria* were the least abundant ( $n=1$ ). The highest values of diversity ( $H'=1.58$ ) and dominance ( $D=0.75$ ) were reported in Quebrada 1, with forest patches of 4% and shaded coffee cultivation of 15%. The number of streams that had wooded patches with low canopy cover was 7, and 5 streams had medium shade coffee cover. A PERMANOVA was carried out which determined significant differences between the months of sampling for all the streams. Based on the physical variables of the water evaluated, no values harmful to the development of the dragonfly populations were determined. As the percentage of wooded patches in the ravines increased, the total diversity decreased. The highest total dominance of dragonfly naiads occurred in those streams that had patches of forest with medium canopy cover. 20% of the streams had a "Poor" ecological status; only the Reference Stream presented an "Excellent" ecological status. Overall, it is important to implement actions that promote the conservation of the lotic aquatic environments investigated, such as proposing the maintenance of the average tree cover (=15-39%), both in the forest patches and in the shaded coffee cultivation." **21399.** Murakami, H.; Hisamatsu, S.; Takechi, R.; Kurokawa, Y.; Matsui, H. (2020): Effects of water management of reservoirs on nymphal development in *Sympetrum uniforme* in Tyuyo, Ehime Prefecture, Japan. *Japanese Journal of Conservation Ecology* 25(1): 279-286. In Japanese, with English summary ["Some dragonflies in East Asia have adapted to traditional paddy cultivation by matching their phenology to the paddy growth cycle, water regime, and the forest and grassland landscapes surrounding the paddy fields. An endangered dragonfly, *Sympetrum uniforme*, lays eggs in reservoirs that supply water to paddy fields and is highly influenced by traditional water management regimes. Here, we studied the effects of water management of reservoirs on *S. uniforme* in Ehime Prefecture, Japan. The water-level management regimes and adult abundances (mature and immature) were surveyed at selected reservoirs. Samples of sand and gravel were collected at each reservoir just below the maximum water level. The samples were kept dry throughout the winter, watered the next spring, and larvae that hatched were counted. Many larvae hatched from the sand and gravel samples, which were collected from areas that dry out in winter. For one reservoir, although the water management regime and spawning rate were similar to those at other reservoirs, few larvae hatched, and the adult emergence rate was low." **21400.** Palacino-Rodríguez, F.; Brito, J.; Calvao, L.B.; Gonzalez, A.S.; Juen, L. (2020): In Neotropical savannas, altitude affects the diversity of the Anisoptera but not the Zygoptera (Insecta: Odonata). *Marine and Freshwater Research* 72(6): 766-773. (in English) ["Lentic and lotic habitats, combined with varying altitudes, may have differential effects on communities of the Order Odonata. We sampled adult odonates at 94 waterbodies of the Orinoquia region of eastern Colombia. Our hypothesis was that species composition and richness, as well as abundance, would be affected by

both altitude and habitat. Overall, 70 of the 100 species recorded in the study were sampled in both lotic and lentic environments, with 16 species (5 in the Suborder Zygoptera and 11 in the Suborder Anisoptera) occurring only in lentic habitats and 14 occurring exclusively in lotic habitats (13 Zygoptera, 1 Anisoptera). The results of the analysis indicated that the species richness and abundance of anisopterans were affected by altitude, whereas the diversity of zygopterans was not affected in any way. Despite these mixed findings, the results for anisopterans were consistent with the results of previous studies, which have indicated altitude as a primary determinant of the Odonata diversity through its effect on the dynamics of water flow and the shift from lentic to more lotic environments. Further studies over a more ample altitudinal gradient should provide more conclusive evidence, particularly regarding the role played by both altitude and habitat on the local diversity of odonates." (Authors)] Address: Palacino-Rodríguez, F., Grupo de Investigación en Biología, Departamento de Biología, Universidad El Bosque Avenida. Carrera 9 No. 131A-02, C.P. 110121 Bogotá, Colombia. **21401.** Šupina, S.; Bojková, J.; Boukal, D.S. (2020): Warming erodes individual-level variability in life history responses to predation risk in larvae of the mayfly *Cloeon dipterum*. *Freshwater Biology* 65(12): 2211-2223. (in English) ["1. Warming and predation risk are ubiquitous environmental factors that can modify life histories and population dynamics of aquatic ectotherms. While separate responses to each of these factors are well understood, their joint effects on individual life histories and population dynamics remain largely unexplored. Current theory predicts that the magnitude of prey behavioural, physiological, and life history responses to predation risk should diminish with warming due to the reduced metabolic scope. However, empirical support for this prediction remains equivocal, and experiments covering a substantial proportion of individual prey ontogeny until maturation are lacking. 2. To fill these gaps, we ran a laboratory experiment to investigate how warming and non-consumptive predation risk influence life history responses in the larvae of the mayfly *Cloeon dipterum*, an aquatic insect with highly plastic development. We reared larvae of varying initial sizes at three temperatures (21, 24, and 27°C) in a risk-free environment and under predation risk signalled by chemical cues from dragonfly larvae (*Aeshna cyanea*), and followed their individual survival, growth, and development until emergence. 3. Some *C. dipterum* larvae substantially prolonged their development and the proportion of these slow individuals declined rapidly with temperature and increased with predation risk. We attribute this response to cohort splitting, a common life history strategy of aquatic insects and other taxa in unpredictable environment. 4. Growth, development, and maturation varied predictably with temperature in the fast larvae that did not prolong their development. They grew and developed faster but matured at smaller sizes with increasing temperature. Predation risk tended to slow down individual growth and development in line with the reduced metabolic scope hypothesis, but the differences were relatively minor and observable only at 21°C. 5. Survival to subimago increased with predation risk, possibly due to indirect effects mediated by dissolved micronutrients, but did not vary significantly with temperature. Survival also tended to be higher in the slow individuals. This partly compensated for a smaller final size relative to the fast individuals and made both strategies comparable in overall fitness. 6. Our results show that warming may erode individual-level variability in life history responses to predation risk. This implies that warming can synchronise

population dynamics and consequently make such populations more vulnerable to unpredictable disturbances." (Authors)] Address: Bojková, Jindřiška, Department of Botany and Zoology, Faculty of Science, Masaryk University, Brno, Czech Republic. E-mail: bojkova@sci.muni.cz

**21402.** van Grunsven, R.; Bos, G.; Poot, M. (2020): Strong changes in Dutch dragonfly fauna. *Covid-19 Special Issue - Agrion* 24(2): 134-138. (in English) ["Conclusion: The Dutch dragonfly fauna is very dynamic with winners and losers over the last 30 years. Unexpectedly, critical species such as *Leucorrhinia caudalis* come back while very common species suddenly decline. Overall we can see differences in trends of species from different habitats. The improved water quality in running waters and the recovery of the dragonfly species of this habitat is a clear, positive example. A major driver of changes in the dragonfly fauna is climate change and this will very likely continue to be so. This is most obvious through the increase of thermophilic species but likely also plays a role in the decline of species of moorlands that prefer lower temperatures. These impacts will not only be through changes in temperature itself but also increasing extremes, in particular droughts. Thanks to the large numbers of citizen scientists that record dragonflies in the Netherlands, we can at least track these changes and aim conservation efforts where they are needed most." (Authors)] Address: Van Grunsven, J.R., De Vlinderstichting, Mennonietenweg 10, Postbus 506, 6700 AM Wageningen, The Netherlands. E-mail: roy.vangrunsvan@vlinderstichting.nl

(in Dutch, with English summary) ["The Odonata fauna along the river tides-Durme (Belgium) has been studied by comparing historical with recent observations between 1979 and 2019. Noteworthy is the increase of *Libellula fulva* and *Platycnemis pennipes* along the tides-Durme. Also new species such as *Aeshna isocetes*, *Crocothemis erythraea*, *Cordulia aenea*, *Coenagrion pulchellum*, *Coenagrion scitulum* and *Sympecma fusca* have colonized the valley of the Durme. The presence of *Aeshna grandis* however remains limited to the flood plain of the river Scheldt." (Author)] Address: Tom Vermeulen: Email: tomvermeulen@proximus.be

**21404.** Zandigiaco, P.; Chiandetti, I.; Fiorenza, T.; Pontarini, R. (2020): Interesting records of Odonata in Friuli Venezia Giulia (North-eastern Italy) in the three-year period from 2016 to 2018. *Gortania* 42: 95-108. (in English, with Italian summary) ["Thanks to the surveys of B. Kiauta and I. Pecile, the Odonata fauna of Friuli Venezia Giulia was relatively well known until the mid 1980s. In recent years, an effort has been made to collect new information for the "Atlas of the Odonata of the Friuli Venezia Giulia region", a project established in 2009. In this paper, the most striking results of the 2016-2018 period are reported. Two species, *Coenagrion ornatum* and *Leucorrhinia pectoralis*, must be inserted in the new regional list (with data collected since 2009), which now includes 64 species representing 67% of the Odonata fauna currently known for Italy. In particular, both *C. ornatum* and *L. pectoralis* are listed in the Annexes of the Habitats Directive. In addition, records relating to another 15 species are reported, among which are rare and threatened species or those of faunistic interest. The main factors threatening the survival of some species are discussed and the need to implement conservation projects is affirmed, in particular concerning: i) *Nehalennia speciosa*; ii) *Cordulegaster heros*; and iii) some alpine species, including *Somatochlora alpestris* and *S. arctica*." (Authors)] Address:

**21405.** Barling, N.T.; Heads, S.W.; Martill, D.M. (2021): Behavioural impacts on the taphonomy of dragonflies and damselflies (Odonata) from the Lower Cretaceous Crato Formation, Brazil. *Palaeoentomology* 4(2): 141-155. In English ["The relative completeness of Odonata fossils from the Crato Formation is investigated and compared to other fossil insect groups from the same formation. Tagma completeness is measured as present, partial, or absent, with some additional subdivision of body components (head, thorax, limbs, individual wings, anterior and posterior abdomen). These data are statistically explored for trends using principal coordinate analysis. While no definitive clustering is identified, most Crato Formation Odonata fossils plot positively on coordinate two, whereas the majority of non-odonatan insect fossils plot negatively on this coordinate. This shows that the Crato Formation odonates are less complete compared to other insect groups from the same beds. Specimens preserved as isolated wings and those preserved with damaged or lost abdomens are identified as contributing to this difference. The causes of these differences are discussed, highlighting collection bias, predation, carcass scavenging, physical conditions of the palaeoenvironment, as well as the autecology of odonates." (Authors)] Address: Barling, N.T., Camborne School of Mines, College of Engineering, Mathematics and Physical Sciences, University of Exeter, Penryn Campus, Treliever Road, Penryn, Cornwall, TR10 9EZ, UK. **21406.** Bezerra, L.L.A.; Pereira da Cruz, R.; Roberto de Azevedo, F. (2021): Capacidade predatória de ninfas de libélulas (Odonata) em larvas de *Aedes aegypti* (Diptera: Culicidae). *Ciências agrárias, indicadores e sistemas de produção sustentáveis*: 228-236. (In Portuguese, with English summary) ["As a result of the persistence of dengue and other arboviruses in Brazil, the government has intensified actions to combat the *Aedes aegypti* mosquito vector. The use of chemical products, the most widely used control method today, has numerous disadvantages in its use, as in addition to impacting human health and the environment, it induces mosquito resistance. Thus, studies in search of sustainable methodologies and promising attributes to nature and society are necessary in the current situation. In view of this, the use of dragonfly nymphs in the biological control of *Aedes aegypti* larvae has important and favorable characteristics, since these are skilled and competitive predators, colonizing different types of aquatic environments, whether with a large or small amount of water, perennial or temporary, show patrolling behavior and territorial defense, has a long nymph stage, which depending on the species can last up to two years, is a more accessible method of control due to its low cost, in addition to *As* much in its nymph stage as in adulthood, the consumption of mosquito larvae is part of its diet, being considered excellent ecological traps." (Authors)] Address: Bezerra, L.L.A., Universidade Federal do Cariri, Crato – CE, Brazil

**21408.** Cerini, F.; Bombi, P.; Cannings, R.; Vignoli, L. (2021): Odonata metacommunity structure in northern ecosystems is driven by temperature and latitude. *Insect Conservation and Diversity* 14(5): 675-685. In English ["The metacommunity concept, defined as a set of local communities connected by species dispersal, provides deep understanding of large-scale ecological processes. The elements of the metacommunity structure (EMS) framework use occurrence data to differentiate among different patterns (i.e., checkerboard, nestedness, species turnover). Metacommunities of tropical Odonata show species turnover following latitude and temperature gradients but there are no such large-scale studies for other regions. We performed EMS analysis with data for the Odonata of British Columbia, Canada, testing the role of five environmental variables (temperature, latitude, precipitation, landcover typology) in structuring the metacommunities and their turnover. The suborder Anisoptera drives the general pattern, with the communities showing a Clementsian-type response (groups of species that replace each other along the environmental gradients) following temperature and latitude ordering. The Clementsian pattern determined by site temperatures reflects the turnover from a group of cold-adapted species to one of warm-adapted species, separated by many species with more generalised temperature requirements. Similarly, the Clementsian pattern associated with the latitude gradient indicates the substitution of a low-latitude group in the south with a high-latitude group in the north. The sites ordered by landcover did not show significant coherence and turnover. In a macro-scale framework, Odonata species assemblages seem to be sensitive to the climatic and geographic variables of local sites (i.e., temperature and latitude), regardless of the surrounding habitat typology. The role of such variables in shaping the assembly of Odonata communities should be considered in large-scale management and conservation projects." **21409.** Chovanec, A. (2021): Libellenkundliche Bewertung von Restrukturierungen der Trattnach in Schlüßberg (Oberösterreich): Vergleich des Prae-Monitorings 2016 mit dem Post-Monitoring 2021. Im Auftrag des Amtes der Oberösterreichischen Landesregierung, Abt. Wasserwirtschaft: 54 pp. (in German) ["In 2019, an approximately 500 m long section of the Trattnach in Schlüßberg (Upper Austria) was restructured. The aim of the dragonfly investigations in 2016 and 2021 was to evaluate this ecological improvement through pre- and post-monitoring. The improvement actions resulted in a doubling of the total number of species in the action section (from five to ten) and the number of certain, probable and possibly native species (from four to eight). In 2021, four of the five water body type-specific indicator species could be detected: *Calopteryx splendens*, *C. virgo*, *Gomphus vulgatissimus* and *Onychogomphus forcipatus*. The native occurrence of these species confirms the hyporhithral/epipotamal transitional character of the Trattnach in this area and indicates the development of suitable heterogeneous flow and substrate conditions as well as corresponding vegetation conditions in the bank area. The rheophilic species in particular were promoted by the hydraulic engineering interventions, water type-specific limnophilic accompanying species could only be detected in isolated cases. The finds of exuviae and sightings of freshly hatched

individuals of *Gomphus vulgatissimus* and *Onychogomphus forcipatus* prove that the entire section of the project was populated by these species with a development time of two years immediately after completion of the construction work. In 2016 only *O. forcipatus* was found on the downstream stretch; *G. vulgatissimus* was absent from the entire section. The restructuring led to an improvement in the dragonfly's ecological status: the affected section (formerly "moderate") was rated "good" in 2021, as were the three individual sections within it (formerly "unsatisfactory" and "moderate"). The dragonfly ecological status of a controlled stretch not affected by the upgrading measures and mapped in both years improved from "unsatisfactory" to "moderate". Radiation effects from the restructuring area are likely to be responsible for this." (Author/Google translate)] Address: Chovanec, A., Krotenbachgasse 68, 2345 Brunn am Gebirge, Austria. **21410.** Deregnaucourt, I.; Bardin, J.; Anderson, J.M.; Béthoux, O. (2021): The wing venation of a new fossil species, reconstructed using geometric morphometrics, adds to the rare fossil record of Triassic Gondwanian Odonata. *Arthropod Structure & Development* 63(6):101056: (in English) ["Highlights: • New morphometric tool allowing reconstruction of incomplete fossil insect wing. • A new species of Triassic stem-Odonata displays an usual combination of traits. • Reconsideration of homology conjecture for the pillar, a particular wing structure. • A major group of Triassic Odonata proves to have been distributed worldwide. Abstract: Probably the most common rock-imprint fossil-insect remain is an incomplete isolated wing. This pitfall has been traditionally addressed by manually reconstructing missing parts, which is not ideal to comprehend long-term evolutionary trends in the group, in particular for morphological diversity (i.e., disparity) approaches. Herein we describe a new Triassic relative of dragon- and damselflies (Odonata), *Moltenophlebia lindae* gen. et sp. nov., from the Molteno Formation (Karoo Basin, South Africa), on the basis of three incomplete, isolated wings. In order to provide a reconstruction of the complete wing venation of the species, we formalized and applied a repeatable method aiming at inferring the missing parts of a given specimen. It is based on homologous veins automatically identified thanks to a standardized color-coding. The dedicated script can be applied broadly to the fossil record of insect wings. The species is identified as a member of the *Zygophlebiida*, within the *Triadophlebiomorpha*. This discovery, therefore, represents the first ascertained occurrence of the latter group in Gondwana, an area where the fossil record of Odonata is depauperate." (Authors)] Address: Deregnaucourt, Isabelle, Centre de Recherche en Paléontologie – Paris (CR2P), Sorbonne Université, MNHN, CNRS, 57 rue Cuvier, CP38, F-75005, Paris, France. **21411.** DiGiacopo, D.G.; Hua, J. (2021): The effects of novel leaf litter deposition on competitive, predator–prey and host–parasite interactions of American toad larvae. *Aquatic Ecology* 56(1): 59-73. (in English) ["Wetland plant communities are changing rapidly due to a wide range of human activities. The deposition of leaf litter from novel plant communities can alter both the chemical and physical habitat of aquatic ecosystems. Lesser understood are the ecological consequences of novel leaf litter inputs in aquatic communities. Toward this goal, we used two plant invasion scenarios (comparing native black huckleberry to exotic autumn olive and native swamp loosestrife to exotic purple loosestrife) to simulate a shift in wetland plant communities. In this study, we investigated the effects of novel leaf litter

leachates on three aquatic ecological interactions: intraspecific competition, predation and parasitism. We examined how leaf litter leachates influence the interactions of American toad larvae (*Anaxyrus americanus*) with their conspecifics, a dragonfly predator (*Anax* spp.) and a trematode parasite (*Echinostomatidae*). We found that leaf litter type influenced competitive interactions only for the huckleberry versus autumn olive comparison. We did not detect any effects of leaf litter type on predator–prey interactions. Finally, litter type strongly influenced host–parasite interactions for both leaf litter comparisons, altering host susceptibility, parasite survival and net infection rates. These results highlight the breadth of potential ecological repercussions of shifting wetland plant communities for native ecosystems." (Authors)] Address: DiGiacopo, D.G., Biological Sciences Dept, Binghamton Univ. (SUNY), 4400 Vestal Parkway East, PO Box 6000, Binghamton, NY, 13902, USA

**21415.** Fabian, S.T.; Zhou, R.; Lin, H.-T. (2021): Dragon-drop: a novel passive mechanism for aerial righting in the dragonfly. *Proc. R. Soc. B* 288: 20202676: 8 pp. (in English) ["Dragonflies perform dramatic aerial manoeuvres when chasing targets but glide for periods during cruising flights. This makes dragonflies a great system to explore the role of passive stabilizing mechanisms that do not compromise manoeuvrability. We challenged dragonflies by dropping them from

selected inverted attitudes and collected 6-degrees-of-freedom aerial recovery kinematics via custom motion capture techniques. From these kinematic data, we performed rigid-body inverse dynamics to reconstruct the forces and torques involved in righting behaviour. We found that inverted dragonflies typically recover themselves with the shortest rotation from the initial body inclination. Additionally, they exhibited a strong tendency to pitch-up with their head leading out of the manoeuvre, despite the lower moment of inertia in the roll axis. Surprisingly, anaesthetized dragonflies could also complete aerial righting reliably. Such passive righting disappeared in recently dead dragonflies but could be partially recovered by waxing their wings to the anaesthetised posture. Our kinematics data, inverse dynamics model and wind-tunnel experiments suggest that the dragonfly's long abdomen and wing posture generate a rotational tendency and passive attitude recovery mechanism during falling. This work demonstrates an aerodynamically stable body configuration in a flying insect and raises new questions in sensorimotor control for small flying systems." **21416.** French, S.K.; Leite, L.M.S.N.; McCauley, S.J.; Searcy, C.A. (2021): Forest edges and their effects on the arrival of dragonflies at north-temperate experimental ponds. *International Journal of Odonatology* 24: 38-50. (in English) ["The matrix, an environment in the landscape that individuals move through but do not reside in, can affect species dispersal and the arrival of individuals at habitat patches. Elements around this matrix that provide refuge or resources may shape the arrival of animals at habitat patches, even when those patches are equivalent in quality. Adult Anisoptera frequently use open terrestrial environments during movement and dispersal in north-temperate regions; however, they can also roost along forest edges. Because of the potential value of forest edges to adult dragonflies, we tested whether pond proximity (i. e., connectivity) to multiple forest edges was positively related to the abundance or diversity of arriving dragonflies. We observed dragonflies arriving at 9 experimental pond sites located within an open field landscape in Ontario, Canada. Experimental ponds differed in their distance to source ponds and to forest edges, a potential refuge for dragonflies. We found no effect of connectivity to forest edges or distance to source ponds on the abundance or diversity of dragonflies arriving at a site. Dragonfly dispersal was therefore not limited at the spatial scale of our study (<305 m to source ponds). In addition, dragonflies did not seem to discriminate among sites based on the amount of nearby forest edge, although all sites within the generally open landscape had at least some forest edge in close proximity (10–79 m). Our results provide greater insight regarding the decisions that dragonflies make in response to landscape elements while dispersing to reproductive habitats." **21419.** Gómez-Tolosa, M.; Rivera-Velázquez, G.; Rioja-Paradela, T.M.; Mendoza-Cuenca, L.F.; Tejada-Cruz, C.; López, S. (2021): The use of Odonata species for environmental assessment: a meta-analysis for the Neotropical region. *Environmental Science and Pollution Research* 28: 1381-1396. (in English) ["The order Odonata has been regularly used as an indicator of the ecosystem's condition. The objective of this review was to analyze the importance of Odonata for environmental assessments (assessment types, statistical approach, life stages, and sampling method, or particular metric), summarizing the current state, the trends, and identifying related research issues in the Neotropical region. Therefore, we selected 62 articles from 2007 to 2018 based on published research to monitor Odonata assessments in the Neotropical region. We compiled a database and ran statistical analyses for the observed frequencies. We found that ecosystem health was the most frequent assessment type and quality the most used objective. In the case of statistical tests and metrics, multivariate analyses and species richness were most used in these papers. However, because there is a great diversity of habitats in this region, there is no unique monitoring protocol to assess the quality of ecosystem health and it is needed to create a proposal for a standard evaluation protocol. Consequently, guidelines for monitoring are presented, and we suggest three stages to establish a specific protocol for each site, which records the set of species most sensitive to the exchange rate evaluated, as well as the use of rarefaction methods, the index of diversity based on the area under the curve, and multivariate analysis, among other recommendations." **21420.** Gould, J. (2021): Hauling up a hefty meal: Long-Jawed spider (Araneae, Tetragnathidae) uses silk lines to transport large prey vertically through the air in the absence of a web. *Ethology* 127(5): 438-442. (in English) ["The most well-known use of silk among spiders is the formation of webs to capture flying prey. However, spiders have evolved many different foraging strategies involving silk, including the capture and subsequent manipulate of prey prior to consumption. Herein, I report on the use of silk lines by a long-

jawed spider from the Tetragnatha genus to move a large prey item vertically through the air. Field observations revealed a long-jawed spider attaching multiple silk lines across the body of an adult dragonfly that had recently emerged from its final moult and attaching these threads to overlying vegetation to incrementally haul the prey item from the surface of a waterbody. My observations suggest that some Tetragnatha spiders are able to move large prey items that are much heavier than themselves using a series of silk lines that allow lift to be accomplished in a gradual and controlled manner. This is an interesting finding, given that other individuals from the same population were using web structures to passively catch much smaller, flying prey. This indicates that some Tetragnatha spiders not only participate in the mobile pursuit of prey but that they possess multiple foraging strategies that may allow them to exploit a larger number of prey types." **21421.** Halassi, I.; Elafri, A.; Halassi, I.; Amari, H.; Houhamdi, M. (2021): Phenotypic plasticity and parental effect on rearing of two diverse habitat environment for laboratory reared *Sympetrum meridionale*. *Journal of Bioresource Management* 8 (2). DOI: <https://doi.org/10.35691/JBM.1202-0186>: 120-130. (in English) ["Laboratory observations on rearing experiment of Odonata serve to answer many evolutionary and ecological questions. In order to evidences the role of species parental habitat provenience in the development behaviour of their offspring, we surveyed several life history traits of two rearing populations of *S. meridionale*, coming from two different habitats across north-eastern Algeria. The first one is a RAMSAR wetland called 'Mekhada' (a perennial water body), and the second one is a temporary pond located at "Maouna" Mountain (1400 m altitude). Overall, the development patterns of the two populations of dragonflies vary with the type of habitat the parental generation of the species occupy (Factorial ANCOVA: all  $p < 0.05$ ). Firstly, egg mortality was very low in dragonfly population inhabiting the RAMSAR wetland compared of those belonging to Maouna Mountain. Secondly new-borne larvae stemming from females inhabiting the Mekhada wetland develop more slowly than did those coming from the "Maouna" Mountain pond. Finally, larvae of *S. meridionale* stemming from females inhabiting the temporary wetland were heavier than those inhabiting the perennial wetland. Such studies will ads considerably to our understanding of the mechanisms that are responsible for possible effects of environmental changes on life history traits of dragonflies across the southern part of their distribution range." **21423.** Harmon, J.J.; Smith, G.R. (2021): Invasive fish (*Gambusia affinis*) as an ecological filter for macroinvertebrate colonization of experimental ponds. *Freshwater Science* 40(1): 151-161. (in English) ["Invasive predators might serve as ecological filters for prey communities, either through non-

consumptive or consumptive effects. The Western Mosquitofish (*Gambusia affinis* [Baird & Girard, 1853]) is an invasive non-native fish that affects native aquatic communities, potentially because of effects on oviposition or initial colonization of habitats (non-consumptive effects), post-colonization effects (i.e., consumptive effects), or a combination of both non-consumptive and consumptive effects. We conducted a mesocosm experiment to examine non-consumptive and consumptive effects of *G. affinis* on colonization of experimental ponds by native macroinvertebrates. We predicted that, if *G. affinis* affects macroinvertebrates through non-consumptive effects, there would be lower abundances in both the non-lethal (caged *G. affinis*) and lethal (free-ranging *G. affinis*) treatments compared to the control (no *G. affinis*), whereas, if the effect of *G. affinis* is primarily due to consumptive effects, there would be lower abundances of macroinvertebrates in the lethal treatment compared to the non-lethal and control treatments. Most macroinvertebrate taxa (dytiscid beetles, baetid Ephemeroptera, corixid and gerrid hemipterans, libellulid odonates) were less abundant, or even absent, in the presence of *G. affinis* in the lethal treatment compared to their abundance in the non-lethal *G. affinis* treatment; however, notonectids were not affected by treatment. The invasive fish predator, *G. affinis*, therefore, can act as an ecological filter for macroinvertebrates in invaded aquatic habitats, primarily through lethal consumptive effects." **21425.** Hermans, J.T. (2021): The Dainty damselfly (*Coenagrion scitulum*) in the Dutch province of Limburg (Odonata: Coenagrionidae). The expansion of a southern damselfly. *Naturhist. maandbl.* 110(3): 39-49. (in Dutch, with English summary) ["*C. scitulum* has a disjunct, mainly southwestern Mediterranean distribution. To the east its distribution becomes more patchy. Since the 1990s it has shown a strong northward expansion and has colonised north-eastern France, south-eastern England, Belgium, Germany and the Netherlands. In 2003, the first male was observed in the Dutch province of Limburg, followed by the discovery of an established population in 2010 in the southern part. From then on it quickly colonised many places, mainly in the southern and central parts of the province. The present distribution in Limburg of this delicate blue damselfly has been thoroughly recorded, as has detailed information on its habitat and preferred vegetation structure. In most of the areas studied in central Limburg it is found around sunny, small and shallow water bodies rich in hydrophytes, where it seems to prefer bankside vegetation dominated by Common Spike-rush (*Eleocharis palustris*). In view of this successful expansion it is expected that it will spread further to the northernmost

parts of the province, which should be carefully followed and monitored." (Author)] Address: Hermans, J.T., Hertestraat 21, 6067 ER Linne, The Netherlands. Email: jthermans21@gmail.com

**21426.** Kanke, E.; Suzuki, K.; Sekiné, K.; Suzuki, T.; Hatta, K.; Yang, M.-M.; Tojo, K. (2021): Unexpected population genetic structure in two closely related euphaeid damselflies from the Yaeyama and Taiwan Islands (Odonata: Euphaeidae). *Biological Journal of the Linnean Society* 134(1): 214-228. (in English) ["In general, population genetics theory predicts that a fragmented smaller population will contain relatively less genetic diversity than a larger population, and so will have a higher rate of genetic fixation due to random genetic drift or inbreeding. However, in this study, having analysed the genetic structure of the mitochondrial DNA COI region between two closely related euphaeid damselflies, we obtained unexpected results which contradict the theoretically expected patterns. Despite their geographical proximity, *Euphaea yayeyamana* was clearly genetically isolated on Ishigaki and Iriomote Islands, and no haplotype crossovers were observed. Even within each island, several diverse haplotypes were observed, indicating a significantly high haplotype intra-island diversity. However, the genetic diversity within Taiwan's population of *Euphaea formosa* was significantly lower than that within either Ishigaki or Iriomote Island, even though Taiwan is significantly larger, with high mountain ranges that reach c. 4000 m a.s.l. and an abundance of habitats, all factors that should contribute to high genetic diversity. The current low diversity status for Taiwan's population may be due to genetic bottleneck effects. In contrast, despite the very small population sizes of Ishigaki and Iriomote Islands coupled with the effects of glacial and interglacial geological events, they have maintained markedly high genetic diversity." **21429.** Lam, Y.T.; Kamarudin, K.R.; Zakaria, M.Z.; Omar, M.S.S.; Tokiman, L.; Jahari, S.; Mohd Salleh, F. (2021): Mitochondrial barcodes of dragonflies and damselflies originated from Taman Negara Endau Rompin, Johor, Malaysia. *IOP Conference Series: Earth and Environmental Science* 736 012032: 5 pp. (in English) ["Odonata are important biological indicators in freshwater ecosystems. However, identification among Odonates is often challenging due to their similar morphological features. Therefore, the incorporation of morphological identification by taxonomists and validation using mitochondrial barcodes such as cytochrome c oxidase subunit I (COI) can be a more reliable approach to enhance the accuracy in species identification. In this study, four COI barcodes for Malaysian dragonflies (*Neurothemis fluctuans*) and damselflies (*Neurobasis chinensis*, *Aristoclypha fenestrella* and *Sundacypha petiolata*) were generated. Three of the generated barcodes (D2 COI, D4 COI and D5 COI) supported the species identified by taxonomists meanwhile D3 COI deduced that the damselfly species was misidentified due to the very similar morphology between the same genus of damselfly. All of the COI barcodes are now available in the GenBank with the accession numbers of MT266926.1 (D2 COI), MT266925.1 (D3 COI), MT266976.1 (D4 COI) and MT266924.1 (D5 COI)." **21430.** Lambret, P.; Janssens, L.; Stoks, R. (2021): The impact of salinity on a saline water insect: contrasting survival and energy budget. *Journal of Insect Physiology* 131(1764): 104224: (in English) ["Highlights: • Salinity has no effect on *Lestes macrostigma* egg hatching success. • Larval growth rate decreased with increasing salinity. • Survival to metamorphosis increased with salinity up to 8 g/L and declines at 16 g/L. • Increasing salinity in the larval stage decreased the energy budget in the adult. • Negative sublethal effects of salinity bridged metamorphosis. Abstract: Water salinity is a major driver of aquatic insects' distribution. Saline species are usually generalists with high survival and performance at both low and high salinity levels. Yet, costs of high salinity may be underestimated as these are most often measured in terms of larval life history traits, while effects of larval stressors may only be detectable when looking at physiological traits and traits in the adult stage. Here, we assessed the lethal and sublethal physiological effects of embryonic and larval exposure to a range of salinity levels in the damselfly *Lestes macrostigma*, both during and after metamorphosis. This species inhabits temporary freshwaters where salinity increases during the drying phase. Salinity had no effect on egg hatching success within the range 2-9.5 g/L sea salt (conductivity range 3.45-14.52 mS/cm). With increasing salinity (up to 16 g/L, 23.35 µS/cm), growth rate decreased and larvae took longer to emerge and did so at a smaller size. Larval survival to metamorphosis increased with salinity up to 8 g/L (12.45 mS/cm) and then declined at 16 g/L. Exposure to salinity in the larval stage had no effect across metamorphosis on both the adult thorax muscle mass and flight performance, and the investment in immune function. Increasing salinity in the larval stage also had no effect on the energy available but increased the energy consumption in the adult stage, resulting in a lower net energy budget. These negative sublethal effects of increasing salinity hence bridged metamorphosis and contrasted with the mortality data, suggesting that the higher mortality at the low salinity levels selected for larvae with the best body condition. Our results highlight the importance of taking into account other life-history and physiological

traits, besides mortality, ideally across different life stages, to better understand and predict consequences of increasing salinization on freshwater insects." **21431.** Maggioni, D.; Assandri, G.; Ramazzotti, F.; Magnani, D.; Pellegrino, I.; Valsecchi, E.; Galimberti, A. (2021): Differential genetic variability at two mtDNA COI regions does not imply mismatches in Odonata molecular identification performances. *The European Zoological Journal* 88(1): 425-435. (in English) ["Molecular-based approaches for species identification and delimitation strongly rely, in terms of universality and efficiency, on the selected markers. Conventionally, when adopting a DNA barcoding approach to discriminate (or identify) metazoans species, the marker choice falls on the 658 base pair region at the 5' end of the mitochondrial COI gene. However, a growing number of studies suggest to use alternative and more variable genetic regions, even from the same gene, such as the 3' end of the COI. In this work, we compared the identification performance of the 5' and 3' end COI regions on a large sequence dataset of odonate species, an order of arthropods among the most studied in terms of conservation importance for aquatic ecosystems. The genetic datasets comprised a total of 236 specimens, 113 species, 51 genera and 12 families spanning the two odonate suborders Zygoptera and Anisoptera, and were analysed under an integrative multiple approach including descriptive statistics and variability of the sequences, phylogenetic reconstructions, DNA-based species delimitations, genetic distances, identification of diagnostic characters and saturation plots. All analyses were congruent in recovering the COI-3' region to be slightly more variable than the COI-5' one, and both regions showed a saturation of transversion at the third codon position. However, phylogenetic reconstructions, genetic distances, and diagnostic characters identification resulted in a similar discrimination power for the two COI regions. Therefore, the COI-3' region does not add much information to the standard COI-5' barcode region, which has in turn largely been demonstrated to successfully delineate invertebrate communities through DNA and eDNA metabarcoding, and to have a much more extensive taxonomic coverage in public databases. Overall, the DNA barcoding inventory assembled in this study will provide valuable insights into the systematics and conservation of many odonate species with implications for future DNA and eDNA monitoring-based studies." **21432.** McEachin, S.C. (2021): Microhabitat selection and interspecific aggression in rubyspot damselflies (*Hetaerina*). PhD thesis, Biology, University of California, Los Angeles: xvii, 126 pp. (in English) ["Interspecific aggression is a complex interaction with important evolutionary and ecological implications. While it can be an adaptive response to reproductive interference, it bears costs including energy expenditure, loss of territory, and missed mating opportunities. Consequently, species may diverge in habitat preferences or exhibit spatial partitioning, which reduce the costs of fighting. However, empirical evidence of such shifts is lacking. I studied the relationship between interspecific aggression, habitat partitioning, and spatial segregation in interspecifically aggressive species of rubyspot (*Hetaerina*) damselflies. In Chapter 1, I explored whether species differences in microhabitat use reduce the frequency of interspecific fighting in 25 sympatric population pairs. I found that

almost all population pairs had lower observed rates of interspecific fighting relative to chance expectations. Reduced rates of interspecific fighting were explained by competitor recognition, species differences in microhabitat use, and spatial segregation. I also found strong positive correlations between heterospecific aggression and species differences in microhabitat use, likely explained by competitive displacement and/or agonistic character displacement, and between heterospecific aggression and spatial segregation. These correlations were explored further in Chapters 2 and 3. In Chapter 2, I tested the competitive displacement hypothesis using removal experiments. If competitive displacement occurs, territory holders of the subordinate species should shift their microhabitat use to that of the dominant species in the absence of the dominant species. However, I found no evidence of such shifts. I therefore reject the competitive displacement hypothesis and conclude that species have likely evolved divergent microhabitat preferences through agonistic character displacement. In Chapter 3, I examined the correlation between heterospecific aggression and spatial segregation. Spatial partitioning is common among competing species, but there are numerous mechanisms that can cause species to be spatially segregated. Conspecific attraction is a widespread habitat selection mechanism, but the potential for it to cause spatial partitioning between interspecifically aggressive species is unknown. I explored this question by comparing the clustering of territories to a model that simulates territory settlement from microhabitat availability. I found that both conspecific attraction and microhabitat preferences contribute to the spatial partitioning between interspecifically aggressive species." **21435.** Moore, M.P. (2021): Larval habitats impose trait-dependent limits on the direction and rate of adult evolution in dragonflies. *Biology Letters* 17(5): 5 pp. (in English) ["Natural selection on juveniles is often invoked as a constraint on adult evolution, but it remains unclear when such restrictions will have their greatest impact. Selection on juveniles could, for example, mainly limit the evolution of adult traits that mostly develop prior to maturity. Alternatively, selection on juveniles might primarily constrain the evolution of adult traits that experience weak or context-dependent selection in the adult stage. Using a comparative study of dragonflies, I tested these hypotheses by examining how a species' larval habitat was related to the evolution of two adult traits that differ in development and exposure to selection: adult size and male ornamentation. Whereas adult size is fixed at metamorphosis and experiences consistent positive selection in the adult stage, ornaments develop throughout adulthood and provide context-dependent fitness benefits. My results show that species that develop in less stable larval habitats have smaller adult sizes and slower rates of adult size evolution. However, these risky larval habitats do not limit ornament expression or rates of ornament evolution. Selection on juveniles may therefore primarily affect the evolution of adult traits that mostly develop prior to maturity." **21436.** Mosquera-Murillo, Z.; Mosquera-Mosquera, M. M. (2021): Riqueza genérica y distribución de los odonatos (Insecta: Odonata) del departamento del Chocó, Colombia. *Bol. Cient. Mus. Hist. Nat. U. de Caldas* 25(1): 191-205. (in Spanish, with English summary) ["Generic richness and distribution of Odonates (Insecta: Odonata) in the department of Chocó, Colombia. Abstract: Objective. To contribute to the taxonomic knowledge and distribution of Odonates in the Department of Chocó and in Colombia. Scope. To present a preliminary record on the richness and distribution of Odonata in the Dept of Chocó. Methodology. Specimens are deposited in the Choco Limnological Collection, CLCH-Insec (Universidad Tecnológica del Chocó), collected between 2004 and 2019 were reviewed. Main results. A total of 1,344 individuals were counted corresponding to 11 families and 29 genera, associated with 97 water currents of different order and 18 lentic ecosystems of the Atrato, San Juan and Baudó river basins located in 20 municipalities of the Department of Choco. Coenagrionidae is the most abundant family and Libellulidae the one with the largest distribution while Gomphidae exhibits the greatest generic richness. The genera *Coryphaeschna*, *Aeschnosoma*, *Aphylla*, *Ophiogomphus*, *Erpetogomphus*, *Orthemis*, *Telebasis*, *Acanthagrion* and *Heteropodagrion* are new records for the department of Chocó. The greatest taxonomic richness is found in the Atrato river basin, followed by San Juan and Baudó. The stone substrate is the one with the highest specific richness.

Conclusions. The first preliminary inventory of the generic richness and distribution of the order Odonata in the department of Chocó is established, which made it possible to demonstrate the diversity of the order in the region." **21438.** Palacio, A. del (2021): Revisión filogenética del Grupo Connata del Género *Erythrodiplax* Brauer, 1868 (Odonata: Libellulidae). Tesis de doctorado, Ciencias Naturales, Universidad Nacional de La Plata: 302 pp. (in Spanish, with English abstract) ["The genus *Erythrodiplax* was established by Brauer (1868), to gather ten American species (order as follows): *E. fusca*, *E. confusa*, *E. chloropleura*, *E. anomala*, *E. umbrata*, *E. superba*, *E. distinguenda*, *E. plebeja*, *E. leontina* and *E. connata*. It is currently the most speciose libellulid genus in the American continent, and presently it comprises 58 species distributed from the south of Canada up to 45 ° S in Patagonia. Its species are inhabitants of different types of wetlands, and many of them may be abundant in lentic habitats like temporary pools, salt marshes and river ponds. Species of the genus can be small to medium (20–50 mm) and are characterized by: brown red or black colored head, with or without a metallic blue reflection; pterothorax yellow/brown to black and covered with bluish pruinescence in mature males. Hyaline wings with black, red or orange spots; last antenodal vein of front wing incomplete (except in some specimens of *E. tenuis*); generally 1 bridge crossvein (rarely 2-3) and 1 cubitoanal crossvein (rarely 2-4); generally with free triangles; medial supplemental vein (Mspl) indistinct, although some species with up to 1 or 2 rows of cells. Posterior lobe of prothorax curved caudally. Abdomen triangular in cross section. Male genitalia with anterior lamina entire; posterior hammule bifid, with the inner branch smaller than the outer branch; distal segment of the vesica spermalis long and cylindrical, with

complex and largely hidden distal lobes, gradually widening to the rounded or bluntly angulated tip except for some specimens of *E. berenice*. Female with vulvar lamina scoop-shaped and ventrally directed. In 1942 Borror made the only available review of the genus *Erythrodiplax*. It offers a complete generic characterization, taxonomic lists, keys, the description of more than one dozen new species and provides a formal division of the genus into 12 groups of species: *Connata* (10 species), *Castanea* (two species), *Attenuata* (three species), *Longitudinalis* (three species), *Unimaculata* (10 species), *Famula* (two species), *Umbrata* (one species), *Funerea* (one species), *Basalis* (11 species), *Nigricans* (one species), *Juliana* (one species) and *Acantha* (one species). However, the characters used to differentiate between the groups are unclear, and many species described after Borror's work have not been formally assigned to any of the groups. The *Connata* group is the most speciose of the genus, and is currently made up of the following 14 species, *E. abjecta*, *E. atroterminata*, *E. basifusca*, *E. bromellicola*, *E. cauca*, *E. cleopatra*, *E. connata*, *E. fusca*, *E. ines*, *E. justiniana*, *E. media*, *E. melanorubra*, *E. minuscula* and *E. paraguayensis*. The group is characterized by the following combination of characters: wide antehumeral stripe, outer branch of the hammule larger than or as long as the inner one, 10-15 spines in femur III, vulvar lamina 2/3 of the width of segment 9, among others. These characters present a certain degree of interspecific variation, therefore, the delimitation of groups is based mainly on characters derived from male genitalia. The main characters derived from the vesica spermalis that define the *Connata* group are: generally with apical tubercle, small and rounded lateral lobes, medium process overlapping the lateral lobes and erectile lobe, apex of middle process with bristles, small and erectile posterior lobe, apical lobe shorter than lateral lobes. The species of this group are relatively abundant in national and international collections. However, its correct identification is extremely complicated mainly due to the morphological and color similarities, and the difficult observation of the characters derived from the lobes of the vesica spermalis. The main objective of this work is to clarify the taxonomic status of the species of the *Connata* group. To this end, a systematic review of the *Connata* group was carried out for which the redescription of the species of this group were provided, the variability of the characters derived from the color pattern was determined, a detailed study of the structures derived from the fourth segment of the vesica spermalis was done, and finally a cladistic analysis of the *Connata* group was also done, including representatives of the remaining groups proposed by Borror, in order to redefine and re-diagnose the stability and composition of groups, based on modern systematic methods. The results verify that the characters derived from the ultrastructure of the vesica spermalis are fundamental in the systematic study of the species of the genus *Erythrodiplax*. The methodology developed for the preparation of vesicas is of utmost importance for the observation of the characters and their correct interpretation. On the other hand, the cladistic analysis discards the monophyly of the genus *Erythrodiplax*. When considering both *Uracis* and *Rhodopygia* as outgroups, the species belonging to the *Castanea*, *Famula* and *Umbrata* groups are basal to the *Uracis*/*Rhodopygia* + the remaining species of *Erythrodiplax*. However, the monophyly of the *Connata* group is supported, although the relationships between its species could not be resolved. Finally a diagnosis of all species within the genus, data on geographical distribution and keys in particular for the species included within the *Connata* group are provided." (2021): Pervasive decline of subtropical aquatic insects over 20 years driven by water transparency, non-native fish and stoichiometric imbalance. *Biol. Lett.* 1720210137/20210137. <http://doi.org/10.1098/rsbl.2021.0137>: 8 pp. (in English) ["Insect abundance and diversity are declining worldwide. Although recent research found freshwater insect populations to be increasing in some regions, there is a critical lack of data from tropical and subtropical regions. Here, we examine a 20-year monitoring dataset of freshwater insects from a subtropical floodplain comprising a diverse suite of rivers, shallow lakes, channels and backwaters. We found a pervasive decline in abundance of all major insect orders (Odonata, Ephemeroptera, Trichoptera, Megaloptera, Coleoptera, Hemiptera and Diptera) and families, regardless of their functional role or body size. Similarly, Chironomidae species richness decreased over the same time period. The main drivers of this pervasive insect decline were increased concurrent invasions of non-native insectivorous fish, water transparency and changes to water stoichiometry (i.e. N : P ratios) over time. All these drivers represent human impacts caused by reservoir construction. This work sheds light on the importance of long-term studies for a deeper understanding of human-induced impacts on aquatic insects. We highlight that extended anthropogenic impact monitoring and mitigation actions are pivotal in maintaining freshwater ecosystem integrity." (2021): Protohemiphlebiidae fam. nov., a stem hemiphlebioid damselfly from Cretaceous amber in Kachin. *Geological Society London Special Publications* 521: 171-184. (in English) ["Hemiphlebiidae are the most basal lestomorphan family following the latest phylogenetic analysis of the

Zygoptera: this unique damselfly family today contains one relict species found in the wetlands of Australia. It was, however, very diverse and widespread during the Mesozoic. Nevertheless, very few species were known obscuring the origin and early evolution of the family. Here we propose a new stem hemiphlebioid taxon (Protohemiphlebiidae Zheng, Jarzembowski & Nel, fam. nov.) based on a new genus and two species: Protohemiphlebia zhangii Zheng, Jarzembowski & Nel, sp. nov. and Protohemiphlebia meiyingae Zheng, Jarzembowski & Nel, sp. nov. The new family shares the characters of both Hemiphlebiidae and Coenagrionidae, but it is more closely related to Hemiphlebiidae in having the pterostigma with a 'star-shaped' microsculpture, and AA originating from the wing base slightly distal of Ax0. Protohemiphlebia Zheng, Jarzembowski & Nel, gen. nov. is further considered to belong to the stem group of Hemiphlebiidae, instead of belonging to the Hemiphlebiidae, in possessing pretibial combs and a weakly kinked RP1 below the Pt-brace. The new damselflies will help to calibrate the origin of Hemiphlebiidae, which could be earlier than their current oldest records in the Kimmeridgian (Late Jurassic)." **21444.** Adak, R.; Mandal, A.; Saha, S. (2022): Aerodynamic performance of a tandem wing configuration inspired from dragonfly gliding flight for MAV application. Proceedings of the 9th International and 49th National Conference on Fluid Mechanics and Fluid Power (FMFP). December 14-16, 2022, IIT Roorkee, Roorkee-247667, Uttarakhand, India, FMFP2022-3398. 5 pp. In English ["The design of micro air vehicles (MAVs) introduces aerodynamic performance challenges due to the small size and, consequently, the low Reynolds number ( $O(10^4-5)$ ). Natural fliers are naturally optimized and are comparable in size to MAVs, making them a potent candidate to mimic for the design of MAVs. The dragonfly frequently uses a gliding mode of flight relative to the other small fliers and operates at a range of  $O(10^2-4)$ . The literature suggests that the corrugated profile improves the aerodynamic efficiency around  $Re$  at 104. It allows us to investigate the aerodynamic advantages of tandem corrugated airfoil inspired by the dragonfly wing. In this paper, we perform direct numerical simulations of flow past bio-inspired corrugated wing to understand the impact of the tandem wing configuration. The horizontal distance between the wings is fixed, and the vertical distance varies. The results reveal that the forewing/hindwing interaction increases the lift of the forewing relative to the isolated wing for all the case studies. The combined drag coefficient drops by  $\approx 7\%$ , and overall efficiency drops by  $\approx 13\%$  relative to an isolated wing for a case study with zero vertical spacing between forewing and hindwing at  $3^\circ$  angle of attack, fixed for both wings. With no vertical gap, the aerodynamic efficiency matches close to the isolated wing with the decrease in tandem wing combined drag coefficient compared to an isolated wing." **21445.** Adu, B.W.; Ileke, K.D.; Olorunmeke, O.A. (2022): A preliminary study of biodiversity and biomonitoring potential of Odonates of Benin-Owena River Basin catchment, Igbara-Oke, Ondo State, Nigeria. International Journal of Tropical Insect Science 42: 2853-2864. (in English) ["Ecologically, Odonata are good indicators of aquatic and terrestrial ecosystem. They are abundant and important members of

the vicinity of inland waters. This study was carried out at Benin – Owena Basin catchment, Igbara-Oke, Nigeria. Sampling was carried out at three water bodies within the catchment of Rivers Aro, Elemo and Owena Dam. The water bodies were selected based on types of water body and prevailing anthropogenic activities around their vicinity. Sampling of specimens was randomly carried out once a month from 9am-2 pm between June, 2017 and July, 2018. Odonata naiads were collected using Kick net. Species composition, distribution and richness of the study sites were calculated using diversity indices (Shannon–Wiener, Simpson, Margalef, Evenness and Equitability). Monthly collections of odonates revealed that January 2018 had the highest number of species while the least was in April 2018. Two anisopterans, Neodythemis klingi and Orthetrum julia both with 30 individuals, were the dominant odonate species. Pseudagrion kersteni (19 individuals) was the dominant zygopteran while Africallagma subtile (2 individuals) was the least represented odonate in this study. From the diversity indices analyses, Owena Dam was the richest (Shannon ( $H'$ ) = 3.12, Simpson = 0.9521, Margalef = 4.42). The site was also the best in terms of distribution and spread of odonate species (Equitability = 0.9693). Similarity in odonate community structure among the 3 study sites was determined using Jaccard Coefficient (Coefficient of Community: CC), The CC analysis showed Elemo Stream and Owena Dam as the sites with similar community structure; and the diversity indices revealed Owena Dam as the richest site with the best species distribution." **21446.** Almeida, T.R. de; Salomoni, S.; Vilela, D.S.; Guillermo-Ferreira, R. (2022): Male agility in relation to mating success in two non-territorial damselflies. Austral Ecology 47(8): 1569-1577. (in English) ["Male body size is usually correlated with mating success in insects. For non-territorial species, the small male advantage hypothesis predicts that smaller males may be favoured in sexual selection because small body size may predict agility and manoeuvrability. Consequently, selection for male size may drive the evolution of female-biased sexual size dimorphism (SSD). Nevertheless, recent evidence shows that non-territorial male damselflies that actively search for females may be larger and more agile than those that perch and wait for females to appear. Thus, here we addressed whether the male size is an indicator of male agility and if it may be used to predict male reproductive success in two non-territorial damselflies. To this end, we conducted a field study with Acanthagrion truncatum Selys, 1876 and A. lancea Selys, 1876 (Zygoptera, Coenagrionidae). Males of A. truncatum adopt a sit-and-wait mating strategy, while the males actively search for females in A. lancea. Hence, we expected different selective forces acting on male body size and agility in these species. We compared the body size and wing length of mated and unmated males, and between sexes, to describe their patterns of SSD. Our results suggest that wing length can be used as a proxy for male body size and agility in both species. However, we have found no evidence for the small male advantage that could explain wing dimorphism in A. truncatum, nor selection for larger males in A. lancea. In conclusion, this study corroborates other studies that suggest agility cannot explain SSD in non-territorial damselflies and fail to support the small male advantage hypothesis." **21447.** Amann, P. (2022): Heuschrecken (Orthoptera) und Libellen (Odonata) im Kleinwalsertal (Vorarlberg, Österreich). *inatura - Forschung online* 104: 17 pp. (in German) ["Due to its isolated location, Kleinwalsertal has been somewhat neglected by Vorarlberg naturalists. The aim of this research project is to provide up-to-date information on species structure and distribution for the two animal groups grasshoppers and dragonflies. In a first step, based on the biotope inventory, areas were selected that could be expected to have a species-rich and characteristic fauna for Kleinwalsertal. A total of 30 grasshopper sites and 16 sites for dragonflies were selected, although these could also be identical. In the summer of 2022, the sites were visited in mid-June, mid-July and mid-August and the species were documented. The focus of the recordings in June was on dragonfly observations; in August, the subalpine areas of the Schwarzwasserhütte and Hohen Ifen were also examined for their fauna. The recordings were marked by a hot summer. In all 3 recording months, average temperatures prevailed that were significantly above the long-term average. For example, the temperature in July was about 5 degrees Celsius warmer than the long-term average. This month also had very little precipitation. As a result, the moors were very dry: In many cases, swales and depressions were dried out, and it was rare to get wet. 17 dragonfly species were recorded in the study area, including *Aeshna subarctica* [also *Somatochlora alpestris* and *S. arctica*] "threatened with extinction" in Vorarlberg. 5 species were newly documented for Kleinwalsertal. ... The subsequent discussion of the grasshopper and dragonfly species found (with information on their protection status) is followed by an attempt to assess the species on the basis of their protection status. A final assessment of the Kleinwalsertal valley as a dragonfly and grasshopper habitat as well as a discussion on responsibility round off the work.] (Author/DeepL)] Address: Amann, P., Wiesenbachweg 8, 6824 Schlins, Austria. **21448.** Battisti, A.; Bosio, G. (2022): The dragonflies (Odonata) of the Mont Avic and Mont Emilius massif (NW-Italy): reflections on the evolution of the community and focus on the genera *Leucorrhinia* and *Somatochlora*. *Rev. Valdôtaine Hist. Nat.* 76: 69-87. In Italian, with English summary ["The surveys carried out in the years 2019 – 2021 permit to improve the knowledge of the dragonflies of the Special Protection Area IT1202020 "Mont Avic and Mont Emilius" (Aosta valley). New populations of *Somatochlora arctica* and *Leucorrhinia dubia* were discovered. The new population of *S. arctica* is located in the Mont Avic Natural Park and represents the southernmost population of the Italian Alps, with confirmation of the species between 1.729 m and 2.053 m of altitude, in habitats shared with *Somatochlora alpestris*. The new population of *L. dubia* is located at 1.700 m, in a small acid lake with the presence of alien fish species (*Salvelinus fontinalis* and *Salmo trutta*) which threaten the entire dragonfly community present here. A detailed distribution of *S. arctica*, *S. alpestris* and *L. dubia* in the SPA IT1202020 is reported, together with first results from semi-quantitative monitoring for these species. The checklist of the Odonata of the SPA IT1202020 is updated; three species are added (*Coenagrion puella*, *S. arctica* and *Sympetrum fonscolombii*) and the highest breeding Italian altitudinal records for *Enallagma cyathigerum* (2.289 m) and *L. dubia* (2.316 m) were reported. Main threats and pressures affecting the dragonfly community are discussed. The presence of alien fish species seems to be the main direct threat for dragonflies in the area. Finally, a preliminary mapping of the wetlands of the study area is provided." (Authors)] Address: Battisti, A.,

(2022): Standardised inventories of lepidopterans and odonates from Serra da Estrela Natural Park (Portugal) - setting the scene for mountain biodiversity monitoring. *Biodiversity Data Journal* 11: e99558: 22 pp. (in English) ["Background: Mountain insect biodiversity is unique, but is menaced by different drivers, particularly climate and land-use changes. In mainland Portugal, the highest mountain - Serra da Estrela - is one of the most important biodiversity hotspots, being classified as Natural Park since 1976. Many lepidopteran and odonate species, including rare and protected species, are known to occur in Serra da Estrela, but basic knowledge on their abundance, distribution and ecology is still lacking. Standardised sampling of these communities is crucial to provide valuable biological information to support short-term decision-making for conservation management, setting simultaneously the standards for mountain biodiversity monitoring aiming to tackle the effects of environmental change in the long-term. New information: This study reports novel information on lepidopteran and odonate species diversity, distribution and abundance from Serra da Estrela Natural Park (Portugal). Seventy-two lepidopteran and 26 odonate species were sampled in this protected area, including the first findings of *Apatura ilia* (Denis & Schiffermüller, 1775), *Macromia splendens* (Pictet, 1843) and *Vanessa virginiensis* (Drury, 1773). New populations of *Euphydryas aurinia* (Rottemburg, 1775) and *Oxygastra curtisii* (Dale, 1834), protected species under the Habitats Directive, were found in this Natural Park and novel distribution and ecological data were collected for most species, including several rare species and subspecies [e.g. *Aeshna juncea* (Linnaeus, 1758), *Coenonympha glycerion iphioides* Staudinger, 1870, *Cyaniris semiargus* (Rottemburg, 1775) and *Sympetrum flavoolum* (Linnaeus, 1758)]. All data were collected using standardised sampling allowing its use as a baseline for biodiversity monitoring in Serra da Estrela." **21453.** Castillo-Pérez, U.; Suárez-Tovar, C.M.; González-Tokman, D.; Schondube, J.E.; Córdoba-Aguilar, A. (2022): Insect thermal limits in warm and perturbed habitats: Dragonflies and damselflies as study cases. *Journal of Thermal Biology* 103, 103164: (in English) ["Highlights: • Loss of plant cover increases ambient temperature thereby affecting insect survival. We compared temperature and thermal limit in odonates related to body size, "conserved" vs "perturbed" habitat and suborder. Anisopterans had a higher temperature than zygopterans, with no difference between habitats. Zygopterans had higher thermal limits in a perturbed site while anisopterans had the opposite trend. Zygopterans appear more strongly affected by ambient temperature than anisopterans. Abstract: Disturbance (e.g. loss of plant cover) increases ambient temperature which can be lethal for ectotherm insects especially in hot places. We compared the thorax temperatures of 26 odonate species as a function of body size, habitat quality ("conserved" and cooler vs "perturbed" and warmer) and suborder (Anisoptera vs Zygoptera), as well as critical thermal maximum (CTmax) and as a function of habitat quality in *Argia pulla* (Zygoptera) and *Orthemis ferruginea* (Anisoptera). We expected thorax temperatures to differ between suborders based on their differences in body size and habitat quality status, and that populations in perturbed sites would have higher critical thermal maxima compared to those in conserved sites. This study was done in a tropical region with high ambient temperatures. Anisopterans had a higher body temperature than zygopterans, with no difference between habitats. Thoracic and air temperature were positively related, yet body temperatures were higher than the ambient temperature. *A. pulla* had higher CTmax in the perturbed sites, while *O. ferruginea* showed the opposite trend. Microenvironmental changes increase the ambient temperature, perhaps filtering insect species. The apparent resilience of odonates to disturbance should be examined more closely (using more species), especially in small species like the zygopterans

which appear to be more strongly affected by ambient temperature." (Authors)] Address: Córdoba-Aguilar, A., Instituto de Ecología, Universidad Nacional Autónoma de México, Apdo. **21454.** DeBlieux, T.S.; Hoverman, J.T. (2022): Pathogens and predators: examining the separate and combined effects of natural enemies on assemblage structure. *Oecologia* 200: 307-322. (in English) ["Natural enemy ecology strives to unify predator-prey and host-pathogen interactions under a common framework to gain insights into community- and ecosystem-level processes. To address this goal, ecologists need a greater emphasis on: (1) quantifying pathogen-mediated effects on community structure to enable comparisons with predator-mediated effects and (2) determining the interactive effects of combined natural enemies on communities. We conducted a mesocosm experiment to assess the individual and combined effects of predators (dragonfly larvae and adult water bugs) and a pathogen (ranavirus) on the abundance and composition of a larval amphibian assemblage. We found that our three natural enemies structured victim assemblages in unique ways, producing distinct assemblages. Additionally, we found that in combination treatments, predators mainly drove assemblage structure such that the assemblages most closely resembled their respective predator treatments. We also found that predators reduced infection prevalence in combination treatments, and that the magnitude of this effect was dependent on predator identity. Compared to virus-alone treatments, the presence of dragonflies and water bugs reduced infection prevalence by 79% and 63%, respectively. Additionally, the presence of dragonflies eliminated ranavirus infection in two species, which demonstrates the prominent role of predators in disease dynamics in this system. Overall, this work demonstrates the importance of considering natural enemies in community ecology, as each enemy can elicit a unique structural change. Additionally, this study provides a unique empirical test of the healthy herds hypothesis for multi-species assemblages and underscores the importance of advancing our understanding of multi-enemy interactions within communities." (2022): Demographic characteristics of *Ichnura elegans* (Vander Linden, 1820) (Odonata: Coenagrionidae) in arid regions: sex and female morphs differences in survival and capture probabilities, space use patterns and spatial density. *Aquatic Insects* 44(1): 64-78. (in English) ["We used the mark-recapture method to gather fundamental information on the population dynamics of *I. elegans* in an arid region of central

Iran. *I. elegans* expresses female-limited colour polymorphism. We investigated sex and female morphs differences in survival and capture probabilities, space use patterns, and spatial density. We used Cormack–Jolly–Seber and spatial capture-recapture models. The estimated capture probability for males was lower than females. The survival probability was not different between either males and females or gynomorphs and andromorphs. We found support for sex differences in density and detection probability, and female morphs differences in density, space use and detection probability. Based on our results the extreme conditions of arid regions can lead to a male-biased dispersal. Our findings also confirm the existence of behavioral differences between andromorph and gynomorph females and suggest a within species spatial habitat partitioning." **21458.** Gazzola, A.; Guadin, B.; Balestrieri, A.; Pellitteri-Rosa, D. (2022): Multimodal cues do not improve predator recognition in Green Toad Tadpoles. *Animals* 2022, 12, 2603. 10 pp. (in English) ["Simple Summary: Tadpoles are known to use their sense of smell to detect the presence of predators, but some studies showed their reliance on vision during social interaction, suggesting that vision might have a role in predatory contexts as well. Here, we investigated how chemical or visual cues of a native predator, or a combination of both, influence the defensive behaviour of green toad tadpoles. We expected tadpoles to reduce their activity when exposed to chemical cues and avoid the area of the experimental arena near to the caged predator when exposed to the visual ones. With both cues, we expected tadpoles to show both responses and with greater intensity. Our results indicate that visual cues alone do not elicit any apparent defensive response, suggesting that tadpoles mainly rely on chemical cues to assess predation risk. Abstract: The anti-predator behaviour of green toad (*Bufo balearicus*) tadpoles was investigated by exposing them to only the visual or chemical cues, or a combination of both, of a native predator, *Aeshna cyanea*. We collected green toad egg strings in the field and tadpoles did not receive any predatory stimulus before the onset of the experiment. To manipulate chemical and visual cues independently, dragonfly larvae were caged inside a transparent plastic container, while chemical cues (odour of tadpole-fed dragonfly larvae) were injected into the surrounding arena. An empty container

and water were used, respectively, as controls. The behaviour of individually tested tadpoles was videorecorded for 40 min, of which 20 were before their exposure to stimuli. Five second-distance frames were compared to assess both tadpole activity and position within the arena with respect to the visual stimulus. The tadpole level of activity strongly decreased after exposure to either chemical cues alone or in combination with visual cues, while visual cues alone apparently did not elicit any defensive response. The position of tadpoles inside the arena was not affected by visual cues, suggesting that green toad tadpoles mainly rely on olfactory cues to assess the level of predation risk." **21460.** Hemnani, M.; Campos Guimarães, I.S.; Kaefer, I.L.; Pires, T.H. (2022): Alarm reaction depends on multiple chemical cues in tadpoles of the cane toad (*Rhinella marina*). *Ethology Ecology & Evolution* 35(3): 363-375. (in English) ["Early detection of predators is fundamental for the survival of the prey. Predator detection can occur by perception of the chemical substances released by predators or injured conspecifics, granting prey the opportunity to avoid the attack. However, overreacting to cues can generate false alarm reactions that result in fruitless energetic costs. Given that chemical cues in natural habitats rarely occur singly, individuals can benefit from obtaining information from multiple sources, such as the combined chemical cues from predators and conspecifics. We experimentally tested the movement reaction of cane toad (*Rhinella marina*) tadpoles when in contact with isolated chemical cues from a conspecific, a predator (dragonfly larvae), and the combination of these two substances. We quantified duration of swimming activity before and after the exposure to the chemical cues and compared it to a control group. A significant reduction in swimming activity was only observed

when the tadpoles were exposed to the combination of both cue types. Our results suggest that the tadpoles can recognise the chemical cues from conspecifics and predators, but a behavioural response is only elicited when both stimuli are detected simultaneously. We suggest that behavioural change in response to predation threat in *R. marina* is a compromise between early detection of predators and avoidance of unnecessary energetic expenditures." **21462.** Khare, V.; Kamle, S. (2022): Biomimicking and evaluation of dragonfly wing morphology with polypropylene nanocomposites. *Acta Mechanica Sinica* 38(12):1431. (in English) ["Dragonfly hindwing inspired two different flapping wing morphologies are investigated for flexible flapping wing micro air vehicles (FWMAV) applications. The Wing skin is developed using 1% functionalized carbon nanotubes reinforced polypropylene nanocomposites with carbon fiber epoxy composite strands as venation pattern. The resonance frequencies are the fundamental information for biomimicking and were calculated theoretically from stiffness data. Bending dominated first natural frequency was obtained from flexural stiffness data and found close to the flapping frequency of natural dragonfly hindwing. Twisting dominated second natural frequency was obtained from torsional stiffness which revealed that the artificial wings can be fabricated thinner. The flapping frequency of artificial wings is unaffected by the twisting deformation. The bending and twisting dominated mode shapes are also studied using DIC system. To verify the static and dynamic results, finite element simulations are performed that agree with experimental findings. It was found that proposed flexible nanocomposite wing skin can control the bending and twisting dominated frequencies by tailoring the wing morphology and without affecting the mode shapes of deformation." **21463.** Liu, Y. (2022): Aquatic assemblages: improving dragonfly habitat and water quality in an urban park. MSc.

thesis, Landscape Architecture, Department of Landscape Architecture of the Rhode Island School of Design, Providence, Rhode Island.: 41 pp. (in English) ["Many scientists have claimed that we are entering into the sixth mass extinction. According to IUCN, about 16% of the 6,016 species of dragonflies and damselflies are at risk of extinction. Dragonfly occupies an essential link in the food chain. Fluctuations in dragonfly numbers can affect the numbers of other species, such as mosquitoes and birds. Dragonflies are also closely related to the health of the water environment. Healthy water bodies can attract more and different species of dragonflies and other aquatic animals. Dragonflies' decline is a symptom of widespread loss of the marshes, swamps, and free-flowing rivers they breed in, driven mainly by the expansion of unsustainable agriculture and urbanization around the globe. In addition to impacting habitat, urbanization has led to severe stormwater issues that impair the health of our rivers and oceans. My thesis aims to address three interrelated issues: restoration of aquatic insect habitat in urban areas, stormwater runoff, and education about species decline. To explore these issues, I focus on Roger Williams park, which has the potential to be high-quality habitat for dragonflies and other animals. However, currently the ponds in the park lack ecological diversity and have serious water quality issues due to stormwater runoff. To address these issues, I propose a series of rock berms in the ponds that change the direction of the water flow. Wetland plants along the berms will help clean the water as it flows through them. In addition, the berms will allow people to walk out into the pond to experience the wetlands and an educational installation that lists species of dragonflies that have gone extinct to help raise awareness about biodiversity loss. Ultimately, rock berms could be developed into a solution to urban stormwater and provide habitats for insects and other aquatic animals in different places." (Author)] Address: not stated

**21465.** Monzo, J.C.; Verdu, J.R. (2022): Effects of restoration and management of Mediterranean traditional water systems on Odonata alpha diversity: a long-term monitoring survey. *Biodiversity and Conservation* 31: 227-243. (in English) ["The progressive abandonment and disappearance of traditional water uses and management of wetlands during the twentieth century has led not only to a loss of identity, heritage, and landscape values, but also to significant declines in the diversity and abundance of many organisms. Here, we take advantage of an existing project for the restoration and management of traditional irrigation infrastructures in the wetland of El Prado (Pinoso, SE Spain) to evaluate the spatio-temporal effect of this action on the alpha diversity and abundance of Odonata. The wetland was organized in different sectors according to the coverage of riparian and aquatic vegetation, width and depth of watercourses, ditches and ponds, water flow, and restoration and management. Odonates were sampled every month for ten years. We used alpha diversity to measure biodiversity using Hill's number diversity. To analyse how alpha diversity measures varied across all sectors sampled over the years, we determined diversity-time relationships. To assess the effects of the different variables on odonate biodiversity we used partial least squares regressions. Our results showed

that restoration of traditional water infrastructures, encouraging the increase of aquatic vegetation cover, an adequate and regular management of riparian vegetation naturalizing the margins, as well as reducing speed of water flow have a positive effect on odonate diversity and abundance. Our study provides useful information for conservation and management of semi-arid wetlands and its associated water infrastructures by showing which actions are most successful to enhance biodiversity in one of the priority habitats for conservation in Europe." **21466.** Moreno-Domínguez, R.; Maccracken, A.; Santos, A.A. de; Wappler, T. (2022): Plant–insect interactions from the Late Oligocene of Spain (La Val fossil site, Estadilla, Huesca) and their palaeoclimatological implications. *Palaeogeography, Palaeoclimatology, Palaeoecology* Volume 586, 15 January 2022, 110782: (in English) ["Highlights: •Reports plant–insect interactions from an Iberian Peninsula Oligocene deposit. •Herbivore interactions decrease in number and richness in the youngest horizons. •A decrease in galling diversity is also observed in the youngest horizons. •Changes in herbivory across horizons may reflect an increase in humidity through time. •The data provide context for previously reported European plant–insect associations. Abstract: Trace fossils of insect herbivory are an important tool, which provide evidence for palaeoecological and palaeoclimatic interpretations, as well as being a unique and direct record of the plant–insect interactions in the geologic past. In the Iberian Peninsula, these types of surveys have been scarce and purely descriptive. The La Val fossil site is an interesting, new megafloora assemblage from the Late Oligocene of Spain, which encompasses numerous plant–insect interactions and their palaeoclimatic and palaeoecological implications. A total of 1337 fossil specimens from 13 stratigraphic levels were analyzed for this study. We identified 28 different types of plant–insect interactions belonging to seven Functional Feeding Groups (FFGs). Hole feeding was the most common category of external-feeding insect damage, followed by margin feeding, skeletonization, and surface feeding. Among the internal-feeding FFGs, galling was the richest and most abundant FFG. All other internal-feeding FFGs were relatively uncommon: piercing/sucking, and incertae sedis (DT114). Among stratigraphic levels, the mean herbivory frequency was significantly greater at lower levels compared to the upper levels. La Val presents a marked drop in the diversity of plant–insect interactions through time, possibly due to changes in temperature or humidity levels. A marked decrease in galling diversity and a generalized decrease in interactions are observed at the youngest levels. This could be related to an increase in humidity though time in the La Val palaeoforest, since modern xeric environments favour the proliferation of galls." **21470.** Palacino-Rodríguez, F.; Cordero-Rivera, A.; Palacino, D.A.; Penagos, A.C. (2022): Captive breeding of odonate larvae: effects of type of water, handling, and sex. *Entomologia Experimentalis et Applicata* 170(6): 505-512. (in English) "Basic information on life histories, ecology, and behaviour for aquatic stages in many species of insects is difficult to obtain in the field. Here, a method to breed and monitor Odonata individual larvae in captivity is proposed. In total, 3788 individuals of six Odonata species – *Rhionaeschna marchali*, *Erythrodiplax abjecta*, *Sympetrum gilvum*, *Ischnura chingaza*, *I. cruzi*, and *Mesamphiagrion laterale* – were reared individually in water-filled plastic containers, whose size was increased to fit larval growth, at ambient temperature (12–34 °C, 12 h light per day, ca. 300 lux, and ad libitum food). We tested the effects of water type (habitat, dechlorinated tap water, and drinking water), handling method, and sex on larval developmental time and number of instars. The number of instars was calculated as the mean number of moults for the individuals that successfully emerged as adults. Life cycle length was calculated by averaging the days over individuals that completed their development until emergence. The probability of achieving the adult stage was not significantly affected by the type of water, sex, or

handling method. On the other hand, the number of instars was affected by species identity, and type of water, with fewer instars in water from the natural habitat, but not affected by sex or handling method. The duration of the life cycle was bimodal in most species, and was affected by type of water, but in an idiosyncratic, species-specific way. The methodology proposed here allows monitoring and breeding large numbers of odonate larvae." **21471.** Pawlaczyk, P.; Bednarek, P.; Dziadowiec, R.; Banaszak, K.; Grzesiak, K.; Jermaczek, A.; Krzysków, T.; Les, E.; Naks, P.; Sierakowski, P.; Zyla, P. (2022): Program ochrony Rzeki Bogadicy w województwie opolskim. Wydawnictwo Klubu Przyrodników, Opolskie: 124 pp. (in Polish, with English summary) ["The Bogacica River is ca 40 km long tributary of the Stobrawa in Odra river basin. The publication presents a program of river conservation measures, developed for the Opolskie Voivodeship - the local authority responsible, among others, for landscape protection, including protected areas: Stobrawa Landscape Park and the Stobrowsko-Turawskie Forests Protected Landscape Area, covering almost the entire course of the river. According to Polish law, the environmental objectives set by the Opolskie Voivodeship for these areas become, as far as the river is concerned, environmental objectives in the sense of the Water Law and are binding for the river manager (PGW Wody Polskie). The nature of the river varies; the river has been intensively transformed since the 19th century (chapter 4.1); currently, more natural sections alternate with more strongly transformed ones (photos 1-10, fig. 9, photos 12-14). The average flow is 1.01 m<sup>3</sup>/s, but it decreases in the long term (fig. 2), probably due to climate change and excessive water abstraction for fish ponds. The phenomenon of river flooding disappears. The river valley has maintained substantial natural values (Chapter 3). A section of the river is proposed to be designed as a nature reserve. Artificial fish ponds host (chapter 4.2) also significant natural values, although water intake for these ponds is a problem in river management. River management planning is currently based on the assessment of its ecological status according to the data of the National Water Monitoring, and the river is divided into two water bodies (RW600019132499, RW600017132449). However, diagnostic monitoring was not carried out at all for the upper part of the river, and most of the required quality elements were not tested in the lower part, making the assessments unreliable. More detailed field studies (hydromorphology, macrophytes, fish, benthos - Chapter 2) show that the condition of individual elements varies along the course of the river and data from a single monitoring site are not representative for the entire river. The objectives of the program of conservation measures should include, in addition to general environmental objectives, the following: maintaining of natural values, maintaining of river flow, restoration of ecological continuity, achieving more natural hydromorphology, riverside afforestation and developing of buffer zones, ensuring self-maintenance of the river bed (chapter 6.2). The following measures are proposed: areal water retention and restoration of wetlands in the catchment (but not construction of reservoirs in the river course!), adjusting water abstraction permits to the requirement of maintenance of environmental flow, removing or mitigating lateral barriers, modification of the river maintenance scheme, introduction of trees on the banks, introduction of small structures imitating natural ones in the river bed, maintaining

of the river's free migration corridor, point restoration of the function of the oxbow lake (chapter 6.3, fig. 31-33)." In the course of research on the odonatafauna of the in Opole, in 2015 and 2021, 16 species of dragonflies were found in the catchment area of Bogacica (Dragonflies Observation Database of the Nature Dept of the Museum of Opole Silesia in Opole - obser. Piotr Zablocki, Michal Wolny). Among the dragonflies associated with the river itself, two protected species deserve attention - *Ophiogomphus cecilia* and *Cordulegaster boltonii*. *O. cecilia* observed near Radomierowice, Swieciny and Domaradzka Kuznia is a species listed in Annex II of the Habitats Directive, while *C. boltonii* found near Swieciny is a species from the Polish Red Book (status VU; Glowacinski and Nowacki 2004). **21473.** Rodrigo de Araujo, B.; Pinto, A.P.; Padial, A.A. (2022): Influence of landscape homogenization due to river damming on dragonfly (Odonata) community structuring in a subtropical forest in the southern Atlantic Forest. *Ecohydrology* 15(3), e2419: (in English) ["Human activities affect the structure, dynamics, and energy flow of aquatic ecosystems. River damming, a common anthropic impact in Brazil, changes solar incidence, water flow, and temperature of waterbodies, thereby affecting their fauna. Due to their high sensitivity to environmental changes, the Odonata may be indicators of these impacts. We sampled two ecologically distinct sites, (1) a quasi-pristine forested area; and (2) a nearby human-impacted reservoir landscape, to evaluate the effects of damming on odonate community structure. The species composition of quasi-pristine communities was more heterogeneous and differed almost completely (indicating high turnover) from that of the reservoir-area communities. The capacity of the reservoir to maintain local fauna was almost nil. The communities in the changed landscape had the highest local diversity, which is related to the high occurrence of widespread generalist South American species. We also tested two recently proposed bioindication ratio tools based on the richness or abundance of high-level taxonomic categories; both effectively reflected the extent of the impacts of damming. The best performing ratios were *Coenagrionidae*/other Zygoptera richness ratio, *Zygoptera*/*Anisoptera* abundance ratio, and *Libellulidae*/other *Anisoptera* richness ratio. The reservoir landscape promotes biotic homogenization. However, the water supply system entails the preservation of part of the native habitat in its surrounding areas, consequently maintaining forest-dependent biodiversity in quasi-pristine environments." **21477.** Somal, D.S.; Walia, G.K (2022): Cytological study of family Aeshnidae (Odonata: Anisoptera) from India: A review. *Biosciences Biotechnology Research Asia* 19(4): 843-855. (in English) ["Cytological review of 59 aeshnid species and cytogenetic investigations on *Anax ephippiger*, *Anax immaculifrons*, *Anax indicus*, *Anax nigrofasciatus nigrolineatus*, *Anax parthenope*, *Gynacantha subinterrupta* of the family Aeshnidae by carbol fuchsin staining 20023 and C - banding have been under taken. All the species possess  $2n = 27m$  with X0 - XX sex determination except *Anax ephippiger* with  $2n = 14 + neo XY$ , resulted by the 13 simultaneous fusions among the autosomes and between autosome and sex chromosome. The structure and behaviour of chromosomes, variation in size of m chromosomes and X chromosome and distribution of C - heterochromatin have been studied and compared among the species. C - bands are mostly present at the terminal regions of autosomal bivalents, while *Anax ephippiger* and *Anax parthenope* also possess C - bands at the interstitial and sub-terminal regions of the bivalents. Moreover, sex chromosome and m bivalent show variation in distribution of C-heterochromatin in the species. Out of these, chromosome complement of *Anax indicus* Lieftinck, 1942 and C - banding on *Anax ephippiger* and *Anax indicus* have been investigated for the first time. List of cytologically studied species of family Aeshnidae has

been updated to 60 species." (Authors)] Address: Walia, Gurinder Kaur, Dept Zool. & Environmental Sciences, Punjab Univ. Patiala, Punjab, India. Email: gurinderkaur\_walia@yahoo.co.in

**21478.** Theivaprakasham, H.; Darshana, S.; Ravi, V.; Sowmya, V.; Gopalakrishnan, E.A.; Soman, K.P. (2022): Odonata identification using Customized Convolutional Neural Networks. *Expert Systems with Applications* 206, 15 November 2022, 117688: (in English) ["Highlights: • We introduce a large-scale research-grade odonates image dataset. • Detailed investigation on CNN models for various input image resolutions. • Customized DenseNet161 (450px × 450px) had the highest top-1 accuracy. • Class Activation Map analysis was performed to evaluate the CNN models. Abstract: Alarming decline of the Odonates population needs urgent conservation efforts to balance nature's food cycle and to reduce the negative impact on humans such as increasing the mosquito borne diseases. The existing odonates identification approaches are not efficient and are mainly based on domain expertise which is highly time-consuming and expensive. The fast-growing Artificial Intelligence technologies have shown impressive solutions to many real-world problems including wildlife conservation and management. In this study, we proposed the use of Convolutional Neural Networks (CNN) for the identification of odonates. Firstly, we create a large Odonates image dataset comprising of 64,176 images belonging to 256 species of odonates. Secondly, we employ nine Customized CNN architectures namely AlexNet, DenseNet121, DenseNet161, DenseNet201, ResNet18, ResNet101, ResNet152, SqueezeNet v1.1, and VGG19 to train our odonates image dataset. Finally, we then compared and empirically studied the performance of our proposed CNN architectures at various image resolutions (224px × 224px, 350px × 350px, 450px × 450px and 550px × 550px). Our pretrained custom DenseNet161 (450px × 450px) performed with highest top-1 accuracy (93.53%), ResNet152 (224px × 224px) with the highest top-3 accuracy (98.07%), DenseNet121 (450px × 450px), and ResNet152 (224px × 224px) with highest top-5 accuracy (98.85%) and DenseNet201 (550px × 550px) with highest F1 score (86.17%). SqueezeNet v1.1 performed the least with highest top-1 accuracy of 83.3%, highest top-3 accuracy (94.24%), highest top-5 accuracy (96.59%), and the highest F1 score (77.68%). The results of our study show that odonates can be reliably and instantly identified using our proposed methodology and the customized model." **21481.** Varadinova, E.; Sakelarieva, L.; Park, J.; Ivanov, M.; Tyufekchieva, V. (2022): Characterisation of macroinvertebrate communities in Maritsa River (South Bulgaria)—Relation to different environmental factors and ecological status assessment. *Diversity* 2022, 14, 833. 12 pp. (in English) ["A survey of the macrozoobenthos communities in the Maritsa River (South Bulgaria) was carried out in the summer of 2021. Benthic samples were collected and physico-chemical parameters (water temperature, pH, conductivity, dissolved oxygen and nutrients) were measured at 15 sites located on the main river and its tributary system. The studied sites belonged to different river types and characterised the diversity of the ecological conditions—from unaffected to anthropogenically influenced river stretches. In addition, data from a study conducted in the summer of 2020 were used to analyse species–factor interactions in the river ecosystems and to assess the bio-indicative potential of the aquatic invertebrates. The dynamics of the taxonomic composition and abundance of the macrozoobenthos were analysed in relation to environmental factors. The physicochemical conditions of the water environment changed during the period of high water, which led to a reduction in the composition of the macrozoobenthos. Plecoptera and Trichoptera decreased in richness and abundance downstream and under human impacts. Ephemeroptera and Chironomidae were permanently present along the whole river. Oligochaeta increased in the lower river reaches and at sites with a greater amount of organic matter. The ecological status determined by the macrozoobenthos varied from high (site 1) to good, moderate and bad (site 13) at the studied sites." (Authors) The study includes "Odonata".] Address: Varadinova, Emilia, Dept Geography, Ecol. & Environ. Protection, Faculty Mathematics & Natural Sci., South-West Univ. **21482.** Westermann, K. (Ed.) (2022): Die Moorlibellen des Südschwarzwalds. Populationen und Lebensräume und ihr Schutz bei fortschreitendem Klimawandel. *Naturschutz am südlichen Oberrhein* 11: 1-248. In German, with English summary ["The moor dragonflies of the Southern Black Forest. Populations and habitats and their protection in the progressing climate change. - From 2011 to 2022, K. and E. Westermann recorded the occurrences of moor dragonfly species in the moors of the Southern Black Forest on a voluntary basis - two to three decades after the only comprehensive investigations were done by K. Sternberg. Over twelve years, around 150 moors or dystrophic ponds were visited at least once. In moors with significant populations, recordings were carried out every one to two weeks at the most and monitoring every five years has started. In some years, the monitoring was limited due to unfavourable weather conditions. In 66 areas at least one species of moor dragonflies was recorded. More than half of all moors did not have

any potential water bodies for reproduction. These moors have been significantly affected by human activity since the Middle Ages through drainage, eutrophication, afforestation, transformation into meadows and pastures or manual peat digging. Some peatlands are currently regenerating in part after renaturation measures, the discontinuation of maintenance of ditches or the settlement of beavers (*Castor fiber*). The regeneration has resulted in positive effects on the occurrence and populations of moor dragonflies, which could be clearly documented in several cases. Species were classified as "moor dragonflies" if they only develop in moor waters or in dystrophic ponds in the Southern Black Forest or if their main distribution is there. *Aeshna subarctica* and *Aeshna juncea*, *Somatochlora alpestris* and *Somatochlora arctica*, *Leucorrhinia dubia*, *Sympetrum danae* and *Coenagrion hastulatum* were identified regularly. The occurrences of *Aeshna subarctica* and *Somatochlora alpestris* are especially of supra-regional importance, and responsibility for their conservation is a priority. The last population of *Aeshna caerulea* apparently ceased to exist about 20 years ago. The populations are concentrated in the moor-rich areas around Hinterzarten, Feldberg and Oberer Hotzenwald. Over the last few decades, the moor dragonfly populations of the Southern Black Forest changed considerably less than the populations in the individual moors. Collection of exuviae was considered as the most meaningful method for recording, and was conducted if it could be carried out with reasonable effort. Proof of successful larval development is a good indicator of the condition of the moors. In years with prolonged hot and dry phases, it was mainly the water bodies in partially drained moors with low or strongly fluctuating water levels or generally flat-water bodies that dried up. As climate change progresses, such extreme weather conditions will occur more frequently, meaning that the populations of most species of moor dragonflies are severely endangered or even threatened by extinction. The further development and care of the moors and their larval waters with high occurrences of moor dragonflies, which make up a decisive part of the respective Southern Black Forest population, are therefore of outstanding importance. However, the rapid renaturation of many affected moors is of similar importance but has not been able to keep up with the progressing climate change. If possible, species protection measures should make a real contribution to stabilizing the regional population. Of primary considerations are waterlogging, deepening and enlargement of small moor ditches as well as waterlogging of former manual peat diggings. Due to climate change, a comprehensive 20-year plan for renaturation measures and the rapid implementation are required. The condition of 133 areas is briefly described and concise proposals for renaturation and species protection measures are presented. If a significant part can be considered feasible and implemented in the next 20 years, the protection of the moors of the Southern Black Forest and their organisms will probably be reasonably secured despite climate change. The Baden-Württemberg moor register is now an excellent tool that can be used to plan future measures. At least the larger or more powerful of the many peat deposits listed there should be protected from further destruction by systematic rewetting, primarily for reasons of climate and moor protection." **21483.** White III, H.B.; White Jr., J.F.; Moore, M.C. (2022): Dragonfly biodiversity at abandoned work sites: Dredge-spoil ponds of the Chesapeake and Delaware Canal, New Castle County, Delaware. *Northeastern Naturalist* 29(2):

262-294. (in English) "There are few undisturbed, freshwater habitats remaining in the populated areas of the United States. Aquatic organisms, such as dragonflies (Odonata), have therefore either had to adapt to disturbed and modified secondary habitats, such as farms, golf courses, storm-water remediation basins, and community-park ponds, or risk extirpation. The species that readily adapt to these habitats are usually widespread common species. However, other aquatic habitats inadvertently created at abandoned work sites often evolve distinctive characteristics over time that provide refuge for species rarely or never found at deliberately created pond habitats. For 17 years, we have monitored the diverse Odonata fauna at several floristically distinct ponds formed in depressions left from the dredging of the Chesapeake and Delaware Canal in the 1960s. Among the species found are ones not known elsewhere locally or ones found in unusual abundance at 1 or more of the ponds, though infrequently encountered regionally. These dredge-spoil ponds are important for conserving regional Odonata biodiversity by providing unique habitats in an increasingly urbanized environment." **21484.** Xu, M.; Fincke, O.M. (2022): Negative body size-dependent resource allocation underlies conspicuous sexual ornaments in a territorial damselfly. *Journal of Evolutionary Biology* 35(2): 288-298. (in English) ["Sexual ornaments, signaling individual quality to choosy females or rival males, often show steeper body size scaling compared to non-sexually selected traits. Theory posits such steeper body size scaling is the result of differential resource allocation, reflecting trade-offs between different components of fitness. Yet the process of resource allocation towards body size-dependent sexual ornaments has been rarely understood empirically. Using the Neotropical territorial damselfly *Megaloprepus caerulatus*, whose males and females carry wax-based, sex-specific white wing bands and white wing tips respectively, we investigated nutrition sensitivity and body size scaling of both traits by manipulating larval food availability and directly quantified both the fat allocated to wing ornaments and the fat reserve from which allocations are made. Both color traits exhibited sensitivity to food availability during larval development and steeper body size scaling compared to control traits. Although the absolute amount of fat invested in developing the color ornaments increased with body size, the proportion of total fat allocated to the ornaments decreased with body size, making exaggerated ornaments less affordable for smaller individuals. Our data demonstrate that measuring the proportion of resource pool from which an individual's ornaments are derived (i.e., its affordability) is essential for understanding the maintenance of honesty of sexual signals." **21485.** Zheng, Y.; Qu, Q.; Liu, P.; Hu, T. (2022): Ground effect of a two-dimensional flapping wing hovering in inclined stroke plane. *Journal of Fluids Engineering* 144(11): 111206: 11 pp. (in English) ["The ground effect aerodynamics and flow physics of a 2D dragonfly wing hovering (the Reynolds number is 157) in an inclined stroke plane are investigated via solving 2D unsteady incompressible laminar flow Navier-Stokes equations. An analysis road map is proposed to explain the influence of the ground on the flow field, pressure distribution on the wing surface, and the aerodynamic force. In the analysis road map, the flow relative

to the wing surface induced by the wing motion and vortex is classified into vertical and parallel wing surface flows. The vertical flow impinges on the wing surface to form a positive pressure zone. In contrast, the parallel flow generates the boundary layer and further concentrated vortex and secondary vortex, which induce negative pressure on the wing surface. The ground impacts the flow relative to the wing in three ways: changing the trajectory of the shed vortex by the mirror effect, promoting the deformation and fusion of the vortices, and causing the cushion effect at extremely small ground clearance." **21486.** Aghade, J.B.; Saraf, S.A. (2023): Seasonal variation of odonate diversity in harsul and Salim Ali Lake, Aurangabad, Maharashtra, India. *Acta Entomology and Zoology* 4(1): 103-105. (in English) ["Odonates are intriguing insects that serve as crucial indicators of the environment's health and water supply. In the form of predators and prey, they are important animals in both the terrestrial and aquatic food webs. In 2021–2022, a study on odonates' variety and seasonal fluctuation were carried out at the Harsul and Salim Ali Lake in Aurangabad, Maharashtra, India. Both locations are popular tourist destinations on the outskirts of Aurangabad, with a sizable pond just next to the palace. The location has luxuriant vegetation and gardens. Photo of adult specimens. The specimens were kept on file. Different identification keys were used to identify species. 11 species of Odonates were found in total, spread across 3 families, according to the study, 8 species were dragonflies and 3 were damselflies. The most prevalent species was *Crocothermis servilia*, and the least prevalent was *Acisoma panorpoides*. The monsoon and post-monsoon seasons saw the highest levels of odonate abundance, whereas summer saw the least amount of reduction. The enhanced abundance can be linked to favorable vegetation, perching places, breeding circumstances, high rainfall, and humidity (83%-94%) with a temperature range of 24.5 °C to 29.5 °C. The findings from the current study serve as the site's baseline for future taxonomy-based research and conservation efforts. Additionally, it will spur interest in odonate diversity studies." (Authors) The study includes three European species, which of course are misidentifications.] Address: Aghade, J.B., Dept of Zoology, Government College of Arts and Science, Dr. B.A.M. University, Chhatrapati Sambhaji Nagar, Aurangabad, Maharashtra, India

**21487.** Archibald, S.B.; Ware, J.L.; Rasmussen, J.A.; Sylvestersen, R.L.; Olsen, K.; Simonsen, T.J. (2023): The damselfly genus *Furagrimon* Petrulevicius et al. (Odonata, Zygoptera) from the early Eocene Fur Formation of Denmark and the dysagrionoid grade. *Zootaxa* 5278(2): 289-317. (in English) ["The earliest Eocene odonate genus *Furagrimon* Petrulevicius et al. from the Danish Fur Formation is revised based on eighteen specimens, two of which apparently have been lost since their publication. The holotype of *Phenacolestes jutlandicus* Henriksen, type species of *Furagrimon*, is incomplete and lacks the characters currently used to differentiate species, genera and higher taxa in Odonata. We, therefore, propose that the holotype is set aside and a recently discovered nearly complete Fur Formation fossil is designated as neotype. *Furagrimon* possesses all of the nine wing character states currently used along with head shape for diagnosing the Dysagrionidae; however, *Furagrimon* has a characteristically zygopteran head, not the distinctive head shape of the suborder Cephalozygoptera. We, therefore,

treat it as a zygopteran unassigned to family. These nine wing character states appear in different combinations not only in various Zygoptera and Cephalozygoptera, but also in the Frenguelliidae, an Eocene family of Argentina that may represent an unnamed suborder. We recognise these taxa as constituting a dysagrionoid grade, in which these character states appear either convergently or as symplesiomorphies. *Furagrion morsi* Zessin is synonymized with *Phenacolestes jutlandicus* Henriksen, syn. nov. and *Morsagrion* Zessin with *Furagrion Petrulevicius*, Wappler, Wedmann, Rust, and Nel, syn. nov." **21488.** Beatty, C.D.; Alves-Martins, F.; Smith, B.D.; Verheyen, J. (2023): Chapter 13 - Biogeographical ecology in Odonata. In: *Dragonflies and Damselflies*. Second Edition. Edited by Alex Córdoba-Aguilar, Christopher D. Beatty and Jason T. Bried, Oxford University Press. © Oxford University Press (2023). DOI: 10.1093/oso/9780192898623.003.0013: 167-186. (in English) ["Biogeography — the study of the factors influencing the distribution of organisms in space and time—has a number of applications in modern research on odonates. Studies considering phylogenetic and geological information to infer past and extant patterns of biodiversity (known as historical biogeography, Jenkins and Ricklefs 2011) are considerably enhanced by ecological biogeography, providing a more complete view of the forces structuring odonate diversity. This chapter reviews current knowledge of the distribution of odonates globally, and also considers work in a number of active research areas in odonate biogeography, including the influence of climate on changing distribution, life-history attributes, adaptation to changing landscapes, and the use of biogeographical methods in odonate conservation. It concludes that, while recent decades have seen much important work, much remains to be done to understand global odonate distributions, and to safeguard odonate diversity." **21492.** Calvão, L.B.; Brito, J.; Ferreira, D.; Cunha, E.J.; Oliveira-Junior, J.M.B.; Juen, L. (2023): Effects of the loss of forest cover on odonate communities in eastern Amazonia. *Journal of Insect Conservation* 27: 205-218. (in English) ["In recent decades, the conversion of native forests into anthropogenic landscapes has been impacting progressively the physical habitat of the aquatic systems of Brazilian Amazonia. Given this, we evaluated the effects of the loss of natural vegetation cover on the diversity and morphology of Amazonian odonates (Zygoptera and Anisoptera). To do so, we sampled adult odonates at 50 streams in eastern Brazilian Amazonia. We evaluated land use patterns at each site together with two morphological metrics (length of the thorax and the abdomen) of the odonates. We found a positive relationship between natural vegetation cover and both odonate species richness, in general, and the proportion of zygopteran species richness. However, the relationship was negative for all the anisopteran diversity metrics. We also found only negative relationships in the anisopteran abdomen when we investigated the variation in morphological trait change points. We identified 12 species that were associated with natural forest cover, six (all zygopterans) with more forested environments, and six species (three anisopterans and three zygopterans) that were associated with environments with reduced vegetation cover. The results of the present study indicate that preserving continuous natural vegetation cover together with the riparian vegetation will be crucial to the maintenance of the physical characteristics of streams and the structure of the odonate community. The presence of adult odonates was also associated with the quality of both the aquatic and the terrestrial environments, given that their effects on odonate diversity were detected within a 500 m buffer around the streams. Implications for insect conservation The analysis of landscape metrics may increase the potential of the associations observed between the characteristics of natural communities and the loss of natural vegetation cover, in particular in the case of the forest specialists. The application of analyses based on these metrics should better support the development of more effective mitigation measures." **21493.** Cheri, C.R.; Finn, D.S. (2023): Odonata as Indicators? Dragonflies and Damselflies Respond to Riparian Conditions along Ozark Spring Streams. *Hydrobiology* 2(1): 260-276. (in English) ["The Odonata are not typically regarded as informative taxa for stream bioassessment in North America compared to other insects, particularly when monitoring the ecological impacts of organic pollution. However, we hypothesized that stream-dwelling odonates are useful bioindicators of riparian conditions because vegetation associated with streams is used for oviposition and establishing breeding territories and is likely a cue for a suitable nymphal habitat. We sampled odonates from multiple microhabitats and all macroinvertebrates from riffle habitat in 12 Ozark Highlands (USA) spring streams along a gradient of riparian conditions. We also measured a standard suite of physical and chemical variables in each stream. We compared various aspects of the odonate and riffle macroinvertebrate assemblages among sites to evaluate sensitivity to variables associated with riparian structure compared to the other physical and chemical variables measured. The odonates were strongly associated with riparian-specific variables, while riffle macroinvertebrates were associated with riparian variables to a lesser degree. The additional environmental variables explained minimal variation in either assemblage. Overall, our results suggest that Odonata alone could be useful for biomonitoring associated with riparian structure around Ozark spring streams. The sensitivity of odonates to riparian conditions in other Nearctic regions should be further studied to identify regional and species-specific differences." **21494.** Cordero-Rivera, A.; Rivas-Torres, A.; Encalada, A.C.; Lorenzo-Carballa, M.O. (2023): Sexual conflict and the evolution of monandry: The case of the damselfly *Ischnura hastata* (Odonata: Coenagrionidae) in the Galápagos Islands. *Ecological Entomology* 48: 336-346. (in English) ["1. Sexual selection favours the evolution and maintenance of polygamy, which is the dominant reproductive strategy in insects. Monogamy can evolve in very short-lived species due to time constraints. Here we study adult activity and mating behaviour of a population of *Ischnura hastata*, a species rarely seen mating, and which has been suggested to be monandric, in wetlands of Isabela Island, Galápagos. 2. By means of mark-recapture methods, we estimated that the daily survival rate was low, ranging from 0.385 to 0.876, yielding average life expectancies of mature individuals of only 1.2–3.2 days. Adults showed very low activity before 7:00, indicating that mating does not occur early. The number of male–female interactions and mating attempts was extremely low, with only 44 copulations recorded on over 230 h of observations. 3. Copulations were brief, with a mean duration of 11 min (but only two were observed from the start). Males showed clear preference to attempt to grasp in tandem females of intermediate age (in 94.3% of cases), rather than young (31.3%) or mature females (24.0%). Males were very persistent once a tandem was achieved, retaining females for up to 139 min, but most females resisted and did not copulate. 4. We conclude that females of *I. hastata* show a very short time window to mate, exactly when they change colour from juvenile to mature, and live only enough to mate once. Short lifespan has selected for female monandry in *I. hastata*, creating an intense sexual conflict over mating rates." **21495.** Costa, F.M.O.; Tubelis, D.P. (2023): Citizen Science for the study of birds in distinct biomes: Diet of the Rufous-Tailed Jacamar (*Galbula ruficauda*) (Aves, Galbulidae) in Brazil. *International Journal of Zoology and Animal Biology* 6(2): 10 pp. (in English) ["Data obtained by citizen scientists have been used by researchers to study the natural history of tropical birds in several countries. For example, this approach has been increasing the knowledge about their feeding ecology, as many photographs show birds holding prey with their foot and/or bill. Due to this, the diet of numerous bird species can be examined with citizen science data. The Rufous-tailed Jacamar (*Galbula ruficauda*) is a forest bird species widely distributed throughout the Neotropics, and its diet was scarcely quantified in a few localities. This study aimed to investigate the diet of the Rufous-tailed Jacamar in three Brazilian biomes: the Caatinga, the Cerrado and the Atlantic Forest. Searches for photographs with evidence of feeding activities were done in February 2021 in the WikiAves and eBird databases, the major citizen science projects regarding birds found in Brazil. For each selected record, the captured prey was tentatively identified to the taxonomic Order level, and the date of obtention was classified as part of dry or rainy periods. The chi-square test was used to compare the numbers of prey of distinct insect orders in different periods and biomes. A total of 283 feeding records were obtained by citizen scientists in the Caatinga (12%) and surrounding portions of the Cerrado (45%) and the Atlantic Forest (43%). Captured prey comprised seven insect orders, and 15% of them could not be identified. In the Cerrado, the most numerous prey in its diet were those of the orders Lepidoptera and Odonata, followed by Hymenoptera and Hemiptera, in both the dry and rainy periods. On the other hand, substantial seasonal variation was observed in the Atlantic Forest. Records with Lepidoptera were more numerous than those with other insects in the dry period, while Hymenoptera had more records than other orders in the rainy period. In the Caatinga, prey with more records were those of the orders Odonata, Lepidoptera and Hymenoptera. This study suggests that photographic records available in citizen science databases, such as WikiAves and eBird, can be used to improve our knowledge about the diet of birds found in the Neotropics." (2023): Uncertainty about old information results in differential predator memory in tadpoles. *Proceedings of Royal Society B* 290: 20230746. <https://doi.org/10.1098/rspb.2023.0746>: 6 pp. (in English) ["As information ages, it may become less accurate, resulting in increased uncertainty for decision makers. For example, chemical alarm cues (AC) are a source of public information about a nearby predator attack, and these cues can become spatially inaccurate through time. These cues can also degrade quickly under natural conditions, and cue receivers are sensitive to such degradation. Although numerous studies have documented predator-recognition learning from fresh AC, no studies have explored learning from aged AC and whether the uncertainty associated with this older information contributes to shortening the retention of learned responses (i.e. the 'memory

window'). Here, we found that wood frog tadpoles, *Lithobates sylvaticus*, learned to recognize a novel odour as a predator when paired with AC aged under natural conditions for up to 1 h. However, only tadpoles conditioned with fresh AC were found to retain this learned response when tested 9 days after conditioning. These results support the hypothesis that the memory window is shortened by the uncertainty associated with older information, preventing the long-term costs of a learned association that was based on potentially outdated information." **21501.** Forister, M.L.; Black, S.H.; Elphick, C.S.; Grames, E.M.; Halsch, C.A.; Schultz, C.B.; Wagner, D.L. (2023): Missing the bigger picture: Why insect monitoring programs are limited in their ability to document the effects of habitat loss. *Conservation Letters*. 2023:e12951.: 6 pp. (in English) ["The fate of insects in the Anthropocene has been widely discussed in the scientific literature, the popular media, and in policy circles. This recent attention is justified because reductions in insect abundance and diversity have the potential to undermine the stability of terrestrial ecosystems. Reports of insect declines have also been accompanied by skepticism that is healthy and to be expected in scientific discussion. However, we are concerned about a prevalent misconception that equates reports from monitored natural areas with the global status of insects. In the vast majority of cases, areas monitored for arthropods are undeveloped and thus do not record or even necessarily reflect the masses of insects that are continuously being impacted by habitat loss to urban, suburban and agricultural expansion. We address this misconception and discuss ways in which conservation and policy can be enhanced by correctly locating results from insect monitoring programs within our broader knowledge of biodiversity loss." (Authors) The paper includes a passing reference to Odonata.] Address: Forister, M.L., Department of Biology, University of Nevada, Reno, NV 89557, USA. Email: forister@gmail.com

**21502.** Fujita, Y.; Lima, M. (2023): Aerodynamic performance of dragonfly wing model that starts impulsively: how vortex motion works. *Journal of Fluid Science and Technology* 18(1): 1-10. (in English) ["The cross-section of dragonfly wings has corrugated structures. In particular, the leading-edge side of the wing consists of V-shaped structures. According to previous studies, a corrugated wing may exhibit high aerodynamic performance at low Reynolds numbers ( $Re = O(10^3)$ ), and vortex dynamics associated with wing structure are expected to play an important role. We study the relationship between the wing structure and vortex dynamics by direct numerical simulations. It is known that, when a two-dimensional flat wing impulsively starts from a rest state, a coherent vortex called lambda vortex, which has the opposite sign to a leading-edge vortex (LEV), is generated and remains for a time interval. Our previous study suggests that, in the case of the corrugated wing, the lambda vortex collapses and is stuck inside V-shaped structures near the leading edge. The collapse of the lambda vortex was proposed as a key factor of high performance for the particular shape of the corrugated wing. In this paper, we investigate the relationship between vortex dynamics

and high performance in a wider parameter range than in our previous studies. We analyse two corrugated models with different Reynolds numbers. It is revealed that the collapse of the lambda vortex is also the key to high performance for these cases." **21503.** Gazzola, A.; Balestrieri, A.; Pellitteri-Rosa, D. (2023): Embryonic exposure to native and alien predator cues tunes tadpole defensive behaviour. *Aquatic Ecology* 57: 421-431. In English ["When exposed to predation risk, some amphibian species show innate responses, while others recognize their predators by learning. To explore the role played by each mechanism in the assessment of predation risk, we investigated the effects of embryonic and larval exposure to predator chemical cues on tadpole defensive responses, including behavioural, morphological and life history traits. In the first experiment, agile frog (*Rana dalmatina*) embryos were exposed to the odour of either native (*Aeshna cyanea* larvae) or alien (*Procambarus clarkii*) predators each day from egg collection to hatchling (14 days). Body measures (mass, developmental stage, body length, tail length and tail depth) were recorded at hatching and a behavioural test was conducted to explore tadpole responses to predator cues and the potential interaction with their previous embryonic experience. In general, embryonic conditioning did not affect life history traits, except for a slight reduction in tail depth:length ratio for tadpoles exposed to odonate odours. Controls (embryos treated with water) after hatchling reduced their activity when exposed to gammarid-fed odonate cues, suggesting that responses were at least partially innate. Tadpoles exposed to odonate cues as embryos showed a strong defensive response when exposed to dragonfly kairomones. Tadpoles exposed to gammarid-fed crayfish as embryos showed clear behavioural responses towards the same cue (irrespective of predator diet). Overall, our results suggest that embryonic exposure may tune the defensive responses of the larval stage and early exposure to naïve stimuli may promote their cautionary associations with predation risk." **21504.** Glutz von Blotzheim, U.N. (2023): Die Libellenfauna eines Gartenweiher am Rande von Schwyz. *Berichte der Schwyzerischen Naturforschenden Gesellschaft* 19: 1, 26 pp, App. (in German, with English and French summaries) ["The dragonfly and damselfly fauna of a small garden pond at the edge of a country town with 15,000 inhabitants in rural Central Switzerland. — After a several years of raising the skill level by observing the Odonata on small ponds in our gardens, I began with subsequent monitoring and taking photos in the year 2005. Up to present I found 8 generalist species reproducing in our garden in Schwyz and another 24 species as episodic guests, some with copulations and egg laying but without real proof of successful reproduction. By comparing with the Odonata species richness of some Swiss wetland nature reserves, this rather surprising result encourages wildlife gardening as contribution to the promotion of biodiversity and to amazing experiences. Wetland plant species richness, important for provision of perches, thermoregulation, oviposition and emergence rate, seems to be the main reason for the rather high species richness of dragonflies and damselflies on our pond. Their survey is fascinating and promises moreover detailed observations, which are not easily achieved on

shores of lakes or rivers. In any case, I got in due time some insight in the Odonata assemblages, as well as the phenology, the population fluctuation and the behaviour of some species." (Author)] Address: not stated

**21505.** Goodman, A.M.; Kass, J.M.; Ware, J. (2023): Dynamic distribution modelling of the swamp tigertail dragonfly *Synthemis eustalacta* (Odonata: Anisoptera: Synthemistidae) over a 20-year bushfire regime. *Ecological Entomology* 48(2): 209-225. (in English) ["Intensity and severity of bushfires in Australia have increased over the past few decades due to climate change, threatening habitat loss for numerous species. Although the impact of bushfires on vertebrates is well-documented, the corresponding effects on insect taxa are rarely examined, although they are responsible for key ecosystem functions and services. Understanding the effects of bushfire seasons on insect distributions could elucidate long-term impacts and patterns of ecosystem recovery. Here, the authors investigated the effects of recent bushfires, land-cover change, and climatic variables on the distribution of a common and endemic dragonfly, (*S. eustalacta*) (Burmeister, 1839), which inhabits forests that have recently undergone severe burning. The authors used a temporally dynamic species distribution modelling approach that incorporated 20 years of community-science data on dragonfly occurrence and predictors based on fire, land cover, and climate to make yearly predictions of suitability. The authors also compared this to an approach that combines multiple temporally static models that use annual data. The authors found that for both approaches, fire-specific variables had negligible importance for the models, while the percentage of tree and non-vegetative cover were most important. The authors also found that the dynamic model outperformed the static ones, based on cross-validation omission rate. Model predictions indicated temporal variation in area and spatial arrangement of suitable habitat, but no patterns of habitat expansion, contraction, or shifting. These results highlight not only the efficacy of dynamic modelling to capture spatiotemporal variables such as vegetation cover for an endemic insect species, but also provide a novel approach to mapping species distributions with sparse locality records." **21506.** Hämäläinen, M.; Fliedner, H. (2023): Why did William Eiford Leach call a small damselfly a 'pirate'? - Revisiting the etymology of the genus *Lestes* (Odonata: Lestidae). *Notulae odonatologicae* 10(1): 8-16. (in English) ["We present evidence supporting the widely accepted interpretation that the genus name *Lestes* Leach, 1815, is based on the Greek masculine word  $\lambda\epsilon\sigma\tau\eta\varsigma$ ; [*lestes*] meaning 'robber or pirate'. Comparison of Leach's brief definition of *Lestes* with that of the genus *Agrion* Fabricius, 1775, from which the new genus was split, suggests that W.E. Leach selected the piratical name because the males of species in this genus are armed with pincer-shaped appendages; hence the name is an allusion to the edged weapons carried by pirates. The common view that the name was suggested by the voracious predatory behaviour of lestids, as well as the interpretation that the genus name is based on the French word *teste* [= nimble] are both rejected." In: Dragonflies and Damselflies. Second Edition. Edited by Alex Córdoba-Aguilar, Christopher D. Beatty and Jason T. Bried, Oxford University Press. © Oxford University Press (2023). DOI: 10.1093/oso/9780192898623.003.0006: 73-84. (in English) ["Parasites and pathogens are a ubiquitous threat facing organisms within every ecological network. To protect themselves from parasites, organisms have evolved immune defenses. Insect immunity has received a great deal of attention, with numerous studies investigating the intersection of parasite pressure, immune function, and ecology. This chapter highlights how the investigation of odonate immunity has provided insight into how insect immunity operates within the ecological theatre under the threat of parasites. It first explains why odonates are an excellent model system for studies of immunity and parasites. It then reviews what is known of the parasites odonates harbor. Then, it covers the myriad mechanisms employed by odonates to defend themselves from their parasitic enemies. It also discusses key ecological and evolutionary studies that fall at the intersection of immunity and parasites" (Authors)] Address: Hasik, A.Z., Department of Biological Sciences, University of Arkansas, SCEN 601, 850 W. **21509.** Huang, L.; Duan, Y.; Shi, Y.; Pang, H. (2023): Bioinspired multiple-degrees-of-freedom responsive metasurface by high-entropy-alloy ribbons with hierarchical nanostructures for electromagnetic wave absorption. *Journal of Colloid and Interface Science* 636: 1-10. (in English) ["The compound eyes of *Pantala flavescens* are covered by micro-scaled ocelli capable of sensing polarized light, an attractive property for radar stealth and counterintelligence. In this work, we fabricated biomimetic electromagnetic wave absorption materials (EAMs) by analyzing the covert information identifications of biological systems and focusing on the design of metastructures and microstructures. Several bionic metasurfaces with anisotropic double-V meta atoms made up of  $(\text{FeCoNiSi}_{8.9}\text{Al}_{8.9})\text{C}_{0.2}$  high-entropy-alloy (HEA) ribbons for multiple-degrees-of-freedom recognition and broadband absorption are presented. The covert phase, amplitude, and angular momentum of electromagnetic waves were controlled and recognized as information by manipulating the rotation angle  $\theta$  of meta atoms. A vortex wave with a topological charge of 1 was generated to recognize linearly polarization and left- and right-handed circular polarization. In addition, the polarization conversion enhanced absorption. The hierarchical nanostructures of HEA ribbons give rise to suitable electromagnetic loss and a superior impedance match. Finally, inspired by the structure of compound eyes, the designed multilayer metamaterials realized effective absorption (reflection loss  $(\text{RL}) \leq -10$  dB) within the 4.5–18 GHz regime under 2.8 mm thickness. These materials provide evidence for a new way

for integrated EAMs and metamaterials." (Authors)] Address: Duan, Y., Key Laboratory of Solidification Control & Digital Preparation Technology (Liaoning Province), School of Materials Science & Engineering, Dalian Univ. Tech., Dalian 116085, P.R. China. Email: duany@dlut.edu.cn

**21510.** Ivkovic, M.; Baranov, V.; Doric, V.; Stankovic, V.M.; Previšić, A.; Vilenica, M. (2023): Aquatic Insects of Plitvice Lakes. In: Marko Miliša & Marija Ivkovic (eds.): *Plitvice Lakes*. Springer Cham: 275-316. (in English) ["Aquatic insects are the most species-rich group that inhabit freshwaters. They are connected to water by at least one life stage, usually that of the larvae, and some spend their entire life in freshwater habitats. The majority of aquatic insects' larvae develop in water; while adults emerge and spend their lives primarily in terrestrial environments where they mate, disperse and in some cases feed. Aquatic insects are sensitive to environmental conditions, which is why they are widely used in biomonitoring. Mayflies, stoneflies and caddisflies are among the most commonly used indicators, but other taxa also show high potential. In the Plitvice Lakes, there are confirmed records of 352 species of aquatic insects. The most abundant order of aquatic insects is Diptera, with 165 recorded species, followed by Trichoptera with 91 species, and Plecoptera with 31 species. All other aquatic insect orders are present with lower species richness, with 25 taxa recorded in Coleoptera, 18 taxa in Ephemeroptera and 14 in Odonata. Megaloptera and Neuroptera each have four species. The aquatic insects reflect the uniqueness and peculiarities of the barrage system of the Plitvice Lakes in both, their composition and ecology. Although some groups of aquatic insects have been well studied throughout the years, there are still many unknowns and many species that need to be recorded." **21511.** Jiang, X.-R.; Dai, Y.-Y.; Wang, Y.-R.; Guo, K.; Du, Y.; Gao, J.-F.; Lin, L.-H.; Li, P.; Li, H.; Ji, X.; Qu, Y.-F. (2023): Dietary and sexual correlates of gut microbiota in the Japanese Gecko, *Gekko japonicus* (Schlegel, 1836). *Animals* 2023, 13, 1365. 15 pp. In English ["Simple Summary: We used wild-caught Japanese geckos (*Gekko japonicus*) and captive conspecifics fed with mealworms and fruit flies to study their differences in gut microbial structure and composition and sexual correlates of gut microbiota. Gut microbial community richness and diversity were higher in mealworm-fed geckos than in wild geckos. The beta rather than alpha diversity of gut microbiota was sex dependent. From this study, we know the following. First, dietary and sexual correlates of gut microbiota are evident in *G. japonicus*. Second, with respect to the composition of gut microbiota, *G. japonicus* is more similar to the common leopard gecko than other reptilian taxa. Third, the diversity of gut microbiota is higher in geckos ingesting food with a higher chitin content. Abstract: Numerous studies have demonstrated that multiple intrinsic and extrinsic factors shape the structure and composition of gut microbiota in a host. The disorder of the gut microbiota may trigger various host diseases. Here, we collected fecal samples from wild-caught Japanese geckos (*Gekko japonicus*) and captive conspecifics fed with mealworms (mealworm-fed geckos) and fruit flies (fly-fed geckos), aiming to examine the dietary and sexual correlates of the gut microbiota. We used 16S rRNA gene sequencing technology to determine the composition of the gut microbiota. The dominant phyla with a mean relative abundance higher than 10% were Verrucomicrobiota, Bacteroidota, and Firmicutes. Gut microbial community richness

and diversity were higher in mealworm-fed geckos than in wild geckos. Neither community evenness nor beta diversity of gut microbiota differed among wild, mealworm-fed, and fly-fed geckos. The beta rather than alpha diversity of gut microbiota was sex dependent. Based on the relative abundance of gut bacteria and their gene functions, we concluded that gut microbiota contributed more significantly to the host's metabolic and immune functions. A higher diversity of gut microbiota in mealworm-fed geckos could result from higher chitin content in insects of the order Coleoptera. This study not only provides basic information about the gut microbiota of *G. japonicus* but also shows that gut microbiota correlates with dietary habits and sex in the species." **21512.** Johansson, F.; Berger, D.; Outomuro, D.; Sniegula, S.; Tunon, M.; Watts, P.C.; Rohner, P.T. (2023): Mixed support for an alignment between phenotypic plasticity and genetic differentiation in damselfly wing shape. *Journal of Evolutionary Biology* 36(2): 368-380. (in English) ["The relationship between genetic differentiation and phenotypic plasticity can provide information on whether plasticity generally facilitates or hinders adaptation to environmental change. Here, we studied wing shape variation in a damselfly (*Lesites sponsa*) across a latitudinal gradient in Europe that differed in time constraints mediated by photoperiod and temperature. We reared damselflies from northern and southern populations in the laboratory using a reciprocal transplant experiment that simulated time-constrained (i.e. northern) and unconstrained (southern) photoperiods and temperatures. After emergence, adult wing shape was analysed using geometric morphometrics. Wings from individuals in the northern and southern populations differed significantly in shape when animals were reared in their respective native environment. Comparing wing shape across environments, we found evidence for phenotypic plasticity in wing shape, and this response differed across populations (i.e.  $G \times E$  interactions). This interaction was driven by a stronger plastic response by individuals from the northern population and differences in the direction of plastic wing shape changes among populations. The alignment between genetic and plastic responses depended on the specific combination of population and rearing environment. For example, there was an alignment between plasticity and genetic differentiation under time-constrained, but not under non-time-constrained conditions for forewings. We thus find mixed support for the hypothesis that environmental plasticity and genetic population differentiation are aligned. Furthermore, although our laboratory treatments mimicked the natural climatic conditions at northern and southern latitudes, the effects of population differences on wing shape were two to four times stronger than plastic effects. We discuss our results in terms of time constraints and the possibility that natural and sexual selection is acting differently on fore- and hindwings." **21513.** Josemans, M.; van der Zee, F. (2023): Biodiversiteit toekomstig zonnepark Oudenhooft: Nulmeting van vegetatie, dagvlinders en libellen. Rapport / Wageningen Environmental Research No. 3246: 47 pp. (in Dutch, with English summary) ["A solar park in Oudenhooft [The Netherlands] will be built by Farm Frites early 2023 and will be operational at the end of 2023. The solar park and nature dikes were monitored in 2021 by students of HAS University of Applied Sciences. In 2022, Wageningen Environmental Research

made another inventory of the location and this inventory serves as a baseline measurement before the construction of the solar park. The following groups of species were inventoried: vegetation, butterflies and dragonflies. The quality of the soil also has been analysed. However, no responsible comparison can be made between the data of 2021 and 2022 due to observer effects, differences in approach, experience and knowledge and inaccurate locations. To improve the coverage of plant species on the nature dikes, it is important to mow the dikes twice a year and to dispose of the grass clippings. Resume The Farm Frites company in Oudenhooft has built a natural dike on its site (completed in March 2020) with clay soil, which comes from harvested potatoes. The dike and the adjacent terrain around the walking path were sown with a herbal mixture of flowers. In 2021, the dike will be inventoried by students from HAS Den Bosch for plants and some insect species. Farm Frites is currently developing a solar park on its property on a site that was previously used as farmland. The actual construction of that park is planned for spring 2023. The solar park will be 20 hectares in size and will have 46,500 panels, with a power production of 23.5 GWh per year. In addition to producing sustainable energy, the park is also intended to contribute to increasing biodiversity. 4 ha of new nature will be added with 2700 m of extra water bodies and more than 14,000 plants, bushes and shrubs will be planted. Farm Frites has asked Wageningen Environmental Research to draw up and implement a monitoring plan to evaluate how biodiversity will develop in the coming years. This report is an account of that monitoring from 2022. The aim was twofold: 1. Research into the development of biodiversity on the nature dike. Are there any changes compared to 2021 in which students have made an initial inventory? 2. Determining the zero situation at the location of the solar park to be built, so that by means of monitoring changes in biodiversity can be determined in the future and management can be adjusted if desired. In 2022, inventories of vegetation, butterflies and dragonflies will be made on the nature dikes, hiking trails and the future solar park. Vegetation recordings were made on fixed quadrats and transects were walked for the monitoring of butterflies and dragonflies. The differences between the vegetation recordings in 2021 and 2022 are large. This has to do with the following: 1. The difference in fieldwork data between 2021 and 2022. In 2021 the fieldwork was carried out from March - May, in 2022 from July - September. Due to differences in approach and experience (of the students versus researchers of WENR), there are observer effects. The differences are not due to changes in biodiversity, but are caused by the difference (and quality) of observation. The species knowledge of the students was limited. In 2022, about twice as many plant species were found compared to 2021. 2. Accuracy of GPS coordinates to find the exact same location: there may be a difference of three to four meters, so that other plant species with different covers may have been found. It is therefore not possible to draw responsible conclusions about differences between 2021 and 2022. The main results and conclusions from the monitoring are: 1. The nature dikes and walking paths north of the Farm Frites business park appear to have become more species-rich and look attractive. Especially around the hiking trails, many plants bloom, which attract many butterflies and other insects. 2. In 2022, 151 plant species have been observed around the nature dike and 90 around the future solar park. A total of 175 different plant species have been found at both locations. 3. The solar park is planned on a location that has been used as a field for many years. The current biodiversity at the location of the solar park is very low. This is due to the use of the

field. Due to crop rotation, several crops are grown alternately, for example potatoes are grown once every four years. There is potential to improve biodiversity on the new solar park, partly because no fertilizers or pesticides will be used on the solar park. The condition is that the solar park has good nature management. 4. Soil analyzes at the location of the future solar park indicate that there are few obstacles in terms of chemical composition and soil type for the development of herb-rich grassland. The report includes advice for management and points of attention for the construction of the solar park. To improve the cover of plant species on the dikes, it is important to mow the dikes twice a year and to dispose of the clippings." (Authors)] Address: not stated

**21514.** Lim, S.-h.; Park, J.-K.; Park, W.-B.; Won, D.-H.; Kim, M.-S.; Hong, S.; Do, Y. (2023): Gut microbiome of three species of Odonata. *Entomological Research* 53(4): 167-172. IN english ["The influence of diet and host specificity on the fecal microbiome of three adult dragonfly species, *Pseudothemis zonata*, *Orthetrum lineostigma*, and *Orthetrum melania*, was investigated. The fecal bacterial communities were analyzed using 16S rRNA gene sequencing, and stable isotope analysis was used to investigate their food sources. The results showed significant differences in the composition of fecal bacterial communities among the three species, with host specificity potentially playing a more important role than diet. The dominant phyla in the fecal bacterial communities of all three species were Firmicutes, Proteobacteria, and Bacteroidetes. The operational taxonomic units (OTUs), Shannon index, and phylogenetic diversity index were not significantly different among the three species, indicating that there were no major differences in the diversity of the fecal bacterial communities. The stable isotope analysis showed that the food sources were similar among the three species, being primarily small insects found near the aquatic habitats. However, the fecal bacterial communities of two closely related species, *O. lineostigma* and *O. melania*, were different despite their similar food sources. In contrast, the fecal bacterial communities of *O. lineostigma* and *P. zonata* were similar, despite the different food sources of these two species. Our findings suggest that host specificity and diet can influence the composition of the intestinal microbiome in these insects, but the degree of influence may depend on the specific host and environmental conditions." (2023): Biomimetic nanopillar silicon surfaces rupture fungal spores. *International Journal of Molecular Sciences* 24(2), 1298; <https://doi.org/10.3390/ijms24021298>: 16 pp. (in English) ["The mechano-bactericidal action of nanostructured surfaces is well-documented; however, synthetic nanostructured surfaces have not yet been explored for their antifungal properties toward filamentous fungal species. In this study, we developed a biomimetic nanostructured surface inspired by dragonfly wings. A high-aspect-ratio nanopillar topography was created on silicon (nano-Si) surfaces using inductively coupled plasma reactive ion etching (ICP RIE). To mimic the superhydrophobic nature of insect wings, the nano-Si was further functionalised with trichloro(1H,1H,2H,2H-perfluorooctyl)silane (PFTS). The viability of *Aspergillus brasiliensis* spores, in contact with either hydrophobic or hydrophilic nano-Si surfaces, was determined using a combination of standard microbiological assays, confocal laser scanning microscopy (CLSM), and focused ion beam scanning electron microscopy (FIB-SEM). Results indicated the breakdown of the fungal spore membrane upon contact with the hydrophilic nano-Si surfaces. By contrast, hydrophobised nano-Si surfaces prevented the initial attachment of the fungal conidia. Hydrophilic nano-Si surfaces exhibited both antifungal and fungicidal properties toward attached *A. brasiliensis* spores via a 4-fold reduction of attached spores and approximately 9-fold reduction of viable conidia from initial solution after 24 h compared to their planar Si counterparts. Thus, we reveal, for the first time, the physical rupturing of attaching fungal spores by biomimetic hydrophilic nanostructured surfaces." **21517.** Linklater, D.; Ivanova, E.P. (2023): Challenges to the design and testing of antimicrobial nanostructured surfaces. *Microbiology Australia* 44(2): 79-82. In English ["Nanomaterials, specifically nano-topographies, have been explored for their antimicrobial activity toward bacteria, fungi and even viruses. A decade ago, we discovered that the nanopillar topography of insect wings such as cicadas, dragonflies and damselflies, were not repelling bacteria as previously surmised, but bacteria were attaching and consequently being killed. The nature of the bactericidal effect associated with nanostructured insect wings has been extended to include antimicrobial activity toward both to environmental and pathogenic fungi. Specifically, the antimicrobial nature is associated with the physical disintegration of attached microbes due to a mechanical stress imposed on the cell membrane, which stretches and breaks. This exciting new discovery implies that, if successfully replicated on the surface of biomaterials and implantable devices, systemic or local administration of antibiotics are no longer required to kill bacteria that attach on such surfaces." **21518.** Mähn, L.A.; Hof, C.; Brandl, R.; Pinkert, S. (2023): Beyond latitude: Temperature, productivity and thermal niche conservatism drive global body size variation in Odonata. *Global Ecology and Biogeography* 32(5): 656-667. (in English) ["Aim: So far, latitudinal body size clines have been discussed primarily in the context of thermoregulation, sensu

Bergmann. However, body size patterns are ambiguous in ectotherms, and this heterogeneity remains poorly understood. We tested whether Bergmann's rule and the resource availability rule, which states that energetic requirements determine species body size, apply to Odonata. Furthermore, we hypothesized that the contrasting effects of thermoregulation and resource availability (e.g., productivity) can obscure the overall gradient in body size variation. Location: Global. Time period: Contemporary. Major taxa studied: Odonata. Methods: Using data for 43% of all odonate species described so far, we tested our hypotheses in phylogenetically and spatially comparative analyses at assemblage and species levels. For the distribution data, we integrated expert range maps and ecoregional ranges based on all available occurrence records. To distinguish between long-term and evolutionarily recent responses of environmental drivers in body size, we constructed a phylogenetically informed classification of all odonate species and decomposed the body size into its phylogenetic and specific components for our subset of species. Results: We documented a weak positive relationship between body length and latitude but found strong and contrasting effects for temperature between dragonflies and damselflies and consistent positive effects for productivity that explained 35–57% of body size variation. Moreover, we showed a strong phylogenetic signal in sized-based thermoregulation that shaped the distribution of dragonflies, but not of damselflies. Main conclusions: We concluded that temperature, productivity and conservatism in size-based thermoregulation synergistically determine the distribution of ectotherms, while the taxon-specific importance of these factors can lead to contrasting and weak latitude–size relationships. Our results reinforce the importance of body size as a determinant of species distributions and responses to climate change." (Authors)] Address: Mähn, Laura Anna, Dept of Animal Ecology, Fac. Biol., Univ. Marburg, Karl-von- Frisch-Str. 8, 35043 Marburg, Germany. Email: lauramaehn@posteo.de

**21519.** Maharani, R.; Triana, E.; Dharma, A.P. (2023): Studi keanekaragaman jenis capung (Ordo Odonata) di blok legok Majalaya resort Sarongge Taman Nasional Gunung gede pangrango. Biopendix 9(2): 195-202. (in Indonesian, with English summary) ["So this study aims to determine the diversity of dragonflies found in the Legok Majalaya Block, which can also be used as a bioindicator of environmental quality. Methods: This research was conducted in July 2022 with the research location in the Legok Majalaya Block. The method used for sampling is using a combination of roaming methods or direct encounter surveys with the TTLTK (Capture Mark Release Capture Back) method. The captured dragonflies were then identified using the book Odonata Semarang Raya (2018) and the book Flying Insect Wendit (2013). Results: 5 species of dragonflies found: *O. sabina*, *O. pruinosum*, *O. glaucum*, *B. contaminata* and *P. flavescens*. With a shanon-wiener diversity index value of 1.36 and an evenness index of 0.34. Conclusion: The evenness index value indicates a depressed community condition that causes the dominance of a species." **21520.** Mairif, M.; Bendifallah, L.; Doumandji, S. (2023): Diversity of odonates (Odonata, Anisoptera & Zygoptera) in the Theniet El Had National Park - North West of Algeria. Journal of Insect Biodiversity and Systematics 9(1): 155-182. (in English, with Arabian summary) ["The aim of this study is to make an inventory of the fauna of the Odonata

in Theniet El Had National Park, which helps managers to make appropriate decisions for the conservation of these species. The site is entirely forested (*Cedrus* and *Quercus* species) with numerous intra-forest natural environments (clearings, grasslands, rocky habitats, springs, pools and ponds, etc.), this mosaic of habitats harbours a remarkable wealth of fauna and flora. Our study focused on the natural and artificial temporary forest ponds, scattered throughout the park, which are of biological and ecological interest for a very wide range of insects, most notably the hemimetabola. These are characterised by a larval stage that is quite different from the adult stage in terms of habitat and lifestyle, namely odonates, where the larvae are aquatic whereas the adults have an aerial life. The inventory of odonates was carried out through monthly surveys of 8 water bodies (7 forest ponds and one hill reservoir) during one year, from March 2017 to February 2018. This preliminary inventory allowed us to inspect 240 individuals of odonates belonging to 18 species i.e. 11 genera and 5 families. The species recorded at the end of this study are the subject of a cartographic representation showing their distribution at the local scale (in the park) and at the national scale." **21522.** Martens, A.; Kohl, S.; Wildermuth, H. (2023): Are anal spines of anisopteran larvae an antipredator device? A case study in *Boyeria irene* (Odonata: Aeshnidae). Odonatologica 52(1/2): 49-60. (in English) ["*B. irene* larvae of different stages sampled at several localities in the headwaters of the Gardon River, Southern France, frequently showed malformations and injuries in their anal pyramid. The majority of these were broken or imperfectly regenerated tips of the anal spines. To quantify this phenomenon in a standardized way, exuviae of *B. irene* were sampled. In addition to running water habitats from the headwaters of the Gardon in France, exuviae from Lake Lucerne, Switzerland, were also analysed. In the Gardon river System, 9 to 26 % of the exuviae collected in 2008 showed damaged spines and para- or epiprocts. In Lake Lucerne, in 2006, 73% of the exuviae were damaged. In most cases the tips of the epiproct or paraproct were broken or malformed. We interpret the damaged and malformed spiny appendages as indicating successful defence against fish attacks. When disturbed, anisopteran larvae spread out the elements of their anal pyramid presenting a spiky crown-like target. We

hypothesise that this behaviour helps reduce the risk of being swallowed by predaceous fish. Presumably, most injuries are caused by the stresses the elements are subject to when puncturing the fish's mouth." **21523.** Martin, R.; Maynou, X. (2023): Larval development and voltinism of rheophilous Odonata from a Mediterranean river in the north-eastern Iberian Peninsula. *Odonatologica* 52(1/2): 25-48. (in English) ["We describe the larval development and voltinism of nine species of running-water dragonflies and damselflies from the upper and middle reaches of the Tordera, a Medi-teranean-climate river located in the north-east of the Iberian Peninsula. We sampled larvae between October 2020 and October 2022. We determined larval growth patterns and identified and estimated the sizes of the late developmental stadia by means of correlation graphs between pairs of body features, i.e., head width and hind wing-sheath length, for *Calopteryx haemorrhoidalis*, *C. virgo meridionalis*, *C. xanthostoma*, *Pyrrhosoma nymphula*, *Platynemis acutipennis*, *P. latipes*, *Boyeria irene*, *Onychogomphus forcipatus unguiculatus*, and *O. uncatius*. *Calopteryx virgo meridionalis*, *B. irene* and *O. uncatius*, characteristic of the upper course, exhibited bifurcations in the timing of their development (cohort splitting), generating patterns of mixed voltinism - 1-2 years per generation in the case of *C. virgo meridionalis* and 2-3 years in the case of *O. uncatius* and *B. irene*. The rest of the taxa, typical of the middle course, were largely univoltine. It is notable that *O. forcipatus unguiculatus*, hitherto reported as semi- or partivoltine (2-3 years) throughout its range, including the Maghreb, is exclusively univoltine in the Tordera river." **21524.** Metz, M. (2023): Mechanistic basis and evolutionary aspects of metabolic allometry in dragonflies and damselflies. Degree project in biology, Master of science (2 years), 2023. Examensarbete i biologi 60 hp till masterexamen, 2023. Biology Education Centre, Uppsala University: 25 pp. (in English) ["Metabolic allometry is the study of how the minimal energy expenditure of an organism, standard metabolic rate (SMR), scales with the body mass. Previous research, predominantly on mammals and birds, typically find allometric relationships between SMR and body mass, with a scaling coefficient (slope) of 0.75, often referred to as "Kleiber's law". This has been suggested to reflect some global physiological constraints. However, recently, it has been suggested that metabolic allometry instead results from life history optimization. Several recent studies on lower phylogenetic scales reveal scaling coefficients deviating from 0.75 and the intraspecific variation of metabolic allometry, along with its mechanistic basis, remains poorly understood. In this study, I aimed to investigate the variation in metabolic rate in an insect species, the common Bluetail Damselfly (*Ischnura elegans*). I measured SMR of individuals in three different temperatures and compared the sexes and three heritable female colour morphs that occur in this variable species. Furthermore, I compared the cell size of 20 species of Odonata to obtain a better understanding of possible physiological constraints on the evolution of SMR. In *I. elegans*, I found low intraspecific variation of metabolic allometry, allometric scaling coefficients that were generally lower than 0.75 and no evidence across species that SMR seemed to be directly constrained by cell size. My results

are in line with recent theories that metabolic allometries probably have higher evolvabilities than previously thought." (Author)] Address: not stated

**21525.** Miga, M.; Jahari, P.N.s.; Parimannan, S.; Rajandas, H.; Abdul-Latiff, M.A.B.; Yap, J.W.; Shamsir, M.S.; Mohd Salleh, F. (2023): The complete mitochondrial genome dataset of the Green Metalwing damselfly, *Neurobasis chinensis* (Hagen, 1887) (Odonata: Zygoptera: Calopterygidae) from Malaysia. Mendeley Data, V1, doi: 10.17632/53zs79xytt.1: (in English) ["This dataset described the complete mitochondrial genome of *N. chinensis* from Malaysia, sequenced using the next-generation sequencing technologies. It has a total length of 15,245bp in length, consisting of 13 protein-coding genes, 22 transfer RNAs, 2 ribosomal rRNAs and a control region. The genomic DNA was extracted from fresh tissue sample of *Ischya marapok* using the Qiagen Blood and Tissue Kit (Qiagen, Valencia, CA) and fragmented using a Bioruptor® system. The library was prepared using NEBNext® Ultra™ II DNA Library Prep Kit for Illumina®. The sample was then sent for sequencing using the Illumina NovaSeq 6000 platform with 150 paired-end mode (PE150). The assembly was done using NOVOPlasty v.4.2 and run through a PALEOMIX BAM pipeline to assess the mitogenome mapping. Annotation was done using the MITOS v2 web server and the predicted protein-coding genes were further verified using the Open Reading Frame (ORF) Finder. The annotated mitogenome sequence file was converted into an accepted Genbank format using the GB2sequin web application. The circular mitogenome map was generated using OGDRAW. The mitogenome is available in Genbank under the accession number ON165246." **21527.** Moreno-Pallares, M.; Lobo Hernández M.; Gutiérrez-Moreno L.C.; Pérez-Gutiérrez, L. (2023): Relación de las larvas de Odonata con las raíces de *Eichhornia crassipes* en la ciénaga La Larga, Atlántico, Colombia. *Intropica* 17(2): 10 pp. (in Spanish, with English summary) ["The purpose of this study was to evaluate the association of Odonata larvae with the roots of *Eichhornia crassipes* in La Larga wetland. For the capture of Odonata larvae, standardized sampling techniques for aquatic macroinvertebrates were used. Six samplings were carried out and in each sampling 100 individuals of *E. crassipes* were collected. The length and volume of each root were obtained. A total of 738 individuals and 10 species of Odonata were collected; *Miathyria marcella* presented the highest abundance, with 83 % of the total sampled. The percentage of occupation of the roots of *E. crassipes* by Odonata larvae was 58 % (346 of the 600 roots collected). The collected roots varied between 5 and 58 cm in length and between 5 and 450 ml in volume. Significant differences were found in the composition and structure of the larvae with respect to the volume of the roots.

Larval lengths ranged from 2.4 to 24.3 mm; most of the collected individuals were found in the length range between 5.1 and 10 mm. In conclusion, the size of the root is not a determinant for the distribution of odonates in the roots of *E. crassipes*, while the volume of the roots of *E. crassipes* does influence the composition of larvae." **21528.** Nienhaus, H.; Fitzpatrick, S.W.; Bloom, D.D.; Schriever, T.A. (2023): Dispersal ability and biogeographic gradients influence gene flow of three aquatic insects in Laurentian Great Lakes interdunal wetlands. *Freshwater Science* 42: 88-103. (in English) "Population genetic connectivity is influenced by multiple abiotic and biotic attributes, including geography, dispersal ability, and life history, which may lead to different patterns of population structure of organisms occupying similar habitats. We investigated how differences in dispersal ability and biogeographic gradients correspond with population structuring of 3 aquatic insect species found within naturally fragmented interdunal wetlands along the eastern shoreline of Lake Michigan in midwestern USA. Interdunal wetlands are small, highly fragmented, and patchily distributed along the eastern coast of Lake Michigan, USA. Our focal species, *Anax junius*, *Notonecta undulata* Say, 1832, and *Caenis amica* Hagen, 1861 were chosen as high, intermediate, and low dispersers, respectively. We hypothesized that all insect populations experience isolation by distance with relatively low gene flow among sites, but that the strength of isolation by distance varies with dispersal ability. We used cytochrome c oxidase subunit I sequence data to confirm species identification and restriction enzyme-association DNA sequencing for population genomic analyses. Our cytochrome c oxidase subunit I data revealed that *Caenis* populations consisted of multiple species split along a latitudinal gradient. Restriction site-association DNA sequencing data showed that *A. junius* displayed strong isolation by distance, where *N. undulata* did not. Additionally, both *A. junius* and *N. undulata* populations displayed 2 genetic clusters along the coastline, and genetic diversity increased along with latitude. These results indicate that biogeographical variables, such as latitude and covarying abiotic factors, may be stronger predictors of population structure than dispersal ability and that inference of population structure within aquatic macroinvertebrates should be on a species-specific basis." (2023): Factors influencing predation on Odonata by *Argiope trifasciata* (Forsskål, 1775). *International Journal of Odonatology* 26: 36-43. (in English) ["Despite a high number of incidental online

records of spiders preying upon dragonflies/damselflies, studies on these interactions are scarce. Here, we describe the predatory behavior of *Argiope trifasciata* on the two most common odonate species in the study area [*Rhionaeschna marchali*, *Mesamphiagrion laterale*], and whether various factors (web width, web length, spider body length, odonate body length, distance of the web from the edge of water body, and height of the web above ground) are related to the number of odonates captured. *Argiope trifasciata* employed stalking and frontal approaches as Odonata predation strategies. Our findings showed that larger Odonata are preyed upon by larger spiders. The greatest numbers of prey were caught in wider, higher webs, whereas narrow webs closer to the ground caught more small prey. Capturing success by *A. trifasciata* was similar in webs at different distances from the water for both species. Contrary to our hypothesis, there was no relationship between capturing success in either prey species and the distance of the web from the water. Habitat architecture may be more important to this interaction, as vegetation attracts both spiders (for anchoring webs) and odonates (as perch sites)." **21532.** Pati, A.; Kundu, S.; Sharma, A.; Dubey, V.K.; Ghosh, M.; Dasgupta, S.; Banerjee, S. (2023): Studies on the diversity of macroinvertebrates in suburban and rural aquatic bodies of West Bengal: Implications of vector control. *Acta Ecologica Sinica* 43(3): 560-575. (in English) ["Biological assessment of the freshwater habitats aims to characterize and monitor the conditions of the aquatic resources. Assessment of species assemblage in these habitats will indicate the possible variations in the resource exploitation and trophic interactions. Macroinvertebrates are the best indicators of aquatic ecosystem and play an important role in freshwater ecosystem functioning through nutrient cycling, primary production, decomposition and biological control of mosquitoes. Observations revealed that the prey individuals of order Diptera were found to be highest (51.16%), however the cumulative predatory taxa including Coleoptera, Odonata, Hemiptera and Orthoptera accounted to 67.02% The values of diversity indices varied significantly across different sampling spots justifying the usage of those wetlands and potentiality of them towards conservation biological control. Based on the biotic index, rice fields at Panskura ranked 'Good' to 'Fair' while all others ranked 'Fair' or 'Poor'. Irrespective of the classes and orders, the representative individuals were observed in high numbers during the post monsoon and the winter months which may be attributed to the fact that with the volume of water, the space available

for the insects increases, thereby promoting population expansion and releasing the crowding effect. The result of three way factorial ANOVA on the number of macroinvertebrates considering the spots, sites and sampling months as explanatory variables, revealed significant differences across all the interactions. A correspondence of the taxonomic diversity with the functional role of the aquatic predatory insects of the order Coleoptera, Hemiptera and Odonata is well established, through their links with multiple prey species including mosquito and chironomid larvae. In an assorted species assemblage of both predator and prey species, conservation biological control may require habitat extension and modification to allow increment of niche width to sustain diverse species in the habitats. Therefore to comment on the chances of the potentials of conservation biological control, monitoring of the macroinvertebrate community becomes imperative." **21535.** Powell, K.E.; Oliver, T.H.; Johns, T.; González-Suárez, M.; England, J.; Roy, D.B. (2023): Abundance trends for river macroinvertebrates vary across taxa, trophic group and river typology. *Global Change Biology* 29(5): 1282-1295. (in English) ["There is mounting evidence that terrestrial arthropods are declining rapidly in many areas of the world. It is unclear whether freshwater invertebrates, which are key providers of ecosystem services, are also declining. We addressed this question by analysing a long-term dataset of macroinvertebrate abundance collected from 2002 to 2019 across 5009 sampling sites in English rivers. Patterns varied

markedly across taxonomic groups. Within trophic groups we detected increases in the abundance of carnivores by 19% and herbivores by 14.8%, while we estimated decomposers have declined by 21.7% in abundance since 2002. We also found heterogeneity in trends across rivers belonging to different typologies based on geological dominance and catchment altitude, with organic lowland rivers having generally higher rates of increase in abundance across taxa and trophic groups, with siliceous lowland rivers having the most declines. Our results reveal a complex picture of change in freshwater macroinvertebrate abundance between taxonomic groups, trophic levels and river typologies. Our analysis helps with identifying priority regions for action on potential environmental stressors where we discover macroinvertebrate abundance declines." (Authors) Trends for Odonata were stable.] Address: Powell, Kathryn, UK Centre for Ecology & Hydrology, Wallingford, UK. Email: katpow@ceh.ac.uk

**21536.** Rosenthal, D.M.; Deng, L.; Rose, T.; Touchon, J.C. (2023): One of these things is not like the other: Mixed predator cues result in lopsided phenotypic responses in a Neotropical tadpole. *PLoS ONE* 18(5): e0285968. <https://doi.org/10.1371/journal.pone.0285968>: 14 pp. (in English) ["Many organisms have evolved to produce different phenotypes in response to environmental variation. *Dendropsophus ebraccatus* tadpoles develop opposing shifts in morphology and coloration when they are exposed to invertebrate vs vertebrate predators. Each of these alternate phenotypes are adaptive, conferring a survival advantage against the predator with which tadpoles were reared but imposing a survival cost with the mismatched predator. Here, we measured the phenotypic response of tadpoles to graded cues and mixed cues of both fish and dragonfly nymphs. Prey species like *D. ebraccatus* commonly co-occur with both of these types of predators, amongst many others as well. In our first experiment, tadpoles increased investment in defensive phenotypes in response to increasing concentrations of predator cues. Whereas morphology only differed in the strongest predation cue, tail spot coloration differed even at the lowest cue concentration. In our second experiment, tadpoles reared with cues from both predators developed an intermediate yet skewed phenotype that was most similar to the fish-induced phenotype. Previous studies have shown that fish are more lethal than dragonfly larvae; thus tadpoles responded most strongly to the more dangerous predator, even though the number of prey consumed by each predator was the same. This may be due to *D. ebraccatus* having evolved a stronger response to fish or because fish produce more kairomones than do dragonflies for a given amount of food. We demonstrate that not only do tadpoles assess predation risk via the concentration of predation cues in the water, they produce a stronger response to a more lethal predator even when the strength of cues is presumed to be identical." **21537.** Schneider, T.; Plyushch, I.G.; Vierstraete, A.; Ike-meyer, D. (2023): *Cordulegaster coronata* in eastern Afghanistan (Odonata: Cordulegasteridae). *Notulae odonatologicae* 10(1): 1-7. (in English) ["In the last decades only a little knowledge has been gained regarding the Odonata fauna of Afghanistan, principally due to ongoing conflict within the country. Nevertheless, Ukrainian scientists have visited there in recent years, mainly to study Lepidoptera and Coleoptera. During one expedition in the Paghman-Dara mountains at an altitude of 2 500 m a.s.l. ca 20 km west of Kabul

a female of *C. coronata* (Morton, 1916) was collected. No further specimens of this species were seen." (Authors)] Address: Schneider, T., Arnold-Knoblach-Ring 76, 14109 Berlin-Wannsee, Germany. Email: thomas.rs@gmx.de

**21538.** Schröter, A.; Borkenstein, A.; Jödicke, R. (2023): Why do mature dragonflies migrate? A critical analysis of Corbet's chapter "Spatial displacement by light" with reference to *Sympetrum striolatum* (Odonata: Libellulidae). *Odonatologica* 52(1/2): 61-78. (in English) ["Migrating dragonflies coming in from the North Sea in north-western Germany in the autumn of 2021 prompted the authors to consider the cause and biological function of undertaking a risky crossing of the open sea. Individuals of the most prevalent species, *Sympetrum striolatum*, were all mature, while some sampled specimens were old. In Corbet's System of spatial displacement, published in his seminal book "Dragonflies: behaviour and ecology of Odonata", *S. striolatum* is provisionally treated as a species exhibiting seasonal flights to and from aestivation refuges but not as a migratory species. In fact, the species belongs to a group of autumn migrants that begin mass movements when mature. An analysis of our observations and the available literature led us to the conclusion that the chapter "Migration beginning in the reproductive period" of Corbet's book treats the subject inadequately. We argue that the flight type assessment of *S. striolatum* must be corrected accordingly: it is also a true autumn migrant whose mass flight is particularly noticeable in high mountain ranges and in Coastal areas. However, there remain question marks over the biological significance and evolutionary benefits of mature dragonflies performing such risky mass flights over open sea." **21539.** Slomczynski, K.; Tonczyk, G.; Plóciennik, M. (2023): New insight into the macroinvertebrates of the Rawka River Nature Reserve (central Poland). *Ecologica Montenegrina* 62: 12-23. (in English) ["This paper presents the results of a preliminary survey on macroinvertebrate communities of a pristine lowland river Rawka in central Poland. The whole river is protected by a nature reserve but its invertebrates haven't yet been investigated extensively. This research has three main objectives: 1) to recognise preliminarily Rawka's macrofauna, 2) to determine the dissimilarity pattern between macroinvertebrates from the riverbed and the local oxbow, 3) to compare the invertebrate assemblages occurring in different habitats. The material was collected at three riverbed sampling points and one oxbow study site. It was found that the oxbow of Rawka River has different aquatic invertebrate communities than the riverbed. Conducted preliminary studies indicate that Rawka and its oxbow reveal high invertebrate diversity that is still vastly underestimated. Seventy-seven invertebrate taxa were collected and twenty-seven of them are first-recorded for Rawka River. Some rare and protected species have been found in the river, e.g. *Ophiogomphus cecilia* - a dragonfly which remains under strict species protection in Poland. The composition of aquatic invertebrates indicates that water quality of Rawka at the investigated section is good, but this needs to be confirmed with more extensive studies." (Authors)] Address: Slomczynski, K., University of Lodz, Department of Invertebrate Zoology and Hydrobiology, Banacha St. 12/16, Lodz 90-237, Poland.

**21540.** Sukkasem, C.; Boonsoong, B. (2023): Species diversity and distribution of dragonfly nymphs (Odonata: Anisoptera) in ponds of Nakhon Nayok and Nakhon Pathom

Provinces. Kasetsart University Academic Conference No. 59: 76-84. (in Thai, with English summary) ["This study aims to investigate the species diversity and distribution of dragonfly nymphs in ponds of Nakhon Nayok and Nakhon Pathom provinces. Dragonfly nymphs were collected from 15 sampling stations (6 reference sites and 9 test sites) on 4 occasions between October 2018 and July 2019. The full-grown nymphs were reared until emerged to adults for species identification. The results showed that 10 species from 9 genera and two families of dragonfly nymphs were found. The result of the PCA and CCA ordination plot showed that the reference sites were strongly correlated with *Brachydiplax chalybea*, *Macrodiplax cora*, *Rhyothemis phyllis*, *Rhyothemis variegata* and *Neurothemis fluctuans* while *Ictinogomphus decoratus*, *Brachythemis contaminata* and *Crocothemis servilia* nymphs correlated with test sites." **21541.** Thakur, Y.; Grover, A.; Sinha, R. (2023): Differential distribution of macroinvertebrate associated with water quality. *World Water Policy* 9(1): 84-112. (in English) ["Streams and rivers are the major source of drinking water and irrigation in many developing countries. Stream health is a major criterion and regulator of the health of its dependents (invertebrates, aquatic flora, fishes, animals, and humans). For the sustenance of a balanced ecosystem, a mutual existence between flora and fauna along with other abiotic factors is a prerequisite. Benthic fauna lying on the riverbed serves as a food source for fish, larger insects, birds, etc. Nowadays, most freshwater bodies are getting polluted through various anthropogenic activities like mining, land-use practices (fertilizers and insecticides), industrial effluent, and sewage inlet. Due to the water contamination, there have been observed changes in the physicochemical parameters of the water. The macroinvertebrate species being sensitive to these changes play an important role not only in determining the health of the water body but also in regulating the ecosystem. After review, it was observed that order like Diptera dominated in various locations, comprising of family Ceratopogonidae and Chironomidae, followed by order Trichoptera and Coleoptera. Species belonging to family Baetidae and Chironomidae possess pollution tolerance capabilities; additionally, these species can survive at a wide range of temperatures. Species from families such as Simuliidae showed their existence at varying water velocities. Families like Limnephilidae, Simuliidae, and Glossosomatidae exhibited their survival in fast moving water whereas Notonectidae, Hydrophilidae Gomphidae, Coenagrionidae, Libellulidae, Aeshnidae, and Dryopidae indicated species of low waterflow. Species of the family Tipulidae have been related to areas of high conductivity, whereas Gomphidae, Dryopidae, and Glossomatidae as species of low conductivity. Hydrophilidae and Notonectidae dominated high temperature areas. The present study will put forth before the government, current scenario of macroinvertebrate structure depending on the different characteristics of the water. This will help in regulating and controlling water pollution." (Authors)] Address: Sinha, Reshma, Dept of Animal Science, School of Life Sci., Central Univ. of Himachal Pradesh, Kangra, India. **21542.** Theischinger, G.; Mitchell, A.; Richards, S.J.; Polhemus, D.A. (2023): Systematics of the *Nososticta salomonis* complex (Odonata: Zygoptera: Platycnemididae). *Zootaxa* 5296(2): 101-146. (in English) ["We examined the morphology, colour patterns and genetic relationships of

Nososticta populations allied to *N. salomonis* (Selys) from across Melanesia. Seven species-level taxa are recognised in the *N. salomonis* 'complex': *N. africana* (Schmidt), *N. boonei* sp. nov., *N. chrimmulleri* Theischinger & Richards, *N. hedigeri* sp. nov., *N. salomonis* (Selys), *N. stueberii* sp. nov., and *N. tagula* sp. nov. All of these species are black damselflies with blue markings, and they differ from all other *Nososticta* by having: 1) a prominent spike on the male superior appendage, 2) a prominent angular base of the male inferior appendage, and 3) a complex posterior lobe on the female pronotum bearing two pairs of processes in the rough shape of a chair when viewed laterally. A molecular phylogeny based on the DNA barcode fragment of the COI gene plus two nuclear genes indicates that these seven species are closely related, but more extensive sampling of *Nososticta* species is required to confirm that they form a monophyletic group." **21543.** Theys, C.; Verheyen, J.; Janssens, L.; Tüzün, N.; Stoks, R. (2023): Effects of heat and pesticide stress on life history, physiology and the gut microbiome of two congeneric damselflies that differ in stressor tolerance. *Science of The Total Environment* 875: (in English) ["Highlights: • Gut microbiota differed between two damselfly species differing in pace-of-life. • Stressor response patterns of the microbiome and the host phenotype were similar. • A heat spike negatively impacted both species' phenotype and microbiome. • Pesticide-induced microbial shift may underlie species differences in tolerance. • Gut microbiota may improve mechanistic insights in combined stressor effects. Abstract: The combined impact of toxicants and warming on organisms is getting increased attention in ecotoxicology, but is still hard to predict, especially with regard to heat waves. Recent studies suggested that the gut microbiome may provide mechanistic insights into the single and combined stressor effects on their host. We therefore investigated effects of sequential exposure to a heat spike and a pesticide on both the phenotype (life history and physiology) and the gut microbiome composition of damselfly larvae. We compared the fast-paced *Ischnura pumilio*, which is more tolerant to both stressors, with the slow-paced *I. elegans*, to obtain mechanistic insights into species-specific stressor effects. The two species differed in gut microbiome composition, potentially contributing to their pace-of-life differences. Intriguingly, there was a general resemblance between the stressor response patterns in the phenotype and in the gut microbiome, whereby both species responded broadly similar to the single and combined stressors. The heat spike negatively affected the life history of both species (increased mortality, reduced growth rate), which could be explained not only by shared negative effects on physiology (inhibition of acetylcholinesterase, increase of malondialdehyde), but also by shared effects on gut bacterial species' abundances. The pesticide only had negative effects (reduced growth rate, reduced net energy budget) in *I. elegans*. The pesticide generated shifts in the bacterial community composition (e.g. increased abundance of *Sphaerotilus* and *Enterobacteriaceae* in the gut microbiome of *I. pumilio*), which potentially contributed to the relatively higher pesticide tolerance of *I. pumilio*. Moreover, in line with the response patterns in the host phenotype, the effects of the heat spike and the pesticide on the gut microbiome were mainly additive. By contrasting two species differing in stress tolerance, our results suggest that response patterns in the gut microbiome may improve our mechanistic understanding of single and combined stressor effects." **21544.** Thor, K.A.; Oldak, K.A.; Klich, D.; Gajewska, K.; Popczyk, B.; Klimaszewski, K.; Olech, W. (2023): Artificial waterholes for European Bison as biodiversity hotspots in forest ecosystems: Ecological effects of species reintroduction activities. *Diversity* 2023, 15(3), 446. 15 pp. (in English) ["Despite the growing population of European bison (*Bison bonasus*), it is necessary to plan the reintroduction of these animals to new areas. Reintroduction of European bison often requires the improvement of natural conditions. Such preparatory activities allow European bison to more easily adapt to new places, but also impact the functioning of animals from other taxa. The aim of the presented study was to examine the impact of waterholes for European bison on the development of local populations of amphibians and dragonflies (Odonata), as well as the creation of new feeding grounds for bats. We examined 15 reservoirs in the Augustów Forest District located in northeastern Poland, of which five were waterholes for European bison built in 2013–2014, four were semi-natural reservoirs transformed into waterholes for European bison in 2018, and six were natural reservoirs. Dragonflies were studied in 2021–2022; amphibians in 2018 and 2020; and bats in 2018, 2019, and 2020. In total, 24 species of dragonflies (Odonata), 10 species of amphibians, and 13 species of bats were found. The results of the inventory of three taxonomic groups using different comparative variants indicate a significant impact of the construction of waterholes for European bison on the biodiversity of the forest ecosystem. We concluded that the waterholes for European bison present better resistance to drying out than natural reservoirs. In addition, waterholes warm up more quickly, supporting better conditions for amphibians. The surface of the reservoirs and their exposed surroundings are favorable for insects (including dragonflies), and these are a source of food for bats, becoming attractive feeding grounds for them." article: 9 pp. (in English) ["In light of the ongoing freshwater biodiversity crisis, detailed knowledge regarding the spatial distribution of freshwater species is urgently required, especially in biodiversity hotspots. Here we present a database of georeferenced occurrence records of four freshwater invertebrate taxa groups across Cuba, namely flatworms (Platyhelminthes: Tricladida), insects (Ephemeroptera, Odonata, Hemiptera, Trichoptera, Coleoptera, Diptera), crabs and shrimps (Crustacea: Decapoda), and mollusks (Mollusca). We collated the geographic occurrence information from scientific literature, unpublished field records, museum collections and online databases. The database, comprising 6292 records of 457 species at 1075 unique localities, is organized in 32 fields that contain the information about the taxonomic classification of each recorded species, the sex and life stage of collected individuals; the geographic coordinates, location, author and date of the record and a reference to the original data source. This database provides an important basis towards an improved understanding of the spatial distribution of freshwater biodiversity in Cuba." **21547.** Valencia Vargas, J.P. (2023): Análisis de Estado de Diversidad de Macroinvertebrados Bentónicos dentro de la Provincia de Esmeraldas. Tesis de Licenciatura en Gestión Ambiental, Pontificia Universidad Católica del Ecuador: VI + 39 pp. (in Spanish, with English summary) ["Benthic macroinvertebrates are currently considered as bioindicators for water quality assessment due to their tolerance to contaminated environments. The general objective of this research was to analyze the state of diversity of the benthic macroinvertebrate community within the province of Esmeraldas and its relationship with environmental indicators. To meet the objective, quantitative research was carried out, where the influence of the variability of environmental indicators in three scales (local, riparian and basin) on the diversity of benthic macroinvertebrates was identified, three documents referring to macroinvertebrate studies carried out in some rivers of the cantons of the Province of Esmeraldas were taken as a guide. As a result, an abundance and richness of benthic macroinvertebrates was evidenced in the analyzed studies of Martínez et al and Molinero without publishing; and within the most significant taxonomic groups were Ephemeroptera, Trichoptera, Diptera, Coleoptera, Heteroptera and Odonata [Libellulidae, Coenagrionidae]. Within the most dominant families stood out Lepoptelebiidae, Baetidae, Leptohyphidae, Chironomidae and Hydropsychidae; and of the rare groups it was evidenced that the family Palaemonidae correlated with the environmental indicator density of roads and low percentage of forest in the basin, that is, where there is environmental alteration. From the study concluded that the presence of forest in both the basin and riparian zone should be indispensable for the conservation of benthic diversity and thus the water resource; It was also demonstrated that the intervention of anthropogenic activities influences the presence of benthic macroinvertebrates tolerant to environmental pollution." **21555.** Zhan, Z.; Zhang, C.; Chen, M.; Wang, J.; Fu, A.; Fan, Y.; Luan, X. (2023): DNA metabarcoding-based winter diet analysis of Eurasian otter (*Lutra lutra*) in the northern Greater Khingan Mountains. *Biodiversity Science*, 31, 22586. doi: 10.17520/biods.2022586: 12 pp. (in Chinese, with English summary) ["Aims: The Eurasian otter (*Lutra lutra*) is a key indicator and flagship species of freshwater ecosystems. Unfortunately, human disturbance and environmental changes have caused a severe decrease in Eurasian otter populations in China, even resulting in extinction in some areas. At present, the species is predominantly found in northeast and southwest China, with the northern part of the Greater Khingan Mountains being one of the most important habitats for Eurasian otter populations in the northeast. Studying the diet composition of Eurasian otter is a valuable tactic in understanding its interspecific relationship and the functioning of its ecosystem. This information is essential when assessing their survival status and carrying out conservation efforts. Method: In this study, 50 suspected

Eurasian otter fecal samples were collected from the northern Greater Khingan Mountains. Based on DNA barcoding technology, 35 samples were confirmed to be Eurasian otter fecal samples. Then, using DNA metabarcoding technology, species in the identified feces were analyzed to gain insight into the feeding habits of the otters. Results: In this study, 22 different species were identified in Eurasian otter fecal samples, including 15 fishes, 2 frogs, and 5 insect species. *Cottus poecilopus* had the highest relative frequency of occurrence (19.35%) and relative read abundance (27.32%) among all the vertebrate foods, followed by *Rana amurensis* (15.48% and 21.73% respectively). At the family level, Cottidae had a significantly higher relative frequency of occurrence (32.26%) and relative read abundance (45.72%) than other fishes. Conclusion: The results of this study revealed that fish, primarily from the family Cottidae, were the main prey of Eurasian otters in the northern part of the Greater Khingan Mountains in winter, followed by frogs. In addition, some aquatic insects such as Odonata, Trichoptera and Plecoptera were found in a small amount of otter feces, which might come from otter prey. This research provides valuable insight into the survival status of otter populations, and can be used to inform the development of relevant policies and conservation efforts." **21556.** Zhao, Z.; Feng, X.; Zhang, Y.; Wang, Y.; Zhou, Z. (2023): Species diversity, hotspot congruence, and conservation of North American damselflies (Odonata: Zygoptera). *Frontiers in Ecology and Evolution* 10:1087866. doi: 10.3389/fevo.2022.1087866: 9 pp. (in English) ["The rapid extinction of species is of considerable concern for biodiversity conservation. Identifying the drivers of species diversity and hotspots is beneficial for developing conservation strategies. Studies on insects have mainly focused on terrestrial species and rarely on semiaquatic species. Using 135,208 georeferenced occurrence records of 296 damselflies across North America, their species richness and endemism (represented by weighted endemism) patterns were mapped in a 100 × 100-km grid size, and the effects of environmental variables on species richness and endemism were investigated using generalized linear models and hierarchical partitioning. Subsequently, the top 5% grids with species richness and weighted endemism were separately selected as hotspots and their congruence was evaluated. Finally, species diversity hotspots were identified by integrating two types of hotspot grids, and gap analysis was performed to evaluate their conservation status. Temperature conditions and water availability had the strongest influence on species richness and endemism, respectively. Low congruence among species richness and endemism hotspots was observed. Moreover, four species diversity hotspots were identified, namely, region of the eastern United States and southeastern Canada, southwestern United States, central Mexico, and southernmost North America. Approximately 69.31% of the hotspot grids are not a part of the existing protected areas, presenting a significant conservation gap. The habitats of taxonomic groups should be considered while identifying the most common driving mechanisms of endemism. Strengthening the establishment of protected areas in regions with conservation gaps is urgently needed to promote the conservation of damselflies in North America." ## 2000

**21558.** Vanderhaeghe, F. (2000): Wanneer zal de Gaffelwaterjuffer (*Coenagrion scitulum*) Nederland bereiken? NVL-Nieuwsbrief nummer 3 (Jrg 4), september 2000: 9-10. (in Dutch) ["With the increased inventory intensity of the last 10 to 20 years in Belgium, it has become clear that a number of dragonfly species are expanding their range to the north (see among others De Knijf & Anselin, 1996; De Knijf, 1999). A recent example is *C. scitulum*, which in 1998 was found back in Belgium for the first time since 1973 (Vanderhaeghe, 1998) ... At a camp of the Vizebeestjeswerkgroep (VBWG) of the Jeugdbond voor Natuurstudie en Milieubescherming (JNM) in the Boulonnais (north-west France) in 1996, to our amazement, there were a number of very northerly sightings of *C. scitulum*, up to 80 km from the Belgian border (West Flanders). This was much closer to Belgium than what could be expected from literature data (Vanderhaeghe, 1997). Two years later (1998), the first new Belgian sightings were a fact. He! involved 4 observations from Belgian Lorraine, always of wandering individuals, on 23/6, 26/6, 4/7 and 18/7. We then tried to get an overview of the state of the species in northern France. To this end, several people from the Societe Francaise d'Odonatologie (SFO) were written to, and with good results! Furthermore, documented information was obtained from the 4 Belgian sightings. A synthase of all this information can be found in Vanderhaeghe (1999). An important finding is that *C. scitulum* has been observed in several places in northern France up to near the Belgian border; here are oak some older sightings, of which it is not clear whether they are vagrants. A clear group of reports comes from the northern French coastal region, up to 30 km from Belgium; there are also records near the Belgian Fagne-Famenne region and near the Gaume. None of the Belgian sightings in 1998 were made in a suitable habitat (even: several specimens flew up from a flowery roadside along a busy road); this also applies to a sighting 4 km from Belgium in 1998 (chalk slope near Epiez-sur-Chiers). These data suggest that damselflies migrated during this period; however, it is difficult to estimate the distance travelled. The possibility of migration is oak cited by Jurzitza (1988). I have not actively collected data on the situation in 1999; in any case, ford damselflies have been observed again: military area near Arion (where 2 observations were made in 1998; there could therefore be a population here) (B. Janssens, T. Vanagt, oral med.), West Coast (= 1st recent observation for Flanders, if confirmed) (D. Bonte, oral med.), Roly (in the Fagne region; Anonymus, 1999). It

is very plausible that this is a northward advance at several sites, independently of each other. The trend therefore appears to be continuing; it will be oak to look out for observations in the coming years. As pointed out by Dijkstra & Kalkman (1998), a first sighting for the Dutch territory, even in the near future, cannot be ruled out. An invasive movement along the coast is one of the most obvious possibilities in this respect (Zeeuws-Vlaanderen!). During migrations, the species can apparently be found in any habitat (oak dry). For population establishment, a diverse range of ponds and slow-flowing waters seem possible; these are often sites with lush aquatic and riparian vegetation (Vanderhaeghe, 1999). *C. scitulum* are not easily distinguished in flight from other blue-coloured damselflies, and it is therefore oak recommended that the species be caught and accurately identified with an loupe (neck shield, abdomen appendages); a photograph is desirable as evidence." ## 2001

**21559.** Machado Caballero, J.E. (2001): Inventario y estudio comparativo de la fauna de Odonata en tres áreas de Honduras. Tesis presentada como requisito parcial para optar al título de Ingeniero Agronomo en el grado académico de Licenciatura. Zamorano Carrera de Ciencia y Produccion Agropecuaria. Zamorano: XI, 31pp. (in Spanish) [The odonate assemblages (84 species) of 3 areas in the departments of Atlantida and Francisco Morazan (Honduras) are described, and the odonate faunae of Honduras, Belize, Costa Rica and Nicaragua are briefly analysed and compared. "For the conservation of forests and the diversity they have, a better knowledge of the species that inhabit them, their distribution and classification is necessary. Most of this diversity is made up of insects. The group of odonata, by its nature, helps in the control of some pests and can be used as an ecological indicator of the quality of ecosystems. Currently there is little information on them in Honduras. The objectives were: to carry out an inventory of the species of the Odonata order, create a database and compare the fauna found with that of Belize, Nicaragua and Costa Rica. Captures were made from February to October in the Zamorano Valley (Yeguaré) and in April and August in the Curo y Salado Wildlife Refuge and the Pico Bonito National Park, complementing with specimens provided by parataxonomists and those existing in the ecological inventory of Zamorano. The trapped insects were laterally placed in paper envelopes and placed in acetone for 24 hours to prevent decomposition and color loss. Then they dried for one or two hours and were transferred to a transparent envelope with data on location, date and collector, as well as family, genus and species. A database was generated to compare the fauna of the three study areas with each other, and with the fauna of Belize, Nicaragua and Costa Rica. There are 84 species in the three study areas, belonging to 43 genera and 10 families. The families with the greatest richness of csppccics were Libellulidac, Cocnagrionidac and Aeshnidae,

which together account for more than 83% of the total fauna found. *Mecistogaster linearis* and *Brechmorhoga nubecula*, reported in the Pico Bonito National Park, are new records for Honduras. Contrasting the odonatofauna of Honduras with that of Belize, 114 species (65%) were found in common of 174 reported in that country. Costa Rica. There are 84 species in the three study areas, belonging to 43 genera and 10 families. Costa Rica shares with Honduras 132 (49%) of its 268 registered species, and Nicaragua coincides with 82 species (82%) of the 100 registered species. Despite having found a high diversity of Odonata species in Honduras, a good percentage is unknown. It is recommended to complete the information with collections in the departments of Ocoatepeque, Lempira, Intibuca and La Paz that have not been studied." ] Address: not stated

**21560.** Hahn von Hessberg, C.M.; Grajales Quintero, A. (2004): Importancia del orden Odonata para la producción de peces en ambientes controlados. *Revista Electrónica de Ingeniería en Producción Acuícola* 1(1): 1-12. (in Spanish) ["It was determined that the immature forms of the Odonata inhabit mostly lentic waters with a lot of aquatic or emergent vegetation, with the exception of the species *Pantala flavescens*, which was also found in ponds without any type of vegetation, determining that this species is the one with the highest presentation in association with fish farming. The larvae that have a high predatory effect on fry of fish between 0.03 and 1.5 g of live weight are *P. flavescens*, fry larger than 1.5 grams (2.1 to 3 grams) are not preyed on due to their size. Other species of naiads that have a predatory effect on fish fry in their order are: *Orthemis* sp., *Aeshna intricata* and *Anax amazili* due to their robust conformation, large size and preliminary observations. Physical factors such as temperature, water depth, presence or absence of vegetation, determine the consumption of the *Pantala flavescens* naiads, the ideal temperature that increased predatory activity was from 24° C average, limited by environmental factors and competition. existing by food. A single naiad can consume 5 fingerlings/day, the cost of a reversed fingerling is \$3,015, therefore, in a 42-day cycle (age and most susceptible weight for the fish) there is a loss of \$633.15; and per m<sup>2</sup> of pond there are losses worth \$12,633.00. In a 150 m<sup>2</sup> pond (average of 20 naiads/m<sup>2</sup>), losses amount to \$1,899,450 and annual losses of \$16,507,125 (Hahn et.al 2001). Based on the high rate of predation observed on larvae and fingerlings of *Oreochromis niloticus* by *Pantala flavescens*, the need is felt to look for alternatives for selective biological or mechanical control without using chemical controls on this species of Odonata.] Address: Hahn von Hessberg, Christine, Profesore Depto Sistemas de Producción, Programa de Medicina Veterinaria y Zootecnia, Facultad de Ciencias Agropecuarias. ## 2005

**21561.** Craves, J. (2005): Canada damer with unusual thorax pattern. *Williamsonia* 9(1): 1. (in English) ["After attending an ornithological meeting in Grayling (Crawford Co.) on 28 Aug 2004, I had a little bit of time to hunt for Odonata before heading back home. Consulting a map, I chose to explore Howe's Lake, a small sandy lake north of M-72 west of Grayling. There wasn't a lot actually plying the lake itself, but the wet, grassy depressions near the lake shore had several species of *Lestes*, *Sympetrum costiferum* (a county record), and quite a few *Aeshna*'s patrolling lazily or ovipositing in the shallow water. I netted a few *Aeshna canadensis*,

and some *A. tuberculifera* (a county record). It appeared that all the blue darners at the site were these two species, until I netted one with broken thoracic stripes, which I took to be *A. interrupta*. When I returned home to sort through the specimens, I turned this specimen over, I found that the other side of the thorax was the standard Canada Damner pattern. A closer examination revealed that this was indeed *canadensis* in all other characters, except that one side of the thorax. While I've found little on this phenomena in the literature, it is apparently not without precedent. For me it underscores the importance of actually collecting specimens - or in the least netting them and carefully examining them in the hand - in order to verify the identity. Even if I had seen this individual perched, I would have misidentified it had I only seen the one side (Variable Damner would have been a county record). This interesting specimen is in my personal reference collection." (Author)] Address: Craves, Julie, Univ. Michigan-Dearborn, USA. Email: jac@rrbo.org
